salt.modules.netscaler.vserver_servicegroup_exists(v_name, sg_name, **connection_args)
```
Checks if a servicegroup is tied to a vserver

CLI Example:
```
salt '*' netscaler.vserver_servicegroup_exists 'vserverName' 'serviceGroupName'
```

```
salt.modules.netscaler.vserver_sslcert_add(v_name, sc_name, **connection_args)
```
Binds a SSL certificate to a vserver

CLI Example:
```
salt '*' netscaler.vserver_sslcert_add 'vserverName' 'sslCertificateName'
```

```
salt.modules.netscaler.vserver_sslcert_delete(v_name, sc_name, **connection_args)
```
Unbinds a SSL certificate from a vserver

CLI Example:
```
salt '*' netscaler.vserver_sslcert_delete 'vserverName' 'sslCertificateName'
```

```
salt.modules.netscaler.vserver_sslcert_exists(v_name, sc_name, **connection_args)
```
Checks if a SSL certificate is tied to a vserver

CLI Example:
```
salt '*' netscaler.vserver_sslcert_exists 'vserverName' 'sslCertificateName'
```

### 31.16.163 salt.modules.network

Module for gathering and managing network information

```
salt.modules.network.active_tcp()
```
Return a dict containing information on all of the running TCP connections

CLI Example:
```
salt '*' network.active_tcp
```

```
salt.modules.network.arp()
```
Return the arp table from the minion

Changed in version 2015.8.0: Added support for SunOS

CLI Example:
```
salt '*' network.arp
```

```
salt.modules.network.calc_net(ip_addr, netmask=None)
```
Returns the CIDR of a subnet based on an IP address (CIDR notation supported) and optional netmask.

CLI Example:
```
salt '*' network.calc_net 172.17.0.5 255.255.255.240
salt '*' network.calc_net 2a02:f6e:a000:80:84d8:8332:7866:4e07/64
```

New in version 2015.8.0.
salt.modules.network.connect(host, port=None, **kwargs)
Test connectivity to a host using a particular port from the minion.
New in version 2014.7.
CLI Example:
```
salt '*' network.connect archlinux.org 80
salt '*' network.connect archlinux.org 80 timeout=3
salt '*' network.connect archlinux.org 80 timeout=3 family=ipv4
salt '*' network.connect google-public-dns-a.google.com port=53 proto=udp timeout=3
```
salt.modules.network.default_route(family=None)
Return default route(s) from routing table
Changed in version 2015.8.0: Added support for SunOS (Solaris 10, Illumos, SmartOS)
CLI Example:
```
salt '*' network.default_route
```
salt.modules.network.dig(host)
Performs a DNS lookup with dig
CLI Example:
```
salt '*' network.dig archlinux.org
```
salt.modules.network.get_bufsize(iface)
Return network buffer sizes as a dict
CLI Example:
```
salt '*' network.getbufsize
```
salt.modules.network.get_hostname()
Get hostname
CLI Example:
```
salt '*' network.get_hostname
```
salt.modules.network.get_route(ip)
Return routing information for given destination ip
New in version 2015.5.3.
Changed in version 2015.8.0: Added support for SunOS (Solaris 10, Illumos, SmartOS) Added support for OpenBSD
CLI Example:
```
salt '*' network.get_route 10.10.10.10
```
salt.modules.network.hw_addr(iface)
Return the hardware address (a.k.a. MAC address) for a given interface
CLI Example:
salt '*' network.hw_addr eth0

```
salt.modules.network.hwaddr(_iface)
    Return the hardware address (a.k.a. MAC address) for a given interface
    CLI Example:
    salt '*' network.hw_addr eth0
```

salt.modules.network.in_subnet(_cidr)
    Returns True if host is within specified subnet, otherwise False.
    CLI Example:
    salt '*' network.in_subnet 10.0.0.0/16

salt.modules.network.interface(_iface)
    Return the inet address for a given interface
    New in version 2014.7.
    CLI Example:
    salt '*' network.interface eth0

salt.modules.network.interface_ip(_iface)
    Return the inet address for a given interface
    New in version 2014.7.
    CLI Example:
    salt '*' network.interface_ip eth0

salt.modules.network.interfaces()
    Return a dictionary of information about all the interfaces on the minion
    CLI Example:
    salt '*' network.interfaces

salt.modules.network.ip_addrs(_interface=None, include_loopback=False, _cidr=None)
    Returns a list of IPv4 addresses assigned to the host. 127.0.0.1 is ignored, unless `include_loopback=True` is indicated. If `interface` is provided, then only IP addresses from that interface will be returned. Providing a CIDR via `cidr="10.0.0.0/8"` will return only the addresses which are within that subnet.
    CLI Example:
    salt '*' network.ip_addrs

salt.modules.network.ip_addrs6(_interface=None, include_loopback=False, _cidr=None)
    Returns a list of IPv6 addresses assigned to the host. ::1 is ignored, unless `include_loopback=True` is indicated. If `interface` is provided, then only IP addresses from that interface will be returned. Providing a CIDR via `cidr="2000::/3"` will return only the addresses which are within that subnet.
    CLI Example:
    salt '*' network.ip_addrs6

salt.modules.network.ip_in_subnet(_ip_addr, _cidr)
    Returns True if given IP is within specified subnet, otherwise False.
    CLI Example:
salt.modules.network.ip_addrs(interface=None, include_loopback=False, cidr=None)

Returns a list of IPv4 addresses assigned to the host. 127.0.0.1 is ignored, unless `include_loopback=True' is indicated. If `interface' is provided, then only IP addresses from that interface will be returned. Providing a CIDR via `cidr="10.0.0.0/8"' will return only the addresses which are within that subnet.

CLI Example:
```
salt '*' network.ip_addrs
```

salt.modules.network.ip_addrs6(interface=None, include_loopback=False, cidr=None)

Returns a list of IPv6 addresses assigned to the host. ::1 is ignored, unless `include_loopback=True' is indicated. If `interface' is provided, then only IP addresses from that interface will be returned. Providing a CIDR via `cidr="2000::/3"' will return only the addresses which are within that subnet.

CLI Example:
```
salt '*' network.ip_addrs6
```

salt.modules.network.is_loopback(ip_addr)

Check if the given IP address is a loopback address

New in version 2014.7.0.

Changed in version 2015.8.0: IPv6 support

CLI Example:
```
salt '*' network.is_loopback 127.0.0.1
```

salt.modules.network.is_private(ip_addr)

Check if the given IP address is a private address

New in version 2014.7.0.

Changed in version 2015.8.0: IPv6 support

CLI Example:
```
salt '*' network.is_private 10.0.0.3
```

salt.modules.network.mod_bufsize(iface, *args, **kwargs)

Modify network interface buffers (currently linux only)

CLI Example:
```
salt '*' network.getBuffers
```

salt.modules.network.mod_hostname(hostname)

Modify hostname

Changed in version 2015.8.0: Added support for SunOS (Solaris 10, Illumos, SmartOS)

CLI Example:
```
salt '*' network.mod_hostname master.saltstack.com
```

salt.modules.network.netstat()

Return information on open ports and states

Note: On BSD minions, the output contains PID info (where available) for each netstat entry, fetched from
sockstat/fstat output.

Changed in version 2014.1.4: Added support for OpenBSD, FreeBSD, and NetBSD
Changed in version 2015.8.0: Added support for SunOS

CLI Example:
```
salt '*' network.netstat
```

```
salt.modules.network.ping( host, timeout=False, return_boolean=False)
```
Performs an ICMP ping to a host

Changed in version 2015.8.0: Added support for SunOS

CLI Example:
```
salt '*' network.ping archlinux.org
```

New in version 2015.5.0.
Return a True or False instead of ping output.

```
salt '*' network.ping archlinux.org return_boolean=True
```
Set the time to wait for a response in seconds.
```
salt '*' network.ping archlinux.org timeout=3
```

```
salt.modules.network.reverse_ip(ip_addr)
```
Returns the reversed IP address

Changed in version 2015.8.0: IPv6 support

CLI Example:
```
salt '*' network.reverse_ip 172.17.0.4
```

```
salt.modules.network.routes(family=None)
```
Return currently configured routes from routing table

Changed in version 2015.8.0: Added support for SunOS (Solaris 10, Illumos, SmartOS)

CLI Example:
```
salt '*' network.routes
```

```
salt.modules.network.subnets(interfaces=None)
```
Returns a list of IPv4 subnets to which the host belongs

CLI Example:
```
salt '*' network.subnets
salt '*' network.subnets interfaces=eth1
```

```
salt.modules.network.subnets6()
```
Returns a list of IPv6 subnets to which the host belongs

CLI Example:
```
salt '*' network.subnets
```
salt.modules.network.traceroute(host)
Perform a traceroute to a 3rd party host

Changed in version 2015.8.0: Added support for SunOS

CLI Example:

```
salt '*' network.traceroute archlinux.org
```

salt.modules.network.wol(mac, bcast='255.255.255.255', destport=9)
Send Wake On Lan packet to a host

CLI Example:

```
salt '*' network.wol 08-00-27-13-69-77
salt '*' network.wol 080027136977 255.255.255.255 7
salt '*' network.wol 08:00:27:13:69:77 255.255.255.255 7
```

31.16.164 salt.modules.neutron

Module for handling OpenStack Neutron calls

depends

- neutronclient Python module

configuration This module is not usable until the user, password, tenant, and auth URL are specified either in a pillar or in the minion's config file. For example:

```
keystone.user: 'admin'
keystone.password: 'password'
keystone.tenant: 'admin'
keystone.auth_url: 'http://127.0.0.1:5000/v2.0/
keystone.region_name: 'RegionOne'
keystone.service_type: 'network'
```

If configuration for multiple OpenStack accounts is required, they can be set up as different configuration profiles: For example:

```
openstack1:
  keystone.user: 'admin'
  keystone.password: 'password'
  keystone.tenant: 'admin'
  keystone.auth_url: 'http://127.0.0.1:5000/v2.0/
  keystone.region_name: 'RegionOne'
  keystone.service_type: 'network'

openstack2:
  keystone.user: 'admin'
  keystone.password: 'password'
  keystone.tenant: 'admin'
  keystone.auth_url: 'http://127.0.0.2:5000/v2.0/
  keystone.region_name: 'RegionOne'
  keystone.service_type: 'network'
```

With this configuration in place, any of the neutron functions can make use of a configuration profile by declaring it explicitly. For example:

```
salt '*' neutron.network_list profile=openstack1
```
salt.modules.neutron.add_gateway_router(router, ext_network, profile=None)
    Adds an external network gateway to the specified router

    CLI Example:
    ```
salt '*' neutron.add_gateway_router router-name ext-network-name
    ```

    Parameters
    • **router** -- ID or name of the router
    • **ext_network** -- ID or name of the external network the gateway
    • **profile** -- Profile to build on (Optional)

    Returns  Added Gateway router information

salt.modules.neutron.add_interface_router(router, subnet, profile=None)
    Adds an internal network interface to the specified router

    CLI Example:
    ```
salt '*' neutron.add_interface_router router-name subnet-name
    ```

    Parameters
    • **router** -- ID or name of the router
    • **subnet** -- ID or name of the subnet
    • **profile** -- Profile to build on (Optional)

    Returns  Added interface information

salt.modules.neutron.create_floatingip(floating_network, port=None, profile=None)
    Creates a new floatingIP

    CLI Example:
    ```
salt '*' neutron.create_floatingip network-name port-name
    ```

    Parameters
    • **floating_network** -- Network name or ID to allocate floatingIP from
    • **port** -- Of the port to be associated with the floatingIP (Optional)
    • **profile** -- Profile to build on (Optional)

    Returns  Created floatingIP information

salt.modules.neutron.create_ikepolicy(name, profile=None, **kwargs)
    Creates a new IKEPolicy

    CLI Example:
    ```
salt '*' neutron.create_ikepolicy ikepolicy-name
    phase1_negotiation_mode=main auth_algorithm=sha1
    encryption_algorithm=aes-128 pfs=group5
    ```

    Parameters
    • **name** -- Name of the IKE policy
• **phase1_negotiation_mode** -- IKE Phase1 negotiation mode in lowercase, default: main (Optional)

• **auth_algorithm** -- Authentication algorithm in lowercase, default: sha1 (Optional)

• **encryption_algorithm** -- Encryption algorithm in lowercase. default:aes-128 (Optional)

• **pfs** -- Prefect Forward Security in lowercase, default: group5 (Optional)

• **units** -- IKE lifetime attribute. default: seconds (Optional)

• **value** -- IKE lifetime attribute. default: 3600 (Optional)

• **ike_version** -- IKE version in lowercase, default: v1 (Optional)

• **profile** -- Profile to build on (Optional)

• **kwargs** --

Returns
Created IKE policy information

```
salt.modules.neutron.create_ipsec_site_connection(name, ipsecpolicy, ikepolicy, vpnservice, peer_cidrs, peer_address, peer_id, psk, admin_state_up=True, profile=None, **kwargs)
```

Creates a new IPsecSiteConnection

CLI Example:

```
salt '*' neutron.show_ipsec_site_connection connection-name ipsecpolicy-name ikepolicy-name vpnservice-name 192.168.XXX.XXX/24 192.168.XXX.XXX 192.168.XXX.XXX secret
```

Parameters

• **name** -- Set friendly name for the connection

• **ipsecpolicy** -- IPSec policy ID or name associated with this connection

• **ikepolicy** -- IKE policy ID or name associated with this connection

• **vpnservice** -- VPN service instance ID or name associated with this connection

• **peer_cidrs** -- Remote subnet(s) in CIDR format

• **peer_address** -- Peer gateway public IPv4/IPv6 address or FQDN

• **peer_id** -- Peer router identity for authentication Can be IPv4/IPv6 address, e-mail address, key id, or FQDN

• **psk** -- Pre-shared key string

• **initiator** -- Initiator state in lowercase, default:bi-directional

• **admin_state_up** -- Set admin state up to true or false, default: True (Optional)

• **mtu** -- size for the connection, default:1500 (Optional)

• **dpd_action** -- Dead Peer Detection attribute: hold/clear/disabled/ restart/restart-by-peer (Optional)

• **dpd_interval** -- Dead Peer Detection attribute (Optional)

• **dpd_timeout** -- Dead Peer Detection attribute (Optional)

• **profile** -- Profile to build on (Optional)
Returns  Created IPSec site connection information

salt.modules.neutron.create_ipsecpolicy(name, profile=None, **kwargs)

Creates a new IPsecPolicy

CLI Example:

```
salt '*' neutron.create_ipsecpolicy ipsecpolicy-name
    transform_protocol=esp auth_algorithm=sha1
    encapsulation_mode=tunnel encryption_algorithm=aes-128
```

Parameters

- **name** -- Name of the IPsec policy
- **transform_protocol** -- Transform protocol in lowercase, default: esp (Optional)
- **auth_algorithm** -- Authentication algorithm in lowercase, default: sha1 (Optional)
- **encapsulation_mode** -- Encapsulation mode in lowercase, default: tunnel (Optional)
- **encryption_algorithm** -- Encryption algorithm in lowercase, default: aes-128 (Optional)
- **pfs** -- Perfect Forward Security in lowercase, default: group5 (Optional)
- **units** -- IPSec lifetime attribute. default: seconds (Optional)
- **value** -- IPSec lifetime attribute. default: 3600 (Optional)
- **profile** -- Profile to build on (Optional)

Returns  Created IPSec policy information

salt.modules.neutron.create_network(name, router_ext=None, admin_state_up=True, network_type=None, physical_network=None, segmentation_id=None, shared=None, profile=None)

Creates a new network

CLI Example:

```
salt '*' neutron.create_network network-name
salt '*' neutron.create_network network-name profile=openstack1
```

Parameters

- **name** -- Name of network to create
- **admin_state_up** -- should the state of the network be up? default: True (Optional)
- **router_ext** -- True then if create the external network (Optional)
- **network_type** -- the Type of network that the provider is such as GRE, VXLAN, VLAN, FLAT, or LOCAL (Optional)
- **physical_network** -- the name of the physical network as neutron knows it (Optional)
- **segmentation_id** -- the vlan id or GRE id (Optional)
- **shared** -- is the network shared or not (Optional)
- **profile** -- Profile to build on (Optional)

Returns  Created network information
salt.modules.neutron.create_port(name, network, device_id=None, admin_state_up=True, profile=None)

Creates a new port

CLI Example:

```
salt '*' neutron.create_port network-name port-name
```

Parameters

- **name** -- Name of port to create
- **network** -- Network name or ID
- **device_id** -- ID of device (Optional)
- **admin_state_up** -- Set admin state up to true or false, default: true (Optional)
- **profile** -- Profile to build on (Optional)

Returns

Created port information

---

click.modules.neutron.create_router(name, ext_network=None, admin_state_up=True, profile=None)

Creates a new router

CLI Example:

```
salt '*' neutron.create_router new-router-name
```

Parameters

- **name** -- Name of router to create (must be first)
- **ext_network** -- ID or name of the external for the gateway (Optional)
- **admin_state_up** -- Set admin state up to true or false, default: true (Optional)
- **profile** -- Profile to build on (Optional)

Returns

Created router information

---

click.modules.neutron.create_security_group(name=None, description=None, profile=None)

Creates a new security group

CLI Example:

```
salt '*' neutron.create_security_group security-group-name description='Security group for servers'
```

Parameters

- **name** -- Name of security group (Optional)
- **description** -- Description of security group (Optional)
- **profile** -- Profile to build on (Optional)

Returns

Created security group information
salt.modules.neutron.create_security_group_rule(security_group, remote_group_id=None, direction='ingress', protocol=None, port_range_min=None, port_range_max=None, ethertype='IPv4', profile=None)

Creates a new security group rule

CLI Example:

```bash
salt '*' neutron.show_security_group_rule security-group-rule-id
```

Parameters

- **security_group** -- Security group name or ID to add rule
- **remote_group_id** -- Remote security group name or ID to apply rule (Optional)
- **direction** -- Direction of traffic: ingress/egress, default: ingress (Optional)
- **protocol** -- Protocol of packet: null/icmp/tcp/udp, default: null (Optional)
- **port_range_min** -- Starting port range (Optional)
- **port_range_max** -- Ending port range (Optional)
- **ethertype** -- IPv4/IPv6, default: IPv4 (Optional)
- **profile** -- Profile to build on (Optional)

Returns Created security group rule information

salt.modules.neutron.create_subnet(network, cidr, name=None, ip_version=4, profile=None)

Creates a new subnet

CLI Example:

```bash
salt '*' neutron.create_subnet network-name 192.168.1.0/24
```

Parameters

- **network** -- Network ID or name this subnet belongs to
- **cidr** -- CIDR of subnet to create (Ex. '192.168.1.0/24')
- **name** -- Name of the subnet to create (Optional)
- **ip_version** -- Version to use, default is 4(IPv4) (Optional)
- **profile** -- Profile to build on (Optional)

Returns Created subnet information

salt.modules.neutron.create_vpnservice(subnet, router, name, admin_state_up=True, profile=None)

Creates a new VPN service

CLI Example:

```bash
salt '*' neutron.create_vpnservice router-name name
```

Parameters

- **subnet** -- Subnet unique identifier for the VPN service deployment
- `router` -- Router unique identifier for the VPN service
- `name` -- Set a name for the VPN service
- `admin_state_up` -- Set admin state up to true or false, default: True (Optional)
- `profile` -- Profile to build on (Optional)

Returns

Created VPN service information

```
salt.modules.neutron.delete_floatingip(floatingip_id, profile=None)
```

Deletes the specified floating IP

CLI Example:
```
salt '*' neutron.delete_floatingip floatingip-id
```

Parameters

- `floatingip_id` -- ID of floating IP to delete
- `profile` -- Profile to build on (Optional)

Returns

True (Succeeded) or False

```
salt.modules.neutron.delete_ikepolicy(ikepolicy, profile=None)
```

Deletes the specified IKE Policy

CLI Example:
```
salt '*' neutron.delete_ikepolicy ikepolicy-name
```

Parameters

- `ikepolicy` -- ID or name of IKE policy to delete
- `profile` -- Profile to build on (Optional)

Returns

True (Succeeded) or False

```
salt.modules.neutron.delete_ipsec_site_connection(ipsec_site_connection, profile=None)
```

Deletes the specified IPsec Site Connection

CLI Example:
```
salt '*' neutron.delete_ipsec_site_connection connection-name
```

Parameters

- `ipsec_site_connection` -- ID or name of ipsec site connection to delete
- `profile` -- Profile to build on (Optional)

Returns

True (Succeeded) or False

```
salt.modules.neutron.delete_ipsecpolicy(ipsecpolicy, profile=None)
```

Deletes the specified IPsec Policy

CLI Example:
```
salt '*' neutron.delete_ipsecpolicy ipsecpolicy-name
```
Parameters

- **ipsecpolicy** -- ID or name of IPSec policy to delete
- **profile** -- Profile to build on (Optional)

**Returns**  True(Succeed) or False

```python
salt.modules.neutron.delete_network(network, profile=None)
```
Removes the specified network

**CLI Example:**
```
salt '*' neutron.delete_network network-name
salt '*' neutron.delete_network network-name profile=openstack1
```

Parameters

- **network** -- ID or name of network to delete
- **profile** -- Profile to build on (Optional)

**Returns**  True(Succeed) or False

```python
salt.modules.neutron.delete_port(port, profile=None)
```
Removes the specified port

**CLI Example:**
```
salt '*' neutron.delete_port port-name
salt '*' neutron.delete_port port-name profile=openstack1
```

Parameters

- **port** -- port name or ID
- **profile** -- Profile to build on (Optional)

**Returns**  True(Succeed) or False

```python
salt.modules.neutron.delete_quota(tenant_id, profile=None)
```
Removes the specified tenant's quota

**CLI Example:**
```
salt '*' neutron.delete_quota tenant-id
salt '*' neutron.delete_quota tenant-id profile=openstack1
```

Parameters

- **tenant_id** -- ID of tenant to quota delete
- **profile** -- Profile to build on (Optional)

**Returns**  True(Delete succeed) or False(Delete failed)

```python
salt.modules.neutron.delete_router(router, profile=None)
```
Removes the specified router

**CLI Example:**
```
```
salt '*' neutron.delete_router router-name

Parameters

- **router** -- ID or name of router to delete
- **profile** -- Profile to build on (Optional)

Returns  True(Succeed) or False

salt.modules.neutron.delete_security_group(security_group, profile=None)
Deletes the specified security group

CLI Example:

    salt '*' neutron.delete_security_group security-group-name

Parameters

- **security_group** -- ID or name of security group to delete
- **profile** -- Profile to build on (Optional)

Returns  True(Succeed) or False

salt.modules.neutron.delete_security_group_rule(security_group_rule_id, profile=None)
Deletes the specified security group rule

CLI Example:

    salt '*' neutron.delete_security_group_rule security-group-rule-id

Parameters

- **security_group_rule_id** -- ID of security group rule to delete
- **profile** -- Profile to build on (Optional)

Returns  True(Succeed) or False

salt.modules.neutron.delete_subnet(subnet, profile=None)
Deletes the specified subnet

CLI Example:

    salt '*' neutron.delete_subnet subnet-name
    salt '*' neutron.delete_subnet subnet-name profile=openstack1

Parameters

- **subnet** -- ID or name of subnet to delete
- **profile** -- Profile to build on (Optional)

Returns  True(Succeed) or False

salt.modules.neutron.delete_vpnservice(vpn_service, profile=None)
Deletes the specified VPN service

CLI Example:
salt '*' neutron.delete_vpnservice vpnservice-name

Parameters

- **vpnservice** -- ID or name of vpn service to delete
- **profile** -- Profile to build on (Optional)

Returns True(Succeed) or False

salt.modules.neutron.get_quotas_tenant(profile=None)
Fetches tenant info in server's context for following quota operation

CLI Example:

```
salt '*' neutron.get_quotas_tenant
salt '*' neutron.get_quotas_tenant profile=openstack1
```

Parameters **profile** -- Profile to build on (Optional)

Returns Quotas information

salt.modules.neutron.list_extensions(profile=None)
Fetches a list of all extensions on server side

CLI Example:

```
salt '*' neutron.list_extensions
salt '*' neutron.list_extensions profile=openstack1
```

Parameters **profile** -- Profile to build on (Optional)

Returns List of extensions

salt.modules.neutron.list_floatingips(profile=None)
Fetch a list of all floatingIPs for a tenant

CLI Example:

```
salt '*' neutron.list_floatingips
salt '*' neutron.list_floatingips profile=openstack1
```

Parameters **profile** -- Profile to build on (Optional)

Returns List of floatingIP

salt.modules.neutron.list_ikepolicies(profile=None)
Fetches a list of all configured IKEPolicies for a tenant

CLI Example:

```
salt '*' neutron.list_ikepolicies
salt '*' neutron.list_ikepolicies profile=openstack1
```

Parameters **profile** -- Profile to build on (Optional)

Returns List of IKE policy
```python
salt.modules.neutron.list_ipsec_site_connections(profile=None)
    Fetches all configured IPsec Site Connections for a tenant
    CLI Example:
    
    salt '*' neutron.list_ipsec_site_connections
    salt '*' neutron.list_ipsec_site_connections profile=openstack1

    Parameters profile -- Profile to build on (Optional)
    Returns List of IPsec site connection

salt.modules.neutron.list_ipsecpolicies(profile=None)
    Fetches a list of all configured IPsecPolicies for a tenant
    CLI Example:
    
    salt '*' neutron.list_ipsecpolicies ipsecpolicy-name
    salt '*' neutron.list_ipsecpolicies ipsecpolicy-name profile=openstack1

    Parameters profile -- Profile to build on (Optional)
    Returns List of IPSec policy

salt.modules.neutron.list_networks(profile=None)
    Fetches a list of all networks for a tenant
    CLI Example:
    
    salt '*' neutron.list_networks
    salt '*' neutron.list_networks profile=openstack1

    Parameters profile -- Profile to build on (Optional)
    Returns List of network

salt.modules.neutron.list_ports(profile=None)
    Fetches a list of all networks for a tenant
    CLI Example:
    
    salt '*' neutron.list_ports
    salt '*' neutron.list_ports profile=openstack1

    Parameters profile -- Profile to build on (Optional)
    Returns List of port

salt.modules.neutron.list_quotas(profile=None)
    Fetches all tenants quotas
    CLI Example:
    
    salt '*' neutron.list_quotas
    salt '*' neutron.list_quotas profile=openstack1

    Parameters profile -- Profile to build on (Optional)
    Returns List of quotas
```
salt.modules.neutron.list_routers(profile=None)
Fetches a list of all routers for a tenant

CLI Example:
```
salt '*' neutron.list_routers
salt '*' neutron.list_routers profile=openstack1
```

**Parameters**  
**profile** -- Profile to build on (Optional)

**Returns**  
List of router

salt.modules.neutron.list_security_group_rules(profile=None)
Fetches a list of all security group rules for a tenant

CLI Example:
```
salt '*' neutron.list_security_group_rules
salt '*' neutron.list_security_group_rules profile=openstack1
```

**Parameters**  
**profile** -- Profile to build on (Optional)

**Returns**  
List of security group rule

salt.modules.neutron.list_security_groups(profile=None)
Fetches a list of all security groups for a tenant

CLI Example:
```
salt '*' neutron.list_security_groups
salt '*' neutron.list_security_groups profile=openstack1
```

**Parameters**  
**profile** -- Profile to build on (Optional)

**Returns**  
List of security group

salt.modules.neutron.list_subnets(profile=None)
Fetches a list of all networks for a tenant

CLI Example:
```
salt '*' neutron.list_subnets
salt '*' neutron.list_subnets profile=openstack1
```

**Parameters**  
**profile** -- Profile to build on (Optional)

**Returns**  
List of subnet

salt.modules.neutron.list_vpnservices(retrieve_all=True, profile=None, **kwargs)
Fetches a list of all configured VPN services for a tenant

CLI Example:
```
salt '*' neutron.list_vpnservices
```

**Parameters**

- **retrieve_all** -- True or False, default: True (Optional)
- **profile** -- Profile to build on (Optional)
Returns  List of VPN service

```
salt.modules.neutron.remove_gateway_router(router, profile=None)
```
Removes an external network gateway from the specified router

CLI Example:
```
salt '*' neutron.remove_gateway_router router-name
```

Parameters
- `router` -- ID or name of router
- `profile` -- Profile to build on (Optional)

Returns  True(Succeed) or False

```
salt.modules.neutron.remove_interface_router(router, subnet, profile=None)
```
Removes an internal network interface from the specified router

CLI Example:
```
salt '*' neutron.remove_interface_router router-name subnet-name
```

Parameters
- `router` -- ID or name of the router
- `subnet` -- ID or name of the subnet
- `profile` -- Profile to build on (Optional)

Returns  True(Succeed) or False

```
salt.modules.neutron.show_floatingip(floatingip_id, profile=None)
```
Fetches information of a certain floatingIP

CLI Example:
```
salt '*' neutron.show_floatingip floatingip-id
```

Parameters
- `floatingip_id` -- ID of floatingIP to look up
- `profile` -- Profile to build on (Optional)

Returns  Floating IP information

```
salt.modules.neutron.show_ikepolicy(ikepolicy, profile=None)
```
Fetches information of a specific IKEPolicy

CLI Example:
```
salt '*' neutron.show_ikepolicy ikepolicy-name
```

Parameters
- `ikepolicy` -- ID or name of ikepolicy to look up
- `profile` -- Profile to build on (Optional)
Returns IKE policy information

salt.modules.neutron.show_ipsec_site_connection(ipsec_site_connection, profile=None)
Fetches information of a specific IPsecSiteConnection

CLI Example:

```
salt '*' neutron.show_ipsec_site_connection connection-name
```

Parameters

- **ipsec_site_connection** -- ID or name of ipsec site connection to look up
- **profile** -- Profile to build on (Optional)

Returns IPsec site connection information

salt.modules.neutron.show_ipsecpolicy(ipsecpolicy, profile=None)
Fetches information of a specific IPsecPolicy

CLI Example:

```
salt '*' neutron.show_ipsecpolicy ipsecpolicy-name
```

Parameters

- **ipsecpolicy** -- ID or name of IPSec policy to look up
- **profile** -- Profile to build on (Optional)

Returns IPSec policy information

salt.modules.neutron.show_network(network, profile=None)
Fetches information of a certain network

CLI Example:

```
salt '*' neutron.show_network network-name
salt '*' neutron.show_network network-name profile=openstack1
```

Parameters

- **network** -- ID or name of network to look up
- **profile** -- Profile to build on (Optional)

Returns Network information

salt.modules.neutron.show_port(port, profile=None)
Fetches information of a certain port

CLI Example:

```
salt '*' neutron.show_port port-id
salt '*' neutron.show_port port-id profile=openstack1
```

Parameters

- **port** -- ID or name of port to look up
- **profile** -- Profile to build on (Optional)
Returns Port information

```
salt.modules.neutron.show_quota(tenant_id, profile=None)
```

Fetches information of a certain tenant's quotas

CLI Example:
```
salt '*' neutron.show_quota tenant-id
salt '*' neutron.show_quota tenant-id profile=openstack1
```

Parameters

- `tenant_id` -- ID of tenant
- `profile` -- Profile to build on (Optional)

Returns Quota information

```
salt.modules.neutron.show_router(router, profile=None)
```

Fetches information of a certain router

CLI Example:
```
salt '*' neutron.show_router router-name
```

Parameters

- `router` -- ID or name of router to look up
- `profile` -- Profile to build on (Optional)

Returns Router information

```
salt.modules.neutron.show_security_group(security_group, profile=None)
```

Fetches information of a certain security group

CLI Example:
```
salt '*' neutron.show_security_group security-group-name
```

Parameters

- `security_group` -- ID or name of security group to look up
- `profile` -- Profile to build on (Optional)

Returns Security group information

```
salt.modules.neutron.show_security_group_rule(security_group_rule_id, profile=None)
```

Fetches information of a certain security group rule

CLI Example:
```
salt '*' neutron.show_security_group_rule security-group-rule-id
```

Parameters

- `security_group_rule_id` -- ID of security group rule to look up
- `profile` -- Profile to build on (Optional)

Returns Security group rule information
salt.modules.neutron.show_subnet(subnet, profile=None)
    Fetches information of a certain subnet
    
    CLI Example:
    
    salt '*' neutron.show_subnet subnet-name

    Parameters
    • subnet -- ID or name of subnet to look up
    • profile -- Profile to build on (Optional)

    Returns Subnet information

salt.modules.neutron.show_vpnservice(vpnservice, profile=None, **kwargs)
    Fetches information of a specific VPN service
    
    CLI Example:
    
    salt '*' neutron.show_vpnservice vpnservice-name

    Parameters
    • vpnservice -- ID or name of vpn service to look up
    • profile -- Profile to build on (Optional)

    Returns VPN service information

salt.modules.neutron.update_floatingip(floatingip_id, port, profile=None)
    Updates a floatingIP
    
    CLI Example:
    
    salt '*' neutron.update_floatingip network-name port-name

    Parameters
    • floatingip_id -- ID of floatingIP
    • port -- ID or name of port
    • profile -- Profile to build on (Optional)

    Returns Value of updated floating IP information

salt.modules.neutron.update_network(network, name, profile=None)
    Updates a network
    
    CLI Example:
    
    salt '*' neutron.update_network network-name new-network-name

    Parameters
    • network -- ID or name of network to update
    • name -- Name of this network
    • profile -- Profile to build on (Optional)

    Returns Value of updated network information
**salt.modules.neutron.update_port** *(port, name, admin_state_up=True, profile=None)*

Updates a port

**CLI Example:**

```
salt '*' neutron.update_port port-name network-name new-port-name
```

**Parameters**

- **port** -- Port name or ID
- **name** -- Name of this port
- **admin_state_up** -- Set admin state up to true or false, default: true (Optional)
- **profile** -- Profile to build on (Optional)

**Returns**

Value of updated port information

**salt.modules.neutron.update_quota** *(tenant_id, subnet=None, router=None, network=None, floatingip=None, port=None, security_group=None, security_group_rule=None, profile=None)*

Update a tenant’s quota

**CLI Example:**

```
salt '*' neutron.update_quota tenant-id subnet=40 router=50 network=10 floatingip=30 port=30
```

**Parameters**

- **tenant_id** -- ID of tenant
- **subnet** -- Value of subnet quota (Optional)
- **router** -- Value of router quota (Optional)
- **network** -- Value of network quota (Optional)
- **floatingip** -- Value of floatingip quota (Optional)
- **port** -- Value of port quota (Optional)
- **security_group** -- Value of security group (Optional)
- **security_group_rule** -- Value of security group rule (Optional)
- **profile** -- Profile to build on (Optional)

**Returns**

Value of updated quota

**salt.modules.neutron.update_router** *(router, name=None, admin_state_up=None, profile=None, **kwargs)*

Updates a router

**CLI Example:**

```
salt '*' neutron.update_router router_id name=new-router-name admin_state_up=1
```

**Parameters**

- **router** -- ID or name of router to update
- **name** -- Name of this router
- **ext_network** -- ID or name of the external for the gateway (Optional)
- **admin_state_up** -- Set admin state up to true or false, default: true (Optional)
- **profile** -- Profile to build on (Optional)
- **kwargs** --

Returns Value of updated router information

```python
salt.modules.neutron.update_security_group(security_group, name=None, description=None, profile=None)
```

Updates a security group

CLI Example:

```
salt '*' neutron.update_security_group security-group-name new-security-group-name
```

Parameters

- **security_group** -- ID or name of security group to update
- **name** -- Name of this security group (Optional)
- **description** -- Description of security group (Optional)
- **profile** -- Profile to build on (Optional)

Returns Value of updated security group information

```python
salt.modules.neutron.update_subnet(subnet, name, profile=None)
```

Updates a subnet

CLI Example:

```
salt '*' neutron.update_subnet subnet-name new-subnet-name
```

Parameters

- **subnet** -- ID or name of subnet to update
- **name** -- Name of this subnet
- **profile** -- Profile to build on (Optional)

Returns Value of updated subnet information

```python
salt.modules.neutron.update_vpnservice(vpnservice, desc, profile=None)
```

Updates a VPN service

CLI Example:

```
salt '*' neutron.update_vpnservice vpnservice-name desc='VPN Service1'
```

Parameters

- **vpnservice** -- ID or name of vpn service to update
- **desc** -- Set a description for the VPN service
- **profile** -- Profile to build on (Optional)

Returns Value of updated VPN service information
31.16.165 salt.modules.nfs3

Module for managing NFS version 3.

`salt.modules.nfs3.del_export`(*exports="/etc/exports", path=None*)

Remove an export

CLI Example:

```
salt '*' nfs.del_export /media/storage
```

`salt.modules.nfs3.list_exports`(*exports="/etc/exports")

List configured exports

CLI Example:

```
salt '*' nfs.list_exports
```

31.16.166 salt.modules.nftables

Support for nftables

`salt.modules.nftables.append`(*table='filter', chain=None, rule=None, family='ipv4')

Append a rule to the specified table & chain.

This function accepts a rule in a standard nftables command format, starting with the chain. Trying to force users to adapt to a new method of creating rules would be irritating at best, and we already have a parser that can handle it.

CLI Example:

```
salt '*' nftables.append filter input \n  rule='input tcp dport 22 log accept'
```

IPv6:

```
salt '*' nftables.append filter input \n  rule='input tcp dport 22 log accept' \n  family=ipv6
```

`salt.modules.nftables.build_rule`(*table=None, chain=None, command=None, position=None, full=None, family='ipv4', **kwargs*)

Build a well-formatted nftables rule based on kwargs. A table and chain are not required, unless full is True.

If full is True, then table, chain and command are required. command may be specified as either insert, append, or delete. This will return the nftables command, exactly as it would be used from the command line.

If a position is required (as with insert or delete), it may be specified as position. This will only be useful if full is True.

If connstate is passed in, it will automatically be changed to state.

CLI Examples:

```
salt '*' nftables.build_rule match=state \n  connstate=RELATED,ESTABLISHED jump=ACCEPT
salt '*' nftables.build_rule filter input command=insert position=3 \n  full=True match=state state=related,established jump=accept
```

IPv6:

```
salt '*' nftables.build_rule match=state \n```

31.16. Full list of builtin execution modules
connstate\nfamily=ipv6
salt '*' nftables.build_rule filter input command=insert position=3 \n    full=True match=state state=related,established jump=accept \n    family=ipv6

salt.modules.nftables.check(table='filter', chain=None, rule=None, family='ipv4')
Check for the existence of a rule in the table and chain

This function accepts a rule in a standard nftables command format, starting with the chain. Trying to force users to adapt to a new method of creating rules would be irritating at best, and we already have a parser that can handle it.

CLI Example:
salt '*' nftables.check filter input \n    rule='input tcp dport 22 log accept'
IPv6:
salt '*' nftables.check filter input \n    rule='input tcp dport 22 log accept' \n    family=ipv6

salt.modules.nftables.check_chain(table='filter', chain=None, family='ipv4')
New in version 2014.7.0.
Check for the existence of a chain in the table

CLI Example:
salt '*' nftables.check_chain filter input
IPv6:
salt '*' nftables.check_chain filter input family=ipv6

salt.modules.nftables.check_table(table=None, family='ipv4')
Check for the existence of a table

CLI Example:
salt '*' nftables.check_table nat

salt.modules.nftables.delete(table, chain=None, position=None, rule=None, family='ipv4')
Delete a rule from the specified table & chain, specifying either the rule in its entirety, or the rule’s position in the chain.

This function accepts a rule in a standard nftables command format, starting with the chain. Trying to force users to adapt to a new method of creating rules would be irritating at best, and we already have a parser that can handle it.

CLI Examples:
salt '*' nftables.delete filter input position=3
salt '*' nftables.delete filter input \n    rule='input tcp dport 22 log accept'
IPv6:
salt '*' nftables.delete filter input position=3 family=ipv6
salt '*(snftables.delete filter input \
 rule='input tcp dport 22 log accept' \n family=ipv6

salt.modules.nftables.delete_chain(table='filter', chain=None, family='ipv4')
New in version 2014.7.0.
Delete the chain from the specified table.

CLI Example:
salt '* nftables.delete_chain filter input
salt '* nftables.delete_chain filter foo

IPv6:
salt '* nftables.delete_chain filter input family=ipv6
salt '* nftables.delete_chain filter foo family=ipv6

salt.modules.nftables.delete_table(table, family='ipv4')
New in version 2014.7.0.
Create new custom table.

CLI Example:
salt '* nftables.delete_table filter

IPv6:
salt '* nftables.delete_table filter family=ipv6

salt.modules.nftables.flush(table='filter', chain='*', family='ipv4')
Flush the chain in the specified table, flush all chains in the specified table if chain is not specified.

CLI Example:
salt '* nftables.flush filter
salt '* nftables.flush filter input
IPv6:
salt '* nftables.flush filter input family=ipv6

salt.modules.nftables.get_rule_handle(table='filter', chain=None, rule=None, family='ipv4')
Get the handle for a particular rule

This function accepts a rule in a standard nftables command format, starting with the chain. Trying to force users to adapt to a new method of creating rules would be irritating at best, and we already have a parser that can handle it.

CLI Example:
salt '* nftables.get_rule_handle filter input \
 rule='input tcp dport 22 log accept'

IPv6:
salt '* nftables.get_rule_handle filter input \
 rule='input tcp dport 22 log accept' \
 family=ipv6
salt.modules.nftables.get_rules(family='ipv4')
Return a data structure of the current, in-memory rules

CLI Example:

```
salt '*' nftables.get_rules
salt '*' nftables.get_rules family=ipv6
```

salt.modules.nftables.get_saved_rules(conf_file=None, family='ipv4')
Return a data structure of the rules in the conf file

CLI Example:

```
salt '*' nftables.get_saved_rules
```

salt.modules.nftables.insert(table='filter', chain=None, position=None, rule=None, family='ipv4')
Insert a rule into the specified table & chain, at the specified position.

If position is not specified, rule will be inserted in first position.

This function accepts a rule in a standard nftables command format, starting with the chain. Trying to force users to adapt to a new method of creating rules would be irritating at best, and we already have a parser that can handle it.

CLI Examples:

```
salt '*' nftables.insert filter input \   
  rule='input tcp dport 22 log accept'
salt '*' nftables.insert filter input position=3 \   
  rule='input tcp dport 22 log accept'

IPv6:
salt '*' nftables.insert filter input \   
  rule='input tcp dport 22 log accept' \   
  family=ipv6
salt '*' nftables.insert filter input position=3 \   
  rule='input tcp dport 22 log accept' \   
  family=ipv6
```

salt.modules.nftables.new_chain(table='filter', chain=None, table_type=None, hook=None, priority=None, family='ipv4')
New in version 2014.7.0.
Create new chain to the specified table.

CLI Example:

```
salt '*' nftables.new_chain filter input
salt '*' nftables.new_chain filter input \   
  table_type=filter hook=input priority=0
salt '*' nftables.new_chain filter foo
IPv6:
salt '*' nftables.new_chain filter input family=ipv6
salt '*' nftables.new_chain filter input \
```
table_type=filter hook=input priority=0 family=ipv6
salt '*' nftables.new_chain filter foo family=ipv6

salt.modules.nftables.new_table(table, family='ipv4')
New in version 2014.7.0.
Create new custom table.
CLI Example:
salt '*' nftables.new_table filter
IPv6:
salt '*' nftables.new_table filter family=ipv6

salt.modules.nftables.save(filename=None, family='ipv4')
Save the current in-memory rules to disk
CLI Example:
salt '*' nftables.save /etc/nftables

salt.modules.nftables.version()
Return version from nftables --version
CLI Example:
salt '*' nftables.version

31.16.167 salt.modules.nginx

Support for nginx
salt.modules.nginx.build_info()
Return server and build arguments
CLI Example:
salt '*' nginx.build_info

salt.modules.nginx.configtest()
test configuration and exit
CLI Example:
salt '*' nginx.configtest

salt.modules.nginx.signal(signal=None)
Signals nginx to start, reload, reopen or stop.
CLI Example:
salt '*' nginx.signal reload

salt.modules.nginx.status(url='http://127.0.0.1/status')
Return the data from an Nginx status page as a dictionary. http://wiki.nginx.org/HttpStubStatusModule
url The URL of the status page. Defaults to 'http://127.0.0.1/status'
CLI Example:
salt ' '* nginx.status

salt.modules.nginx.version()
    Return server version from nginx -v
    CLI Example:
    salt ' '* nginx.version

31.16.168 salt.modules.node

Module for full system inspection.

salt.modules.node.inspect(mode='all', priority=19, **kwargs)
    Start node inspection and save the data to the database for further query.
    Parameters:
    • mode: Clarify inspection mode: configuration, payload, all (default)
    payload
    - filter: Comma-separated directories to track payload.
    • priority: (advanced) Set priority of the inspection. Default is low priority.
    CLI Example:
    salt ' '* node.inspect
    salt ' '* node.inspect configuration
    salt ' '* node.inspect payload filter=/opt,,/ext/oracle

salt.modules.node.query(scope, **kwargs)
    Query the node for specific information.
    Parameters:
    • scope: Specify scope of the query.
    - System: Return system data.
    - Software: Return software information.
    - Services: Return known services.
    - Identity: Return user accounts information for this system.
        accounts Can be either 'local', 'remote' or 'all' (equal to ```local,remote```). Remote accounts cannot be resolved on all systems, but only those, which supports `passwd -S -a`.
        disabled True (or False, default) to return only disabled accounts.
    - payload: Payload scope parameters:
        filter Include only results which path starts from the filter string.
        time Display time in Unix ticks or format according to the configured TZ (default) Values: ticks, tz (default)
        size Format size. Values: B, KB, MB, GB
        type Include payload type. Values (comma-separated): directory (or dir), link, file (default)
        Example (returns everything): type=directory,link,file
owners  Resolve UID/GID to an actual names or leave them numeric (default). Values: name (default), id

brief  Return just a list of payload elements, if True. Default: False.

—all: Return all information (default).

CLI Example:

```
salt '*' node.query scope=os
salt '*' node.query payload type=file,link filter=/etc size=Kb brief=False
```

### 31.16.169 salt.modules.nova

Module for handling OpenStack Nova calls

**depends**

- novaclient Python module

**configuration**  This module is not usable until the user, password, tenant, and auth URL are specified either in a pillar or in the minion's config file. For example:

```
keystone.user: admin
keystone.password: verybadpass
keystone.tenant: admin
keystone.auth_url: 'http://127.0.0.1:5000/v2.0/'
# Optional
keystone.region_name: 'regionOne'
```

If configuration for multiple OpenStack accounts is required, they can be set up as different configuration profiles: For example:

```
openstack1:
  keystone.user: admin
  keystone.password: verybadpass
  keystone.tenant: admin
  keystone.auth_url: 'http://127.0.0.1:5000/v2.0/'

openstack2:
  keystone.user: admin
  keystone.password: verybadpass
  keystone.tenant: admin
  keystone.auth_url: 'http://127.0.0.2:5000/v2.0/'
```

With this configuration in place, any of the nova functions can make use of a configuration profile by declaring it explicitly. For example:

```
salt '*' nova.flavor_list profile=openstack1
```

**salt.modules.nova.boot(name, flavor_id=0, image_id=0, profile=None, timeout=300)**

Boot (create) a new instance

**name**  Name of the new instance (must be first)

**flavor_id**  Unique integer ID for the flavor

**image_id**  Unique integer ID for the image

**timeout**  How long to wait, after creating the instance, for the provider to return information about it (default 300 seconds).
New in version 2014.1.0.

CLI Example:

```
salt '*' nova.boot myinstance flavor_id=4596 image_id=2
```

The flavor_id and image_id are obtained from `nova.flavor_list` and `nova.image_list`

```
salt '*' nova.flavor_list
salt '*' nova.image_list
```

```text
class modules.nova.delete

Delete an instance

- instance_id: ID of the instance to be deleted

CLI Example:

```
salt '*' nova.delete 1138
```
```
class modules.nova.flavor_create

Add a flavor to nova (nova flavor-create). The following parameters are required:

- name: Name of the new flavor (must be first)
- flavor_id: Unique integer ID for the new flavor
- ram: Memory size in MB
- disk: Disk size in GB
- vcpus: Number of vcpus

CLI Example:

```
salt '*' nova.flavor_create myflavor flavor_id=6 ram=4096 disk=10 vcpus=1
```
```
class modules.nova.flavor_delete

Delete a flavor from nova by id (nova flavor-delete)

CLI Example:

```
salt '*' nova.flavor_delete 7
```
```
class modules.nova.flavor_list

Return a list of available flavors (nova flavor-list)

CLI Example:

```
salt '*' nova.flavor_list
```
```
class modules.nova.image_list

Return a list of available images (nova images-list + nova image-show) If a name is provided, only that image will be displayed.

CLI Examples:

```
salt '*' nova.image_list
salt '*' nova.image_list myimage
```
```
class modules.nova.image_meta_delete

Delete a key=value pair from the metadata for an image (nova image-meta set)

CLI Examples:

```
Salt Documentation, Release 2015.8.0

salt 'localhost' nova.image_meta_delete 6f52b2ff-0b31-4d84-8fd1-af45b84824f6 keys=cheese
salt 'localhost' nova.image_meta_delete name=myimage keys=salad,beans

salt.modules.nova.image_meta_set(image_id=None, name=None, profile=None, **kwargs)
Sets a key=value pair in the metadata for an image (nova image-meta set)

CLI Examples:
salt 'localhost' nova.image_meta_set 6f52b2ff-0b31-4d84-8fd1-af45b84824f6 cheese=gruyere
salt 'localhost' nova.image_meta_set name=myimage salad=pasta beans=baked

salt.modules.nova.keypair_add(name, pubfile=None, pubkey=None, profile=None)
Add a keypair to nova (nova keypair-add)

CLI Examples:
salt 'localhost' nova.keypair_add mykey pubfile='/home/myuser/.ssh/id_rsa.pub'
salt 'localhost' nova.keypair_add mykey pubkey='ssh-rsa <key> myuser@mybox'

salt.modules.nova.keypair_delete(name, profile=None)
Add a keypair to nova (nova keypair-delete)

CLI Example:
salt 'localhost' nova.keypair_delete mykey

salt.modules.nova.keypair_list(profile=None)
Return a list of available keypairs (nova keypair-list)

CLI Example:
salt 'localhost' nova.keypair_list

salt.modules.nova.list(profile=None)
To maintain the feel of the nova command line, this function simply calls the server_list function.

salt.modules.nova.lock(instance_id, profile=None)
Lock an instance

instance_id ID of the instance to be locked

CLI Example:
salt 'localhost' nova.lock 1138

salt.modules.nova.resume(instance_id, profile=None)
Resume an instance

instance_id ID of the instance to be resumed

CLI Example:
salt 'localhost' nova.resume 1138

salt.modules.nova.secgroup_create(name, description, profile=None)
Add a secgroup to nova (nova secgroup-create)

CLI Example:
salt 'localhost' nova.secgroup_create mygroup 'This is my security group'
### salt.modules.nova.secgroup_delete(name, profile=None)
Delete a secgrouptonova (nova segroup-delete)

**CLI Example:**
```
salt '*' nova.secgroup_delete mygroup
```

### salt.modules.nova.secgroup_list(profile=None)
Return a list of available security groups (nova items-list)

**CLI Example:**
```
salt '*' nova.secgroup_list
```

### salt.modules.nova.server_by_name(name, profile=None)
Return information about a server

**name** Server Name

**CLI Example:**
```
salt '*' nova.server_by_name myserver profile=openstack
```

### salt.modules.nova.server_list(profile=None)
Return list of active servers

**CLI Example:**
```
salt '*' nova.show
```

### salt.modules.nova.server_list_detailed(profile=None)
Return detailed list of active servers

**CLI Example:**
```
salt '*' nova.server_list_detailed
```

### salt.modules.nova.server_show(server_id, profile=None)
Return detailed information for an active server

**CLI Example:**
```
salt '*' nova.server_show <server_id>
```

### salt.modules.nova.show(server_id, profile=None)
To maintain the feel of the nova command line, this function simply calls the server_show function.

**CLI Example:**
```
salt '*' nova.show
```

### salt.modules.nova.suspend(instance_id, profile=None)
Suspend an instance

**instance_id** ID of the instance to be suspended

**CLI Example:**
```
salt '*' nova.suspend 1138
```

### salt.modules.nova.volume_attach(name, server_name, device='/dev/xvdb', profile=None, timeout=300)
Attach a block storage volume
name Name of the new volume to attach
server_name Name of the server to attach to
device Name of the device on the server
profile Profile to build on

CLI Example:

```
salt '*' nova.volume_attach myblock slice.example.com profile=openstack
dsalt '*' nova.volume_attach myblock server.example.com device='/dev/xvdb' profile=openstack
```

```
salt.modules.nova.volume_create(name=name, size=100, snapshot=None, voltype=None, profile=None)
  Create a block storage volume
  name Name of the new volume (must be first)
  size Volume size
  snapshot Block storage snapshot id
  voltype Type of storage
  profile Profile to build on
  CLI Example:
  salt '*' nova.volume_create myblock size=300 profile=openstack
```

```
salt.modules.nova.volume_delete(name, profile=None)
  Destroy the volume
  name Name of the volume
  profile Profile to build on
  CLI Example:
  salt '*' nova.volume_delete myblock profile=openstack
```

```
salt.modules.nova.volume_detach(name, profile=None, timeout=300)
  Attach a block storage volume
  name Name of the new volume to attach
  server_name Name of the server to detach from
  profile Profile to build on
  CLI Example:
  salt '*' nova.volume_detach myblock profile=openstack
```

```
salt.modules.nova.volume_list(search_opts=None, profile=None)
  List storage volumes
  search_opts Dictionary of search options
  profile Profile to use
  CLI Example:
  salt '*' nova.volume_list search_opts='{"display_name": "myblock"}''
```

```
salt.modules.nova.volume_show(name, profile=None)
  Create a block storage volume
```

31.16. Full list of builtin execution modules
name  Name of the volume
profile  Profile to use

CLI Example:

```bash
salt '*' nova.volume_show myblock profile=openstack
```

### 31.16.170 salt.modules.npm

Manage and query NPM packages.

**salt.modules.npm.install** *(pkg=None, pkgs=None, dir=None, runas=None, registry=None, env=None)*

Install an NPM package.

If no directory is specified, the package will be installed globally. If no package is specified, the dependencies (from package.json) of the package in the given directory will be installed.

- **pkg** A package name in any format accepted by NPM, including a version identifier
- **pkgs** A list of package names in the same format as the name parameter

New in version 2014.7.0.

- **dir** The target directory in which to install the package, or None for global installation
- **runas** The user to run NPM with
- **registry** The NPM registry to install the package from.

New in version 2014.7.0.

- **env** Environment variables to set when invoking npm. Uses the same env format as the cmd.run execution function.

New in version 2014.7.0.

CLI Example:

```bash
salt '*' npm.install coffee-script
```

```bash
salt '*' npm.install coffee-script@1.0.1
```

**salt.modules.npm.list** *(pkg=None, dir=None, runas=None, registry=None, env=None)*

List installed NPM packages.

If no directory is specified, this will return the list of globally-installed packages.

- **pkg** Limit package listing by name
- **dir** The directory whose packages will be listed, or None for global installation
- **runas** The user to run NPM with

New in version 2014.7.0.

- **env** Environment variables to set when invoking npm. Uses the same env format as the cmd.run execution function.

New in version 2014.7.0.

CLI Example:

```bash
salt '*' npm.list
```
salt.modules.npm.uninstall(pkg, dir=None, runas=None, env=None)

Uninstall an NPM package.

pkg  A package name in any format accepted by NPM

dir  The target directory from which to uninstall the package, or None for global installation

runas  The user to run NPM with

env  Environment variables to set when invoking npm. Uses the same env format as the cmd.run execution function.

New in version 2015.5.3.

CLI Example:

```
salt '*' npm.uninstall coffee-script
```

### 31.16.171 salt.modules.nspawn

Manage nspawn containers

New in version 2015.8.0.

systemd-nspawn(1) is a tool used to manage lightweight namespace containers. This execution module provides several functions to help manage these containers.

Minions running systemd >= 219 will place new containers in /var/lib/machines, while those running systemd < 219 will place them in /var/lib/container.

salt.modules.nspawn.bootstrap_container(name, dist=None, version=None)

Bootstrap a container from package servers, if dist is None the os the minion is running as will be created, otherwise the needed bootstrapping tools will need to be available on the host.

CLI Example:

```
salt myminion nspawn.bootstrap_container <name>
```

salt.modules.nspawn.bootstrap_salt(name, config=None, approve_key=True, install=True, pub_key=None, priv_key=None, bootstrap_url=None, force_install=False, unconditional_install=False, bootstrap_delay=None, bootstrap_args=None, bootstrap_shell=None)

Bootstrap a container from package servers, if dist is None the os the minion is running as will be created, otherwise the needed bootstrapping tools will need to be available on the host.

CLI Example:

```
salt '*' nspawn.bootstrap_salt arch1
```

salt.modules.nspawn.copy_to(name, *args, **kwargs)

Copy a file from the host into a container

name  Container name

source  File to be copied to the container

dest  Destination on the container. Must be an absolute path.

overwrite  [False] Unless this option is set to True, then if a file exists at the location specified by the dest argument, an error will be raised.
makedirs: False

Create the parent directory on the container if it does not already exist.

CLI Example:

```bash
salt 'minion' nspawn.copy_to /tmp/foo /root/foo
```

salt.modules.nspawn.disable(name, *args, **kwargs)
Set the named container to not be launched at boot

CLI Example:

```bash
salt myminion nspawn.enable <name>
```

salt.modules.nspawn.enable(name, *args, **kwargs)
Set the named container to be launched at boot

CLI Example:

```bash
salt myminion nspawn.enable <name>
```

salt.modules.nspawn.exists(name)
Returns true if the named container exists

CLI Example:

```bash
salt myminion nspawn.exists <name>
```

salt.modules.nspawn.info(name, **kwargs)
Return info about a container

**Note:** The container must be running for machinectl to gather information about it. If the container is stopped, then this function will start it.

```bash
start [False] If True, then the container will be started to retrieve the info. A Started key will be in the return data if the container was started.
```

CLI Example:

```bash
salt myminion nspawn.info arch1
salt myminion nspawn.info arch1 force_start=True
```

salt.modules.nspawn.list_all()
Lists all nspawn containers

CLI Example:

```bash
salt myminion nspawn.list_all
```

salt.modules.nspawn.list_running()
Lists running nspawn containers

**Note:** nspawn.list also works to list running containers

CLI Example:

```bash
salt myminion nspawn.list_running
salt myminion nspawn.list
```
salt.modules.nspawn.list_stopped()

Lists stopped nspawn containers

CLI Example:
salt myminion nspawn.list_stopped

salt.modules.nspawn.pid(name, *args, **kwargs)

Returns the PID of a container

name Container name

CLI Example:
salt myminion nspawn.pid arch1

salt.modules.nspawn.poweroff(name)

Issue a clean shutdown to the container. Equivalent to running `machinectl poweroff` on the named container.

For convenience, running `nspawn.stop` (as shown in the CLI examples below) is equivalent to running `nspawn.poweroff`.

Note: `machinectl poweroff` is only supported in systemd >= 219. On earlier systemd versions, running this function will simply issue a clean shutdown via `systemctl`.

CLI Examples:
salt myminion nspawn.poweroff arch1
salt myminion nspawn.stop arch1

salt.modules.nspawn.pull_dkr(url, name, index)

Execute a `machinectl pull-dkr` to download a docker image and add it to `/var/lib/machines` as a new container.

Note: Requires systemd >= 219

url URL from which to download the container
name Name for the new container
index URL of the Docker index server from which to pull (must be an `http://` or `https://` URL).

CLI Examples:
salt myminion nspawn.pull_dkr centos/centos6 cent6 index=https://get.docker.com
salt myminion nspawn.pull_docker centos/centos6 cent6 index=https://get.docker.com

salt.modules.nspawn.pull_raw(url, name, verify=False)

Execute a `machinectl pull-raw` to download a `.qcow2` or raw disk image, and add it to `/var/lib/machines` as a new container.

Note: Requires systemd >= 219

url URL from which to download the container
name Name for the new container
**verify** [False] Perform signature or checksum verification on the container. See the machinectl(1) man page (section titled `Image Transfer Commands`) for more information on requirements for image verification. To perform signature verification, use `verify=signature`. For checksum verification, use `verify=checksum`. By default, no verification will be performed.

CLI Examples:

```
```

**salt.modules.nspawn.pull_tar**(url, name, verify=False)

Execute a machinectl pull-raw to download a .tar container image, and add it to /var/lib/machines as a new container.

**Note:** Requires systemd >= 219

- **url** URL from which to download the container
- **name** Name for the new container
- **verify** [False] Perform signature or checksum verification on the container. See the machinectl(1) man page (section titled `Image Transfer Commands`) for more information on requirements for image verification. To perform signature verification, use `verify=signature`. For checksum verification, use `verify=checksum`. By default, no verification will be performed.

CLI Examples:

```
salt myminion nspawn.pull_tar http://foo.domain.tld/containers/archlinux-2015.02.01.tar.gz arch2
```

**salt.modules.nspawn.reboot**(name, *args, **kwargs)

Reboot the container by sending a SIGINT to its init process. Equivalent to running machinectl reboot on the named container.

For convenience, running `nspawn.restart` (as shown in the CLI examples below) is equivalent to running `nspawn.reboot`.

**Note:** machinectl reboot is only supported in systemd >= 219. On earlier systemd versions, running this function will instead restart the container via systemctl.

CLI Examples:

```
salt myminion nspawn.reboot arch1
salt myminion nspawn.restart arch1
```

**salt.modules.nspawn.remove**(name, *args, **kwargs)

Remove the named container

**Warning:** This function will remove all data associated with the container. It will not, however, remove the btrfs subvolumes created by pulling container images (`nspawn.pull_raw`, `nspawn.pull_tar`, `nspawn.pull_dkr`).

- **stop** [False] If True, the container will be destroyed even if it is running/frozen.

CLI Examples:

```
salt '*' nspawn.remove foo
salt '*' nspawn.remove foo stop=True
```
salt.modules.nspawn.retcode(name, cmd, no_start=False, preserve_state=True, stdin=None, python_shell=True, output_loglevel='debug', use_vt=False, ignore_retcode=False, keep_env=None)

Run cmd.retcode within a container

- **name**  Name of the container in which to run the command
- **cmd**  Command to run
- **no_start**  [False] If the container is not running, don’t start it
- **preserve_state**  [True] After running the command, return the container to its previous state
- **stdin**  [None] Standard input to be used for the command
- **output_loglevel**  [debug] Level at which to log the output from the command. Set to quiet to suppress logging.
- **use_vt**  [False] Use SaltStack’s utils.vt to stream output to console. Assumes output=all.
- **keep_env**  [None] If not passed, only a sane default PATH environment variable will be set. If True, all environment variables from the container’s host will be kept. Otherwise, a comma-separated list (or Python list) of environment variable names can be passed, and those environment variables will be kept.

CLI Example:
```
salt myminion nspawn.retcode mycontainer 'ip addr show'
```

salt.modules.nspawn.run(name, cmd, no_start=False, preserve_state=True, stdin=None, python_shell=True, output_loglevel='debug', use_vt=False, ignore_retcode=False, keep_env=None)

Run cmd.run within a container

- **name**  Name of the container in which to run the command
- **cmd**  Command to run
- **no_start**  [False] If the container is not running, don’t start it
- **preserve_state**  [True] After running the command, return the container to its previous state
- **stdin**  [None] Standard input to be used for the command
- **output_loglevel**  [debug] Level at which to log the output from the command. Set to quiet to suppress logging.
- **use_vt**  [False] Use SaltStack’s utils.vt to stream output to console.
- **keep_env**  [None] If not passed, only a sane default PATH environment variable will be set. If True, all environment variables from the container’s host will be kept. Otherwise, a comma-separated list (or Python list) of environment variable names can be passed, and those environment variables will be kept.

CLI Example:
```
salt myminion nspawn.run mycontainer 'ifconfig -a'
```

salt.modules.nspawn.run_all(name, cmd, no_start=False, preserve_state=True, stdin=None, python_shell=True, output_loglevel='debug', use_vt=False, ignore_retcode=False, keep_env=None)

Run cmd.run_all within a container

**Note:** While the command is run within the container, it is initiated from the host. Therefore, the PID in the return dict is from the host, not from the container.
**name** Name of the container in which to run the command

**cmd** Command to run

**no_start** [False] If the container is not running, don’t start it

**preserve_state** [True] After running the command, return the container to its previous state

**stdin** [None] Standard input to be used for the command

**output_loglevel** [debug] Level at which to log the output from the command. Set to quiet to suppress logging.

**use_vt** [False] Use SaltStack’s utils.vtt to stream output to console. Assumes output=all.

**keep_env** [None] If not passed, only a sane default PATH environment variable will be set. If True, all environment variables from the container’s host will be kept. Otherwise, a comma-separated list (or Python list) of environment variable names can be passed, and those environment variables will be kept.

CLI Example:

```bash
salt myminion nspawn.run_all mycontainer 'ip addr show'
```

**salt.modules.nspawn.run_stderr**

```python
salt.modules.nspawn.run_stderr(name, cmd, no_start=False, preserve_state=True, stdin=None, python_shell=True, output_loglevel='debug', use_vt=False, ignore_retcode=False, keep_env=None)
```

Run `cmd.run_stderr` within a container

**name** Name of the container in which to run the command

**cmd** Command to run

**no_start** [False] If the container is not running, don’t start it

**preserve_state** [True] After running the command, return the container to its previous state

**stdin** [None] Standard input to be used for the command

**output_loglevel** [debug] Level at which to log the output from the command. Set to quiet to suppress logging.

**use_vt** [False] Use SaltStack’s utils.vtt to stream output to console. Assumes output=all.

**keep_env** [None] If not passed, only a sane default PATH environment variable will be set. If True, all environment variables from the container’s host will be kept. Otherwise, a comma-separated list (or Python list) of environment variable names can be passed, and those environment variables will be kept.

CLI Example:

```bash
salt myminion nspawn.run_stderr mycontainer 'ip addr show'
```

**salt.modules.nspawn.run_stdout**

```python
salt.modules.nspawn.run_stdout(name, cmd, no_start=False, preserve_state=True, stdin=None, python_shell=True, output_loglevel='debug', use_vt=False, ignore_retcode=False, keep_env=None)
```

Run `cmd.run_stdout` within a container

**name** Name of the container in which to run the command

**cmd** Command to run

**no_start** [False] If the container is not running, don’t start it

**preserve_state** [True] After running the command, return the container to its previous state

**stdin** [None] Standard input to be used for the command
**output_loglevel** [debug] Level at which to log the output from the command. Set to quiet to suppress logging.

**use_vt** [False] Use SaltStack’s utils.vt to stream output to console. Assumes output=all.

**keep_env** [None] If not passed, only a sane default PATH environment variable will be set. If True, all environment variables from the container’s host will be kept. Otherwise, a comma-separated list (or Python list) of environment variable names can be passed, and those environment variables will be kept.

**CLI Example:**

```
salt myminion nspawn.run_stdout mycontainer 'ifconfig -a'
```

**salt.modules.nspawn.start**(name, *args, **kwargs)
Start the named container

**CLI Example:**

```
salt myminion nspawn.start <name>
```

**salt.modules.nspawn.state**(name, *args, **kwargs)
Return state of container (running or stopped)

**CLI Example:**

```
salt myminion nspawn.state <name>
```

**salt.modules.nspawn.terminate**(name)
Kill all processes in the container without issuing a clean shutdown. Equivalent to running `machinectl terminate` on the named container.

For convenience, running `nspawn.stop` and passing `kill=True` (as shown in the CLI examples below) is equivalent to running `nspawn.terminate`.

**Note:** `machinectl terminate` is only supported in systemd >= 219. On earlier systemd versions, running this function will simply issue a clean shutdown via `systemctl`.

**CLI Examples:**

```
salt myminion nspawn.terminate arch1
salt myminion nspawn.stop arch1 kill=True
```

### 31.16.172 salt.modules.omapi

This module interacts with an ISC DHCP Server via OMAPI. `server_ip` and `server_port` params may be set in the minion config or pillar:

```
omapi.server_ip: 127.0.0.1
omapi.server_port: 7991
```

**depends** pypureomapi Python module

**salt.modules.omapi.add_host**(mac, name=None, ip=None, ddns=False, group=None, supersede_host=False)
Add a host object for the given mac.

**CLI Example:**

```
```
salt dhcp-server omapi.add_host ab:ab:ab:ab:ab name=host1

Add ddns-hostname and a fixed-ip statements:

salt dhcp-server omapi.add_host ab:ab:ab:ab:ab name=host1 ip=10.1.1.1 ddns=true

salt.modules.omapi.delete_host(mac=None, name=None)
Delete the host with the given mac or name.

CLI Examples:

salt dhcp-server omapi.delete_host name=host1
salt dhcp-server omapi.delete_host mac=ab:ab:ab:ab:ab

31.16.173 salt.modules.openbsd_sysctl

Module for viewing and modifying OpenBSD sysctl parameters

salt.modules.openbsd_sysctl.assign(name, value)
Assign a single sysctl parameter for this minion

CLI Example:

salt '*' sysctl.assign net.inet.ip.forwarding 1

salt.modules.openbsd_sysctl.get(name)
Return a single sysctl parameter for this minion

CLI Example:

salt '*' sysctl.get hw.physmem

salt.modules.openbsd_sysctl.persist(name, value, config='/etc/sysctl.conf')
Assign and persist a simple sysctl parameter for this minion

CLI Example:

salt '*' sysctl.persist net.inet.ip.forwarding 1

salt.modules.openbsd_sysctl.show(config_file=False)
Return a list of sysctl parameters for this minion

CLI Example:

salt '*' sysctl.show

31.16.174 salt.modules.openbsdpkg

Package support for OpenBSD

salt.modules.openbsdpkg.install(name=None, pkgs=None, sources=None, **kwargs)
Install the passed package

Return a dict containing the new package names and versions:

{'<package>': {'old': '<old-version>', 'new': '<new-version>'}}
CLI Example, Install one package:
```
salt '*' pkg.install <package name>
```

CLI Example, Install more than one package:
```
salt '*' pkg.install pkgs='["<package name">", "<package name">"]'
```

CLI Example, Install more than one package from an alternate source (e.g. salt file-server, HTTP, FTP, local filesystem):
```
salt '*' pkg.install sources='[{"<pkg name>": "salt://pkgs/<pkg filename>"}]'
```

salt.modules.openbsdpkg.latest_version(*names, **kwargs)
The available version of the package in the repository
CLI Example:
```
salt '*' pkg.latest_version <package name>
```

salt.modules.openbsdpkg.list_pkgs(versions_as_list=False, **kwargs)
List the packages currently installed as a dict:
```
{'<package_name>': '<version>'}
```

CLI Example:
```
salt '*' pkg.list_pkgs
```

salt.modules.openbsdpkg.purge(name=None, pkgs=None, **kwargs)
Package purges are not supported, this function is identical to remove().

- **name**: The name of the package to be deleted.
  
  Multiple Package Options:
  
- **pkgs**: A list of packages to delete. Must be passed as a python list. The `name` parameter will be ignored if this option is passed.

  New in version 0.16.0.

  Returns a dict containing the changes.

  CLI Example:
  
  ```
salt '*' pkg.purge <package name>
salt '*' pkg.purge <package1>,<package2>,<package3>
salt '*' pkg.purge pkgs='["foo", "bar"]'
```

salt.modules.openbsdpkg.remove(name=None, pkgs=None, **kwargs)
Remove a single package with pkg_delete

Multiple Package Options:

- **pkgs**: A list of packages to delete. Must be passed as a python list. The `name` parameter will be ignored if this option is passed.

  New in version 0.16.0.

  Returns a dict containing the changes.

  CLI Example:
salt '*' pkg.remove <package name>
salt '*' pkg.remove <package1>,<package2>,<package3>
salt '*' pkg.remove pkgs=['"foo", "bar"]'

salt.modules.openbsdpkg.version('names', **kwargs)
Returns a string representing the package version or an empty string if not installed. If more than one package
name is specified, a dict of name/version pairs is returned.

CLI Example:
salt '*' pkg.version <package name>
salt '*' pkg.version <package1> <package2> <package3> ...

31.16.175 salt.modules.openbsdrcctl

The rcctl service module for OpenBSD

salt.modules.openbsdrcctl.available(name)
Return True if the named service is available.

CLI Example:
salt '*' service.available ssdh

salt.modules.openbsdrcctl.disable(name, **kwargs)
Disable the named service to not start at boot.

CLI Example:
salt '*' service.disable <service name>

salt.modules.openbsdrcctl.disabled(name)
Return True if the named service is disabled at boot, False otherwise.

CLI Example:
salt '*' service.disabled <service name>

salt.modules.openbsdrcctl.enable(name, **kwargs)
Enable the named service to start at boot.
flags [None] Set optional flags to run the service with.
service.flags can be used to change the default flags.

CLI Example:
salt '*' service.enable <service name>
salt '*' service.enable <service name> flags=<flags>

salt.modules.openbsdrcctl.enabled(name, **kwargs)
Return True if the named service is enabled at boot and the provided flags match the configured ones (if any).
Return False otherwise.

name Service name

CLI Example:
salt '*' service.enabled <service name>
salt '*' service.enabled <service name> flags=<flags>
salt.modules.openbsdrcctl.get_all()
Return all installed services.
CLI Example:
salt '*' service.get_all

salt.modules.openbsdrcctl.get_disabled()
Return what services are available but not enabled to start at boot.
CLI Example:
salt '*' service.get_disabled

salt.modules.openbsdrcctl.get_enabled()
Return what services are set to run on boot.
CLI Example:
salt '*' service.get_enabled

salt.modules.openbsdrcctl.missing(name)
The inverse of service.available. Return True if the named service is not available.
CLI Example:
salt '*' service.missing sshd

salt.modules.openbsdrcctl.reload(name)
Reload the named service.
CLI Example:
salt '*' service.reload <service name>

salt.modules.openbsdrcctl.restart(name)
Restart the named service.
CLI Example:
    salt '*' service.restart <service name>

salt.modules.openbsdrcctl.start(name)
Start the named service.
CLI Example:
    salt '*' service.start <service name>

salt.modules.openbsdrcctl.status(name, sig=None)
Return the status for a service, returns a bool whether the service is running.
CLI Example:
    salt '*' service.status <service name>

salt.modules.openbsdrcctl.stop(name)
Stop the named service.
CLI Example:
    salt '*' service.stop <service name>
31.16.176 salt.modules.openbsdservice

The service module for OpenBSD

salt.modules.openbsdservice.available(name)
  New in version 2014.7.0.
  Returns True if the specified service is available, otherwise returns False.
  CLI Example:
  ```
  salt '*' service.available sshd
  ```

salt.modules.openbsdservice.disabled(name)
  New in version 2014.7.0.
  Return True if the named service is disabled, false otherwise
  CLI Example:
  ```
  salt '*' service.disabled <service name>
  ```

salt.modules.openbsdservice.enabled(name, **kwargs)
  New in version 2014.7.0.
  Return True if the named service is enabled, false otherwise
  CLI Example:
  ```
  salt '*' service.enabled <service name>
  ```

salt.modules.openbsdservice.get_all()
  New in version 2014.7.0.
  Return all available boot services
  CLI Example:
  ```
  salt '*' service.get_all
  ```

salt.modules.openbsdservice.get_disabled()
  New in version 2014.7.0.
  Return a set of services that are installed but disabled
  CLI Example:
  ```
  salt '*' service.get_disabled
  ```

salt.modules.openbsdservice.get_enabled()
  New in version 2014.7.0.
  Return a list of service that are enabled on boot
  CLI Example:
  ```
  salt '*' service.get_enabled
  ```

salt.modules.openbsdservice.missing(name)
  New in version 2014.7.0.
  The inverse of service.available. Returns True if the specified service is not available, otherwise returns False.
  CLI Example:
salt '*' service.missing sshd

salt.modules.openbsdservice.reload(name)
    New in version 2014.7.0.
    Reload the named service
    CLI Example:
    ```
salt '*' service.reload <service name>
```

salt.modules.openbsdservice.restart(name)
    Restart the named service
    CLI Example:
    ```
salt '*' service.restart <service name>
```

salt.modules.openbsdservice.start(name)
    Start the specified service
    CLI Example:
    ```
salt '*' service.start <service name>
```

salt.modules.openbsdservice.status(name, sig=None)
    Return the status for a service, returns a bool whether the service is running.
    CLI Example:
    ```
salt '*' service.status <service name>
```

salt.modules.openbsdservice.stop(name)
    Stop the specified service
    CLI Example:
    ```
salt '*' service.stop <service name>
```

31.16.177 salt.modules.openstack_config

Modify, retrieve, or delete values from OpenStack configuration files.

    maintainer  Jeffrey C. Ollie <jeff@ocjtech.us>
    maturity    new
    depends
    platform    linux

salt.modules.openstack_config.delete(filename, section, parameter)
    Delete a value from an OpenStack configuration file.

    filename    The full path to the configuration file
    section     The section from which to delete the parameter
    parameter   The parameter to delete
    CLI Example:
salt-call openstack_config.delete /etc/keystone/keystone.conf sql connection

salt.modules.openstack_config.get(filename, section, parameter)
Get a value from an OpenStack configuration file.

filename The full path to the configuration file
section The section from which to search for the parameter
parameter The parameter to return

CLI Example:

```
salt-call openstack_config.get /etc/keystone/keystone.conf sql connection
```

salt.modules.openstack_config.set(filename, section, parameter, value)
Set a value in an OpenStack configuration file.

filename The full path to the configuration file
section The section in which the parameter will be set
parameter The parameter to change
value The value to set

CLI Example:

```
salt-call openstack_config.set /etc/keystone/keystone.conf sql connection foo
```

31.16.178 salt.modules.oracle

Oracle DataBase connection module

maintainer Vladimir Bormotov <bormotov@gmail.com>
maturity new
depends cx_Oracle
platform all
configuration module provide connections for multiple Oracle DB instances.

OS Environment

```
ORACLE_HOME: path to oracle product
PATH: path to Oracle Client libs need to be in PATH
```

pillar

```
oracle.dbs: list of known based
oracle.dbs.<db>.uri: connection credentials in format:
    user/password@host[:port]/sid[ as {sysdba|sysoper}]
```

salt.modules.oracle.client_version()
Oracle Client Version

CLI Example:

```
salt '*' oracle.client_version
```

1106 Chapter 31. Reference
salt.modules.oracle.run_query(db, query)
   Run SQL query and return result
   CLI Example:
   salt '*' oracle.run_query my_db "select * from my_table"

salt.modules.oracle.show_dbs(*dbs)
   Show databases configuration from pillar. Filter by *args
   CLI Example:
   salt '*' oracle.show_dbs
   salt '*' oracle.show_dbs my_db

salt.modules.oracle.show_env()
   Show Environment used by Oracle Client
   CLI Example:
   salt '*' oracle.show_env

   Note: at first _connect() NLS_LANG will forced to `.AL32UTF8`

salt.modules.oracle.show_pillar(item=None)
   Show Pillar segment oracle:* and subitem with notation ``item:subitem``
   CLI Example:
   salt '*' oracle.show_pillar
   salt '*' oracle.show_pillar dbs:my_db

salt.modules.oracle.version(*dbs)
   Server Version (select banner from v$version)
   CLI Example:
   salt '*' oracle.version
   salt '*' oracle.version my_db

31.16.179 salt.modules.osquery

New in version 2015.8.0.

salt.modules.osquery.acpi_tables(attrs=None, where=None)
   Return acpi_tables information from osquery
   CLI Example:
   salt '*' osquery.acpi_tables

salt.modules.osquery.alf(attrs=None, where=None)
   Return alf information from osquery
   CLI Example:
   salt '*' osquery.alf
```

salt.modules.osquery.alf_exceptions(attrs=None, where=None)
    Return alf_exceptions information from osquery
    CLI Example:
    ```
    salt '*' osquery.alf_exceptions
    ```

salt.modules.osquery.alf_explicit_auths(attrs=None, where=None)
    Return alf_explicit_auths information from osquery
    CLI Example:
    ```
    salt '*' osquery.alf_explicit_auths
    ```

salt.modules.osquery.alf_services(attrs=None, where=None)
    Return alf_services information from osquery
    CLI Example:
    ```
    salt '*' osquery.alf_services
    ```

salt.modules.osquery.apps(attrs=None, where=None)
    Return apps information from osquery
    CLI Example:
    ```
    salt '*' osquery.apps
    ```

salt.modules.osquery.apt_sources(attrs=None, where=None)
    Return apt_sources information from osquery
    CLI Example:
    ```
    salt '*' osquery.apt_sources
    ```

salt.modules.osquery.arp_cache(attrs=None, where=None)
    Return arp_cache information from osquery
    CLI Example:
    ```
    salt '*' osquery.arp_cache
    ```

salt.modules.osquery.block_devices(attrs=None, where=None)
    Return block_devices information from osquery
    CLI Example:
    ```
    salt '*' osquery.block_devices
    ```

salt.modules.osquery.certificates(attrs=None, where=None)
    Return certificates information from osquery
    CLI Example:
    ```
    salt '*' osquery.certificates
    ```

salt.modules.osquery.chrome_extensions(attrs=None, where=None)
    Return chrome_extensions information from osquery
    CLI Example:
    ```
    salt '*' osquery.chrome_extensions
    ```
```
salt.modules.osquery.cpuid(**attrs=None**, **where=None**)  
Return cpuid information from osquery  

CLI Example:
```
salt '*' osquery.cpuid
```

salt.modules.osquery.crontab(**attrs=None**, **where=None**)  
Return crontab information from osquery  

CLI Example:
```
salt '*' osquery.crontab
```

salt.modules.osquery.deb_packages(**attrs=None**, **where=None**)  
Return deb_packages information from osquery  

CLI Example:
```
salt '*' osquery.deb_packages
```

salt.modules.osquery.etc_hosts(**attrs=None**, **where=None**)  
Return etc_hosts information from osquery  

CLI Example:
```
salt '*' osquery.etc_hosts
```

salt.modules.osquery.etc_services(**attrs=None**, **where=None**)  
Return etc_services information from osquery  

CLI Example:
```
salt '*' osquery.etc_services
```

salt.modules.osquery.file(**attrs=None**, **where=None**)  
Return file information from osquery  

CLI Example:
```
salt '*' osquery.file
```

salt.modules.osquery.file_changes(**attrs=None**, **where=None**)  
Return file_changes information from osquery  

CLI Example:
```
salt '*' osquery.file_changes
```

salt.modules.osquery.firefox_addons(**attrs=None**, **where=None**)  
Return firefox_addons information from osquery  

CLI Example:
```
salt '*' osquery.firefox_addons
```

salt.modules.osquery.groups(**attrs=None**, **where=None**)  
Return groups information from osquery  

CLI Example:
```
salt '*' osquery.groups
```

31.16. Full list of builtin execution modules
salt.modules.osquery.hardware_events(\textit{attrs=}\textit{None}, \textit{where=}\textit{None})

Return hardware\_events information from osquery

CLI Example:

\texttt{salt '*/ osquery.hardware_events}

salt.modules.osquery.hash(\textit{attrs=}\textit{None}, \textit{where=}\textit{None})

Return hash information from osquery

CLI Example:

\texttt{salt '*/ osquery.hash}

salt.modules.osquery.homebrew_packages(\textit{attrs=}\textit{None}, \textit{where=}\textit{None})

Return homebrew\_packages information from osquery

CLI Example:

\texttt{salt '*/ osquery.homebrew_packages}

salt.modules.osquery.interface_addresses(\textit{attrs=}\textit{None}, \textit{where=}\textit{None})

Return interface\_addresses information from osquery

CLI Example:

\texttt{salt '*/ osquery.interface_addresses}

salt.modules.osquery.interface_details(\textit{attrs=}\textit{None}, \textit{where=}\textit{None})

Return interface\_details information from osquery

CLI Example:

\texttt{salt '*/ osquery.interface_details}

salt.modules.osquery.iokit_devicetree(\textit{attrs=}\textit{None}, \textit{where=}\textit{None})

Return iokit\_devicetree information from osquery

CLI Example:

\texttt{salt '*/ osquery.iokit_devicetree}

salt.modules.osquery.iokit_registry(\textit{attrs=}\textit{None}, \textit{where=}\textit{None})

Return iokit\_registry information from osquery

CLI Example:

\texttt{salt '*/ osquery.iokit_registry}

salt.modules.osquery.kernel_extensions(\textit{attrs=}\textit{None}, \textit{where=}\textit{None})

Return kernel\_extensions information from osquery

CLI Example:

\texttt{salt '*/ osquery.kernel_extensions}

salt.modules.osquery.kernel_info(\textit{attrs=}\textit{None}, \textit{where=}\textit{None})

Return kernel\_info information from osquery

CLI Example:

\texttt{salt '*/ osquery.kernel_info}
The code block contains descriptions of various functions from the `salt.modules.osquery` module, which are used to retrieve different types of information from the system. Here's a breakdown of each function and its corresponding description:

- **kernel_integrity**: Returns kernel integrity information from `osquery`.
  - CLI Example: `salt '*' osquery.kernel_integrity`

- **kernel_modules**: Returns kernel modules information from `osquery`.
  - CLI Example: `salt '*' osquery.kernel_modules`

- **keychain_items**: Returns keychain items information from `osquery`.
  - CLI Example: `salt '*' osquery.keychain_items`

- **last**: Returns last information from `osquery`.
  - CLI Example: `salt '*' osquery.last`

- **launchd**: Returns launchd information from `osquery`.
  - CLI Example: `salt '*' osquery.launchd`

- **listening_ports**: Returns listening ports information from `osquery`.
  - CLI Example: `salt '*' osquery.listening_ports`

- **logged_in_users**: Returns logged in users information from `osquery`.
  - CLI Example: `salt '*' osquery.logged_in_users`

- **memory_map**: Returns memory map information from `osquery`.
  - CLI Example: `salt '*' osquery.memory_map`

- **mounts**: Returns mounts information from `osquery`.
  - CLI Example: `salt '*' osquery.mounts`

These functions are part of the `osquery` module in Salt, a popular open-source software for distributed server management.
salt.modules.osquery.nfs_shares(attrs=None, where=None)
    Return nfs_shares information from osquery
    CLI Example:
    
    ```
salt '*' osquery.nfs_shares
    ```

salt.modules.osquery.nvram(attrs=None, where=None)
    Return nvram information from osquery
    CLI Example:
    
    ```
salt '*' osquery.nvram
    ```

salt.modules.osquery.os_version(attrs=None, where=None)
    Return os_version information from osquery
    CLI Example:
    
    ```
salt '*' osquery.os_version
    ```

salt.modules.osquery.osquery_extensions(attrs=None, where=None)
    Return osquery_extensions information from osquery
    CLI Example:
    
    ```
salt '*' osquery.osquery_extensions
    ```

salt.modules.osquery.osquery_flags(attrs=None, where=None)
    Return osquery_flags information from osquery
    CLI Example:
    
    ```
salt '*' osquery.osquery_flags
    ```

salt.modules.osquery.osquery_info(attrs=None, where=None)
    Return osquery_info information from osquery
    CLI Example:
    
    ```
salt '*' osquery.osquery_info
    ```

salt.modules.osquery.osquery_registry(attrs=None, where=None)
    Return osquery_registry information from osquery
    CLI Example:
    
    ```
salt '*' osquery.osquery_registry
    ```

salt.modules.osquerypasswd_changes(attrs=None, where=None)
    Return passwd_changes information from osquery
    CLI Example:
    
    ```
salt '*' osquery.passwd_changes
    ```

salt.modules.osquery.pci_devices(attrs=None, where=None)
    Return pci_devices information from osquery
    CLI Example:
Salt Documentation, Release 2015.8.0

```
salt '*' osquery.pci_devices

salt.modules.osquery.preferences
    (attrs=None, where=None)
    Return preferences information from osquery
    CLI Example:
    salt '*' osquery.preferences

salt.modules.osquery.process_envs
    (attrs=None, where=None)
    Return process_envs information from osquery
    CLI Example:
    salt '*' osquery.process_envs

salt.modules.osquery.process_memory_map
    (attrs=None, where=None)
    Return process_memory_map information from osquery
    CLI Example:
    salt '*' osquery.process_memory_map

salt.modules.osquery.process_open_files
    (attrs=None, where=None)
    Return process_open_files information from osquery
    CLI Example:
    salt '*' osquery.process_open_files

salt.modules.osquery.process_open_sockets
    (attrs=None, where=None)
    Return process_open_sockets information from osquery
    CLI Example:
    salt '*' osquery.process_open_sockets

salt.modules.osquery_processes
    (attrs=None, where=None)
    Return processes information from osquery
    CLI Example:
    salt '*' osquery.processes

salt.modules.osquery.quarantine
    (attrs=None, where=None)
    Return quarantine information from osquery
    CLI Example:
    salt '*' osquery.quarantine

salt.modules.osquery.query
    (sql=None)
    Return time information from osquery
    CLI Example:
    salt '*' osquery.query "select * from users;"

salt.modules.osquery.routes
    (attrs=None, where=None)
    Return routes information from osquery
    CLI Example:
```

31.16. Full list of builtin execution modules
salt '*' osquery.routes

salt.modules.osquery.rpm_packages(attrs=None, where=None)
  Return cpuid information from osquery
  CLI Example:
  
salt '*' osquery.rpm_packages

salt.modules.osquery.safari_extensions(attrs=None, where=None)
  Return safari_extensions information from osquery
  CLI Example:
  
salt '*' osquery.safari_extensions

salt.modules.osquery.shared_memory(attrs=None, where=None)
  Return shared_memory information from osquery
  CLI Example:
  
salt '*' osquery.shared_memory

salt.modules.osquery.shell_history(attrs=None, where=None)
  Return shell_history information from osquery
  CLI Example:
  
salt '*' osquery.shell_history

salt.modules.osquery.smbios_tables(attrs=None, where=None)
  Return smbios_tables information from osquery
  CLI Example:
  
salt '*' osquery.smbios_tables

salt.modules.osquery.startup_items(attrs=None, where=None)
  Return startup_items information from osquery
  CLI Example:
  
salt '*' osquery.startup_items

salt.modules.osquery.suid_bin(attrs=None, where=None)
  Return suid_bin information from osquery
  CLI Example:
  
salt '*' osquery.suid_bin

salt.modules.osquery.system_controls(attrs=None, where=None)
  Return system_controls information from osquery
  CLI Example:
  
salt '*' osquery.system_controls

salt.modules.osquery.time(attrs=None)
  Return time information from osquery
  CLI Example:
salt '*' osquery.time

salt.modules.osquery.usb_devices
    ( attrs=None, where=None )
    Return usb_devices information from osquery
    CLI Example:
        salt '*' osquery.usb_devices

salt.modules.osquery.users
    ( attrs=None, where=None )
    Return users information from osquery
    CLI Example:
        salt '*' osquery.users

salt.modules.osquery.version()
    Return version of osquery
    CLI Example:
        salt '*' osquery.version

salt.modules.osquery.xattr_where_from
    ( attrs=None, where=None )
    Return xattr_where_from information from osquery
    CLI Example:
        salt '*' osquery.xattr_where_from

salt.modules.osquery.xprotect_entries
    ( attrs=None, where=None )
    Return xprotect_entries information from osquery
    CLI Example:
        salt '*' osquery.xprotect_entries

salt.modules.osquery.xprotect_reports
    ( attrs=None, where=None )
    Return xprotect_reports information from osquery
    CLI Example:
        salt '*' osquery.xprotect_reports

31.16.180 salt.modules.osxdesktop

Mac OS X implementations of various commands in the ``desktop'' interface

salt.modules.osxdesktop.get_output_volume()
    Get the output volume (range 0 to 100)
    CLI Example:
        salt '*' desktop.get_output_volume

salt.modules.osxdesktop.lock()
    Lock the desktop session
    CLI Example:
```
salt '*' desktop.lock
```

salt.modules.osxdesktop.say('words')

Say some words.

CLI Example:
```
salt '*' desktop.say <word0> <word1> ... <wordN>
```

```
salt.modules.osxdesktop.screensaver()
```

Launch the screensaver

CLI Example:
```
salt '*' desktop.screensaver
```

```
salt.modules.osxdesktop.set_output_volume(volume)
```

Set the volume of sound (range 0 to 100)

CLI Example:
```
salt '*' desktop.set_output_volume <volume>
```

### 31.16.181 salt.modules.pacman

A module to wrap pacman calls, since Arch is the best (https://wiki.archlinux.org/index.php/Arch_is_the_best)

salt.modules.pacman.file_dict(*packages)

List the files that belong to a package, grouped by package. Not specifying any packages will return a list of _every_ file on the system's package database (not generally recommended).

CLI Examples:
```
salt '*' pkg.file_list httpd
salt '*' pkg.file_list httpd postfix
salt '*' pkg.file_list
```

salt.modules.pacman.file_list(*packages)

List the files that belong to a package. Not specifying any packages will return a list of _every_ file on the system's package database (not generally recommended).

CLI Examples:
```
salt '*' pkg.file_list httpd
salt '*' pkg.file_list httpd postfix
salt '*' pkg.file_list
```

salt.modules.pacman.install(name=None, refresh=False, sysupgrade=False, pkgs=None, sources=None, **kwargs)

Install (pacman -S) the passed package, add refresh=True to install with -y, add sysupgrade=True to install with -u.

**name** The name of the package to be installed. Note that this parameter is ignored if either ``pkgs`` or ``sources`` is passed. Additionally, please note that this option can only be used to install packages from a software repository. To install a package file manually, use the ``sources`` option.

CLI Example:
salt '*' pkg.install <package name>

**refresh** Whether or not to refresh the package database before installing.

**sysupgrade** Whether or not to upgrade the system packages before installing.

Multiple Package Installation Options:

**pkgs** A list of packages to install from a software repository. Must be passed as a python list. A specific version number can be specified by using a single-element dict representing the package and its version. As with the **version** parameter above, comparison operators can be used to target a specific version of a package.

CLI Examples:

```sh
salt '*' pkg.install pkgs='["foo", "bar"]'
salt '*' pkg.install pkgs='["foo", {"bar": "1.2.3-4"}]'
salt '*' pkg.install pkgs='["foo", {"bar": ":1.2.3-4"}]'
```

**sources** A list of packages to install. Must be passed as a list of dicts, with the keys being package names, and the values being the source URI or local path to the package.

CLI Example:

```sh
salt '*' pkg.install sources='[{"foo": "salt://foo.pkg.tar.xz"}]
```

Returns a dict containing the new package names and versions:

```json
{
'foo': { 'old': '1.0.0-1', 'new': '1.1.0-1' }
}
```

**salt.modules.pacman.latest_version(names, **kwargs)**

Return the latest version of the named package available for upgrade or installation. If more than one package name is specified, a dict of name/version pairs is returned.

If the latest version of a given package is already installed, an empty string will be returned for that package.

CLI Example:

```sh
salt '*' pkg.latest_version <package name>
salt '*' pkg.latest_version <package1> <package2> <package3> ...
```

**salt.modules.pacman.list_pkgs(versions_as_list=False, **kwargs)**

List the packages currently installed as a dict:

```json
{
'<package_name>': '<version>'
}
```

CLI Example:

```sh
salt '*' pkg.list_pkgs
```

**salt.modules.pacman.list_upgrades(refresh=False)**

List all available package upgrades on this system.

CLI Example:

```sh
salt '*' pkg.list_upgrades
```

**salt.modules.pacman.owner(paths)**

New in version 2014.7.0.
Return the name of the package that owns the file. Multiple file paths can be passed. Like `pkg.version <salt.modules.yumpkg.version`, if a single path is passed, a string will be returned, and if multiple paths are passed, a dictionary of file/package name pairs will be returned.

If the file is not owned by a package, or is not present on the minion, then an empty string will be returned for that path.

**CLI Example:**

```bash
salt '*' pkg.owner /usr/bin/apachectl salt '*' pkg.owner /usr/bin/apachectl /usr/bin/zsh
```

**salt.modules.pacman.purge(name=None, pkgs=None, **kwargs)**

Recursively remove a package and all dependencies which were installed with it, this will call a `pacman -Rsc`

- `name`: The name of the package to be deleted.
- `pkgs`: A list of packages to delete. Must be passed as a python list. The name parameter will be ignored if this option is passed.

New in version 0.16.0.

Returns a dict containing the changes.

**CLI Example:**

```bash
salt '*' pkg.purge <package name>
salt '*' pkg.purge <package1>,<package2>,<package3>
salt '*' pkg.purge pkgs=["foo", "bar"]
```

**salt.modules.pacman.refresh_db()**

Just run a `pacman -Sy`, return a dict:

```python
{'<database name>': Bool}
```

**CLI Example:**

```bash
salt '*' pkg.refresh_db
```

**salt.modules.pacman.remove(name=None, pkgs=None, **kwargs)**

Remove packages with `pacman -R`.

- `name`: The name of the package to be deleted.
- `pkgs`: A list of packages to delete. Must be passed as a python list. The name parameter will be ignored if this option is passed.

New in version 0.16.0.

Returns a dict containing the changes.

**CLI Example:**

```bash
salt '*' pkg.remove <package name>
salt '*' pkg.remove <package1>,<package2>,<package3>
salt '*' pkg.remove pkgs=["foo", "bar"]
```

**salt.modules.pacman.upgrade(refresh=False)**

Run a full system upgrade, a `pacman -Sy`

- `refresh`: Whether or not to refresh the package database before installing.
Return a dict containing the new package names and versions:

```
{'<package>': {'old': '<old-version>',
               'new': '<new-version>'}}
```

**CLI Example:**

```
salt '*' pkg.upgrade
```

**salt.modules.pacman.upgrade_available** *(name)*

Check whether or not an upgrade is available for a given package

**CLI Example:**

```
salt '*' pkg.upgrade_available <package name>
```

**salt.modules.pacman.version** *(names, **kwargs)*

Returns a string representing the package version or an empty string if not installed. If more than one package name is specified, a dict of name/version pairs is returned.

**CLI Example:**

```
salt '*' pkg.version <package name>
salt '*' pkg.version <package1> <package2> <package3> ...
```

### 31.16.182 salt.modules.pagerduty

Module for Firing Events via PagerDuty

New in version 2014.1.0.

**configuration** This module can be used by specifying the name of a configuration profile in the minion config, minion pillar, or master config.

For example:

```
my-pagerduty-account:
pagerduty.api_key: F3Rbyjbe43rfFw2214
pagerduty.subdomain: mysubdomain
```

**salt.modules.pagerduty.create_event** *(service_key=None, description=None, details=None, incident_key=None, profile=None)*

Create an event in PagerDuty. Designed for use in states.

**CLI Example:**

```
salt myminion pagerduty.create_event <service_key> <description> <details>
```

The following parameters are required:

**service_key** This key can be found by using pagerduty.list_services.

**description** This is a short description of the event.

**details** This can be a more detailed description of the event.

**profile** This refers to the configuration profile to use to connect to the PagerDuty service.

**salt.modules.pagerduty.list_escalation_policies** *(profile=None, api_key=None)*

List escalation policies belonging to this account

**CLI Example:**
salt myminion pagerduty.list_policies my-pagerduty-account
salt myminion pagerduty.list_escalation_policies my-pagerduty-account

salt.modules.pagerduty.list_incidents(profile=None, api_key=None)
List incidents belonging to this account

CLI Example:
salt myminion pagerduty.list_incidents my-pagerduty-account

salt.modules.pagerduty.list_maintenance_windows(profile=None, api_key=None)
List maintenance windows belonging to this account

CLI Example:
salt myminion pagerduty.list_windows my-pagerduty-account salt myminion pagerduty.list_maintenance_windows my-pagerduty-account

salt.modules.pagerduty.list_policies(profile=None, api_key=None)
List escalation policies belonging to this account

CLI Example:
salt myminion pagerduty.list_policies my-pagerduty-account salt myminion pagerduty.list_escalation_policies my-pagerduty-account

salt.modules.pagerduty.list_schedules(profile=None, api_key=None)
List schedules belonging to this account

CLI Example:
salt myminion pagerduty.list_schedules my-pagerduty-account

salt.modules.pagerduty.list_services(profile=None, api_key=None)
List services belonging to this account

CLI Example:
salt myminion pagerduty.list_services my-pagerduty-account

salt.modules.pagerduty.list_users(profile=None, api_key=None)
List users belonging to this account

CLI Example:
salt myminion pagerduty.list_users my-pagerduty-account

salt.modules.pagerduty.list_windows(profile=None, api_key=None)
List maintenance windows belonging to this account

CLI Example:
salt myminion pagerduty.list_windows my-pagerduty-account salt myminion pagerduty.list_maintenance_windows my-pagerduty-account

31.16.183 salt.modules.pagerduty_util

Module for managing PagerDuty resource

configuration This module can be used by specifying the name of a configuration profile in the minion
config, minion pillar, or master config. The default configuration profile name is `pagerduty`.

For example:
For PagerDuty API details, see https://developer.pagerduty.com/documentation/rest

salt.modules.pagerduty_util.create_or_update_resource(resource_name, identifier_fields, data, diff=None, profile='pagerduty', subdomain=None, api_key=None)

create or update any pagerduty resource Helper method for present().

Determining if two resources are the same is different for different PD resource, so this method accepts a
diff function. The diff function will be invoked as 
diff(state_information, object_returned_from_pagerduty),
and should return a dict of data to pass to the PagerDuty update API method, or None if no update is to be
performed. If no diff method is provided, the default behavior is to scan the keys in the state_information,
comparing the matching values in the object_returned_from_pagerduty, and update any values that differ.

examples:
create_or_update_resource(¨user¨, [¨id¨,¨name¨,¨email¨])
create_or_update_resource(¨escalation_policies¨, [¨id¨,¨name¨], diff=my_diff_function)

salt.modules.pagerduty_util.delete_resource(resource_name, key, identifier_fields, profile='pagerduty', subdomain=None, api_key=None)

delete any pagerduty resource

Helper method for absent()

example:
delete_resource(¨users¨, key, [¨id¨,¨name¨,¨email¨]) # delete by id or name or email

salt.modules.pagerduty_util.get_escalation_policies(profile='pagerduty', subdomain=None, api_key=None)

List escalation_policies belonging to this account

CLI Example:
salt myminion pagerduty.get_escalation_policies

salt.modules.pagerduty_util.get_resource(resource_name, key, identifier_fields, profile='pagerduty', subdomain=None, api_key=None)

Get any single pagerduty resource by key.

We allow flexible lookup by any of a list of identifier_fields. So, for example, you can look up users by email
address or name by calling:

get_resource(¨users¨, key, [¨name¨,¨email¨], ...)

This method is mainly used to translate state sls into pagerduty id's for dependent objects. For example, a
pagerduty escalation policy contains one or more schedules, which must be passed by their pagerduty id. We
look up the schedules by name (using this method), and then translate the names into id's.

This method is implemented by getting all objects of the resource type (cached into __context__), then brute
force searching through the list and trying to match any of the identifier_fields. The __context__ cache is
purged after any create, update or delete to the resource.

salt.modules.pagerduty_util.get_schedules(profile='pagerduty', subdomain=None, api_key=None)

List schedules belonging to this account

CLI Example:
salt myminion pagerduty.get_schedules
salt.modules.pagerduty_util.get_services(profile='pagerduty', subdomain=None, api_key=None)

List services belonging to this account

CLI Example:
salt myminion pagerduty.get_services

salt.modules.pagerduty_util.get_users(profile='pagerduty', subdomain=None, api_key=None)

List users belonging to this account

CLI Example:
salt myminion pagerduty.get_users

salt.modules.pagerduty_util.resource_absent(resource, identifier_fields, profile='pagerduty', subdomain=None, api_key=None, **kwargs)

Generic resource.absent state method. Pagerduty state modules should be a thin wrapper over this method, with a custom diff function.

This method calls delete_resource() and formats the result as a salt state return value.

example: resource_absent(``users'', [``id'',``name'',``email''])

salt.modules.pagerduty_util.resource_present(resource, identifier_fields, diff=None, profile='pagerduty', subdomain=None, api_key=None, **kwargs)

Generic resource.present state method. Pagerduty state modules should be a thin wrapper over this method, with a custom diff function.

This method calls create_or_update_resource() and formats the result as a salt state return value.

example: resource_present(``users'', [``id'',``name'',``email''])

31.16.184 salt.modules.pam

Support for pam

salt.modules.pam.read_file(file_name)

This is just a test function, to make sure parsing works

CLI Example:

salt '*' pam.read_file /etc/pam.d/login

31.16.185 salt.modules.parted

Module for managing partitions on POSIX-like systems.

depends

- parted, partprobe, lsblk (usually parted and util-linux packages)

Some functions may not be available, depending on your version of parted.

Check the manpage for parted(8) for more information, or the online docs at:

In light of parted not directly supporting partition IDs, some of this module has been written to utilize sfdisk instead. For further information, please reference the man page for sfdisk(8).
salt.modules.parted.align_check(device, part_type, partition)
  partition.align_check device part_type partition
  Check if partition satisfies the alignment constraint of part_type. Type must be 'minimal' or 'optimal'.
  CLI Example:
  ```
  salt '*' partition.align_check /dev/sda minimal 1
  ```

salt.modules.parted.check(device, minor)
  partition.check device minor
  Checks if the file system on partition <minor> has any errors.
  CLI Example:
  ```
  salt '*' partition.check 1
  ```

salt.modules.parted.cp(device, from_minor, to_minor)
  partition.check device from_minor to_minor
  Copies the file system on the partition <from-minor> to partition <to-minor>, deleting the original contents of the destination partition.
  CLI Example:
  ```
  salt '*' partition.cp /dev/sda 2 3
  ```

salt.modules.parted.exists(device='')
  partition.exists device
  Check to see if the partition exists
  CLI Example:
  ```
  salt '*' partition.exists /dev/sdb1
  ```

salt.modules.parted.get_block_device()
  Retrieve a list of disk devices
  New in version 2014.7.0.
  CLI Example:
  ```
  salt '*' partition.get_block_device
  ```

salt.modules.parted.get_id(device, minor)
  Prints the system ID for the partition. Some typical values are:
  ```
  b:  FAT32 (vfat)
  7:  HPFS/NTFS
  82: Linux Swap
  83: Linux
  8e: Linux LVM
  fd: Linux RAID Auto
  ```
  CLI Example:
  ```
  salt '*' partition.get_id /dev/sda 1
  ```

salt.modules.parted.list(device, unit=None)
  partition.list device unit
  Prints partition information of given <device>
salt.modules.parted.mkfs(device, fs_type)

Makes a file system `<fs_type>` on partition `<device>`, destroying all data that resides on that partition. `<fs_type>` must be one of ``ext2'', ``fat32'', ``fat16'', ``linux-swap'' or ``reiserfs'' (if `libreiserfs` is installed)

CLI Example:
```
salt '*' partition.mkfs /dev/sda2 fat32
```

salt.modules.parted.mklabel(device, label_type)

Create a new disklabel (partition table) of label_type. Type should be one of ``aix'', ``amiga'', ``bsd'', ``dvh'', ``gpt'', ``loop'', ``mac'', ``msdos'', ``pc98'', or ``sun''.

CLI Example:
```
salt '*' partition.mklabel /dev/sda msdos
```

salt.modules.parted.mkpart(device, part_type, fs_type=None, start=None, end=None)

Make a `<part_type>` partition for filesystem `<fs_type>`, beginning at `<start>` and ending at `<end>` (by default in megabytes). `<part_type>` should be one of ``primary'', ``logical'', or ``extended''.

CLI Examples:
```
salt '*' partition.mkpart /dev/sda primary fs_type=fat32 start=0 end=639
salt '*' partition.mkpart /dev/sda primary start=0 end=639
```

salt.modules.parted.mkpartfs(device, part_type, fs_type, start, end)

Make a `<part_type>` partition with a new filesystem of `<fs_type>`, beginning at `<start>` and ending at `<end>` (by default in megabytes). `<part_type>` should be one of ``primary'', ``logical'', or ``extended''. `<fs_type>` must be one of ``ext2'', ``fat32'', ``fat16'', ``linux-swap'' or ``reiserfs'' (if `libreiserfs` is installed)

CLI Example:
```
salt '*' partition.mkpartfs /dev/sda logical ext2 440 670
```

salt.modules.parted.name(device, partition, name)

Set the name of partition to name. This option works only on Mac, PC98, and GPT disklabels. The name can be placed in quotes, if necessary.

CLI Example:
```
salt '*' partition.name /dev/sda 1 'My Documents'
```

salt.modules.parted.probe(*devices)

Ask the kernel to update its local partition data. When no args are specified all block devices are tried.

Caution: Generally only works on devices with no mounted partitions and may take a long time to return if specified devices are in use.
CLI Examples:

```python
salt '*' partition.probe
salt '*' partition.probe /dev/sda
salt '*' partition.probe /dev/sda /dev/sdb
```

**salt.modules.parted.rescue**(device, start, end)

- `rescue` device start end

Rescue a lost partition that was located somewhere between start and end. If a partition is found, parted will ask if you want to create an entry for it in the partition table.

CLI Example:

```python
salt '*' partition.rescue /dev/sda 0 8056
```

**salt.modules.parted.resize**(device, minor, start, end)

- `resize` device minor, start, end

Resizes the partition with number <minor>. The partition will start <start> from the beginning of the disk, and end <end> from the beginning of the disk. resize never changes the minor number. Extended partitions can be resized, so long as the new extended partition completely contains all logical partitions.

CLI Example:

```python
salt '*' partition.resize /dev/sda 3 200 850
```

**salt.modules.parted.rm**(device, minor)

- `rm` device minor

Removes the partition with number <minor>.

CLI Example:

```python
salt '*' partition.rm /dev/sda 5
```

**salt.modules.parted.set**(device, minor, flag, state)

- `set` device minor flag state

Changes a flag on the partition with number <minor>. A flag can be either `on` or `off`. Some or all of these flags will be available, depending on what disk label you are using.

CLI Example:

```python
salt '*' partition.set /dev/sda 1 boot on
```

**salt.modules.parted.set_id**(device, minor, system_id)

Sets the system ID for the partition. Some typical values are:

- `b`: FAT32 (vfat)
- `7`: HPFS/NTFS
- `82`: Linux Swap
- `83`: Linux
- `8e`: Linux LVM
- `fd`: Linux RAID Auto

CLI Example:

```python
salt '*' partition.set_id /dev/sda 1 83
```

**salt.modules.parted.system_types()**

List the parted system types that are supported by the installed version of sfdisk
CLI Example:

```python
salt '*' partition.system_types
```

```python
taxt.modules.parted.toggle(device, partition, flag)
    partition.toggle device partition flag
    Toggle the state of <flag> on <partition>
CLI Example:
    salt '*' partition.name /dev/sda 1 boot
```

### 31.16.186 salt.modules.pecl

Manage PHP pecl extensions.

```python
taxt.modules.pecl.install(pecls, defaults=False, force=False, preferred_state='stable')
    New in version 0.17.0.
    Installs one or several pecl extensions.
    pecls The pecl extensions to install.
    defaults Use default answers for extensions such as pecl_http which ask questions before installation. Without this option, the pecl.installed state will hang indefinitely when trying to install these extensions.
    force Whether to force the installed version or not
CLI Example:
    salt '*' pecl.install fuse
```

```python
taxt.modules.pecl.list(channel=None)
    List installed pecl extensions.
CLI Example:
    salt '*' pecl.list
```

```python
taxt.modules.pecl.uninstall(pecls)
    Uninstall one or several pecl extensions.
    pecls The pecl extensions to uninstall.
CLI Example:
    salt '*' pecl.uninstall fuse
```

```python
taxt.modules.pecl.update(pecls)
    Update one or several pecl extensions.
    pecls The pecl extensions to update.
CLI Example:
    salt '*' pecl.update fuse
```
31.16.187 salt.modules.pillar

Extract the pillar data for this minion

```python
salt.modules.pillar.ext(external, pillar=None)
```

Generate the pillar and apply an explicit external pillar

CLI Example:

```bash
salt '*' pillar.ext '{libvirt: _}'
```

```python
salt.modules.pillar.get(key, default=<type`exceptions.KeyError'>, merge=False, delimiter=':')
```

New in version 0.14.

Attempt to retrieve the named value from pillar, if the named value is not available return the passed default. The default return is an empty string except __opts__['pillar_raise_on_missing'] is set to True, in which case a KeyError will be raised.

If the merge parameter is set to True, the default will be recursively merged into the returned pillar data.

The value can also represent a value in a nested dict using a "::" delimiter for the dict. This means that if a dict in pillar looks like this:

```python
{'pkg': {'apache': 'httpd'}}
```

To retrieve the value associated with the apache key in the pkg dict this key can be passed:

```bash
pkg:apache
```

**merge** Specify whether or not the retrieved values should be recursively merged into the passed default.

New in version 2014.7.0.

**delimiter** Specify an alternate delimiter to use when traversing a nested dict

New in version 2014.7.0.

CLI Example:

```bash
salt '*' pillar.get pkg:apache
```

```python
salt.modules.pillar.item(*args, **kwargs)
```

New in version 0.16.2.

Return one or more pillar entries

**pillar** [none] if specified, allows for a dictionary of pillar data to be made available to pillar and ext_pillar rendering. These pillar variables will also override any variables of the same name in pillar or ext_pillar.

New in version 2015.5.0.

CLI Examples:

```bash
salt '*' pillar.item foo
salt '*' pillar.item foo bar baz
```
salt.modules.pillar.items(*args, **kwargs)
Calls the master for a fresh pillar and generates the pillar data on the fly
Contrast with raw() which returns the pillar data that is currently loaded into the minion.

pillar [none] if specified, allows for a dictionary of pillar data to be made available to pillar and ext_pillar rendering. these pillar variables will also override any variables of the same name in pillar or ext_pillar.

New in version 2015.5.0.

CLI Example:
```
salt '*' pillar.items
```

salt.modules.pillar.keys(key, delimiter=': ')
New in version 2015.8.0.
Attempt to retrieve a list of keys from the named value from the pillar.
The value can also represent a value in a nested dict using a ":" delimiter for the dict, similar to how pillar.get works.
delimiter Specify an alternate delimiter to use when traversing a nested dict

CLI Example:
```
salt '*' pillar.keys web:sites
```

salt.modules.pillar.ls(*args)
New in version 2015.8.0.
Calls the master for a fresh pillar, generates the pillar data on the fly (same as items()), but only shows the available main keys.

CLI Examples:
```
salt '*' pillar.ls
```

salt.modules.pillar.obfuscate(*args)
Same as items(), but replace pillar values with a simple type indication.
New in version 2015.8.0.
This is useful to avoid displaying sensitive information on console or flooding the console with long output, such as certificates. For many debug or control purposes, the stakes lie more in dispatching than in actual values.
In case the value is itself a collection type, obfuscation occurs within the value. For mapping types, keys are not obfuscated. Here are some examples:

- 'secret password' becomes '<str>'
- ['secret', 1] becomes ['<str>', '<int>']
- {'login': 'somalgin', 'pwd': 'secret'} becomes {'login': '<str>', 'pwd': '<str>'}

CLI Examples:
```
salt '*' pillar.obfuscate
```

salt.modules.pillar.raw(key=None)
Return the raw pillar data that is currently loaded into the minion.
Contrast with items() which calls the master to fetch the most up-to-date Pillar.
CLI Example:

```
salt '*' pillar.raw
```

With the optional key argument, you can select a subtree of the pillar raw data:

```
salt '*' pillar.raw key='roles'
```

### 31.16.188 salt.modules.pip

Install Python packages with pip to either the system or a virtualenv

**Windows Support**

New in version 2014.7.4.

Salt now uses a portable python. As a result the entire pip module is now functional on the salt installation itself. You can pip install dependencies for your custom modules. You can even upgrade salt itself using pip. For this to work properly, you must specify the Current Working Directory (`cwd`) and the Pip Binary (`bin_env`) salt should use. The variable `pip_bin` can be either a virtualenv path or the path to the pip binary itself.

For example, the following command will list all software installed using pip to your current salt environment:

```
salt <minion> pip.list cwd='C:\salt\bin\Scripts' bin_env='C:\salt\bin\Scripts\pip.exe'
```

Specifying the `cwd` and `bin_env` options ensures you're modifying the salt environment. If these are omitted, it will default to the local installation of python. If python is not installed locally it will fail saying it couldn't find pip.

**State File Support**

This functionality works in states as well. If you need to pip install colorama with a state, for example, the following will work:

```
install_colorama:
  pip.installed:
    - name: colorama
    - cwd: 'C:\salt\bin\Scripts'
    - bin_env: 'C:\salt\bin\Scripts\pip.exe'
    - upgrade: True
```

**Upgrading Salt using Pip**

You can now update salt using pip to any version from the 2014.7 branch forward. Previous versions require recompiling some of the dependencies which is painful in windows.

To do this you just use pip with git to update to the version you want and then restart the service. Here is a sample state file that upgrades salt to the head of the 2015.5 branch:

```
install_salt:
  pip.installed:
    - cwd: 'C:\salt\bin\Scripts'
    - bin_env: 'C:\salt\bin\Scripts\pip.exe'
    - editable: git+https://github.com/saltstack/salt@2015.5#egg=salt
    - upgrade: True
```
restart_service:
  service.running:
    - name: salt-minion
    - enable: True
    - watch:
      - pip: install_salt

Note: If you’re having problems, you might try doubling the back slashes. For example, cwd: `C:salt\bin\scripts`. Sometimes python thinks the single back slash is an escape character.

salt.modules.pip.freeze

Return a list of installed packages either globally or in the specified virtualenv

bin_env path to pip bin or path to virtualenv. If doing an uninstall from the system python and want to use a specific pip bin (pip-2.7, pip-2.6, etc.) just specify the pip bin you want. If uninstalling from a virtualenv, just use the path to the virtualenv (/home/code/path/to/virtualenv/)

user The user under which to run pip

cwd Current working directory to run pip from

CLI Example:

    salt '*' pip.freeze /home/code/path/to/virtualenv/

salt.modules.pip.install

Install packages with pip

Install packages individually or from a pip requirements file. Install packages globally or to a virtualenv.

pkgs Comma separated list of packages to install

requirements Path to requirements

bin_env Path to pip bin or path to virtualenv. If doing a system install, and want to use a specific pip bin (pip-2.7, pip-2.6, etc..) just specify the pip bin you want.

Note: If installing into a virtualenv, just use the path to the virtualenv (e.g. /home/code/path/to/virtualenv/)

ev Deprecated, use bin_env now

use_wheel Prefer wheel archives (requires pip>=1.4)

no_use_wheel Force to not use wheel archives (requires pip>=1.4)

log Log file where a complete (maximum verbosity) record will be kept
proxy Specify a proxy in the form `user:passwd@proxy.server:port`. Note that the `user:password@` is optional and required only if you are behind an authenticated proxy. If you provide `user@proxy.server:port` then you will be prompted for a password.

timeout Set the socket timeout (default 15 seconds)

editable install something editable (e.g. `git+https://github.com/worldcompany/djangoembed.git#egg=djangoembed`)

find_links URL to search for packages

index_url Base URL of Python Package Index

extra_index_url Extra URLs of package indexes to use in addition to `index_url`

no_index Ignore package index

mirrors Specific mirror URL(s) to query (automatically adds `--use-mirrors`)

build Unpack packages into build dir

target Install packages into target dir

download Download packages into download instead of installing them

download_cache Cache downloaded packages in download_cache dir

source Checkout editable packages into source dir

upgrade Upgrade all packages to the newest available version

force_reinstall When upgrading, reinstall all packages even if they are already up-to-date.

ignore_installed Ignore the installed packages (reinstalling instead)

exists_action Default action when a path already exists: (s)witch, (i)gnore, (w)ipe, (b)ackup

no_deps Ignore package dependencies

no_install Download and unpack all packages, but don't actually install them

no_download Don't download any packages, just install the ones already downloaded (completes an install run with `--no-install`)

install_options Extra arguments to be supplied to the setup.py install command (e.g. like `--install-option='--install-scripts=/usr/local/bin'`). Use multiple `--install-option` options to pass multiple options to setup.py install. If you are using an option with a directory path, be sure to use absolute path.

global_options Extra global options to be supplied to the setup.py call before the install command.

user The user under which to run pip

no_chown When user is given, do not attempt to copy and chown a requirements file

cwd Current working directory to run pip from

activate Activates the virtual environment, if given via `bin_env`, before running install.

    Deprecated since version 2014.7.2: If `bin_env` is given, pip will already be sourced from that virtualenv, making `activate` effectively a noop.

pre_releases Include pre-releases in the available versions

cert Provide a path to an alternate CA bundle

allow_all_external Allow the installation of all externally hosted files

allow_external Allow the installation of externally hosted files (comma separated list)

31.16. Full list of builtin execution modules
allow_unverified  Allow the installation of insecure and unverifiable files (comma separated list)

process_dependency_links  Enable the processing of dependency links

use_vt  Use VT terminal emulation (see output while installing)

env_vars  Set environment variables that some builds will depend on. For example, a Python C-module may have a Makefile that needs INCLUDE_PATH set to pick up a header file while compiling.

trusted_host  Mark this host as trusted, even though it does not have valid or any HTTPS.

CLI Example:

```
salt '*' pip.install <package name>,<package2 name>
salt '*' pip.install requirements=/path/to/requirements.txt
salt '*' pip.install <package name> bin_env=/path/to/virtualenv
salt '*' pip.install <package name> bin_env=/path/to/pip_bin
```

Complicated CLI example:

```
salt '*' pip.install markdown,django editable=git+https://github.com/worldcompany/djangoembed.git#egg=djangoembed upgrade=True no_deps=True
```

salt.modules.pip.list(prefix=None, bin_env=None, user=None, cwd=None)

Filter list of installed apps from freeze and check to see if prefix exists in the list of packages installed.

CLI Example:

```
salt '*' pip.list salt
```

salt.modules.pip.list_upgrades(bin_env=None, user=None, cwd=None)

Check whether or not an upgrade is available for all packages.

CLI Example:

```
salt '*' pip.list_upgrades
```

salt.modules.pip.uninstall(pkgs=None, requirements=None, bin_env=None, log=None, proxy=None, timeout=None, user=None, no_chown=False, cwd=None, __env__=None, saltenv='base', use_vt=False)

Uninstall packages with pip

Uninstall packages individually or from a pip requirements file. Uninstall packages globally or from a virtualenv.

pkgs  comma separated list of packages to install

requirements  path to requirements.

bin_env  path to pip bin or path to virtualenv. If doing an uninstall from the system python and want to use a specific pip bin (pip-2.7, pip-2.6, etc..) just specify the pip bin you want. If uninstalling from a virtualenv, just use the path to the virtualenv (/home/code/path/to/virtualenv/)

log  Log file where a complete (maximum verbosity) record will be kept

proxy  Specify a proxy in the form user:passwd@proxy.server:port. Note that the user:password@ is optional and required only if you are behind an authenticated proxy. If you provide user@proxy.server:port then you will be prompted for a password.

timeout  Set the socket timeout (default 15 seconds)

user  The user under which to run pip

no_chown  When user is given, do not attempt to copy and chown a requirements file (needed if the requirements file refers to other files via relative paths, as the copy-and-chown procedure does not account for such files)
cwd  Current working directory to run pip from

use_vt  Use VT terminal emulation (see output while installing)

CLI Example:

```
salt '*' pip.uninstall <package name>,<package2 name>
salt '*' pip.uninstall requirements=/path/to/requirements.txt
salt '*' pip.uninstall <package name> bin_env=/path/to/virtualenv
salt '*' pip.uninstall <package name> bin_env=/path/to/pip_bin
```

cwd

```
salt.modules.pip.upgrade(bin_env=None, user=None, cwd=None, use_vt=False)
```

New in version 2015.5.0.

Upgrades outdated pip packages

Returns a dict containing the changes.

```
{`<package>`: `{old': `<old-version>', 
`new': `<new-version>'}`}
```

CLI Example:

```
salt '*' pip.upgrade
```

cwd

```
salt.modules.pip.upgrade_available(pkg, bin_env=None, user=None, cwd=None)
```

New in version 2015.5.0.

Check whether or not an upgrade is available for a given package

CLI Example:

```
salt '*' pip.upgrade_available <package name>
```

cwd

```
salt.modules.pip.version(bin_env=None)
```

New in version 0.17.0.

Returns the version of pip. Use bin_env to specify the path to a virtualenv and get the version of pip in that virtualenv.

If unable to detect the pip version, returns None.

CLI Example:

```
salt '*' pip.version
```

cwd

**31.16.189  salt.modules.pkg_resource**

Resources needed by pkg providers

```
salt.modules.pkg_resource.add_pkg(pkgs, name, pkgver)
```

Add a package to a dict of installed packages.

CLI Example:

```
salt '*' pkg_resource.add_pkg '{}' bind 9
```

cwd

```
salt.modules.pkg_resource.check_extra_requirements(pkgsname, pkgver)
```

Check if the installed package already has the given requirements. This function will return the result of pkg.check_extra_requirements if this function exists for the minion, otherwise it will return True.

CLI Example:
salt.modules.pkg_resource.pack_sources(sources, normalize=True)
Accepts list of dicts (or a string representing a list of dicts) and packs the key/value pairs into a single dict.

'[["foo": "salt://foo.rpm"], {"bar": "salt://bar.rpm"}]]' would become {"foo": "salt://foo.rpm", "bar": "salt://bar.rpm"}

normalize [True] Normalize the package name by removing the architecture, if the architecture of the package is different from the architecture of the operating system. The ability to disable this behavior is useful for poorly-created packages which include the architecture as an actual part of the name, such as kernel modules which match a specific kernel version.

New in version 2015.8.0.

CLI Example:
salt '*' pkg_resource.pack_sources '[["foo": "salt://foo.rpm"], {"bar": "salt://bar.rpm"}]]'

salt.modules.pkg_resource.parse_targets(name=None, pkgs=None, sources=None, saltenv='base', normalize=True, **kwargs)
Parses the input to pkg.install and returns back the package(s) to be installed. Returns a list of packages, as well as a string noting whether the packages are to come from a repository or a binary package.

CLI Example:
salt '*' pkg_resource.parse_targets

salt.modules.pkg_resource.sort_pkglist(pkgs)
Accepts a dict obtained from pkg.list_pkgs() and sorts in place the list of versions for any packages that have multiple versions installed, so that two package lists can be compared to one another.

CLI Example:
salt '*' pkg_resource.sort_pkglist '[["3.45", "2.13"]'

salt.modules.pkg_resource.stringify(pkgs)
Takes a dict of package name/version information and joins each list of installed versions into a string.

CLI Example:
salt '*' pkg_resource.stringify 'vim: 7.127'

salt.modules.pkg_resource.version(*names, **kwargs)
Common interface for obtaining the version of installed packages.

CLI Example:
salt '*' pkg_resource.version vim
salt '*' pkg_resource.version foo bar baz
salt '*' pkg_resource.version 'python*'

salt.modules.pkg_resource.version_clean(verstr)
Clean the version string removing extra data. This function will simply try to call pkg.version_clean.

CLI Example:
salt '*' pkg_resource.version_clean <version_string>
### 31.16.190 salt.modules.pkgin

Package support for pkgin based systems, inspired from freebsd-pkg module

**salt.modules.pkgin.available_version(names, **kwargs)**

Return the latest version of the named package available for upgrade or installation.

If the latest version of a given package is already installed, an empty string will be returned for that package.

**CLI Example:**

```bash
salt '*' pkg.latest_version <package name>
salt '*' pkg.latest_version <package1> <package2> ...
```

**salt.modules.pkgin.file_dict(package)**

List the files that belong to a package.

**CLI Examples:**

```bash
salt '*' pkg.file_list nginx
```

**salt.modules.pkgin.file_list(package)**

List the files that belong to a package.

**CLI Examples:**

```bash
salt '*' pkg.file_list nginx
```

**salt.modules.pkgin.install(name=None, refresh=False, fromrepo=None, pkgs=None, sources=None, **kwargs)**

Install the passed package

- **name**  The name of the package to be installed.
- **refresh**  Whether or not to refresh the package database before installing.
- **fromrepo**  Specify a package repository to install from.

**Multiple Package Installation Options:**

- **pkgs**  A list of packages to install from a software repository. Must be passed as a python list.

  **CLI Example:**

  ```bash
  salt '*' pkg.install pkgs='["foo","bar"]'
  ```

- **sources**  A list of packages to install. Must be passed as a list of dicts, with the keys being package names, and the values being the source URI or local path to the package.

  **CLI Example:**

  ```bash
  salt '*' pkg.install sources=[{"foo": "salt://foo.deb"},{"bar": "salt://bar.deb"}]'
  ```

Return a dict containing the new package names and versions:

```json
{ '<package>': { 'old': '<old-version>', 'new': '<new-version>' }}
```

**CLI Example:**

```bash
salt '*' pkg.install <package name>
```
salt.modules.pkgin.latest_version(*names, **kwargs)
Return the latest version of the named package available for upgrade or installation.

If the latest version of a given package is already installed, an empty string will be returned for that package.

CLI Example:

```
salt '*' pkg.latest_version <package name>
salt '*' pkg.latest_version <package1> <package2> ...
```

salt.modules.pkgin.list_pkgs(versions_as_list=False, **kwargs)
List the packages currently installed as a dict:

```
{'<package_name>': '<version>'}
```

CLI Example:

```
salt '*' pkg.list_pkgs
```

class purge(name=None, pkgs=None, **kwargs)
Package purges are not supported, this function is identical to remove().

name The name of the package to be deleted.

Multiple Package Options:

pkgs A list of packages to delete. Must be passed as a python list. The name parameter will be ignored if this option is passed.

New in version 0.16.0.

Returns a dict containing the changes.

CLI Example:

```
salt '*' pkg.purge <package name>
salt '*' pkg.purge <package1>,<package2>,<package3>
salt '*' pkg.purge pkgs=('["foo", "bar"]')
```

class refresh_db()
Use pkg update to get latest pkg_summary

CLI Example:

```
salt '*' pkg.refresh_db
```

class remove(name=None, pkgs=None, **kwargs)

name The name of the package to be deleted.

Multiple Package Options:

pkgs A list of packages to delete. Must be passed as a python list. The name parameter will be ignored if this option is passed.

New in version 0.16.0.

Returns a list containing the removed packages.

CLI Example:

```
salt '*' pkg.remove <package name>
salt '*' pkg.remove <package1>,<package2>,<package3>
salt '*' pkg.remove pkgs=('["foo", "bar"]')
```
salt.modules.pkgin.search(pkg_name)
    Searches for an exact match using pkgin `package$

    CLI Example:
    ```
salt '*' pkg.search 'mysql-server'
    ```

salt.modules.pkgin.upgrade()
    Run pkg upgrade, if pkgin used. Otherwise do nothing.
    Return a dict containing the new package names and versions:

    ```
    {'<package>': {'old': '<old-version>',
                   'new': '<new-version>'}}
    ```

    CLI Example:
    ```
salt '*' pkg.upgrade
    ```

salt.modules.pkgin.version(*names, **kwargs)
    Returns a string representing the package version or an empty string if not installed. If more than one package
    name is specified, a dict of name/version pairs is returned.

    CLI Example:
    ```
salt '*' pkg.version <package name>
salt '*' pkg.version <package1> <package2> <package3> ...
    ```

31.16.191 salt.modules.pkgng

Support for pkgng, the new package manager for FreeBSD

**Warning:** This module has been completely rewritten. Up to and including version 0.17.x, it was available as the
pkgng module, (pkgng.install, pkgng.delete, etc.), but moving forward this module will no longer be
available as pkgng, as it will behave like a normal Salt pkg provider. The documentation below should not be
considered to apply to this module in versions <= 0.17.x. If your minion is running a 0.17.x release or older, then
the documentation for this module can be viewed using the sys.doc function:

```
salt bsdminion sys.doc pkgng
```

This module provides an interface to pkg(8). It acts as the default package provider for FreeBSD 10 and newer. For
FreeBSD hosts which have been upgraded to use pkgng, you will need to override the pkg provider by setting the
providers parameter in your Minion config file, in order to use this module to manage packages, like so:

```
providers:
    pkg: pkgng
```

salt.modules.pkgng.audit(jail=None, chroot=None)
    Audits installed packages against known vulnerabilities

    CLI Example:
    ```
salt '*' pkg.audit
    ```

    ```
    jail  Audit packages within the specified jail
    ```

    CLI Example:
salt 'x' pkg.audit jail=<jail name or id>

**chroot** Audit packages within the specified chroot (ignored if jail is specified)

CLI Example:
```
salt 'x' pkg.audit chroot=/path/to/chroot
```

salt.modules.pkgng.autoremove(*jail=None, chroot=None, dryrun=False*)
Delete packages which were automatically installed as dependencies and are not required anymore.

**dryrun** Dry-run mode. The list of changes to packages is always printed, but no changes are actually made.

CLI Example:
```
salt 'x' pkg.autoremove
salt 'x' pkg.autoremove jail=<jail name or id>
salt 'x' pkg.autoremove dryrun=True
salt 'x' pkg.autoremove jail=<jail name or id> dryrun=True
```

salt.modules.pkgng.backup(*file_name, jail=None, chroot=None*)
Export installed packages into yaml+mtree file

CLI Example:
```
salt 'x' pkg.backup /tmp/pkg
```

**jail** Backup packages from the specified jail. Note that this will run the command within the jail, and so the path to the backup file will be relative to the root of the jail

CLI Example:
```
salt 'x' pkg.backup /tmp/pkg jail=<jail name or id>
```

**chroot** Backup packages from the specified chroot (ignored if jail is specified). Note that this will run the command within the chroot, and so the path to the backup file will be relative to the root of the chroot.

CLI Example:
```
salt 'x' pkg.backup /tmp/pkg chroot=/path/to/chroot
```

salt.modules.pkgng.check(*jail=None, chroot=None, depends=False, recompute=False, checksum=False*)
Sanity checks installed packages

**jail** Perform the sanity check in the specified jail

CLI Example:
```
salt 'x' pkg.check jail=<jail name or id>
```

**chroot** Perform the sanity check in the specified chroot (ignored if jail is specified)

CLI Example:
```
salt 'x' pkg.check chroot=/path/to/chroot
```

Of the below, at least one must be set to True.
depends  Check for and install missing dependencies.
   CLI Example:
   salt '*' pkg.check recompute=True

recompute  Recompute sizes and checksums of installed packages.
   CLI Example:
   salt '*' pkg.check depends=True

checksum  Find invalid checksums for installed packages.
   CLI Example:
   salt '*' pkg.check checksum=True

salt.modules.pkgng.clean(jail=None, chroot=None)
   Cleans the local cache of fetched remote packages
   CLI Example:
   salt '*' pkg.clean
   salt '*' pkg.clean jail=<jail name or id>
   salt '*' pkg.clean chroot=/path/to/chroot

salt.modules.pkgng.fetch(name, jail=None, chroot=None, fetch_all=False, quiet=False, fromrepo=None, glob=True, regex=False, pcre=False, local=False, depends=False)
   Fetches remote packages
   CLI Example:
   salt '*' pkg.fetch <package name>

   jail  Fetch package in the specified jail
   CLI Example:
   salt '*' pkg.fetch <package name> jail=<jail name or id>

   chroot  Fetch package in the specified chroot (ignored if jail is specified)
   CLI Example:
   salt '*' pkg.fetch <package name> chroot=/path/to/chroot

   fetch_all  Fetch all packages.
   CLI Example:
   salt '*' pkg.fetch <package name> fetch_all=True

   quiet  Quiet mode. Show less output.
   CLI Example:
   salt '*' pkg.fetch <package name> quiet=True

   fromrepo  Fetches packages from the given repo if multiple repo support is enabled. See pkg.conf(5).
   CLI Example:
```
salt '*' pkg.fetch <package name> fromrepo=repo
```

**glob**  Treat `pkg_name` as a shell glob pattern.

CLI Example:
```
salt '*' pkg.fetch <package name> glob=True
```

**regex**  Treat `pkg_name` as a regular expression.

CLI Example:
```
salt '*' pkg.fetch <regular expression> regex=True
```

**pcre**  Treat `pkg_name` as an extended regular expression.

CLI Example:
```
salt '*' pkg.fetch <extended regular expression> pcre=True
```

**local**  Skip updating the repository catalogs with `pkg-update(8)`. Use the local cache only.

CLI Example:
```
salt '*' pkg.fetch <package name> local=True
```

**depends**  Fetch the package and its dependencies as well.

CLI Example:
```
salt '*' pkg.fetch <package name> depends=True
```

```
salt.modules.pkgng.install(name=None, fromrepo=None, pkgs=None, sources=None, jail=None, chroot=None, orphan=False, force=False, glob=False, local=False, dryrun=False, quiet=False, reinstall_requires=False, regex=False, pcre=False, **kwargs)
```

Install package(s) from a repository

**name**  The name of the package to install

CLI Example:
```
salt '*' pkg.install <package name>
```

**jail**  Install the package into the specified jail

**chroot**  Install the package into the specified chroot (ignored if `jail` is specified)

**orphan**  Mark the installed package as orphan. Will be automatically removed if no other packages depend on them. For more information please refer to `pkg-autoremove(8)`.

CLI Example:
```
salt '*' pkg.install <package name> orphan=True
```

**force**  Force the reinstallation of the package if already installed.

CLI Example:
```
salt '*' pkg.install <package name> force=True
```
glob  Treat the package names as shell glob patterns.

   CLI Example:
   
   salt '*' pkg.install <package name> glob=True

local  Do not update the repository catalogs with pkg-update(8). A value of True here is equivalent to
       using the -U flag with pkg install.

   CLI Example:
   
   salt '*' pkg.install <package name> local=True

dryrun  Dry-run mode. The list of changes to packages is always printed, but no changes are actually made.

   CLI Example:
   
   salt '*' pkg.install <package name> dryrun=True

quiet  Force quiet output, except when dryrun is used, where pkg install will always show packages to be
       installed, upgraded or deleted.

   CLI Example:
   
   salt '*' pkg.install <package name> quiet=True

reinstall_requires  When used with force, reinstalls any packages that require the given package.

   CLI Example:
   
   salt '*' pkg.install <package name> reinstall_requires=True force=True

   Changed in version 2014.7.0: require kwarg renamed to reinstall_requires

fromrepo  In multi-repo mode, override the pkg.conf ordering and only attempt to download packages from
       the named repository.

   CLI Example:
   
   salt '*' pkg.install <package name> fromrepo=repo

regex  Treat the package names as a regular expression

   CLI Example:
   
   salt '*' pkg.install <regular expression> regex=True

pcre  Treat the package names as extended regular expressions.

   CLI Example:
   
   salt '*' pkg.install <extended regular expression> pcre=True

salt.modules.pkgng.latest_version(*names, **kwargs)
Return the latest version of the named package available for upgrade or installation. If more than one package
name is specified, a dict of name/version pairs is returned.
If the latest version of a given package is already installed, an empty string will be returned for that package.

   CLI Example:
   
   salt '*' pkg.latest_version <package name>
salt '*' pkg.latest_version <package name> jail=<jail name or id>
salt '*' pkg.latest_version <package name> chroot=/path/to/chroot
salt.modules.pkgng.list_pkgs(versions_as_list=False, jail=None, chroot=None, with_origin=False, **kwargs)

List the packages currently installed as a dict:

```python
{'<package_name>': '<version>'}
```

- **jail** List the packages in the specified jail
- **chroot** List the packages in the specified chroot (ignored if **jail** is specified)
- **with_origin** [False] Return a nested dictionary containing both the origin name and version for each installed package.
  
  New in version 2014.1.0.

CLI Example:

```
salt '*' pkg.list_pkgs
salt '*' pkg.list_pkgs jail=<jail name or id>
salt '*' pkg.list_pkgs chroot=/path/to/chroot
```

salt.modules.pkgng.parse_config(file_name='/usr/local/etc/pkg.conf')

Return dict of uncommented global variables.

CLI Example:

```
salt '*' pkg.parse_config
```

**NOTE:** not working properly right now

salt.modules.pkgng.refresh_db(jail=None, chroot=None, force=False)

Refresh PACKAGESITE contents

**Note:** This function can accessed using pkg.update in addition to pkg.refresh_db, to more closely match the CLI usage of pkg(8).

CLI Example:

```
salt '*' pkg.refresh_db
```

- **jail** Refresh the pkg database within the specified jail
- **chroot** Refresh the pkg database within the specified chroot (ignored if **jail** is specified)
- **force** Force a full download of the repository catalog without regard to the respective ages of the local and remote copies of the catalog.

CLI Example:

```
salt '*' pkg.refresh_db force=True
```

salt.modules.pkgng.remove(name=None, pkgs=None, jail=None, chroot=None, all_installed=False, force=False, glob=False, dryrun=False, recurse=False, regex=False, pcre=False, **kwargs)

Remove a package from the database and system

**Note:** This function can accessed using pkg.delete in addition to pkg.remove, to more closely match the CLI usage of pkg(8).
**name**  The package to remove

CLI Example:

```
salt '*' pkg.remove <package name>
```

**jail**  Delete the package from the specified jail

**chroot**  Delete the package from the specified chroot (ignored if jail is specified)

**all_installed**  Deletes all installed packages from the system and empties the database. use with caution!

CLI Example:

```
salt '*' pkg.remove all all_installed=True force=True
```

**force**  Forces packages to be removed despite leaving unresolved dependencies. 

CLI Example:

```
salt '*' pkg.remove <package name> force=True
```

**glob**  Treat the package names as shell glob patterns.

CLI Example:

```
salt '*' pkg.remove <package name> glob=True
```

**dryrun**  Dry run mode. The list of packages to delete is always printed, but no packages are actually deleted. 

CLI Example:

```
salt '*' pkg.remove <package name> dryrun=True
```

**recurse**  Delete all packages that require the listed package as well.

CLI Example:

```
salt '*' pkg.remove <package name> recurse=True
```

**regex**  Treat the package names as regular expressions.

CLI Example:

```
salt '*' pkg.remove <regular expression> regex=True
```

**pcre**  Treat the package names as extended regular expressions.

CLI Example:

```
salt '*' pkg.remove <extended regular expression> pcre=True
```

salt.modules.pkgng.restore(file_name, jail=None, chroot=None)

Reads archive created by pkg backup -d and recreates the database.

CLI Example:

```
salt '*' pkg.restore /tmp/pkg
```

**jail**  Restore database to the specified jail. Note that this will run the command within the jail, and so the path to the file from which the pkg database will be restored is relative to the root of the jail.

CLI Example:
salt 'x' pkg.restore /tmp/pkg jail=<jail name or id>

chroot  Restore database to the specified chroot (ignored if jail is specified). Note that this will run the command within the chroot, and so the path to the file from which the pkg database will be restored is relative to the root of the chroot.

CLI Example:

salt 'x' pkg.restore /tmp/pkg chroot=/path/to/chroot

salt.modules.pkgng.search(name, jail=None, chroot=None, exact=False, glob=False, regex=False, pcre=False, comment=False, desc=False, full=False, depends=False, size=False, quiet=False, origin=False, prefix=False)

Searches in remote package repositories

CLI Example:

salt 'x' pkg.search pattern

jail  Perform the search using the pkg.conf(5) from the specified jail

CLI Example:

salt 'x' pkg.search pattern jail=<jail name or id>

chroot  Perform the search using the pkg.conf(5) from the specified chroot (ignored if jail is specified)

CLI Example:

salt 'x' pkg.search pattern chroot=/path/to/chroot

effect  Treat pattern as exact pattern.

CLI Example:

salt 'x' pkg.search pattern exact=True

glob  Treat pattern as a shell glob pattern.

CLI Example:

salt 'x' pkg.search pattern glob=True

regex  Treat pattern as a regular expression.

CLI Example:

salt 'x' pkg.search pattern regex=True

pcre  Treat pattern as an extended regular expression.

CLI Example:

salt 'x' pkg.search pattern pcre=True

comment  Search for pattern in the package comment one-line description.

CLI Example:

salt 'x' pkg.search pattern comment=True
**desc**  Search for pattern in the package description.

   CLI Example:

   ```
salt '*' pkg.search pattern desc=True
   ```

**full**  Displays full information about the matching packages.

   CLI Example:

   ```
salt '*' pkg.search pattern full=True
   ```

**depends**  Displays the dependencies of pattern.

   CLI Example:

   ```
salt '*' pkg.search pattern depends=True
   ```

**size**  Displays the size of the package

   CLI Example:

   ```
salt '*' pkg.search pattern size=True
   ```

**quiet**  Be quiet. Prints only the requested information without displaying many hints.

   CLI Example:

   ```
salt '*' pkg.search pattern quiet=True
   ```

**origin**  Displays pattern origin.

   CLI Example:

   ```
salt '*' pkg.search pattern origin=True
   ```

**prefix**  Displays the installation prefix for each package matching pattern.

   CLI Example:

   ```
salt '*' pkg.search pattern prefix=True
   ```

salt.modules.pkgng.stats(**local=False, remote=False, jail=None, chroot=None**)  Return pkgng stats.

   CLI Example:

   ```
salt '*' pkg.stats
   ```

**local**  Display stats only for the local package database.

   CLI Example:

   ```
salt '*' pkg.stats local=True
   ```

**remote**  Display stats only for the remote package database(s).

   CLI Example:

   ```
salt '*' pkg.stats remote=True
   ```
**jail**  Retrieve stats from the specified jail.

CLI Example:

```bash
salt '*' pkg.stats jail=<jail name or id>
salt '*' pkg.stats jail=<jail name or id> local=True
salt '*' pkg.stats jail=<jail name or id> remote=True
```

**chroot**  Retrieve stats from the specified chroot (ignored if jail is specified).

CLI Example:

```bash
salt '*' pkg.stats chroot=/path/to/chroot
salt '*' pkg.stats chroot=/path/to/chroot local=True
salt '*' pkg.stats chroot=/path/to/chroot remote=True
```

---

salt.modules.pkgng.update_package_site(*new_url*)

Updates remote package repo URL, PACKAGESITE var to be exact.

Must use http://, ftp://, or https:// protocol

CLI Example:

```bash
salt '*' pkg.update_package_site http://127.0.0.1/
```

salt.modules.pkgng.updating(*name*, jail=None, chroot=None, filedate=None, filename=None)

`Displays UPDATING entries of software packages`

CLI Example:

```bash
salt '*' pkg.updating foo
```

**jail**  Perform the action in the specified jail

CLI Example:

```bash
salt '*' pkg.updating foo jail=<jail name or id>
```

**chroot**  Perform the action in the specified chroot (ignored if jail is specified)

CLI Example:

```bash
salt '*' pkg.updating foo chroot=/path/to/chroot
```

**filedate**  Only entries newer than date are shown. Use a YYYYMMDD date format.

CLI Example:

```bash
salt '*' pkg.updating foo filedate=20130101
```

**filename**  Defines an alternative location of the UPDATING file.

CLI Example:

```bash
salt '*' pkg.updating foo filename=/tmp/UPDATING
```

salt.modules.pkgng.upgrade(*names*, **kwargs)

Upgrade named or all packages (run a pkg upgrade). If <package name> is ommitted, the operation is executed on all packages.

CLI Example:
salt 'x' pkg.upgrade <package name>

jail Audit packages within the specified jail
   CLI Example:
   salt 'x' pkg.upgrade <package name> jail=<jail name or id>

chroot Audit packages within the specified chroot (ignored if jail is specified)
   CLI Example:
   salt 'x' pkg.upgrade <package name> chroot=/path/to/chroot

Any of the below options can also be used with jail or chroot.

force Force reinstalling/upgrading the whole set of packages.
   CLI Example:
   salt 'x' pkg.upgrade <package name> force=True

local Do not update the repository catalogs with pkg-update(8). A value of True here is equivalent to using the -U flag with pkg upgrade.
   CLI Example:
   salt 'x' pkg.upgrade <package name> local=True

dryrun Dry-run mode: show what packages have updates available, but do not perform any upgrades. Repository catalogs will be updated as usual unless the local option is also given.
   CLI Example:
   salt 'x' pkg.upgrade <package name> dryrun=True

salt.modules.pkgng.version(*names, **kwargs)

Returns a string representing the package version or an empty string if not installed. If more than one package name is specified, a dict of name/version pairs is returned.

Note: This function can accessed using pkg.info in addition to pkg.version, to more closely match the CLI usage of pkg(8).

jail Get package version information for the specified jail

chroot Get package version information for the specified chroot (ignored if jail is specified)

with_origin [False] Return a nested dictionary containing both the origin name and version for each specified package.
   New in version 2014.1.0.

   CLI Example:
   salt 'x' pkg.version <package name>
salt 'x' pkg.version <package name> jail=<jail name or id>
salt 'x' pkg.version <package1> <package2> <package3> ...
salt.modules.pkgng.which  
\([\text{path}, \text{jail=None, chroot=None, origin=False, quiet=False}]\)

Displays which package installed a specific file

CLI Example:
```
salt '*' pkg.which <file name>
```

jail  Perform the check in the specified jail

CLI Example:
```
salt '*' pkg.which <file name> jail=<jail name or id>
```

chroot  Perform the check in the specified chroot (ignored if jail is specified)

CLI Example:
```
salt '*' pkg.which <file name> chroot=/path/to/chroot
```

origin  Shows the origin of the package instead of name-version.

CLI Example:
```
salt '*' pkg.which <file name> origin=True
```

quiet  Quiet output.

CLI Example:
```
salt '*' pkg.which <file name> quiet=True
```

31.16.192 salt.modules.pkgutil

Pkgutil support for Solaris

salt.modules.pkgutil.install  
\([\text{name=None, refresh=False, version=None, pkgs=None, **kwargs}]\)

Install packages using the pkgutil tool.

CLI Example:
```
salt '*' pkg.install <package_name>
salt '*' pkg.install SMClgcc346
```

Multiple Package Installation Options:

pkgs  A list of packages to install from OpenCSW. Must be passed as a python list.

CLI Example:
```
salt '*' pkg.install pkgs='["foo", "bar"]'
salt '*' pkg.install pkgs='["foo", {"bar": "1.2.3"}]'
```

Returns a dict containing the new package names and versions:

```
{"<package>": {"old": '<old-version>',
              "new": '<new-version>'}}
```

salt.modules.pkgutil.latest_version  
\([\text{names, **kwargs}]\)

Return the latest version of the named package available for upgrade or installation. If more than one package name is specified, a dict of name/version pairs is returned.
If the latest version of a given package is already installed, an empty string will be returned for that package.

CLI Example:

```
salt '*' pkgutil.latest_version CSWpython
salt '*' pkgutil.latest_version <package1> <package2> <package3> ...
```

```
salt.modules.pkgutil.list_pkgs(versions_as_list=False, **kwargs)
```

List the packages currently installed as a dict:

```
{'<package_name>': '<version>'}
```

CLI Example:

```
salt '*' pkg.list_pkgs
salt '*' pkg.list_pkgs versions_as_list=True
```

```
salt.modules.pkgutil.list_upgrades(refresh=True)
```

List all available package upgrades on this system

CLI Example:

```
salt '*' pkgutil.list_upgrades
```

```
salt.modules.pkgutil.purge(name=None, pkgs=None, **kwargs)
```

Package purges are not supported, this function is identical to `remove()`.

name The name of the package to be deleted.

Multiple Package Options:

pkgs A list of packages to delete. Must be passed as a python list. The name parameter will be ignored if this option is passed.

New in version 0.16.0.

Returns a dict containing the changes.

CLI Example:

```
salt '*' pkg.purge <package name>
salt '*' pkg.purge <package1>,<package2>,<package3>
salt '*' pkg.purge pkgs='["foo", "bar"]'
```

```
salt.modules.pkgutil.refresh_db()
```

Updates the pkgutil repo database (pkgutil -U)

CLI Example:

```
salt '*' pkgutil.refresh_db
```

```
salt.modules.pkgutil.remove(name=None, pkgs=None, **kwargs)
```

Remove a package and all its dependencies which are not in use by other packages.

name The name of the package to be deleted.

Multiple Package Options:

pkgs A list of packages to delete. Must be passed as a python list. The name parameter will be ignored if this option is passed.

New in version 0.16.0.

Returns a dict containing the changes.
CLI Example:

```
salt '*' pkg.remove <package name>
salt '*' pkg.remove <package1>,<package2>,<package3>
salt '*' pkg.remove pkgs='["foo", "bar"]'
```

`salt.modules.pkgutil.upgrade(refresh=True)`

Upgrade all of the packages to the latest available version.

Returns a dict containing the changes:

```
{'<package>': {'old': '<old-version>',
              'new': '<new-version>'}}
```

CLI Example:

```
salt '*' pkgutil.upgrade
```

`salt.modules.pkgutil.upgrade_available(name)`

Check if there is an upgrade available for a certain package

CLI Example:

```
salt '*' pkgutil.upgrade_available CSWpython
```

`salt.modules.pkgutil.version(*names, **kwargs)`

Returns a version if the package is installed, else returns an empty string

CLI Example:

```
salt '*' pkgutil.version CSWpython
```

### 31.16.193 salt.modules.portage_config

Configure `portage(5)`

`salt.modules.portage_config.append_to_package_conf(conf, atom='', flags=None, string='', overwrite=False)`

Append a string or a list of flags for a given package or DEPEND atom to a given configuration file.

CLI Example:

```
salt '*' portage_config.append_to_package_conf use string="app-admin/salt ldap -libvirt"
salt '*' portage_config.append_to_package_conf use atom="> = app-admin/salt-0.14.1" flags='["ldap", '-libvirt"]'
```

`salt.modules.portage_config.append_use_flags(atom, uses=None, overwrite=False)`

Append a list of use flags for a given package or DEPEND atom

CLI Example:

```
salt '*' portage_config.append_use_flags "app-admin/salt[ldap, -libvirt]"
salt '*' portage_config.append_use_flags ">=app-admin/salt-0.14.1" ['ldap', '-libvirt']"
```

`salt.modules.portage_config.enforce_nice_config()`

Enforce a nice tree structure for `/etc/portage/package.*` configuration files.

See also:

`salt.modules.ebuild.ex_mod_init()` for information on automatically running this when pkg is used.
CLI Example:

```bash
salt '*/' portage_config.enforce_nice_config
```

```
salt.modules.portage_config.filter_flags(use, use_expand_hidden, usemasked, useforced)
    New in version 2015.8.0.
    Filter function to remove hidden or otherwise not normally visible USE flags from a list.
    @type use: list @param use: the USE flag list to be filtered. @type use_expand_hidden: list @param
    use_expand_hidden: list of flags hidden. @type usemasked: list @param usemasked: list of masked USE
    flags. @type useforced: list @param useforced: the forced USE flags. @rtype: list @return the filtered USE
    flags.
```

```
salt.modules.portage_config.get_all_cpv_use(cp)
    New in version 2015.8.0.
    Uses portage to determine final USE flags and settings for an emerge.
    @type cp: string @param cp: eg cat/pkg @rtype: list @return use, use_expand_hidden, usemask, useforce
```

```
salt.modules.portage_config.get_cleared_flags(cp)
    New in version 2015.8.0.
    Uses portage for compare use flags which is used for installing package and use flags which now exist int
    /etc/portage/package.use/
    @type cp: string @param cp: eg cat/pkg @rtype: tuple @return: tuple with two lists - list of used flags and
    list of flags which will be used
```

```
salt.modules.portage_config.get_flags_from_package_conf(conf, atom)
    Get flags for a given package or DEPEND atom. Warning: This only works if the configuration files tree is in
    the correct format (the one enforced by enforce_nice_config)
    CLI Example:
    ```bash
    salt '*/' portage_config.get_flags_from_package_conf license salt
    ```
```

```
salt.modules.portage_config.get_installed_use(cp, use='USE')
    New in version 2015.8.0.
    Gets the installed USE flags from the VARDB.
    @type cp: string @param cp: cat/pkg @type use: string @param use: 1 of ['USE', `PKGUSE`] @rtype list
    @returns [] or the list of IUSE flags
```

```
salt.modules.portage_config.get_iuse(cp)
    New in version 2015.8.0.
    Gets the current IUSE flags from the tree.
    @type cpv: string @param cpv: cat/pkg @rtype list @returns [] or the list of IUSE flags
```

```
salt.modules.portage_config.get_missing_flags(conf, atom, flags)
    Find out which of the given flags are currently not set. CLI Example:
    ```bash
    salt '*/' portage_config.get_missing_flags use salt [['ldap', '-libvirt', 'openssl']]''
    ```
```

```
salt.modules.portage_config.has_flag(conf, atom, flag)
    Verify if the given package or DEPEND atom has the given flag. Warning: This only works if the configuration
    files tree is in the correct format (the one enforced by enforce_nice_config)
    CLI Example:
```

31.16. Full list of builtin execution modules

1151
salt '海报' portage_config.has_flag license salt Apache-2.0

salt.modules.portage_config.has_use(atom, use)
    Verify if the given package or DEPEND atom has the given use flag. Warning: This only works if the configuration files tree is in the correct format (the one enforced by enforce_nice_config)

    CLI Example:
    salt '海报' portage_config.has_use salt libvirt

salt.modules.portage_config.is_changed_uses(cp)
    New in version 2015.8.0.
    Uses portage to determine if the use flags of installed package is compatible with use flags in portage configs.

    @type cp: string
    @param cp: eg cat/pkg

salt.modules.portage_config.is_present(conf, atom)
    Tell if a given package or DEPEND atom is present in the configuration files tree. Warning: This only works if the configuration files tree is in the correct format (the one enforced by enforce_nice_config)

    CLI Example:
    salt '海报' portage_config.is_present unmask salt

### 31.16.194 salt.modules.postfix

Support for Postfix

This module is currently little more than a config file viewer and editor. It is able to read the master.cf file (which is one style) and files in the style of main.cf (which is a different style, that is used in multiple postfix configuration files).

The design of this module is such that when files are edited, a minimum of changes are made to them. Each file should look as if it has been edited by hand; order, comments and whitespace are all preserved.

salt.modules.postfix.delete(queue_id)
    Delete message(s) from the mail queue

    CLI Example:
    salt '海报' postfix.delete 5C33CA0DEA
    salt '海报' postfix.delete ALL

salt.modules.postfix.hold(queue_id)
    Put message(s) on hold from the mail queue

    CLI Example:
    salt '海报' postfix.hold 5C33CA0DEA
    salt '海报' postfix.hold ALL

salt.modules.postfix.requeue(queue_id)
    Requeue message(s) in the mail queue

    CLI Example:
salt.modules.postfix.set_main(key, value, path="/etc/postfix/main.cf")
Set a single config value in the main.cf file. If the value does not already exist, it will be appended to the end.

CLI Example:

```
salt <minion> postfix.set_main mailq_path /usr/bin/mailq
```

salt.modules.postfix.set_master(service, conn_type, private='y', unpriv='y', chroot='y',
                                 wakeup='n', maxproc='100', command='', write_conf=True,
                                 path="/etc/postfix/master.cf")
Set a single config value in the master.cf file. If the value does not already exist, it will be appended to the end.

Because of shell parsing issues, `-` cannot be set as a value, as is normal in the master.cf file; either `y`, `n` or a number should be used when calling this function from the command line. If the value used matches the default, it will internally be converted to a `-`. Calling this function from the Python API is not affected by this limitation.

The settings and their default values, in order, are: service (required), conn_type (required), private (y), unpriv (y), chroot (y), wakeup (n), maxproc (100), command (required).

By default, this function will write out the changes to the master.cf file, and then returns the full contents of the file. By setting the write_conf option to False, it will skip writing the file.

CLI Example:

```
salt <minion> postfix.set_master smtp inet n y n n 100 smtpd
```

salt.modules.postfix.show_main(path="/etc/postfix/main.cf")
Return a dict of active config values. This does not include comments, spacing or order. Bear in mind that order is functionally important in the main.cf file, since keys can be referred to as variables. This means that the data returned from this function should not be used for direct modification of the main.cf file; other functions are available for that.

CLI Examples:

```
salt <minion> postfix.show_main	salt <minion> postfix.show_main path=/path/to/main.cf
```

salt.modules.postfix.show_master(path="/etc/postfix/master.cf")
Return a dict of active config values. This does not include comments, spacing or order.

The data returned from this function should not be used for direct modification of the main.cf file; other functions are available for that.

CLI Examples:

```
salt <minion> postfix.show_master	salt <minion> postfix.show_master path=/path/to/master.cf
```

salt.modules.postfix.show_queue()
Show contents of the mail queue

CLI Example:

```
salt '*' postfix.show_queue
```

salt.modules.postfix.unhold(queue_id)
Set held message(s) in the mail queue to unheld

CLI Example:
31.16.195 salt.modules.postgres

Module to provide Postgres compatibility to salt.

**configuration** In order to connect to Postgres, certain configuration is required in /etc/salt/minion on the relevant minions. Some sample configs might look like:

```
postgres.host: 'localhost'
postgres.port: '5432'
postgres.user: 'postgres' -> db user
postgres.pass: ''
postgres.maintenance_db: 'postgres'
```

The default for the maintenance_db is 'postgres' and in most cases it can be left at the default setting. This data can also be passed into pillar. Options passed into opts will overwrite options passed into pillar

**note** This module uses MD5 hashing which may not be compliant with certain security audits.

```python
salt.modules.postgres.available_extensions(user=None, host=None, port=None, maintenance_db=None, password=None, runas=None)
```

List available postgresql extensions

CLI Example:

```
salt '*' postgres.available_extensions
```

```python
salt.modules.postgres.create_extension(name, if_not_exists=None, schema=None, ext_version=None, from_version=None, user=None, host=None, port=None, maintenance_db=None, password=None, runas=None)
```

Install a postgresql extension

CLI Example:

```
salt '*' postgres.create_extension 'adminpack'
```

```python
salt.modules.postgres.create_metadata(name, ext_version=None, schema=None, user=None, host=None, port=None, maintenance_db=None, password=None, runas=None)
```

Get lifecycle information about an extension

CLI Example:

```
salt '*' postgres.create_metadata adminpack
```

```python
salt.modules.postgres.db_alter(name, user=None, host=None, port=None, maintenance_db=None, password=None, tablespace=None, owner=None, owner_recurse=False, runas=None)
```

Change tablespace or/and owner of database.

CLI Example:
salt.modules.postgres.db_create(name, user=None, host=None, port=None, maintenance_db=None, password=None, tablespace=None, encoding=None, lc_collate=None, lc_ctype=None, owner=None, template=None, runas=None)

Adds a database to the Postgres server.

CLI Example:

```
salt '*' postgres.db_create 'dbname'
```

```
salt '*' postgres.db_create 'dbname' template=template_postgis
```

salt.modules.postgres.db_exists(name, user=None, host=None, port=None, maintenance_db=None, password=None, runas=None)

Checks if a database exists on the Postgres server.

CLI Example:

```
salt '*' postgres.db_exists 'dbname'
```

salt.modules.postgres.db_list(user=None, host=None, port=None, maintenance_db=None, password=None, runas=None)

Return dictionary with information about databases of a Postgres server.

CLI Example:

```
salt '*' postgres.db_list
```

salt.modules.postgres.db_remove(name, user=None, host=None, port=None, maintenance_db=None, password=None, runas=None)

Removes a database from the Postgres server.

CLI Example:

```
salt '*' postgres.db_remove 'dbname'
```

salt.modules.postgres.drop_extension(name, if_exists=None, restrict=None, cascade=None, user=None, host=None, port=None, maintenance_db=None, password=None, runas=None)

Drop an installed postgresql extension

CLI Example:

```
salt '*' postgres.drop_extension 'adminpack'
```

salt.modules.postgres.get_available_extension(name, user=None, host=None, port=None, maintenance_db=None, password=None, runas=None)

Get information about an available postgresql extension

CLI Example:

```
salt '*' postgres.get_available_extension plpgsql
```

salt.modules.postgres.get_installed_extension(name, user=None, host=None, port=None, maintenance_db=None, password=None, runas=None)

Get information about an installed postgresql extension

CLI Example:
salt '*' postgres.get_installed_extension plpgsql

**salt.modules.postgres.group_create**(groupname, user=None, host=None, port=None, maintenance_db=None, password=None, createdb=None, createuser=None, createdbroles=None, encrypted=None, login=None, inherit=None, superuser=None, replication=None, rolepassword=None, groups=None, runas=None)

Creates a Postgres group. A group is postgres is similar to a user, but cannot login.

CLI Example:

```
salt '*' postgres.group_create 'groupname' user='user' \ 
    host='hostname' port='port' password='password' \ 
    rolepassword='rolepassword'
```

**salt.modules.postgres.group_remove**(groupname, user=None, host=None, port=None, maintenance_db=None, password=None, runas=None)

Removes a group from the Postgres server.

CLI Example:

```
salt '*' postgres.group_remove 'groupname'
```

**salt.modules.postgres.group_update**(groupname, user=None, host=None, port=None, maintenance_db=None, password=None, createdb=None, createuser=None, createroles=None, createuser=None, encrypted=None, login=None, inherit=None, superuser=None, replication=None, rolepassword=None, groups=None, runas=None)

Updates a postgres group

CLI Examples:

```
salt '*' postgres.group_update 'username' user='user' \ 
    host='hostname' port='port' password='password' \ 
    rolepassword='rolepassword'
```

**salt.modules.postgres.installed_extensions**(user=None, host=None, port=None, maintenance_db=None, password=None, runas=None)

List installed postgresql extensions

CLI Example:

```
salt '*' postgres.installed_extensions
```

**salt.modules.postgres.is_available_extension**(name, user=None, host=None, port=None, maintenance_db=None, password=None, runas=None)

Test if a specific extension is available

CLI Example:

```
salt '*' postgres.is_available_extension
```

**salt.modules.postgres.is_installed_extension**(name, user=None, host=None, port=None, maintenance_db=None, password=None, runas=None)

Test if a specific extension is installed

CLI Example:
salt 'postgres.is_installed_extension

salt.modules.postgres.owner_to(dbname, ownername, user=None, host=None, port=None, password=None, runas=None)
Set the owner of all schemas, functions, tables, views and sequences to the given username.
CLI Example:
salt '*' postgres.owner_to 'dbname' 'username'

salt.modules.postgres.psql_query(query, user=None, host=None, port=None, maintenance_db=None, password=None, runas=None)
Run an SQL-Query and return the results as a list. This command only supports SELECT statements. This limitation can be worked around with a query like this:
WITH updated AS (UPDATE pg_authid SET rolconnlimit = 2000 WHERE rolnname = 'rolename' RETURNING rolconnlimit) SELECT * FROM updated;
CLI Example:
salt '*' postgres.psql_query 'select * from pg_stat_activity'

salt.modules.postgres.role_get(name, user=None, host=None, port=None, maintenance_db=None, password=None, runas=None, return_password=False)
Return a dict with information about users of a Postgres server.
Set return_password to True to get password hash in the result.
CLI Example:
salt '*' postgres.role_get postgres

salt.modules.postgres.schema_create(dbname, name, owner=None, user=None, db_user=None, db_password=None, db_host=None, db_port=None)
Creates a Postgres schema.
CLI Example:
salt '*' postgres.schema_create dbname name owner='owner' \
user='user' \ 
db_user='user' db_password='password' \
db_host='hostname' db_port='port'

salt.modules.postgres.schema_exists(dbname, name, db_user=None, db_password=None, db_host=None, db_port=None)
Checks if a schema exists on the Postgres server.
CLI Example:
salt '*' postgres.schema_exists dbname schemaname

dbname Database name we query on
name Schema name we look for
db_user database username if different from config or default
db_password user password if any password for a specified user
db_host Database host if different from config or default
db_port Database port if different from config or default
salt.modules.postgres.schema_get(dbname, name, db_user=None, db_password=None, 
                              db_host=None, db_port=None)

Return a dict with information about schemas in a database.

CLI Example:

```
salt '*' postgres.schema_get dbname name
```

- **dbname** Database name we query on
- **name** Schema name we look for
- **db_user** database username if different from config or default
- **db_password** user password if any password for a specified user
- **db_host** Database host if different from config or default
- **db_port** Database port if different from config or default

salt.modules.postgres.schema_list(dbname, db_user=None, db_password=None, db_host=None, 
                                   db_port=None)

Return a dict with information about schemas in a Postgres database.

CLI Example:

```
salt '*' postgres.schema_list dbname
```

- **dbname** Database name we query on
- **db_user** database username if different from config or default
- **db_password** user password if any password for a specified user
- **db_host** Database host if different from config or default
- **db_port** Database port if different from config or default

salt.modules.postgres.schema_remove(dbname, name, user=None, 
                                      db_user=None, db_password=None, 
                                      db_host=None, db_port=None)

Removes a schema from the Postgres server.

CLI Example:

```
salt '*' postgres.schema_remove dbname schemaname
```

- **dbname** Database name we work on
- **schemaname** The schema’s name we’ll remove
- **user** System user all operations should be performed on behalf of
- **db_user** database username if different from config or default
- **db_password** user password if any password for a specified user
- **db_host** Database host if different from config or default
- **db_port** Database port if different from config or default
salt.modules.postgres.tablespace_alter(name, user=None, host=None, port=None, maintenance_db=None, password=None, new_name=None, new_owner=None, set_option=None, reset_option=None, runas=None)

Change tablespace name, owner, or options.

CLI Example:

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>salt '*' postgres.tablespace_alter tsname new_owner=otheruser</td>
<td>Change tablespace owner</td>
</tr>
<tr>
<td>salt '*' postgres.tablespace_alter index_space new_name=fast_raid</td>
<td>Change tablespace name</td>
</tr>
<tr>
<td>salt '*' postgres.tablespace_alter test set_option='{seq_page_cost': '1.1'}&quot;</td>
<td>Change tablespace option</td>
</tr>
<tr>
<td>salt '*' postgres.tablespace_alter tsname reset_option=seq_page_cost</td>
<td>Reset tablespace option</td>
</tr>
</tbody>
</table>

New in version 2015.8.0.

salt.modules.postgres.tablespace_create(name, location, options=None, owner=None, user=None, host=None, port=None, maintenance_db=None, password=None, runas=None)

Adds a tablespace to the Postgres server.

CLI Example:

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>salt '*' postgres.tablespace_create /path/datadir</td>
<td>Create a new tablespace</td>
</tr>
</tbody>
</table>

New in version 2015.8.0.

salt.modules.postgres.tablespace_exists(name, user=None, host=None, port=None, maintenance_db=None, password=None, runas=None)

Checks if a tablespace exists on the Postgres server.

CLI Example:

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>salt '*' postgres.tablespace_exists 'dbname'</td>
<td>Check if a tablespace exists</td>
</tr>
</tbody>
</table>

New in version 2015.8.0.

salt.modules.postgres.tablespace_list(user=None, host=None, port=None, maintenance_db=None, password=None, runas=None)

Return dictionary with information about tablespaces of a Postgres server.

CLI Example:

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>salt '*' postgres.tablespace_list</td>
<td>List all tablespaces</td>
</tr>
</tbody>
</table>

New in version 2015.8.0.

salt.modules.postgres.tablespace_remove(name, user=None, host=None, port=None, maintenance_db=None, password=None, runas=None)

Removes a tablespace from the Postgres server.

CLI Example:

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>salt '*' postgres.tablespace_remove tsname</td>
<td>Remove a tablespace</td>
</tr>
</tbody>
</table>

New in version 2015.8.0.

salt.modules.postgres.user_create(username, user=None, host=None, port=None, maintenance_db=None, password=None, createdb=None, createuser=None, createroles=None, inherit=None, login=None, connlimit=None, encrypted=None, superuser=None, replication=None, rolepassword=None, groups=None, runas=None)

Creates a Postgres user.
CLI Examples:

salt '*' postgres.user_create 'username' user='user' \ 
    host='hostname' port='port' password='password' \ 
    rolepassword='rolepassword'

salt.modules.postgres.user_exists(name, user=None, host=None, port=None, maintenance_db=None, password=None, runas=None)
Checks if a user exists on the Postgres server.

CLI Example:

salt '*' postgres.user_exists 'username'

salt.modules.postgres.user_list(user=None, host=None, port=None, maintenance_db=None, password=None, runas=None, return_password=False)
Return a dict with information about users of a Postgres server.
Set return_password to True to get password hash in the result.

CLI Example:

salt '*' postgres.user_list

salt.modules.postgres.user_remove(username, user=None, host=None, port=None, maintenance_db=None, password=None, runas=None)
Removes a user from the Postgres server.

CLI Example:

salt '*' postgres.user_remove 'username'

salt.modules.postgres.user_update(username, user=None, host=None, port=None, maintenance_db=None, password=None, createdb=None, createdb=None, createuser=None, createdb=None, encrypted=None, superuser=None, inherit=None, login=None, connlimit=None, replication=None, rolepassword=None, groups=None, runas=None)
Updates a Postgres user.

CLI Examples:

salt '*' postgres.user_update 'username' user='user' \ 
    host='hostname' port='port' password='password' \ 
    rolepassword='rolepassword'

salt.modules.postgres.version(user=None, host=None, port=None, maintenance_db=None, password=None, runas=None)
Return the version of a Postgres server.

CLI Example:

salt '*' postgres.version

31.16.196 salt.modules.poudriere

Support for poudriere

salt.modules.poudriere.bulk_build(jail, pkg_file, keep=False)
Run bulk build on poudriere server.
Return number of pkg builds, failures, and errors, on error dump to CLI

CLI Example:
```
salt -N buildbox_group poudriere.bulk_build 90amd64 /root/pkg_list
```

salt.modules.poudriere.create_jail(name, arch, version='9.0-RELEASE')
Creates a new poudriere jail if one does not exist

NOTE creating a new jail will take some time the master is not hanging

CLI Example:
```
salt '*' poudriere.create_jail 90amd64 amd64
```

salt.modules.poudriere.create_ports_tree()
Not working need to run portfetch non interactive

salt.modules.poudriere.delete_jail(name)
Deletes poudriere jail with name

CLI Example:
```
salt '*' poudriere.delete_jail 90amd64
```

salt.modules.poudriere.is_jail(name)
Return True if jail exists False if not

CLI Example:
```
salt '*' poudriere.is_jail <jail name>
```

salt.modules.poudriere.list_jails()
Return a list of current jails managed by poudriere

CLI Example:
```
salt '*' poudriere.list_jails
```

salt.modules.poudriere.list_ports()
Return a list of current port trees managed by poudriere

CLI Example:
```
salt '*' poudriere.list_ports
```

salt.modules.poudriere.make_pkgng_aware(jname)
Make jail jname pkgng aware

CLI Example:
```
salt '*' poudriere.make_pkgng_aware <jail name>
```

salt.modules.poudriere.parse_config(config_file=None)
Returns a dict of poudriere main configuration definitions

CLI Example:
```
salt '*' poudriere.parse_config
```

salt.modules.poudriere.update_jail(name)
Run freebsd-update on name poudriere jail
CLI Example:
```
salt '*' poudriere.update_jail freebsd:10:x86:64
```

```
salt.modules.poudriere.update_ports_tree(ports_tree)
    Updates the ports tree, either the default or the ports_tree specified
```

CLI Example:
```
salt '*' poudriere.update_ports_tree staging
```

```
salt.modules.poudriere.version()
    Return poudriere version
```

CLI Example:
```
salt '*' poudriere.version
```

### 31.16.197 salt.modules.powerpath

powerpath support.

Assumes RedHat

```
salt.modules.powerpath.add_license(key)
    Add a license
```

```
salt.modules.powerpath.has_powerpath()
```

```
salt.modules.powerpath.list_licenses()
    returns a list of applied powerpath license keys
```

```
salt.modules.powerpath.remove_license(key)
    Remove a license
```

### 31.16.198 salt.modules.publish

Publish a command from a minion to a target

```
salt.modules.publish.full_data(tgt, fun, arg=None, expr_form='glob'; returner='', timeout=5)
    Return the full data about the publication, this is invoked in the same way as the publish function
```

CLI Example:
```
salt system.example.com publish.full_data '*' cmd.run 'ls -la /tmp'
```

**Attention**

If you need to pass a value to a function argument and that value contains an equal sign, you **must** include the argument name. For example:
```
salt '*' publish.full_data test.kwarg arg='cheese=spam'
```

```
salt.modules.publish.publish(tgt, fun, arg=None, expr_form='glob'; returner='', timeout=5)
    Publish a command from the minion out to other minions.
```

Publications need to be enabled on the Salt master and the minion needs to have permission to publish the command. The Salt master will also prevent a recursive publication loop, this means that a minion cannot command another minion to command another minion as that would create an infinite command loop.
The expr_form argument is used to pass a target other than a glob into the execution, the available options are:

- glob
- pcre
- grain
- grain_pcre
- pillar
- pillar_pcre
- ipcidr
- range
- compound

Note that for pillar matches must be exact, both in the pillar matcher and the compound matcher. No globbing is supported.

The arguments sent to the minion publish function are separated with commas. This means that for a minion executing a command with multiple args it will look like this:

```
salt system.example.com publish.publish '*'
user.add 'foo,1020,1020'
```

```
salt system.example.com publish.publish 'os:Fedora'
 network.interfaces '' grain
```

**CLI Example:**
```
salt system.example.com publish.publish '*'
cmd.run 'ls -la /tmp'
```

**Attention**
If you need to pass a value to a function argument and that value contains an equal sign, you must include the argument name. For example:
```
salt '*' publish.publish test.kwarg arg='cheese=spam'
```

Multiple keyword arguments should be passed as a list.
```
salt '*' publish.publish test.kwarg arg="['cheese=spam','spam=cheese']"
```

```
salt.modules.publish.runner(fun, arg=None, timeout=5)
```
Execute a runner on the master and return the data from the runner function

**CLI Example:**
```
salt publish.runner manage.down
```

**31.16.199 salt.modules.puppet**
Execute puppet routines
```
salt.modules.puppet.disable(message=None)
```
New in version 2014.7.0.
Disable the puppet agent
message  New in version 2015.5.2.

Disables message to send to puppet

CLI Example:

```bash
salt '*' puppet.disable
salt '*' puppet.disable 'disabled for a good reason'
```

`salt.modules.puppet.enable()`

New in version 2014.7.0.

Enable the puppet agent

CLI Example:

```bash
salt '*' puppet.enable
```

`salt.modules.puppet.fact(name, puppet=False)`

Run facter for a specific fact

CLI Example:

```bash
salt '*' puppet.fact kernel
```

`salt.modules.puppet.facts(puppet=False)`

Run facter and return the results

CLI Example:

```bash
salt '*' puppet.facts
```

`salt.modules.puppet.noop(*args, **kwargs)`

Execute a puppet noop run and return a dict with the stderr, stdout, return code, etc. Usage is the same as for `puppet.run`.

CLI Example:

```bash
salt '*' puppet.noop
salt '*' puppet.noop tags=basefiles::edit,apache::server
salt '*' puppet.noop debug
salt '*' puppet.noop apply /a/b/manifest.pp modulepath=/a/b/modules tags=basefiles::edit,apache::server
```

`salt.modules.puppet.plugin_sync()`

Runs a plugin sync between the puppet master and agent

CLI Example: .. code-block:: bash

```bash
salt '*' puppet.plugin_sync
```

`salt.modules.puppet.run(*args, **kwargs)`

Execute a puppet run and return a dict with the stderr, stdout, return code, etc. The first positional argument given is checked as a subcommand. Following positional arguments should be ordered with arguments required by the subcommand first, followed by non-keyword arguments. Tags are specified by a tag keyword and comma separated list of values. -- http://docs.puppetlabs.com/puppet/latest/reference/lang_tags.html

CLI Examples:

```bash
salt '*' puppet.run
salt '*' puppet.run tags=basefiles::edit,apache::server
salt '*' puppet.run agent onetime no-daemonize no-usecacheonfailure no-splay ignorecache
salt '*' puppet.run debug
salt '*' puppet.run apply /a/b/manifest.pp modulepath=/a/b/modules tags=basefiles::edit,apache::server
```
salt.modules.puppet.status()
    New in version 2014.7.0.
    Display puppet agent status
    CLI Example:
        salt '*' puppet.status

salt.modules.puppet.summary()
    New in version 2014.7.0.
    Show a summary of the last puppet agent run
    CLI Example:
        salt '*' puppet.summary

31.16.200  salt.modules.pushover_notify

Module for sending messages to Pushover (https://www.pushover.net)
New in version Boron.

    configuration  This module can be used by either passing an api key and version directly or by specifying
                    both in a configuration profile in the salt master/minion config.
                    For example:
                        pushover:
                            token: abAHuZyCLtdH8P4zhmFZmgUHUsv1ei8

salt.modules.pushover_notify.post_message(user=None, device=None, message=None, title=None, priority=None, expire=None, retry=None, sound=None, api_version=1, token=None)

    Send a message to a Pushover user or group.

    Parameters
    • user -- The user or group to send to, must be key of user or group not email address.
    • message -- The message to send to the PushOver user or group.
    • title -- Specify who the message is from.
    • priority -- The priority of the message, defaults to 0.
    • expire -- The message should expire after N number of seconds.
    • retry -- The number of times the message should be retried.
    • sound -- The sound to associate with the message.
    • api_version -- The PushOver API version, if not specified in the configuration.
    • token -- The PushOver token, if not specified in the configuration.

    Returns  Boolean if message was sent successfully.

    CLI Example:
**salt.modules.pw_group**

Manage groups on FreeBSD

salt.modules.pw_group.add(name, gid=None, **kwargs)

Add the specified group

CLI Example:

```
salt '*' group.add foo 3456
```

salt.modules.pw_group.chgid(name, gid)

Change the gid for a named group

CLI Example:

```
salt '*' group.chgid foo 4376
```

salt.modules.pw_group.delete(name)

Remove the named group

CLI Example:

```
salt '*' group.delete foo
```

salt.modules.pw_group.getent(refresh=False)

Return info on all groups

CLI Example:

```
salt '*' group.getent
```

salt.modules.pw_group.info(name)

Return information about a group

CLI Example:

```
salt '*' group.info foo
```

salt.modules.pw_group.members(name, members_list)

Replaces members of the group with a provided list.

New in version 2015.5.4.

CLI Example:

```
salt '*' group.members foo `user1,user2,user3,...`
```

Replaces a membership list for a local group `foo`. foo:x:1234:user1,user2,user3,...

**salt.modules.pw_user**

Manage users with the useradd command
salt.modules.pw_user.add(name, uid=None, gid=None, groups=None, home=None, shell=None, unique=True, fullname='', roomnumber='', workphone='', homephone='', createhome=True, **kwargs)

Add a user to the minion

CLI Example:
```
salt '*' user.add name <uid> <gid> <groups> <home> <shell>
```

salt.modules.pw_user.chfullname(name, fullname)

Change the user's Full Name

CLI Example:
```
salt '*' user.chfullname foo "Foo Bar"
```

salt.modules.pw_user.chgid(name, gid)

Change the default group of the user

CLI Example:
```
salt '*' user.chgid foo 4376
```

salt.modules.pw_user.chgroups(name, groups, append=False)

Change the groups this user belongs to, add append to append the specified groups

CLI Example:
```
salt '*' user.chgroups foo wheel,root True
```

salt.modules.pw_user.chhome(name, home, persist=False)

Change the home directory of the user, pass true for persist to copy files to the new home dir

CLI Example:
```
salt '*' user.chhome foo /home/users/foo True
```

salt.modules.pw_user.chhomephone(name, homephone)

Change the user's Home Phone

CLI Example:
```
salt '*' user.chhomephone foo "7735551234"
```

salt.modules.pw_user.chroomnumber(name, roomnumber)

Change the user's Room Number

CLI Example:
```
salt '*' user.chroomnumber foo 123
```

salt.modules.pw_user.chshell(name, shell)

Change the default shell of the user

CLI Example:
```
salt '*' user.chshell foo /bin/zsh
```

salt.modules.pw_user.chuid(name, uid)

Change the uid for a named user

CLI Example:
salt '*' user.chuid foo 4376

salt.modules.pw_user.\texttt{chworkphone}(name, workphone)
Change the user's Work Phone
CLI Example:

    salt '*' user.chworkphone foo "7735550123"

salt.modules.pw_user.\texttt{delete}(name, remove=False, force=False)
Remove a user from the minion
CLI Example:

    salt '*' user.delete name remove=True force=True

salt.modules.pw_user.\texttt{getent}(refresh=False)
Return the list of all info for all users
CLI Example:

    salt '*' user.getent

salt.modules.pw_user.\texttt{info}(name)
Return user information
CLI Example:

    salt '*' user.info root

salt.modules.pw_user.\texttt{list_groups}(name)
Return a list of groups the named user belongs to
CLI Example:

    salt '*' user.list_groups foo

salt.modules.pw_user.\texttt{list_users}()
Return a list of all users
CLI Example:

    salt '*' user.list_users

salt.modules.pw_user.\texttt{rename}(name, new_name)
Change the username for a named user
CLI Example:

    salt '*' user.rename name new_name

\section*{31.16.203 \texttt{salt.modules.pyenv}}

Manage python installations with \texttt{pyenv}.

New in version v2014.04.

\begin{verbatim}
salt.modules.pyenv.default(\texttt{python=None, runas=None})
Returns or sets the currently defined default python.

    python=\texttt{None} The version to set as the default. Should match one of the versions listed by \texttt{pyenv.versions}. Leave blank to return the current default.
\end{verbatim}
CLI Example:
```
salt '*' pyenv.default
salt '*' pyenv.default 2.0.0-p0
```

`salt.modules.pyenv.do(cmdline=None, runas=None)`
Execute a python command with pyenv's shims from the user or the system.

CLI Example:
```
salt '*' pyenv.do 'gem list bundler'
salt '*' pyenv.do 'gem list bundler' deploy
```

`salt.modules.pyenv.do_with_python python, cmdline, runas=None)`
Execute a python command with pyenv's shims using a specific python version.

CLI Example:
```
salt '*' pyenv.do_with_python 2.0.0-p0 'gem list bundler'
salt '*' pyenv.do_with_python 2.0.0-p0 'gem list bundler' deploy
```

`salt.modules.pyenv.install(runas=None, path=None)`
Install pyenv systemwide

CLI Example:
```
salt '*' pyenv.install
```

`salt.modules.pyenv.install_python python, runas=None)`
Install a python implementation.

CLI Example:
```
salt '*' pyenv.install_python 2.0.0-p0
```

`salt.modules.pyenv.is_installed(runas=None)`
Check if pyenv is installed.

CLI Example:
```
salt '*' pyenv.is_installed
```

`salt.modules.pyenv.list(runas=None)`
List the installable versions of python.

CLI Example:
```
salt '*' pyenv.list
```

`salt.modules.pyenv.rehash(runas=None)`
Run pyenv rehash to update the installed shims.

CLI Example:
```
salt '*' pyenv.rehash
```

`salt.modules.pyenv.uninstall_python python, runas=None)`
Uninstall a python implementation.

CLI Example:
```
salt '*' pyenv.uninstall_python 2.0.0-p0
```
CLI Example:

```
salt '*' pyenv.uninstall_python 2.0.0-p0
```

```python
salt.modules.pyenv.update(runas=None, path=None)
```

Updates the current versions of pyenv and python-Build

CLI Example:

```
salt '*' pyenv.update
```

```python
salt.modules.pyenv.versions(runas=None)
```

List the installed versions of python.

CLI Example:

```
salt '*' pyenv.versions
```

### 31.16.204 `salt.modules.qemu_img`

**Qemu-img Command Wrapper**

The qemu img command is wrapped for specific functions

```python
depends qemu-img
```

```python
salt.modules.qemu_img.make_image(location, size, fmt)
```

Create a blank virtual machine image file of the specified size in megabytes. The image can be created in any format supported by qemu

CLI Example:

```
salt '*' qemu_img.make_image /tmp/image.qcow 2048 qcow2
salt '*' qemu_img.make_image /tmp/image.raw 10240 raw
```

### 31.16.205 `salt.modules.qemu_nbd`

**Qemu Command Wrapper**

The qemu system comes with powerful tools, such as qemu-img and qemu-nbd which are used here to build up kvm images.

```python
salt.modules.qemu_nbd.clear(mnt)
```

Pass in the mnt dict returned from nbd_mount to unmount and disconnect the image from nbd. If all of the partitions are unmounted return an empty dict, otherwise return a dict containing the still mounted partitions

CLI Example:

```
salt '*' qemu_nbd.clear '{"/mnt/foo": "/dev/nbd0p1"}"
```

```python
salt.modules.qemu_nbd.connect(image)
```

Activate nbd for an image file.

CLI Example:

```
salt '*' qemu_nbd.connect /tmp/image.raw
```
salt.modules.qemu_nbd.init(image)
    Mount the named image via qemu-nbd and return the mounted roots
    CLI Example:
    ```
salt '*' qemu_nbd.init /srv/image.qcow2
    ```

salt.modules.qemu_nbd.mount(nbd)
    Pass in the nbd connection device location, mount all partitions and return a dict of mount points
    CLI Example:
    ```
salt '*' qemu_nbd.mount /dev/nbd0
    ```

31.16.206 salt.modules.quota

Module for managing quotas on POSIX-like systems.
salt.modules.quota.get_mode(device)
    Report whether the quota system for this device is on or off
    CLI Example:
    ```
salt '*' quota.get_mode
    ```

salt.modules.quota.off(device)
    Turns off the quota system
    CLI Example:
    ```
salt '*' quota.off
    ```

salt.modules.quota.on(device)
    Turns on the quota system
    CLI Example:
    ```
salt '*' quota.on
    ```

salt.modules.quota.report(mount)
    Report on quotas for a specific volume
    CLI Example:
    ```
salt '*' quota.report /media/data
    ```

salt.modules.quota.set(device, **kwargs)
    Calls out to setquota, for a specific user or group
    CLI Example:
    ```
salt '*' quota.set /media/data user=larry block-soft-limit=1048576
group=painters file-hard-limit=1000
    ```

salt.modules.quota.stats()
    Runs the quotastats command, and returns the parsed output
    CLI Example:
    ```
salt '*' quota.stats
    ```
salt.modules.quota.warn()
    Runs the warnquota command, to send warning emails to users who are over their quota limit.

    CLI Example:
    
    ```
    salt '*' quota.warn
    ```

31.16.207 salt.modules.rabbitmq

Module to provide RabbitMQ compatibility to Salt. Todo: A lot, need to add cluster support, logging, and minion configuration data.

salt.modules.rabbitmq.add_user(name, password=None, runas=None)
    Add a rabbitMQ user via rabbitmqctl user_add <user> <password>

    CLI Example:
    
    ```
    salt '*' rabbitmq.add_user rabbit_user password
    ```

salt.modules.rabbitmq.add_vhost(vhost, runas=None)
    Adds a vhost via rabbitmqctl add_vhost.

    CLI Example:
    
    ```
    salt '*' rabbitmq add_vhost '<vhost_name>'
    ```

salt.modules.rabbitmq.change_password(name, password, runas=None)
    Changes a user's password.

    CLI Example:
    
    ```
    salt '*' rabbitmq.change_password rabbit_user password
    ```

salt.modules.rabbitmq.clear_password(name, runas=None)
    Removes a user's password.

    CLI Example:
    
    ```
    salt '*' rabbitmq.clear_password rabbit_user
    ```

salt.modules.rabbitmq.cluster_status(runas=None)
    return rabbitmq cluster_status

    CLI Example:
    
    ```
    salt '*' rabbitmq.cluster_status
    ```

salt.modules.rabbitmq.delete_policy(vhost, name, runas=None)
    Delete a policy based on rabbitmqctl clear_policy.

    CLI Example:
    
    ```
    salt '*' rabbitmq.delete_policy / HA'
    ```

salt.modules.rabbitmq.delete_user(name, runas=None)
    Deletes a user via rabbitmqctl delete_user.

    CLI Example:
salt '!' rabbitmq.delete_user rabbit_user

salt.modules.rabbitmq.delete_vhost(vhost, runas=None)
    Deletes a vhost rabbitmqctl delete_vhost.
    CLI Example:
    
    salt '!' rabbitmq.delete_vhost '<vhost_name>'

salt.modules.rabbitmq.disable_plugin(name, runas=None)
    Disable a RabbitMQ plugin via the rabbitmq-plugins command.
    CLI Example:
    
    salt '!' rabbitmq.disable_plugin foo

salt.modules.rabbitmq.enable_plugin(name, runas=None)
    Enable a RabbitMQ plugin via the rabbitmq-plugins command.
    CLI Example:
    
    salt '!' rabbitmq.enable_plugin foo

salt.modules.rabbitmq.force_reset(runas=None)
    Forcefully Return a RabbitMQ node to its virgin state
    CLI Example:
    
    salt '!' rabbitmq.force_reset

salt.modules.rabbitmq.join_cluster(host, user='rabbit', ram_node=None, runas=None)
    Join a rabbit cluster
    CLI Example:
    
    salt '!' rabbitmq.join_cluster 'rabbit.example.com' 'rabbit'

salt.modules.rabbitmq.list_permissions(vhost, runas=None)
    Lists permissions for vhost via rabbitmqctl list_permissions
    CLI Example:
    
    salt '!' rabbitmq.list_permissions '/myvhost'

salt.modules.rabbitmq.list_policies(vhost='/', runas=None)
    Return a dictionary of policies nested by vhost and name based on the data returned from rabbitmqctl list_policies.
    Reference: http://www.rabbitmq.com/ha.html
    CLI Example:
    
    salt '!' rabbitmq.list_policies'

salt.modules.rabbitmq.list_queues(runas=None, **kwargs)
    Returns queue details of the / virtual host
    CLI Example:
    
    salt '!' rabbitmq.list_queues messages consumers
salt.modules.rabbitmq.list_queues_vhost

Returns queue details of specified virtual host. This command will consider first parameter as the vhost name and rest will be treated as queue info item. For getting details on vhost /, use list_queues instead.

CLI Example:

```
salt '*' rabbitmq.list_queues messages consumers
```

salt.modules.rabbitmq.list_user_permissions

List permissions for a user via rabbitmqctl list_user_permissions

CLI Example:

```
salt '*' rabbitmq.list_user_permissions 'user'.
```

salt.modules.rabbitmq.list_users

Return a list of users based off of rabbitmqctl user_list.

CLI Example:

```
salt '*' rabbitmq.list_users
```

salt.modules.rabbitmq.list_vhosts

Return a list of vhost based on rabbitmqctl list_vhosts.

CLI Example:

```
salt '*' rabbitmq.list_vhosts
```

salt.modules.rabbitmq.plugin_is_enabled

Return whether the plugin is enabled.

CLI Example:

```
salt '*' rabbitmq.plugin_is_enabled foo
```

salt.modules.rabbitmq.policy_exists

Return whether the policy exists based on rabbitmqctl list_policies.

Reference: http://www.rabbitmq.com/ha.html

CLI Example:

```
salt '*' rabbitmq.policy_exists / HA
```

salt.modules.rabbitmq.reset

Return a RabbitMQ node to its virgin state

CLI Example:

```
salt '*' rabbitmq.reset
```

salt.modules.rabbitmq.set_permissions

Sets permissions for vhost via rabbitmqctl set_permissions

CLI Example:

```
salt '*' rabbitmq.set_permissions 'myvhost' 'myuser'
```

salt.modules.rabbitmq.set_policy

Set a policy based on rabbitmqctl set_policy.

Reference: http://www.rabbitmq.com/ha.html
CLI Example:
```
salt '*' rabbitmq.set_policy / HA '*' '{"ha-mode":"all"}'
```

```
salt.modules.rabbitmq.set_user_tags(name, tags, runas=None)
   Add user tags via rabbitmqctl set_user_tags
   CLI Example:
   salt '*' rabbitmq.set_user_tags 'myadmin' 'administrator'
```

```
salt.modules.rabbitmq.start_app(runas=None)
   Start the RabbitMQ application.
   CLI Example:
   salt '*' rabbitmq.start_app
```

```
salt.modules.rabbitmq.status(runas=None)
   return rabbitmq status
   CLI Example:
   salt '*' rabbitmq.status
```

```
salt.modules.rabbitmq.stop_app(runas=None)
   Stops the RabbitMQ application, leaving the Erlang node running.
   CLI Example:
   salt '*' rabbitmq.stop_app
```

```
salt.modules.rabbitmq.user_exists(name, runas=None)
   Return whether the user exists based on rabbitmqctl list_users.
   CLI Example:
   salt '*' rabbitmq.user_exists rabbit_user
```

```
salt.modules.rabbitmq.vhost_exists(name, runas=None)
   Return whether the vhost exists based on rabbitmqctl list_vhosts.
   CLI Example:
   salt '*' rabbitmq.vhost_exists rabbit_host
```

### 31.16.208 salt.modules.raet_publish

Publish a command from a minion to a target

```
salt.modules.raet_publish.full_data(tgt, fun, arg=None, expr_form='glob', returner='`, timeout=5)
   Return the full data about the publication, this is invoked in the same way as the publish function
   CLI Example:
   salt system.example.com publish.full_data '*' cmd.run 'ls -la /tmp'
```

Attention
If you need to pass a value to a function argument and that value contains an equal sign, you must include the argument name. For example:

```bash
salt '*' publish.full_data test.kwarg arg='cheese=spam'
```

salt.modules.raet_publish.publish(tgt, fun, arg=None, expr_form='glob', returner='.', timeout=5)

Publish a command from the minion out to other minions.

Publications need to be enabled on the Salt master and the minion needs to have permission to publish the command. The Salt master will also prevent a recursive publication loop, this means that a minion cannot command another minion to command another minion as that would create an infinite command loop.

The expr_form argument is used to pass a target other than a glob into the execution, the available options are:

- glob
- pcre
- grain
- grain_pcre
- pillar
- pillar_pcre
- ipcidr
- range
- compound

The arguments sent to the minion publish function are separated with commas. This means that for a minion executing a command with multiple args it will look like this:

```bash
salt system.example.com publish.publish '*' user.add 'foo,1020,1020'
salt system.example.com publish.publish 'os:Fedora' network.interfaces '' grain
```

CLI Example:

```bash
salt system.example.com publish.publish '*' cmd.run 'ls -la /tmp'
```

Attention

If you need to pass a value to a function argument and that value contains an equal sign, you must include the argument name. For example:

```bash
salt '*' publish.publish test.kwarg arg='cheese=spam'
```

salt.modules.raet_publish.runner(fun, arg=None, timeout=5)

Execute a runner on the master and return the data from the runner function

CLI Example:

```bash
salt publish.runner manage.down
```

31.16.209 salt.modules.rallydev

Support for RallyDev
New in version 2015.8.0.

Requires a username and a password in /etc/salt/minion:

```python
salt.modules.rallydev.list_items(name)
```
List items of a particular type

CLI Examples:

```bash
salt myminion rallydev.list_<item name>s
salt myminion rallydev.list_users
salt myminion rallydev.list_artifacts
```

```python
salt.modules.rallydev.list_users()
```
List the users

CLI Example:

```bash
salt myminion rallydev.list_users
```

```python
salt.modules.rallydev.query_item(name, query_string, order='Rank')
```
Query a type of record for one or more items. Requires a valid query string. See https://rally1.rallydev.com/slm/doc/webservice/introduction.jsp for information on query syntax.

CLI Example:

```bash
salt myminion rallydev.query_<item name> <query string> [order]
salt myminion rallydev.query_task '(Name contains github)'
salt myminion rallydev.query_task '(Name contains reactor)' Rank
```

```python
salt.modules.rallydev.query_user(query_string, order='UserName')
```
Update a user

CLI Example:

```bash
salt myminion rallydev.query_user '(Name contains Jo)'
```

```python
salt.modules.rallydev.show_artifact(id_)
```
Show an artifact

CLI Example:

```bash
salt myminion rallydev.show_artifact <artifact id>
```

```python
salt.modules.rallydev.show_item(name, id_)
```
Show an item

CLI Example:

```bash
salt myminion rallydev.show_<item name> <item id>
```

```python
salt.modules.rallydev.show_user(id_)
```
Show a user

CLI Example:

```bash
salt myminion rallydev.show_user <user id>
```

```python
salt.modules.rallydev.update_item(name, id_, field=None, value=None, postdata=None)
```
Update an item. Either a field and a value, or a chunk of POST data, may be used, but not both.

CLI Example:
31.16.210 salt.modules.random_org

Module for retrieving random information from Random.org

New in version 2015.5.0.

classification This module can be used by either passing an api key and version directly or by specifying both in a configuration profile in the salt master/minion config.

For example:

```
random_org:
  api_key: 7be1402d-5719-5bd3-a306-3def9f135da5
  api_version: 1
```

```
salt.modules.random_org.generateBlobs(api_key=None, api_version=None, **kwargs)
```

List all Slack users.

**Parameters**

- `api_key` -- The Random.org api key.
- `api_version` -- The Random.org api version.
- `format` -- Specifies the format in which the blobs will be returned. Values allowed are base64 and hex.

**Returns** The user list.

CLI Example:

```
salt '*' get_integers number=5 min=1 max=6
salt '*' get_integers number=5 min=1 max=6
```

```
salt.modules.random_org.generateDecimalFractions(api_key=None, api_version=None, **kwargs)
```

Generates true random decimal fractions

**Parameters**

- `api_key` -- The Random.org api key.
- `api_version` -- The Random.org api version.
- `number` -- How many random decimal fractions you need. Must be within the [1,1e4] range.
- `decimalPlaces` -- The number of decimal places to use. Must be within the [1,20] range.
- `replacement` -- Specifies whether the random numbers should be picked with replacement. The default (true) will cause the numbers to be picked with replacement, i.e., the
resulting numbers may contain duplicate values (like a series of dice rolls). If you want the
numbers picked to be unique (like raffle tickets drawn from a container), set this value to
false.

Returns  A list of decimal fraction

CLI Example:

```
salt '*' random_org.generateDecimalFractions number=10 decimalPlaces=4
```

```
salt '*' random_org.generateDecimalFractions number=10 decimalPlaces=4 replacement=True
```

```
salt.modules.random_org.generateGaussians(api_key=None, api_version=None, **kwargs)
```

This method generates true random numbers from a Gaussian distribution (also known as a normal distribu-
tion).

Parameters

- `api_key` -- The Random.org api key.
- `api_version` -- The Random.org api version.
- `number` -- How many random numbers you need. Must be within the [1,1e4] range.
- `mean` -- The distribution’s mean. Must be within the [-1e6,1e6] range.
- `standardDeviation` -- The distribution’s standard deviation. Must be within the 
[-1e6,1e6] range.
- `significantDigits` -- The number of significant digits to use. Must be within the 

Returns  The user list.

CLI Example:

```
salt '*' random_org.generateGaussians number=10 mean=0.0 standardDeviation=1.0 significantDigits=8
```

```
salt.modules.random_org.generateIntegers(api_key=None, api_version=None, **kwargs)
```

Generate random integers

Parameters

- `api_key` -- The Random.org api key.
- `api_version` -- The Random.org api version.
- `number` -- The number of integers to generate
- `minimum` -- The lower boundary for the range from which the random numbers will be
picked. Must be within the [-1e9,1e9] range.
- `maximum` -- The upper boundary for the range from which the random numbers will be
picked. Must be within the [-1e9,1e9] range.
- `replacement` -- Specifies whether the random numbers should be picked with replace-
ment. The default (true) will cause the numbers to be picked with replacement, i.e., the
resulting numbers may contain duplicate values (like a series of dice rolls). If you want the
numbers picked to be unique (like raffle tickets drawn from a container), set this value to
false.
- `base` -- Specifies the base that will be used to display the numbers. Values allowed are 2,
8, 10 and 16. This affects the JSON types and formatting of the resulting data as discussed
below.
Returns  A list of integers.

CLI Example:

```
salt '*' random_org.generateIntegers number=5 minimum=1 maximum=6
salt '*' random_org.generateIntegers number=5 minimum=2 maximum=255 base=2
```

```
salt.modules.random_org.generateStrings (api_key=None, api_version=None, **kwargs)
  Generate random strings.

Parameters

- **api_key** -- The Random.org api key.
- **api_version** -- The Random.org api version.
- **number** -- The number of strings to generate.
- **length** -- The length of each string. Must be within the [1,20] range. All strings will be of the same length
- **characters** -- A string that contains the set of characters that are allowed to occur in the random strings. The maximum number of characters is 80.
- **replacement** -- Specifies whether the random strings should be picked with replacement. The default (true) will cause the strings to be picked with replacement, i.e., the resulting list of strings may contain duplicates (like a series of dice rolls). If you want the strings to be unique (like raffle tickets drawn from a container), set this value to false.

Returns  A list of strings.

CLI Example:

```
salt '*' random_org.generateStrings number=5 length=8 characters='abcdefghijklmnopqrstuvwxyz'
salt '*' random_org.generateStrings number=10 length=16 characters='abcdefghijklmnopqrstuvwxyz'
```

salt.modules.random_org.generateUUIDs (api_key=None, api_version=None, **kwargs)
  Generate a list of random UUIDs

Parameters

- **api_key** -- The Random.org api key.
- **api_version** -- The Random.org api version.
- **number** -- How many random UUIDs you need. Must be within the [1,1e3] range.

Returns  A list of UUIDs

CLI Example:

```
salt '*' random_org.generateUUIDs number=5
```

salt.modules.random_org.getUsage (api_key=None, api_version=None)

Show current usages statistics

Parameters

- **api_key** -- The Random.org api key.
- **api_version** -- The Random.org api version.

Returns  The current usage statistics.
CLI Example:

```
salt '*' random_org.getUsage

salt '*' random_org.getUsage api_key=peWcBiMOS9HrZG15peWcBiMOS9HrZG15 api_version=1
```

### 31.16.211 salt.modules.rbenv

Manage ruby installations with rbenv. Rbenv is supported on Linux and Mac OS X. Rbenv doesn't work on Windows (and isn't really necessary on Windows as there is no system Ruby on Windows). On Windows, the RubyInstaller and/or Pik are both good alternatives to work with multiple versions of Ruby on the same box.

http://misheska.com/blog/2013/06/15/using-rbenv-to-manage-multiple-versions-of-ruby/

New in version 0.16.0.

**salt.modules.rbenv.default**(ruby=None, runas=None)

Returns or sets the currently defined default ruby.

- `ruby=None` The version to set as the default. Should match one of the versions listed by `rbenv.versions`.
  
  Leave blank to return the current default.

**CLI Example:**

```
salt '*' rbenv.default
salt '*' rbenv.default 2.0.0-p0
```

**salt.modules.rbenv.do**(cmdline=None, runas=None)

Execute a ruby command with rbenv's shims from the user or the system.

**CLI Example:**

```
salt '*' rbenv.do 'gem list bundler'
salt '*' rbenv.do 'gem list bundler' deploy
```

**salt.modules.rbenv.do_with_ruby**(ruby, cmdline, runas=None)

Execute a ruby command with rbenv's shims using a specific ruby version.

**CLI Example:**

```
salt '*' rbenv.do_with_ruby 2.0.0-p0 'gem list bundler'
salt '*' rbenv.do_with_ruby 2.0.0-p0 'gem list bundler' deploy
```

**salt.modules.rbenv.install**(runas=None, path=None)

Install Rbenv systemwide

**CLI Example:**

```
salt '*' rbenv.install
```

**salt.modules.rbenv.install_ruby**(ruby, runas=None)

Install a ruby implementation.

- `ruby` The version of Ruby to install, should match one of the versions listed by `rbenv.list`

Additional environment variables can be configured in pillar / grains / master:

- `rbenv`
  
  `build_env` : 'CONFIGURE_OPTS="--no-tcmalloc" CFLAGS="-fno-tree-dce"'

**CLI Example:**
salt 'x' rbenv.install_ruby 2.0.0-p0

salt.modules.rbenv.is_installed\(runas=None\)
Check if Rbenv is installed.
CLI Example:

```
salt '*' rbenv.is_installed
```

salt.modules.rbenv.list\(runas=None\)
List the installable versions of ruby.
CLI Example:

```
salt '*' rbenv.list
```

salt.modules.rbenv.rehash\(runas=None\)
Run rbenv rehash to update the installed shims.
CLI Example:

```
salt '*' rbenv.rehash
```

salt.modules.rbenv.uninstall_ruby\(ruby, runas=None\)
Uninstall a ruby implementation.
\- ruby The version of ruby to uninstall. Should match one of the versions listed by \code{rbenv.versions}
CLI Example:

```
salt '*' rbenv.uninstall_ruby 2.0.0-p0
```

salt.modules.rbenv.update\(runas=None, path=None\)
Updates the current versions of Rbenv and Ruby-Build
CLI Example:

```
salt '*' rbenv.update
```

salt.modules.rbenv.versions\(runas=None\)
List the installed versions of ruby.
CLI Example:

```
salt '*' rbenv.versions
```

### 31.16.212 salt.modules.rdp

Manage RDP Service on Windows servers

salt.modules.rdp.disable()
Disable RDP the service on the server
CLI Example:

```
salt '*' rdp.disable
```

salt.modules.rdp.enable()
Enable RDP the service on the server
CLI Example:
salt '*' rdp.enable

salt.modules.rdp.status()
    Show if rdp is enabled on the server
    CLI Example:
        salt '*' rdp.status

31.16.213 salt.modules.redis

Module to provide redis functionality to Salt
New in version 2014.7.0.

configuration This module requires the redis python module and uses the following defaults which may be overridden in the minion configuration:

    redis.host: 'localhost'
    redis.port: 6379
    redis.db: 0
    redis.password: None

salt.modules.redismod.bgrewriteaof(host=None, port=None, db=None, password=None)
    Asynchronously rewrite the append-only file
    CLI Example:
        salt '*' redis.bgrewriteaof

salt.modules.redismod.bgsave(host=None, port=None, db=None, password=None)
    Asynchronously save the dataset to disk
    CLI Example:
        salt '*' redis.bgsave

salt.modules.redismod.config_get(pattern='*', host=None, port=None, db=None, password=None)
    Get redis server configuration values
    CLI Example:
        salt '*' redis.config_get
        salt '*' redis.config_get port

salt.modules.redismod.config_set(name, value, host=None, port=None, db=None, password=None)
    Set redis server configuration values
    CLI Example:
        salt '*' redis.config_set masterauth luv_kittens

salt.modules.redismod.dbsize(host=None, port=None, db=None, password=None)
    Return the number of keys in the selected database
    CLI Example:
        salt '*' redis.dbsize
salt.modules.redismod.delete(*keys, **connection_args)
    Deletes the keys from redis, returns number of keys deleted
    CLI Example:
    salt '*' redis.delete foo

salt.modules.redismod.exists(key, host=None, port=None, db=None, password=None)
    Return true if the key exists in redis
    CLI Example:
    salt '*' redis.exists foo

salt.modules.redismod.expire(key, seconds, host=None, port=None, db=None, password=None)
    Set a keys time to live in seconds
    CLI Example:
    salt '*' redis.expire foo 300

salt.modules.redismod.expireat(key, timestamp, host=None, port=None, db=None, password=None)
    Set a keys expire at given UNIX time
    CLI Example:
    salt '*' redis.expireat foo 1400000000

salt.modules.redismod.flushall(host=None, port=None, db=None, password=None)
    Remove all keys from all databases
    CLI Example:
    salt '*' redis.flushall

salt.modules.redismod.flushdb(host=None, port=None, db=None, password=None)
    Remove all keys from the selected database
    CLI Example:
    salt '*' redis.flushdb

salt.modules.redismod.get_key(key, host=None, port=None, db=None, password=None)
    Get redis key value
    CLI Example:
    salt '*' redis.get_key foo

salt.modules.redismod.hget(key, field, host=None, port=None, db=None, password=None)
    Get specific field value from a redis hash, returns dict
    CLI Example:
    salt '*' redis.hget foo_hash bar_field

salt.modules.redismod.hgetall(key, host=None, port=None, db=None, password=None)
    Get all fields and values from a redis hash, returns dict
    CLI Example:
```python
salt '*' redis.hgetall foo_hash

salt.modules.redismod.info(host=None, port=None, db=None, password=None)
    Get information and statistics about the server
    CLI Example:
    salt '*' redis.info

salt.modules.redismod.key_type(key, host=None, port=None, db=None, password=None)
    Get redis key type
    CLI Example:
    salt '*' redis.type foo

salt.modules.redismod.keys(pattern='*', host=None, port=None, db=None, password=None)
    Get redis keys, supports glob style patterns
    CLI Example:
    salt '*' redis.keys
    salt '*' redis.keys test*

salt.modules.redismod.lrange(key, start, stop, host=None, port=None, db=None, password=None)
    Get a range of values from a list in Redis
    CLI Example:
    salt '*' redis.lrange foo_list 0 10

salt.modules.redismod.ping(host=None, port=None, db=None, password=None)
    Ping the server, returns False on connection errors
    CLI Example:
    salt '*' redis.ping

salt.modules.redismod.save(host=None, port=None, db=None, password=None)
    Synchronously save the dataset to disk
    CLI Example:
    salt '*' redis.save

salt.modules.redismod.set_key(key, value, host=None, port=None, db=None, password=None)
    Set redis key value
    CLI Example:
```

31.16. Full list of builtin execution modules
Synchronously save the dataset to disk and then shut down the server

CLI Example:

    salt '*' redis.shutdown

Make the server a slave of another instance, or promote it as master

CLI Example:

    # Become slave of redis-n01.example.com:6379
    salt '*' redis.slaveof redis-n01.example.com 6379
    salt '*' redis.slaveof redis-n01.example.com
    # Become master
    salt '*' redis.slaveof

Get members in a Redis set

CLI Example:

    salt '*' redis.smembers foo_set

Return the current server UNIX time in seconds

CLI Example:

    salt '*' redis.time

Get the length of a sorted set in Redis

CLI Example:

    salt '*' redis.zcard foo_sorted

Get a range of values from a sorted set in Redis by index

CLI Example:

    salt '*' redis.zrange foo_sorted 0 10

31.16.214 salt.modules.reg

Manage the Windows registry

The read_key and set_key functions will be updated in Boron to reflect proper registry usage. The registry has three main components. Hives, Keys, and Values.
Hives

Hives are the main sections of the registry and all begin with the word HKEY. - HKEY_LOCAL_MACHINE - HKEY_CURRENT_USER - HKEY_USER

Keys

Keys are the folders in the registry. Keys can have many nested subkeys. Keys can have a value assigned to them under the (Default)

Values or Entries

Values/Entries are name/data pairs. There can be many values in a key. The (Default) value corresponds to the Key, the rest are their own value pairs.

depends

• winreg Python module

class salt.modules.reg.Registry

Delay `\_winreg` usage until this module is used

salt.modules.reg.create_key(hkey, path, key=None, value=None, reflection=True)

**Important**: The name of this function is misleading and will be changed to reflect proper usage in the Boron release of Salt. The path option will be removed and the key will be the actual key. See the following issue:

https://github.com/saltstack/salt/issues/25618

In order to not break existing state files this function will call the set_value function if key is passed. Key will be passed as the value name. If key is not passed, this function will return the default value for the key.

In the Boron release path will be removed and key will be the path. You will not pass value.

Create a registry key

CLI Example:

```
salt '*' reg.create_key HKEY_CURRENT_USER 'SOFTWARE\Salt' 'version' '0.97'
```

salt.modules.reg.delete_key(hkey, path, key=None, reflection=True, force=False)

**Important**: The name of this function is misleading and will be changed to reflect proper usage in the Boron release of Salt. The path option will be removed and the key will be the actual key. See the following issue:

https://github.com/saltstack/salt/issues/25618

In order to not break existing state files this function will call the delete_value function if a key is passed. Key will be passed as the value name. If key is not passed, this function will return the default value for the key.

In the Boron release path will be removed and key will be the path. reflection will also be removed.

Delete a registry key

CLI Example:
salt 'salt' reg.delete_key HKEY_CURRENT_USER 'SOFTWARE\Salt'

Parameters

- **hkey** *(str)* -- (will be changed to hive) The name of the hive. Can be one of the following - HKEY_LOCAL_MACHINE or HKLM - HKEY_CURRENT_USER or HKCU - HKEY_USER or HKU

- **path** *(str)* -- (will be changed to key) The key (looks like a path) to remove.

- **key** *(str)* -- (used incorrectly) Will be removed in Boron

- **reflection** *(bool)* -- A boolean value indicating that the value should also be removed from the Wow6432Node portion of the registry. Only applies to 64 bit Windows. This setting is ignored for 32 bit Windows.

  Only applies to delete value. If the key parameter is passed, this function calls delete_value instead. Will be changed in Boron.

- **force** *(bool)* -- A boolean value indicating that all subkeys should be removed as well. If this is set to False (default) and there are subkeys, the delete_key function will fail.

Returns Returns True if successful, False if not If force=True, the results of delete_key_recursive are returned.

Return type bool

salt.modules.reg.delete_key_recursive(hive, key)

New in version 2015.5.4.

Delete a registry key to include all subkeys.

Parameters

- **hive** -- The name of the hive. Can be one of the following - HKEY_LOCAL_MACHINE or HKLM - HKEY_CURRENT_USER or HKCU - HKEY_USER or HKU

- **key** -- The key to remove (looks like a path)

Returns A dictionary listing the keys that deleted successfully as well as those that failed to delete.

Return type dict

The following example will remove salt and all its subkeys from the SOFTWARE key in HKEY_LOCAL_MACHINE:

CLI Example:

```
salt '*' reg.delete_key_recursive HKLM SOFTWARE\salt
```

salt.modules.reg.delete_value(hive, key, vname=None, reflection=True)

Delete a registry value entry or the default value for a key.

Parameters

- **hive** *(str)* -- The name of the hive. Can be one of the following - HKEY_LOCAL_MACHINE or HKLM - HKEY_CURRENT_USER or HKCU - HKEY_USER or HKU

- **key** *(str)* -- The key (looks like a path) to the value name.

- **vname** *(str)* -- The value name. These are the individual name/data pairs under the key. If not passed, the key (Default) value will be deleted.
- **reflection** *(bool)* -- A boolean value indicating that the value should also be set in the Wow6432Node portion of the registry. Only applies to 64 bit Windows. This setting is ignored for 32 bit Windows.

**Returns**  Returns True if successful, False if not

**Return type**  bool

CLI Example:

```bash
salt '*' reg.delete_value HKEY_CURRENT_USER 'SOFTWARE\Salt' 'version'
```

salt.modules.reg.read_key *(hkey, path, key=None)*

**Important:** The name of this function is misleading and will be changed to reflect proper usage in the Boron release of Salt. The path option will be removed and the key will be the actual key. See the following issue:

https://github.com/saltstack/salt/issues/25618

In order to not break existing state files this function will call the read_value function if a key is passed. Key will be passed as the value name. If key is not passed, this function will return the default value for the key.

In the Boron release this function will be removed in favor of read_value.

Read registry key value

Returns the first unnamed value (Default) as a string. Returns none if first unnamed value is empty. Returns False if key not found.

CLI Example:

```bash
salt '*' reg.read_key HKEY_LOCAL_MACHINE 'SOFTWARE\Salt' 'version'
```

salt.modules.reg.read_value *(hive, key, vname=None)*

Reads a registry value entry or the default value for a key.

**Parameters**

- **hive** *(str)* -- The name of the hive. Can be one of the following - HKEY_LOCAL_MACHINE or HKLM - HKEY_CURRENT_USER or HKCU - HKEY_USER or HKU

- **key** *(str)* -- The key (looks like a path) to the value name.

- **vname** *(str)* -- The value name. These are the individual name/data pairs under the key. If not passed, the key (Default) value will be returned

**Returns**

A dictionary containing the passed settings as well as the value_data if successful. If unsuccessful, sets success to False

If vname is not passed: - Returns the first unnamed value (Default) as a string. - Returns none if first unnamed value is empty. - Returns False if key not found.

**Return type**  dict

CLI Example:

```bash
salt '*' reg.read_value HKEY_LOCAL_MACHINE 'SOFTWARE\Salt' 'version'
```
salt.modules.reg.set_key(hkey, path, value, key=None, vtype='REG_DWORD', reflection=True)

**Important:** The name of this function is misleading and will be changed to reflect proper usage in the Boron release of Salt. The path option will be removed and the key will be the actual key. See the following issue:

https://github.com/saltstack/salt/issues/25618

In order to not break existing state files this function will call the set_value function if a key is passed. Key will be passed as the value name. If key is not passed, this function will return the default value for the key. In the Boron release this function will be removed in favor of set_value.

Set a registry key

vtype: [http://docs.python.org/2/library/_winreg.html#value-types](http://docs.python.org/2/library/_winreg.html#value-types)

CLI Example:

```python
salt '*' reg.set_key HKEY_CURRENT_USER 'SOFTWARE\Salt' 'version' '0.97' REG_DWORD
```

salt.modules.reg.set_value(hive, key, vname=None, vdata=None, vtype='REG_SZ', reflection=True)

Sets a registry value entry or the default value for a key.

**Parameters**

- **hive (str)** -- The name of the hive. Can be one of the following - HKEY_LOCAL_MACHINE or HKLM - HKEY_CURRENT_USER or HKCU - HKEY_USER or HKU
- **key (str)** -- The key (looks like a path) to the value name.
- **vname (str)** -- The value name. These are the individual name/data pairs under the key. If not passed, the key (Default) value will be set.
- **vdata (str)** -- The value data to be set.
- **vtype (str)** -- The value type. Can be one of the following: - REG_BINARY - REG_DWORD - REG_EXPAND_SZ - REG_MULTI_SZ - REG_SZ
- **reflection (bool)** -- A boolean value indicating that the value should also be set in the Wow6432Node portion of the registry. Only applies to 64 bit Windows. This setting is ignored for 32 bit Windows.

**Returns** Returns True if successful, False if not

**Return type** bool

CLI Example:

```python
salt '*' reg.set_value HKEY_LOCAL_MACHINE 'SOFTWARE\Salt' 'version' '2015.5.2'
```

31.16.215 salt.modules.rest_package

Service support for the REST example

salt.modules.rest_package.install(name=None, refresh=False, fromrepo=None, pkgs=None, **kwargs)

salt.modules.rest_package.installed(name, version=None, refresh=False, fromrepo=None, skip_verify=False, pkgs=None, sources=None, **kwargs)

salt.modules.rest_package.list_pkgs(versions_as_list=False, **kwargs)
salt.modules.rest_package.remove(name=None, pkgs=None, **kwargs)

salt.modules.rest_package.version(*names, **kwargs)
    Returns a string representing the package version or an empty string if not installed. If more than one package name is specified, a dict of name/version pairs is returned.

    CLI Example:
    salt '*' pkg.version <package name>
    salt '***' pkg.version <package1> <package2> <package3> ...

31.16.216 salt.modules.rest_sample

Module for interfacing to the REST example
pre-pre-ALPHA QUALITY code.

salt.modules.rest_sample.grains_refresh()
    Refresh the cache.

salt.modules.rest_sample.ping()

31.16.217 salt.modules.rest_service

Service support for the REST example

salt.modules.rest_service.list()
    List services.

    CLI Example:
    salt '*' rest_service.list <service name>

salt.modules.rest_service.restart(name)
    Restart the named service

    CLI Example:
    salt '*' rest_service.restart <service name>

salt.modules.rest_service.start(name)
    Start the specified service

    CLI Example:
    salt '*' rest_service.start <service name>

salt.modules.rest_service.status(name)
    Return the status for a service, returns a bool whether the service is running.

    CLI Example:
    salt '*' rest_service.status <service name>

salt.modules.rest_service.stop(name)
    Stop the specified service

    CLI Example:
```bash
salt '*' rest_service.stop <service name>
```

### 31.16.218 salt.modules.ret

Module to integrate with the returner system and retrieve data sent to a salt returner.

```python
salt.modules.ret.get_fun(retuner, fun)
```

Return info about last time fun was called on each minion.

CLI Example:

```bash
salt '*' ret.get_fun mysql network.interfaces
```

```python
salt.modules.ret.get_jid(retuner, jid)
```

Return the information for a specified job id.

CLI Example:

```bash
salt '*' ret.get_jid redis 20421104181954700505
```

```python
salt.modules.ret.get_jids(retuner)
```

Return a list of all job ids.

CLI Example:

```bash
salt '*' ret.get_jids mysql
```

```python
salt.modules.ret.get_minions(retuner)
```

Return a list of all minions.

CLI Example:

```bash
salt '*' ret.get_minions mysql
```

### 31.16.219 salt.modules.rh_ip

The networking module for RHEL/Fedora based distros.

```python
salt.modules.rh_ip.apply_network_settings(**settings)
```

Apply global network configuration.

CLI Example:

```bash
salt '*' ip.apply_network_settings
```

```python
salt.modules.rh_ip.build_bond(iface, **settings)
```

Create a bond script in /etc/modprobe.d with the passed settings and load the bonding kernel module.

CLI Example:

```bash
salt '*' ip.build_bond bond0 mode=balance-alb
```

```python
salt.modules.rh_ip.build_interface(iface, iface_type, enabled, **settings)
```

Build an interfacescript for a network interface.

CLI Example:

```bash
salt '*' ip.build_interface eth0 eth <settings>
```
salt.modules.rh_ip.build_network_settings(**settings)
    Build the global network script.
    CLI Example:
    ```
    salt '*' ip.build_network_settings <settings>
    ```

salt.modules.rh_ip.build_routes(iface, **settings)
    Build a route script for a network interface.
    CLI Example:
    ```
    salt '*' ip.build_routes eth0 <settings>
    ```

salt.modules.rh_ip.down(iface, iface_type)
    Shutdown a network interface
    CLI Example:
    ```
    salt '*' ip.down eth0
    ```

salt.modules.rh_ip.get_bond(iface)
    Return the content of a bond script
    CLI Example:
    ```
    salt '*' ip.get_bond bond0
    ```

salt.modules.rh_ip.get_interface(iface)
    Return the contents of an interface script
    CLI Example:
    ```
    salt '*' ip.get_interface eth0
    ```

salt.modules.rh_ip.get_network_settings()
    Return the contents of the global network script.
    CLI Example:
    ```
    salt '*' ip.get_network_settings
    ```

salt.modules.rh_ip.get_routes(iface)
    Return the contents of the interface routes script.
    CLI Example:
    ```
    salt '*' ip.get_routes eth0
    ```

salt.modules.rh_ip.up(iface, iface_type)
    Start up a network interface
    CLI Example:
    ```
    salt '*' ip.up eth0
    ```

31.16.220 salt.modules.rh_service

Service support for RHEL-based systems, including support for both upstart and sysvinit
salt.modules.rh_service.available(name, limit="")
Return True if the named service is available. Use the limit param to restrict results to services of that type.

CLI Examples:
```
salt '*' service.available sshd
salt '*' service.available sshd limit=upstart
salt '*' service.available sshd limit=sysvinit
```

salt.modules.rh_service.disable(name, **kwargs)
Disable the named service to start at boot

CLI Example:
```
salt '*' service.disable <service name>
```

salt.modules.rh_service.disabled(name)
Check to see if the named service is disabled to start on boot

CLI Example:
```
salt '*' service.disabled <service name>
```

salt.modules.rh_service.enable(name, **kwargs)
Enable the named service to start at boot

CLI Example:
```
salt '*' service.enable <service name>
```

salt.modules.rh_service.enabled(name, **kwargs)
Check to see if the named service is enabled to start on boot

CLI Example:
```
salt '*' service.enabled <service name>
```

salt.modules.rh_service.get_all(limit="")
Return all installed services. Use the limit param to restrict results to services of that type.

CLI Example:
```
salt '*' service.get_all
salt '*' service.get_all limit=upstart
salt '*' service.get_all limit=sysvinit
```

salt.modules.rh_service.get_disabled(limit="")
Return the disabled services. Use the limit param to restrict results to services of that type.

CLI Example:
```
salt '*' service.get_disabled
salt '*' service.get_disabled limit=upstart
salt '*' service.get_disabled limit=sysvinit
```

salt.modules.rh_service.get_enabled(limit="")
Return the enabled services. Use the limit param to restrict results to services of that type.

CLI Examples:
```
salt '*' service.get_enabled
salt '*' service.get_enabled limit=upstart
salt '*' service.get_enabled limit=sysvinit
```
salt.modules.rh_service.missing(name, limit='')
The inverse of service.available. Return True if the named service is not available. Use the limit param to restrict results to services of that type.

CLI Examples:
```
salt '*' service.missing sshd
salt '*' service.missing sshd limit=upstart
salt '*' service.missing sshd limit=sysvinit
```

salt.modules.rh_service.reload(name)
Reload the named service

CLI Example:
```
salt '*' service.reload <service name>
```

salt.modules.rh_service.restart(name)
Restart the named service

CLI Example:
```
salt '*' service.restart <service name>
```

salt.modules.rh_service.start(name)
Start the specified service

CLI Example:
```
salt '*' service.start <service name>
```

salt.modules.rh_service.status(name, sig=None)
Return the status for a service, returns a bool whether the service is running.

CLI Example:
```
salt '*' service.status <service name>
```

salt.modules.rh_service.stop(name)
Stop the specified service

CLI Example:
```
salt '*' service.stop <service name>
```

31.16.221 salt.modules.riak

Riak Salt Module

salt.modules.riak.cluster_commit()
Commit Cluster Changes

Changed in version 2015.8.0.

CLI Example:
```
salt '*' riak.cluster_commit
```

salt.modules.riak.cluster_join(username, hostname)
Join a Riak cluster

Changed in version 2015.8.0.
CLI Example:

```bash
salt '*' riak.cluster_join <user> <host>
```

*username* - The riak username to join the cluster
*hostname* - The riak hostname you are connecting to

**salt.modules.riak.cluster_leave**(*username*, *hostname*)
Leave a Riak cluster
New in version 2015.8.0.

CLI Example:

```bash
salt '*' riak.cluster_leave <username> <host>
```

*username* - The riak username to join the cluster
*hostname* - The riak hostname you are connecting to

**salt.modules.riak.cluster_plan()**
Review Cluster Plan
Changed in version 2015.8.0.

CLI Example:

```bash
salt '*' riak.cluster_plan
```

**salt.modules.riak.member_status()**
Get cluster member status
Changed in version 2015.8.0.

CLI Example:

```bash
salt '*' riak.member_status
```

**salt.modules.riak.services()**
List available services on a node
New in version 2015.8.0.

CLI Example:

```bash
salt '*' riak.services
```

**salt.modules.riak.start()**
Start Riak

CLI Example:

```bash
salt '*' riak.start
```

**salt.modules.riak.status()**
Current node status
New in version 2015.8.0.

CLI Example:

```bash
salt '*' riak.status
```

**salt.modules.riak.stop()**
Stop Riak
Changed in version 2015.8.0.

CLI Example:
salt '*' riak.stop

salt.modules.riak.test()
    Runs a test of a few standard Riak operations
    New in version 2015.8.0.
    CLI Example:

        salt '*' riak.test

31.16.222 salt.modules.rpm

Support for rpm

salt.modules.rpm.bin_pkg_info(path, saltenv='base')
    New in version 2015.8.0.
    Parses RPM metadata and returns a dictionary of information about the package (name, version, etc.).
    path Path to the file. Can either be an absolute path to a file on the minion, or a salt fileserver URL (e.g. salt://path/to/file.rpm). If a salt fileserver URL is passed, the file will be cached to the minion so that it can be examined.
    saltenv [base] Salt fileserver environment from which to retrieve the package. Ignored if path is a local file path on the minion.
    CLI Example:

        salt '*' lowpkg.bin_pkg_info /root/salt-2015.5.1-2.el7.noarch.rpm
        salt '*' lowpkg.bin_pkg_info salt://salt-2015.5.1-2.el7.noarch.rpm

salt.modules.rpm.diff(package, path)
    Return a formatted diff between current file and original in a package. NOTE: this function includes all files (configuration and not), but does not work on binary content.
    Parameters
    • package -- The name of the package
    • path -- Full path to the installed file
    Returns Difference or empty string. For binary files only a notification.
    CLI example:

        salt '*' lowpkg.diff apache2 /etc/apache2/httpd.conf

salt.modules.rpm.file_dict(*packages)
    List the files that belong to a package, sorted by group. Not specifying any packages will return a list of _every_ file on the system's rpm database (not generally recommended).
    CLI Examples:

        salt '*' lowpkg.file_dict httpd
        salt '*' lowpkg.file_dict httpd postfix
        salt '*' lowpkg.file_dict

salt.modules.rpm.file_list(*packages)
    List the files that belong to a package. Not specifying any packages will return a list of _every_ file on the system's rpm database (not generally recommended).
CLI Examples:

```bash
salt '*' lowpkg.file_list httpd
salt '*' lowpkg.file_list httpd postfix
salt '*' lowpkg.file_list
```

salt.modules.rpm.info('packages')

Return a detailed package(s) summary information. If no packages specified, all packages will be returned.

**Parameters** packages --

**Returns**

**CLI example:**

```bash
salt '*' lowpkg.info apache2 bash
```

salt.modules.rpm.list_pkgs('packages')

List the packages currently installed in a dict:

```yaml
{'<package_name>': '<version>'
```

**CLI Example:**

```bash
salt '*' lowpkg.list_pkgs
```

salt.modules.rpm.modified('packages', 'flags')

List the modified files that belong to a package. Not specifying any packages will return a list of all modified files on the system's RPM database.

New in version 2015.5.0.

**CLI examples:**

```bash
salt '*' lowpkg.modified httpd
salt '*' lowpkg.modified httpd postfix
salt '*' lowpkg.modified
```

salt.modules.rpm.owner('paths')

Return the name of the package that owns the file. Multiple file paths can be passed. If a single path is passed, a string will be returned, and if multiple paths are passed, a dictionary of file/package name pairs will be returned.

If the file is not owned by a package, or is not present on the minion, then an empty string will be returned for that path.

**CLI Examples:**

```bash
salt '*' lowpkg.owner /usr/bin/apachectl
salt '*' lowpkg.owner /usr/bin/apachectl /etc/httpd/conf/httpd.conf
```

salt.modules.rpm.verify('package', **kwargs)

Runs an rpm -Va on a system, and returns the results in a dict

Files with an attribute of config, doc, ghost, license or readme in the package header can be ignored using the ignore_types keyword argument

**CLI Example:**

```bash
salt '*' lowpkg.verify
salt '*' lowpkg.verify httpd
```
31.16.223 salt.modules.rpmbuild

RPM Package builder system

New in version 2015.8.0.

This system allows for all of the components to build rpms safely in chrooted environments. This also provides a function to generate yum repositories

This module implements the pkgbuild interface

```
salt.modules.rpmbuild.build(runas, tgt, dest_dir, spec, sources, deps, env, template, saltenv='base')
```

Given the package destination directory, the spec file source and package sources, use mock to safely build the rpm defined in the spec file

CLI Example:
```
```

This example command should build the libnacl package for rhel 7 using user mock and place it in /var/www/html/ on the minion

```
salt.modules.rpmbuild.make_repo(repodir, keyid=None, env=None)
```

Given the repodir, create a yum repository out of the rpms therein

CLI Example:
```
salt '*' pkgbuild.make_repo /var/www/html/
```

```
salt.modules.rpmbuild.make_src_pkg(dest_dir, spec, sources, env=None, template=None, saltenv='base')
```

Create a source rpm from the given spec file and sources

CLI Example:
```
```

This example command should build the libnacl SOURCE package and place it in /var/www/html/ on the minion

31.16.224 salt.modules.rsync

Wrapper for rsync

New in version 2014.1.0.

This data can also be passed into pillar. Options passed into opts will overwrite options passed into pillar.

```
salt.modules.rsync.config(confile='/etc/rsyncd.conf')
```

Return rsync config

CLI Example:
```
salt '*' rsync.config
```
salt.modules.rsync.rsync(src, dst, delete=False, force=False, update=False, passwordfile=None, exclude=None, excludefrom=None)

Rsync files from src to dst

CLI Example:

salt '*' rsync.rsync {src} {dst} {delete=True} {update=True} {passwordfile=/etc/pass.crt} {exclude=xx} {excludefrom=/xx.ini}

salt.modules.rsync.version()

Return rsync version

CLI Example:

salt '*' rsync.version

31.16.225 salt.modules.runit

runit service module

This module is compatible with the service states, so it can be used to maintain services using the provider argument:

myservice:
  service:
    - running
    - provider: runit

Note that the enabled argument is not available with this provider.

salt.modules.runit.available(name)

Returns True if the specified service is available, otherwise returns False.

CLI Example:

salt '*' runit.available foo

salt.modules.runit.full_restart(name)

Calls runit.restart() function

CLI Example:

salt '*' runit.full_restart <service name>

salt.modules.runit.get_all()

Return a list of all available services

CLI Example:

salt '*' runit.get_all

salt.modules.runit.missing(name)

The inverse of runit.available. Returns True if the specified service is not available, otherwise returns False.

CLI Example:

salt '*' runit.missing foo

salt.modules.runit.reload(name)

Send a HUP to service via runit
**CLI Example:**

```
salt '*' runit.reload <service name>
```

### salt.modules.runit.restart(name)

Restart service via runit. This will stop/start service

**CLI Example:**

```
salt '*' runit.restart <service name>
```

### salt.modules.runit.start(name)

Starts service via runit

**CLI Example:**

```
salt '*' runit.start <service name>
```

### salt.modules.runit.status(name, sig=None)

Return the status for a service via runit, return pid if running

**CLI Example:**

```
salt '*' runit.status <service name>
```

### salt.modules.runit.stop(name)

Stops service via runit

**CLI Example:**

```
salt '*' runit.stop <service name>
```

### salt.modules.runit.term(name)

Send a TERM to service via runit

**CLI Example:**

```
salt '*' runit.term <service name>
```

---

**31.16.226 salt.modules.rvm**

Manage ruby installations and gemsets with RVM, the Ruby Version Manager.

### salt.modules.rvm.do(ruby, command, runas=None, cwd=None)

Execute a command in an RVM controlled environment.

- **ruby:** The ruby to use.
- **command:** The command to execute.
- **runas** [None] The user to run rvm as.
- **cwd** [None] The current working directory.

**CLI Example:**

```
salt '*' rvm.do 2.0.0 <command>
```

### salt.modules.rvm.gemset_copy(source, destination, runas=None)

Copy all gems from one gemset to another.

- **source** The name of the gemset to copy, complete with ruby version.
- **destination** The destination gemset.

---

**31.16. Full list of builtin execution modules**

1201
runas [None] The user to run rvm as.

CLI Example:

```bash
salt '*' rvm.gemset_copy foobar bazquo
```

```bash
salt.modules.rvm.gemset_create(ruby, gemset, runas=None)
```

Creates a gemset.

ruby The ruby version to create the gemset for.

gemset The name of the gemset to create.

runas [None] The user to run rvm as.

CLI Example:

```bash
salt '*' rvm.gemset_create 2.0.0 foobar
```

```bash
salt.modules.rvm.gemset_delete(ruby, gemset, runas=None)
```

Deletes a gemset.

ruby The ruby version the gemset belongs to.

gemset The gemset to delete.

runas [None] The user to run rvm as.

CLI Example:

```bash
salt '*' rvm.gemset_delete 2.0.0 foobar
```

```bash
salt.modules.rvm.gemset_empty(ruby, gemset, runas=None)
```

Remove all gems from a gemset.

ruby The ruby version the gemset belongs to.

gemset The gemset to empty.

runas [None] The user to run rvm as.

CLI Example:

```bash
salt '*' rvm.gemset_empty 2.0.0 foobar
```

```bash
salt.modules.rvm.gemset_list(ruby='default', runas=None)
```

List all gemsets for the given ruby.

ruby [default] The ruby version to list the gemsets for

runas [None] The user to run rvm as.

CLI Example:

```bash
salt '*' rvm.gemset_list
```

```bash
salt.modules.rvm.gemset_list_all(runas=None)
```

List all gemsets for all installed rubies.

Note that you must have set a default ruby before this can work.

runas [None] The user to run rvm as.

CLI Example:
salt '*' rvm.gemset_list_all

salt.modules.rvm.get(version='stable', runas=None)
    Update RVM.
    version  [stable] Which version of RVM to install, e.g. stable or head.
    ruby     The version of ruby to reinstall.
    CLI Example:
    salt '*' rvm.get

salt.modules.rvm.install(runas=None)
    Install RVM system wide.
    CLI Example:
    salt '*' rvm.install

salt.modules.rvm.install_ruby(ruby, runas=None)
    Install a ruby implementation.
    ruby     The version of ruby to install.
    runas    [None] The user to run rvm as.
    CLI Example:
    salt '*' rvm.install_ruby 1.9.3-p385

salt.modules.rvm.is_installed(runas=None)
    Check if RVM is installed.
    CLI Example:
    salt '*' rvm.is_installed

salt.modules.rvm.list(runas=None)
    List all rvm installed rubies.
    runas    [None] The user to run rvm as.
    CLI Example:
    salt '*' rvm.list

salt.modules.rvm.reinstall_ruby(ruby, runas=None)
    Reinstall a ruby implementation.
    ruby     The version of ruby to reinstall.
    runas    [None] The user to run rvm as.
    CLI Example:
    salt '*' rvm.reinstall_ruby 1.9.3-p385

salt.modules.rvm.rubygems(ruby, version, runas=None)
    Installs a specific rubygems version in the given ruby.
    ruby     The ruby to install rubygems for.
    version   The version of rubygems to install or `remove` to use the version that ships with 1.9
runas [None] The user to run rvm as.

CLI Example:
```
salt '*' rvm.rubygems 2.0.0 1.8.24
```

salt.modules.rvm.set_default(ruby, runas=None)
Set the default ruby.

- ruby The version of ruby to make the default.
- runas [None] The user to run rvm as.

CLI Example:
```
salt '*' rvm.set_default 2.0.0
```

salt.modules.rvm.wrapper(ruby_string, wrapper_prefix, runas=None, *binaries)
Install RVM wrapper scripts.

- ruby_string Ruby/gemset to install wrappers for.
- wrapper_prefix What to prepend to the name of the generated wrapper binaries.
- runas [None] The user to run rvm as.
- binaries [None] The names of the binaries to create wrappers for. When nothing is given, wrappers for ruby, gem, rake, irb, rdoc, ri and testrb are generated.

CLI Example:
```
salt '*' rvm.wrapper <ruby_string> <wrapper_prefix>
```

31.16.227 salt.modules.s3

Connection module for Amazon S3

**configuration** This module accepts explicit s3 credentials but can also utilize IAM roles assigned to the instance through Instance Profiles. Dynamic credentials are then automatically obtained from AWS API and no further configuration is necessary. More Information available at:

If IAM roles are not used you need to specify them either in a pillar or in the minion's config file:

```
s3.keyid: GKTADJGHEIQSXMKKRBJ08H
s3.key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
```

A service_url may also be specified in the configuration:

```
s3.service_url: s3.amazonaws.com
```

If a service_url is not specified, the default is s3.amazonaws.com. This may appear in various documentation as an "endpoint". A comprehensive list for Amazon S3 may be found at:

$$http://docs.aws.amazon.com/general/latest/gr/rande.html#s3_region$$

The service_url will form the basis for the final endpoint that is used to query the service.

SSL verification may also be turned off in the configuration:

```
s3.verify_ssl: False
```
This is required if using S3 bucket names that contain a period, as these will not match Amazon's S3 wildcard certificates. Certificate verification is enabled by default.

AWS region may be specified in the configuration:

s3.location: eu-central-1

Default is us-east-1.

This module should be usable to query other S3-like services, such as Eucalyptus.

depends  requests

salt.modules.s3.delete(bucket, path=None, action=None, key=None, keyid=None, service_url=None, verify_ssl=None, location=None)

Delete a bucket, or delete an object from a bucket.

CLI Example to delete a bucket:

```bash
salt myminion s3.delete mybucket
```

CLI Example to delete an object from a bucket:

```bash
salt myminion s3.delete mybucket remoteobject
```

salt.modules.s3.get(bucket=None, path=None, return_bin=False, action=None, local_file=None, key=None, keyid=None, service_url=None, verify_ssl=None, location=None)

List the contents of a bucket, or return an object from a bucket. Set return_bin to True in order to retrieve an object wholesale. Otherwise, Salt will attempt to parse an XML response.

CLI Example to list buckets:

```bash
salt myminion s3.get
```

CLI Example to list the contents of a bucket:

```bash
salt myminion s3.get mybucket
```

CLI Example to return the binary contents of an object:

```bash
salt myminion s3.get mybucket myfile.png return_bin=True
```

CLI Example to save the binary contents of an object to a local file:

```bash
salt myminion s3.get mybucket myfile.png local_file=/tmp/myfile.png
```

It is also possible to perform an action on a bucket. Currently, S3 supports the following actions:

- acl
- cors
- lifecycle
- policy
- location
- logging
- notification
- tagging
- versions
- requestPayment
- versioning
- website

To perform an action on a bucket:
```
salt myminion s3.get mybucket myfile.png  action=acl

salt.modules.s3.head(bucket, path=None, key=None, keyid=None, service_url=None, verify_ssl=None, location=None)

    Return the metadata for a bucket, or an object in a bucket.

    CLI Examples:
    salt myminion s3.head mybucket
    salt myminion s3.head mybucket myfile.png

salt.modules.s3.put(bucket, path=None, return_bin=False, action=None, local_file=None, key=None, keyid=None, service_url=None, verify_ssl=None, location=None)

    Create a new bucket, or upload an object to a bucket.

    CLI Example to create a bucket:
    salt myminion s3.put mybucket

    CLI Example to upload an object to a bucket:
    salt myminion s3.put mybucket remotepath local_file=/path/to/file
```

### 31.16.228 salt.modules.saltcloudmod

Control a salt cloud system

```
salt.modules.saltcloudmod.create(name, profile)

    Create the named vm

    CLI Example:
    salt <minion-id> saltcloud.create webserver rackspace_centos_512
```

### 31.16.229 salt.modules.saltutil

The Saltutil module is used to manage the state of the salt minion itself. It is used to manage minion modules as well as automate updates to the salt minion.

```
depends
    
    * esky Python module for update functionality

salt.modules.saltutil.clear_cache()

    Forcibly removes all caches on a minion.

    New in version 2014.7.0.

    WARNING: The safest way to clear a minion cache is by first stopping the minion and then deleting the cache files before restarting it.

    CLI Example:
    salt '*' saltutil.clear_cache

salt.modules.saltutil.cmd(tgt, fun, arg=(), timeout=None, expr_form='glob', ret='*', kwarg=None, ssh=False, **kwargs)

    Assuming this minion is a master, execute a salt command

    CLI Example:
```
salt '*' saltutil.cmd

salt.modules.saltutil.cmd_iter(tgt, fun, arg=(), timeout=None, expr_form='glob', ret='`, kwarg=None, ssh=False, **kwargs)

Assuming this minion is a master, execute a salt command

CLI Example:

salt '*' saltutil.cmd_iter

salt.modules.saltutil.find_cached_job(jid)

Return the data for a specific cached job id

CLI Example:

salt '*' saltutil.find_cached_job <job id>

salt.modules.saltutil.find_job(jid)

Return the data for a specific job id

CLI Example:

salt '*' saltutil.find_job <job id>

salt.modules.saltutil.is_running(fun)

If the named function is running return the data associated with it/them. The argument can be a glob

CLI Example:

salt '*' saltutil.is_running state.highstate

salt.modules.saltutil.kill_job(jid)

Sends a kill signal (SIGKILL 9) to the named salt job's process

CLI Example:

salt '*' saltutil.kill_job <job id>

salt.modules.saltutil.mmodule(saltenv, fun, *args, **kwargs)

Loads minion modules from an environment so that they can be used in pillars for that environment

CLI Example:

salt '*' saltutil.mmodule base test.ping

salt.modules.saltutil.refresh_beacons()

Signal the minion to refresh the beacons.

CLI Example:

salt '*' saltutil.refresh_beacons

salt.modules.saltutil.refresh_modules(async=True)

Signal the minion to refresh the module and grain data

The default is to refresh module asynchronously. To block until the module refresh is complete, set the 'async' flag to False.

CLI Example:

salt '*' saltutil.refresh_modules
salt.modules.saltutil.refreshpillar()
   Signal the minion to refresh the pillar data.
   CLI Example:
   salt '*' saltutil.refreshpillar

salt.modules.saltutil.regen_keys()
   Used to regenerate the minion keys.
   CLI Example:
   salt '*' saltutil.regen_keys

salt.modules.saltutil.revoke_auth(preserve_minion_cache=False)
   The minion sends a request to the master to revoke its own key. Note that the minion session will be revoked and
   the minion may not be able to return the result of this command back to the master.
   If the 'preserve_minion_cache' flag is set to True, the master cache for this minion will not be removed.
   CLI Example:
   salt '*' saltutil.revoke_auth

salt.modules.saltutil.runner(_fun, **kwargs)
   Execute a runner module (this function must be run on the master)
   New in version 2014.7.
   name The name of the function to run
   kwargs Any keyword arguments to pass to the runner function
   CLI Example:
   salt '*' saltutil.runner jobs.list_jobs

salt.modules.saltutil.running()
   Return the data on all running salt processes on the minion
   CLI Example:
   salt '*' saltutil.running

salt.modules.saltutil.signal_job(jid, sig)
   Sends a signal to the named salt job's process
   CLI Example:
   salt '*' saltutil.signal_job <job id> 15

salt.modules.saltutil.sync_all(saltenv=None, refresh=True)
   Sync down all of the dynamic modules from the file server for a specific environment
   refresh [True] Also refresh the execution modules available to the minion.
   Important: If this function is executed using a module.run state, the SLS file will not have access to newly
   synced execution modules unless a refresh argument is added to the state, like so:
   load_my_custom_module:
      module.run:
         - name: saltutil.sync_all
         - refresh: True
See [here](#) for a more detailed explanation of why this is necessary.

**CLI Example:**

```bash
salt '*' saltutil.sync_all
```

**salt.modules.saltutil.sync_beacons** *(saltenv=None, refresh=True)*

Sync the beacons from the _beacons directory on the salt master file server. This function is environment aware, pass the desired environment to grab the contents of the _beacons directory, base is the default environment.

New in version 2015.5.1.

**CLI Example:**

```bash
salt '*' saltutil.sync_beacons
```

**salt.modules.saltutil.sync_grains** *(saltenv=None, refresh=True)*

Sync the grains from the _grains directory on the salt master file server. This function is environment aware, pass the desired environment to grab the contents of the _grains directory, base is the default environment.

**CLI Example:**

```bash
salt '*' saltutil.sync_grains
```

**salt.modules.saltutil.sync_log_handlers** *(saltenv=None, refresh=True)*

New in version 2015.8.0.

Sync utility source files from the _log_handlers directory on the salt master file server. This function is environment aware, pass the desired environment to grab the contents of the _log_handlers directory, base is the default environment.

**CLI Example:**

```bash
salt '*' saltutil.sync_log_handlers
```

**salt.modules.saltutil.sync_modules** *(saltenv=None, refresh=True)*

Sync the modules from the _modules directory on the salt master file server. This function is environment aware, pass the desired environment to grab the contents of the _modules directory, base is the default environment.

**Important:** If this function is executed using a `module.run` state, the SLS file will not have access to newly synced execution modules unless a `refresh` argument is added to the state, like so:

```yaml
load_my_custom_module:
  module.run:
    - name: saltutil.sync_modules
      refresh: True
```

See [here](#) for a more detailed explanation of why this is necessary.

New in version 2015.5.1.

**CLI Example:**

```bash
salt '*' saltutil.sync_modules
```

**salt.modules.saltutil.sync_outputters** *(saltenv=None, refresh=True)*

Sync the outputters from the _outputters directory on the salt master file server. This function is environment
aware, pass the desired environment to grab the contents of the _outputters directory, base is the default environment.

CLI Example:
```
salt '*' saltutil.sync_outputters
```

```
salt.modules.saltutil.sync_renderers(saltenv=None, refresh=True)
Sync the renderers from the _renderers directory on the salt master file server. This function is environment aware, pass the desired environment to grab the contents of the _renderers directory, base is the default environment.

CLI Example:
```
salt '*' saltutil.sync_renderers
```

```
salt.modules.saltutil.sync_returners(saltenv=None, refresh=True)
Sync the returners from the _returners directory on the salt master file server. This function is environment aware, pass the desired environment to grab the contents of the _returners directory, base is the default environment.

CLI Example:
```
salt '*' saltutil.sync_returners
```

```
salt.modules.saltutil.sync_states(saltenv=None, refresh=True)
Sync the states from the _states directory on the salt master file server. This function is environment aware, pass the desired environment to grab the contents of the _states directory, base is the default environment.

CLI Example:
```
salt '*' saltutil.sync_states
```

```
salt.modules.saltutil.sync_utils(saltenv=None, refresh=True)
Sync utility source files from the _utils directory on the salt master file server. This function is environment aware, pass the desired environment to grab the contents of the _utils directory, base is the default environment.

CLI Example:
```
salt '*' saltutil.sync_utils
```

```
salt.modules.saltutil.term_job(jid)
Sends a termination signal (SIGTERM 15) to the named salt job’s process

CLI Example:
```
salt '*' saltutil.term_job <job id>
```

```
salt.modules.saltutil.update(version=None)
Update the salt minion from the URL defined in opts['update_url'] SaltStack, Inc provides the latest builds here: update_url: https://repo.saltstack.com/windows/

Be aware that as of 2014-8-11 there's a bug in esky such that only the latest version available in the update_url can be downloaded and installed.

This feature requires the minion to be running a bdist_esky build.

The version number is optional and will default to the most recent version available at opts['update_url'].

Returns details about the transaction upon completion.

CLI Example:
```
salt 'saltutil.update
salt 'saltutil.update 0.10.3

salt.modules.saltutil.wheel(_fun, **kwargs)
  Execute a wheel module (this function must be run on the master)
  New in version 2014.7.
  name  The name of the function to run
  kwargs  Any keyword arguments to pass to the wheel function
  CLI Example:
  salt 'saltutil.wheel key.accept match=jerry

31.16.230  salt.modules.schedule

Module for managing the Salt schedule on a minion
New in version 2014.7.0.
salt.modules.schedule.add(name, **kwargs)
  Add a job to the schedule
  CLI Example:
  
  salt 'schedule.add job1 function='test.ping' seconds=3600
  # If function have some arguments, use job_args
  salt 'schedule.add job2 function='cmd.run' job_args=['date >> /tmp/date.log']' seconds=60

salt.modules.schedule.build_schedule_item(name, **kwargs)
  Build a schedule job
  CLI Example:
  salt 'schedule.build_schedule_item job1 function='test.ping' seconds=3600

salt.modules.schedule.copy(name, target, **kwargs)
  Copy scheduled job to another minion or minions.
  CLI Example:
  salt 'schedule.copy jobname target

salt.modules.schedule.delete(name, **kwargs)
  Delete a job from the minion's schedule
  CLI Example:
  salt 'schedule.delete job1

salt.modules.schedule.disable(**kwargs)
  Disable all scheduled jobs on the minion
  CLI Example:
  salt 'schedule.disable

31.16.  Full list of builtin execution modules
salt.modules.schedule.disable_job(name, **kwargs)
    Disable a job in the minion's schedule
    CLI Example:
    ```
salt '*' schedule.disable_job job1
    ```

salt.modules.schedule.enable(**kwargs)
    Enable all scheduled jobs on the minion
    CLI Example:
    ```
salt '*' schedule.enable
    ```

salt.modules.schedule.enable_job(name, **kwargs)
    Enable a job in the minion's schedule
    CLI Example:
    ```
salt '*' schedule.enable_job job1
    ```

salt.modules.schedule.is_enabled(name)
    List a Job only if its enabled
    New in version 2015.5.3.
    CLI Example:
    ```
salt '*' schedule.is_enabled name=job_name
    ```

salt.modules.schedule.list(show_all=False, where=None, return_yaml=True)
    List the jobs currently scheduled on the minion
    CLI Example:
    ```
salt '*' schedule.list
salt '*' schedule.list show_all=True
    ```

salt.modules.schedule.modify(name, **kwargs)
    Modify an existing job in the schedule
    CLI Example:
    ```
salt '*' schedule.modify job1 function='test.ping' seconds=3600
    ```

salt.modules.schedule.move(name, target, **kwargs)
    Move scheduled job to another minion or minions.
    CLI Example:
    ```
salt '*' schedule.move jobname target
    ```

salt.modules.schedule.purge(**kwargs)
    Purge all the jobs currently scheduled on the minion
    CLI Example:
    ```
salt '*' schedule.purge
    ```

salt.modules.schedule.reload()
    Reload saved scheduled jobs on the minion
CLI Example:
```bash
salt '*' schedule.reload
```

`salt.modules.schedule.run_job(name, force=False)`
Run a scheduled job on the minion immediately

CLI Example:
```bash
salt '*' schedule.run_job job1
salt '*' schedule.run_job job1 force=True
```
Force the job to run even if it is disabled.

`salt.modules.schedule.save(**kwargs)`
Save all scheduled jobs on the minion

CLI Example:
```bash
salt '*' schedule.save
```

### 31.16.231 `salt.modules.scsi`

SCSI administration module

`salt.modules.scsi.ls()`
List SCSI devices, with details

CLI Example:
```bash
salt '*' scsi.ls
```

`salt.modules.scsi.rescan_all(host)`
List scsi devices

CLI Example:
```bash
salt '*' scsi.rescan_all(0)
```

### 31.16.232 `salt.modules.sdb`

Module for Manipulating Data via the Salt DB API

`salt.modules.sdb.get(uri)`
Get a value from a db, using a uri in the form of sdb://<profile>/<key>. If the uri provided does not start with sdb://, then it will be returned as-is.

CLI Example:
```bash
salt '*' sdb.get sdb://mymemcached/foo
```

`salt.modules.sdb.set(uri, value)`
Set a value in a db, using a uri in the form of sdb://<profile>/<key>. If the uri provided does not start with sdb:// or the value is not successfully set, return False.

CLI Example:
31.16.233 salt.modules.seed

Virtual machine image management tools

salt.modules.seed.apply(path, id_=None, config=None, approve_key=True, install=True, prep_install=False)

Seed a location (disk image, directory, or block device) with the minion config, approve the minion's key, and/or install salt-minion.

CLI Example:

```bash
salt '*' seed.apply path id [config=config_data] \[gen_key=(true|false)] [approve_key=(true|false)] \[install=(true|false)]
```

**path**  Full path to the directory, device, or disk image on the target minion's file system.

**id**  Minion id with which to seed the path.

**config**  Minion configuration options. By default, the `master` option is set to the target host's `master`.

**approve_key**  Request a pre-approval of the generated minion key. Requires that the salt-master be configured to either auto-accept all keys or expect a signing request from the target host. Default: true.

**install**  Install salt-minion, if absent. Default: true.

**prep_install**  Prepare the bootstrap script, but don't run it. Default: false

salt.modules.seed.mkconfig(config=None, tmp=None, id_=None, approve_key=True, pub_key=None, priv_key=None)

Generate keys and config and put them in a tmp directory.

**pub_key**  absolute path or file content of an optional preseeded salt key

**priv_key**  absolute path or file content of an optional preseeded salt key

CLI Example:

```bash
salt '*' seed.mkconfig [config=config_data] [tmp=tmp_dir] \[id=minion_id] [approve_key=(true|false)]
```

salt.modules.seed.prep_bootstrap(mpt)

Update and get the random script to a random place

CLI Example:

```bash
salt '*' seed.prep_bootstrap /tmp
```

31.16.234 salt.modules.selinux

Execute calls on selinux

Note: This module requires the `semanage` and `setsebool` commands to be available on the minion. On RHEL-based distros, this means that the `policycoreutils` and `policycoreutils-python` packages must be installed. If not on a RHEL-based distribution, consult the selinux documentation for your distro to ensure that the proper packages are installed.
salt.modules.selinux.getenforce()
  Return the mode selinux is running in
  CLI Example:
  ```
salt '*' selinux.getenforce
  ```

salt.modules.selinux.getsebool(boolean)
  Return the information on a specific selinux boolean
  CLI Example:
  ```
salt '*' selinux.getsebool virt_use_usb
  ```

salt.modules.selinux.list_sebool()
  Return a structure listing all of the selinux booleans on the system and what state they are in
  CLI Example:
  ```
salt '*' selinux.list_sebool
  ```

salt.modules.selinux.selinux_fs_path(args)
  Return the location of the SELinux VFS directory
  CLI Example:
  ```
salt '*' selinux.selinux_fs_path
  ```

salt.modules.selinux.setenforce(mode)
  Set the SELinux enforcing mode
  CLI Example:
  ```
salt '*' selinux.setenforce enforcing
  ```

salt.modules.selinux.setsebool(boolean, value, persist=False)
  Set the value for a boolean
  CLI Example:
  ```
salt '*' selinux.setsebool virt_use_usb off
  ```

salt.modules.selinux.setsebools(pairs, persist=False)
  Set the value of multiple booleans
  CLI Example:
  ```
salt '*' selinux.setsebools '{virt_use_usb: on, squid_use_tproxy: off}'
  ```

31.16.235  salt.modules.sensors

Read lm-sensors
New in version 2014.1.3.

salt.modules.sensors.sense(chip, fahrenheit=False)
  Gather lm-sensors data from a given chip
  To determine the chip to query, use the `sensors` command and see the leading line in the block.
Example:

/usr/bin/sensors

coretemp-isa-0000 Adapter: ISA adapter Physical id 0: +56.0°C (high = +87.0°C, crit = +105.0°C) Core 0: +52.0°C (high = +87.0°C, crit = +105.0°C) Core 1: +50.0°C (high = +87.0°C, crit = +105.0°C) Core 2: +56.0°C (high = +87.0°C, crit = +105.0°C) Core 3: +53.0°C (high = +87.0°C, crit = +105.0°C)

Given the above, the chip is `coretemp-isa-0000'.

31.16.236 salt.modules.serverdensity_device

Wrapper around Server Density API

New in version 2014.7.0.

salt.modules.serverdensity_device.create(name, **params)

Function to create device in Server Density. For more info, see the API docs.

CLI Example:

salt '*' serverdensity_device.create lama
salt '*' serverdensity_device.create rich_lama group=lama_band installedRAM=32768

salt.modules.serverdensity_device.delete(device_id)

Delete a device from Server Density. For more information, see the API docs.

CLI Example:

salt '*' serverdensity_device.delete 51f7eafcdba4bb235e000ae4

salt.modules.serverdensity_device.get_sd_auth(val, sd_auth_pillar_name='serverdensity')

Returns requested Server Density authentication value from pillar.

CLI Example:

salt '*' serverdensity_device.get_sd_auth <val>

salt.modules.serverdensity_device.install_agent(agent_key)

Function downloads Server Density installation agent, and installs sd-agent with agent_key.

CLI Example:

salt '*' serverdensity_device.install_agent c2bbdd6689ff46282bd0a07555641498

salt.modules.serverdensity_device.ls(**params)

List devices in Server Density

Results will be filtered by any params passed to this function. For more information, see the API docs on listing and searching.

CLI Example:

salt '*' serverdensity_device.ls
salt '*' serverdensity_device.ls name=lama
salt '*' serverdensity_device.ls name=lama group=lama_band installedRAM=32768

salt.modules.serverdensity_device.update(device_id, **params)

Updates device information in Server Density. For more information see the API docs.

CLI Example:
31.16.237 salt.modules.service

The default service module, if not otherwise specified salt will fall back to this basic module

```python
salt.modules.service.available(name)
    Returns True if the specified service is available, otherwise returns False.
    CLI Example:
    salt '*' service.available sshd
```

```python
data.modules.service.get_all()
    Return a list of all available services
    CLI Example:
    salt '*' service.get_all
```

```python
data.modules.service.missing(name)
    The inverse of service.available. Returns True if the specified service is not available, otherwise returns False.
    CLI Example:
    salt '*' service.missing sshd
```

```python
data.modules.service.reload(name)
    Refreshes config files by calling service reload. Does not perform a full restart.
    CLI Example:
    salt '*' service.reload <service name>
```

```python
data.modules.service.restart(name)
    Restart the specified service
    CLI Example:
    salt '*' service.restart <service name>
```

```python
data.modules.service.start(name)
    Start the specified service
    CLI Example:
    salt '*' service.start <service name>
```

```python
data.modules.service.status(name, sig=None)
    Return the status for a service, returns the PID or an empty string if the service is running or not, pass a signature to use to find the service via ps
    CLI Example:
    salt '*' service.status <service name> [service signature]
```

```python
data.modules.service.stop(name)
    Stop the specified service
```

31.16. Full list of builtin execution modules
31.16.238 salt.modules.shadow

Manage the shadow file

salt.modules.shadow.default_hash()
  Returns the default hash used for unset passwords
  CLI Example:
  salt '*' shadow.default_hash

salt.modules.shadow.del_password(name)
  New in version 2014.7.0.
  Delete the password from name user
  CLI Example:
  salt '*' shadow.del_password username

salt.modules.shadow.gen_password(password, crypt_salt=None, algorithm='sha512')
  New in version 2014.7.0.
  Generate hashed password
  password  Plaintext password to be hashed.
  crypt_salt  Cryptographic salt. If not given, a random 8-character salt will be generated.
  algorithm  The following hash algorithms are supported:
    • md5
    • blowfish (not in mainline glibc, only available in distros that add it)
    • sha256
    • sha512 (default)
  CLI Example:
  salt '*' shadow.gen_password 'I_am_password'
  salt '*' shadow.gen_password 'I_am_password' crypt_salt='I_am_salt' algorithm=sha256

salt.modules.shadow.info(name)
  Return information for the specified user
  CLI Example:
  salt '*' shadow.info root

salt.modules.shadow.set_date(name, date)
  Sets the value for the date the password was last changed to days since the epoch (January 1, 1970). See man chage.
  CLI Example:
  salt '*' shadow.set_date username 0
salt.modules.shadow.set_expire(name, expire)
   Changed in version 2014.7.0.
   Sets the value for the date the account expires as days since the epoch (January 1, 1970). Using a value of -1 will clear expiration. See man chage.
   CLI Example:
   ```
salt '*' shadow.set_expire username -1
   ```

salt.modules.shadow.set_inactdays(name, inactdays)
   Set the number of days of inactivity after a password has expired before the account is locked. See man chage.
   CLI Example:
   ```
salt '*' shadow.set_inactdays username 7
   ```

salt.modules.shadow.set_maxdays(name, maxdays)
   Set the maximum number of days during which a password is valid. See man chage.
   CLI Example:
   ```
salt '*' shadow.set_maxdays username 90
   ```

salt.modules.shadow.set_mindays(name, mindays)
   Set the minimum number of days between password changes. See man chage.
   CLI Example:
   ```
salt '*' shadow.set_mindays username 7
   ```

salt.modules.shadow.set_password(name, password, use_usermod=False)
   Set the password for a named user. The password must be a properly defined hash. The password hash can be generated with this command:
   ```python
   python -c "import crypt; print crypt.crypt('password', '\$6\$SALTsalt\$')"
   ```
   SALTsalt is the 8-character crpytographic salt. Valid characters in the salt are ../, and any alphanumeric character.
   Keep in mind that the $6 represents a sha512 hash, if your OS is using a different hashing algorithm this needs to be changed accordingly
   CLI Example:
   ```
salt '*' shadow.set_password root '$1$UYCIxa628.9qXjpQcJ4a..' 
   ```

salt.modules.shadow.set_warndays(name, warnadays)
   Set the number of days of warning before a password change is required. See man chage.
   CLI Example:
   ```
salt '*' shadow.set_warndays username 7
   ```

31.16.239 salt.modules.slack_notify

Module for sending messages to Slack
New in version 2015.5.0.
configuration  This module can be used by either passing an api key and version directly or by specifying
both in a configuration profile in the salt master/minion config.
For example:

```
slack:
  api_key: peWcBiMOS9HrZG15peWcBiMOS9HrZG15
```

```
salt.modules.slack_notify.find_room(name, api_key=None)
  Find a room by name and return it.  :param name: The room name.  :param api_key: The Slack admin api key.
  :return: The room object.

  CLI Example:
  
  salt '*' slack.find_room name="random"

  salt '*' slack.find_room name="random" api_key=peWcBiMOS9HrZG15peWcBiMOS9HrZG15
```

```
salt.modules.slack_notify.find_user(name, api_key=None)
  Find a user by name and return it.  :param name: The user name.  :param api_key: The Slack admin api key.
  :return: The user object.

  CLI Example:
  
  salt '*' slack.find_user name="ThomasHatch"

  salt '*' slack.find_user name="ThomasHatch" api_key=peWcBiMOS9HrZG15peWcBiMOS9HrZG15
```

```
salt.modules.slack_notify.list_rooms(api_key=None)
  List all Slack rooms.
  Parameters api_key -- The Slack admin api key.

  Returns  The room list.

  CLI Example:
  
  salt '*' slack.list_rooms

  salt '*' slack.list_rooms api_key=peWcBiMOS9HrZG15peWcBiMOS9HrZG15
```

```
salt.modules.slack_notify.list_users(api_key=None)
  List all Slack users.  :param api_key: The Slack admin api key.  :return: The user list.

  CLI Example:
  
  salt '*' slack.list_users

  salt '*' slack.list_users api_key=peWcBiMOS9HrZG15peWcBiMOS9HrZG15
```

```
salt.modules.slack_notify.post_message(channel, message, from_name, api_key=None)
  Send a message to a Slack channel.  :param channel: The channel name, either will work.  :param message: The
  message to send to the Slack channel.  :param from_name: Specify who the message is from.  :param api_key: The
  Slack api key, if not specified in the configuration.  :return: Boolean if message was sent successfully.

  CLI Example:
  
  salt '*' slack.post_message channel="Development Room" message="Build is done" from_name="Build"
31.16.240 salt.modules.smartos_imgadm

Module for running imgadm command on SmartOS

salt.modules.smartos_imgadm.avail(search=None, verbose=False)
Return a list of available images
   search [string] Specifies search keyword
   verbose [boolean (False)] Specifies verbose output
   CLI Example:
   ```
salt '*' imgadm.avail [percona]
salt '*' imgadm.avail verbose=True
```  
salt.modules.smartos_imgadm.delete(uuid=None)
Remove an installed image
   uuid [string] Specifies uuid to import
   CLI Example:
   ```
salt '*' imgadm.delete e42f8c84-bbea-11e2-b920-078fab2aabb1f
```  
salt.modules.smartos_imgadm.get(uuid=None)
Return info on an installed image
   CLI Example:
   ```
salt '*' imgadm.get e42f8c84-bbea-11e2-b920-078fab2aabb1f
```  
salt.modules.smartos_imgadm.import(uuid=None, verbose=False)
Import an image from the repository
   uuid [string] Specifies uuid to import
   verbose [boolean (False)] Specifies verbose output
   CLI Example:
   ```
salt '*' imgadm.import e42f8c84-bbea-11e2-b920-078fab2aabb1f [verbose=True]
```  
salt.modules.smartos_imgadm.list(verbose=False)
Return a list of installed images
   verbose [boolean (False)] Specifies verbose output
   CLI Example:
   ```
salt '*' imgadm.list [verbose=True]
```  
salt.modules.smartos_imgadm.show(uuid=None)
Show manifest of a given image
   CLI Example:
   ```
salt '*' imgadm.show e42f8c84-bbea-11e2-b920-078fab2aabb1f
```  
salt.modules.smartos_imgadm.update(uuid='``
Gather info on unknown image(s) (locally installed)
   uuid [string] Specifies uuid of image
CLI Example:

```
salt '*' imgadm.update [uuid]
```

```python
salt.modules.smartos_imgadm.vacuum(verbos=False)

Remove unused images

verbos [boolean (False)] Specifies verbose output

CLI Example:

```
salt '*' imgadm.vacuum [verbos=True]
```

```
salt.modules.smartos_imgadm.version()

Return imgadm version

CLI Example:

```
salt '*' imgadm.version
```

### 31.16.241 salt.modules.smartos_vmadm

Module for running vmadm command on SmartOS

```
salt.modules.smartos_vmadm.create(**kwargs)

Create a new vm

from_file [string] Specifies the json file to create the vm from. Note: when this is present all other options will be ignored.

*: string... Specifies options to set for the vm. Example: image_uuid=UUID, will specify the image_uuid for the vm to be created.

    nics=["nic_tag": "admin", "ip": "198.51.100.123", "netmask": "255.255.255.0"], adds 1 nic over the admin tag

CLI Example:

```
salt '*' vmadm.create from_file=/tmp/new_vm.json
salt '*' vmadm.create image_uuid='...' alias='...' nics=[{"nic_tag": "admin", "ip": "198.51.100.123", "netmask": "255.255.255.0"}], adds 1 nic over the admin tag
```

```
salt.modules.smartos_vmadm.create_snapshot(vm=None, name=None, key='uuid')

Create snapshot of a vm

vm [string] Specifies the vm

name [string] Name of snapshot. The snapshot name must be 64 characters or less and must only contain alphanumeric characters and characters in the set [._:.] to comply with ZFS restrictions.

key [string] Specifies what `vm` is. Value = uuid|alias|hostname

CLI Example:

```
salt '*' vmadm.create_snapshot 186da9ab-7392-4f55-91a5-b8f1fe770543 baseline
salt '*' vmadm.create_snapshot nacl baseline key=alias
```

```
salt.modules.smartos_vmadm.delete(vm=None, key='uuid')

Delete a vm

vm [string] Specifies the vm
key [string] Specifies what 'vm' is. Value = uuid|alias|hostname

CLI Example:

    salt '*' vmadm.delete 186da9ab-7392-4f55-91a5-b8f1fe770543
    salt '*' vmadm.delete nacl key=alias

salt.modules.smartos_vmadm.delete_snapshot(vm=None, name=None, key='uuid')
Delete snapshot of a vm

    vm [string] Specifies the vm
    name [string] Name of snapshot. The snapname must be 64 characters or less and must only contain alphanumeric characters and characters in the set [\-._:%] to comply with ZFS restrictions.
    key [string] Specifies what 'vm' is. Value = uuid|alias|hostname

CLI Example:

    salt '*' vmadm.delete_snapshot 186da9ab-7392-4f55-91a5-b8f1fe770543 baseline
    salt '*' vmadm.delete_snapshot nacl baseline key=alias

salt.modules.smartos_vmadm.get(vm=None, key='uuid')
Output the JSON object describing a VM

    vm [string] Specifies the vm
    key [string] Specifies what 'vm' is. Value = uuid|alias|hostname

CLI Example:

    salt '*' vmadm.get 186da9ab-7392-4f55-91a5-b8f1fe770543
    salt '*' vmadm.get nacl key=alias

salt.modules.smartos_vmadm.info(vm=None, info_type='all', key='uuid')
Lookup info on running kvm

    vm [string] Specifies the vm
    info_type [string] Specifies what info to return. Value = all|block|blockstats|chardev|cpus|kvm|pci|spice|version|vnc
    key [string] Specifies what 'vm' is. Value = uuid|alias|hostname

CLI Example:

    salt '*' vmadm.info 186da9ab-7392-4f55-91a5-b8f1fe770543
    salt '*' vmadm.info 186da9ab-7392-4f55-91a5-b8f1fe770543 vnc
    salt '*' vmadm.info nacl key=alias
    salt '*' vmadm.info nacl vnc key=alias

salt.modules.smartos_vmadm.list(search=None, sort=None, order='uuid, type, ram, state, alias', keyed=False)
Return a list of VMs

    search [string] Specifies the vmadm filter property
    sort [string] Specifies the vmadm sort (-s) property
    order [string] Specifies the vmadm order (-o) property Default: uuid,type,ram,state,alias
    keyed [boolean]
        Specified if the output should be an array (False) or dict (True) Dict key is first field from order parameter Note: if key is not unique last vm wins.
CLI Example:
```
salt '*' vmadm.list
salt '*' vmadm.list order=alias,ram,cpu_cap sort=-ram,-cpu_cap
salt '*' vmadm.list search='type=KVM'
```

```
salt.modules.smartos_vmadm.lookup(search=None, order=None, one=False)
Return a list of VMs using lookup

    search [string] Specifies the vmadm filter property
    order [string] Specifies the vmadm order (-o) property Default: uuid,type,ram,state,alias
    one [boolean] Specifies if to one result only (-1)
```

CLI Example:
```
salt '*' vmadm.lookup search='state=running'
salt '*' vmadm.lookup search='state=running' order=uuid(alias,hostname
salt '*' vmadm.lookup search='alias-nacl' one=True
```

```
salt.modules.smartos_vmadm.reboot(vm=None, force=False, key='uuid')
Reboot a vm

    vm [string] Specifies the vm to be rebooted
    force [boolean] Specifies if the vm should be force rebooted
    key [string] Specifies if `vm` is a uuid, alias or hostname.
```

CLI Example:
```
salt '*' vmadm.reboot 186da9ab-7392-4f55-91a5-b8f1fe770543
salt '*' vmadm.reboot 186da9ab-7392-4f55-91a5-b8f1fe770543 True
salt '*' vmadm.reboot vm=nacl key=alias
salt '*' vmadm.reboot vm=nina.example.org key=hostname
```

```
salt.modules.smartos_vmadm.receive(uuid=None, source=None)
Receive a vm from a directory

    uuid [string] Specifies uuid of vm to receive
    source [string] Specifies the target. Can be a directory path.
```

CLI Example:
```
salt '*' vmadm.receive 186da9ab-7392-4f55-91a5-b8f1fe770543 /opt/backups
```

```
salt.modules.smartos_vmadm.reprovision(vm=None, image=None, key='uuid')
Reprovision a vm

    vm [string] Specifies the vm
    image [string] uuid of new image
    key [string] Specifies what `vm` is. Value = uuid|alias|hostname
```

CLI Example:
```
salt '*' vmadm.reprovision 186da9ab-7392-4f55-91a5-b8f1fe770543 c02a2044-c1bd-11e4-bd8c-dfc1db8b0182 key=alias
```

```
salt.modules.smartos_vmadm.rollback_snapshot(vm=None, name=None, key='uuid')
Rollback snapshot of a vm
```

1224 Chapter 31. Reference
**vm**  [string] Specifies the vm

**name**  [string] Name of snapshot. The snapshot name must be 64 characters or less and must only contain alphanumeric characters and characters in the set [-_.%] to comply with ZFS restrictions.

**key**  [string] Specifies what 'vm' is. Value = uuid|alias|hostname

**CLI Example:**
```
salt '*' vmadm.rollback_snapshot 186da9ab-7392-4f55-91a5-b8f1fe770543 baseline
salt '*' vmadm.rollback_snapshot nacl baseline key=alias
```

**salt.modules.smartos_vmadm.send**(vm=None, target=None, key='uuid')

Send a vm to a directory

**vm**  [string] Specifies the vm to be started

**target**  [string] Specifies the target. Can be a directory path.

**key**  [string] Specifies if 'vm' is a uuid, alias or hostname.

**CLI Example:**
```
salt '*' vmadm.send 186da9ab-7392-4f55-91a5-b8f1fe770543 /opt/backups
salt '*' vmadm.send vm=nacl target=/opt/backups key=alias
```

**salt.modules.smartos_vmadm.start**(vm=None, options=None, key='uuid')

Start a vm

**vm**  [string] Specifies the vm to be started

**options**  [string] Specifies additional options

**key**  [string] Specifies if 'vm' is a uuid, alias or hostname.

**CLI Example:**
```
salt '*' vmadm.start 186da9ab-7392-4f55-91a5-b8f1fe770543
salt '*' vmadm.start nacl key=alias
salt '*' vmadm.start vm=nina.example.org key=hostname
```

**salt.modules.smartos_vmadm.stop**(vm=None, force=False, key='uuid')

Stop a vm

**vm**  [string] Specifies the vm to be stopped

**force**  [boolean] Specifies if the vm should be force stopped

**key**  [string] Specifies if 'vm' is a uuid, alias or hostname.

**CLI Example:**
```
salt '*' vmadm.stop 186da9ab-7392-4f55-91a5-b8f1fe770543
salt '*' vmadm.stop nacl key=alias
salt '*' vmadm.stop vm=nina.example.org key=hostname
```

**salt.modules.smartos_vmadm.sysrq**(vm=None, action='nmi', key='uuid')

Send non-maskable interrupt to vm or capture a screenshot

**vm**  [string] Specifies the vm

**action**  [string] Specifies the action nmi or screenshot

**key**  [string] Specifies what 'vm' is. Value = uuid|alias|hostname

---

**31.16. Full list of builtin execution modules**  1225
**CLI Example:**

```
salt '*' vmadm.sysrq 186da9ab-7392-4f55-91a5-b8f1fe770543 nmi
salt '*' vmadm.sysrq 186da9ab-7392-4f55-91a5-b8f1fe770543 screenshot
salt '*' vmadm.sysrq nacl nmi key=alias
```

salt.modules.smartos_vmadm.update(**kwargs)

Update a new vm

**vm** [string] Specifies the vm to be updated

**key** [string] Specifies if `vm` is a uuid, alias or hostname.

**from_file** [string] Specifies the json file to update the vm with. Note: when this is present all other options except `vm` and `key` will be ignored.

- : string[int]... Specifies options to update for the vm. Example: image_uuid=UUID, will specify the image_uuid for the vm to be created.

  ```python
  add_nics=[``nic_tag'': ``admin'', ``ip'': ``198.51.100.123'', ``netmask'': ``255.255.255.0''}],
  ```

**CLI Example:**

```
salt '*' vmadm.update vm=186da9ab-7392-4f55-91a5-b8f1fe770543 from_file=/tmp/new_vm.json
salt '*' vmadm.update vm=nacl key=alias from_file=/tmp/new_vm.json
salt '*' vmadm.update vm=186da9ab-7392-4f55-91a5-b8f1fe770543 max_physical_memory=1024
```

31.16.242 salt.modules.smbios

Interface to SMBIOS/DMI

(Parsing through dmidecode)

**External References**

- Desktop Management Interface (DMI)
- System Management BIOS
- DMIdecode

salt.modules.smbios.get(string, clean=``True``)

Get an individual DMI string from SMBIOS info

**string**

The string to fetch. DMIdecode supports:

- bios-vendor
- bios-version
- bios-release-date
- system-manufacturer
- system-product-name
• `system-version`
• `system-serial-number`
• `system-uuid`
• `baseboard-manufacturer`
• `baseboard-product-name`
• `baseboard-version`
• `baseboard-serial-number`
• `baseboard-asset-tag`
• `chassis-manufacturer`
• `chassis-type`
• `chassis-version`
• `chassis-serial-number`
• `chassis-asset-tag`
• `processor-family`
• `processor-manufacturer`
• `processor-version`
• `processor-frequency`

`clean`

Don’t return well-known false information
(invalid UUID’s, serial 000000000’s, etcetera)
Defaults to True

CLI Example:
```bash
salt '*' smbios.get system-uuid clean=False
```

salt.modules.smbios.records(
  `rec_type=None, fields=None, clean=True`
)

Return DMI records from SMBIOS

**type**  Return only records of type(s) The SMBIOS specification defines the following DMI types:

<table>
<thead>
<tr>
<th>Type</th>
<th>Information</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>BIOS</td>
</tr>
<tr>
<td>1</td>
<td>System</td>

</tbody>
</table>

clean

Don’t return well-known false information
(invalid UUID’s, serial 000000000’s, etcetera)
Defaults to True

CLI Example:

```
salt '*' smbios.records clean=False
salt '*' smbios.records 14
salt '*' smbios.records 4 core_count,thread_count,current_speed
```

31.16.243 salt.modules.smf

Service support for Solaris 10 and 11, should work with other systems that use SMF also. (e.g. SmartOS)
salt.modules.smf.available(name)

Returns True if the specified service is available, otherwise returns False.
We look up the name with the svcs command to get back the FMRI. This allows users to use simpler service names.

CLI Example:
```
salt '*' service.available net-snmp
```

```python
salt.modules.smf.disable(name, **kwargs)
    Disable the named service to start at boot

CLI Example:
```
salt '*' service.disable <service name>
```

```python
salt.modules.smf.disabled(name)
    Check to see if the named service is disabled to start on boot

CLI Example:
```
salt '*' service.disabled <service name>
```

```python
salt.modules.smf.enable(name, **kwargs)
    Enable the named service to start at boot

CLI Example:
```
salt '*' service.enable <service name>
```

```python
salt.modules.smf.enabled(name, **kwargs)
    Check to see if the named service is enabled to start on boot

CLI Example:
```
salt '*' service.enabled <service name>
```

```python
salt.modules.smf.get_all()
    Return all installed services

CLI Example:
```
salt '*' service.get_all
```

```python
salt.modules.smf.get_disabled()
    Return the disabled services

CLI Example:
```
salt '*' service.get_disabled
```

```python
salt.modules.smf.get_enabled()
    Return the enabled services

CLI Example:
```
salt '*' service.get_enabled
```

```python
salt.modules.smf.get_running()
    Return the running services

CLI Example:
```
salt '*' service.get_running
```
salt.modules.smf.get_stopped()  
Return the stopped services

CLI Example:

```
salt '*' service.get_stopped
```

salt.modules.smf.missing(name)  
The inverse of service.available. Returns True if the specified service is not available, otherwise returns False.

CLI Example:

```
salt '*' service.missing net-snmp
```
salt.modules.smf.reload(name)  
Reload the named service

CLI Example:

```
salt '*' service.reload <service name>
```

salt.modules.smf.restart(name)  
Restart the named service

CLI Example:

```
salt '*' service.restart <service name>
```

salt.modules.smf.start(name)  
Start the specified service

CLI Example:

```
salt '*' service.start <service name>
```

salt.modules.smf.status(name, sig=None)  
Return the status for a service, returns a bool whether the service is running.

CLI Example:

```
salt '*' service.status <service name>
```

salt.modules.smf.stop(name)  
Stop the specified service

CLI Example:

```
salt '*' service.stop <service name>
```

### 31.16.244 salt.modules.smtp

Module for Sending Messages via SMTP

New in version 2014.7.0.

```
depends
  • smtplib python module
```
configuration This module can be used by either passing a jid and password directly to `send_message`,
or by specifying the name of a configuration profile in the minion config, minion pillar, or master
config.

For example:

```
my-smtp-login:
  smtp.server: smtp.domain.com
  smtp.tls: True
  smtp.sender: admin@domain.com
  smtp.username: myuser
  smtp.password: verybadpass
```

The resourcename refers to the resource that is using this account. It is user-definable, and optional.
The following configurations are both valid:

```
my-smtp-login:
  smtp.server: smtp.domain.com
  smtp.tls: True
  smtp.sender: admin@domain.com
  smtp.username: myuser
  smtp.password: verybadpass

another-smtp-login:
  smtp.server: smtp.domain.com
  smtp.tls: True
  smtp.sender: admin@domain.com
  smtp.username: myuser
  smtp.password: verybadpass
```

`salt.modules.smtp.send_msg(recipient, message, subject='Message from Salt', sender=None, 
server=None, use_ssl='True', username=None, password=None, pro-
file=None)`

Send a message to an SMTP recipient. Designed for use in states.

CLI Examples:

```
salt.smtp.send_msg 'admin@example.com' 'This is a salt module test' profile='my-smtp-account'
salt.smtp.send_msg 'admin@example.com' 'This is a salt module test' username='myuser' password='verybadpass'
```

31.16.245 salt.modules.softwareupdate

Support for the softwareupdate command on MacOS.

`salt.modules.softwareupdate.download('updates')`

Download a named update so that it can be installed later with the install or upgrade function. It returns a list
of all updates that are now downloaded.

CLI Example:

```
salt '*' softwareupdate.download <update name>
salt '*' softwareupdate.download "<update with whitespace>"
salt '*' softwareupdate.download <update1> <update2> <update3>
```

`salt.modules.softwareupdate.download_all(rec=False, restart=True)`

Download all available updates so that they can be installed later with the install or upgrade function. It
returns a list of updates that are now downloaded.

CLI Example:
salt 'salt' softwareupdate.download_all

salt.modules.softwareupdate.ignore('updates')
Ignore a specific program update. When an update is ignored the `-` and version number at the end will be omitted, so ``SecUpd2014-001-1.0'' becomes ``SecUpd2014-001''. It will be removed automatically if present. An update is successfully ignored when it no longer shows up after list_upgrades.

CLI Example:

```
salt '*' softwareupdate.ignore <update-name>
salt '*' softwareupdate.ignore "<update with whitespace>"
```

salt.modules.softwareupdate.install('updates')
Install a named upgrade. Returns a dictionary containing the name of the update and the status of its installation.

Return values: - True: The update was installed. - False: The update was not installed. - None: There is no update available with that name.

CLI Example:

```
salt '*' softwareupdate.install <update-name>
salt '*' softwareupdate.install "<update with whitespace>"
```

salt.modules.softwareupdate.list_downloads()
Return a list of all updates that have been downloaded locally.

CLI Example:

```
salt '*' softwareupdate.list_downloads
```

salt.modules.softwareupdate.list_ignored()
List all upgrades that has been ignored. Ignored updates are shown without the `-` and version number at the end, this is how the softwareupdate command works.

CLI Example:

```
salt '*' softwareupdate.list_ignored
```

salt.modules.softwareupdate.list_upgrades(rec=False, restart=False)
List all available updates.

rec Return only the recommended updates.
restart Return only the updates that require a restart.

CLI Example:

```
salt '*' softwareupdate.list_upgrades
```

salt.modules.softwareupdate.reset_ignored()
Make sure the ignored updates are not ignored anymore, returns a list of the updates that are no longer ignored.

CLI Example:

```
salt '*' softwareupdate.reset_ignored
```

salt.modules.softwareupdate.schedule('status')
Decide if automatic checking for upgrades should be on or off. If no arguments are given it will return the current status. Append on or off to change the status.
Return values: - True: Automatic checking is now on, - False: Automatic checking is now off, - None: Invalid argument.

CLI Example:

```
salt '*' softwareupdate.schedule
salt '*' softwareupdate.schedule on|off
```

`salt.modules.softwareupdate.upgrade(rec=False, restart=True)`

Install all available upgrades. Returns a dictionary containing the name of the update and the status of its installation.

Return values: - True: The update was installed. - False: The update was not installed.

* rec If set to True, only install all the recommended updates.
* restart Set this to False if you do not want to install updates that require a restart.

CLI Example:

```
salt '*' softwareupdate.upgrade
```

`salt.modules.softwareupdate.upgrade_available(update)`

Check whether or not an upgrade is available with a given name.

CLI Example:

```
salt '*' softwareupdate.upgrade_available <update-name>
salt '*' softwareupdate.upgrade_available "$<update with whitespace>"
```

31.16.246 `salt.modules.solaris_group`

Manage groups on Solaris

`salt.modules.solaris_group.add(name, gid=None, **kwargs)`

Add the specified group

CLI Example:

```
salt '*' group.add foo 3456
```

`salt.modules.solaris_group.chgid(name, gid)`

Change the gid for a named group

CLI Example:

```
salt '*' group.chgid foo 4376
```

`salt.modules.solaris_group.delete(name)`

Remove the named group

CLI Example:

```
salt '*' group.delete foo
```

`salt.modules.solaris_group.getent(refresh=False)`

Return info on all groups

CLI Example:
salt '*' group.getent

salt.modules.solaris_group.info(name)
Return information about a group

CLI Example:

    salt '*' group.info foo

31.16.247 salt.modules.solaris_shadow

Manage the password database on Solaris systems

salt.modules.solaris_shadow.default_hash()
Returns the default hash used for unset passwords

CLI Example:

    salt '*' shadow.default_hash

salt.modules.solaris_shadow.info(name)
Return information for the specified user

CLI Example:

    salt '*' shadow.info root

salt.modules.solaris_shadow.set_maxdays(name, maxdays)
Set the maximum number of days during which a password is valid. See man passwd.

CLI Example:

    salt '*' shadow.set_maxdays username 90

salt.modules.solaris_shadow.set_mindays(name, mindays)
Set the minimum number of days between password changes. See man passwd.

CLI Example:

    salt '*' shadow.set_mindays username 7

salt.modules.solaris_shadow.set_password(name, password)
Set the password for a named user. The password must be a properly defined hash, the password hash can be generated with this command: openssl passwd -1 <plaintext password>

CLI Example:

    salt '*' shadow.set_password root $1$UYCIxa628.9qXjpQCjM4a..

salt.modules.solaris_shadow.set_warndays(name, warndays)
Set the number of days of warning before a password change is required. See man passwd.

CLI Example:

    salt '*' shadow.set_warndays username 7
31.16.248  salt.modules.solaris_user

Manage users with the useradd command

```
salt.modules.solaris_user.add(name, uid=None, gid=None, groups=None, home=None, shell=None,
unique=True, fullname='', roomnumber='', workphone='', homephone='', createhome=True, **kwargs)
```

Add a user to the minion

CLI Example:
```
salt '*' user.add name <uid> <gid> <groups> <home> <shell>
```

```
salt.modules.solaris_user.chfullname(name, fullname)
```

Change the user's Full Name

CLI Example:
```
salt '*' user.chfullname foo "Foo Bar"
```

```
salt.modules.solaris_user.chgid(name, gid)
```

Change the default group of the user

CLI Example:
```
salt '*' user.chgid foo 4376
```

```
salt.modules.solaris_user.chgroups(name, groups, append=False)
```

Change the groups this user belongs to, add append to append the specified groups

CLI Example:
```
salt '*' user.chgroups foo wheel,root True
```

```
salt.modules.solaris_user.chhome(name, home, persist=False)
```

Change the home directory of the user, pass true for persist to copy files to the new home dir

CLI Example:
```
salt '*' user.chhome foo /home/users/foo True
```

```
salt.modules.solaris_user.chhomephone(name, homephone)
```

Change the user's Home Phone

CLI Example:
```
salt '*' user.chhomephone foo "7735551234"
```

```
salt.modules.solaris_user.chroomnumber(name, roomnumber)
```

Change the user's Room Number

CLI Example:
```
salt '*' user.chroomnumber foo 123
```

```
salt.modules.solaris_user.chshell(name, shell)
```

Change the default shell of the user

CLI Example:
```
salt '*' user.chshell foo /bin/zsh
```
salt.modules.solaris_user.chuid(name, uid)
    Change the uid for a named user
    CLI Example:
    ```
salt '*' user.chuid foo 4376
    ```

salt.modules.solaris_user.chworkphone(name, workphone)
    Change the user's Work Phone
    CLI Example:
    ```
salt '*' user.chworkphone foo "7735550123"
    ```

salt.modules.solaris_user.delete(name, remove=False, force=False)
    Remove a user from the minion
    CLI Example:
    ```
salt '*' user.delete name remove=True force=True
    ```

salt.modules.solaris_user.getent(refresh=False)
    Return the list of all info for all users
    CLI Example:
    ```
salt '*' user.getent
    ```

salt.modules.solaris_user.info(name)
    Return user information
    CLI Example:
    ```
salt '*' user.info root
    ```

salt.modules.solaris_user.list_groups(name)
    Return a list of groups the named user belongs to
    CLI Example:
    ```
salt '*' user.list_groups foo
    ```

salt.modules.solaris_user.rename(name, new_name)
    Change the username for a named user
    CLI Example:
    ```
salt '*' user.rename name new_name
    ```

31.16.249 salt.modules.solarisips

IPS pkg support for Solaris

This module provides support for Solaris 11 new package management - IPS (Image Packaging System). This is the default pkg module for Solaris 11 (and later).

If you want to use also other packaging module (e.g. pkgutil) together with IPS, you need to override the pkg provider in sls for each package:

```python
mypackage:
    pkg.installed:
        - provider: pkgutil
```
Or you can override it globally by setting the `providers` parameter in your Minion config file like this:

```
providers:
  pkg: pkgutil
```

Or you can override it globally by setting the `providers` parameter in your Minion config file like this:

```
providers:
  pkg: pkgutil
```

```

salt.modules.solarisips.available_version(name, **kwargs)

The available version of the package in the repository. In case of multiple match, it returns list of all matched packages. Accepts full or partial FMRI. Please use `pkg.latest_version` as `pkg.available_version` is being deprecated.

CLI Example:

```
salt '*' pkg.latest_version pkg://solaris/entire
```

```

salt.modules.solarisips.get_fmri(name, **kwargs)

Returns FMRI from partial name. Returns empty string ('') if not found. In case of multiple match, the function returns list of all matched packages.

CLI Example:

```
salt '*' pkg.get_fmri bash
```

```

salt.modules.solarisips.install(name=None, refresh=False, pkgs=None, version=None, test=False, **kwargs)

Install the named package using the IPS pkg command. Accepts full or partial FMRI.

Returns a dict containing the new package names and versions:

```
{'<package>': {'old': '<old-version>',
              'new': '<new-version>'}}
```

Multiple Package Installation Options:

pkgs A list of packages to install. Must be passed as a python list.

CLI Example:

```
salt '*' pkg.install vim
salt '*' pkg.install pkg://solaris/editor/vim
salt '*' pkg.install pkg://solaris/editor/vim refresh=True
salt '*' pkg.install pkgs='["foo", "bar"]'
```

```

salt.modules.solarisips.is_installed(name, **kwargs)

Returns True if the package is installed. Otherwise returns False. Name can be full or partial FMRI. In case of multiple match from partial FMRI name, it returns True.

CLI Example:

```
salt '*' pkg.is_installed bash
```

```

salt.modules.solarisips.latest_version(name, **kwargs)

The available version of the package in the repository. In case of multiple match, it returns list of all matched packages. Accepts full or partial FMRI. Please use `pkg.latest_version` as `pkg.available_version` is being deprecated.

CLI Example:

```
```

---

31.16. Full list of builtin execution modules

1237
salt '*' pkg.latest_version pkg://solaris/entire

salt.modules.solarisips.list_pkgs(versions_as_list=False, **kwargs)
List the currently installed packages as a dict:

```python
{
    '<package_name>': '<version>'
}
```

CLI Example:
salt '*' pkg.list_pkgs

salt.modules.solarisips.list_upgrades(refresh=False)
Lists all packages available for update. When run in global zone, it reports only upgradable packages for
the global zone. When run in non-global zone, it can report more upgradable packages than `pkg update
-vn` because `pkg update` hides packages that require newer version of pkg://solaris/entire (which means
that they can be upgraded only from global zone). Simply said: if you see pkg://solaris/entire in the list of
upgrades, you should upgrade the global zone to get all possible updates. You can force full pkg DB refresh
before listing.

CLI Example:
salt '*' pkg.list_upgrades
salt '*' pkg.list_upgrades_refresh=True

salt.modules.solarisips.normalize_name(name, **kwargs)
Internal function. Normalizes pkg name to full FMRI before running pkg.install. In case of multiple match or
no match, it returns the name without modifications and lets the `pkg install` to decide what to do.

CLI Example:
salt '*' pkg.normalize_name vim

salt.modules.solarisips.purge(name=None, pkgs=None, **kwargs)
Remove specified package. Accepts full or partial FMRI.
Returns a list containing the removed packages.

CLI Example:
salt '*' pkg.purge <package name>

salt.modules.solarisips.refresh_db(full=False)
Updates the remote repos database. You can force the full pkg DB refresh from all publishers regardless the
last refresh time.

CLI Example:
salt '*' pkg.refresh_db
salt '*' pkg.refresh_db full=True

salt.modules.solarisips.remove(name=None, pkgs=None, **kwargs)
Remove specified package. Accepts full or partial FMRI. In case of multiple match, the command fails and
won't modify the OS.

name The name of the package to be deleted.

Multiple Package Options:

pkgs A list of packages to delete. Must be passed as a python list. The name parameter will be ignored if this
      option is passed.
Returns a list containing the removed packages.

CLI Example:

```bash
salt '*' pkg.remove <package name>
salt '*' pkg.remove tcsh
salt '*' pkg.remove pkg://solaris/shell/tcsh
salt '*' pkg.remove pkgs='["foo", "bar"]'
```

```python
salt.modules.solarisips.search(name, versions_as_list=False, **kwargs)
```

Searches the repository for given pkg name. The name can be full or partial FMRI. All matches are printed. Globss are also supported.

CLI Example:

```bash
salt '*' pkg.search bash
```

```python
salt.modules.solarisips.upgrade(refresh=False, **kwargs)
```

Upgrade all packages to the latest possible version. When run in global zone, it updates also all non-global zones. In non-global zones upgrade is limited by dependency constrains linked to the version of `pkg://solaris/entire`.

Returns also a raw output of `"pkg update" command (because if update creates a new boot environment, no immediate changes are visible in `"pkg list"`).

CLI Example:

```bash
salt '*' pkg.upgrade
```

```python
salt.modules.solarisips.upgrade_available(name)
```

Check if there is an upgrade available for a certain package Accepts full or partial FMRI. Returns all matches found.

CLI Example:

```bash
salt '*' pkg.upgrade_available apache-22
```

```python
salt.modules.solarisips.version(*names, **kwargs)
```

Common interface for obtaining the version of installed packages. Accepts full or partial FMRI. If called using pkg_resource, full FMRI is required.

CLI Example:

```bash
salt '*' pkg.version vim
salt '*' pkg.version foo bar baz
salt '*' pkg_resource.version pkg://solaris/entire
```

31.16.250 salt.modules.solarispkg

Package support for Solaris

```python
salt.modules.solarispkg.install(name=None, sources=None, saltenv='base', **kwargs)
```

Install the passed package. Can install packages from the following sources:

* Locally (package already exists on the minion
* HTTP/HTTPS server
* FTP server
* Salt master

Returns a dict containing the new package names and versions:
CLI Example, installing a data stream pkg that already exists on the minion:

```sh
salt '*' pkg.install sources='[{"<pkg name>": "/dir/on/minion/<pkg filename>"}]'
salt '*' pkg.install sources='[{"SMClgcc346": "/var/spool/pkg/gcc-3.4.6-sol10-sparc-local.pkg"}]
```

CLI Example, installing a data stream pkg that exists on the salt master:

```sh
salt '*' pkg.install sources='[{"<pkg name>": "salt://pkgs/<pkg filename>"}]'
salt '*' pkg.install sources='[{"SMClgcc346": "salt://pkgs/gcc-3.4.6-sol10-sparc-local.pkg"}]
```

CLI Example, installing a data stream pkg that exists on a HTTP server:

```sh
salt '*' pkg.install sources='[{"<pkg name>": "http://packages.server.com/<pkg filename>"}]'
salt '*' pkg.install sources='[{"SMClgcc346": "http://packages.server.com/gcc-3.4.6-sol10-sparc-local.pkg"}]
```

If working with solaris zones and you want to install a package only in the global zone you can pass `current_zone_only=True` to salt to have the package only installed in the global zone. (Behind the scenes this is passing `-G` to the pkgadd command.) Solaris default when installing a package in the global zone is to install it in all zones. This overrides that and installs the package only in the global.

CLI Example, installing a data stream package only in the global zone:

```sh
salt 'global_zone' pkg.install sources='[{"SMClgcc346": "/var/spool/pkg/gcc-3.4.6-sol10-sparc-local.pkg"}]' current_zone_only=True
```

By default salt automatically provides an adminfile, to automate package installation, with these options set:

```
email=
instance=quit
partial=nocheck
runlevel=nocheck
idepend=nocheck
rdepend=nocheck
space=nocheck
setuid=nocheck
conflict=nocheck
action=nocheck
basedir=default
```

You can override any of these options in two ways. First you can optionally pass any of the options as a kwarg to the module/state to override the default value or you can optionally pass the `admin_source` option providing your own adminfile to the minions.

Note: You can find all of the possible options to provide to the adminfile by reading the admin man page:

```
man -s 4 admin
```

CLI Example - Overriding the `instance` adminfile option when calling the module directly:

```
salt '*' pkg.install sources='[{"<pkg name>": "salt://pkgs/<pkg filename>"}]' instance="overwrite"
```

CLI Example - Overriding the `instance` adminfile option when used in a state:

```
SMClgcc346:
  pkg.installed:
    - sources:
      - SMClgcc346: salt://srv/salt/pkgs/gcc-3.4.6-sol10-sparc-local.pkg
      - instance: overwrite
```
CLI Example - Providing your own adminfile when calling the module directly:

```bash
salt '*' pkg.install sources='["<pkg name>": "salt://pkgs/<pkg filename>"]' admin_source='salt://pkgs/<adminfile filename>'
```

CLI Example - Providing your own adminfile when using states:

```bash
<pkg name>:
  pkg.installed:
    - sources:
      - <pkg name>: salt://pkgs/<pkg filename>
    - admin_source: salt://pkgs/<adminfile filename>
```

Note: the ID declaration is ignored, as the package name is read from the `sources` parameter.

```python
salt.modules.solarispkg.latest_version(names, **kwargs)
```

Return the latest version of the named package available for upgrade or installation. If more than one package name is specified, a dict of name/version pairs is returned.

If the latest version of a given package is already installed, an empty string will be returned for that package.

CLI Example:

```bash
salt '*' pkg.latest_version <package name>
salt '*' pkg.latest_version <package1> <package2> <package3> ...
```

NOTE: As package repositories are not presently supported for Solaris pkgadd, this function will always return an empty string for a given package.

```python
salt.modules.solarispkg.list_pkgs(versions_as_list=False, **kwargs)
```

List the packages currently installed as a dict:

```bash
{'<package_name>': '<version>'}
```

CLI Example:

```bash
salt '*' pkg.list_pkgs
```

```python
salt.modules.solarispkg.purge(name=None, pkgs=None, **kwargs)
```

Package purges are not supported, this function is identical to remove().

- **name**: The name of the package to be deleted

Multiple Package Options:

- **pkgs**: A list of packages to delete. Must be passed as a python list. The name parameter will be ignored if this option is passed.

New in version 0.16.0.

Returns a dict containing the changes.

CLI Example:

```bash
salt '*' pkg.purge <package name>
salt '*' pkg.purge <package1>,<package2>,<package3>
salt '*' pkg.purge pkgs=['foo', 'bar']
```

```python
salt.modules.solarispkg.remove(name=None, pkgs=None, saltenv='base', **kwargs)
```

Remove packages with pkgrm

- **name**: The name of the package to be deleted
By default salt automatically provides an adminfile, to automate package removal, with these options set:

```plaintext
email=
instance=quit
partial=nocheck
runlevel=nocheck
depend=nocheck
rdepend=nocheck
space=nocheck
setuid=nocheck
conflict=nocheck
action=nocheck
basedir=default
```

You can override any of these options in two ways. First you can optionally pass any of the options as a kwarg to the module/state to override the default value or you can optionally pass the `admin_source` option providing your own adminfile to the minions.

Note: You can find all of the possible options to provide to the adminfile by reading the admin man page:

```plaintext
man -s 4 admin
```

Multiple Package Options:

- **pkgs** A list of packages to delete. Must be passed as a python list. The `name` parameter will be ignored if this option is passed.

New in version 0.16.0.

Returns a dict containing the changes.

CLI Example:

```plaintext
salt '*' pkg.remove <package name>
salt '*' pkg.remove SUNWgit
salt '*' pkg.remove <package1>,<package2>,<package3>
salt '*' pkg.remove pkgs='["foo", "bar"]'
```

salt.modules.solarispkg.**upgrade_available**(name)

Check whether or not an upgrade is available for a given package.

CLI Example:

```plaintext
salt '*' pkg.upgrade_available <package name>
```

salt.modules.solarispkg.**version**(names,**kwargs)

Returns a string representing the package version or an empty string if not installed. If more than one package name is specified, a dict of name/version pairs is returned.

CLI Example:

```plaintext
salt '*' pkg.version <package name>
salt '*' pkg.version <package1> <package2> <package3> ...
```

31.16.251 salt.modules.solr

Apache Solr Salt Module

Author: Jed Glazner Version: 0.2.1 Modified: 12/09/2011
This module uses HTTP requests to talk to the apache solr request handlers to gather information and report errors. Because of this the minion doesn't necessarily need to reside on the actual slave. However if you want to use the signal function the minion must reside on the physical solr host.

This module supports multi-core and standard setups. Certain methods are master/slave specific. Make sure you set the solr.type. If you have questions or want a feature request please ask.

**Coming Features in 0.3**

1. Add command for checking for replication failures on slaves
2. Improve match_index_versions since it's pointless on busy solr masters
3. Add additional local fs checks for backups to make sure they succeeded

**Override these in the minion config**

`solr.cores` A list of core names e.g. ['core1','core2']. An empty list indicates non-multicore setup.

`solr.baseurl` The root level URL to access solr via HTTP

`solr.request_timeout` The number of seconds before timing out an HTTP/HTTPS/FTP request. If nothing is specified then the python global timeout setting is used.

`solr.type` Possible values are `master` or `slave`

`solr.backup_path` The path to store your backups. If you are using cores and you can specify to append the core name to the path in the backup method.

`solr.num_backups` For versions of solr >= 3.5. Indicates the number of backups to keep. This option is ignored if your version is less.

`solr.init_script` The full path to your init script with start/stop options

`solr.dih.options` A list of options to pass to the DIH.

**Required Options for DIH**

*clean [False]* Clear the index before importing

*commit [True]* Commit the documents to the index upon completion

*optimize [True]* Optimize the index after commit is complete

*verbose [True]* Get verbose output

```python
salt.modules.solr.abort_import(handler, host=None, core_name=None, verbose=False)
```

MASTER ONLY Aborts an existing import command to the specified handler. This command can only be run if the minion is configured with solr.type=master

*handler [str]* The name of the data import handler.

*host [str (None)]* The solr host to query. __opts__['host'] is default.

*core [str (None)]* The core the handler belongs to.

*verbose [boolean (False)]* Run the command with verbose output.

Return : dict<str,obj>:

{ 'success':boolean, 'data':dict, 'errors':list, 'warnings':list }
**CLI Example:**

```
salt '*' solr.abort_import dataimport None music {'clean':True}
```

```python
salt.modules.solr.backup(host=None, core_name=None, append_core_to_path=False)
```

Tell solr make a backup. This method can be mis-leading since it uses the backup API. If an error happens during the backup you are not notified. The status: `OK' in the response simply means that solr received the request successfully.

- **host** [str (None)] The solr host to query. `__opts__['host']` is default.
- **core_name** [str (None)] The name of the solr core if using cores. Leave this blank if you are not using cores or if you want to check all cores.
- **append_core_to_path** [boolean (False)] If True add the name of the core to the backup path. Assumes that minion backup path is not None.

Return: dict<str,obj>:

```python
{ 'success':boolean, 'data':dict, 'errors':list, 'warnings':list }
```

**CLI Example:**

```
salt '*' solr.backup music
```

```python
salt.modules.solr.core_status(host=None, core_name=None)
```

MULTI-CORE HOSTS ONLY Get the status for a given core or all cores if no core is specified

- **host** [str (None)] The solr host to query. `__opts__['host']` is default.
- **core_name** [str] The name of the core to reload

Return: dict<str,obj>:

```python
{ 'success':boolean, 'data':dict, 'errors':list, 'warnings':list }
```

**CLI Example:**

```
salt '*' solr.core_status None music
```

```python
salt.modules.solr.delta_import(handler, host=None, core_name=None, options=None, extra=None)
```

Submits an import command to the specified handler using specified options. This command can only be run if the minion is configured with solr.type=master

- **handler** [str] The name of the data import handler.
- **host** [str (None)] The solr host to query. `__opts__['host']` is default.
- **core** [str (None)] The core the handler belongs to.
- **options** [dict (__opts__)] A list of options such as clean, optimize commit, verbose, and pause_replication. leave blank to use __opts__ defaults. options will be merged with __opts__
- **extra** [dict ({}):] Extra name value pairs to pass to the handler. e.g. ['"name=value"']

Return: dict<str,obj>:

```python
{ 'success':boolean, 'data':dict, 'errors':list, 'warnings':list }
```

**CLI Example:**

```
salt '*' solr.delta_import dataimport None music {'clean':True}
```
salt.modules.solr.full_import(handler, host=None, core_name=None, options=None, extra=None)
MASTER ONLY Submits an import command to the specified handler using specified options. This command can only be run if the minion is configured with solr.type=master

**handler** [str] The name of the data import handler.

**host** [str (None)] The solr host to query. __opts__['host'] is default.

**core** [str (None)] The core the handler belongs to.

**options** [dict (__opts__) A list of options such as clean, optimize commit, verbose, and pause_replication. leave blank to use __opts__ defaults. options will be merged with __opts__

**extra** [dict ([]) Extra name value pairs to pass to the handler. e.g. ["name=value"]

Return: dict<str,obj>:
{'success':boolean, 'data':dict, 'errors':list, 'warnings':list}

CLI Example:
salt '*' solr.full_import dataimport None music {'clean':True}

salt.modules.solr.import_status(handler, host=None, core_name=None, verbose=False)
Submits an import command to the specified handler using specified options. This command can only be run if the minion is configured with solr.type: `master`

**handler** [str] The name of the data import handler.

**host** [str (None)] The solr host to query. __opts__['host'] is default.

**core** [str (None)] The core the handler belongs to.

**verbose** [boolean (False)] Specifies verbose output

Return: dict<str,obj>:
{'success':boolean, 'data':dict, 'errors':list, 'warnings':list}

CLI Example:
salt '*' solr.import_status dataimport None music False

salt.modules.solr.is_replication_enabled(host=None, core_name=None)
SLAVE CALL Check for errors, and determine if a slave is replicating or not.

**host** [str (None)] The solr host to query. __opts__['host'] is default.

**core_name** [str (None)] The name of the solr core if using cores. Leave this blank if you are not using cores or if you want to check all cores.

Return: dict<str,obj>:
{'success':boolean, 'data':dict, 'errors':list, 'warnings':list}

CLI Example:
salt '*' solr.is_replication_enabled music

salt.modules.solr.lucene_version(core_name=None)
Gets the lucene version that solr is using. If you are running a multi-core setup you should specify a core name since all the cores run under the same servlet container, they will all have the same version.

**core_name** [str (None)] The name of the solr core if using cores. Leave this blank if you are not using cores or if you want to check all cores.
Return: dict<str,obj>:

```python
{'success':boolean, 'data':dict, 'errors':list, 'warnings':list}
```

**CLI Example:**
```
salt '*' solr.lucene_version
```

**salt.modules.solr.match_index_versions**

```python
salt.modules.solr.match_index_versions(host=None, core_name=None)
```

**SLAVE CALL** Verifies that the master and the slave versions are in sync by comparing the index version. If you are constantly pushing updates to the index the master and slave versions will seldom match. A solution to this is pause indexing every so often to allow the slave to replicate and then call this method before allowing indexing to resume.

**host** [str (None)] The solr host to query. `__opts__['host']` is default.

**core_name** [str (None)] The name of the solr core if using cores. Leave this blank if you are not using cores or if you want to check all cores.

Return : dict<str,obj>:

```python
{'success':boolean, 'data':dict, 'errors':list, 'warnings':list}
```

**CLI Example:**
```
salt '*' solr.match_index_versions music
```

**salt.modules.solr.optimize**

```python
salt.modules.solr.optimize(host=None, core_name=None)
```

Search queries fast, but it is a very expensive operation. The ideal process is to run this with a master/slave configuration. Then you can optimize the master, and push the optimized index to the slaves. If you are running a single solr instance, or if you are going to run this on a slave be aware that search performance will be horrible while this command is being run. Additionally it can take a LONG time to run and your HTTP request may timeout. If that happens adjust your timeout settings.

**host** [str (None)] The solr host to query. `__opts__['host']` is default.

**core_name** [str (None)] The name of the solr core if using cores. Leave this blank if you are not using cores or if you want to check all cores.

Return : dict<str,obj>:

```python
{'success':boolean, 'data':dict, 'errors':list, 'warnings':list}
```

**CLI Example:**
```
salt '*' solr.optimize music
```

**salt.modules.solr.ping**

```python
salt.modules.solr.ping(host=None, core_name=None)
```

Does a health check on solr, makes sure solr can talk to the indexes.

**host** [str (None)] The solr host to query. `__opts__['host']` is default.

**core_name** [str (None)] The name of the solr core if using cores. Leave this blank if you are not using cores or if you want to check all cores.

Return : dict<str,obj>:

```python
{'success':boolean, 'data':dict, 'errors':list, 'warnings':list}
```

**CLI Example:**
Cache Management

salt.modules.solr.reload_core

MULTI-CORE HOSTS ONLY Load a new core from the same configuration as an existing registered core. While the "new" core is initializing, the "old" one will continue to accept requests. Once it has finished, all new request will go to the "new" core, and the "old" core will be unloaded.

- **host** [str (None)] The solr host to query. __opts__['host'] is default.
- **core_name** [str] The name of the core to reload

Return: dict<str,obj>:

{'success': boolean, 'data': dict, 'errors': list, 'warnings': list}

CLI Example:
salt '*' solr.reload_core None music

Return data is in the following format:

{'success': bool, 'data': dict, 'errors': list, 'warnings': list}

---

salt.modules.solr.reload_import_config

MASTER ONLY re-loads the handler config XML file. This command can only be run if the minion is a `master' type

- **handler** [str] The name of the data import handler.
- **host** [str (None)] The solr host to query. __opts__['host'] is default.
- **core** [str (None)] The core the handler belongs to.
- **verbose** [boolean (False)] Run the command with verbose output.

Return: dict<str,obj>:

{'success': boolean, 'data': dict, 'errors': list, 'warnings': list}

CLI Example:
salt '*' solr.reload_import_config dataimport None music {'clean':True}

---

salt.modules.solr.replication_details

Get the full replication details.

- **host** [str (None)] The solr host to query. __opts__['host'] is default.
- **core_name** [str (None)] The name of the solr core if using cores. Leave this blank if you are not using cores or if you want to check all cores.

Return: dict<str,obj>:

{'success': boolean, 'data': dict, 'errors': list, 'warnings': list}

CLI Example:
salt '*' solr.replication_details music

---

salt.modules.solr.set_is_polling

SLAVE CALL Prevent the slaves from polling the master for updates.
polling [boolean] True will enable polling. False will disable it.

host [str (None)] The solr host to query. __opts__['host'] is default.

core_name [str (None)] The name of the solr core if using cores. Leave this blank if you are not using cores or if you want to check all cores.

Return: dict<str,obj>:

{'success':boolean, 'data':dict, 'errors':list, 'warnings':list}

CLI Example:
salt '*' solr.set_is_polling False

salt.modules.solr.set_replication_enabled(status, host=None, core_name=None)

MASTER ONLY Sets the master to ignore poll requests from the slaves. Useful when you don't want the slaves replicating during indexing or when clearing the index.

status [boolean] Sets the replication status to the specified state.

host [str (None)] The solr host to query. __opts__['host'] is default.

core_name [str (None)] The name of the solr core if using cores. Leave this blank if you are not using cores or if you want to set the status on all cores.

Return: dict<str,obj>:

{'success':boolean, 'data':dict, 'errors':list, 'warnings':list}

CLI Example:
salt '*' solr.set_replication_enabled false, None, music

salt.modules.solr.signal(signal=None)

Signals Apache Solr to start, stop, or restart. Obviously this is only going to work if the minion resides on the solr host. Additionally Solr doesn't ship with an init script so one must be created.

signal [str (None)] The command to pass to the apache solr init valid values are `start`, `stop`, and `restart`

CLI Example:
salt '*' solr.signal restart

salt.modules.solr.version(core_name=None)

Gets the solr version for the core specified. You should specify a core here as all the cores will run under the same servlet container and so will all have the same version.

core_name [str (None)] The name of the solr core if using cores. Leave this blank if you are not using cores or if you want to check all cores.

Return: dict<str,obj>:

{'success':boolean, 'data':dict, 'errors':list, 'warnings':list}

CLI Example:
salt '*' solr.version

31.16.252 salt.modules.splay

Splay function calls across targeted minions
salt.modules.splay.show(splaytime=600)
Show calculated splaytime for this minion Will use default value of 600 (seconds) if splaytime value not provided

CLI Example: salt example-host splay.show salt example-host splay.show 60

salt.modules.splay.splay(*args, **kwargs)
Splay a salt function call execution time across minions over a number of seconds (default: 600)

Note: You probably want to use --async here and look up the job results later. If you’re dead set on getting the output from the CLI command, then make sure to set the timeout (with the -t flag) to something greater than the splaytime (max splaytime + time to execute job). Otherwise, it’s very likely that the cli will time out before the job returns.

CLI Examples:

```
salt --async '*' splay.splay pkg.install cowsay version=3.03-8.el6
```

```
# With specified splaytime (5 minutes) and timeout with 10 second buffer
salt -t 310 '*' splay.splay 300 pkg.version cowsay
```

31.16.253 salt.modules.splunk_search
Module for interop with the Splunk API
New in version 2015.5.0.

depends
• splunk-sdk python module

configuration Configure this module by specifying the name of a configuration profile in the minion config, minion pillar, or master config. The module will use the `splunk` key by default, if defined.

For example:

```
splunk:
  username: alice
  password: abc123
  host: example.splunkcloud.com
  port: 8080
```

salt.modules.splunk_search.create(name, profile='splunk', **kwargs)
Create a splunk search

CLI Example:
```
splunk_search.create `my search name` search='error msg'
```

salt.modules.splunk_search.delete(name, profile='splunk')
Delete a splunk search

CLI Example:
```
splunk_search.delete `my search name`
```

salt.modules.splunk_search.get(name, profile='splunk')
Get a splunk search

CLI Example:
splunk_search.get `my search name`
salt.modules.splunk_search.list(profile='splunk')
List splunk searches (names only)

CLI Example: splunk_search.list

salt.modules.splunk_search.list_all(prefix=None, app=None, owner=None, description_contains=None, name_not_contains=None, profile='splunk')
Get all splunk search details. Produces results that can be used to create an sls file.

if app or owner are specified, results will be limited to matching saved searches.

if description_contains is specified, results will be limited to those where ```description_contains in description```
is true if name_not_contains is specified, results will be limited to those where ```name_not_contains not in name```
is true.

If prefix parameter is given, alarm names in the output will be prepended with the prefix; alarms that have the
prefix will be skipped. This can be used to convert existing alarms to be managed by salt, as follows:

CLI example:

1. Make a ```backup`` of all existing searches $ salt-call splunk_search.list_all --out=txt | sed `\``s/local: //``" > legacy_searches.sls
2. Get all searches with new prefixed names $ salt-call splunk_search.list_all `\`prefix=**MANAGED BY SALT**`` --out=txt | sed `\``s/local: //``" > managed_searches.sls
3. Insert the managed searches into splunk $ salt-call state.sls managed_searches.sls
4. Manually verify that the new searches look right
5. Delete the original searches $ sed s/present/absent/ legacy_searches.sls > remove_legacy_searches.sls $ salt-call state.sls remove_legacy_searches.sls
6. Get all searches again, verify no changes $ salt-call splunk_search.list_all --out=txt | sed `\``s/local: //``" > final_searches.sls $ diff final_searches.sls managed_searches.sls

salt.modules.splunk_search.update(name, profile='splunk', **kwargs)
Update a splunk search

CLI Example:

splunk_search.update `my search name` sharing=app

31.16.254 salt.modules.sqlite3

Support for SQLite3

salt.modules.sqlite3.fetch(db=None, sql=None)
Retrieve data from an sqlite3 db (returns all rows, be careful!)

CLI Example:

```text
salt '*' sqlite3.fetch /root/test.db 'SELECT * FROM test;'
```
salt.modules.sqlite3.indexes(db=None)
Show all indices in the database, for people with poor spelling skills

CLI Example:
salt '*' sqlite3.indexes /root/test.db

salt.modules.sqlite3.indices(db=None)
    Show all indices in the database
    CLI Example:
    salt '*' sqlite3.indices /root/test.db

salt.modules.sqlite3.modify(db=None, sql=None)
    Issue an SQL query to sqlite3 (with no return data), usually used to modify the database in some way (insert, delete, create, etc)
    CLI Example:
    salt '*' sqlite3.modify /root/test.db 'CREATE TABLE test(id INT, testdata TEXT);'

salt.modules.sqlite3.sqlite_version()
    Return version of sqlite
    CLI Example:
    salt '*' sqlite3.sqlite_version

salt.modules.sqlite3.tables(db=None)
    Show all tables in the database
    CLI Example:
    salt '*' sqlite3.tables /root/test.db

salt.modules.sqlite3.version()
    Return version of pysqlite
    CLI Example:
    salt '*' sqlite3.version

31.16.255 salt.modules.ssh

Manage client ssh components

Note: This module requires the use of MD5 hashing. Certain security audits may not permit the use of MD5. For those cases, this module should be disabled or removed.

salt.modules.ssh.auth_keys(user=None, config='.ssh/authorized_keys')
    Return the authorized keys for users
    CLI Example:
    salt '*' ssh.auth_keys
    salt '*' ssh.auth_keys root
    salt '*' ssh.auth_keys user=root
    salt '*' ssh.auth_keys user="[user1, user2]"

salt.modules.ssh.check_key(user, key, enc, comment, options, config='.ssh/authorized_keys', cache_keys=None)
    Check to see if a key needs updating, returns "update", "add" or "exists"
CLI Example:
```
salt '*' ssh.check_key <user> <key> <enc> <comment> <options>
```

salt.modules.ssh.check_key_file(user, source, config='.ssh/authorized_keys', saltenv='base', env=None)
Check a keyfile from a source destination against the local keys and return the keys to change

CLI Example:
```
salt '*' ssh.check_key_file root salt://ssh/keyfile
```

salt.modules.ssh.check_known_host(user=None, hostname=None, key=None, fingerprint=None, config=None, port=None)
Check the record in known_hosts file, either by its value or by fingerprint (it’s enough to set up either key or fingerprint, you don’t need to set up both).
If provided key or fingerprint doesn’t match with stored value, return `update`, if no value is found for a given host, return `add`, otherwise return `exists`.
If neither key, nor fingerprint is defined, then additional validation is not performed.

CLI Example:
```
salt '*' ssh.check_known_host <user> <hostname> key='AAAA...FAaQ=='
```

salt.modules.ssh.get_known_host(user, hostname, config=None, port=None)
Return information about known host from the config file, if any. If there is no such key, return None.

CLI Example:
```
salt '*' ssh.get_known_host <user> <hostname>
```

salt.modules.ssh.hash_known_hosts(user=None, config=None)
Hash all the hostnames in the known hosts file.
New in version 2014.7.0.

CLI Example:
```
salt '*' ssh.hash_known_hosts
```

salt.modules.ssh.host_keys(keydir=None, private=True)
Return the minion’s host keys

CLI Example:
```
salt '*' ssh.host_keys
salt '*' ssh.host_keys keydir=/etc/ssh
salt '*' ssh.host_keys keydir=/etc/ssh private=False
```

salt.modules.ssh.recv_known_host(hostname, enc=None, port=None, hash_hostname=False)
Retrieve information about host public key from remote server

CLI Example:
```
salt '*' ssh.recv_known_host <hostname> enc=<enc> port=<port>
```

salt.modules.ssh.rm_auth_key(user, key, config='.ssh/authorized_keys')
Remove an authorized key from the specified user’s authorized key file

CLI Example:
salt '...' ssh.rm_auth_key <user> <key>

salt.modules.ssh.rm_auth_key_from_file(user, source, config='ssh/authorized_keys', saltenv='base', env=None)
Remove an authorized key from the specified user's authorized key file, using a file as source

CLI Example:
salt '*' ssh.rm_auth_key_from_file <user> salt://ssh_keys/<user>.id_rsa.pub

salt.modules.ssh.rm_known_host(user=None, hostname=None, config=None, port=None)
Remove all keys belonging to hostname from a known_hosts file.

CLI Example:
salt '*' ssh.rm_known_host <user> <hostname>

salt.modules.ssh.set_auth_key(user, key, enc='ssh-rsa', comment=' ', options=None, config='ssh/authorized_keys', cache_keys=None)
Add a key to the authorized_keys file. The ``key'' parameter must only be the string of text that is the encoded key. If the key begins with ``ssh-rsa'' or ends with user@host, remove those from the key before passing it to this function.

CLI Example:
salt '*' ssh.set_auth_key <user> '<key>' enc='dsa'

salt.modules.ssh.set_auth_key_from_file(user, source, config='ssh/authorized_keys', saltenv='base', env=None)
Add a key to the authorized_keys file, using a file as the source.

CLI Example:

salt '*' ssh.set_auth_key_from_file <user> salt://ssh_keys/<user>.id_rsa.pub

salt.modules.ssh.set_known_host(user=None, hostname=None, fingerprint=None, key=None, port=None, enc=None, hash_hostname=True, config=None)
Download SSH public key from remote host ``hostname'', optionally validate its fingerprint against ``fingerprint'' variable and save the record in the known_hosts file.

If such a record does already exists in there, do nothing.

CLI Example:
salt '*' ssh.set_known_host <user> fingerprint='xx:xx:...:xx' enc='ssh-rsa' config='.ssh/known_hosts'

salt.modules.ssh.user_keys(user=None, pubfile=None, prvfile=None)
Return the user's ssh keys on the minion

New in version 2014.7.0.

CLI Example:
salt '*' ssh.user_keys
salt '*' ssh.user_keys user=user1
salt '*' ssh.user_keys user=user1 pubfile=/home/user1/.ssh/id_rsa.pub prvfile=/home/user1/.ssh/id_rsa
salt '*' ssh.user_keys user=user1 prvfile=False
salt '*' ssh.user_keys user=[['user1','user2']] pubfile=id_rsa.pub prvfile=id_rsa

As you can see you can tell Salt not to read from the user's private (or public) key file by setting the file path to False. This can be useful to prevent Salt from publishing private data via Salt Mine or others.
31.16.256  salt.modules.state

Control the state system on the minion.

State Caching

When a highstate is called, the minion automatically caches a copy of the last high data. If you then run a highstate with cache=True it will use that cached highdata and won’t hit the fileserver except for salt:// links in the states themselves.

```
salt.modules.state.apply(mods=None, **kwargs)
```

New in version 2015.5.0.

Apply states! This function will call highstate or state.sls based on the arguments passed in, state.apply is intended to be the main gateway for all state executions.

CLI Example:
```
salt '*' state.apply
salt '*' state.apply test
salt '*' state.apply test,pkgs
```

```
salt.modules.state.check_request(name=None)
```

New in version 2015.5.0.

Return the state request information, if any

CLI Example:
```
salt '*' state.check_request
```

```
salt.modules.state.clear_cache()
```

Clear out cached state files, forcing even cache runs to refresh the cache on the next state execution.

Remember that the state cache is completely disabled by default, this execution only applies if cache=True is used in states

CLI Example:
```
salt '*' state.clear_cache
```

```
salt.modules.state.clear_request(name=None)
```

New in version 2015.5.0.

Clear out the state execution request without executing it

CLI Example:
```
salt '*' state.clear_request
```

```
salt.modules.state.disable(states)
```

Disable state runs.

CLI Example:
```
salt '*' state.disable highstate
```

```
salt '*' state.disable highstate,test.succeed_without_changes
```
Note: To disable a state file from running provide the same name that would be passed in a state.sls call.
salt '*' state.disable bind.config

```
salt.modules.state.enable(states)
Enable state function or sls run

CLI Example:
salt '*' state.enable highstate
salt '*' state.enable test.succeed_without_changes
```

Note: To enable a state file from running provide the same name that would be passed in a state.sls call.
salt '*' state.disable bind.config

```
salt.modules.state.high(data, test=False, queue=False, **kwargs)
Execute the compound calls stored in a single set of high data This function is mostly intended for testing the state system

CLI Example:
salt '*' state.high '{"vim": {"pkg": ["installed"]}}'
```

```
salt.modules.state.highstate(test=None, queue=False, **kwargs)
Retrieve the state data from the salt master for this minion and execute it

test  Notify states to execute in test-only (dry-run) mode.

pillar Custom Pillar data can be passed with the pillar kwarg. Values passed here will override hard-coded Pillar values.

queue [False] Instead of failing immediately when another state run is in progress, queue the new state run to begin running once the other has finished.

This option starts a new thread for each queued state run so use this option sparingly.

localconfig: Instead of using running minion opts, load localconfig and merge that with the running minion opts. This functionality is intended for using "roots" of salt directories (with their own minion config, pillars, file_roots) to run highstate out of.

CLI Example:
salt '*' state.highstate

salt '*' state.highstate whitelist=sls1_to_run,sls2_to_run
salt '*' state.highstate exclude=sls_to_exclude
salt '*' state.highstate exclude="[{'id': 'id_to_exclude'}, {'sls': 'sls_to_exclude'}]"
salt '*' state.highstate pillar="{foo: 'Foo!', bar: 'Bar!'}"
```

```
salt.modules.state.list_disabled()
List the states which are currently disabled

CLI Example:
```

31.16. Full list of builtin execution modules
salt '*' state.list_disabled

salt.modules.state.low(data, queue=False, **kwargs)
Execute a single low data call. This function is mostly intended for testing the state system.

CLI Example:
salt '*' state.low '{"state": "pkg", "fun": "installed", "name": "vi"}"

salt.modules.state.pkg(pkg_path, pkg_sum, hash_type, test=False, **kwargs)
Execute a packaged state run. The packaged state run will exist in a tarball available locally. This packaged state can be generated using salt-ssh.

CLI Example:
salt '*' state.pkg /tmp/state_pkg.tgz

salt.modules.state.request(mods=None, **kwargs)
New in version 2015.5.0.
Request that the local admin execute a state run via salt-call state.run_request. All arguments match state.apply.

CLI Example:
salt '*' state.request
salt '*' state.request test
taxt '*' state.request test, pkgs

salt.modules.state.run_request(name='default', **kwargs)
New in version 2015.5.0.
Execute the pending state request.

CLI Example:
salt '*' state.run_request

salt.modules.state.running(concurrent=False)
Return a list of strings that contain state return data if a state function is already running. This function is used to prevent multiple state calls from being run at the same time.

CLI Example:
salt '*' state.running

salt.modules.state.show_highstate(queue=False, **kwargs)
Retrieve the highstate data from the salt master and display it.
Custom Pillar data can be passed with the pillar kwarg.

CLI Example:
salt '*' state.show_highstate

salt.modules.state.show_low_sls(mods, saltenv='base', test=None, queue=False, env=None, **kwargs)
Display the low data from a specific sls. The default environment is base, use saltenv (env in Salt 0.17.x and older) to specify a different environment.

CLI Example:
```
salt '*' state.show_low_sls foo
```

salt.modules.state.show_lowstate(queue=False, **kwargs)
List out the low data that will be applied to this minion

CLI Example:
```
salt '*' state.show_lowstate
```

salt.modules.state.show_sls(mods, saltenv='base', test=None, queue=False, env=None, **kwargs)
Display the state data from a specific sls or list of sls files on the master. The default environment is base, use saltenv (env in Salt 0.17.x and older) to specify a different environment.

This function does not support top files. For top.sls please use show_top instead.

Custom Pillar data can be passed with the pillar kwarg.

CLI Example:
```
salt '*' state.show_sls core,edit.vim dev
```

salt.modules.state.show_top(queue=False, **kwargs)
Return the top data that the minion will use for a highstate

CLI Example:
```
salt '*' state.show_top
```

salt.modules.state.single(fun, name, test=None, queue=False, **kwargs)
Execute a single state function with the named kwargs, returns False if insufficient data is sent to the command

By default, the values of the kwargs will be parsed as YAML. So, you can specify lists values, or lists of single entry key-value maps, as you would in a YAML salt file. Alternatively, JSON format of keyword values is also supported.

CLI Example:
```
salt '*' state.single pkg.installed name=vim
```

salt.modules.state.sls(mods, saltenv=None, test=None, exclude=None, queue=False, env=None, pillarenv=None, **kwargs)
Execute a set list of state files from an environment.

**test** Notify states to execute in test-only (dry-run) mode.

Sets the test variable in the minion opts for the duration of the state run.

**pillar** Custom Pillar data can be passed with the pillar kwarg. Values passed here will override hard-coded Pillar values.

**queue** [False] Instead of failing immediately when another state run is in progress, queue the new state run to begin running once the other has finished.

This option starts a new thread for each queued state run so use this option sparingly.

**saltenv** [None] Specify a file_roots environment.

Changed in version 0.17.0: Argument name changed from env to saltenv.

Changed in version 2014.7: Defaults to None. If no saltenv is specified, the minion config will be checked for a saltenv and if found, it will be used. If none is found, base will be used.

**pillarenv** [None] Specify a pillar_roots environment. By default all pillar environments merged together will be used.
**concurrent:** WARNING: This flag is potentially dangerous. It is designed for use when multiple state runs can safely be run at the same time. Do not use this flag for performance optimization.

**localconfig:** Instead of using running minion opts, load localconfig and merge that with the running minion opts. This functionality is intended for using "roots" of salt directories (with their own minion config, pillars, file_roots) to run highstate out of.

CLI Example:

```
salt '*' state.sls core,edit.vim dev
salt '*' state.sls core exclude="[{'id': 'id_to_exclude'}, {'sls': 'sls_to_exclude'}]"
salt '*' state.sls myslsfile pillar="{'foo': 'Foo!', bar: 'Bar!'}"
```

**salt.modules.state.sls_id**

```
salt.modules.state.sls_id(id_, mods, saltenv='base', test=None, queue=False, **kwargs)
```

Call a single ID from the named module(s) and handle all requisites

New in version 2014.7.0.

CLI Example:

```
salt '*' state.sls_id apache http
```

**salt.modules.state.template**

```
salt.modules.state.template(tem, queue=False, **kwargs)
```

Execute the information stored in a template file on the minion.

This function does not ask a master for a SLS file to render but instead directly processes the file at the provided path on the minion.

CLI Example:

```
salt '*' state.template '<Path to template on the minion>'
```

**salt.modules.state.template_str**

```
salt.modules.state.template_str(tem, queue=False, **kwargs)
```

Execute the information stored in a string from an sls template

CLI Example:

```
salt '*' state.template_str '<Template String>'
```

**salt.modules.state.top**

```
salt.modules.state.top(topfn, test=None, queue=False, saltenv=None, **kwargs)
```

Execute a specific top file instead of the default

CLI Example:

```
salt '*' state.top reverse_top.sls
salt '*' state.top reverse_top.sls exclude=sls_to_exclude
salt '*' state.top reverse_top.sls exclude="[{'id': 'id_to_exclude'}, {'sls': 'sls_to_exclude'}]"
```

### 31.16.257 salt.modules.status

Module for returning various status data about a minion. These data can be useful for compiling into stats later.

```
salt.modules.status.all_status()
```

Return a composite of all status data and info for this minion. Warning: There is a LOT here!

CLI Example:

```
salt '*' status.all_status
```
salt.modules.status.cpuinfo()
Return the CPU info for this minion

CLI Example:
```
salt '*' status.cpuinfo
```

salt.modules.status.cpustats()
Return the CPU stats for this minion

CLI Example:
```
salt '*' status.cpustats
```

salt.modules.status.custom()
Return a custom composite of status data and info for this minion, based on the minion config file. An example config like might be:
```
status.cpustats.custom: [ 'cpu', 'ctxt', 'btime', 'processes' ]
```

Where status refers to status.py, cpustats is the function where we get our data, and custom is this function. It is followed by a list of keys that we want returned.

This function is meant to replace all_status(), which returns anything and everything, which we probably don't want.

By default, nothing is returned. Warning: Depending on what you include, there can be a LOT here!

CLI Example:
```
salt '*' status.custom
```

salt.modules.status.diskstats()
Return the disk stats for this minion

CLI Example:
```
salt '*' status.diskstats
```

salt.modules.status.diskusage(*args)
Return the disk usage for this minion

Usage:
```
salt '*' status.diskusage [paths and/or filesystem types]
```

CLI Example:
```
salt '*' status.diskusage # usage for all filesystems
salt '*' status.diskusage /tmp # usage for / and /tmp
salt '*' status.diskusage ext? # usage for ext[234] filesystems
salt '*' status.diskusage / ext? # usage for / and all ext filesystems
```

salt.modules.status.loadavg()
Return the load averages for this minion

CLI Example:
```
salt '*' status.loadavg
```

salt.modules.status.master(master=None, connected=True)
New in version 2014.7.0.

31.16. Full list of built-in execution modules
Fire an event if the minion gets disconnected from its master. This function is meant to be run via a scheduled job from the minion. If master_ip is an FQDN/Hostname, it must be resolvable to a valid IPv4 address.

CLI Example:

```bash
salt '*' status.master
```

```python
salt.modules.status.meminfo()
```

Return the memory info for this minion

CLI Example:

```bash
salt '*' status.meminfo
```

```python
salt.modules.status.netdev()
```

Return the network device stats for this minion

CLI Example:

```bash
salt '*' status.netdev
```

```python
salt.modules.status.netstats()
```

Return the network stats for this minion

CLI Example:

```bash
salt '*' status.netstats
```

```python
salt.modules.status.nproc()
```

Return the number of processing units available on this system

CLI Example:

```bash
salt '*' status.nproc
```

```python
salt.modules.status.pid(sig)
```

Return the PID or an empty string if the process is running or not. Pass a signature to use to find the process via ps. Note you can pass a Python-compatible regular expression to return all pids of processes matching the regexp.

CLI Example:

```bash
salt '*' status.pid <sig>
```

```python
salt.modules.status.procs()
```

Return the process data

CLI Example:

```bash
salt '*' status.procs
```

```python
salt.modules.status.uptime()
```

Return the uptime for this minion

CLI Example:

```bash
salt '*' status.uptime
```

```python
salt.modules.status.version()
```

Return the system version for this minion

CLI Example:
salt '*' status.version

salt.modules.status.vmstats()
Return the virtual memory stats for this minion
CLI Example:
salt '*' status.vmstats

salt.modules.status.w()
Return a list of logged in users for this minion, using the w command
CLI Example:
salt '*' status.w

31.16.258 salt.modules.stormpath

Support for Stormpath
New in version 2015.8.0.
salt.modules.stormpath.create_account(directory_id, email, password, givenName, surname, **kwargs)
Create an account
CLI Examples:
salt myminion stormpath.create_account <directory_id> shemp@example.com letmein Shemp Howard

salt.modules.stormpath.delete_account(account_id)
Delete an account.
CLI Examples:
salt myminion stormpath.delete_account <account_id>

salt.modules.stormpath.list_accounts()
Show all accounts.
CLI Example:
salt myminion stormpath.list_accounts

salt.modules.stormpath.list_directories()
Show all directories.
CLI Example:
salt myminion stormpath.list_directories

salt.modules.stormpath.show_account(account_id=None, email=None, directory_id=None, application_id=None, group_id=None, **kwargs)
Show a specific account.
CLI Example:
salt myminion stormpath.show_account <account_id>

salt.modules.stormpath.show_tenant()
Get the tenant for the login being used.

31.16. Full list of builtin execution modules
salt.modules.stormpath.update_account(account_id, key=None, value=None, items=None)

Update one or more items for this account. Specifying an empty value will clear it for that account.

CLI Examples:

- salt myminion stormpath.update_account <account_id> givenName shemp
- salt myminion stormpath.update_account <account_id> middleName 
- salt myminion stormpath.update_account <account_id> items='{``givenName'': ``Shemp''} 
- salt myminion stormpath.update_account <account_id> items='{``middleName'': ``''} 

31.16.259  salt.modules.sudo

Allow for the calling of execution modules via sudo.

This module is invoked by the minion if the sudo_user minion config is present.

Example minion config:

```
sudo_user: saltdev
```

Once this setting is made, any execution module call done by the minion will be run under sudo -u <sudo_user> salt-call. For example, with the above minion config,

```
salt sudo_minion cmd.run 'cat /etc/sudoers'
```

is equivalent to

```
sudo -u saltdev salt-call cmd.run 'cat /etc/sudoers'
```

being run on sudo_minion.

salt.modules.sudo.salt_call(runas, fun, *args, **kwargs)

Wrap a shell execution out to salt call with sudo

Example:

```
/etc/salt/minion
```

```
sudo_user: saltdev
```

```
salt '*!' test.ping  # is run as saltdev user
```

31.16.260  salt.modules.supervisord

Provide the service module for system supervisord or supervisord in a virtualenv

salt.modules.supervisord.add(name, user=None, conf_file=None, bin_env=None)

Activates any updates in config for process/group.

- user user to run supervisorctl as
- conf_file path to supervisord config file
- bin_env path to supervisorctl bin or path to virtualenv with supervisor installed

CLI Example:

```
salt '*!' supervisord.add <name>
```

salt.modules.supervisord.custom(command, user=None, conf_file=None, bin_env=None)

Run any custom supervisord command
user  user to run supervisorctl as
conf_file  path to supervisord config file
bin_env  path to supervisorctl bin or path to virtualenv with supervisor installed

CLI Example:
salt '*' supervisord.custom "mstop '*'gunicorn*'"

```python
salt.modules.supervisord.options(name, conf_file=None)
```
New in version 2014.1.0.
Read the config file and return the config options for a given process
name  Name of the configured process
conf_file  path to supervisord config file

CLI Example:
salt '*' supervisord.options foo

```python
salt.modules.supervisord.remove(name, user=None, conf_file=None, bin_env=None)
```
Removes process/group from active config
user  user to run supervisorctl as
conf_file  path to supervisord config file
bin_env  path to supervisorctl bin or path to virtualenv with supervisor installed

CLI Example:
salt '*' supervisord.remove <name>

```python
salt.modules.supervisord.reread(user=None, conf_file=None, bin_env=None)
```
Reload the daemon’s configuration files
user  user to run supervisorctl as
conf_file  path to supervisord config file
bin_env  path to supervisorctl bin or path to virtualenv with supervisor installed

CLI Example:
salt '*' supervisord.reread

```python
salt.modules.supervisord.restart(name='all', user=None, conf_file=None, bin_env=None)
```
Restart the named service. Process group names should not include a trailing asterisk.
user  user to run supervisorctl as
conf_file  path to supervisord config file
bin_env  path to supervisorctl bin or path to virtualenv with supervisor installed

CLI Example:
salt '*' supervisord.restart <service>
salt '*' supervisord.restart <group>:

```python
salt.modules.supervisord.start(name='all', user=None, conf_file=None, bin_env=None)
```
Start the named service. Process group names should not include a trailing asterisk.
user  user to run supervisorctl as
conf_file  path to supervisord config file
bin_env   path to supervisorctl bin or path to virtualenv with supervisor installed

CLI Example:
salt '*' supervisord.start <service>
salt '*' supervisord.start <group>:

```
salt.modules.supervisord.status(name=None, user=None, conf_file=None, bin_env=None)
```
List programs and its state
```python
user    user to run supervisorctl as
conf_file  path to supervisord config file
bin_env   path to supervisorctl bin or path to virtualenv with supervisor installed
```
CLI Example:
salt '*' supervisord.status

```
salt.modules.supervisord.status_raw(name=None, user=None, conf_file=None, bin_env=None)
```
Display the raw output of status
```python
user    user to run supervisorctl as
conf_file  path to supervisord config file
bin_env   path to supervisorctl bin or path to virtualenv with supervisor installed
```
CLI Example:
salt '*' supervisord.status_raw

```
salt.modules.supervisord.stop(name='all', user=None, conf_file=None, bin_env=None)
```
Stop the named service. Process group names should not include a trailing asterisk.
```python
user    user to run supervisorctl as
conf_file  path to supervisord config file
bin_env   path to supervisorctl bin or path to virtualenv with supervisor installed
```
CLI Example:
salt '*' supervisord.stop <service>
salt '*' supervisord.stop <group>:

```
salt.modules.supervisord.update(user=None, conf_file=None, bin_env=None)
```
Reload config and add/remove as necessary
```python
user    user to run supervisorctl as
conf_file  path to supervisord config file
bin_env   path to supervisorctl bin or path to virtualenv with supervisor installed
```
CLI Example:
salt '*' supervisord.update
31.16.261 salt.modules.svn

Subversion SCM

salt.modules.svn.add(cwd, targets, user=\text{None}, username=\text{None}, password=\text{None}, *opts)

Add files to be tracked by the Subversion working-copy checkout

- \text{cwd} The path to the Subversion repository
- \text{targets} [\text{None}] files and directories to pass to the command as arguments
- \text{user} [\text{None}] Run svn as a user other than what the minion runs as
- \text{username} [\text{None}] Connect to the Subversion server as another user
- \text{password} [\text{None}] Connect to the Subversion server with this password

New in version 0.17.0.

CLI Example:

```bash
salt '*' svn.add /path/to/repo /path/to/new/file
```

salt.modules.svn.checkout(cwd, remote, target=\text{None}, user=\text{None}, username=\text{None}, password=\text{None}, *opts)

Download a working copy of the remote Subversion repository directory or file

- \text{cwd} The path to the Subversion repository
- \text{remote} [\text{None}] URL to checkout
- \text{target} [\text{None}] The name to give the file or directory working copy Default: svn uses the remote basename
- \text{user} [\text{None}] Run svn as a user other than what the minion runs as
- \text{username} [\text{None}] Connect to the Subversion server as another user
- \text{password} [\text{None}] Connect to the Subversion server with this password

New in version 0.17.0.

CLI Example:

```bash
salt '*' svn.checkout /path/to/repo svn://remote/repo
```

salt.modules.svn.commit(cwd, targets=\text{None}, msg=\text{None}, user=\text{None}, username=\text{None}, password=\text{None}, *opts)

Commit the current directory, files, or directories to the remote Subversion repository

- \text{cwd} The path to the Subversion repository
- \text{targets} [\text{None}] files and directories to pass to the command as arguments Default: svn uses `.`
- \text{msg} [\text{None}] Message to attach to the commit log
- \text{user} [\text{None}] Run svn as a user other than what the minion runs as
- \text{username} [\text{None}] Connect to the Subversion server as another user
- \text{password} [\text{None}] Connect to the Subversion server with this password

New in version 0.17.0.

CLI Example:

```bash
salt '*' svn.commit /path/to/repo
```
salt.modules.svn.diff(
cwd, targets=None, user=None, username=None, password=None, *opts)

Return the diff of the current directory, files, or directories from the remote Subversion repository

cwd  The path to the Subversion repository

targets  [None] files and directories to pass to the command as arguments Default: svn uses `.

user  [None] Run svn as a user other than what the minion runs as

username  [None] Connect to the Subversion server as another user

password  [None] Connect to the Subversion server with this password

New in version 0.17.0.

CLI Example:

```
salt '*' svn.diff /path/to/repo
```

salt.modules.svn.export(
cwd, remote, target=None, user=None, username=None, password=None, revision='HEAD', *opts)

Create an unversioned copy of a tree.

cwd  The path to the Subversion repository

remote  [None] URL and path to file or directory checkout

target  [None] The name to give the file or directory working copy Default: svn uses the remote basename

user  [None] Run svn as a user other than what the minion runs as

username  [None] Connect to the Subversion server as another user

password  [None] Connect to the Subversion server with this password

New in version 0.17.0.

CLI Example:

```
salt '*' svn.export /path/to/repo svn://remote/repo
```

salt.modules.svn.info(
cwd, targets=None, user=None, username=None, password=None, fmt='str')

Display the Subversion information from the checkout.

cwd  The path to the Subversion repository

targets  [None] files, directories, and URLs to pass to the command as arguments svn uses `.` by default

user  [None] Run svn as a user other than what the minion runs as

username  [None] Connect to the Subversion server as another user

password  [None] Connect to the Subversion server with this password

New in version 0.17.0.

fmt  [str] How to fmt the output from info. (str, xml, list, dict)

CLI Example:

```
salt '*' svn.info /path/to/svn/repo
```

salt.modules.svn.remove(
cwd, targets, msg=None, user=None, username=None, password=None, *opts)

Remove files and directories from the Subversion repository

cwd  The path to the Subversion repository
targets [None] files, directories, and URLs to pass to the command as arguments
msg [None] Message to attach to the commit log
user [None] Run svn as a user other than what the minion runs as
username [None] Connect to the Subversion server as another user
password [None] Connect to the Subversion server with this password

New in version 0.17.0.

CLI Example:
```bash
salt '*' svn.remove /path/to/repo /path/to/repo/remove
```

salt.modules.svn.status(cwd, targets=None, user=None, username=None, password=None, *opts)
Display the status of the current directory, files, or directories in the Subversion repository

cwd The path to the Subversion repository
targets [None] files, directories, and URLs to pass to the command as arguments Default: svn uses `.'
user [None] Run svn as a user other than what the minion runs as
username [None] Connect to the Subversion server as another user
password [None] Connect to the Subversion server with this password

New in version 0.17.0.

CLI Example:
```bash
salt '*' svn.status /path/to/repo
```

salt.modules.svn.switch(cwd, remote, target=None, user=None, username=None, password=None, *opts)
New in version 2014.1.0.
Switch a working copy of a remote Subversion repository directory
cwd The path to the Subversion repository
remote [None] URL to switch
target [None] The name to give the file or directory working copy Default: svn uses the remote basename
user [None] Run svn as a user other than what the minion runs as
username [None] Connect to the Subversion server as another user
password [None] Connect to the Subversion server with this password

CLI Example:
```bash
salt '*' svn.switch /path/to/repo svn://remote/repo
```

salt.modules.svn.update(cwd, targets=None, user=None, username=None, password=None, *opts)
Update the current directory, files, or directories from the remote Subversion repository
cwd The path to the Subversion repository
targets [None] files and directories to pass to the command as arguments Default: svn uses `.'
user [None] Run svn as a user other than what the minion runs as
password [None] Connect to the Subversion server with this password

New in version 0.17.0.
username [None] Connect to the Subversion server as another user

CLI Example:
salt '*' svn.update /path/to/repo

31.16.262 salt.modules.swift

Module for handling OpenStack Swift calls

Author: Anthony Stanton <anthony.stanton@gmail.com>

Inspired by the S3 and Nova modules

depends

- swiftclient Python module

configuration This module is not usable until the user, password, tenant, and auth URL are specified either in a pillar or in the minion's config file. For example:

<table>
<thead>
<tr>
<th>keystone.user: admin</th>
</tr>
</thead>
<tbody>
<tr>
<td>keystone.password: verybadpass</td>
</tr>
<tr>
<td>keystone.tenant: admin</td>
</tr>
<tr>
<td>keystone.auth_url: '<a href="http://127.0.0.1:5000/v2.0/">http://127.0.0.1:5000/v2.0/</a>'</td>
</tr>
</tbody>
</table>

If configuration for multiple OpenStack accounts is required, they can be set up as different configuration profiles: For example:

openstack1:
- keystone.user: admin
- keystone.password: verybadpass
- keystone.tenant: admin
- keystone.auth_url: 'http://127.0.0.1:5000/v2.0/'

openstack2:
- keystone.user: admin
- keystone.password: verybadpass
- keystone.tenant: admin
- keystone.auth_url: 'http://127.0.0.2:5000/v2.0/'

With this configuration in place, any of the swift functions can make use of a configuration profile by declaring it explicitly. For example:

salt '*' swift.get mycontainer myfile /tmp/file profile=openstack1

salt.modules.swift.delete(cont, path=None, profile=None)
Delete a container, or delete an object from a container.

CLI Example to delete a container:
salt myminion swift.delete mycontainer

CLI Example to delete an object from a container:
salt myminion swift.delete mycontainer remoteobject

salt.modules.swift.get(cont=None, path=None, local_file=None, return_bin=False, profile=None)
List the contents of a container, or return an object from a container. Set return_bin to True in order to retrieve an object wholesale. Otherwise, Salt will attempt to parse an XML response.

CLI Example to list containers:
salt myminion swift.get

CLI Example to list the contents of a container:

```shell
salt myminion swift.get mycontainer
```

CLI Example to return the binary contents of an object:

```shell
salt myminion swift.get mycontainer myfile.png return_bin=True
```

CLI Example to save the binary contents of an object to a local file:

```shell
salt myminion swift.get mycontainer myfile.png local_file=/tmp/myfile.png
```

```python
salt.modules.swift.head()
```

```python
salt.modules.swift.put(cont, path=None, local_file=None, profile=None)
```

Create a new container, or upload an object to a container.

CLI Example to create a container:

```shell
salt myminion swift.put mycontainer
```

CLI Example to upload an object to a container:

```shell
salt myminion swift.put mycontainer remotepath local_file=/path/to/file
```

31.16.263 salt.modules.sysbench

The `sysbench` module is used to analyze the performance of the minions, right from the master! It measures various system parameters such as CPU, Memory, File I/O, Threads and Mutex.

```python
salt.modules.sysbench.cpu()
```

Tests for the CPU performance of minions.

CLI Examples:

```shell
salt '*' sysbench.cpu
```

```python
salt.modules.sysbench.fileio()
```

This tests for the file read and write operations. Various modes of operations are

- sequential write
- sequential rewrite
- sequential read
- random read
- random write
- random read and write

The test works with 32 files with each file being 1Gb in size. The test consumes a lot of time. Be patient!

CLI Examples:

```shell
salt '*' sysbench.fileio
```
salt.modules.sysbench.memory()
    This tests the memory for read and write operations.
    CLI Examples:
    
    salt '*' sysbench.memory

salt.modules.sysbench.mutex()
    Tests the implementation of mutex
    CLI Examples:
    
    salt '*' sysbench.mutex

salt.modules.sysbench.ping()

salt.modules.sysbench.threads()
    This tests the performance of the processor's scheduler
    CLI Example:
    
    salt '*' sysbench.threads

31.16.264 salt.modules.syslog_ng

Module for getting information about syslog-ng

    maintainer  Tibor Benke <btibi@sch.bme.hu>
    maturity    new
    depends     cmd
    platform    all

This module is capable of managing syslog-ng instances which were installed via a package manager or from source. Users can use a directory as a parameter in the case of most functions, which contains the syslog-ng and syslog-ng-ctl binaries.

Syslog-ng can be installed via a package manager or from source. In the latter case, the syslog-ng and syslog-ng-ctl binaries are not available from the PATH, so users should set the location of the sbin directory with syslog_ng.set_binary_path.

Similarly, users can specify the location of the configuration file with syslog_ng.set_config_file, then the module will use it. If it is not set, syslog-ng uses the default configuration file.

class salt.modules.syslog_ng.Argument(value=’’)
    A TypedParameterValue has one or more Arguments. For example this can be the value of key_file.
    Doesn't need examples.

    build()

class salt.modules.syslog_ng.Buildable(iterable, join_body_on=’,’, append_extra_newline=True)
    Base class of most classes, which have a build method.
    It contains a common build function.
    Doesn't need examples.

    build()
    Builds the textual representation of the whole configuration object with it's children.
build_body()  
Builds the body of a syslog-ng configuration object.

build_header()  
Builds the header of a syslog-ng configuration object.

build_tail()  
Builds the tail of a syslog-ng configuration object.

class salt.modules.syslog_ng.GivenStatement(value, add_newline=True)  
This statement returns a string without modification. It can be used to use existing configuration snippets.  
Does not need examples.

build()  
class salt.modules.syslog_ng.NamedStatement(type=", id='", options=None)  
It represents a configuration statement, which has a name, e.g. a source.  
Does not need examples.

class salt.modules.syslog_ng.Option(type=", params=None)  
A Statement class contains Option instances.  
An instance of Option can represent a file(), tcp(), udp(), etc. option.  
Does not need examples.

add_parameter(param)  
build()  
class salt.modules.syslog_ng.Parameter(iterable=None, join_body_on="")  
An Option has one or more Parameter instances.  
Does not need examples.

class salt.modules.syslog_ng.ParameterValue(iterable=None, join_body_on="")  
A TypedParameter can have one or more values.  
Does not need examples.

class salt.modules.syslog_ng.SimpleParameter(value='')  
A Parameter is a SimpleParameter, if it's just a simple type, like a string.  
For example:

destination d_file {
    file("/var/log/messages")
};

/var/log/messages is a SimpleParameter.  
Does not need examples.

build()  
class salt.modules.syslog_ng.SimpleParameterValue(value='')  
A ParameterValue which holds a simple type, like a string or a number.  
For example in ip(127.0.0.1) 127.0.0.1 is a SimpleParameterValue.  
Does not need examples.
build()

class salt.modules.syslog_ng.Statement(type, id='`, options=None, has_name=True)
   It represents a syslog-ng configuration statement, e.g. source, destination, filter.
   Does not need examples.
   add_child(option)
   build_header()
   build_tail()

exception salt.modules.syslog_ng.SyslogNgError

class salt.modules.syslog_ng.TypedParameter(type='`, values=None)
   A Parameter, which has a type:

   \[
   \text{destination} \ d_{tcp} \{ \\
   \quad \text{tcp(} \\
   \quad \quad \text{ip(127.0.0.1)} \\
   \quad \}; \\
   \\]

   ip(127.0.0.1) is a TypedParameter.
   Does not need examples.
   add_value(value)
   build()

class salt.modules.syslog_ng.TypedParameterValue(type='`, arguments=None)
   We have to go deeper...

   A TypedParameter can have a `parameter', which also have a type. For example key_file and cert_file:

   \[
   \text{source} \ \text{demo}_tls_source \{ \\
   \quad \text{tcp(} \\
   \quad \quad \text{ip(0.0.0.0)} \\
   \quad \quad \text{port(1999)} \\
   \quad \quad \text{tls(} \\
   \quad \quad \quad \text{key_file(}`/opt/syslog-ng/etc/syslog-ng/key.d/syslog-ng.key`)} \\
   \quad \quad \quad \text{cert_file(}`/opt/syslog-ng/etc/syslog-ng/cert.d/syslog-ng.cert`)} \\
   \quad \}; \\
   \\]

   Does not need examples.
   add_argument(arg)
   build()

class salt.modules.syslog_ng.UnnamedStatement(type, options=None)
   It represents a configuration statement, which doesn't have a name, e.g. a log path.
   Does not need examples.

salt.modules.syslog_ng.config(name, config, write=True)
   Builds syslog-ng configuration. This function is intended to be used from the state module, users should not use it directly!
   name : the id of the Salt document or it is the format of <statement name>.id config : the parsed YAML code write : if True, it writes the config into the configuration file, otherwise just returns it
CLI Example:
```
salt '*' syslog_ng.config name="s_local" config="[{'tcp': [{'ip': '127.0.0.1'}, {'port': 1233}]]"
```

```
salt.modules.syslog_ng.config_test(syslog_ng_sbin_dir=None, cfgfile=None)
```
Runs syntax check against `cfgfile`. If `syslog_ng_sbin_dir` is specified, it is added to the PATH during the test.

CLI Example:
```
salt '*' syslog_ng.config_test
salt '*' syslog_ng.config_test /home/user/install/syslog-ng/sbin
salt '*' syslog_ng.config_test /home/user/install/syslog-ng/sbin /etc/syslog-ng/syslog-ng.conf
```

```
salt.modules.syslog_ng.get_config_file()
```
Returns the configuration directory, which contains `syslog-ng.conf`.

CLI Example:
```
salt '*' syslog_ng.get_config_file
```

```
salt.modules.syslog_ng.modules(syslog_ng_sbin_dir=None)
```
Returns the available modules. If `syslog_ng_sbin_dir` is specified, it is added to the PATH during the execution of the command `syslog-ng`.

CLI Example:
```
salt '*' syslog_ng.modules
salt '*' syslog_ng.modules /home/user/install/syslog-ng/sbin
```

```
salt.modules.syslog_ng.reload(name)
```
Reloads `syslog-ng`. This function is intended to be used from states.

If `syslog_ng.set_config_file`, is called before, this function will use the set binary path.

CLI Example:
```
salt '*' syslog_ng.reload
```

```
salt.modules.syslog_ng.set_binary_path(name)
```
Sets the path, where the `syslog-ng` binary can be found. This function is intended to be used from states.

If `syslog-ng` is installed via a package manager, users don’t need to use this function.

CLI Example:
```
salt '*' syslog_ng.set_binary_path name="/usr/sbin"
```

```
salt.modules.syslog_ng.set_config_file(name)
```
Sets the configuration’s name. This function is intended to be used from states.

CLI Example:
```
salt '*' syslog_ng.set_config_file name="/etc/syslog-ng"
```

```
salt.modules.syslog_ng.set_parameters(version=None, binary_path=None, config_file=None, *args, **kwargs)
```
Sets variables.

CLI Example:
```
salt '*' syslog_ng.set_parameters version="3.6"
salt '*' syslog_ng.set_parameters binary_path="/home/user/install/syslog-ng/sbin" config_file="""
salt.modules.syslog_ng.start(name=None, user=None, group=None, chroot=None, caps=None, no_caps=False, pidfile=None, enable_core=False, fd_limit=None, verbose=False, debug=False, trace=False, yydebug=False, persist_file=None, control=None, worker_threads=None)

Ensures, that syslog-ng is started via the given parameters. This function is intended to be used from the state module.

Users shouldn't use this function, if the service module is available on their system. If syslog_ng.set_config_file, is called before, this function will use the set binary path.

CLI Example:
salt '*' syslog_ng.start

salt.modules.syslog_ng.stats(syslog_ng_sbin_dir=None)

Returns statistics from the running syslog-ng instance. If syslog_ng_sbin_dir is specified, it is added to the PATH during the execution of the command syslog-ng-ctl.

CLI Example:
salt '*' syslog_ng.stats	salt '*' syslog_ng.stats /home/user/install/syslog-ng/sbin

salt.modules.syslog_ng.stop(name=None)

Kills syslog-ng. This function is intended to be used from the state module.

Users shouldn't use this function, if the service module is available on their system. If syslog_ng.set_config_file is called before, this function will use the set binary path.

CLI Example:
salt '*' syslog_ng.stop

salt.modules.syslog_ng.version(syslog_ng_sbin_dir=None)

Returns the version of the installed syslog-ng. If syslog_ng_sbin_dir is specified, it is added to the PATH during the execution of the command syslog-ng.

CLI Example:
salt '*' syslog_ng.version	salt '*' syslog_ng.version /home/user/install/syslog-ng/sbin

salt.modules.syslog_ng.write_config(config, newlines=2)

Writes the given parameter config into the config file. This function is intended to be used from states.

If syslog_ng.set_config_file, is called before, this function will use the set config file.

CLI Example:
salt '*' syslog_ng.write_config config="# comment"

salt.modules.syslog_ng.write_version(name)

Removes the previous configuration file, then creates a new one and writes the name line. This function is intended to be used from states.

If syslog_ng.set_config_file, is called before, this function will use the set config file.

CLI Example:
salt '*' syslog_ng.write_version name="3.6"
31.16.265 salt.modules.sysmod

The sys module provides information about the available functions on the minion

salt.modules.sysmod.argspec(module='')
Return the argument specification of functions in Salt execution modules.

CLI Example:

salt '*' sys.argspec pkg.install
salt '*' sys.argspec sys
salt '*' sys.argspec

Module names can be specified as globs.
New in version 2015.5.0.

salt '*' sys.argspec 'pkg.*'

salt.modules.sysmod.doc('args')
Return the docstrings for all modules. Optionally, specify a module or a function to narrow the selection.
The strings are aggregated into a single document on the master for easy reading.
Multiple modules/functions can be specified.

CLI Example:

salt '*' sys.doc
salt '*' sys.doc sys
salt '*' sys.doc sys.doc
salt '*' sys.doc network.traceroute user.info

Modules can be specified as globs.
New in version 2015.5.0.

salt '*' sys.doc 'sys.*'
salt '*' sys.doc 'sys.list_*'

salt.modules.sysmod.list_functions('args', **kwargs)
List the functions for all modules. Optionally, specify a module or modules from which to list.

CLI Example:

salt '*' sys.list_functions
salt '*' sys.list_functions sys
salt '*' sys.list_functions sys user

Function names can be specified as globs.
New in version 2015.5.0.

salt '*' sys.list_functions 'sys.list_*'

salt.modules.sysmod.list_modules('args')
List the modules loaded on the minion
New in version 2015.5.0.

CLI Example:
salt '*' sys.list_modules

Module names can be specified as globs.

salt '*' sys.list_modules 's*'

salt.modules.sysmod.list_renderers(*args)
List the renderers loaded on the minion
New in version 2015.5.0.
CLI Example:
salt '*' sys.list_renderers

Render names can be specified as globs.
salt '*' sys.list_renderers 'yaml*'

salt.modules.sysmod.list_returner_functions(*args, **kwargs)
List the functions for all returner modules. Optionally, specify a returner module or modules from which to list.
New in version 2014.7.0.
CLI Example:
salt '*' sys.list_returner_functions	salt '*' sys.list_returner_functions mysql	salt '*' sys.list_returner_functions mysql etcd

Returner names can be specified as globs.
New in version 2015.5.0.
salt '*' sys.list_returner_functions 'sqlite3.get_*'

salt.modules.sysmod.list_runners(*args)
List the runners loaded on the minion
New in version 2014.7.0.
CLI Example:
salt '*' sys.list_runners

Runner names can be specified as globs.
New in version 2015.5.0.
salt '*' sys.list_runners 's*'

salt.modules.sysmod.list_runner_functions(*args, **kwargs)
List the functions for all runner modules. Optionally, specify a runner module or modules from which to list.
New in version 2014.7.0.
CLI Example:
salt '*' sys.list_runner_functions	salt '*' sys.list_runner_functions state	salt '*' sys.list_runner_functions state virt
Runner function names can be specified as globs.
New in version 2015.5.0.

```
salt '*' sys.list_runner_functions 'state.*' 'virt.*'
```

salt.modules.sysmod.list_runners(*args)
List the runners loaded on the minion
New in version 2014.7.0.
CLI Example:
```
salt '*' sys.list_runners
```

Runner names can be specified as globs.
New in version 2015.5.0.

```
salt '*' sys.list_runners 'm*'
```

salt.modules.sysmod.list_state_functions(*args, **kwargs)
List the functions for all state modules. Optionally, specify a state module or modules from which to list.
New in version 2014.7.0.
CLI Example:
```
salt '*' sys.list_state_functions
salt '*' sys.list_state_functions file
salt '*' sys.list_state_functions pkg user
```

State function names can be specified as globs.
New in version 2015.5.0.

```
salt '*' sys.list_state_functions 'file.*'
salt '*' sys.list_state_functions 'file.s*'
```

salt.modules.sysmod.list_state_modules(*args)
List the modules loaded on the minion
New in version 2014.7.0.
CLI Example:
```
salt '*' sys.list_state_modules
```

State module names can be specified as globs.
New in version 2015.5.0.

```
salt '*' sys.list_state_modules 'mysql_.*'
```

salt.modules.sysmod.reload_modules()
Tell the minion to reload the execution modules
CLI Example:
```
salt '*' sys.reload_modules
```

salt.modules.sysmod.renderer_doc(*args)
Return the docstrings for all renderers. Optionally, specify a renderer or a function to narrow the selection.
The strings are aggregated into a single document on the master for easy reading.
Multiplerendererscanbespecified.
Newinversion2015.5.0.

CLIExample:

```bash
salt '*' sys.renderer_doc
salt '*' sys.renderer_doc cheetah
salt '*' sys.renderer_doc jinja json
```

Renderer names can be specified as globs.

```bash
salt '*' sys.renderer_doc 'c*' 'j*' 
```

```bash
salt.modules.sysmod.returner_argspec(module='')
```
Return the argument specification of functions in Salt returner modules.
Newinversion2015.5.0.

CLIExample:

```bash
salt '*' sys.returner_argspec xmpp
salt '*' sys.returner_argspec xmpp smtp
salt '*' sys.returner_argspec
```

Returner names can be specified as globs.

```bash
salt '*' sys.returner_argspec 'sqlite3.*'
```

```bash
salt.modules.sysmod.returner_doc('args')
```
Return the docstrings for all returners. Optionally, specify a returner or a function to narrow the selection.
The strings are aggregated into a single document on the master for easy reading.
Multiplereturners/functions can be specified.
Newinversion2014.7.0.

CLIExample:

```bash
salt '*' sys.returner_doc
salt '*' sys.returner_doc sqlite3
salt '*' sys.returner_doc sqlite3.get_fun
salt '*' sys.returner_doc sqlite3.get_fun etcd.get_fun
```

Returner names can be specified as globs.

Newinversion2015.5.0.

```bash
salt '*' sys.returner_doc 'sqlite3.get_*'
```

```bash
salt.modules.sysmod.runner_argspec(module='')
```
Return the argument specification of functions in Salt runner modules.
Newinversion2015.5.0.

CLIExample:

```bash
salt '*' sys.runner_argspec state
salt '*' sys.runner_argspec http
salt '*' sys.runner_argspec
```
Runner names can be specified as globs.

```
salt 'winrepo.*' sys.runner_argspec
```

```
salt.modules.sysmod.runner_doc(*args)
```

Return the docstrings for all runners. Optionally, specify a runner or a function to narrow the selection.

The strings are aggregated into a single document on the master for easy reading.

Multiple runners/functions can be specified.

New in version 2014.7.0.

CLI Example:

```
salt '*' sys.runner_doc
salt '*' sys.runner_doc cache
salt '*' sys.runner_doc cache.grains
salt '*' sys.runner_doc cache.grains mine.get
```

Runner names can be specified as globs.

New in version 2015.5.0.

```
salt 'cache.clear_*'
```

```
salt.modules.sysmod.state_argspec(module='')
```

Return the argument specification of functions in Salt state modules.

New in version 2015.5.0.

CLI Example:

```
salt '*' sys.state_argspec pkg.installed
salt '*' sys.state_argspec file
salt '*' sys.state_argspec
```

State names can be specified as globs.

```
salt '*' sys.state_argspec 'pkg.*'
```

```
salt.modules.sysmod.state_doc(*args)
```

Return the docstrings for all states. Optionally, specify a state or a function to narrow the selection.

The strings are aggregated into a single document on the master for easy reading.

Multiple states/functions can be specified.

New in version 2014.7.0.

CLI Example:

```
salt '*' sys.state_doc
salt '*' sys.state_doc service
salt '*' sys.state_doc service.running
salt '*' sys.state_doc service.running ipables.append
```

State names can be specified as globs.

New in version 2015.5.0.

```
salt '*' sys.state_doc 'service.*' 'iptables.*'
```
31.16.266 salt.modules.sysrc

sysrc module for FreeBSD

salt.modules.sysrc.get(**kwargs)
   Return system rc configuration variables
   CLI Example:
   ```
salt '*' sysrc.get includeDefaults=True
   ```

salt.modules.sysrc.remove(name, **kwargs)
   Remove system rc configuration variables
   CLI Example:
   ```
salt '*' sysrc.remove name=sshd_enable
   ```

salt.modules.sysrc.set(name, value, **kwargs)
   Set system rc configuration variables
   CLI Example:
   ```
salt '*' sysrc.remove name=sshd_enable
   ```

31.16.267 salt.modules.system

Support for reboot, shutdown, etc

salt.modules.system.halt()
   Halt a running system
   CLI Example:
   ```
salt '*' system.halt
   ```

salt.modules.system.init(runlevel)
   Change the system runlevel on sysV compatible systems
   CLI Example:
   ```
salt '*' system.init 3
   ```

salt.modules.system.poweroff()
   Poweroff a running system
   CLI Example:
   ```
salt '*' system.poweroff
   ```

salt.modules.system.reboot()
   Reboot the system using the `reboot` command
   CLI Example:
   ```
salt '*' system.reboot
   ```

salt.modules.system.shutdown(at_time=None)
   Shutdown a running system
   ```
   at_time  The wait time in minutes before the system will be shutdown.
   ```
CLI Example:
```
salt '*' system.shutdown 5
```

### 31.16.268 salt.modules.system_profiler

System Profiler Module

Interface with Mac OSX's command-line System Profiler utility to get information about package receipts and installed applications.

New in version 2015.5.0.

**salt.modules.system_profiler**

- **applications()**
  Return the results of a call to `system_profiler -xml -detail full SPApplicationsDataType` as a dictionary. Top-level keys of the dictionary are the names of each set of install receipts, since there can be multiple receipts with the same name. Contents of each key are a list of dictionaries.

  CLI Example:
  ```
salt '*' systemprofiler.applications
  ```

- **receipts()**
  Return the results of a call to `system_profiler -xml -detail full SPInstallHistoryDataType` as a dictionary. Top-level keys of the dictionary are the names of each set of install receipts, since there can be multiple receipts with the same name. Contents of each key are a list of dictionaries.

  CLI Example:
  ```
salt '*' systemprofiler.receipts
  ```

### 31.16.269 salt.modules.systemd

Provide the service module for systemd

- **available(name)**
  Check that the given service is available taking into account template units.

  CLI Example:
  ```
salt '*' service.available sshd
  ```

- **disable(name, **kwargs)**
  Disable the named service to not start when the system boots

  CLI Example:
  ```
salt '*' service.disable <service name>
  ```

- **disabled(name)**
  Return if the named service is disabled to start on boot

  CLI Example:
  ```
salt '*' service.disabled <service name>
  ```
salt.modules.systemd.enable(name, **kwargs)
    Enable the named service to start when the system boots
    
    CLI Example:
    
    salt '*' service.enable <service name>

salt.modules.systemd.enabled(name, **kwargs)
    Return if the named service is enabled to start on boot
    
    CLI Example:
    
    salt '*' service.enabled <service name>

salt.modules.systemd.execs()
    Return a list of all files specified as ExecStart for all services.
    
    CLI Example:
    
    salt '*' service.execs

salt.modules.systemd.force_reload(name)
    Force-reload the specified service with systemd
    
    CLI Example:
    
    salt '*' service.force_reload <service name>

salt.modules.systemd.get_all()
    Return a list of all available services
    
    CLI Example:
    
    salt '*' service.get_all

salt.modules.systemd.get_disabled()
    Return a list of all disabled services
    
    CLI Example:
    
    salt '*' service.get_disabled

salt.modules.systemd.get_enabled()
    Return a list of all enabled services
    
    CLI Example:
    
    salt '*' service.get_enabled

salt.modules.systemd.mask(name)
    Mask the specified service with systemd
    
    CLI Example:
    
    salt '*' service.mask <service name>

salt.modules.systemd.masked(name)
    Return if the named service is masked.
    
    New in version 2015.8.0.
    
    CLI Example:
salt 'service.masked <service name>'

salt.modules.systemd.missing(name)
The inverse of service.available. Returns True if the specified service is not available, otherwise returns False.

CLI Example:
salt 'service.missing sshd'

salt.modules.systemd.reload(name)
Reload the specified service with systemd

CLI Example:
salt 'service.reload <service name>'

salt.modules.systemd.restart(name)
Restart the specified service with systemd

CLI Example:
salt 'service.restart <service name>'

salt.modules.systemd.show(name)
Show properties of one or more units/jobs or the manager

CLI Example:
salt 'service.show <service name>'

salt.modules.systemd.start(name)
Start the specified service with systemd

CLI Example:
salt 'service.start <service name>'

salt.modules.systemd.status(name, sig=None)
Return the status for a service via systemd, returns a bool whether the service is running.

CLI Example:
salt 'service.status <service name>'

salt.modules.systemd.stop(name)
Stop the specified service with systemd

CLI Example:
salt 'service.stop <service name>'

salt.modules.systemd.systemctl_reload()
Reloads systemctl, an action needed whenever unit files are updated.

CLI Example:
salt 'service.systemctl_reload'

salt.modules.systemd.unmask(name)
Unmask the specified service with systemd

CLI Example:
31.16.270 salt.modules.temp

Simple module for creating temporary directories and files
This is a thin wrapper around Python’s tempfile module
New in version 2015.8.0.

```
salt.modules.temp.dir(suffix='`, prefix='tmp', parent=None)
```
Create a temporary directory

CLI Example:
```
salt '*' temp.dir
salt '*' temp.dir prefix='mytemp-' parent='/var/run/'
```

```
salt.modules.temp.file(suffix='`, prefix='tmp', parent=None)
```
Create a temporary file

CLI Example:
```
salt '*' temp.file
salt '*' temp.file prefix='mytemp-' parent='/var/run/'
```

31.16.271 salt.modules.test

Module for running arbitrary tests

```
salt.modules.test.arg(*args, **kwargs)
```
Print out the data passed into the function `*args` and `**kwargs`, this is used to both test the publication data and cli argument passing, but also to display the information available within the publication data. Returns `{``args'': args,``kwargs'': kwargs}.

CLI Example:
```
salt '*' test.arg 1 "two" 3.1 txt="hello" wow='{a: 1, b: "hello"}'
```

```
salt.modules.test.arg_repr(*args, **kwargs)
```
Print out the data passed into the function `*args` and `**kwargs`, this is used to both test the publication data and cli argument passing, but also to display the information available within the publication data. Returns `{``args'': repr(args),``kwargs'': repr(kwargs)}`.

CLI Example:
```
salt '*' test.arg_repr 1 "two" 3.1 txt="hello" wow='{a: 1, b: "hello"}'
```

```
salt.modules.test.arg_type(*args, **kwargs)
```
Print out the types of the args and kwargs. This is used to test the types of the args and kwargs passed down to the minion

CLI Example:
```
salt '*' test.arg_type 1 'int'
```
salt.modules.test.assertion(assertion)
    Assert the given argument
    CLI Example:
    ```
salt '*' test.assert False
    ```

salt.modules.test.attr_call()
    Call grains.items via the attribute
    CLI Example:
    ```
salt '*' test.attr_call
    ```

salt.modules.test.collatz(start)
    Execute the collatz conjecture from the passed starting number, returns the sequence and the time it took to compute. Used for performance tests.
    CLI Example:
    ```
salt '*' test.collatz 3
    ```

salt.modules.test.conf_test()
    Return the value for test.foo in the minion configuration file, or return the default value
    CLI Example:
    ```
salt '*' test.conf_test
    ```

salt.modules.test.cross_test(func, args=None)
    Execute a minion function via the __salt__ object in the test module, used to verify that the minion functions can be called via the __salt__ module.
    CLI Example:
    ```
salt '*' test.cross_test file.gid_to_group 0
    ```

salt.modules.test.echo(text)
    Return a string - used for testing the connection
    CLI Example:
    ```
salt '*' test.echo 'foo bar baz quo qux'
    ```

salt.modules.test.exception(message='Test Exception')
    Raise an exception
    Optionally provide an error message or output the full stack.
    CLI Example:
    ```
salt '*' test.exception 'Oh noes!' 
    ```

salt.modules.test.false()
    Always return False
    CLI Example:
    ```
salt '*' test.false
    ```
salt.modules.test.fib(num)
   Return the num-th Fibonacci number, and the time it took to compute in seconds. Used for performance tests.
   This function is designed to have terrible performance.
   CLI Example:
   
   salt '*' test.fib 3

salt.modules.test.get_opts()
   Return the configuration options passed to this minion
   CLI Example:
   
   salt '*' test.get_opts

salt.modules.test.kwarg(**kwargs)
   Print out the data passed into the function **kwargs, this is used to both test the publication data and cli kwarg passing, but also to display the information available within the publication data.
   CLI Example:
   
   salt '*' test.kwarg num=1 txt="two" env='{a: 1, b: "hello"}"

salt.modules.test.missing_func()

salt.modules.test.module_report()
   Return a dict containing all of the execution modules with a report on the overall availability via different references
   CLI Example:
   
   .. code-block:: bash

       salt '*' test.module_report

salt.modules.test.not_loaded()
   List the modules that were not loaded by the salt loader system
   CLI Example:
   
   salt '*' test.not_loaded

salt.modules.test.opts_pkg()
   Return an opts package with the grains and opts for this minion. This is primarily used to create the options used for master side state compiling routines
   CLI Example:
   
   salt '*' test.opts_pkg

salt.modules.test.outputter(data)
   Test the outputter, pass in data to return
   CLI Example:
   
   salt '*' test.outputter foobar

salt.modules.test.ping()
   Used to make sure the minion is up and responding. Not an ICMP ping.
   Returns True.
CLI Example:
```bash
salt '*' test.ping
```

salt.modules.test.provider(module)
Pass in a function name to discover what provider is being used
CLI Example:
```bash
salt '*' test.provider service
```

salt.modules.test.providers()
Return a dict of the provider names and the files that provided them
CLI Example:
```bash
salt '*' test.providers
```

salt.modules.test.rand_sleep(max=60)
Sleep for a random number of seconds, used to test long-running commands and minions returning at differing intervals
CLI Example:
```bash
salt '*' test.rand_sleep 60
```

salt.modules.test.rand_str(size=9999999999, hash_type=None)
Return a random string
```
size  size of the string to generate
hash_type  hash type to use
                      New in version 2015.5.2.
```
CLI Example:
```bash
salt '*' test.rand_str
```

salt.modules.test.retcodencode=42)
Test that the returncode system is functioning correctly
CLI Example:
```bash
salt '*' test.retcodencode=42
```

salt.modules.test.sleep(length)
Instruct the minion to initiate a process that will sleep for a given period of time.
CLI Example:
```bash
salt '*' test.sleep 20
```

salt.modules.test.stack()
Return the current stack trace
CLI Example:
```bash
salt '*' test.stack
```

salt.modules.test.true()
Always return True
CLI Example:
salt '*' test.true

salt.modules.test.try_(module, return_try_exception=False, **kwargs)
Try to run a module command. On an exception return None. If return_try_exception is set True return the exception. This can be helpful in templates where running a module might fail as expected.

CLI Example:

```
<pre>
{% for i in range(0,230) %}
    {{ salt['test.try'](module='ipmi.get_users', bmc_host='172.2.2.'+i)|yaml(None) }}
{% endfor %}
</pre>
```

salt.modules.test.tty(*args, **kwargs)
Depreciated! Moved to cmdmod.

CLI Example:

```
salt '*' test.tty tty0 'This is a test'
salt '*' test.tty pts3 'This is a test'
```

salt.modules.test.version()
Return the version of salt on the minion

CLI Example:

```
salt '*' test.version
```

salt.modules.test.versions()
Returns versions of components used by salt

CLI Example:

```
salt '*' test.versions_report
```

salt.modules.test.versions_information()
Report the versions of dependent and system software

CLI Example:

```
salt '*' test.versions_information
```

salt.modules.test.versions_report()
Returns versions of components used by salt

CLI Example:

```
salt '*' test.versions_report
```

31.16.272  salt.modules.test_virtual
Module for running arbitrary tests with a __virtual__ function

salt.modules.test_virtual.ping()

31.16.273  salt.modules.timezone
Module for managing timezone on POSIX-like systems.
salt.modules.timezone.get_hwclock()  
Get current hardware clock setting (UTC or localtime)  
   CLI Example:  
   ```py
   salt '*' timezone.get_hwclock
   ```

salt.modules.timezone.get_offset()  
Get current numeric timezone offset from UCT (i.e. -0700)  
   CLI Example:  
   ```py
   salt '*' timezone.get_offset
   ```

salt.modules.timezone.get_zone()  
Get current timezone (i.e. America/Denver)  
   CLI Example:  
   ```py
   salt '*' timezone.get_zone
   ```

salt.modules.timezone.get_zonecode()  
Get current timezone (i.e. PST, MDT, etc)  
   CLI Example:  
   ```py
   salt '*' timezone.get_zonecode
   ```

salt.modules.timezone.set_hwclock(clock)  
Sets the hardware clock to be either UTC or localtime  
   CLI Example:  
   ```py
   salt '*' timezone.set_hwclock UTC
   ```

salt.modules.timezone.set_zone(timezone)  
Unlinks, then symlinks /etc/localtime to the set timezone.  
   The timezone is crucial to several system processes, each of which SHOULD be restarted (for instance, whatever you system uses as its cron and syslog daemons). This will not be automagically done and must be done manually!  
   CLI Example:  
   ```py
   salt '*' timezone.set_zone 'America/Denver'
   ```

salt.modules.timezone.zone_compare(timezone)  
Checks the hash sum between the given timezone, and the one set in /etc/localtime. Returns True if they match, and False if not. Mostly useful for running state checks.  
   CLI Example:  
   ```py
   salt '*' timezone.zone_compare 'America/Denver'
   ```

### 31.16.274 salt.modules.tls

A salt module for SSL/TLS. Can create a Certificate Authority (CA) or use Self-Signed certificates.

   depends  
   - PyOpenSSL Python module (0.10 or later, 0.14 or later for
X509 extension support

**configuration** Add the following values in `/etc/salt/minion` for the CA module to function properly:

```plaintext
cacert_base_path: '/etc/pki'
```

### CLI Example #1 Creating a CA, a server request and its signed certificate:

```bash
# salt-call tls.create_ca my_little \
days=5 \nCN='My Little CA' \nC=US \nST=Utah \nL=Salt Lake City \nO=Saltstack \nemailAddress=pleasedonemail@thisisnot.coms

Created Private Key: "/etc/pki/my_little/my_little_ca_cert.key"
Created CA "my_little_ca": "/etc/pki/my_little_ca/my_little_ca_cert.crt"

# salt-call tls.create_csr my_little CN=www.thisisnot.coms
Created Private Key: "/etc/pki/my_little/certs/www.thisisnot.coms.key"
Created CSR for "www.thisisnot.coms": "/etc/pki/my_little/certs/www.thisisnot.coms.csr"

# salt-call tls.create_ca_signed_cert my_little CN=www.thisisnot.coms
Created Certificate for "www.thisisnot.coms": "/etc/pki/my_little/certs/www.thisisnot.coms.crt"
```

### CLI Example #2: Creating a client request and its signed certificate

```bash
# salt-call tls.create_csr my_little CN=DBReplica_No.1 cert_type=client
Created Private Key: "/etc/pki/my_little/certs/DBReplica_No.1.key".
Created CSR for "DBReplica_No.1": "/etc/pki/my_little/certs/DBReplica_No.1.csr".

# salt-call tls.create_ca_signed_cert my_little CN=DBReplica_No.1
Created Certificate for "DBReplica_No.1": "/etc/pki/my_little/certs/DBReplica_No.1.crt"
```

### CLI Example #3: Creating both a server and client req + cert for the same CN

```bash
# salt-call tls.create_csr my_little CN=MasterDBReplica_No.2 \
   cert_type=client
Created Private Key: "/etc/pki/my_little/certs/MasterDBReplica_No.2.key".
Created CSR for "DBReplica_No.1": "/etc/pki/my_little/certs/MasterDBReplica_No.2.csr".

# salt-call tls.create_ca_signed_cert my_little CN=MasterDBReplica_No.2
Created Certificate for "DBReplica_No.1": "/etc/pki/my_little/certs/MasterDBReplica_No.2.crt"

# salt-call tls.create_csr my_little CN=MasterDBReplica_No.2 \
   cert_type=server
Certificate "MasterDBReplica_No.2" already exists
(doh!)

# salt-call tls.create_csr my_little CN=MasterDBReplica_No.2 \
   cert_type=server type_ext=True
Created Private Key: "/etc/pki/my_little/certs/DBReplica_No.1_client.key".
Created CSR for "DBReplica_No.1": "/etc/pki/my_little/certs/DBReplica_No.1_client.csr".

# salt-call tls.create_ca_signed_cert my_little CN=MasterDBReplica_No.2
Certificate "MasterDBReplica_No.2" already exists
# salt-call tls.create_ca_signed_cert my_little CN=MasterDBReplica_No.2 cert_type=server type_ext=True
Created Certificate for "MasterDBReplica_No.2": "/etc/pki/my_little/certs/MasterDBReplica_No.2_server.crt"

CLI Example #4: Create a server req + cert with non-CN filename for the cert

# salt-call tls.create_csr my_little CN=www.anothersometh.ing cert_type=server type_ext=True
Created Private Key: "/etc/pki/my_little/certs/www.anothersometh.ing_server.key." Created CSR for "DBReplica_No.1": "/etc/pki/my_little/certs/www.anothersometh.ing_server.csr."

# salt-call tls_create_ca_signed_cert my_little CN=www.anothersometh.ing cert_type=server cert_filename="something_completely_different"
Created Certificate for "www.anothersometh.ing": /etc/pki/my_little/certs/something_completely_different.crt

salt.modules.tls.ca_exists(ca_name, cacert_path=None, ca_filename=None)
Verify whether a Certificate Authority (CA) already exists
    ca_name  name of the CA
    cacert_path  absolute path to ca certificates root directory
    ca_filename  alternative filename for the CA

    New in version 2015.5.3.
    CLI Example:
    salt '*' tls.ca_exists test_ca /etc/certs

salt.modules.tls.cert_base_path(cacert_path=None)
Return the base path for certs from CLI or from options
    cacert_path  absolute path to ca certificates root directory

    CLI Example:
    salt '*' tls.cert_base_path

salt.modules.tls.cert_info(cert_path, digest='sha256')
Return information for a particular certificate
    cert_path  path to the cert file
    digest  what digest to use for fingerprinting

    CLI Example:
    salt '*' tls.cert_info /dir/for/certs/cert.pem

salt.modules.tls.create_ca(ca_name, bits=2048, days=365, CN='localhost', C='US', ST='Utah', L='Salt Lake City', O='SaltStack', OU=None, emailAddress='xyz@pdq.net', fix-mode=False, cacert_path=None, ca_filename=None, digest='sha256', onlyif=None, unless=None, replace=False)
Create a Certificate Authority (CA)
    ca_name  name of the CA
    bits  number of RSA key bits, default is 2048
    days  number of days the CA will be valid, default is 365
CN common name in the request, default is `localhost`
C country, default is `US`
ST state, default is `Utah`
L locality, default is `Centerville`, the city where SaltStack originated
O organization, default is `SaltStack`
OU organizational unit, default is None
emailAddress email address for the CA owner, default is `xyz@pdq.net`
cacert_path absolute path to ca certificates root directory
c_filename alternative filename for the CA

digest The message digest algorithm. Must be a string describing a digest algorithm supported by OpenSSL
(by EVP_get_digestbyname, specifically). For example, `md5` or `sha1`. Default: `sha256`
replace Replace this certificate even if it exists

Writes out a CA certificate based upon defined config values. If the file already exists, the function just returns
assuming the CA certificate already exists.

If the following values were set:

```
cert_base_path='/etc/pki'
ca_name='koji'
```

the resulting CA, and corresponding key, would be written in the following location:

```
/etc/pki/koji/koji_ca_cert.crt
/etc/pki/koji/koji_ca_cert.key
```

CLI Example:

```
salt '*' tls.create_ca test_ca
```

salt.modules.tls.create_ca_signed_cert(ca_name, CN, days=365, cacert_path=None, ca_filename=None, cert_path=None, cert_filename=None, digest='sha256', cert_type=None, type_ext=False, replace=False)

Create a Certificate (CERT) signed by a named Certificate Authority (CA)

If the certificate file already exists, the function just returns assuming the CERT already exists.

The CN must match an existing CSR generated by create_csr. If it does not, this method does nothing.

c_name name of the CA
CN common name matching the certificate signing request
days number of days certificate is valid, default is 365 (1 year)
cacert_path absolute path to ca certificates root directory
c_filename alternative filename for the CA

cert_path full path to the certificates directory
cert_filename  alternative filename for the certificate, useful when using special characters in the CN. If this option is set it will override the certificate filename output effects of cert_type. type_ext will be completely overridden.

New in version 2015.5.3.

digest  The message digest algorithm. Must be a string describing a digest algorithm supported by OpenSSL (by EVP_get_digestbyname, specifically). For example, `md5` or `sha1`. Default: `sha256`

replace  Replace this certificate even if it exists

New in version 2015.5.1.

cert_type  string. Either `server` or `client` (see create_csr() for details).

If create_csr(type_ext=True) this function must be called with the same cert_type so it can find the CSR file.

Note:  create_csr() defaults to cert_type='server'; therefore, if it was also called with type_ext, cert_type becomes a required argument for create_ca_signed_cert()

type_ext  bool. If set True, use cert_type as an extension to the CN when formatting the filename.

e.g.: some_subject_CN_server.crt or some_subject_CN_client.crt

This facilitates the context where both types are required for the same subject

If cert_filename is not None, setting type_ext has no effect

If the following values were set:

| ca.cert_base_path='/etc/pki' |
| ca_name='koji' |
| CN='test.egavas.org' |

the resulting signed certificate would be written in the following location:

| /etc/pki/koji/certs/test.egavas.org.crt |

CLI Example:

| salt '*' tls.create_ca_signed_cert test localhost |

salt.modules.tls.create_csr(ca_name, bits=2048, CN='localhost', C='US', ST='Utah', L='Salt Lake City', O='SaltStack', OU=None, emailAddress='xyz@pdq.net', subjectAltName=None, cacert_path=None, ca_filename=None, csr_path=None, csr_filename=None, digest='sha256', type_ext=False, cert_type='server', replace=False)

Create a Certificate Signing Request (CSR) for a particular Certificate Authority (CA)

c_a_name  name of the CA

bits  number of RSA key bits, default is 2048

CN  common name in the request, default is `localhost`

C  country, default is `US`

ST  state, default is `Utah`

L  locality, default is `Centerville`, the city where SaltStack originated

O  organization, default is `SaltStack` NOTE: Must the same as CA certificate or an error will be raised
OU organizational unit, default is None

e-mailAddress email address for the request, default is `xyz@pdq.net`

subjectAltName valid subjectAltNames in full form, e.g. to add DNS entry you would call this function with this value:

examples: ['DNS:somednsname.com', 'DNS:1.2.3.4', 'IP:1.2.3.4', 'IP:2001:4801:7821:77:be76:4eff:fe11:e51', 'email:me@i.like.pie.com']

Note: some libraries do not properly query IP: prefixes, instead looking for the given req. source with a DNS: prefix. To be thorough, you may want to include both DNS: and IP: entries if you are using subjectAltNames for destinations for your TLS connections. e.g.: requests to https://1.2.3.4 will fail from python's requests library w/out the second entry in the above list

New in version 2015.8.0.

cert_type Specify the general certificate type. Can be either server or client. Indicates the set of common extensions added to the CSR.

server: {
    'basicConstraints': 'CA:FALSE',
    'extendedKeyUsage': 'serverAuth',
    'keyUsage': 'digitalSignature, keyEncipherment'
}

client: {
    'basicConstraints': 'CA:FALSE',
    'extendedKeyUsage': 'clientAuth',
    'keyUsage': 'nonRepudiation, digitalSignature, keyEncipherment'
}

type_ext boolean. Whether or not to extend the filename with CN_[cert_type] This can be useful if a server and client certificate are needed for the same CN. Defaults to False to avoid introducing an unexpected file naming pattern

The files normally named some_subject_CN.csr and some_subject_CN.key will then be saved

replace Replace this signing request even if it exists

New in version 2015.5.1.

Writes out a Certificate Signing Request (CSR) If the file already exists, the function just returns assuming the CSR already exists.

If the following values were set:

c.a.cert_base_path='/etc/pki'
c.a_name='koji'
CN='test.egavas.org'

the resulting CSR, and corresponding key, would be written in the following location:

/etc/pki/koji/certs/test.egavas.org.csr
/etc/pki/koji/certs/test.egavas.org.key

CLI Example:
salt '*' tls.create_csr test
salt.modules.tls.create_empty_crl(ca_name, cacert_path=None, ca_filename=None, crl_file=None)

Create an empty Certificate Revocation List.
New in version 2015.8.0.

cr_name name of the CA
cacert_path absolute path to ca certificates root directory
c_filename alternative filename for the CA

New in version 2015.5.3.

c_filename full path to the CRL file

CLI Example:
salt '*' tls.create_empty_crl ca_name='koji' ca_filename='ca'

salt.modules.tls.create_pkcs12(ca_name, CN, passphrase='`, cacert_path=None, replace=False)

Create a PKCS#12 browser certificate for a particular Certificate (CN)

cr_name name of the CA
CN common name matching the certificate signing request
passphrase used to unlock the PKCS#12 certificate when loaded into the browser
cacert_path absolute path to ca certificates root directory
replace Replace this certificate even if it exists

New in version 2015.5.1.

If the following values were set:
ca.cert_base_path='/etc/pki'
ca_name='koji'
CN='test.egavas.org'

the resulting signed certificate would be written in the following location:

/etc/pki/koji/certs/test.egavas.org.p12

CLI Example:
salt '*' tls.create_pkcs12 test localhost

salt.modules.tls.create_self_signed_cert(tls_dir='tls', bits=2048, days=365, CN='localhost', C='US', ST='Utah', L='Salt Lake City', O='SaltStack', OU=None, emailAddress='xyz@pdq.net', cacert_path=None, cert_filename=None, digest='sha256', replace=False)

Create a Self-Signed Certificate (CERT)

tls_dir location appended to the ca.cert_base_path, default is `tls'
bts number of RSA key bits, default is 2048
CN common name in the request, default is `localhost'
C country, default is `US'
ST state, default is `Utah'
locality, default is "Centerville", the city where SaltStack originated
organization, default is "SaltStack" NOTE: Must the same as CA certificate or an error will be raised
organizational unit, default is None
email address for the request, default is `xyz@pdq.net`
absolute path to ca certificates root directory
The message digest algorithm. Must be a string describing a digest algorithm supported by OpenSSL
(by EVP_get_digestbyname, specifically). For example, `md5` or `sha1`. Default: `sha256`
Replace this certificate even if it exists
New in version 2015.5.1.
Writes out a Self-Signed Certificate (CERT). If the file already exists, the function just returns.
If the following values were set:
```
cacert_path='/etc/pki'
tls_dir='koji'
CN='test.egavas.org'
```
the resulting CERT, and corresponding key, would be written in the following location:
```
/etc/pki/koji/certs/test.egavas.org.crt
/etc/pki/koji/certs/test.egavas.org.key
```
CLI Example:
```
salt '*' tls.create_self_signed_cert
```
Passing options from the command line:
```
salt 'minion' tls.create_self_signed_cert CN='test.mysite.org'
```
salt.modules.tls.get_ca(ca_name , as_text=False, cacert_path=None)
Get the certificate path or content
```
ca_name name of the CA
as_text if true, return the certificate content instead of the path
cacert_path absolute path to ca certificates root directory
```
CLI Example:
```
salt '*' tls.get_ca test_ca as_text=False cacert_path=/etc/certs
```
salt.modules.tls.get_ca_signed_cert(ca_name , CN='localhost', as_text=False, cacert_path=None, cert_filename=None)
Get the certificate path or content
```
ca_name name of the CA
CN common name of the certificate
as_text if true, return the certificate content instead of the path
cacert_path absolute path to certificates root directory
```
Alternative filename for the certificate, useful when using special characters in the CN
New in version 2015.5.3.
CLI Example:

```
salt '*' tls.get_ca_signed_cert test_ca CN=localhost as_text=False cacert_path=/etc/certs
```

salt.modules.tls.get_ca_signed_key(ca_name, CN='localhost', as_text=False, cacert_path=None, key_filename=None)

Get the certificate path or content

- **ca_name**  name of the CA
- **CN**  common name of the certificate
- **as_text**  if true, return the certificate content instead of the path
- **cacert_path**  absolute path to certificates root directory
- **key_filename**  alternative filename for the key, useful when using special characters

New in version 2015.5.3.

CLI Example:

```
salt '*' tls.get_ca_signed_key test_ca CN=localhost as_text=False cacert_path=/etc/certs
```

salt.modules.tls.get_extensions(cert_type)

Fetch X509 and CSR extension definitions from tls:extensions: (common|server|client) or set them to standard defaults.

New in version 2015.8.0.

- **cert_type**  The type of certificate such as server or client.

CLI Example:

```
salt '*' tls.get_extensions client
```

salt.modules.tls.maybe_fix_ssl_version(ca_name, cacert_path=None, ca_filename=None)

Check that the X509 version is correct (was incorrectly set in previous salt versions). This will fix the version if needed.

- **ca_name**  ca authority name
- **cacert_path**  absolute path to ca certificates root directory
- **ca_filename**  alternative filename for the CA

New in version 2015.5.3.

CLI Example:

```
salt '*' tls.maybe_fix_ssl_version test_ca /etc/certs
```

salt.modules.tls.revoke_cert(ca_name, CN, cacert_path=None, ca_filename=None, cert_path=None, cert_filename=None, crl_file=None)

Revoke a certificate.

New in version 2015.8.0.

- **ca_name**  Name of the CA.
- **CN**  Common name matching the certificate signing request.
- **cacert_path**  Absolute path to ca certificates root directory.
- **ca_filename**  Alternative filename for the CA.
cert_path  Path to the cert file.
cert_filename  Alternative filename for the certificate, useful when using special characters in the CN.
crl_file  Full path to the CRL file.

CLI Example:
salt '*' tls.revoke_cert ca_name='koji' ca_filename='ca'

```
salt.modules.tls.set_ca_path(cacert_path)
If wanted, store the aforementioned cacert_path in context to be used as the basepath for further operations

CLI Example:
salt '*' tls.set_ca_path /etc/certs
```

31.16.275 salt.modules.tomcat

Support for Tomcat

This module uses the manager webapp to manage Apache tomcat webapps. If the manager webapp is not configured some of the functions won't work.

Note: The config format was changed in 2014.7.0, but backwards compatibility for the old-style config will be in the 2014.7.1 release.

The following grains/pillar should be set:

```
tomcat-manager:
  user: <username>
  passwd: <password>
```

or the old format:

```
tomcat-manager.user: <username>
tomcat-manager.passwd: <password>
```

Also configure a user in the conf/tomcat-users.xml file:

```
<?xml version='1.0' encoding='utf-8'?>
<tomcat-users>
  <role rolename="manager-script"/>
  <user username="tomcat" password="tomcat" roles="manager-script"/>
</tomcat-users>
```

Note:

- if you use only this module for deployments you've might want to strict access to the manager only from localhost for more info: http://tomcat.apache.org/tomcat-7.0-doc/manager-howto.html#Configuring_Manager_Application_Access

- Tested on:
  JVM Vendor: Sun Microsystems Inc.
  JVM Version: 1.6.0_43-b01
  OS Architecture: amd64
OS Name: Linux
OS Version: 2.6.32-358.el6.x86_64
Tomcat Version: Apache Tomcat/7.0.37

```
salt.modules.tomcat.deploy_war(war, context, force='no', url='http://localhost:8080/manager',
saltenv='base', timeout=180, env=None,
temp_war_location=None)
```

Deploy a WAR file

- `war` absolute path to WAR file (should be accessible by the user running tomcat) or a path supported by the salt.modules.cp.get_file function
- `context` the context path to deploy
- `force` [False] set True to deploy the webapp even one is deployed in the context
- `url` [http://localhost:8080/manager] the URL of the server manager webapp
- `saltenv` [base] the environment for WAR file in used by salt.modules.cp.get_url function
- `timeout` [180] timeout for HTTP request
- `temp_war_location` [None] use another location to temporarily copy to war file by default the system's temp directory is used

CLI Examples:

```
cp module
salt '*' tomcat.deploy_war salt://application.war /api
salt '*' tomcat.deploy_war salt://application.war /api no
salt '*' tomcat.deploy_war salt://application.war /api yes http://localhost:8080/manager
```

minion local file system

```
salt '*' tomcat.deploy_war /tmp/application.war /api
salt '*' tomcat.deploy_war /tmp/application.war /api no
salt '*' tomcat.deploy_war /tmp/application.war /api yes http://localhost:8080/manager
```

```
salt.modules.tomcat.fullversion()
```

Return all server information from catalina.sh version

CLI Example:
```
salt '*' tomcat.fullversion
```

```
salt.modules.tomcat.leaks(url='http://localhost:8080/manager', timeout=180)
```

Find memory leaks in tomcat

- `url` [http://localhost:8080/manager] the URL of the server manager webapp
- `timeout` [180] timeout for HTTP request

CLI Examples:
```
salt '*' tomcat.leaks
```

```
salt.modules.tomcat.ls(url='http://localhost:8080/manager', timeout=180)
```

list all the deployed webapps

- `url` [http://localhost:8080/manager] the URL of the server manager webapp
- `timeout` [180] timeout for HTTP request

31.16. Full list of builtin execution modules
CLI Examples:

salt '*' tomcat.ls
salt '*' tomcat.ls http://localhost:8080/manager

salt.modules.tomcat.passwd(passwd, user='-', alg='md5', realm=None)
This function replaces the $CATALINA_HOME/bin/digest.sh script convert a clear-text password to the
$CATALINA_BASE/conf/tomcat-users.xml format

CLI Examples:

salt '*' tomcat.passwd secret
salt '*' tomcat.passwd secret tomcat sha1
salt '*' tomcat.passwd secret tomcat sha1 'Protected Realm'

salt.modules.tomcat.reload(app, url='http://localhost:8080/manager', timeout=180)
Reload the webapp
app the webapp context path
url [http://localhost:8080/manager] the URL of the server manager webapp
timeout [180] timeout for HTTP request

CLI Examples:

salt '*' tomcat.reload /jenkins
salt '*' tomcat.reload /jenkins http://localhost:8080/manager

salt.modules.tomcat.serverinfo(url='http://localhost:8080/manager', timeout=180)
return details about the server
url [http://localhost:8080/manager] the URL of the server manager webapp
timeout [180] timeout for HTTP request

CLI Examples:

salt '*' tomcat.serverinfo
salt '*' tomcat.serverinfo http://localhost:8080/manager

salt.modules.tomcat.sessions(app, url='http://localhost:8080/manager', timeout=180)
return the status of the webapp sessions
app the webapp context path
url [http://localhost:8080/manager] the URL of the server manager webapp
timeout [180] timeout for HTTP request

CLI Examples:

salt '*' tomcat.sessions /jenkins
salt '*' tomcat.sessions /jenkins http://localhost:8080/manager

salt.modules.tomcat.signal(signal=None)
Signals catalina to start, stop, securestart, forcestop.

CLI Example:

salt '*' tomcat.signal start

salt.modules.tomcat.start(app, url='http://localhost:8080/manager', timeout=180)
Start the webapp
**app** the webapp context path

**url** [http://localhost:8080/manager] the URL of the server manager webapp

**timeout** timeout for HTTP request

CLI Examples:

```shell
salt '*' tomcat.start /jenkins
salt '*' tomcat.start /jenkins http://localhost:8080/manager
```

**salt.modules.tomcat.status**(*url='http://localhost:8080/manager', timeout=180*)

Used to test if the tomcat manager is up

**url** [http://localhost:8080/manager] the URL of the server manager webapp

**timeout** [180] timeout for HTTP request

CLI Examples:

```shell
salt '*' tomcat.status
salt '*' tomcat.status http://localhost:8080/manager
```

**salt.modules.tomcat.status_webapp**(*app, url='http://localhost:8080/manager', timeout=180*)

return the status of the webapp (stopped | running | missing)

**app** the webapp context path

**url** [http://localhost:8080/manager] the URL of the server manager webapp

**timeout** [180] timeout for HTTP request

CLI Examples:

```shell
salt '*' tomcat.status_webapp /jenkins
salt '*' tomcat.status_webapp /jenkins http://localhost:8080/manager
```

**salt.modules.tomcat.stop**(*app, url='http://localhost:8080/manager', timeout=180*)

Stop the webapp

**app** the webapp context path

**url** [http://localhost:8080/manager] the URL of the server manager webapp

**timeout** [180] timeout for HTTP request

CLI Examples:

```shell
salt '*' tomcat.stop /jenkins
salt '*' tomcat.stop /jenkins http://localhost:8080/manager
```

**salt.modules.tomcat.undeploy**(*app, url='http://localhost:8080/manager', timeout=180*)

Undeploy a webapp

**app** the webapp context path

**url** [http://localhost:8080/manager] the URL of the server manager webapp

**timeout** [180] timeout for HTTP request

CLI Examples:

```shell
salt '*' tomcat.undeploy /jenkins
salt '*' tomcat.undeploy /jenkins http://localhost:8080/manager
```
salt.modules.tomcat.version()
   Return server version from catalina.sh version
   
   CLI Example:
   salt '*' tomcat.version

31.16.276 salt.modules.trafficserver

Apache Traffic Server execution module.

New in version 2015.8.0.

traffic_line is used to execute individual Traffic Server commands and to script multiple commands in a shell.

salt.modules.trafficserver.alarms()
   List all alarm events that have not been acknowledged (cleared).
   salt '*' trafficserver.alarms

salt.modules.trafficserver.bounce_cluster()
   Bounce all Traffic Server nodes in the cluster. Bouncing Traffic Server shuts down and immediately restarts
   Traffic Server, node-by-node.
   salt '*' trafficserver.bounce_cluster

salt.modules.trafficserver.bounce_local(drain=False)
   Bounce Traffic Server on the local node. Bouncing Traffic Server shuts down and immediately restarts the
   Traffic Server node.
   
   This option modifies the behavior of traffic_line -b and traffic_line -L such that traffic_server is
   not shut down until the number of active client connections drops to the number given by the
   proxy.config.restart.active_client_threshold configuration variable.
   
   salt '*' trafficserver.bounce_local
   salt '*' trafficserver.bounce_local drain=True

salt.modules.trafficserver.clear_alarms(alarm)
   Clear (acknowledge) an alarm event. The arguments are “all” for all current alarms, a specific alarm number
   (e.g. “1”), or an alarm string identifier (e.g. “MGMT_ALARM_PROXY_CONFIG_ERROR”).
   
   salt '*' trafficserver.clear_alarms [all | #event | name]

salt.modules.trafficserver.clear_cluster()
   Clears accumulated statistics on all nodes in the cluster.
   
   salt '*' trafficserver.clear_cluster

salt.modules.trafficserver.clear_node()
   Clears accumulated statistics on the local node.
   
   salt '*' trafficserver.clear_node

salt.modules.trafficserver.match_var(regex)
   Display the current values of all performance statistics or configuration variables whose names match the
   given regular expression.
salt '%%' trafficserver.match_var regex

salt.modules.trafficserver.offline(path)
Mark a cache storage device as offline. The storage is identified by a path which must match exactly a path
specified in storage.config. This removes the storage from the cache and redirects requests that would have
used this storage to other storage. This has exactly the same effect as a disk failure for that storage. This does
not persist across restarts of the traffic_server process.

salt '%%' trafficserver.offline /path/to/cache

salt.modules.trafficserver.read_var('args)
Read variable definitions from the traffic_line command
This allows reading arbitrary key=value pairs from within trafficserver

salt '%%' trafficserver.read_var proxy.process.http.tcp_hit_count_stat

salt.modules.trafficserver.refresh()
Initiate a Traffic Server configuration file reread. Use this command to update the running configuration after
any configuration file modification.
The timestamp of the last reconfiguration event (in seconds since epoch) is published in the
proxy.node.config.reconfigure_time metric.

salt '%%' trafficserver.refresh

salt.modules.trafficserver.restart_cluster()
Restart the traffic_manager process and the traffic_server process on all the nodes in a cluster.

salt '%%' trafficserver.restart_cluster

salt.modules.trafficserver.restart_local(drain=False)
Restart the traffic_manager and traffic_server processes on the local node.
This option modifies the behavior of traffic_line -b and traffic_line -L such that traffic_server is
not shut down until the number of active client connections drops to the number given by the
proxy.config.restart.active_client_threshold configuration variable.

salt '%%' trafficserver.restart_local
salt '%%' trafficserver.restart_local drain=True

salt.modules.trafficserver.set_var(variable, value)

salt '%%' trafficserver.set_var proxy.config.http.server_ports

salt.modules.trafficserver.shutdown()
Shut down Traffic Server on the local node.

salt '%%' trafficserver.shutdown

salt.modules.trafficserver.startup()
Start Traffic Server on the local node.

salt '%%' trafficserver.start

salt.modules.trafficserver.status()
Show the current proxy server status, indicating if we’re running or not.
salt ' '*' trafficserver.status

salt.modules.trafficserver.zero_cluster()
Reset performance statistics to zero across the cluster.
salt ' '*' trafficserver.zero_cluster

salt.modules.trafficserver.zero_node()
Reset performance statistics to zero on the local node.
salt ' '*' trafficserver.zero_cluster

31.16.277 salt.modules.tuned

Interface to Red Hat tuned-adm module

maintainer  Syed Ali <alicsyed@gmail.com>
maturity  new
depends  tuned-adm
platform  Linux

salt.modules.tuned.active()
Return current active profile
CLI Example:
salt ' '*' tuned.active

salt.modules.tuned.list()
List the profiles available
CLI Example:
salt ' '*' tuned.list

salt.modules.tuned.off()
Turn off all profiles
CLI Example:
salt ' '*' tuned.off

salt.modules.tuned.profile(profile_name)
Activate specified profile
CLI Example:
salt ' '*' tuned.profile virtual-guest

31.16.278 salt.modules.twilio_notify

Module for notifications via Twilio
New in version 2014.7.0.

depends
  • twilio python module
configuration Configure this module by specifying the name of a configuration profile in the minion
config, minion pillar, or master config.

For example:

```
my-twilio-account:
twilio.account_sid: AC32a3c83990934481add5ce1659f04d2
twilio.auth_token: mytoken
```

```
salt.modules.twilio_notify.send_sms(profile, body, to, from_)
```

Send an sms

CLI Example:

```
twilio.send_sms twilio-account "Test sms" +18019999999 +18011111111
```

### 31.16.279 salt.modules.udev

Manage and query udev info

New in version 2015.8.0.

```
salt.modules.udev.env(dev)
```

Return all environment variables udev has for dev

CLI Example:

```
salt '*' udev.env /dev/sda
salt '*' udev.env /sys/class/net/eth0
```

```
salt.modules.udev.info(dev)
```

Extract all info delivered by udevadm

CLI Example:

```
salt '*' udev.info /dev/sda
salt '*' udev.info /sys/class/net/eth0
```

```
salt.modules.udev.links(dev)
```

Return all udev-created device symlinks

CLI Example:

```
salt '*' udev.links /dev/sda
salt '*' udev.links /sys/class/net/eth0
```

```
salt.modules.udev.name(dev)
```

Return the actual dev name(s?) according to udev for dev

CLI Example:

```
salt '*' udev.dev /dev/sda
salt '*' udev.dev /sys/class/net/eth0
```

```
salt.modules.udev.path(dev)
```

Return the physical device path(s?) according to udev for dev

CLI Example:

```
salt '*' udev.path /dev/sda
salt '*' udev.path /sys/class/net/eth0
```
31.16.280 salt.modules.upstart

Module for the management of upstart systems. The Upstart system only supports service starting, stopping and restarting.

Currently (as of Ubuntu 12.04) there is no tool available to disable Upstart services (like update-rc.d). This[1] is the recommended way to disable an Upstart service. So we assume that all Upstart services that have not been disabled in this manner are enabled.

But this is broken because we do not check to see that the dependent services are enabled. Otherwise we would have to do something like parse the output of `"initctl show-config"` to determine if all service dependencies are enabled to start on boot. For example, see the "start on" condition for the lightdm service below[2]. And this would be too hard. So we wait until the upstart developers have solved this problem. :) This is to say that an Upstart service that is enabled may not really be enabled.

Also, when an Upstart service is enabled, should the dependent services be enabled too? Probably not. But there should be a notice about this, at least.

[2] example upstart configuration file:

```
lightdm
emits login-session-start
emits desktop-session-start
emits desktop-shutdown
start on (((filesystem and runlevel ![06]) and started dbus) and (drm-device-added card0 PRIMARY_DEVICE_FOR_DISPLAY=1 or stopped udev-fallback-graphics)) or runlevel PREVLEVEL=S)
stop on runlevel [016]
```

**Warning:** This module should not be used on Red Hat systems. For these, the rh_service module should be used, as it supports the hybrid upstart/sysvinit system used in RHEL/CentOS 6.

salt.modules.upstart.available(name)

   Returns True if the specified service is available, otherwise returns False.

   CLI Example:

   ```
salt '*' service.available sshd
   ```

salt.modules.upstart.disable(name, **kwargs)

   Disable the named service from starting on boot

   CLI Example:

   ```
salt '*' service.disable <service name>
   ```

salt.modules.upstart.disabled(name)

   Check to see if the named service is disabled to start on boot

   CLI Example:

   ```
salt '*' service.disabled <service name>
   ```

salt.modules.upstart.enable(name, **kwargs)

   Enable the named service to start at boot

   CLI Example:

   ```
salt '*' service.enable <service name>
   ```
### Salt Modules: upstart

#### enabled

**salt.modules.upstart.enabled(name, **kwargs)**

Check to see if the named service is enabled to start on boot

**CLI Example:**

```
salt '*' service.enabled <service name>
```

#### force_reload

**salt.modules.upstart.force_reload(name)**

Force-reload the named service

**CLI Example:**

```
salt '*' service.force_reload <service name>
```

#### full_restart

**salt.modules.upstart.full_restart(name)**

Do a full restart (stop/start) of the named service

**CLI Example:**

```
salt '*' service.full_restart <service name>
```

#### get_all

**salt.modules.upstart.get_all()**

Return all installed services

**CLI Example:**

```
salt '*' service.get_all
```

#### get_disabled

**salt.modules.upstart.get_disabled()**

Return the disabled services

**CLI Example:**

```
salt '*' service.get_disabled
```

#### get_enabled

**salt.modules.upstart.get_enabled()**

Return the enabled services

**CLI Example:**

```
salt '*' service.get_enabled
```

#### missing

**salt.modules.upstart.missing(name)**

The inverse of service.available. Returns True if the specified service is not available, otherwise returns False.

**CLI Example:**

```
salt '*' service.missing sshd
```

#### reload

**salt.modules.upstart.reload(name)**

Reload the named service

**CLI Example:**

```
salt '*' service.reload <service name>
```

#### restart

**salt.modules.upstart.restart(name)**

Restart the named service

**CLI Example:**
salt '*' service.restart <service name>

salt.modules.upstart.start(name)
Start the specified service
CLI Example:
    salt '*' service.start <service name>

salt.modules.upstart.status(name, sig=None)
Return the status for a service, returns a bool whether the service is running.
CLI Example:
    salt '*' service.status <service name>

salt.modules.upstart.stop(name)
Stop the specified service
CLI Example:
    salt '*' service.stop <service name>

31.16.281 salt.modules.uptime

Wrapper around uptime API

salt.modules.uptime.check_exists(name)
Check if a given URL is in being monitored by uptime
CLI Example:
    salt '*' uptime.check_exists http://example.org

salt.modules.uptime.checks_list()
List URL checked by uptime
CLI Example:
    salt '*' uptime.checks_list

salt.modules.uptime.create(name, **params)
Create a check on a given URL.
Additional parameters can be used and are passed to API (for example interval, maxTime, etc). See the documentation https://github.com/fzaninotto/uptime for a full list of the parameters.
CLI Example:
    salt '*' uptime.create http://example.org

salt.modules.uptime.delete(name)
Delete a check on a given URL
CLI Example:
    salt '*' uptime.delete http://example.org
31.16.282  salt.modules.useradd

Manage users with the useradd command

```python
salt.modules.useradd.add(name, uid=None, gid=None, groups=None, home=None, shell=None,
unique=True, system=False, fullname='`, roomnumber='`, workphone='`,
homephone='`, createhome=True, loginclass=None)
```

Add a user to the minion

CLI Example:

```bash
salt '*' user.add name <uid> <gid> <groups> <home> <shell>
```

```python
salt.modules.useradd.chfullname(name, fullname)
```

Change the user's Full Name

CLI Example:

```bash
salt '*' user.chfullname foo "Foo Bar"
```

```python
salt.modules.useradd.chgid(name, gid)
```

Change the default group of the user

CLI Example:

```bash
salt '*' user.chgid foo 4376
```

```python
salt.modules.useradd.chgroups(name, groups, append=False)
```

Change the groups to which this user belongs

- **name**: User to modify
- **groups**: Groups to set for the user
- **append**: [False] If True, append the specified group(s). Otherwise, this function will replace the user's groups with the specified group(s).

CLI Examples:

```bash
salt '*' user.chgroups foo wheel,root
salt '*' user.chgroups foo wheel,root append=True
```

```python
salt.modules.useradd.chhome(name, home, persist=False)
```

Change the home directory of the user, pass True for persist to move files to the new home directory if the old home directory exist.

CLI Example:

```bash
salt '*' user.chhome foo /home/users/foo True
```

```python
salt.modules.useradd.chhomephone(name, homephone)
```

Change the user's Home Phone

CLI Example:

```bash
salt '*' user.chhomephone foo 7735551234
```

```python
salt.modules.useradd.chloginclass(name, loginclass)
```

Change the default login class of the user

- **Note**: This function only applies to OpenBSD systems.

31.16. Full list of builtin execution modules
CLI Example:

```
salt '*' user.chloginclass foo staff
```

```python
salt.modules.useradd.chroomnumber(name, roomnumber)

Change the user's Room Number

CLI Example:

```
salt '*' user.chroomnumber foo 123
```
```
salt.modules.useradd.chshell(name, shell)

Change the default shell of the user

CLI Example:

```
salt '*' user.chshell foo /bin/zsh
```
```
salt.modules.useradd.chuid(name, uid)

Change the uid for a named user

CLI Example:

```
salt '*' user.chuid foo 4376
```
```
salt.modules.useradd.chworkphone(name, workphone)

Change the user's Work Phone

CLI Example:

```
salt '*' user.chworkphone foo 7735550123
```
```
salt.modules.useradd.delete(name, remove=False, force=False)

Remove a user from the minion

CLI Example:

```
salt '*' user.delete name remove=True force=True
```
```
salt.modules.useradd.get_loginclass(name)

Get the login class of the user

Note: This function only applies to OpenBSD systems.

CLI Example:

```
salt '*' user.get_loginclass foo
```
```
salt.modules.useradd.getent(refresh=False)

Return the list of all info for all users

CLI Example:

```
salt '*' user.getent
```
```
salt.modules.useradd.info(name)

Return user information

CLI Example:

```
salt '*' user.info root
```
salt.modules.useradd.list_groups(name)
Return a list of groups the named user belongs to
CLI Example:
```
salt '*' user.list_groups foo
```

salt.modules.useradd.list_users()
Return a list of all users
CLI Example:
```
salt '*' user.list_users
```

salt.modules.useradd.rename(name, new_name)
Change the username for a named user
CLI Example:
```
salt '*' user.rename name new_name
```

31.16.283 salt.modules.uwsgi

maintainer Peter Baumgartner <pete@lincolnloop.com>
maturity new
platform all
salt.modules.uwsgi.stats(socket)
Return the data from uwsgi --connect-and-read as a dictionary.
socket The socket the uWSGI stats server is listening on
CLI Example:
```
salt '*' uwsgi.stats /var/run/mystatsserver.sock
salt '*' uwsgi.stats 127.0.0.1:5050
```

31.16.284 salt.modules.varnish

Support for Varnish
New in version 2014.7.0.

Note: These functions are designed to work with all implementations of Varnish from 3.x onwards

salt.modules.varnish.ban(ban_expression)
Add ban to the varnish cache
CLI Example:
```
salt '*' varnish.ban ban_expression
```
salt.modules.varnish.ban_list()
List varnish cache current bans

CLI Example:
salt '*' varnish.ban_list

salt.modules.varnish.param_set(param, value)
Set a param in varnish cache

CLI Example:
salt '*' varnish.param_set param value

salt.modules.varnish.param_show(param=None)
Show params of varnish cache

CLI Example:
salt '*' varnish.param_show param

salt.modules.varnish.purge()
Purge the varnish cache

CLI Example:
salt '*' varnish.purge

salt.modules.varnish.version()
Return server version from varnishd -V

CLI Example:
salt '*' varnish.version

31.16.285 salt.modules.vbox_guest

VirtualBox Guest Additions installer

salt.modules.vbox_guest.additions_install(*args, **kwargs)
Install VirtualBox Guest Additions. Uses the CD, connected by VirtualBox.

To connect VirtualBox Guest Additions via VirtualBox graphical interface press `Host+D` (`Host` is usually `Right Ctrl`).

See https://www.virtualbox.org/manual/ch04.html#idp52733088 for more details.

CLI Example:
salt '*' vbox_guest.additions_install
salt '*' vbox_guest.additions_install reboot=True
salt '*' vbox_guest.additions_install upgrade_os=True

Parameters

- **reboot** (bool) -- reboot computer to complete installation
- **upgrade_os** (bool) -- upgrade OS (to ensure the latests version of kernel and developer tools are installed)

Returns version of VirtualBox Guest Additions or string with error
**salt.modules.vbox_guest.additions_mount()**

Mount VirtualBox Guest Additions CD to the temp directory.

To connect VirtualBox Guest Additions via VirtualBox graphical interface press `Host+D` (`Host` is usually `Right Ctrl`).

CLI Example:

```
salt '*' vbox_guest.additions_mount
```

Returns True or OSError exception

**salt.modules.vbox_guest.additions_remove(**kwargs**)**

Remove VirtualBox Guest Additions.

Firstly it tries to uninstall itself by executing `/opt/VBoxGuestAdditions-VERSION/uninstall.run uninstall`. It uses the CD, connected by VirtualBox if it fails.

CLI Example:

```
salt '*' vbox_guest.additions_remove
salt '*' vbox_guest.additions_remove force=True
```

Parameters **force** *(bool)* -- force VirtualBox Guest Additions removing

Returns True if VirtualBox Guest Additions were removed successfully else False

**salt.modules.vbox_guest.additions_umount(mount_point)**

Unmount VirtualBox Guest Additions CD from the temp directory.

CLI Example:

```
salt '*' vbox_guest.additions_umount
```

Parameters **mount_point** -- directory VirtualBox Guest Additions is mounted to

Returns True or an string with error

**salt.modules.vbox_guest.additions_version()**

Check VirtualBox Guest Additions version.

CLI Example:

```
salt '*' vbox_guest.additions_version
```

Returns version of VirtualBox Guest Additions or False if they are not installed

**salt.modules.vbox_guest.grant_access_to_shared_folders_to(name, users=None)**

Grant access to auto-mounted shared folders to the users.

User is specified by it's name. To grant access for several users use argument `users`. Access will be denied to the users not listed in `users` argument.

CLI Example:

```
salt '*' vbox_guest.grant_access_to_shared_folders_to fred
salt '*' vbox_guest.grant_access_to_shared_folders_to users ['fred', 'roman']
```
Parameters

- **name** *(str)* -- name of the user to grant access to auto-mounted shared folders to
- **users** *(list of str)* -- list of names of users to grant access to auto-mounted shared folders to (if specified, `name` will not be taken into account)

Returns list of users who have access to auto-mounted shared folders

```python
salt.modules.vbox_guest.list_shared_folders_users()
```

List users who have access to auto-mounted shared folders.

CLI Example:

```
salt '*' vbox_guest.list_shared_folders_users
```

Returns list of users who have access to auto-mounted shared folders

### 31.16.286 `salt.modules.victorops`

Support for VictorOps

New in version 2015.8.0.

Requires an `api_key` in `/etc/salt/minion`

```python
salt.modules.victorops.create_event(message_type=None, routing_key='everybody', **kwargs)
```

Create an event in VictorOps. Designed for use in states.

The following parameters are required:

Parameters `message_type` -- One of the following values: INFO, WARNING, ACKNOWLEDGEMENT, CRITICAL, RECOVERY.

The following parameters are optional:

Parameters

- **routing_key** -- The key for where messages should be routed. By default, sent to `everyone` route.
- **entity_id** -- The name of alerting entity. If not provided, a random name will be assigned.
- **timestamp** -- Timestamp of the alert in seconds since epoch. Defaults to the time the alert is received at VictorOps.

:param timestamp_fmt The date format for the timestamp parameter.

Parameters

- **state_start_time** -- The time this entity entered its current state (seconds since epoch). Defaults to the time alert is received.
- **state_start_time_fmt** -- The date format for the timestamp parameter.
- **state_message** -- Any additional status information from the alert item.
- **entity_is_host** -- Used within VictorOps to select the appropriate display format for the incident.
- **entity_display_name** -- Used within VictorOps to display a human-readable name for the entity.
- **ack_message** -- A user entered comment for the acknowledgment.
- **ack_author** -- The user that acknowledged the incident.

Returns A dictionary with result, entity_id, and message if result was failure.

CLI Example:

```shell
salt myminion victorops.create_event message_type='CRITICAL' routing_key='everyone'
salt myminion victorops.create_event message_type='ACKNOWLEDGEMENT' routing_key='everyone'
salt myminion victorops.create_event message_type='RECOVERY' routing_key='everyone'
```

The following parameters are required: message_type

### 31.16.287 salt.modules.virt

Work with virtual machines managed by libvirt

**depends** libvirt Python module

- `salt.modules.virt.create(vm_)`
  Start a defined domain
  
  CLI Example:
  ```shell
  salt '*' virt.create <vm name>
  ```

- `salt.modules.virt.create_xml_path(path)`
  Start a domain based on the XML-file path passed to the function
  
  CLI Example:
  ```shell
  salt '*' virt.create_xml_path <path to XML file on the node>
  ```

- `salt.modules.virt.create_xml_str(xml)`
  Start a domain based on the XML passed to the function
  
  CLI Example:
  ```shell
  salt '*' virt.create_xml_str <XML in string format>
  ```

- `salt.modules.virt.ctrl_alt_del(vm_)`
  Sends CTRL+ALT+DEL to a VM
  
  CLI Example:
  ```shell
  salt '*' virt.ctrl_alt_del <vm name>
  ```

- `salt.modules.virt.define_vol_xml_path(path)`
  Define a volume based on the XML-file path passed to the function
  
  CLI Example:
  ```shell
  salt '*' virt.define_vol_xml_path <path to XML file on the node>
  ```
salt.modules.virt.define_vol_xml_str(xml)
    Define a volume based on the XML passed to the function
    CLI Example:
    ```
salt '*' virt.define_vol_xml_str <XML in string format>
    ```

salt.modules.virt.define_xml_path(path)
    Define a domain based on the XML-file path passed to the function
    CLI Example:
    ```
salt '*' virt.define_xml_path <path to XML file on the node>
    ```

salt.modules.virt.define_xml_str(xml)
    Define a domain based on the XML passed to the function
    CLI Example:
    ```
salt '*' virt.define_xml_str <XML in string format>
    ```

salt.modules.virt.destroy(vm_)
    Hard power down the virtual machine, this is equivalent to pulling the power
    CLI Example:
    ```
salt '*' virt.destroy <vm name>
    ```

salt.modules.virt.freecpu()
    Return an int representing the number of unallocated cpus on this hypervisor
    CLI Example:
    ```
salt '*' virt.freecpu
    ```

salt.modules.virt.freemem()
    Return an int representing the amount of memory (in MB) that has not been given to virtual machines on this node
    CLI Example:
    ```
salt '*' virt.freemem
    ```

salt.modules.virt.full_info()
    Return the node_info, vm_info and freemem
    CLI Example:
    ```
salt '*' virt.full_info
    ```

salt.modules.virt.get_disks(vm_)
    Return the disks of a named vm
    CLI Example:
    ```
salt '*' virt.get_disks <vm name>
    ```

salt.modules.virt.get_graphics(vm_)
    Returns the information on vnc for a given vm
    CLI Example:
salt.modules.virt.get_graphics <vm name>

salt.modules.virt.get_macs(vm_)
    Return a list of MAC addresses from the named vm
    CLI Example:
    salt '*' virt.get_macs <vm name>

salt.modules.virt.get_nics(vm_)
    Return info about the network interfaces of a named vm
    CLI Example:
    salt '*' virt.get_nics <vm name>

salt.modules.virt.get_profiles(hypervisor=None)
    Return the virt profiles for hypervisor.
    Currently there are profiles for:
    • nic
    • disk
    CLI Example:
    salt '*' virt.get_profiles
    salt '*' virt.get_profiles hypervisor=esxi

salt.modules.virt.get_xml(vm_)
    Returns the XML for a given vm
    CLI Example:
    salt '*' virt.get_xml <vm name>

salt.modules.virt.init(name, cpu, mem, image=None, nic='default', hypervisor='kvm', start=True, disk='default', saltenv='base', **kwargs)
    Initialize a new vm
    CLI Example:
    salt 'hypervisor' virt.init vm_name 4 512 salt://path/to/image.raw
    salt 'hypervisor' virt.init vm_name 4 512 nic=profile disk=profile

salt.modules.virt.is_hyper()
    Returns a bool whether or not this node is a hypervisor of any kind
    CLI Example:
    salt '*' virt.is_hyper

salt.modules.virt.is_kvm_hyper()
    Returns a bool whether or not this node is a KVM hypervisor
    CLI Example:
    salt '*' virt.is_kvm_hyper

salt.modules.virt.is_xen_hyper()
    Returns a bool whether or not this node is a XEN hypervisor
CLI Example:
```
salt '*' virt.is_xen_hyper
```

`salt.modules.virt.list_active_vms()`
Return a list of names for active virtual machine on the minion
CLI Example:
```
salt '*' virt.list_active_vms
```

`salt.modules.virt.list_inactive_vms()`
Return a list of names for inactive virtual machine on the minion
CLI Example:
```
salt '*' virt.list_inactive_vms
```

`salt.modules.virt.list_vms()`
Return a list of virtual machine names on the minion
CLI Example:
```
salt '*' virt.list_vms
```

`salt.modules.virt.migrate(vm_, target, ssh=False)`
Shared storage migration
CLI Example:
```
salt '*' virt.migrate <vm name> <target hypervisor>
```

`salt.modules.virt.migrate_non_shared(vm_, target, ssh=False)`
Attempt to execute non-shared storage "all" migration
CLI Example:
```
salt '*' virt.migrate_non_shared <vm name> <target hypervisor>
```

`salt.modules.virt.migrate_non_shared_inc(vm_, target, ssh=False)`
Attempt to execute non-shared storage "all" migration
CLI Example:
```
salt '*' virt.migrate_non_shared_inc <vm name> <target hypervisor>
```

`salt.modules.virt.node_info()`
Return a dict with information about this node
CLI Example:
```
salt '*' virt.node_info
```

`salt.modules.virt.pause(vm_)`
Pause the named vm
CLI Example:
```
salt '*' virt.pause <vm name>
```

`salt.modules.virt.purge(vm_, dirs=False)`
Recursively destroy and delete a virtual machine, pass True for dir's to also delete the directories containing the virtual machine disk images - USE WITH EXTREME CAUTION!
CLI Example:

```bash
salt '*' virt.purge <vm name>
```

 предназначен для удаления виртуальной машины.

CLI Example:

```bash
salt '*' virt.reboot <vm name>
```

Reboota domain via ACPI request

CLI Example:

```bash
salt '*' virt.reset <vm name>
```

Reset a VM by emulating the reset button on a physical machine

CLI Example:

```bash
salt '*' virt.resume <vm name>
```

Resume the named vm

CLI Example:

```bash
salt '*' virt.seed_non_shared_migrate <disks>
```

Non shared migration requires that the disks be present on the migration destination, pass the disks information via this function, to the migration destination before executing the migration.

CLI Example:

```bash
salt '*' virt.set_autostart <vm name> <on | off>
```

Set the autostart flag on a VM so that the VM will start with the host system on reboot.

CLI Example:

```bash
salt '*' virt.set_mem <vm name> <memory> <on | off>
```

Changes the amount of memory allocated to VM. The VM must be shutdown for this to work.

CLI Example:

```bash
salt '*' virt.set_cpu <vm name> <vcpus>
```

Changes the amount of vcpus allocated to VM. The VM must be shutdown for this to work.

CLI Example:
salt '*' virt.shutdown <vm name>

salt.modules.virt.start(vm_)

    Alias for the obscurely named `create` function

    CLI Example:

    salt '*' virt.start <vm name>

salt.modules.virt.stop(vm_)

    Alias for the obscurely named `destroy` function

    CLI Example:

    salt '*' virt.stop <vm name>

salt.modules.virt.undefine(vm_)

    Remove a defined vm, this does not purge the virtual machine image, and this only works if the vm is powered down

    CLI Example:

    salt '*' virt.undefine <vm name>

salt.modules.virt.virt_type()

    Returns the virtual machine type as a string

    CLI Example:

    salt '*' virt.virt_type

salt.modules.virt.vm_cputime(vm_=None)

    Return cputime used by the vms on this hyper in a list of dicts:

    [  
      'your-vm': {  
        'cputime' <int>,  
        'cputime_percent' <int>  
      },  
      ...  
    ]

    If you pass a VM name in as an argument then it will return info for just the named VM, otherwise it will return all VMs.

    CLI Example:

    salt '*' virt.vm_cputime

salt.modules.virt.vm_diskstats(vm_=None)

    Return disk usage counters used by the vms on this hyper in a list of dicts:

    [  
      'your-vm': {  
        'rd_req' : 0,  
        'rd_bytes' : 0,  
        'wr_req' : 0,  
        'wr_bytes' : 0,  
        'errs' : 0  
      },  
    ]
If you pass a VM name in as an argument then it will return info for just the named VM, otherwise it will return all VMs.

CLI Example:

```
salt '*' virt.vm_blockstats
```

```
salt.modules.virt.vm_info(vm_=None)

Return detailed information about the vms on this hyper in a list of dicts:

```
[
    'your-vm': {
        'cpu': <int>,
        'maxMem': <int>,
        'mem': <int>,
        'state': '<state>',
        'cputime' <int>
    },
    ...
]
```

If you pass a VM name in as an argument then it will return info for just the named VM, otherwise it will return all VMs.

CLI Example:

```
salt '*' virt.vm_info
```

```
salt.modules.virt.vm_netstats(vm_=None)

Return combined network counters used by the vms on this hyper in a list of dicts:

```
[
    'your-vm': {
        'rx_bytes' : 0,
        'rx_packets' : 0,
        'rx_errs' : 0,
        'rx_drop' : 0,
        'tx_bytes' : 0,
        'tx_packets' : 0,
        'tx_errs' : 0,
        'tx_drop' : 0
    },
    ...
]
```

If you pass a VM name in as an argument then it will return info for just the named VM, otherwise it will return all VMs.

CLI Example:

```
salt '*' virt.vm_netstats
```

```
salt.modules.virt.vm_state(vm_=None)

Return list of all the vms and their state.

If you pass a VM name in as an argument then it will return info for just the named VM, otherwise it will return all VMs.

31.16. Full list of builtin execution modules
### 31.16.288 `salt.modules.virtualenv`

Create virtualenv environments

```python
salt.modules.virtualenv_mod.create(path, venv_bin=None, system_site_packages=False, distribute=False, clear=False, python=None, extra_search_dir=None, never_download=None, prompt=None, pip=False, symlinks=None, upgrade=None, user=None, use_vt=False, saltenv='base')
```

Create a virtualenv

- **path** The path to create the virtualenv
- **venv_bin** [None (default `virtualenv`)] The name (and optionally path) of the virtualenv command. This can also be set globally in the minion config file as `virtualenv.venv_bin`.
- **system_site_packages** [False] Passthrough argument given to virtualenv or pyenv
- **distribute** [False] Passthrough argument given to virtualenv
- **pip** [False] Install pip after creating a virtual environment, implies distribute=True
- **clear** [False] Passthrough argument given to virtualenv or pyenv
- **python** [None (default)] Passthrough argument given to virtualenv
- **extra_search_dir** [None (default)] Passthrough argument given to virtualenv
- **never_download** [None (default)] Passthrough argument given to virtualenv if True
- **prompt** [None (default)] Passthrough argument given to virtualenv if not None
- **symlinks** [None] Passthrough argument given to pyenv if True
- **upgrade** [None] Passthrough argument given to pyenv if True
- **user** [None] Set ownership for the virtualenv
- **runas** [None] Set ownership for the virtualenv
- **use_vt** Use VT terminal emulation (see output while installing)

Note: The `runas` argument is deprecated as of 2014.1.0. `user` should be used instead.

```python
salt.modules.virtualenv_mod.get_resource_content(venv, package_or_requirement, resource_name)
```

Returns the content of a resource of a package or a distribution inside a virtualenv

```python
salt.modules.virtualenv_mod.get_resource_path(venv, package_or_requirement, resource_name)
```

Returns the path to a resource of a package or a distribution inside a virtualenv
CLI Example:

```bash
salt '*' virtualenv.get_resource_path /path/to/my/venv my_package my/resource.xml
```

```python
salt.modules.virtualenv_mod.get_site_packages(venv)

Returns the path to the site-packages directory inside a virtualenv
```

CLI Example:

```bash
salt '*' virtualenv.get_site_packages /path/to/my/venv
```

### 31.16.289 salt.modules.win_autoruns

Module for listing programs that automatically run on startup (very alpha...not tested on anything but my Win 7x64)

```python
salt.modules.win_autoruns.list()

Get a list of automatically running programs
```

CLI Example:

```bash
salt '*' autoruns.list
```

### 31.16.290 salt.modules.win_dacl

Manage DACLs on Windows

```python
depends
    • winreg Python module
```

```python
class salt.modules.win_dacl.User

class object that returns a users SID
```

```python
class salt.modules.win_dacl.add_ace(path, objectType, user, permission, acetype, propagation)

add an ace to an object
```

- path: path to the object (i.e. `c:\temp\file`, `HKEY_LOCAL_MACHINE\SOFTWARE\KEY`, etc)
- user: user to add
- permission: permissions for the user acetypes: either allow/deny for each user/permission (ALLOW, DENY)
- propagation: how the ACE applies to children for Registry Keys and Directories (KEY, KEY&SUBKEYS, SUBKEYS)

CLI Example:

```bash
allow domain\fakeuser full control on HKLM\SOFTWARE\somekey, propagate to this key and subkeys
salt 'myminion' win_dacl.add_ace 'HKEY_LOCAL_MACHINE\SOFTWARE\somekey' 'Registry' 'domain\fakeuser' 'FULLCONTROL' 'ALLOW' 'KEY&SUBKEYS'
```

```python
class salt.modules.win_dacl.check_ace(path, objectType, user=None, permission=None, acetype=None, propagation=None, exactPermissionMatch=False)

checks a path to verify the ACE (access control entry) specified exists returns 'Exists' true if the ACE exists, false if it does not
```

- path: path to the file/reg key user: user that the ACL is for permission: permission to test for (READ, FULLCONTROL, etc) acetype: the type of ACE (ALLOW or DENY) propagation: the propagation type of the ACE (FILES, FOLDERS, KEY, KEY&SUBKEYS, SUBKEYS, etc) exactPermissionMatch: the ACL must match exactly, IE if READ is specified, the user must have READ exactly and not FULLCONTROL (which also has the READ permission obviously)
salt.modules.win_dacl.check_inheritance(path, objectType)
check a specified path to verify if inheritance is enabled returns 'Inheritance' of True/False
hkey: HKEY_LOCAL_MACHINE, HKEY_CURRENT_USER, etc path: path of the registry key to check

class salt.modules.win_dacl.daclConstants
dacl constants used throughout the module

getAceTypeBit(t)
returns the acetype bit of a text value

getAceTypeText(t)
returns the textual representation of a acetype bit

ggetObjectTypeBit(t)
returns the bit value of the string object type

getPermissionBit(t, m)
returns a permission bit of the string permission value for the specified object type

getPermissionText(t, m)
returns the permission textual representation of a specified permission bit/object type

getPropagationBit(t, p)
returns the propagation bit of a text value

getPropagationText(t, p)
returns the textual representation of a propagation bit

getSecurityHkey(s)
returns the necessary string value for an HKEY for the win32security module

processPath(path, objectType)
processes a path/object type combo and returns: registry types with the correct HKEY text representation files/directories with environment variables expanded

salt.modules.win_dacl.disable_inheritance(path, objectType, copy=True)
disable inheritance on an object
copy = True will copy the Inerhited ACEs to the DACL before disabling inheritance

salt.modules.win_dacl.enable_inheritance(path, objectType, clear=False)
enable/disable inheritance on an object
clear = True will remove non-Inherited ACEs from the ACL

salt.modules.win_dacl.get(path, objectType)
get the acl of an object

salt.modules.win_dacl.rm_ace(path, objectType, user, permission, acetype, propagation)
remove an ace to an object
path: path to the object (i.e. c:\temp\file, HKEY_LOCAL_MACHINE\SOFTWARE\KEY, etc) user: user to remove permission: permissions for the user acetypes: either allow/deny for each user/permission (ALLOW, DENY) propagation: how the ACE applies to children for Registry Keys and Directories(KEY, KEY&SUBKEYS, SUBKEYS)

"The entire ACE must match to be removed"

CLI Example:
remove allow domain\fakeuser full control on HKLM\SOFTWARE\somekey propagated to this key and
salt 'myminion' win_dacl.rm_ace 'Registry' 'HKEY_LOCAL_MACHINE\SOFTWARE\somekey' 'domain\fakeuser'
31.16.291 salt.modules.win_disk

Module for gathering disk information on Windows

    depends

    • win32api Python module

salt.modules.win_disk.usage()
    Return usage information for volumes mounted on this minion

    CLI Example:

    salt '*' disk.usage

31.16.292 salt.modules.win_dns_client

Module for configuring DNS Client on Windows systems

    salt.modules.win_dns_client.add_dns(ip, interface='Local Area Connection', index=1)
    Add the DNS server to the network interface (index starts from 1)

    Note: if the interface DNS is configured by DHCP, all the DNS servers will be removed from the interface and
    the requested DNS will be the only one

    CLI Example:

    salt '*' win_dns_client.add_dns <ip> <interface> <index>

    salt.modules.win_dns_client.dns_dhcp(interface='Local Area Connection')
    Configure the interface to get its DNS servers from the DHCP server

    CLI Example:

    salt '*' win_dns_client.dns_dhcp <interface>

    salt.modules.win_dns_client.get_dns_config(interface='Local Area Connection')
    Get the type of DNS configuration (dhcp / static)

    CLI Example:

    salt '*' win_dns_client.get_dns_config 'Local Area Connection'

    salt.modules.win_dns_client.get_dns_servers(interface='Local Area Connection')
    Return a list of the configured DNS servers of the specified interface

    CLI Example:

    salt '*' win_dns_client.get_dns_servers 'Local Area Connection'

    salt.modules.win_dns_client.rm_dns(ip, interface='Local Area Connection')
    Remove the DNS server from the network interface

    CLI Example:

    salt '*' win_dns_client.rm_dns <ip> <interface>
31.16.293 salt.modules.win_file

Manage information about files on the minion, set/read user, group data

depends

- win32api
- win32file
- win32security

salt.modules.win_file.chgrp(path, group)
Change the group of a file

Under Windows, this will do nothing.

While a file in Windows does have a 'primary group', this rarely used attribute generally has no bearing
on permissions unless intentionally configured and is only used to support Unix compatibility features (e.g.
Services For Unix, NFS services).

Salt, therefore, remaps this function to do nothing while still being compatible with Unix behavior. When
managing Windows systems, this function is superfluous and will generate an info level log entry if used
directly.

If you do actually want to set the 'primary group' of a file, use file.chgrp.

CLI Example:

```
salt '*' file.chgrp c:\temp\test.txt administrators
```

salt.modules.win_file.chown(path, user=None, group=None, pgroup=None, follow_symlinks=True)
Chown a file, pass the file the desired user and group

Under Windows, the group parameter will be ignored.

This is because while files in Windows do have a 'primary group' property, this is rarely used. It generally
has no bearing on permissions unless intentionally configured and is most commonly used to provide Unix
compatibility (e.g. Services For Unix, NFS services).

If you do want to change the 'primary group' property and understand the implications, pass the Windows
only parameter, pgroup, instead.

To set the primary group to 'None', it must be specified in quotes. Otherwise Salt will interpret it as the Python
value of None and no primary group changes will occur. See the example below.

CLI Example:

```
salt '*' file.chown c:\temp\test.txt myusername
salt '*' file.chown c:\temp\test.txt myusername pgroup=Administrators
salt '*' file.chown c:\temp\test.txt myusername "pgroup='None'"
```

salt.modules.win_file.chpgrp(path, group)
Change the group of a file

Under Windows, this will set the rarely used primary group of a file. This generally has no bearing on permis-
sions unless intentionally configured and is most commonly used to provide Unix compatibility (e.g. Services
For Unix, NFS services).

Ensure you know what you are doing before using this function.

To set the primary group to 'None', it must be specified in quotes. Otherwise Salt will interpret it as the Python
value of None and no primary group changes will occur. See the example below.

CLI Example:
salt.modules.win_file.get_attributes(path)
Return a dictionary object with the Windows file attributes for a file.

CLI Example:
```
salt '*' file.get_attributes c:\temp\test.txt
```

salt.modules.win_file.get_gid(path, follow_symlinks=True)
Return the id of the group that owns a given file

Under Windows, this will return the uid of the file.

While a file in Windows does have a `primary group', this rarely used attribute generally has no bearing on permissions unless intentionally configured and is only used to support Unix compatibility features (e.g. Services For Unix, NFS services).

Salt, therefore, remaps this function to provide functionality that somewhat resembles Unix behavior for API compatibility reasons. When managing Windows systems, this function is superfluous and will generate an info level log entry if used directly.

If you do actually want to access the `primary group' of a file, use file.get_pgid.

CLI Example:
```
salt '*' file.get_gid c:\temp\test.txt
```

salt.modules.win_file.get_group(path, follow_symlinks=True)
Return the group that owns a given file

Under Windows, this will return the user (owner) of the file.

While a file in Windows does have a `primary group', this rarely used attribute generally has no bearing on permissions unless intentionally configured and is only used to support Unix compatibility features (e.g. Services For Unix, NFS services).

Salt, therefore, remaps this function to provide functionality that somewhat resembles Unix behavior for API compatibility reasons. When managing Windows systems, this function is superfluous and will generate an info level log entry if used directly.

If you do actually want to access the `primary group' of a file, use file.get_pgroup.

CLI Example:
```
salt '*' file.get_group c:\temp\test.txt
```

salt.modules.win_file.get_mode(path)
Return the mode of a file

Right now we're just returning None because Windows' doesn't have a mode like Linux

CLI Example:
```
salt '*' file.get_mode /etc/passwd
```

salt.modules.win_file.get_pgid(path, follow_symlinks=True)
Return the id of the primary group that owns a given file (Windows only)

This function will return the rarely used primary group of a file. This generally has no bearing on permissions unless intentionally configured and is most commonly used to provide Unix compatibility (e.g. Services For Unix, NFS services).
Ensure you know what you are doing before using this function.

CLI Example:

```bash
salt '*' file.get_pgid c:\temp\test.txt
```

salt.modules.win_file.get_pgroup(path, follow_symlinks=True)
Return the name of the primary group that owns a given file (Windows only)

This function will return the rarely used primary group of a file. This generally has no bearing on permissions unless intentionally configured and is most commonly used to provide Unix compatibility (e.g. Services For Unix, NFS services).

Ensure you know what you are doing before using this function.

The return value may be `None', e.g. if the user is not on a domain. This is a valid group - do not confuse this with the Salt/Python value of None which means no value was returned. To be certain, use the get_pgid function which will return the SID, including for the system `None' group.

CLI Example:

```bash
salt '*' file.get_pgid c:\temp\test.txt
```

salt.modules.win_file.get_uid(path, follow_symlinks=True)
Return the id of the user that owns a given file

Symlinks are followed by default to mimic Unix behavior. Specify follow_symlinks=False to turn off this behavior.

CLI Example:

```bash
salt '*' file.get_uid c:\temp\test.txt
salt '*' file.get_uid c:\temp\test.txt follow_symlinks=False
```

salt.modules.win_file.get_user(path, follow_symlinks=True)
Return the user that owns a given file

Symlinks are followed by default to mimic Unix behavior. Specify follow_symlinks=False to turn off this behavior.

CLI Example:

```bash
salt '*' file.get_user c:\temp\test.txt
salt '*' file.get_user c:\temp\test.txt follow_symlinks=False
```

salt.modules.win_file.gid_to_group(gid)
Convert the group id to the group name on this system

Under Windows, because groups are just another ACL entity, this function behaves the same as uid_to_user.

For maintaining Windows systems, this function is superfluous and only exists for API compatibility with Unix. Use the uid_to_user function instead; an info level log entry will be generated if this function is used directly.

CLI Example:

```bash
salt '*' file.gid_to_group S-1-5-21-626487655-2533044672-482107328-1010
```

salt.modules.win_file.group_to_gid(group)
Convert the group to the gid on this system

Under Windows, because groups are just another ACL entity, this function behaves the same as user_to_uid, except if None is given, ” is returned.
For maintaining Windows systems, this function is superfluous and only exists for API compatibility with Unix. Use the user_to_uid function instead; an info level log entry will be generated if this function is used directly.

CLI Example:
```
salt '...' file.group_to_gid administrators
```

`salt.modules.win_file.is_link(path)`

Return the path that a symlink points to

This is only supported on Windows Vista or later.

Inline with Unix behavior, this function will raise an error if the path is not a symlink, however, the error raised will be a SaltInvocationError, not an OSError.

CLI Example:
```
salt '...' file.is_link /path/to/link
```

`salt.modules.win_file.lchown(path, user, group=None, pgroup=None)`

Chown a file, pass the file the desired user and group without following any symlinks.

Under Windows, the group parameter will be ignored.

This is because while files in Windows do have a 'primary group' property, this is rarely used. It generally has no bearing on permissions unless intentionally configured and is most commonly used to provide Unix compatibility (e.g. Services For Unix, NFS services).

If you do want to change the 'primary group' property and understand the implications, pass the Windows only parameter, pgroup, instead.

To set the primary group to 'None', it must be specified in quotes. Otherwise Salt will interpret it as the Python value of None and no primary group changes will occur. See the example below.

CLI Example:
```
salt '...' file.lchown c:\temp\test.txt myusername
salt '...' file.lchown c:\temp\test.txt myusername pgroup=Administrators
salt '...' file.lchown c:\temp\test.txt myusername "pgroup='None'"
```

`salt.modules.win_file.readlink(path)`

Return the path that a symlink points to

This is only supported on Windows Vista or later.

Inline with Unix behavior, this function will raise an error if the path is not a symlink, however, the error raised will be a SaltInvocationError, not an OSError.

CLI Example:
```
salt '...' file.readlink /path/to/link
```

`salt.modules.win_file.set_attributes(path, archive=None, hidden=None, normal=None, notIndexed=None, readonly=None, system=None, temporary=None)`

Set file attributes for a file. Note that the normal attribute means that all others are false. So setting it will clear all others.

CLI Example:
```
salt '...' file.set_attributes c:\temp\a.txt normal=True
salt '...' file.set_attributes c:\temp\a.txt readonly=True hidden=True
```
salt.modules.win_file.set_mode(path, mode)
Set the mode of a file
This just calls get_mode, which returns None because we don’t use mode on Windows

CLI Example:
```
salt '*' file.set_mode /etc/passwd 0644
```

salt.modules.win_file.stats(path, hash_type='md5', follow_symlinks=True)
Return a dict containing the stats for a given file
Under Windows, gid will equal uid and group will equal user.
While a file in Windows does have a `primary group`, this rarely used attribute generally has no bearing
on permissions unless intentionally configured and is only used to support Unix compatibility features (e.g.
Services For Unix, NFS services).
Salt, therefore, remaps these properties to keep some kind of compatibility with Unix behavior. If the `primary
group` is required, it can be accessed in the pgroup and pgid properties.

CLI Example:
```
salt '*' file.stats /etc/passwd
```

salt.modules.win_file.symlink(src, link)
Create a symbolic link to a file
This is only supported with Windows Vista or later and must be executed by a user with the SeCreateSymbolicLink privilege.
The behavior of this function matches the Unix equivalent, with one exception - invalid symlinks cannot be
created. The source path must exist. If it doesn’t, an error will be raised.

CLI Example:
```
salt '*' file.symlink /path/to/file /path/to/link
```

salt.modules.win_file.uid_to_user(uid)
Convert a uid to a user name

CLI Example:
```
salt '*' file.uid_to_user S-1-5-21-626487655-2533044672-482107328-1010
```

salt.modules.win_file.user_to_uid(user)
Convert user name to a uid

CLI Example:
```
salt '*' file.user_to_uid myusername
```

31.16.294 salt.modules.win_firewall
Module for configuring Windows Firewall
salt.modules.win_firewall.add_rule(name, localport, protocol='tcp', action='allow', dir='in')
New in version 2015.5.0.
Add a new firewall rule

CLI Example:
salt '*' firewall.add_rule 'test' '8080' 'tcp'

salt.modules.win_firewall.delete_rule(name, localport, protocol='tcp', dir='in')

- New in version 2015.8.0.
- Delete an existing firewall rule

**CLI Example:**

```
salt '*' firewall.delete_rule 'test' '8080' 'tcp' 'in'
```

salt.modules.win_firewall.disable(profile='allprofiles')

- Disable firewall profile
- **param profile:** (default: allprofiles)

**CLI Example:**

```
salt '*' firewall.disable
```

salt.modules.win_firewall.enable(profile='allprofiles')

- Enable firewall profile
- **param profile:** (default: allprofiles)

- New in version 2015.5.0.

**CLI Example:**

```
salt '*' firewall.enable
```

salt.modules.win_firewall.get_config()

- Get the status of all the firewall profiles

**CLI Example:**

```
salt '*' firewall.get_config
```

salt.modules.win_firewall.get_rule(name='all')

- New in version 2015.5.0.
- Get firewall rule(s) info

**CLI Example:**

```
salt '*' firewall.get_rule 'MyAppPort'
```

### 31.16.295 salt.modules.win_groupadd

Manage groups on Windows

salt.modules.win_groupadd.add(name, gid=None, system=False)

- Add the specified group

**CLI Example:**

```
salt '*' group.add foo
```

salt.modules.win_groupadd.adduser(name, username)

- add a user to a group

**CLI Example:**

```
salt '*' group.adduser foo username
```

---

31.16. Full list of builtin execution modules 1331
salt.modules.win_groupadd.delete(name)
    Remove the named group
    CLI Example:
    ```
salt '*' group.delete foo
    ```

salt.modules.win_groupadd.deluser(name, username)
    remove a user from a group
    CLI Example:
    ```
salt '*' group.deluser foo username
    ```

salt.modules.win_groupadd.getent(refresh=False)
    Return info on all groups
    CLI Example:
    ```
salt '*' group.getent
    ```

salt.modules.win_groupadd.info(name)
    Return information about a group
    CLI Example:
    ```
salt '*' group.info foo
    ```

salt.modules.win_groupadd.members(name, members_list)
    remove a user from a group
    CLI Example:
    ```
salt '*' group.members foo 'user1,user2,user3'
    ```

31.16.296 salt.modules.win_ip

The networking module for Windows based systems

salt.modules.win_ip.disable(iface)
    Disable an interface
    CLI Example:
    ```
salt -G 'os_family:Windows' ip.disable 'Local Area Connection #2'
    ```

salt.modules.win_ip.enable(iface)
    Enable an interface
    CLI Example:
    ```
salt -G 'os_family:Windows' ip.enable 'Local Area Connection #2'
    ```

salt.modules.win_ip.get_all_interfaces()
    Return configs for all interfaces
    CLI Example:
    ```
salt -G 'os_family:Windows' ip.get_all_interfaces
    ```
salt.modules.win_ip.get_default_gateway()
    Set DNS source to DHCP on Windows
    CLI Example:
    ```
salt -G 'os_family:Windows' ip.get_default_gateway
    ```

salt.modules.win_ip.get_interface(iface)
    Return the configuration of a network interface
    CLI Example:
    ```
salt -G 'os_family:Windows' ip.get_interface 'Local Area Connection'
    ```

salt.modules.win_ip.get_subnet_length(mask)
    Convenience function to convert the netmask to the CIDR subnet length
    CLI Example:
    ```
salt -G 'os_family:Windows' ip.get_subnet_length 255.255.255.0
    ```

salt.modules.win_ip.is_disabled(iface)
    Returns True if interface is disabled, otherwise False
    CLI Example:
    ```
salt -G 'os_family:Windows' ip.is_disabled 'Local Area Connection #2'
    ```

salt.modules.win_ip.is_enabled(iface)
    Returns True if interface is enabled, otherwise False
    CLI Example:
    ```
salt -G 'os_family:Windows' ip.is_enabled 'Local Area Connection #2'
    ```

salt.modules.win_ip.raw_interface_configs()
    Return raw configs for all interfaces
    CLI Example:
    ```
salt -G 'os_family:Windows' ip.raw_interface_configs
    ```

salt.modules.win_ip.set_dhcp_all(iface)
    Set both IP Address and DNS to DHCP
    CLI Example:
    ```
salt -G 'os_family:Windows' ip.set_dhcp_all 'Local Area Connection'
    ```

salt.modules.win_ip.set_dhcp_dns(iface)
    Set DNS source to DHCP on Windows
    CLI Example:
    ```
salt -G 'os_family:Windows' ip.set_dhcp_dns 'Local Area Connection'
    ```

salt.modules.win_ip.set_dhcp_ip(iface)
    Set Windows NIC to get IP from DHCP
    CLI Example:
salt -G 'os_family:Windows' ip.set_dhcp_ip 'Local Area Connection'

salt.modules.win_ip.set_static_dns(iface, 'addrs')
Set static DNS configuration on a Windows NIC

CLI Example:
salt -G 'os_family:Windows' ip.set_static_dns 'Local Area Connection' '192.168.1.1'
salt -G 'os_family:Windows' ip.set_static_dns 'Local Area Connection' '192.168.1.252' '192.168.1.253'

salt.modules.win_ip.set_static_ip(iface, addr, gateway=None, append=False)
Set static IP configuration on a Windows NIC

iface The name of the interface to manage

addr IP address with subnet length (ex. 10.1.2.3/24). The ip.get_subnet_length function can be used to calculate the subnet length from a netmask.

gateway [None] If specified, the default gateway will be set to this value.

append [False] If True, this IP address will be added to the interface. Default is False, which overrides any existing configuration for the interface and sets addr as the only address on the interface.

CLI Example:
salt -G 'os_family:Windows' ip.set_static_ip 'Local Area Connection' 10.1.2.3/24 gateway=10.1.2.1
salt -G 'os_family:Windows' ip.set_static_ip 'Local Area Connection' 10.1.2.4/24 append=True

31.16.297 salt.modules.win_network

Module for gathering and managing network information

salt.modules.win_network.dig(host)
Performs a DNS lookup with dig

Note: dig must be installed on the Windows minion

CLI Example:
salt '*' network.dig archlinux.org

salt.modules.win_network.hw_addr(iface)
Return the hardware address (a.k.a. MAC address) for a given interface

CLI Example:
salt '*' network.hw_addr 'Wireless Connection #1'

salt.modules.win_network.hwaddr(iface)
Return the hardware address (a.k.a. MAC address) for a given interface

CLI Example:
salt '*' network.hw_addr 'Wireless Connection #1'

salt.modules.win_network.in_subnet(cidr)
Returns True if host is within specified subnet, otherwise False

CLI Example:
salt '*' network.in_subnet 10.0.0.0/16

salt.modules.win_network.interfaces()
    Return a dictionary of information about all the interfaces on the minion
    CLI Example:
        salt '*' network.interfaces

salt.modules.win_network.interfaces_names()
    Return a list of all the interfaces names
    CLI Example:
        salt '*' network.interfaces_names

salt.modules.win_network.ip_addrs(interface=None, include_loopback=False)
    Returns a list of IPv4 addresses assigned to the host. 127.0.0.1 is ignored, unless `include_loopback=True' is indicated. If `interface' is provided, then only IP addresses from that interface will be returned.
    CLI Example:
        salt '*' network.ip_addrs

salt.modules.win_network.ip_addrs6(interface=None, include_loopback=False)
    Returns a list of IPv6 addresses assigned to the host. ::1 is ignored, unless `include_loopback=True' is indicated. If `interface' is provided, then only IP addresses from that interface will be returned.
    CLI Example:
        salt '*' network.ip_addrs6

salt.modules.win_network.ipaddr(interface=None, include_loopback=False)
    Returns a list of IPv4 addresses assigned to the host. 127.0.0.1 is ignored, unless `include_loopback=True' is indicated. If `interface' is provided, then only IP addresses from that interface will be returned.
    CLI Example:
        salt '*' network.ip_addr

salt.modules.win_network.ipaddr6(interface=None, include_loopback=False)
    Returns a list of IPv6 addresses assigned to the host. ::1 is ignored, unless `include_loopback=True' is indicated. If `interface' is provided, then only IP addresses from that interface will be returned.
    CLI Example:
        salt '*' network.ip_addrs6

salt.modules.win_network.netstat()
    Return information on open ports and states
    CLI Example:
        salt '*' network.netstat

salt.modules.win_network.nslookup(host)
    Query DNS for information about a domain or ip address
    CLI Example:
        salt '*' network.nslookup archlinux.org
salt.modules.win_network.ping(host)
Performs a ping to a host

CLI Example:
salt '*' network.ping archlinux.org

salt.modules.win_network.subnets()
Returns a list of subnets to which the host belongs

CLI Example:
salt '*' network.subnets

salt.modules.win_network.traceroute(host)
Performs a traceroute to a 3rd party host

CLI Example:
salt '*' network.traceroute archlinux.org

31.16.298 salt.modules.win_ntp

Management of NTP servers on Windows
New in version 2014.1.0.
salt.modules.win_ntp.get_servers()
Get list of configured NTP servers

CLI Example:
salt '*' ntp.get_servers

salt.modules.win_ntp.set_servers(*servers)
Set Windows to use a list of NTP servers

CLI Example:
salt '*' ntp.set_servers 'pool.ntp.org' 'us.pool.ntp.org'

31.16.299 salt.modules.win_path

Manage the Windows System PATH
Note that not all Windows applications will rehash the PATH environment variable, Only the ones that listen to the WM_SETTINGCHANGE message http://support.microsoft.com/kb/104011
salt.modules.win_path.add(path, index=0)
Add the directory to the SYSTEM path in the index location

Returns: boolean True if successful, False if unsuccessful

CLI Example:
# Will add to the beginning of the path
salt '*' win_path.add 'c:\python27' 0

# Will add to the end of the path
salt '*' win_path.add 'c:\python27' index='-1'
### salt.modules.win_path

- **exists** *(path)*
  
  Check if the directory is configured in the SYSTEM path Case-insensitive and ignores trailing backslash

  **Returns**: boolean True if path exists, False if not

  **CLI Example**:

  ```
  salt '*' win_path.exists 'c:\python27'
  salt '*' win_path.exists 'c:\python27\'
  salt '*' win_path.exists 'C:\pyThon27'
  ```

- **get_path** *
  
  Returns a list of items in the SYSTEM path

  **CLI Example**:

  ```
  salt '*' win_path.get_path
  ```

- **rehash** *
  
  Send a WM_SETTINGCHANGE Broadcast to Windows to refresh the Environment variables

  **CLI Example**:

  ```
  ... code-block:: bash
  salt '*' win_path.rehash
  ```

- **remove** *(path)*
  
  Remove the directory from the SYSTEM path

  **Returns**: boolean True if successful, False if unsuccessful

  **CLI Example**:

  ```
  # Will remove C:\Python27 from the path
  salt '*' win_path.remove 'c:\\python27'
  ```

### salt.modules.win_pkg

A module to manage software on Windows

- **depends** *
  
  - win32com
  - win32con
  - win32api
  - pywintypes

- **compare_versions** *(ver1=", oper='==', ver2=")*
  
  Compare software package versions

- **genrepo** *(saltenv='base')*
  
  Generate winrepo_cachefile based on sls files in the winrepo

  **CLI Example**:

  ```
  salt-run winrepo.genrepo
  ```

- **get_name_map** *
  
  31.16.300 salt.modules.win_pkg

A module to manage software on Windows

- **depends** *
  
  - win32com
  - win32con
  - win32api
  - pywintypes

- **compare_versions** *(ver1=", oper='==', ver2=")*
  
  Compare software package versions

- **genrepo** *(saltenv='base')*
  
  Generate winrepo_cachefile based on sls files in the winrepo

  **CLI Example**:

  ```
  salt-run winrepo.genrepo
  ```

- **get_name_map** *
salt.modules.win_pkg.get_repo_data(saltenv='base')
Returns the cached winrepo data

CLI Example:
salt '*' pkg.get_repo_data

salt.modules.win_pkg.install(name=None, refresh=False, pkgs=None, saltenv='base', **kwargs)
Install the passed package(s) on the system using winrepo

Parameters
- **name** *(str, list, or None)* -- The name of a single package, or a comma-separated list of packages to install. (no spaces after the commas)
- **version** *(str)* -- The specific version to install. If omitted, the latest version will be installed. If passed with multiple install, the version will apply to all packages. Recommended for single installation only.
- **refresh** *(bool)* -- Boolean value representing whether or not to refresh the winrepo db
- **pkgs** *(list or None)* -- A list of packages to install from a software repository. All packages listed under pkgs will be installed via a single command.
- **saltenv** *(str)* -- The salt environment to use. Default is base.
- **kwargs** *(dict)* -- Any additional argument that may be passed from the state module. If they don't apply, they are ignored.

Returns  Return a dict containing the new package names and versions:

Return type
dict

If the package is installed by pkg.install:

\{<package>': {'old': '<old-version>',
              'new': '<new-version>'}}

If the package is already installed:

\{<package>': {'current': '<current-version>'}}

The following example will refresh the winrepo and install a single package, 7zip.

CLI Example:
salt '*' pkg.install 7zip refresh=True

CLI Example:
salt '*' pkg.install 7zip
salt '*' pkg.install 7zip,filezilla
salt '*' pkg.install pkgs='["7zip","filezilla"]'

salt.modules.win_pkg.latest_version(*names, **kwargs)
Return the latest version of the named package available for upgrade or installation. If more than one package name is specified, a dict of name/version pairs is returned.

If the latest version of a given package is already installed, an empty string will be returned for that package.

CLI Example:
salt.modules.win_pkg.list_available('names')
    Return a list of available versions of the specified package.
    CLI Example:
    salt '*' pkg.list_available <package name>
salt.modules.win_pkg.list_pkgs(versions_as_list=False, **kwargs)
    List the packages currently installed in a dict:
    {'<package_name>': '<version>'}
    CLI Example:
    salt '*' pkg.list_pkgs
    salt '*' pkg.list_pkgs versions_as_list=True
salt.modules.win_pkg.list_upgrades(refresh=True)
    List all available package upgrades on this system
    CLI Example:
    salt '*' pkg.list_upgrades
salt.modules.win_pkg.purge(name=None, pkgs=None, version=None, **kwargs)
    Package purges are not supported, this function is identical to remove().
    name  The name of the package to be deleted.
    version  The version of the package to be deleted. If this option is used in combination with the pkgs option below, then this version will be applied to all targeted packages.
    Multiple Package Options:
    pkgs  A list of packages to delete. Must be passed as a python list. The name parameter will be ignored if this option is passed.
    New in version 0.16.0.
    Returns a dict containing the changes.
    CLI Example:
    salt '*' pkg.purge <package name>
salt.modules.win_pkg.remove(name=None, pkgs=None, version=None, **kwargs)
    Remove the passed package(s) from the system using winrepo
Parameters

- **name** *(str, list, or None)* -- The name of the package to be uninstalled.
- **version** *(str)* -- The version of the package to be uninstalled. If this option is used to uninstall multiple packages, then this version will be applied to all targeted packages. Recommended using only when uninstalling a single package. If this parameter is omitted, the latest version will be uninstalled.

Multiple Package Options:

**Parameters** **pkgs** *(list or None)* -- A list of packages to delete. Must be passed as a python list. The name parameter will be ignored if this option is passed.

New in version 0.16.0.

**Returns** Returns a dict containing the changes.

**Return type** dict

If the package is removed by `pkg.remove`:

```
{`<package>`: {`old`: `<old-version>`, `new`: `<new-version>`}}
```

If the package is already uninstalled:

```
{`<package>`: {`current`: `notinstalled`}}
```

CLI Example:

```
salt '*' pkg.remove <package name>
salt '*' pkg.remove <package1>,<package2>,<package3>
salt '*' pkg.remove pkgs=['foo', 'bar']
```

salt.modules.win_pkg.upgrade(*refresh=True*)
Run a full system upgrade

Return a dict containing the new package names and versions:

```
{`<package>`: {`old`: `<old-version>`,
              `new`: `<new-version>`}}
```

CLI Example:

```
salt '*' pkg.upgrade
```

salt.modules.win_pkg.upgrade_available(*name*)
Check whether or not an upgrade is available for a given package

CLI Example:

```
salt '*' pkg.upgrade_available <package name>
```

salt.modules.win_pkg.version(*names*, **kwargs)*
Returns a version if the package is installed, else returns an empty string

CLI Example:

```
salt '*' pkg.version <package name>
```
31.16.301 salt.modules.win_powercfg

This module allows you to control the power settings of a windows minion via powercfg.

New in version 2015.8.0.

```python
salt '*' powercfg.set_monitor_timeout 0 power=dc
salt '*' powercfg.set_disk_timeout 120 power=ac
```

salt.modules.win_powercfg.get_disk_timeout()
Get the current disk timeout of the current scheme

CLI Example:

```python
salt '*' powercfg.get_disk_timeout
```

salt.modules.win_powercfg.get_hibernate_timeout()
Get the current hibernate timeout of the current scheme

CLI Example:

```python
salt '*' powercfg.get_hibernate_timeout
```

salt.modules.win_powercfg.get_monitor_timeout()
Get the current monitor timeout of the current scheme

CLI Example:

```python
salt '*' powercfg.get_monitor_timeout
```

salt.modules.win_powercfg.get_standby_timeout()
Get the current standby timeout of the current scheme

CLI Example:

```python
salt '*' powercfg.get_standby_timeout
```

salt.modules.win_powercfg.set_disk_timeout(timeout, power='ac')
Set the disk timeout in minutes for the current power scheme

CLI Example:

```python
salt '*' powercfg.set_disk_timeout 30 power=dc
```

**timeout**  The amount of time in minutes before the disk will timeout

**power**  Should we set the value for AC or DC (battery)? Valid options ac,dc.

salt.modules.win_powercfg.set_hibernate_timeout(timeout, power='ac')
Set the hibernate timeout in minutes for the current power scheme

CLI Example:

```python
salt '*' powercfg.set_hibernate_timeout 30 power=pc
```

**timeout**  The amount of time in minutes before the computer hibernates

**power**  Should we set the value for AC or DC (battery)? Valid options ac,dc.
salt.modules.win_powercfg.set_monitor_timeout(timeout, power='ac')
Set the monitor timeout in minutes for the current power scheme

CLI Example:

```
salt '*' powercfg.set_monitor_timeout 30 power=ac
```

timeout  The amount of time in minutes before the monitor will timeout
power  Should we set the value for AC or DC (battery)? Valid options ac,dc.

salt.modules.win_powercfg.set_standby_timeout(timeout, power='ac')
Set the standby timeout in minutes for the current power scheme

CLI Example:

```
salt '*' powercfg.set_standby_timeout 30 power=dc
```

timeout  The amount of time in minutes before the computer sleeps
power  Should we set the value for AC or DC (battery)? Valid options ac,dc.

31.16.302  salt.modules.win_repo

Module to manage Windows software repo on a Standalone Minion

```
file_client: local must be set in the minion config file.
```

For documentation on Salt's Windows Repo feature, see here <windows-package-manager

salt.modules.win_repo.genrepo()
Generate winrepo_cachefile based on sls files in the winrepo_dir

CLI Example:

```
salt-call winrepo.genrepo
```

salt.modules.win_repo.show_sls(name, saltenv='base')
New in version 2015.8.0.

Display the rendered software definition from a specific sls file in the local winrepo cache. This will parse all
Jinja. Run pkg.refresh_db to pull the latest software definitions from the master.

Parameters

- **name** *(str)*  -- The name of the package you want to view. Start from the local winrepo
root. If you have .sls files organized in subdirectories you’ll have to denote them with ..
For example, if I have a test directory in the winrepo root with a gvim.sls file inside,
I would target that file like so: test.gvim. Directories can be targeted as well as long
as they contain an init.sls inside. For example, if I have a node directory with an
init.sls inside, I would target that like so: node.

- **saltenv** *(str)*  -- The default environment is base

Returns  Returns a dictionary containing the rendered data structure

Return type  *dict*

CLI Example:
```
salt '*' winrepo.show_sls gvim
salt '*' winrepo.show_sls test.npp
```

```python
salt.modules.win_repo.update_git_repos(clean=False)
```

Checkout git repos containing *Windows Software Package Definitions*

**Important:** This function requires *Git for Windows* to be installed in order to work. When installing, make sure to select an installation option which permits the git executable to be run from the Command Prompt.

**clean** [False] Clean repo cachedirs which are not configured under `winrepo_remotes`.

**Note:** This option only applies if either *pygit2* or *GitPython* is installed into Salt's bundled Python.

**Warning:** This argument should not be set to *True* if a mix of git and non-git repo definitions are being used, as it will result in the non-git repo definitions being removed.

New in version 2015.8.0.

CLI Example:
```
salt-call winrepo.update_git_repos
```

### 31.16.303 `salt.modules.win_servermanager`

Manage Windows features via the `ServerManager powershell module`

```python
salt.modules.win_servermanager.install(feature, recurse=False)
```

Install a feature

**Note:** Some features requires reboot after un/installation, if so until the server is restarted Other features can not be installed!

**Note:** Some features takes a long time to complete un/installation, set `t` with a long timeout

CLI Example:
```
salt '*' win_servermanager.install Telnet-Client
salt '*' win_servermanager.install SNMP-Service True
```

```python
salt.modules.win_servermanager.list_available()
```

List available features to install

CLI Example:
```
salt '*' win_servermanager.list_available
```

```python
salt.modules.win_servermanager.list_installed()
```

List installed features. Supported on Windows Server 2008 and Windows 8 and newer.

CLI Example:
```
salt '*' win_servermanager.list_installed
```

```python
salt.modules.win_servermanager.remove(feature)
```

Remove an installed feature
Note: Some features require a reboot after installation/uninstallation. If one of these features are modified, then other features cannot be installed until the server is restarted. Additionally, some features take a while to complete installation/uninstallation, so it is a good idea to use the `-t` option to set a longer timeout.

CLI Example:

```
salt -t 600 '*\ win_servermanager.remove Telnet-Client
```

### 31.16.304 salt.modules.win_service

Windows Service module.

**salt.modules.win_service.available(name)**

Returns `True` if the specified service is available, otherwise returns `False`.

CLI Example:

```
salt '*\ service.available <service name>
```

**salt.modules.win_service.create(name, binpath, DisplayName=None, type='own', start='demand', error='normal', group=None, tag='no', depend=None, obj=None, password=None, **kwargs)**

Create the named service.

New in version 2015.8.0.

Required parameters: name: Specifies the service name returned by the getkeyname operation binpath: Specifies the path to the service binary file, backslashes must be escaped

  • eg: C:\path\to\binary.exe

Optional parameters: DisplayName: the name to be displayed in the service manager type: Specifies the service type, default is own

  • own (default): Service runs in its own process
  • share: Service runs as a shared process
  • interact: Service can interact with the desktop
  • kernel: Service is a driver
  • filesys: Service is a system driver
  • rec: Service is a file system-recognized driver that identifies filesystems on the computer

**start**: Specifies the start type for the service

  • boot: Device driver that is loaded by the boot loader
  • system: Device driver that is started during kernel initialization
  • auto: Service that automatically starts
  • demand (default): Service must be started manually
  • disabled: Service cannot be started
  • delayed-auto: Service starts automatically after other auto-services start

**error**: Specifies the severity of the error

  • normal (default): Error is logged and a message box is displayed
Salt Documentation, Release 2015.8.0

- severe: Error is logged and computer attempts a restart with last known good configuration
- critical: Error is logged, computer attempts to restart with last known good configuration, system halts on failure
- ignore: Error is logged and startup continues, no notification is given to the user

group: Specifies the name of the group of which this service is a member
tag: Specifies whether or not to obtain a TagID from the CreateService call. For boot-start and system-start drivers
  * yes/no

depend: Specifies the names of services or groups that must start before this service. The names are separated by forward slashes.
obj: Specifies the name of an account in which a service will run. Default is LocalSystem
password: Specifies a password. Required if other than LocalSystem account is used.

CLI Example:

```bash
salt '*' service.create <service name> <path to exe> display_name='display name'
```

salt.modules.win_service.create_win_salt_restart_task()  
Create a task in Windows task scheduler to enable restarting the salt-minion

CLI Example:

```bash
salt '*' service.create_win_salt_restart_task()
```

salt.modules.win_service.delete(name)
  Delete the named service

CLI Example:

```bash
salt '*' service.delete <service name>
```

salt.modules.win_service.disable(name, **kwargs)
  Disable the named service to start at boot

CLI Example:

```bash
salt '*' service.disable <service name>
```

salt.modules.win_service.disabled(name, **kwargs)
  Check to see if the named service is disabled to start on boot

CLI Example:

```bash
salt '*' service.disabled <service name>
```

salt.modules.win_service.enable(name, **kwargs)
  Enable the named service to start at boot

CLI Example:

```bash
salt '*' service.enable <service name>
```

salt.modules.win_service.enabled(name, **kwargs)
  Check to see if the named service is enabled to start on boot

CLI Example:

```bash
salt '*' service.enabled <service name>
```
salt.modules.win_service.execute_salt_restart_task()
Run the Windows Salt restart task
    CLI Example:
    salt '*' service.execute_salt_restart_task()

salt.modules.win_service.get_all()
Return all installed services
    CLI Example:
    salt '*' service.get_all

salt.modules.win_service.get_disabled()
Return the disabled services
    CLI Example:
    salt '*' service.get_disabled

salt.modules.win_service.get_enabled()
Return the enabled services
    CLI Example:
    salt '*' service.get_enabled

salt.modules.win_service.get_service_name(*args)
The Display Name is what is displayed in Windows when services.msc is executed. Each Display Name has
an associated Service Name which is the actual name of the service. This function allows you to discover the
Service Name by returning a dictionary of Display Names and Service Names, or filter by adding arguments
of Display Names.

    If no args are passed, return a dict of all services where the keys are the service Display Names and the values
    are the Service Names.

    If arguments are passed, create a dict of Display Names and Service Names
    CLI Example:
    salt '*' service.get_service_name
    salt '*' service.get_service_name 'Google Update Service (gupdate)' 'DHCP Client'

salt.modules.win_service.getsid(name)
Return the sid for this windows service
    CLI Example:
    salt '*' service.getsid <service name>

salt.modules.win_service.has_powershell()
Confirm if Powershell is available
    CLI Example:
    salt '*' service.has_powershell

salt.modules.win_service.missing(name)
The inverse of service.available. Returns True if the specified service is not available, otherwise returns
False.
    CLI Example:
salt '*' service.missing <service name>

salt.modules.win_service.restart(name)
    Restart the named service
    CLI Example:
    
salt '*' service.restart <service name>

salt.modules.win_service.start(name)
    Start the specified service
    CLI Example:
    salt '*' service.start <service name>

salt.modules.win_service.status(name, sig=None)
    Return the status for a service, returns the PID or an empty string if the service is running or not, pass a
    signature to use to find the service via ps
    CLI Example:
    salt '*' service.status <service name> [service signature]

salt.modules.win_service.stop(name)
    Stop the specified service
    CLI Example:
    salt '*' service.stop <service name>

31.16.305 salt.modules.win_shadow

Manage the shadow file
salt.modules.win_shadow.info(name)
    Return information for the specified user This is just returns dummy data so that salt states can work.
    CLI Example:
    
salt '*' shadow.info root

salt.modules.win_shadow.set_password(name, password)
    Set the password for a named user.
    CLI Example:
    salt '*' shadow.set_password root mysecretpassword

31.16.306 salt.modules.win_status

Module for returning various status data about a minion. These data can be useful for compiling into stats later, or
for problem solving if your minion is having problems.
New in version 0.12.0.

    depends
        • pythoncom
• wmi

salt.modules.win_status.cpulead()  
New in version 2015.8.0.
Return the processor load as a percentage
CLI Example:
```python
salt '*' status.cpulead
```

salt.modules.win_status.diskusage(human_readable=False, path=None)  
New in version 2015.8.0.
Return the disk usage for this minion
human_readable [False] If True, usage will be in KB/MB/GB etc.
CLI Example:
```python
salt '*' status.disk_usage path=c:/salt
```

salt.modules.win_status.master(master=None, connected=True)  
New in version 2015.5.0.
Fire an event if the minion gets disconnected from its master. This function is meant to be run via a scheduled job from the minion. If master_ip is an FQDN/Hostname, is must be resolvable to a valid IPv4 address.
CLI Example:
```python
salt '*' status.master
```

salt.modules.win_status.procs(count=False)  
Return the process data
count [False] If True, this function will simply return the number of processes.
New in version 2015.8.0.
CLI Example:
```python
salt '*' status.procs
salt '*' status.procs count
```

salt.modules.win_status.saltmem(human_readable=False)  
New in version 2015.8.0.
Returns the amount of memory that salt is using
human_readable [False] return the value in a nicely formatted number
CLI Example:
```python
salt '*' status.salt_mem
salt '*' status.salt_mem human_readable=True
```

salt.modules.win_status.uptime(human_readable=False)  
New in version 2015.8.0.
Return the system uptime for this machine in seconds
human_readable [False] If True, then the number of seconds will be translated into years, months, days, etc.
CLI Example:
31.16.307 salt.modules.win_system

Module for managing windows systems.

depends
  • win32net

Support for reboot, shutdown, etc

salt.modules.win_system.get_computer_desc()
Get the Windows computer description

Returns Returns the computer description if found. Otherwise returns False

CLI Example:

```
salt 'minion-id' system.get_computer_desc
```

salt.modules.win_system.get_computer_name()
Get the Windows computer name

Returns Returns the computer name if found. Otherwise returns False

CLI Example:

```
salt 'minion-id' system.get_computer_name
```

salt.modules.win_system.get_pending_computer_name()
Get a pending computer name. If the computer name has been changed, and the change is pending a system reboot, this function will return the pending computer name. Otherwise, None will be returned. If there was an error retrieving the pending computer name, False will be returned, and an error message will be logged to the minion log.

Returns Returns the pending name if pending restart. Returns none if not pending restart.

CLI Example:

```
salt 'minion-id' system.get_pending_computer_name
```

salt.modules.win_system.get_system_date()
Get the Windows system date

Returns Returns the system date.

Return type str

CLI Example:

```
salt '*' system.get_system_date
```

salt.modules.win_system.get_system_info()
Get system information.

Returns Returns a Dictionary containing information about the system to include name, description, version, etc...

Return type dict
salt.modules.win_system.get_system_time()

Get the system time.

Returns Returns the system time in HH:MM AM/PM format.

Return type str

salt.modules.win_system.halt(timeout=5, in_seconds=False)

Halt a running system.

Parameters timeout (int) -- Number of seconds before halting the system. Default is 5 seconds.

Returns True is successful.

Return type bool

timeout The wait time before the system will be shutdown.

in_seconds Whether to treat timeout as seconds or minutes.

New in version 2015.8.0.

CLI Example:

salt '*' system.halt 5

salt.modules.win_system.init(runlevel)

Change the system runlevel on sysV compatible systems

CLI Example:

salt '*' system.init 3

salt.modules.win_system.join_domain()

Join a computer to an Active Directory domain

Parameters

• domain (str) -- The domain to which the computer should be joined, e.g. my-company.com

• username (str) -- Username of an account which is authorized to join computers to the specified domain. Need to be either fully qualified like user@domain.tld or simply user

• password (str) -- Password of the specified user

• account_ou (str) -- The DN of the OU below which the account for this computer should be created when joining the domain, e.g. ou=computers,ou=department_432,dc=my-company,dc=com

• account_exists (bool) -- Needs to be set to True to allow re-using an existing account

CLI Example:

salt 'minion-id' system.join_domain domain='domain.tld' \ username='joinuser' password='joinpassword' \ account_ou='ou=clients,ou=org,dc=my-company,dc=tld' \ account_exists=False

salt.modules.win_system.lock()

Lock the workstation.
Returns True if successful
Return type bool

salt.modules.win_system.poweroff(timeout=5, in_seconds=False)
Power off a running system.

Parameters timeout (int) -- Number of seconds before powering off the system. Default is 5 seconds.

Returns True if successful
Return type bool

timeout The wait time before the system will be shutdown.
in_seconds Whether to treat timeout as seconds or minutes.

New in version 2015.8.0.

CLI Example:
salt '*' system.poweroff 5

salt.modules.win_system.reboot(timeout=5, in_seconds=False)
Reboot a running system.

Parameters timeout (int) -- Number of seconds before rebooting the system. Default is 5 seconds.

Returns True if successful
Return type bool

timeout The wait time before the system will be shutdown.
in_seconds Whether to treat timeout as seconds or minutes.

New in version 2015.8.0.

CLI Example:
salt '*' system.reboot 5

salt.modules.win_system.set_computer_desc(desc=None)
Set the Windows computer description

Parameters desc (str) -- The computer description

Returns False if it fails. Description if successful.

CLI Example:
salt 'minion-id' system.set_computer_desc 'This computer belongs to Dave!' 

salt.modules.win_system.set_computer_name(name)
Set the Windows computer name

Parameters name (str) -- The new name to give the computer. Requires a reboot to take effect.

Returns Returns a dictionary containing the old and new names if successful. False if not.

CLI Example:
salt 'minion-id' system.set_computer_name 'DavesComputer'
salt.modules.win_system.set_system_date(newdate)
Set the Windows system date. Use <mm-dd-yyyy> format for the date.

Parameters

- **newdate** *(str)* -- The date to set. Can be any of the following formats - YYYY-MM-DD
  - MM-DD-YYYY - MM-DD-YY - MM/DD/YYYY - MM/DD/YY - YYYY/MM/DD

CLI Example:

```
salt '*' system.set_system_date '03-28-13'
```

salt.modules.win_system.set_system_date_time(years=None, months=None, days=None, hours=None, minutes=None, seconds=None)
Set the system date and time. Each argument is an element of the date, but not required. If an element is not passed, the current system value for that element will be used. For example, if you don’t pass the year, the current system year will be used. (Used by set_system_date and set_system_time)

Parameters

- **years** *(int)* -- Years digit, ie: 2015
- **months** *(int)* -- Months digit: 1 - 12
- **days** *(int)* -- Days digit: 1 - 31
- **hours** *(int)* -- Hours digit: 0 - 23
- **minutes** *(int)* -- Minutes digit: 0 - 59
- **seconds** *(int)* -- Seconds digit: 0 - 59

Returns

True if successful. Otherwise False.

Return type  **bool**

CLI Example:

```
salt '*' system.set_system_date_time 2015 5 12 11 37 53
```

salt.modules.win_system.set_system_time(newtime)
Set the system time.

Parameters

- **newtime** *(str)* -- The time to set. Can be any of the following formats. - HH:MM:SS

Returns

Returns True if successful. Otherwise False.

Return type  **bool**

salt.modules.win_system.shutdown(message=None, timeout=5, force_close=True, reboot=False, in_seconds=False)
Shutdown a running system.

Parameters

- **message** *(str)* -- A message to display to the user before shutting down.
- **timeout** *(int)* -- The length of time that the shutdown dialog box should be displayed, in seconds. While this dialog box is displayed, the shutdown can be stopped by the shutdown_abort function.

If dwTimeout is not zero, InitiateSystemShutdown displays a dialog box on the specified computer. The dialog box displays the name of the user who called the function, displays the message specified by the lpMessage parameter, and prompts the user to log off. The dialog box beeps when it is created and remains on top of other windows in the system.
The dialog box can be moved but not closed. A timer counts down the remaining time before a forced shutdown.

If dwTimeout is zero, the computer shuts down without displaying the dialog box, and the shutdown cannot be stopped by shutdown_abort.

Default is 5

- **in_seconds (bool)** -- Whether to treat timeout as seconds or minutes.
  
  New in version 2015.8.0.

- **force_close (bool)** -- True to force close all open applications. False displays a dialog box instructing the user to close the applications.

- **reboot (bool)** -- True restarts the computer immediately after shutdown. False caches to disk and safely powers down the system.

**Returns**  True if successful

**Return type**  bool

**CLI Example:**

```python
salt '*' system.shutdown 5
```

salt.modules.win_system.shutdown_abort()

Abort a shutdown. Only available while the dialog box is being displayed to the user. Once the shutdown has initiated, it cannot be aborted.

**Returns**  True if successful

**Return type**  bool

salt.modules.win_system.shutdown_hard()

Shutdown a running system with no timeout or warning.

**Parameters**  **timeout (int)** -- Number of seconds before shutting down the system. Default is 5 seconds.

**Returns**  True if successful

**Return type**  bool

**CLI Example:**

```python
salt '*' system.shutdown_hard
```

salt.modules.win_system.start_time_service()

Start the Windows time service

**Returns**  True if successful. Otherwise False

**Return type**  bool

**CLI Example:**

```python
salt '*' system.start_time_service
```

salt.modules.win_system.stop_time_service()

Stop the Windows time service

**Returns**  True if successful. Otherwise False

**Return type**  bool
Salt Documentation, Release 2015.8.0

CLI Example:
```
salt '*' system.stop_time_service
```

`salt.modules.win_system.unjoin_domain(username=None, password=None, disable=False)`
Unjoin a computer from an Active Directory Domain

Parameters
- **username** -- Username of an account which is authorized to join computers to the specified domain. Need to be either fully qualified like user@domain.tld or simply user
- **password (str)** -- Password of the specified user
- **disable (bool)** -- Disable the user account in Active Directory. True to disable.

Returns
True if successful. False if not. Log contains error code.

Return type  bool

CLI Example:
```
salt 'minion-id' system.unjoin_domain username='unjoinuser' \ password='unjoinpassword' disable=True
```

31.16.308 `salt.modules.win_timezone`

Module for managing timezone on Windows systems.

`salt.modules.win_timezone.get_hwclock()`
Get current hardware clock setting (UTC or localtime)

CLI Example:
```
salt '*' timezone.get_hwclock
```

`salt.modules.win_timezone.get_offset()`
Get current numeric timezone offset from UCT (i.e. -0700)

CLI Example:
```
salt '*' timezone.get_offset
```

`salt.modules.win_timezone.get_zone()`
Get current timezone (i.e. America/Denver)

CLI Example:
```
salt '*' timezone.get_zone
```

`salt.modules.win_timezone.get_zonecode()`
Get current timezone (i.e. PST, MDT, etc)

CLI Example:
```
salt '*' timezone.get_zonecode
```

`salt.modules.win_timezone.set_hwclock(clock)`
Sets the hardware clock to be either UTC or localtime

CLI Example:
salt '*' timezone.set_hwclock UTC

salt.modules.win_timezone.set_zone(timezone)
Unlinks, then symlinks /etc/localtime to the set timezone.
The timezone is crucial to several system processes, each of which SHOULD be restarted (for instance, whatever you system uses as its cron and syslog daemons). This will not be magically done for you!
CLI Example:
salt '*' timezone.set_zone 'America/Denver'

class salt.modules.win_timezone.zone_compare(timezone)
Checks the md5sum between the given timezone, and the one set in /etc/localtime. Returns True if they match, and False if not. Mostly useful for running state checks.
Example:
salt '*' timezone.zone_compare 'America/Denver'

31.16.309 salt.modules.win_update

Module for running windows updates.

depends
  • win32com
  • win32con
  • win32api
  • pywintypes

New in version 2014.7.0.
class salt.modules.win_update.PyWinUpdater(categories=None, skipUI=True, skipDownloaded=False, skipInstalled=True, skipReboot=False, skipPresent=False, softwareUpdates=True, driverUpdates=False, skipHidden=True)

AutoSearch()
  this function generates a search string. simplifying the search function while still providing as many features as possible.

Download()
GetAvailableCategories()
GetCategories()
GetDownloadResults()
GetInstallationResults()
  this gets results of installation process.
GetInstallationResultsPretty()
  converts the installation results into a pretty print.
GetSearchResults()
GetSearchResultsPretty()
Install()
Search(searchString)
SetCategories(categories)
SetInclude(include, state)
SetIncludes(includes)

salt.modules.win_update.download_updates(includes=None, retries=5, categories=None)
Downloads all available updates, skipping those that require user interaction.
Various aspects of the updates can be included or excluded. This feature is still in development.

- **retries**: Number of retries to make before giving up. This is total, not per step.
- **categories**: Specify the categories to update. Must be passed as a list.

```python
salt '*' win_update.download_updates categories=['Updates']
```

Categories include the following:
- Updates
- Windows 7
- Critical Updates
- Security Updates
- Update Rollups

**CLI Examples:**

```bash
# Normal Usage
salt '*' win_update.download_updates
# Download critical updates only
salt '*' win_update.download_updates categories=['Critical Updates']
```

salt.modules.win_update.install_updates(includes=None, retries=5, categories=None)
Downloads and installs all available updates, skipping those that require user interaction.

Add cached to only install those updates which have already been downloaded.
you can set the maximum number of retries to n in the search process by adding: retries=n
various aspects of the updates can be included or excluded. This function is still under development.

- **retries**: Number of retries to make before giving up. This is total, not per step.
- **categories**: Specify the categories to install. Must be passed as a list.

```python
salt '*' win_update.install_updates categories=['Updates']
```

Categories include the following:
- Updates
- Windows 7
- Critical Updates
- Security Updates
- Update Rollups
CLI Examples:

# Normal Usage
salt '*' win_update.install_updates

# Install all critical updates
salt '*' win_update.install_updates categories="[Critical Updates']"

salt.modules.win_update.list_updates(
    verbose=False, includes=None, retries=5, categories=None)

Returns a summary of available updates, grouped into their non-mutually exclusive categories.

verbose  Print results in greater detail
retries  Number of retries to make before giving up. This is total, not per step.
categories  Specify the categories to list. Must be passed as a list.

salt '*' win_update.list_updates categories="[Updates']"

Categories include the following:
- Updates
- Windows 7
- Critical Updates
- Security Updates
- Update Rollups

CLI Examples:

# Normal Usage
salt '*' win_update.list_updates

# List all critical updates list in verbose detail
salt '*' win_update.list_updates categories="[Critical Updates'] verbose=True

31.16.310  salt.modules.win_useradd

Module for managing Windows Users

depends
- pywintypes
- win32api
- win32net
- win32netcon
- win32profile
- win32security
- win32ts

Note:  This currently only works with local user accounts, not domain accounts
salt.modules.win_useradd.

\texttt{add}\ (name, \texttt{password=None}, \texttt{fullname=False}, \texttt{description=None}, \texttt{groups=None}, \texttt{home=None}, \texttt{homedrive=None}, \texttt{profile=None}, \texttt{logonscript=None})

Add a user to the minion.

**Parameters**

- \texttt{name (str)} -- User name
- \texttt{password (str)} -- User's password in plain text.
- \texttt{fullname (str)} -- The user's full name.
- \texttt{description (str)} -- A brief description of the user account.
- \texttt{groups (list)} -- A list of groups to add the user to.
- \texttt{home (str)} -- The path to the user's home directory.
- \texttt{homedrive (str)} -- The drive letter to assign to the home directory. Must be the Drive Letter followed by a colon. ie: U:
- \texttt{profile (str)} -- An explicit path to a profile. Can be a UNC or a folder on the system. If left blank, windows uses it's default profile directory.
- \texttt{logonscript (str)} -- Path to a login script to run when the user logs on.

**Returns**  
True if successful. False is unsuccessful.

**Return type**  
\texttt{bool}

**CLI Example:**

```
salt '*' user.add name password
```

salt.modules.win_useradd.

\texttt{addgroup}\ (name, group)

Add user to a group

**Parameters**

- \texttt{name (str)} -- user name to add to the group
- \texttt{group (str)} -- name of the group to which to add the user

**Returns**  
True if successful. False is unsuccessful.

**Return type**  
\texttt{bool}

**CLI Example:**

```
salt '*' user.addgroup jsnuffy 'Power Users'
```

salt.modules.win_useradd.

\texttt{chfullname}\ (name, fullname)

Change the full name of the user

**Parameters**

- \texttt{name (str)} -- user name for which to change the full name
- \texttt{fullname (str)} -- the new value for the full name

**Returns**  
True if successful. False is unsuccessful.

**Return type**  
\texttt{bool}

**CLI Example:**
salt '‡' user.chfullname user 'First Last'

```python
salt.modules.win_useradd.chgroups(name, groups, append=True)
```

Change the groups this user belongs to, add `append=False` to make the user a member of only the specified groups.

**Parameters**

- `name (str)` -- user name for which to change groups
- `groups (list, str)` -- a single group or a list of groups to assign to the user
- `append (bool)` -- True adds the passed groups to the user’s current groups False sets the user’s groups to the passed groups only

**Returns**

True if successful. False is unsuccessful.

**Return type**

bool

**CLI Example:**

```
salt '‡' user.chgroups jsnuffy Administrators,Users True
```

salt.modules.win_useradd.chhome(name, home, persist=False)

Change the home directory of the user, pass `True` for `persist` to move files to the new home directory if the old home directory exist.

**Parameters**

- `name (str)` -- name of the user whose home directory you wish to change
- `home (str)` -- new location of the home directory
- `persist (bool)` -- True to move the contents of the existing home directory to the new location

**Returns**

True if successful. False is unsuccessful.

**Return type**

bool

**CLI Example:**

```
salt '‡' user.chhome foo \\fileserver\home\foo True
```

salt.modules.win_useradd.chprofile(name, profile)

Change the profile directory of the user

**Parameters**

- `name (str)` -- name of the user whose profile you wish to change
- `profile (str)` -- new location of the profile

**Returns**

True if successful. False is unsuccessful. :rtype: bool

**CLI Example:**

```
salt '‡' user.chprofile foo \\fileserver\profiles\foo
```

salt.modules.win_useradd.current(sam=False)

Get the username that salt-minion is running under. If salt-minion is running as a service it should return the Local System account. If salt is running from a command prompt it should return the username that started the command prompt.
New in version 2015.5.6.

Parameters **sam** *(bool)* -- False returns just the username without any domain notation. True returns the domain with the username in the SAM format. I.e:

```
domain\username
```

Returns Returns False if the username cannot be returned. Otherwise returns the username.

Return type **bool str**

CLI Example:

```
salt '*' user.current
```

### **salt.modules.win_useradd.delete** *(name, purge=False, force=False)*

Remove a user from the minion

Parameters

- **name** *(str)* -- The name of the user to delete
- **purge** *(bool)* -- Boolean value indicating that the user profile should also be removed when the user account is deleted. If set to True the profile will be removed.
- **force** *(bool)* -- Boolean value indicating that the user account should be deleted even if the user is logged in. True will log the user out and delete user.

Returns True if successful

Return type **bool**

CLI Example:

```
salt '*' user.delete name
```

### **salt.modules.win_useradd.getUserSid** *(username)*

Get the Security ID for the user

Parameters **username** *(str)* -- user name for which to look up the SID

Returns Returns the user SID

Return type **str**

CLI Example:

```
salt '*' user.getUserSid jsnuffy
```

### **salt.modules.win_useradd.getent** *(refresh=False)*

Return the list of all info for all users

Parameters **refresh** *(bool)* -- Refresh the cached user information. Default is False. Useful when used from within a state function.

Returns A dictionary containing information about all users on the system

Return type **dict**

CLI Example:

```
salt '*' user.getent
```

### **salt.modules.win_useradd.info** *(name)*

Return user information

Parameters **name** *(str)* -- Username for which to display information
Returns

A dictionary containing user information

- fullname
- username
- SID
- passwd (will always return None)
- comment (same as description, left here for backwards compatibility)
- description
- active
- logonscript
- profile
- home
- homedrive
- groups
- gid

Return type  dict

CLI Example:

```bash
salt '*' user.info jsnuffy
```

salt.modules.win_useradd.list_groups(name)

Return a list of groups the named user belongs to

Parameters  name (str) -- user name for which to list groups

Returns  list of groups to which the user belongs

Return type  list

CLI Example:

```bash
salt '*' user.list_groups foo
```

salt.modules.win_useradd.list_users()

Return a list of users on Windows

Returns  list of users on the system

Return type  list

CLI Example:

```bash
salt '*' user.list_users
```

salt.modules.win_useradd.removegroup(name, group)

Remove user from a group

Parameters

- name (str) -- user name to remove from the group
- group (str) -- name of the group from which to remove the user
Returns True if successful. False is unsuccessful.

Return type bool

CLI Example:

    salt '*' user.removegroup jsnuffy 'Power Users'

salt.modules.win_useradd.rename(name, new_name)
Change the username for a named user

Parameters

• name (str) -- user name to change
• new_name (str) -- the new name for the current user

Returns True if successful. False is unsuccessful.

Return type bool

CLI Example:

    salt '*' user.rename jsnuffy jshmoe

salt.modules.win_useradd.setPassword(name, password)
Set the user's password

Parameters

• name (str) -- user name for which to set the password
• password (str) -- the new password

Returns True if successful. False is unsuccessful.

Return type bool

CLI Example:

    salt '*' user.setPassword jsnuffy sup3rs3cr3t

salt.modules.win_useradd.update(name, password=None, fullname=None, description=None, home=None, homedrive=None, logonscript=None, profile=None)
Updates settings for the windows user. Name is the only required parameter. Settings will only be changed if the parameter is passed a value.

New in version 2015.8.0.

Parameters

• name (str) -- The user name to update.
• password (str) -- New user password in plain text.
• fullname (str) -- The user's full name.
• description (str) -- A brief description of the user account.
• home (str) -- The path to the user's home directory.
• homedrive (str) -- The drive letter to assign to the home directory. Must be the Drive Letter followed by a colon. ie: U:
• logonscript (str) -- The path to the logon script.
• profile (str) -- The path to the user's profile directory.
**Returns**

True if successful. False is unsuccessful.

**Return type**

`bool`

**CLI Example:**

```
salt '*' user.update bob password=secret profile=C:\Users\Bob
     home=\server\homeshare\bob homedrive=U:
```

31.16.311 **salt.modules.win_wua**

Module for managing Windows Updates using the Windows Update Agent.

New in version 2015.8.0.

**depends**

- `win32com`
- `pythoncom`

**salt.modules.win_wua.download_update(**`guid=None`**)**

Downloads a single update

**Parameters**

- `guid` -- str A GUID for the update to be downloaded

**Returns**

A dictionary containing the status, a message, and a list of updates that were downloaded.

**CLI Examples:**

```
salt '*' win_wua.download_update 12345678-abcd-1234-abcd-1234567890ab
```

**salt.modules.win_wua.download_updates(**`guid=None`**)**

Downloads updates that match the list of passed GUIDs. It's easier to use this function by using list_updates and setting install=True.

**Parameters**

- `guid` -- A list of GUIDs to be downloaded

**Returns**

A dictionary containing the status, a message, and a list of updates that were downloaded.

**CLI Examples:**

```
# Normal Usage
salt '*' win_wua.download_updates guid=['12345678-abcd-1234-abcd-1234567890ab',
     '87654321-dcba-4321-dcba-ba0987654321']
```

**salt.modules.win_wua.get_needs_reboot()**

Determines if the system needs to be rebooted.

**Returns**

`bool` True if the system requires a reboot, False if not

**CLI Examples:**

```
salt '*' win_wua.get_needs_reboot
```

**salt.modules.win_wua.get_wu_settings()**

Get current Windows Update settings.

**Returns**

- **Featured Updates**: Boolean value that indicates whether to display notifications for featured updates.
- **Group Policy Required (Read-only)**: Boolean value that indicates whether Group Policy requires the Automatic Updates service.
**Microsoft Update**: Boolean value that indicates whether to turn on Microsoft Update for other Microsoft Products

**Needs Reboot**: Boolean value that indicates whether the machine is in a reboot pending state.

**Non Admins Elevated**: Boolean value that indicates whether non-administrators can perform some update-related actions without administrator approval.

**Notification Level**:

Number 1 to 4 indicating the update level:
1. Never check for updates
2. Check for updates but let me choose whether to download and install them
3. Download updates but let me choose whether to install them
4. Install updates automatically

**Read Only (Read-only)**: Boolean value that indicates whether the Automatic Update settings are read-only.

**Recommended Updates**: Boolean value that indicates whether to include optional or recommended updates when a search for updates and installation of updates is performed.

**Scheduled Day**: Days of the week on which Automatic Updates installs or uninstalls updates.

**Scheduled Time**: Time at which Automatic Updates installs or uninstalls updates.

CLI Examples:

```shell
salt '*' win_wua.get_wu_settings
```

```python
salt.modules.win_wua.install_update(guid=None)
```
Installs a single update

**Parameters**
- `guid` -- str A GUID for the update to be installed

**Returns**
- `dict` A dictionary containing the details about the installed update

CLI Examples:

```shell
salt '*' win_wua.install_update 12345678-abcd-1234-abcd-1234567890ab
```

```python
salt.modules.win_wua.install_updates(guid=None)
```
Installs updates that match the passed criteria. It may be easier to use the list_updates function and set install=True.

**Parameters**
- `guid` -- list A list of GUIDs to be installed

**Returns**
- `dict` A list of GUIDs to be installed

CLI Examples:

```shell
# Normal Usage
salt '*' win_wua.install_updates
guid=['12345678-abcd-1234-abcd-1234567890ab', '87654321-dcbe-4321-dcbe-ba0987654321']
```

```python
salt.modules.win_wua.list_update(name=None, download=False, install=False)
```
Returns details for all updates that match the search criteria

**Parameters**
• **name (str)** -- The name of the update you're searching for. This can be the GUID (preferred), a KB number, or the full name of the update. Run `list_updates` to get the GUID for the update you're looking for.

• **download (bool)** -- Download the update returned by this function. Run this function first to see if the update exists, then set `download=True` to download the update.

• **install (bool)** -- Install the update returned by this function. Run this function first to see if the update exists, then set `install=True` to install the update. This will override `download=True`.

**Returns**

Returns a dict containing a list of updates that match the name if `download` and `install` are both set to False. Should usually be a single update, but can return multiple if a partial name is given. If `download` or `install` is set to True it will return the results of `win_wua.download_updates`.

List of Updates:

```python
{'<GUID>': {'Title': <title>,
    'KB': <KB>,
    'GUID': <the globally unique identifier for the update>
    'Description': <description>,
    'Downloaded': <has the update been downloaded>,
    'Installed': <has the update been installed>,
    'Mandatory': <is the update mandatory>,
    'UserInput': <is user input required>,
    'EULAAccepted': <has the EULA been accepted>,
    'Severity': <update severity>,
    'NeedsReboot': <is the update installed and awaiting reboot>,
    'RebootBehavior': <will the update require a reboot>,
    'Categories': [{'<category 1>'},
        {'<category 2>'},
        ...
    ]
}
```

**Return type**  
dict

**CLI Examples:**

```bash
# Recommended Usage using GUID without braces
# Use this to find the status of a specific update
salt '*' wua.list_update 12345678-abcd-1234-abcd-1234567890ab

# Use the following if you don't know the GUID:

# Using a KB number (could possibly return multiple results)
# Not all updates have an associated KB
salt '*' wua.list_update KB3030298

# Using part or all of the name of the update
# Could possibly return multiple results
# Not all updates have an associated KB
salt '*' wua.list_update 'Microsoft Camera Codec Pack'
```

```
salt.modules.win_wua.list_updates(software=True, drivers=False, summary=False, installed=False, categories=None, severities=None, download=False, install=False)
```

Returns a detailed list of available updates or a summary.
Parameters

- **software** *(bool)* -- Include software updates in the results (default is True)
- **drivers** *(bool)* -- Include driver updates in the results (default is False)
- **summary** *(bool)* -- True: Return a summary of updates available for each category. False (default): Return a detailed list of available updates.
- **installed** *(bool)* -- Include installed updates in the results (default if False)
- **download** *(bool)* -- (Overrides reporting functionality) Download the list of updates returned by this function. Run this function first to see what will be installed, then set download=True to download the updates.
- **install** *(bool)* -- (Overrides reporting functionality) Install the list of updates returned by this function. Run this function first to see what will be installed, then set install=True to install the updates. This will override download=True
- **categories** *(list)* -- Specify the categories to list. Must be passed as a list. All categories returned by default.

Categories include the following:
- Critical Updates
- Definition Updates
- Drivers (make sure you set drivers=True)
- Feature Packs
- Security Updates
- Update Rollups
- Updates
- Update Rollups
- Windows 7
- Windows 8.1
- Windows 8.1 drivers
- Windows 8.1 and later drivers
- Windows Defender

- **severities** *(list)* -- Specify the severities to include. Must be passed as a list. All severities returned by default.

Severities include the following:
- Critical
- Important

Returns

Returns a dict containing either a summary or a list of updates:

```
List of Updates:
{'<GUID>': {'Title': <title>,
             'KB': <KB>,
             'GUID': <the globally unique identifier for the update>}
```
{'Description': <description>,
'Downloaded': <has the update been downloaded>,
'Installed': <has the update been installed>,
'Mandatory': <is the update mandatory>,
'UserInput': <is user input required>,
'EULAAccepted': <has the EULA been accepted>,
'Severity': <update severity>,
'NeedsReboot': <is the update installed and awaiting reboot>,
'RebootBehavior': <will the update require a reboot>,
'Categories': [ '<category 1>',
    '<category 2>',
    ...
]}
}

Summary of Updates:
{"Total': <total number of updates returned>,
 'Available': <updates that are not downloaded or installed>,
 'Downloaded': <updates that are downloaded but not installed>,
 'Installed': <updates installed (usually 0 unless installed=True)>,
 'Categories': { <category 1>: <total for that category>,
    <category 2>: <total for category 2>,
    ... }
}

Return type  dict

CLI Examples:

# Normal Usage (list all software updates)
salt '*' wua.list_updates

# List all updates with categories of Critical Updates and Drivers
salt '*' wua.list_updates categories=['Critical Updates', 'Drivers']

# List all Critical Security Updates
salt '*' wua.list_updates categories=['Security Updates'] severities=['Critical']

# List all updates with a severity of Critical
salt '*' wua.list_updates severities=['Critical']

# A summary of all available updates
salt '*' wua.list_updates summary=True

# A summary of all Feature Packs and Windows 8.1 Updates
salt '*' wua.list_updates categories=['Feature Packs', 'Windows 8.1'] summary=True

salt.modules.win_wua.set_wu_settings(level=None, recommended=None, featured=None, elevated=None, msupdate=None, day=None, time=None)

Change Windows Update settings. If no parameters are passed, the current value will be returned.

Parameters

• **level** *(int)* --

  Number from 1 to 4 indicating the update level:

  1. Never check for updates
  2. Check for updates but let me choose whether to download and install them
3. Download updates but let me choose whether to install them
4. Install updates automatically
   - recommended (bool) -- Boolean value that indicates whether to include optional or recommended updates when a search for updates and installation of updates is performed.
   - featured (bool) -- Boolean value that indicates whether to display notifications for featured updates.
   - elevated (bool) -- Boolean value that indicates whether non-administrators can perform some update-related actions without administrator approval.
   - msupdate (bool) -- Boolean value that indicates whether to turn on Microsoft Update for other Microsoft products.
   - day (str) -- Days of the week on which Automatic Updates installs or uninstalls updates. Accepted values: - Everyday - Monday - Tuesday - Wednesday - Thursday - Friday - Saturday
   - time (str) -- Time at which Automatic Updates installs or uninstalls updates. Must be in the ###:## 24hr format, eg. 3:00 PM would be 15:00

Returns
Returns a dictionary containing the results.

CLI Examples:
```
salt '*' win_wua.set_wu_settings level=4 recommended=True featured=False
```

31.16.312 salt.modules.x509
Manage X509 certificates
New in version 2015.8.0.
salt.modules.x509.create_certificate(path=None, text=False, ca_server=None, **kwargs)
Create an X509 certificate.

path: Path to write the certificate to.
text: If True, return the PEM text without writing to a file. Default False.
kwargs: Any of the properties below can be included as additional keyword arguments.

ca_server: Request a remotely signed certificate from ca_server. For this to work, a signing_policy must be specified, and that same policy must be configured on the ca_server. See signing_policy for details. Also the salt master must permit peers to call the sign_remote_certificate function.

Example:
```
/etc/salt/master.d/peer.conf
```
peer:
  .*:
    - x509.sign_remote_certificate

subject properties: Any of the values below can be included to set subject properties Any other subject properties supported by OpenSSL should also work.

C: 2 letter Country code
CN: Certificate common name, typically the FQDN.
Email: Email address

GN: Given Name
L: Locality
O: Organization
OU: Organization Unit
SN: SurName
ST: State or Province

signing_private_key: A path or string of the private key in PEM format that will be used to sign this certificate. If neither signing_cert, public_key, or csr are included, it will be assumed that this is a self-signed certificate, and the public key matching signing_private_key will be used to create the certificate.

signing_cert: A certificate matching the private key that will be used to sign this certificate. This is used to populate the issuer values in the resulting certificate. Do not include this value for self-signed certificates.

public_key: The public key to be included in this certificate. This can be sourced from a public key, certificate, csr or private key. If a private key is used, the matching public key from the private key will be generated before any processing is done. This means you can request a certificate from a remote CA using a private key file as your public_key and only the public key will be sent across the network to the CA. If neither public_key or csr are specified, it will be assumed that this is a self-signed certificate, and the public key derived from signing_private_key will be used. Specify either public_key or csr, not both. Because you can input a CSR as a public key or as a CSR, it is important to understand the difference. If you import a CSR as a public key, only the public key will be added to the certificate, subject or extension information in the CSR will be lost.

csr: A file or PEM string containing a certificate signing request. This will be used to supply the subject, extensions and public key of a certificate. Any subject or extensions specified explicitly will overwrite any in the CSR.

basicConstraints: X509v3 Basic Constraints extension.

extensions: The following arguments set X509v3 Extension values. If the value starts with "critical", the extension will be marked as critical.

Some special extensions are subjectKeyIdentifier and authorityKeyIdentifier.

subjectKeyIdentifier can be an explicit value or it can be the special string hash. hash will set the subjectKeyIdentifier equal to the SHA1 hash of the modulus of the public key in this certificate. Note that this is not the exact same hashing method used by OpenSSL when using the hash value.

authorityKeyIdentifier Use values acceptable to the openssl CLI tools. This will automatically populate authorityKeyIdentifier with the subjectKeyIdentifier of signing_cert. If this is a self-signed cert these values will be the same.

basicConstraints: X509v3 Basic Constraints

keyUsage: X509v3 Key Usage

extendedKeyUsage: X509v3 Extended Key Usage

subjectKeyIdentifier: X509v3 Subject Key Identifier

issuerAltName: X509v3 Issuer Alternative Name

subjectAltName: X509v3 Subject Alternative Name

crlDistributionPoints: X509v3 CRL distribution points
**issuingDistributionPoint:** X509v3 Issuing Distribution Point

**certificatePolicies:** X509v3 Certificate Policies

**policyConstraints:** X509v3 Policy Constraints

**inhibitAnyPolicy:** X509v3 Inhibit Any Policy

**nameConstraints:** X509v3 Name Constraints

**noCheck:** X509v3 OCSP No Check

**nsComment:** Netscape Comment

**nsCertType:** Netscape Certificate Type

**days_valid:** The number of days this certificate should be valid. This sets the notAfter property of the certificate. Defaults to 365.

**version:** The version of the X509 certificate. Defaults to 3. This is automatically converted to the version value, so version=3 sets the certificate version field to 0x2.

**serial_number:** The serial number to assign to this certificate. If omitted a random serial number of size **serial_bits** is generated.

**serial_bits:** The number of bits to use when randomly generating a serial number. Defaults to 64.

**algorithm:** The hashing algorithm to be used for signing this certificate. Defaults to sha256.

**copypath:** An additional path to copy the resulting certificate to. Can be used to maintain a copy of all certificates issued for revocation purposes.

**signing_policy:** A signing policy that should be used to create this certificate. Signing policies should be defined in the minion configuration, or in a minion pillar. It should be a yaml formatted list of arguments which will override any arguments passed to this function. If the minions key is included in the signing policy, only minions matching that pattern will be permitted to remotely request certificates from that policy.

Example:

```yaml
x509_signing_policies:
  www:
    - minions: 'www*
    - signing_private_key: /etc/pki/ca.key
    - signing_cert: /etc/pki/ca.crt
    - C: US
    - ST: Utah
    - L: Salt Lake City
    - basicConstraints: "critical CA:false"
    - keyUsage: "critical cRLSign, keyCertSign"
    - subjectKeyIdentifier: hash
    - authorityKeyIdentifier: keyid,issuer:always
    - days_valid: 90
    - copypath: /etc/pki/issued_certs/
```

The above signing policy can be invoked with signing_policy=www

**CLI Example:**

```
salt '*' x509.create_certificate path=/etc/pki/myca.crt \
    signing_private_key='/etc/pki/myca.key' csr='/etc/pki/myca.csr'}
```
salt.modules.x509.create_crl(path=None, text=False, signing_private_key=None, signing_cert=None, revoked=None, include_expired=False, days_valid=100)

Create a CRL

Depends

- PyOpenSSL Python module

path: Path to write the crl to.

text: If True, return the PEM text without writing to a file. Default False.

signing_private_key: A path or string of the private key in PEM format that will be used to sign this crl. This is required.

signing_cert: A certificate matching the private key that will be used to sign this crl. This is required.

revoked: A list of dicts containing all the certificates to revoke. Each dict represents one certificate. A dict must contain either the key serial_number with the value of the serial number to revoke, or certificate with either the PEM encoded text of the certificate, or a path of the certificate to revoke.

The dict can optionally contain the revocation_date key. If this key is omitted the revocation date will be set to now. If should be a string in the format ``%Y-%m-%d %H:%M:%S``.

The dict can also optionally contain the not_after key. This is redundant if the certificate key is included. If the Certificate key is not included, this can be used for the logic behind the include_expired parameter. If should be a string in the format ``%Y-%m-%d %H:%M:%S``.

The dict can also optionally contain the reason key. This is the reason code for the revocation. Available choices are unspecified, keyCompromise, CACompromise, affiliationChanged, superseded, cessationOfOperation and certificateHold.

include_expired: Include expired certificates in the CRL. Default is False.

days_valid: The number of days that the CRL should be valid. This sets the Next Update field in the CRL.

CLI Example:

```
salt '*' x509.create_crl path=/etc/pki/mykey.key signing_private_key=/etc/pki/ca.key 
    signing_cert=/etc/pki/ca.crt 
    revoked="[{'compromised-web-key': {'certificate': '/etc/pki/certs/www1.crt', 
        'revocation_date': '2015-03-01 00:00:00'}}]
```

salt.modules.x509.create_csr(path=None, text=False, **kwargs)

Create a certificate signing request.

path: Path to write the certificate to.

text: If True, return the PEM text without writing to a file. Default False.

kwargs: The subject, extension and version arguments from x509.create_certificate can be used.

CLI Example:

```
salt '*' x509.create_csr path=/etc/pki/myca.csr public_key='/etc/pki/myca.key' CN='My Cert
```

salt.modules.x509.create_private_key(path=None, text=False, bits=2048)

Creates a private key in PEM format.

path: The path to write the file to, either path or text are required.

text: If True, return the PEM text without writing to a file. Default False.
bits: Lenth of the private key in bits. Default 2048

CLI Example:
```
salt '*' x509.create_private_key path=/etc/pki/mykey.key
```

salt.modules.x509.get_pem_entries(glob_path)
Returns a dict containing PEM entries in files matching a glob

glob_path: A path to certificates to be read and returned.

CLI Example:
```
salt '*' x509.read_pem_entries "/etc/pki/*/crt"
```

salt.modules.x509.get_pem_entry(text, pem_type=None)
Returns a properly formatted PEM string from the input text fixing any whitespace or line-break issues

text: Text containing the X509 PEM entry to be returned or path to a file containing the text.
Pem_type: If specified, this function will only return a pem of a certain type, for example `CERTIFICATE` or `CERTIFICATE REQUEST`.

CLI Example:
```
salt '*' x509.get_pem_entry "-----BEGIN CERTIFICATE REQUEST-----MIICyzCC Ar8CAQI..."-----END CERTIFICATE REQUEST"
```

salt.modules.x509.get_private_key_size(private_key)
Returns the bit length of a private key in PEM format.

private_key: A path or PEM encoded string containing a private key.

CLI Example:
```
salt '*' x509.get_private_key_size /etc/pki/mycert.key
```

salt.modules.x509.get_public_key(key)
Returns a string containing the public key in PEM format.

key: A path or PEM encoded string containing a CSR, Certificate or Private Key from which a public key can be retrieved.

CLI Example:
```
salt '*' x509.get_public_key /etc/pki/mycert.cer
```

salt.modules.x509.get_signing_policy(signing_policy_name)
Returns the details of a names signing policy, including the text of the public key that will be used to sign it. Does not return the private key.

CLI Example:
```
salt '*' x509.get_signing_policy www
```

salt.modules.x509.read_certificate(certificate)
Returns a dict containing details of a certificate. Input can be a PEM string or file path.

certificate: The certificate to be read. Can be a path to a certificate file, or a string containing the PEM formatted text of the certificate.

CLI Example:
```
salt '*' x509.read_certificate /etc/pki/mycert.crt
```
salt.modules.x509.read_certificates(glob_path)
Returns a dict containing details of all certificates matching a glob

glob_path: A path to certificates to be read and returned.

CLI Example:
```
salt '***' x509.read_certificates "'/etc/pki/*.*.crt"
```

salt.modules.x509.read_crl(crl)
Returns a dict containing details of a certificate revocation list. Input can be a PEM string or file path.

Depends

- OpenSSL command line tool
csl: A path or PEM encoded string containing the CSL to read.

CLI Example:
```
salt '***' x509.read_crl /etc/pki/mycrl.crl
```

salt.modules.x509.read_csr(csr)
Returns a dict containing details of a certificate request.

Depends

- OpenSSL command line tool
csr: A path or PEM encoded string containing the CSR to read.

CLI Example:
```
salt '***' x509.read_csr /etc/pki/mycert.csr
```

salt.modules.x509.sign_remote_certificate(argdic, **kwargs)
Request a certificate to be remotely signed according to a signing policy.

argdic: A dict containing all the arguments to be passed into the create_certificate function. This will become kwargs when passed to create_certificate.

kwargs: kwargs delivered from publish.publish

CLI Example:
```
salt '***' x509.sign_remote_certificate argdic={"public_key": '/etc/pki/www.key', \ 'signing_policy': 'www'}" __pub_id='www1'
```

salt.modules.x509.verify_crl(crl, cert)
Validate a CRL against a certificate. Parses openssl command line output, this is a workaround for M2Crypto's inability to get them from CSR objects.
crl: The CRL to verify
cert: The certificate to verify the CRL against

CLI Example:
```
salt '***' x509.verify_crl crl=/etc/pki/myca.crl cert=/etc/pki/myca.crt
```

salt.modules.x509.verify_private_key(private_key, public_key)
Verify that `private_key` matches `public_key`
**private_key**: The private key to verify, can be a string or path to a private key in PEM format.

**public_key**: The public key to verify, can be a string or path to a PEM formatted certificate, csr, or another private key.

CLI Example:
```
salt '*' x509.verify_private_key private_key=/etc/pki/myca.key public_key=/etc/pki/myca.crt
```

```
salt.modules.x509.verify_signature (certificate, signing_pub_key= None)
```
Verify that certificate has been signed by signing_pub_key

certificate: The certificate to verify. Can be a path or string containing a PEM formatted certificate.

**signing_pub_key**: The public key to verify, can be a string or path to a PEM formatted certificate, csr, or private key.

CLI Example:
```
salt '*' x509.verify_private_key private_key=/etc/pki/myca.key public_key=/etc/pki/myca.crt
```

```
salt.modules.x509.write_pem (text, path, pem_type=None)
```
Writes out a PEM string fixing any formatting or whitespace issues before writing.

text: PEM string input to be written out.

path: Path of the file to write the pem out to.

**pem_type**: The PEM type to be saved, for example CERTIFICATE or PUBLIC KEY. Adding this will allow the function to take input that may contain multiple pem types.

CLI Example:
```
salt '*' x509.write_pem "-----BEGIN CERTIFICATE-----MIIGMzCCBBugA..." path=/etc/pki/mycert.crt
```

### 31.16.313 salt.modules.xapi

This module (mostly) uses the XenAPI to manage Xen virtual machines.

Big fat warning: the XenAPI used in this file is the one bundled with Xen Source, NOT XenServer nor Xen Cloud Platform. As a matter of fact it will fail under those platforms. From what I’ve read, little work is needed to adapt this code to XS/XCP, mostly playing with XenAPI version, but as XCP is not taking precedence on Xen Source on many platforms, please keep compatibility in mind.

Useful documentation:

- [http://downloads.xen.org/Wiki/XenAPI/xenapi-1.0.6.pdf](http://downloads.xen.org/Wiki/XenAPI/xenapi-1.0.6.pdf)
- [http://docs.vmd.citrix.com/XenServer/6.0.0/1.0/en_gb/api/](http://docs.vmd.citrix.com/XenServer/6.0.0/1.0/en_gb/api/)
- [https://github.com/xapi-project/xen-api/tree/master/scripts/examples/python](https://github.com/xapi-project/xen-api/tree/master/scripts/examples/python)
- [http://xenbits.xen.org/gitweb/?p=xen.git;a=tree;f=tools/python/xen/xm;hb=HEAD](http://xenbits.xen.org/gitweb/?p=xen.git;a=tree;f=tools/python/xen/xm;hb=HEAD)

```
salt.modules.xapi.create (config_)
```
Start a defined domain

CLI Example:
```
salt '*' virt.create <path to Xen cfg file>
```

```
salt.modules.xapi.destroy (vm_)
```
Hard power down the virtual machine, this is equivalent to pulling the power

CLI Example:
<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
<th>CLI Example</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>salt '*' virt.destroy &lt;vm name&gt;</code></td>
<td>Returns an int representing the number of unallocated cpus on this hypervisor</td>
<td><code>salt '*' virt.destroy</code></td>
</tr>
<tr>
<td><code>salt.modules.xapi.freecpu()</code></td>
<td>Return an int representing the number of unallocated cpus on this hypervisor</td>
<td><code>salt '*' virt.freecpu</code></td>
</tr>
<tr>
<td><code>salt.modules.xapi.freemem()</code></td>
<td>Return an int representing the amount of memory that has not been given to virtual machines on this node</td>
<td><code>salt '*' virt.freemem</code></td>
</tr>
<tr>
<td><code>salt.modules.xapi.full_info()</code></td>
<td>Return the node_info, vm_info and freemem</td>
<td><code>salt '*' virt.full_info</code></td>
</tr>
<tr>
<td><code>salt.modules.xapi.get_disks(vm_)</code></td>
<td>Return the disks of a named vm</td>
<td><code>salt '*' virt.get_disks &lt;vm name&gt;</code></td>
</tr>
<tr>
<td><code>salt.modules.xapi.get_macs(vm_)</code></td>
<td>Return a list of MAC addresses from the named vm</td>
<td><code>salt '*' virt.get_macs &lt;vm name&gt;</code></td>
</tr>
<tr>
<td><code>salt.modules.xapi.get_nics(vm_)</code></td>
<td>Return info about the network interfaces of a named vm</td>
<td><code>salt '*' virt.get_nics &lt;vm name&gt;</code></td>
</tr>
<tr>
<td><code>salt.modules.xapi.is_hyper()</code></td>
<td>Returns a bool whether or not this node is a hypervisor of any kind</td>
<td><code>salt '*' virt.is_hyper</code></td>
</tr>
<tr>
<td><code>salt.modules.xapi.list_vms()</code></td>
<td>Return a list of virtual machine names on the minion</td>
<td><code>salt '*' virt.list_vms</code></td>
</tr>
<tr>
<td><code>salt.modules.xapi.migrate(vm_, target, live=1, port=0, node=-1, ssl=None, change_home_server=0)</code></td>
<td>Migrates the virtual machine to another hypervisor</td>
<td><code>salt '*' virt.migrate</code></td>
</tr>
</tbody>
</table>
```
salt '*' virt.migrate <vm name> <target hypervisor> [live] [port] [node] [ssl] [change_home_server]
```

Optional values:

- `live` Use live migration
- `port` Use a specified port
- `node` Use specified NUMA node on target
- `ssl` Use ssl connection for migration
- `change_home_server` change home server for managed domains

```
salt.modules.xapi.node_info()
```

Return a dict with information about this node

CLI Example:
```
salt '*' virt.node_info
```

```
salt.modules.xapi.pause(vm_)
```

Pause the named vm

CLI Example:
```
salt '*' virt.pause <vm name>
```

```
salt.modules.xapi.reboot(vm_)
```

Reboot a domain via ACPI request

CLI Example:
```
salt '*' virt.reboot <vm name>
```

```
salt.modules.xapi.reset(vm_)
```

Reset a VM by emulating the reset button on a physical machine

CLI Example:
```
salt '*' virt.reset <vm name>
```

```
salt.modules.xapi.resume(vm_)
```

Resume the named vm

CLI Example:
```
salt '*' virt.resume <vm name>
```

```
salt.modules.xapi.setmem(vm_, memory)
```

Changes the amount of memory allocated to VM.

Memory is to be specified in MB

CLI Example:
```
salt '*' virt.setmem myvm 768
```

```
salt.modules.xapi.setvcpus(vm_, vcpus)
```

Changes the amount of vcpus allocated to VM.

`vcpus` is an int representing the number to be assigned

CLI Example:
salt '*' virt.setvcpus myvm 2

salt.modules.xapi.shutdown(vm_)
    Send a soft shutdown signal to the named vm
    CLI Example:
    salt '*' virt.shutdown <vm name>

salt.modules.xapi.start(config_)
    Alias for the obscurely named 'create' function
    CLI Example:
    salt '*' virt.start <path to Xen cfg file>

salt.modules.xapi.vcpu_pin(vm_, vcpu, cpus)
    Set which CPUs a VCPU can use.
    CLI Example:
    salt 'foo' virt.vcpu_pin domU-id 2 1
    salt 'foo' virt.vcpu_pin domU-id 2 2-6

salt.modules.xapi.vm_cputime(vm_=None)
    Return cpu time used by the vms on this hyper in a list of dicts:
    
    ['your-vm': {'cputime': <int>,
                 'cputime_percent': <int>},
     ...]

    If you pass a VM name in as an argument then it will return info for just the named VM, otherwise it will return all VMs.
    CLI Example:
    salt '*' virt.vm_cputime

salt.modules.xapi.vm_diskstats(vm_=None)
    Return disk usage counters used by the vms on this hyper in a list of dicts:
    
    ['your-vm': {'io_read_kbs': 0, 'io_write_kbs': 0},
     ...]

    If you pass a VM name in as an argument then it will return info for just the named VM, otherwise it will return all VMs.
    CLI Example:
    salt '*' virt.vm_diskstats
salt.modules.xapi.vm_info(vm_=None)
Return detailed information about the vms.
If you pass a VM name in as an argument then it will return info for just the named VM, otherwise it will return all VMs.
CLI Example:
salt '*' virt.vm_info

salt.modules.xapi.vm_netstats(vm_=None)
Return combined network counters used by the vms on this hyper in a list of dicts:

```
[  
  'your-vm': {  
    'io_read_kbs':     0,  
    'io_total_read_kbs': 0,  
    'io_total_write_kbs': 0,  
    'io_write_kbs':     0  
  },  
  ...
]
```
If you pass a VM name in as an argument then it will return info for just the named VM, otherwise it will return all VMs.
CLI Example:
salt '*' virt.vm_netstats

salt.modules.xapi.vm_state(vm_=None)
Return list of all the vms and their state.
If you pass a VM name in as an argument then it will return info for just the named VM, otherwise it will return all VMs.
CLI Example:
salt '*' virt.vm_state <vm name>

31.16.314  salt.modules.xfs
Module for managing XFS file systems.
salt.modules.xfs.defragment(device)
Defragment mounted XFS filesystem. In order to mount a filesystem, device should be properly mounted and writable.
CLI Example:
salt '*' xfs.defragment /dev/sda1

salt.modules.xfs.devices()
Get known XFS formatted devices on the system.
CLI Example:
salt '*' xfs.devices
salt.modules.xfs.dump( device, destination, level=0, label=None, noerase=None)

Dump filesystem device to the media (file, tape etc).

Required parameters:
- **device**: XFS device, content of which to be dumped.
- **destination**: Specifies a dump destination.

Valid options are:
- **label**: Label of the dump. Otherwise automatically generated label is used.
- **level**: Specifies a dump level of 0 to 9.
- **noerase**: Pre-erase media.

Other options are not used in order to let xfsdump use its default values, as they are most optimal. See the xfsdump(8) manpage for a more complete description of these options.

CLI Example:
```
salt '*' xfs.dump /dev/sda1 /destination/on/the/client
salt '*' xfs.dump /dev/sda1 /destination/on/the/client label='Company accountancy'
salt '*' xfs.dump /dev/sda1 /destination/on/the/client noerase=True
```

salt.modules.xfs.estimate(path)

Estimate the space that an XFS filesystem will take. For each directory estimate the space that directory would take if it were copied to an XFS filesystem. Estimation does not cross mount points.

CLI Example:
```
salt '*' xfs.estimate /path/to/file
salt '*' xfs.estimate /path/to/dir/*
```

salt.modules.xfs.info(device)

Get filesystem geometry information.

CLI Example:
```
salt '*' xfs.info /dev/sda1
```

salt.modules.xfs.inventory()

Display XFS dump inventory without restoration.

CLI Example:
```
salt '*' xfs.inventory
```

salt.modules.xfs.mkfs(device, label=None, ssize=None, noforce=None, bso=None, gmo=None, ino=None, lso=None, rso=None, nmo=None, dso=None)

Create a filesystem on the specified device. By default wipes out with force.

General options:
- **label**: Specify volume label.
- **ssize**: Specify the fundamental sector size of the filesystem.
- **noforce**: Do not force create filesystem, if disk is already formatted.

Filesystem geometry options:
- **bso**: Block size options.
- **gmo**: Global metadata options.
• **dso**: Data section options. These options specify the location, size, and other parameters of the data section of the filesystem.

• **ino**: Inode options to specify the inode size of the filesystem, and other inode allocation parameters.

• **lso**: Log section options.

• **nno**: Naming options.

• **rso**: Realtime section options.

See the `mkfs.xfs(8)` manpage for a more complete description of corresponding options description.

**CLI Example:**

```bash
salt '*' xfs.mkfs /dev/sda1
dso='su=32k,sw=6' noforce=True

salt '*' xfs.mkfs /dev/sda1
dso='su=32k,sw=6' lso='logdev=/dev/sda2,size=10000b'
```

**salt.modules.xfs.modify(device, label=None, lazy_counting=None, uuid=None)**

Modify parameters of an XFS filesystem.

**CLI Example:**

```bash
salt '*' xfs.modify /dev/sda1 label='My backup' lazy_counting=False
salt '*' xfs.modify /dev/sda1 uuid=False
salt '*' xfs.modify /dev/sda1 uuid=True
```

**salt.modules.xfs.prune_dump(sessionid)**

Prunes the dump session identified by the given session id.

**CLI Example:**

```bash
salt '*' xfs.prune_dump b74a3586-e52e-4a4a-8775-c3334fa8ea2c
```

### 31.16.315 `salt.modules.xmpp`

Module for Sending Messages via XMPP (a.k.a. Jabber)

New in version 2014.1.0.

**depends**

- sleekxmpp>=1.3.1
- pyasn1
- pyasn1-modules
- dnspython

**configuration** This module can be used by either passing a jid and password directly to `send_message`, or by specifying the name of a configuration profile in the minion config, minion pillar, or master config.

For example:

```yaml
my-xmpp-login:
  xmpp.jid: myuser@jabber.example.org/resource\name
  xmpp.password: verybadpass
```

The resource\name refers to the resource that is using this account. It is user-definable, and optional.

The following configurations are both valid:
Salt Documentation, Release 2015.8.0

my-xmpp-login:
xmpp.jid: myuser@jabber.example.org/salt
xmmp.password: verybadpass

my-xmpp-login:
xmpp.jid: myuser@jabber.example.org
xmmp.password: verybadpass

class salt.modules.xmpp.SendMsgBot(jid, password, recipient, msg)

    classmethod create_multi(jid, password, recipients=None, rooms=None, nick='SaltStack Bot')
    Alternate constructor that accept multiple recipients and rooms

    start(event)

class salt.modules.xmpp.SleekXMPPMUC(name='')

    filter(record)

salt.modules.xmpp.send_msg(recipient, message, jid=None, password=None, profile=None)
    Send a message to an XMPP recipient. Designed for use in states.

    CLI Examples:

            xmpp.send_msg 'admins@xmpp.example.com' 'This is a salt module test' profile='my-xmpp-account'
            xmpp.send_msg 'admins@xmpp.example.com' 'This is a salt module test' jid='myuser@xmpp.example.com'

salt.modules.xmpp.send_msg_multi(message, recipients=None, rooms=None, jid=None, password=None, nick='SaltStack Bot', profile=None)
    Send a message to an XMPP recipient, support send message to multiple recipients or chat room.

    CLI Examples:

            xmpp.send_msg recipients=['admins@xmpp.example.com'] rooms=['secret@conference.xmpp.example.com']
            xmpp.send_msg recipients=['admins@xmpp.example.com'] rooms=['secret@conference.xmpp.example.com']

31.16.3.16 salt.modules.yumpkg

Support for YUM

Note: This module makes heavy use of the repoquery utility, from the yum-utils package. This package will be installed as a dependency if salt is installed via EPEL. However, if salt has been installed using pip, or a host is being managed using salt-ssh, then as of version 2014.7.0 yum-utils will be installed automatically to satisfy this dependency.

salt.modules.yumpkg.check_db(*names, **kwargs)
    New in version 0.17.0.
    Returns a dict containing the following information for each specified package:

    1. A key found, which will be a boolean value denoting if a match was found in the package database.

    2. If found is False, then a second key called suggestions will be present, which will contain a list of possible matches.

    The fromrepo, enablerepo and disablerepo arguments are supported, as used in pkg states, and the disableexcludes option is also supported.
New in version 2014.7.0: Support for the `disableexcludes` option

**CLI Examples:**

```bash
salt '*' pkg.check_db <package1> <package2> <package3>
salt '*' pkg.check_db <package1> <package2> <package3> fromrepo=epel-testing
salt '*' pkg.check_db <package1> <package2> <package3> disableexcludes=main
```

```python
salt.modules.yumpkg.clean_metadata(**kwargs)
```

New in version 2014.1.0.

Cleans local yum metadata. Functionally identical to `refresh_db()`.

**CLI Example:**

```bash
salt '*' pkg.clean_metadata
```

```python
salt.modules.yumpkg.del_repo(repo, basedir=None, **kwargs)
```

Delete a repo from <basedir> (default basedir: all dirs in `reposdir` yum option).

If the .repo file that the repo exists in does not contain any other repo configuration, the file itself will be deleted.

**CLI Examples:**

```bash
salt '*' pkg.del_repo myrepo
salt '*' pkg.del_repo myrepo basedir=/path/to/dir
salt '*' pkg.del_repo myrepo basedir=/path/to/dir,/path/to/another/dir
```

```python
salt.modules.yumpkg.diff('paths')
```

Return a formatted diff between current files and original in a package. NOTE: this function includes all files (configuration and not), but does not work on binary content.

**Parameters** path -- Full path to the installed file

**Returns** Difference string or raises and exception if examined file is binary.

**CLI example:**

```bash
salt '*' pkg.diff /etc/apache2/httpd.conf /etc/sudoers
```

```python
salt.modules.yumpkg.download('packages')
```

New in version 2015.5.0.

Download packages to the local disk. Requires `yumdownloader` from `yum-utils` package.

**Note:** `yum-utils` will already be installed on the minion if the package was installed from the Fedora / EPEL repositories.

**CLI example:**

```bash
salt '*' pkg.download httpd
salt '*' pkg.download httpd postfix
```

```python
salt.modules.yumpkg.expand_repo_def(repokwargs)
```

Take a repository definition and expand it to the full pkg repository dict that can be used for comparison. This is a helper function to make certain repo managers sane for comparison in the pkgrepo states.

There is no use to calling this function via the CLI.

```python
salt.modules.yumpkg.file_dict('packages')
```

New in version 2014.1.0.
List the files that belong to a package, grouped by package. Not specifying any packages will return a list of every file on the system's rpm database (not generally recommended).

CLI Examples:

- `salt '*' pkg.file_list httpd`
- `salt '*' pkg.file_list httpd postfix`
- `salt '*' pkg.file_list`

```
salt.modules.yumpkg.file_list(*packages)
```

New in version 2014.1.0.

List the files that belong to a package. Not specifying any packages will return a list of every file on the system's rpm database (not generally recommended).

CLI Examples:

- `salt '*' pkg.file_list httpd`
- `salt '*' pkg.file_list httpd postfix`
- `salt '*' pkg.file_list`

```
salt.modules.yumpkg.get_locked_packages(pattern=None, full=True)
```

Get packages that are currently locked `yum -q versionlock list`.

CLI Example:

```
salt '*' pkg.get_locked_packages
```

```
salt.modules.yumpkg.get_repo(repo, basedir=None, **kwargs)
```

Display a repo from <basedir> (default basedir: all dirs in `reposdir yum option`).

CLI Examples:

- `salt '*' pkg.get_repo myrepo`
- `salt '*' pkg.get_repo myrepo basedir=/path/to/dir`
- `salt '*' pkg.get_repo myrepo basedir=/path/to/dir,/path/to/another/dir`

```
salt.modules.yumpkg.group_diff(name)
```

New in version 2014.1.0.

Lists packages belonging to a certain group, and which are installed

CLI Example:

```
salt '*' pkg.group_diff 'Perl Support'
```

```
salt.modules.yumpkg.group_info(name)
```

New in version 2014.1.0.

Lists packages belonging to a certain group

CLI Example:

```
salt '*' pkg.group_info 'Perl Support'
```

```
salt.modules.yumpkg.group_install(name, skip=(), include=(), **kwargs)
```

New in version 2014.1.0.

Install the passed package group(s). This is basically a wrapper around `pkg.install`, which performs package group resolution for the user. This function is currently considered experimental, and should be expected to undergo changes.
**name**  Package group to install. To install more than one group, either use a comma-separated list or pass the value as a python list.

**CLI Examples:**

```bash
salt '*' pkg.group_install 'Group 1'
salt '*' pkg.group_install 'Group 1,Group 2'
salt '*' pkg.group_install ['"Group 1", "Group 2"]
```

**skip**  Packages that would normally be installed by the package group (``default'' packages), which should not be installed. Can be passed either as a comma-separated list or a python list.

**CLI Examples:**

```bash
salt '*' pkg.group_install 'My Group' skip='foo,bar'
salt '*' pkg.group_install 'My Group' skip=['"foo", "bar"]'
```

**include**  Packages which are included in a group, which would not normally be installed by a `yum groupinstall` (``optional'' packages). Note that this will not enforce group membership; if you include packages which are not members of the specified groups, they will still be installed. Can be passed either as a comma-separated list or a python list.

**CLI Examples:**

```bash
salt '*' pkg.group_install 'My Group' include='foo,bar'
salt '*' pkg.group_install 'My Group' include=['"foo", "bar"]'
```

---

**Note:**  Because this is essentially a wrapper around `pkg.install`, any argument which can be passed to `pkg.install` may also be included here, and it will be passed along wholesale.

---

**salt.modules.yumpkg.group_list()**

New in version 2014.1.0.

Lists all groups known by yum on this system

**CLI Example:**

```bash
salt '*' pkg.group_list
```

**salt.modules.yumpkg.hold(name=None, pkgs=None, sources=None, **kwargs)**

New in version 2014.7.0.

Hold packages with `yum -q versionlock`.

**name**  The name of the package to be held.

Multiple Package Options:

**pkgs**  A list of packages to hold. Must be passed as a python list. The `name` parameter will be ignored if this option is passed.

Returns a dict containing the changes.

**CLI Example:**

```bash
salt '*' pkg.hold <package name>
salt '*' pkg.hold pkgs=['"foo", "bar"]'
```

**salt.modules.yumpkg.info_installed(names)**

Return the information of the named package(s), installed on the system.

**CLI example:**
```
salt '*' pkg.info_installed <package1>
salt '*' pkg.info_installed <package1> <package2> <package3> ...
```

```python
salt.modules.yumpkg.install(name=None, refresh=False, fromrepo=None, skip_verify=False, pkgs=None, sources=None, reinstall=False, normalize=True, **kwargs)
```

Install the passed package(s), add refresh=True to clean the yum database before package is installed.

**name** The name of the package to be installed. Note that this parameter is ignored if either ``pkgs'' or ``sources'' is passed. Additionally, please note that this option can only be used to install packages from a software repository. To install a package file manually, use the ``sources'' option.

32-bit packages can be installed on 64-bit systems by appending the architecture designation (`.i686`, `.i586`, etc.) to the end of the package name.

CLI Example:
```
salt '*' pkg.install <package name>
```

**refresh** Whether or not to update the yum database before executing.

**reinstall** Specifying reinstall=True will use `yum reinstall` rather than `yum install` for requested packages that are already installed.

If a version is specified with the requested package, then `yum reinstall` will only be used if the installed version matches the requested version.

Works with `sources` when the package header of the source can be matched to the name and version of an installed package.

New in version 2014.7.0.

**skip_verify** Skip the GPG verification check (e.g., `--nogpgcheck`)

**version** Install a specific version of the package, e.g. 1.2.3-4.el5. Ignored if ``pkgs'' or ``sources'' is passed.

Repository Options:

**fromrepo** Specify a package repository (or repositories) from which to install. (e.g., `yum --disablerepo='*' --enablerepo='somerepo'`)

**enablerepo** (ignored if **fromrepo** is specified) Specify a disabled package repository (or repositories) to enable. (e.g., `yum --enablerepo='somerepo'`)

**disablerepo** (ignored if **fromrepo** is specified) Specify an enabled package repository (or repositories) to disable. (e.g., `yum --disablerepo='somerepo'`)

**disableexcludes** Disable exclude from main, for a repo or for everything. (e.g., `yum --disableexcludes='main'`)

New in version 2014.7.0.

Multiple Package Installation Options:

**pkgs** A list of packages to install from a software repository. Must be passed as a python list. A specific version number can be specified by using a single-element dict representing the package and its version.

CLI Examples:
```
salt '*' pkg.install pkgs=["foo", "bar"]
salt '*' pkg.install pkgs=["foo", {"bar": "1.2.3-4.el5"}]
```

**sources** A list of RPM packages to install. Must be passed as a list of dicts, with the keys being package names, and the values being the source URI or local path to the package.
**CLI Example:**
```
salt '* pkg.install sources=\[\{"foo": "salt://foo.rpm"}, \{"bar": "salt://bar.rpm"}\]\]
```

**normalize** [True] Normalize the package name by removing the architecture. This is useful for poorly created packages which might include the architecture as an actual part of the name such as kernel modules which match a specific kernel version.

```
salt -G role:nsd pkg.install gpfs.gplbin-2.6.32-279.31.1.el6.x86_64 normalize=False
```

New in version 2014.7.0.

Returns a dict containing the new package names and versions:
```
{ '<package>': { 'old': '<old-version>', 'new': '<new-version>' }}
```

**salt.modules.yumpkg.latest_version(**names**, **kwargs)**
Return the latest version of the named package available for upgrade or installation. If more than one package name is specified, a dict of name/version pairs is returned.

If the latest version of a given package is already installed, an empty string will be returned for that package.

A specific repo can be requested using the fromrepo keyword argument, and the disableexcludes option is also supported.

New in version 2014.7.0: Support for the disableexcludes option

**CLI Example:**
```
salt '* pkg.latest_version <package name>
salt '* pkg.latest_version <package name> fromrepo=epel-testing
salt '* pkg.latest_version <package name> disableexcludes=main
salt '* pkg.latest_version <package1> <package2> <package3> ...
```

**salt.modules.yumpkg.list_pkgs**(versions_as_list=False, **kwargs)**
List the packages currently installed in a dict:
```
{ '<package_name>': '<version>' }
```

**CLI Example:**
```
salt '* pkg.list_pkgs
```

**salt.modules.yumpkg.list_repo_pkgs**(args, **kwargs)**
New in version 2014.7.0.

Changed in version 2014.7.0: All available versions of each package are now returned. This required a slight modification to the structure of the return dict. The return data shown below reflects the updated return dict structure.

Returns all available packages. Optionally, package names (and name globs) can be passed and the results will be filtered to packages matching those names. This is recommended as it speeds up the function considerably.

This function can be helpful in discovering the version or repo to specify in a pkg.installed state.

The return data is a dictionary of repo names, with each repo containing a dictionary in which the keys are package names, and the values are a list of version numbers. Here is an example of the return data:
```
{
    'base': {
        'bash': ['4.1.2-15.el6_4'],
    }
}
from repo [None] Only include results from the specified repo(s). Multiple repos can be specified, comma-separated.

CLI Example:
```
salt '*' pkg.list_repo_pkgs
salt '*' pkg.list_repo_pkgs foo bar baz
salt '*' pkg.list_repo_pkgs 'samba4*' fromrepo=base,updates
```

salt.modules.yumpkg.list_repos(basedir=None)
Lists all repos in <basedir> (default: all dirs in reposdir yum option).

CLI Example:
```
salt '*' pkg.list_repos
salt '*' pkg.list_repos basedir=/path/to/dir
salt '*' pkg.list_repos basedir=/path/to/dir,/path/to/another/dir
```

salt.modules.yumpkg.list_upgrades(refresh=True, **kwargs)
Check whether or not an upgrade is available for all packages

The fromrepo, enablerepo, and disablerepo arguments are supported, as used in pkg states, and the
disableexcludes option is also supported.

New in version 2014.7.0: Support for the disableexcludes option

CLI Example:
```
salt '*' pkg.list_upgrades
```

salt.modules.yumpkg.mod_repo(repo, basedir=None, **kwargs)
Modify one or more values for a repo. If the repo does not exist, it will be created, so long as the following
values are specified:

repo name by which the yum refers to the repo
name a human-readable name for the repo
baseurl the URL for yum to reference
mirrorlist the URL for yum to reference

Key/Value pairs may also be removed from a repo's configuration by setting a key to a blank value. Bear in
mind that a name cannot be deleted, and a baseurl can only be deleted if a mirrorlist is specified (or vice versa).
CLI Examples:

```bash
salt '*' pkg.mod_repo reponame enabled=1 gpgcheck=1
salt '*' pkg.mod_repo reponame basedir=/path/to/dir enabled=1
salt '*' pkg.mod_repo reponame baseurl=mirrorlist=http://host.com/
```

```python
salt.modules.yumpkg.modified('packages', **'flags')
```

List the modified files that belong to a package. Not specifying any packages will return a list of _all_ modified files on the system’s RPM database.

New in version 2015.5.0.

Filtering by flags (True or False):

- **size** Include only files where size changed.
- **mode** Include only files which file’s mode has been changed.
- **checksum** Include only files which MD5 checksum has been changed.
- **device** Include only files which major and minor numbers has been changed.
- **symlink** Include only files which are symbolic link contents.
- **owner** Include only files where owner has been changed.
- **group** Include only files where group has been changed.
- **time** Include only files where modification time of the file has been changed.
- **capabilities** Include only files where capabilities differ or not. Note: supported only on newer RPM versions.

CLI Examples:

```bash
salt '*' pkg.modified
salt '*' pkg.modified httpd
salt '*' pkg.modified httpd postfix
salt '*' pkg.modified httpd owner=True group=False
```

```python
salt.modules.yumpkg.normalize_name(name)
```

Strips the architecture from the specified package name, if necessary. Circumstances where this would be done include:

- If the arch is 32 bit and the package name ends in a 32-bit arch.
- If the arch matches the OS arch, or is noarch.

CLI Example:

```bash
salt '*' pkg.normalize_name zsh.x86_64
```

```python
salt.modules.yumpkg.owner('paths')
```

New in version 2014.7.0.

Return the name of the package that owns the file. Multiple file paths can be passed. Like `pkg.version` <salt.modules.yumpkg.version>, if a single path is passed, a string will be returned, and if multiple paths are passed, a dictionary of file/package name pairs will be returned.

If the file is not owned by a package, or is not present on the minion, then an empty string will be returned for that path.

CLI Examples:

```bash
salt '*' pkg.owner /usr/bin/apachectl
salt '*' pkg.owner /etc/httpd/conf/httpd.conf
```
salt.modules.yumpkg.purge(name=None, pkgs=None, **kwargs)

Package purges are not supported by yum, this function is identical to pkg.remove.

name The name of the package to be deleted.

Multiple Package Options:

pkgs A list of packages to delete. Must be passed as a python list. The name parameter will be ignored if this option is passed.

New in version 0.16.0.

Returns a dict containing the changes.

CLI Example:

salt '*' pkg.purge <package name>
salt '*' pkg.purge <package1>,<package2>,<package3>
salt '*' pkg.purge pkgs='["foo", "bar"]'

salt.modules.yumpkg.refresh_db(branch_arg=None, repo_arg=None, exclude_arg=None, branch=None, repo=None, exclude=None)

Check the yum repos for updated packages

Returns:

- True: Updates are available
- False: An error occurred
- None: No updates are available

CLI Example:

salt '*' pkg.refresh_db

salt.modules.yumpkg.remove(name=None, pkgs=None, **kwargs)

Remove packages with yum -q -y remove.

name The name of the package to be deleted.

Multiple Package Options:

pkgs A list of packages to delete. Must be passed as a python list. The name parameter will be ignored if this option is passed.

New in version 0.16.0.

Returns a dict containing the changes.

CLI Example:

salt '*' pkg.remove <package name>
salt '*' pkg.remove <package1>,<package2>,<package3>
salt '*' pkg.remove pkgs='["foo", "bar"]'

salt.modules.yumpkg.unhold(name=None, pkgs=None, sources=None, **kwargs)

New in version 2014.7.0.

Hold packages with yum -q versionlock.

name The name of the package to be deleted.

Multiple Package Options:
**pkgs** A list of packages to unhold. Must be passed as a python list. The `name` parameter will be ignored if this option is passed.

Returns a dict containing the changes.

CLI Example:

```
salt '*' pkg.unhold <package name>
salt '*' pkg.unhold pkgs=['"foo", "bar"]
```

**salt.modules.yumpkg.upgrade**(refresh=True, fromrepo=None, skip_verify=False, **kwargs)

Run a full system upgrade, a yum upgrade

Changed in version 2014.7.0.

Return a dict containing the new package names and versions:

```
{'<package>': {'old': '<old-version>', 'new': '<new-version>'}}
```

CLI Example:

```
salt '*' pkg.upgrade
```

Repository Options:

- `fromrepo` Specify a package repository (or repositories) from which to install. (e.g., `yum --disablerepo='*' --enablerepo='somerepo'`)
- `enablerepo` (ignored if `fromrepo` is specified) Specify a disabled package repository (or repositories) to enable. (e.g., `yum --enablerepo='somerepo'`)
- `disablerepo` (ignored if `fromrepo` is specified) Specify an enabled package repository (or repositories) to disable. (e.g., `yum --disablerepo='somerepo'`)
- `disableexcludes` Disable exclude from main, for a repo or for everything. (e.g., `yum --disableexcludes='main'`)

New in version 2014.7.0.

**salt.modules.yumpkg.upgrade_available**(name)

Check whether or not an upgrade is available for a given package

CLI Example:

```
salt '*' pkg.upgrade_available <package name>
```

**salt.modules.yumpkg.verify**(names, **kwargs)

New in version 2014.1.0.

Runs an rpm -Va on a system, and returns the results in a dict

Files with an attribute of config, doc, ghost, license or readme in the package header can be ignored using the `ignore_types` keyword argument

CLI Example:

```
salt '*' pkg.verify
salt '*' pkg.verify httpd
salt '*' pkg.verify 'httpd postfix'
salt '*' pkg.verify 'httpd postfix' ignore_types=['config','doc']
```
```
salt.modules.yumpkg.version(*names, **kwargs)
    Returns a string representing the package version or an empty string if not installed. If more than one package
    name is specified, a dict of name/version pairs is returned.
    
    CLI Example:
    salt '*' pkg.version <package name>
    salt '*' pkg.version <package1> <package2> <package3> ...

salt.modules.yumpkg.version_cmp(pkg1, pkg2)
    New in version 2015.5.4.
    Do a cmp-style comparison on two packages. Return -1 if pkg1 < pkg2, 0 if pkg1 == pkg2, and 1 if pkg1 >
    pkg2. Return None if there was a problem making the comparison.
    
    CLI Example:
    salt '*' pkg.version_cmp '0.2-001' '0.2.0.1-002'
```

### 31.16.317 salt.modules.zcbuildout

Management of zc.buildout

New in version 2014.1.0.

This module is inspired by minitage's buildout maker

---

**Note:** The zc.buildout integration is still in beta; the API is subject to change

**General notes**

You have those following methods:

- upgrade_bootstrap
- bootstrap
- run_buildout
- buildout

```
salt.modules.zcbuildout.bootstrap(*a, **kw)
    Run the buildout bootstrap dance (python bootstrap.py).
    
    directory  directory to execute in
    config    alternative buildout configuration file to use
    runas     User used to run buildout as
    env       environment variables to set when running
    buildout_ver  force a specific buildout version (1 | 2)
    test_release    buildout accept test release
    offline    are we executing buildout in offline mode
    distribute Forcing use of distribute
    new_st    Forcing use of setuptools >= 0.7
```
Salt Documentation, Release 2015.8.0

python path to a python executable to use in place of default (salt one)
onlyif Only execute cmd if statement on the host return 0
unless Do not execute cmd if statement on the host return 0
use_vt Use the new salt VT to stream output [experimental]

CLI Example:

```
salt '*' buildout.bootstrap /srv/mybuildout
```

salt.modules.zcbuildout.buildout(*a,**kw)
Run buildout in a directory.
directory directory to execute in
config buildout config to use
parts specific buildout parts to run
runas user used to run buildout as
env environment variables to set when running
buildout_ver force a specific buildout version (1 | 2)
test_release buildout accept test release
new_st Forcing use of setuptools >= 0.7
distribute use distribute over setuptools if possible
offline does buildout run offline
python python to use
debug run buildout with -D debug flag
onlyif Only execute cmd if statement on the host return 0
unless Do not execute cmd if statement on the host return 0
newest run buildout in newest mode
verbose run buildout in verbose mode (-vvvvv)
use_vt Use the new salt VT to stream output [experimental]

CLI Example:

```
salt '*' buildout.buildout /srv/mybuildout
```

salt.modules.zcbuildout.run_buildout(*a,**kw)
Run a buildout in a directory.
directory directory to execute in
config alternative buildout configuration file to use
offline are we executing buildout in offline mode
runas user used to run buildout as
env environment variables to set when running
onlyif Only execute cmd if statement on the host return 0
unless Do not execute cmd if statement on the host return 0
newest  run buildout in newest mode
force  run buildout unconditionally
verbose  run buildout in verbose mode (-vvvvv)
use_vt  Use the new salt VT to stream output [experimental]

CLI Example:
```bash
salt '*' buildout.run_buildout /srv/mybuildout
```

```
salt.modules.zcbuildout.upgrade_bootstrap(*a,**kw)
    Upgrade current bootstrap.py with the last released one.
```
Indeed, when we first run a buildout, a common source of problem is to have a locally stale bootstrap, we just try to grab a new copy
directory  directory to execute in
offline  are we executing buildout in offline mode
buildout_ver  forcing to use a specific buildout version (1 | 2)
onlyif  Only execute cmd if statement on the host return 0
unless  Do not execute cmd if statement on the host return 0

CLI Example:
```bash
salt '*' buildout.upgrade_bootstrap /srv/mybuildout
```

### 31.16.318 salt.modules.zfs
Salt interface to ZFS commands

codeauthor  Nitin Madhok <nmadhok@clemson.edu>

```
salt.modules.zfs.create(name, **kwargs)
    New in version 2015.5.0.
    Create a ZFS File System.
```

CLI Example:
```bash
salt '*' zfs.create myzpool/mydataset [create_parent=True|False]
```

**Note:** ZFS properties can be specified at the time of creation of the filesystem by passing an additional argument called "properties" and specifying the properties with their respective values in the form of a python dictionary:

```
properties="{'property1': 'value1', 'property2': 'value2'}"
```
Example:
```bash
salt '*' zfs.create myzpool/mydataset properties="{'mountpoint': '/export/zfs', 'sharenfs': 'on'}"
```

```
salt.modules.zfs.destroy(name, **kwargs)
    New in version 2015.5.0.
    Destroy a ZFS File System.
```
CLI Example:

```bash
salt '*' zfs.destroy myzpool/mydataset [force=True|False]
```

**salt.modules.zfs.exists**(name)

New in version 2015.5.0.

Check if a ZFS filesystem or volume or snapshot exists.

CLI Example:

```bash
salt '*' zfs.exists myzpool/mydataset
```

**salt.modules.zfs.list**(name='*', **kwargs)

New in version 2015.5.0.

Return a list of all datasets or a specified dataset on the system and the values of their used, available, referenced, and mountpoint properties.

**Note:** Information about the dataset and all of its descendent datasets can be displayed by passing `recursive=True` on the CLI.

CLI Example:

```bash
salt '*' zfs.list [recursive=True|False]
salt '*' zfs.list /myzpool/mydataset [recursive=True|False]
```

**Note:** Dataset property value output can be customized by passing an additional argument called `"properties"` in the form of a python list:

```python
properties="[property1, property2, property3]"
```

**Example:**

```bash
salt '*' zfs.list /myzpool/mydataset properties="[name, sharenfs, mountpoint]"
```

**salt.modules.zfs.rename**(name, new_name)

New in version 2015.5.0.

Rename or Relocate a ZFS File System.

CLI Example:

```bash
salt '*' zfs.rename myzpool/mydataset myzpool/renameddataset
```

### 31.16.319 salt.modules.zk_concurrency

**Concurrency controls in zookeeper**

This module allows you to acquire and release a slot. This is primarily useful for ensuring that no more than N hosts take a specific action at once. This can also be used to coordinate between masters.

**salt.modules.zk_concurrency.lock**(path, zk_hosts, identifier=None, max_concurrency=1, timeout=None, ephemeral_lease=False, force=False)

Get lock (with optional timeout)

- **path** The path in zookeeper where the lock is
zk_hosts  zookeeper connect string
identifier  Name to identify this minion
max_concurrency  Maximum number of lock holders
timeout  timeout to wait for the lock. A None timeout will block forever
ephemeral_lease  Whether the locks in zookeeper should be ephemeral
force  Forcibly acquire the lock regardless of available slots

Example:
... code-block: bash
salt minion zk_concurrency.lock /lock/path host1:1234,host2:1234

salt.modules.zk_concurrency.lock_holders(path, zk_hosts, max_concurrency=1, ephemeral_lease=False)

Return an un-ordered list of lock holders
path  The path in zookeeper where the lock is
zk_hosts  zookeeper connect string
identifier  Name to identify this minion
max_concurrency  Maximum number of lock holders
timeout  timeout to wait for the lock. A None timeout will block forever
ephemeral_lease  Whether the locks in zookeeper should be ephemeral

Example:
... code-block: bash
salt minion zk_concurrency.lock_holders /lock/path host1:1234,host2:1234

salt.modules.zk_concurrency.party_members(path, zk_hosts)
Get the List of identifiers in a particular party
path  The path in zookeeper where the lock is
zk_hosts  zookeeper connect string

Example:
... code-block: bash
salt minion zk_concurrency.party_members /lock/path host1:1234,host2:1234

salt.modules.zk_concurrency.unlock(path, zk_hosts=None, identifier=None, max_concurrency=1, ephemeral_lease=False)
Remove lease from semaphore
path  The path in zookeeper where the lock is
zk_hosts  zookeeper connect string
identifier  Name to identify this minion
max_concurrency  Maximum number of lock holders
timeout  timeout to wait for the lock. A None timeout will block forever
ephemeral_lease  Whether the locks in zookeeper should be ephemeral
Example:

```bash
salt minion zk_concurrency.unlock /lock/path host1:1234,host2:1234
```

### 31.16.320 salt.modules.znc

**znc** - An advanced IRC bouncer

New in version 2014.7.0.

Provides an interface to basic ZNC functionality

```python
salt.modules.znc.buildmod(modules)

Build module using znc-buildmod
```

CLI Example:

```bash
salt '*' znc.buildmod module.cpp [...]
```

```python
salt.modules.znc.dumpconf()

Write the active configuration state to config file
```

CLI Example:

```bash
salt '*' znc.dumpconf
```

```python
salt.modules.znc.rehashconf()

Rehash the active configuration state from config file
```

CLI Example:

```bash
salt '*' znc.rehashconf
```

```python
salt.modules.znc.version()

Return server version from znc --version
```

CLI Example:

```bash
salt '*' znc.version
```

### 31.16.321 salt.modules.zpool

Module for running ZFS zpool command

#### codeauthor
Nitin Madhok <nmadhok@clemson.edu>

```python
salt.modules.zpool.add(pool_name, *vdevs)

Add the specified vdev's to the given pool
```

CLI Example:

```bash
salt '*' zpool.add myzpool /path/to/vdev1 /path/to/vdev2 [...]
```

```python
salt.modules.zpool.create(pool_name, *vdevs, **kwargs)

New in version 2015.5.0.

Create a simple zpool, a mirrored zpool, a zpool having nested VDEVs, a hybrid zpool with cache, spare and log drives or a zpool with RAIDZ-1, RAIDZ-2 or RAIDZ-3
```

CLI Example:
salt '*' zpool.create myzpool /path/to/vdev1 [...] [force=True|False]
salt '*' zpool.create myzpool mirror /path/to/vdev1 /path/to/vdev2 [...] [force=True|False]
salt '*' zpool.create myzpool raidz1 /path/to/vdev1 /path/to/vdev2 raidz2 /path/to/vdev3 [...] mirror /path/to/vdev2 /path/to/vdev3 [...] [force=True|False]
salt '*' zpool.create myhybridzpool mirror /tmp/file1 [...] log mirror /path/to/vdev1 [...] cache /path/to/vdev2 [...] spare /path/to/vdev3 [...] [force=True|False]

Note: Zpool properties can be specified at the time of creation of the pool by passing an additional argument called ''properties'' and specifying the properties with their respective values in the form of a python dictionary:

```
properties={"property1": 'value1', 'property2': 'value2'}
```

Example:

```
salt '*' zpool.create myzpool /path/to/vdev1 [...] properties={"property1": 'value1', 'property2': 'value2'}
```

salt.modules.zpool.create_file_vdev(size, *vdevs)

Creates file based virtual devices for a zpool

*vdevs is a list of full paths for mkfile to create

CLI Example:

```
salt '*' zpool.create_file_vdev 7g /path/to/vdev1 [/path/to/vdev2] [...] 
```

Note: Depending on file size, the above command may take a while to return.

salt.modules.zpool.destroy(pool_name)

Destroys a storage pool

CLI Example:

```
salt '*' zpool.destroy myzpool
```

salt.modules.zpool.exists(pool_name)

Check if a ZFS storage pool is active

CLI Example:

```
salt '*' zpool.exists myzpool
```

salt.modules.zpool.export(*pools, **kwargs)

New in version 2015.5.0.

Export storage pools

CLI Example:

```
salt '*' zpool.export myzpool ...
```

salt.modules.zpool.import(pool_name='`, new_name='`, **kwargs)

New in version 2015.5.0.

Import storage pools or list pools available for import

CLI Example:
### salt.modules.zpool

<table>
<thead>
<tr>
<th>Documentation Function</th>
<th>Description</th>
<th>Example Syntax</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>iostat</code></td>
<td>Display I/O statistics for the given pools</td>
<td><code>salt '*' zpool.iostat myzpool</code></td>
</tr>
<tr>
<td><code>list()</code></td>
<td>Return a list of all pools in the system with health status and space usage</td>
<td><code>salt '*' zpool.list</code></td>
</tr>
<tr>
<td><code>offline(pool_name, *vdevs, **kwargs)</code></td>
<td>Ensure that the specified devices are offline</td>
<td>`salt '*' zpool.offline myzpool /path/to/vdev1 [... ] [temporary=True</td>
</tr>
<tr>
<td><code>online(pool_name, *vdevs, **kwargs)</code></td>
<td>Ensure that the specified devices are online</td>
<td><code>salt '*' zpool.online myzpool /path/to/vdev1 [... ]</code></td>
</tr>
<tr>
<td><code>replace(pool_name, old, new)</code></td>
<td>Replaces old device with new device.</td>
<td><code>salt '*' zpool.replace myzpool /path/to/vdev1 /path/to/vdev2</code></td>
</tr>
<tr>
<td><code>scrub(pool_name=None)</code></td>
<td>Begin a scrub</td>
<td><code>salt '*' zpool.scrub myzpool</code></td>
</tr>
<tr>
<td><code>status(name='')</code></td>
<td>Return the status of the named zpool</td>
<td><code>salt '*' zpool.status myzpool</code></td>
</tr>
</tbody>
</table>

---

**Warning:** By default, the OFFLINE state is persistent. The device remains offline when the system is rebooted. To temporarily take a device offline, use `temporary=True`. |
salt.modules.zpool.zpool_list()

Deprecated since version 2014.7.0: Use list_() instead.

Return a list of all pools in the system with health status and space usage

CLI Example:

```
salt '*' zpool.zpool_list
```

### 31.16.322 salt.modules.zypper

Package support for openSUSE via the zypper package manager

```python
def depends
    • zypp Python module. Install with zypper install python-zypp
```

salt.modules.zypper.add_lock(name=None, pkgs=None, **kwargs)

Add a package lock. Specify packages to lock by exact name.

CLI Example:

```
salt '*' pkg.add_lock <package name>
salt '*' pkg.add_lock <package1>,<package2>,<package3>
salt '*' pkg.add_lock pkgs='["foo", "bar"]'
```

salt.modules.zypper.clean_locks()

Remove unused locks that do not currently (with regard to repositories used) lock any package.

CLI Example:

```
salt '*' pkg.clean_locks
```

salt.modules.zypper.del_repo(repo)

Delete a repo.

CLI Examples:

```
salt '*' pkg.del_repo alias
```

salt.modules.zypper.diff('paths)

Return a formatted diff between current files and original in a package. NOTE: this function includes all files (configuration and not), but does not work on binary content.

**Parameters** path -- Full path to the installed file

**Returns** Difference string or raises and exception if examined file is binary.

CLI example:

```
salt '*' pkg.diff /etc/apache2/httpd.conf /etc/sudoers
```

salt.modules.zypper.download('packages)

Download packages to the local disk.

CLI example:

```
salt '*' pkg.download httpd
salt '*' pkg.download httpd postfix
```
salt.modules.zypper.file_dict(packages)
    List the files that belong to a package, grouped by package. Not specifying any packages will return a list of every file on the system's rpm database (not generally recommended).

    CLI Examples:
    salt '*' pkg.file_list httpd
    salt '*' pkg.file_list httpd postfix
    salt '*' pkg.file_list

salt.modules.zypper.file_list(packages)
    List the files that belong to a package. Not specifying any packages will return a list of every file on the system's rpm database (not generally recommended).

    CLI Examples:
    salt '*' pkg.file_list httpd
    salt '*' pkg.file_list httpd postfix
    salt '*' pkg.file_list

salt.modules.zypper.get_repo(repo, **kwargs)
    Display a repo.

    CLI Example:
    salt '*' pkg.get_repo alias
	salt.modules.zypper.info(names, **kwargs)
    Deprecated since version Nitrogen: Use info_available() instead.
    Return the information of the named package available for the system.

    CLI example:
    salt '*' pkg.info <package1>
    salt '*' pkg.info <package1> <package2> <package3> ...

salt.modules.zypper.info_available(names, **kwargs)
    Return the information of the named package available for the system.

    CLI example:
    salt '*' pkg.info_available <package1>
    salt '*' pkg.info_available <package1> <package2> <package3> ...

salt.modules.zypper.info_installed(names)
    Return the information of the named package(s), installed on the system.

    CLI example:
    salt '*' pkg.info_installed <package1>
    salt '*' pkg.info_installed <package1> <package2> <package3> ...

salt.modules.zypper.install(name=None, refresh=False, fromrepo=None, pkgs=None, sources=None, downloadonly=None, **kwargs)
    Install the passed package(s), add refresh=True to run `zypper refresh' before package is installed.

    name The name of the package to be installed. Note that this parameter is ignored if either ``pkgs'' or ``sources'' is passed. Additionally, please note that this option can only be used to install packages from a software repository. To install a package file manually, use the ``sources'' option.

    CLI Example:
salt '...' pkg.install <package name>

**refresh** Whether or not to refresh the package database before installing.

**fromrepo** Specify a package repository to install from.

**downloadonly** Only download the packages, do not install.

**version** Can be either a version number, or the combination of a comparison operator (<, >, <=, >=, =) and a version number (ex. `>1.2.3-4`). This parameter is ignored if `"pkgs"` or `"sources"` is passed.

Multiple Package Installation Options:

**pkgs** A list of packages to install from a software repository. Must be passed as a python list. A specific version number can be specified by using a single-element dict representing the package and its version. As with the version parameter above, comparison operators can be used to target a specific version of a package.

CLI Examples:

```
salt '...' pkg.install pkgs='["foo", "bar"]'
salt '...' pkg.install pkgs='["foo", {"bar": "1.2.3-4"}]'
salt '...' pkg.install pkgs='["foo", {"bar": "<1.2.3-4"}]'
```

**sources** A list of RPM packages to install. Must be passed as a list of dicts, with the keys being package names, and the values being the source URI or local path to the package.

CLI Example:

```
salt '...' pkg.install sources='[{"foo": "salt://foo.rpm"},{"bar": "salt://bar.rpm"}]'
```

Returns a dict containing the new package names and versions:

```python
{ '<package>': { 'old': '<old-version>', 'new': '<new-version>' }}
```

salt.modules.zypper.latest_version(*names, **kwargs)

Return the latest version of the named package available for upgrade or installation. If more than one package name is specified, a dict of name/version pairs is returned.

If the latest version of a given package is already installed, an empty dict will be returned for that package.

CLI example:

```
salt '...' pkg.latest_version <package name>
salt '...' pkg.latest_version <package1> <package2> <package3> ...
```

salt.modules.zypper.list_installed_patterns()

List installed patterns on the system.

CLI Examples:

```
salt '...' pkg.list_installed_patterns
```

salt.modules.zypper.list_locks()

List current package locks.

Return a dict containing the locked package with attributes:

```python
{ '<package>': { 'case_sensitive': 'case_sensitive', 'match_type': 'match_type', 'type': 'type' }}
```
CLI Example:

```python
salt '* pkg.list_locks
```

```
salt.modules.zypper.list_patterns()

List all known patterns from available repos.

CLI Examples:

```python
salt '* pkg.list_patterns
```

```
salt.modules.zypper.list_pkgs(versions_as_list=False, **kwargs)

List the packages currently installed as a dict:

```python
{ '<package_name>': '<version>'}
```

CLI Example:

```python
salt '* pkg.list_pkgs
```

```
salt.modules.zypper.list_products()

List all installed SUSE products.

CLI Examples:

```python
salt '* pkg.list_products
```

```
salt.modules.zypper.list_repos()

List all repos.

CLI Example:

```python
salt '* pkg.list_repos
```

```
salt.modules.zypper.list_upgrades(refresh=True)

List all available package upgrades on this system

CLI Example:

```python
salt '* pkg.list_upgrades
```

```
salt.modules.zypper.mod_repo(repo, **kwargs)

Modify one or more values for a repo. If the repo does not exist, it will be created, so long as the following values are specified:

- **repo or alias** alias by which the zypper refers to the repo
- **url, mirrorlist or baseurl** the URL for zypper to reference
- **enabled** enable or disable (True or False) repository, but do not remove if disabled.
- **refresh** enable or disable (True or False) auto-refresh of the repository.
- **cache** Enable or disable (True or False) RPM files caching.
- **gpgcheck** Enable or disable (True or False) GOG check for this repository.
- **gpgautoimport** Automatically trust and import new repository.

Key/Value pairs may also be removed from a repo's configuration by setting a key to a blank value. Bear in mind that a name cannot be deleted, and a url can only be deleted if a mirrorlist is specified (or vice versa).

CLI Examples:
salt.modules.zypper.modified(*packages, **flags)
List the modified files that belong to a package. Not specifying any packages will return a list of _all_ modified files on the system’s RPM database.

New in version 2015.5.0.
Filtering by flags (True or False):
- size: Include only files where size changed.
- mode: Include only files which file’s mode has been changed.
- checksum: Include only files which MD5 checksum has been changed.
- device: Include only files which major and minor numbers has been changed.
- symlink: Include only files which are symbolic link contents.
- owner: Include only files where owner has been changed.
- group: Include only files where group has been changed.
- time: Include only files where modification time of the file has been changed.
- capabilities: Include only files where capabilities differ or not. Note: supported only on newer RPM versions.

CLI Examples:
```
salt '*' pkg.modified
salt '*' pkg.modified httpd
salt '*' pkg.modified httpd postfix
salt '*' pkg.modified httpd owner=True group=False
```

salt.modules.zypper.owner(*paths)
Return the name of the package that owns the file. Multiple file paths can be passed. If a single path is passed, a string will be returned, and if multiple paths are passed, a dictionary of file/package name pairs will be returned.

If the file is not owned by a package, or is not present on the minion, then an empty string will be returned for that path.

CLI Examples:
```
salt '*' pkg.owner /usr/bin/apachectl
salt '*' pkg.owner /usr/bin/apachectl /etc/httpd/conf/httpd.conf
```

salt.modules.zypper.purge(name=None, pkgs=None, **kwargs)
Recursively remove a package and all dependencies which were installed with it, this will call a zypper -n remove -u

- name: The name of the package to be deleted.
- pkgs: A list of packages to delete. Must be passed as a python list. The name parameter will be ignored if this option is passed.

New in version 0.16.0.

Returns a dict containing the changes.

CLI Example:
salt '*' pkg.purge <package name>
salt '*' pkg.purge <package1>,<package2>,<package3>
salt '*' pkg.purge pkgs='["foo", "bar"]'

salt.modules.zypper.refresh_db()
    Just run a zypper refresh, return a dict:

    {'<database name>': Bool}

    CLI Example:
    salt '*' pkg.refresh_db

salt.modules.zypper.remove(name=None, pkgs=None, **kwargs)
    Remove packages with zypper -n remove
    name The name of the package to be deleted.
    Multiple Package Options:
    pkgs A list of packages to delete. Must be passed as a python list. The name parameter will be ignored if this
    option is passed.
    New in version 0.16.0.
    Returns a dict containing the changes.
    CLI Example:
    salt '*' pkg.remove <package name>
salt '*' pkg.remove <package1>,<package2>,<package3>
salt '*' pkg.remove pkgs='["foo", "bar"]'

salt.modules.zypper.remove_lock(name=None, pkgs=None, **kwargs)
    Remove specified package lock.
    CLI Example:
    salt '*' pkg.remove_lock <package name>
salt '*' pkg.remove_lock <package1>,<package2>,<package3>
salt '*' pkg.remove_lock pkgs='["foo", "bar"]'

salt.modules.zypper.search(criteria)
    List known packages, available to the system.
    CLI Examples:
    salt '*' pkg.search <criteria>

salt.modules.zypper.upgrade(refresh=True)
    Run a full system upgrade, a zypper upgrade
    Return a dict containing the new package names and versions:

    {'<package>': {'old': '<old-version>',
                  'new': '<new-version>'}}

    CLI Example:
    salt '*' pkg.upgrade
salt.modules.zypper.upgrade_available(name)
Check whether or not an upgrade is available for a given package

CLI Example:

```
salt '* pkg.upgrade_available <package name>
```

salt.modules.zypper.verify("names", **kwargs)
Runs an rpm -Va on a system, and returns the results in a dict

Files with an attribute of config, doc, ghost, license or readme in the package header can be ignored using the ignore_types keyword argument

CLI Example:

```
salt '* pkg.verify
salt '* pkg.verify httpd
salt '* pkg.verify 'httpd postfix'
salt '* pkg.verify 'httpd postfix' ignore_types=['config','doc']
```

salt.modules.zypper.version("names", **kwargs)
Returns a string representing the package version or an empty dict if not installed. If more than one package name is specified, a dict of name/version pairs is returned.

CLI Example:

```
salt '* pkg.version <package name>
salt '* pkg.version <package1> <package2> <package3> ...
```

### 31.17 Full list of netapi modules

#### 31.17.1 rest_cherrypy

A REST API for Salt

New in version 2014.7.0.

**depends**

- CherryPy Python module. Version 3.2.3 is currently recommended when SSL is enabled, since this version worked the best with SSL in internal testing. Versions 3.2.3 - 4.x can be used if SSL is not enabled. Be aware that there is a known SSL error introduced in version 3.2.5. The issue was reportedly resolved with CherryPy milestone 3.3, but the patch was committed for version 3.6.1.

**optdepends**

- ws4py Python module for websockets support.

**client_libraries**

- Java: [https://github.com/SUSE/saltstack-netapi-client-java](https://github.com/SUSE/saltstack-netapi-client-java)
- Python: [https://github.com/saltstack/pepper](https://github.com/saltstack/pepper)

**configuration** All authentication is done through Salt’s external auth system which requires additional configuration not described here.

Example production-ready configuration; add to the Salt master config file and restart the salt-master and salt-api daemons:
rest_cherrypy:
  port: 8000
  ssl_crt: /etc/pki/tls/certs/localhost.crt
  ssl_key: /etc/pki/tls/certs/localhost.key

Using only a secure HTTPS connection is strongly recommended since Salt authentication credentials will be sent over the wire.

A self-signed certificate can be generated using the `create_self_signed_cert()` execution function. Running this function requires pyOpenSSL and the `salt-call` script is available in the `salt-minion` package.

```
salt-call --local tls.create_self_signed_cert
```

All available configuration options are detailed below. These settings configure the CherryPy HTTP server and do not apply when using an external server such as Apache or Nginx.

**port Required**

The port for the webserver to listen on.

**host** [0.0.0.0] The socket interface for the HTTP server to listen on.

**debug** [False] Starts the web server in development mode. It will reload itself when the underlying code is changed and will output more debugging info.

**ssl_crt** The path to a SSL certificate. (See below)

**ssl_key** The path to the private key for your SSL certificate. (See below)

**disable_ssl** A flag to disable SSL. Warning: your Salt authentication credentials will be sent in the clear!

**webhook_disable_auth** [False] The Webhook URL requires authentication by default but external services cannot always be configured to send authentication. See the Webhook documentation for suggestions on securing this interface.

**webhook_url** [/hook] Configure the URL endpoint for the Webhook entry point.

**thread_pool** [100] The number of worker threads to start up in the pool.

**socket_queue_size** [30] Specify the maximum number of HTTP connections to queue.

**expireResponses** [True] Whether to check for and kill HTTP responses that have exceeded the default timeout.

**max_request_body_size** [1048576] Maximum size for the HTTP request body.

**collect_stats** [False] Collect and report statistics about the CherryPy server

Reports are available via the Stats URL.

**static** A filesystem path to static HTML/JavaScript/CSS/image assets.

**static_path** [/static] The URL prefix to use when serving static assets out of the directory specified in the static setting.

**app** A filesystem path to an HTML file that will be served as a static file. This is useful for bootstrapping a single-page JavaScript app.

**app_path** [/app] The URL prefix to use for serving the HTML file specified in the app setting. This should be a simple name containing no slashes.

Any path information after the specified path is ignored; this is useful for apps that utilize the HTML5 history API.
root_prefix  [/] A URL path to the main entry point for the application. This is useful for serving multiple applications from the same URL.

Authentication

Authentication is performed by passing a session token with each request. Tokens are generated via the Login URL.

The token may be sent in one of two ways:

- Include a custom header named X-Auth-Token.
  
  For example, using curl:

  ```bash
  curl -sSk https://localhost:8000/login \
  -H 'Accept: application/x-yaml' \
  -d username=saltdev \
  -d password=saltdev \
  -d eauth=auto
  
  Copy the token value from the output and include it in subsequent requests:

  ```bash
  curl -sSk https://localhost:8000 \
  -H 'Accept: application/x-yaml' \
  -H 'X-Auth-Token: 697adbdc8fe971d09ae4c2a3add7248859c87079' \
  -d client=local \n  -d tgt='*' \
  -d fun=test.ping
  ```

- Sent via a cookie. This option is a convenience for HTTP clients that automatically handle cookie support (such as browsers).
  
  For example, using curl:

  ```bash
  # Write the cookie file:
  curl -sSk https://localhost:8000/login \
  -c ~/cookies.txt \
  -H 'Accept: application/x-yaml' \
  -d username=saltdev \
  -d password=saltdev \
  -d eauth=auto

  # Read the cookie file:
  curl -sSk https://localhost:8000 \
  -b ~/cookies.txt \
  -H 'Accept: application/x-yaml' \
  -d client=local \n  -d tgt='*' \
  -d fun=test.ping
  ```

See also:

You can bypass the session handling via the Run URL.

Usage

Commands are sent to a running Salt master via this module by sending HTTP requests to the URLs detailed below.
Content negotiation
This REST interface is flexible in what data formats it will accept as well as what formats it will return (e.g., JSON, YAML, x-www-form-urlencoded).

- Specify the format of data in the request body by including the `Content-Type` header.
- Specify the desired data format for the response body with the `Accept` header.

Data sent in `POST` and `PUT` requests must be in the format of a list of lowstate dictionaries. This allows multiple commands to be executed in a single HTTP request. The order of commands in the request corresponds to the return for each command in the response.

Lowstate, broadly, is a dictionary of values that are mapped to a function call. This pattern is used pervasively throughout Salt. The functions called from netapi modules are described in `Client Interfaces`.

The following example (in JSON format) causes Salt to execute two commands, a command sent to minions as well as a runner function on the master:

```json
[{
    "client": "local",
    "tgt": "*",
    "fun": "test.fib",
    "arg": ["10"]
},
{
    "client": "runner",
    "fun": "jobs.lookup_jid",
    "jid": "20130603122505459265"
}
]
```

Sending JSON or YAML in the request body is simple and most flexible, however sending data in urlencoded format is also supported with the caveats below. It is the default format for HTML forms, many JavaScript libraries, and the `curl` command.

For example, the equivalent to running `salt '*' test.ping` is sending `fun=test.ping&arg&client=local&tgt=*` in the HTTP request body.

Caveats:
- Only a single command may be sent per HTTP request.
- Repeating the `arg` parameter multiple times will cause those parameters to be combined into a single list.

Note, some popular frameworks and languages (notably jQuery, PHP, and Ruby on Rails) will automatically append empty brackets onto repeated parameters. E.g., `arg=one, arg=two` will be sent as `arg[]=one, arg[]=two`. This is not supported; send JSON or YAML instead.

Deployment

The `rest_cherrypy` netapi module is a standard Python WSGI app. It can be deployed one of two ways.

**salt-api using the CherryPy server**

The default configuration is to run this module using `salt-api` to start the Python-based CherryPy server. This server is lightweight, multi-threaded, encrypted with SSL, and should be considered production-ready.
Using a WSGI-compliant web server

This module may be deployed on any WSGI-compliant server such as Apache with mod_wsgi or Nginx with FastCGI, to name just two (there are many).

Note, external WSGI servers handle URLs, paths, and SSL certs directly. The rest_cherrypy configuration options are ignored and the salt-api daemon does not need to be running at all. Remember Salt authentication credentials are sent in the clear unless SSL is being enforced!

An example Apache virtual host configuration:

```xml
<VirtualHost *:80>
    ServerName example.com
    ServerAlias *.example.com
    
    ServerAdmin webmaster@example.com
    LogLevel warn
    ErrorLog /var/www/example.com/logs/error.log
    CustomLog /var/www/example.com/logs/access.log combined
    
    DocumentRoot /var/www/example.com/htdocs
    
    WSGIScriptAlias / /path/to/salt/netapi/rest_cherrypy/wsgi.py
</VirtualHost>
```

REST URI Reference

- `/`
- `/login`
- `/logout`
- `/minions`
- `/jobs`
- `/run`
- `/events`
- `/hook`
- `/keys`
- `/ws`
- `/stats`

/  

class salt.netapi.rest_cherrypy.app.LowDataAdapter

The primary entry point to Salt's REST API

**GET()**

An explanation of the API with links of where to go next

**GET /**

**Request Headers**

- **Accept** -- the desired response format.

**Status Codes**

- **200** -- success
• **401** -- authentication required
• **406** -- requested Content-Type not available

Example request:

curl -i localhost:8000

```plaintext
GET / HTTP/1.1
Host: localhost:8000
Accept: application/json
```

Example response:

```
HTTP/1.1 200 OK
Content-Type: application/json
```

**POST**

Mock out specified imports

This allows autodoc to do its thing without having oodles of req’d installed libs. This doesn’t work with `import *` imports.

http://read-the-docs.readthedocs.org/en/latest/faq.html#i-get-import-errors-on-libraries-that-depend-on-c-modules

/class

`salt.netapi.rest_cherrypy.app.Login(args, **kwargs)`

Log in to receive a session token

*Authentication information.*

**GET()**

Present the login interface

**GET /login**

An explanation of how to log in.

*Status Codes*

• **200** -- success
• **401** -- authentication required
• **406** -- requested Content-Type not available

Example request:

curl -i localhost:8000/login

```plaintext
GET /login HTTP/1.1
Host: localhost:8000
Accept: text/html
```

Example response:

```
HTTP/1.1 200 OK
Content-Type: text/html
```

**POST(**kwargs)**

*Authenticate* against Salt’s eauth system

**POST /login**

Request Headers
- **X-Auth-Token** -- a session token from *Login*.
- **Accept** -- the desired response format.
- **Content-Type** -- the format of the request body.

Form Parameters
- **eauth** -- the eauth backend configured for the user
- **username** -- username
- **password** -- password

Status Codes
- **200** -- success
- **401** -- authentication required
- **406** -- requested Content-Type not available

Example request:
```
curl -si localhost:8000/login
  -H "Accept: application/json"
  -d username='saltuser'
  -d password='saltpass'
  -d eauth='pam'
```

Example response:
```
HTTP/1.1 200 OK
Content-Type: application/json
Content-Length: 206
X-Auth-Token: 6d1b722e
Set-Cookie: session_id=6d1b722e; expires=Sat, 17 Nov 2012 03:23:52 GMT; Path=/

{"return": {
  "token": "6d1b722e",
  "start": 1363805943.776223,
  "expire": 1363849143.776224,
  "user": "saltuser",
  "eauth": "pam",
  "perms": [
    "grains.*",
    "status.*",
    "sys.*",
    "test.*"
  ]
}}
```

### /logout

class salt.netapi.rest_cherrypy.app.Logout

Class to remove or invalidate sessions

**POST**

Destroy the currently active session and expire the session cookie
/minions

class salt.netapi.rest_cherrypy.app.Minions

Convenience URLs for working with minions

GET(mid=None)
A convenience URL for getting lists of minions or getting minion details

GET /minions/ (mid)
Request Headers
- X-Auth-Token -- a session token from Login.
- Accept -- the desired response format.
Status Codes
- 200 -- success
- 401 -- authentication required
- 406 -- requested Content-Type not available

Example request:
curl -i localhost:8000/minions/ms-3

GET /minions/ms-3 HTTP/1.1
Host: localhost:8000
Accept: application/x-yaml

Example response:
HTTP/1.1 200 OK
Content-Length: 129005
Content-Type: application/x-yaml

return:
- ms-3:
  grains.items:
  ...

POST(**kwargs)
Start an execution command and immediately return the job id

POST /minions
Request Headers
- X-Auth-Token -- a session token from Login.
- Accept -- the desired response format.
- Content-Type -- the format of the request body.
Response Headers
- Content-Type -- the format of the response body; depends on the Accept request header.
Status Codes
- 200 -- success
- 401 -- authentication required
- 406 -- requested Content-Type not available

lowstate data describing Salt commands must be sent in the request body. The client option will be set to local_async().

Example request:
curl -sSi localhost:8000/minions \
   -H "Accept: application/x-yaml" \

POST /minions HTTP/1.1
Host: localhost:8000
Accept: application/x-yaml
Content-Length: 26
Content-Type: application/x-www-form-urlencoded

tgt=*&fun=status.diskusage

Example response:

HTTP/1.1 202 Accepted
Content-Length: 86
Content-Type: application/x-yaml

return:
- jid: '20130603122505459265'
  minions: [ms-4, ms-3, ms-2, ms-1, ms-0]
  _links:
    jobs:
      - href: /jobs/20130603122505459265

/jobs

class salt.netapi.rest_cherrypy.app.Jobs

**GET** *(jid=None, timeout='')*
A convenience URL for getting lists of previously run jobs or getting the return from a single job

**GET** /jobs/* *(jid)*
List jobs or show a single job from the job cache.

Request Headers
- X-Auth-Token -- a session token from Login.
- Accept -- the desired response format.

Status Codes
- 200 -- success
- 401 -- authentication required
- 406 -- requested Content-Type not available

Example request:
curl -i localhost:8000/jobs

Example response:

HTTP/1.1 200 OK
Content-Length: 165
Content-Type: application/x-yaml

return:
- '20121130104633606931':
  Arguments:
  - '3'
  Function: test.fib
  Target: jerry
  Target-type: glob

Example request:

curl -i localhost:8000/jobs/20121130104633606931

```
GET /jobs/20121130104633606931 HTTP/1.1
Host: localhost:8000
Accept: application/x-yaml
```

Example response:

```
HTTP/1.1 200 OK
Content-Length: 73
Content-Type: application/x-yaml

info:
  - Arguments:
    - '3'
    Function: test.fib
    Minions:
    - jerry
    Target: '*'
    Target-type: glob
    User: saltdev
  jid: '20121130104633606931'

return:
  - jerry:
    - 0
    - 1
    - 1
    - 2
    - 6.9141387939453125e-06
```

/run

class salt.netapi.rest_cherrypy.app.Run

Class to run commands without normal session handling

```python
POST(**kwargs)

Run commands bypassing the normal session handling

POST /run

This entry point is primarily for ``one-off`` commands. Each request must pass full Salt authentication credentials. Otherwise this URL is identical to the root URL (/).

lowstate data describing Salt commands must be sent in the request body.

Status Codes
- **200** -- success
- **401** -- authentication required
```
- **406** -- requested Content-Type not available

Example request:

```bash
curl -sS localhost:8000/run \
   -H 'Accept: application/x-yaml' \ 
   -d client='local' \ 
   -d tgt='*' \ 
   -d fun='test.ping' \ 
   -d username='saltdev' \ 
   -d password='saltdev' \ 
   -d eauth='pam'
```

```plaintext
POST /run HTTP/1.1
Host: localhost:8000
Accept: application/x-yaml
Content-Length: 75
Content-Type: application/x-www-form-urlencoded

client=local&tgt=*&fun=test.ping&username=saltdev&password=saltdev&eauth=pam
```

Example response:

```plaintext
HTTP/1.1 200 OK
Content-Length: 73
Content-Type: application/x-yaml

return:
- ms-0: true
  ms-1: true
  ms-2: true
  ms-3: true
  ms-4: true
```

The `/run` endpoint can also be used to issue commands using the salt-ssh subsystem.

When using salt-ssh, eauth credentials should not be supplied. Instead, authentication should be handled by the SSH layer itself. The use of the salt-ssh client does not require a salt master to be running. Instead, only a roster file must be present in the salt configuration directory.

All SSH client requests are synchronous.

**Example SSH client request:**

```bash
curl -sS localhost:8000/run \
   -H 'Accept: application/x-yaml' \ 
   -d client='ssh' \ 
   -d tgt='*' \ 
   -d fun='test.ping'
```

```plaintext
POST /run HTTP/1.1
Host: localhost:8000
Accept: application/x-yaml
Content-Length: 75
Content-Type: application/x-www-form-urlencoded

client=ssh&tgt=*&fun=test.ping
```

Example SSH response:
The event bus on the Salt master exposes a large variety of things, notably when executions are started on the master and also when minions ultimately return their results. This URL provides a real-time window into a running Salt infrastructure.

See also:

**events**

**GET** *(token=none, salt_token=none)*

An HTTP stream of the Salt master event bus

This stream is formatted per the Server Sent Events (SSE) spec. Each event is formatted as JSON.

**GET** /events

**Status Codes**

- **200** -- success
- **401** -- authentication required
- **406** -- requested Content-Type not available

**Query Parameters**

- **token** -- optional parameter containing the token ordinarily supplied via the X-Auth-Token header in order to allow cross-domain requests in browsers that do not include CORS support in the EventSource API. E.g., `curl -NsS localhost:8000/events?token=308650d`
- **salt_token** -- optional parameter containing a raw Salt `eauth token` (not to be confused with the token returned from the /login URL). E.g., `curl -NsS localhost:8000/events?salt_token=30742765`

**Example request:**

```
curl -NsS localhost:8000/events
```

**Example response:**

Note, the `tag` field is not part of the spec. SSE compliant clients should ignore unknown fields. This addition allows non-compliant clients to only watch for certain tags without having to deserialize the JSON object each time.

**HTTP/1.1 200 OK**

**Connection:** keep-alive

**Cache-Control:** no-cache
The event stream can be easily consumed via JavaScript:

```javascript
var source = new EventSource('/events');
source.onopen = function() { console.debug('opening') };
source.onerror = function(e) { console.debug('error!', e) };
source.onmessage = function(e) {
  console.debug('Tag: ', e.data.tag)
  console.debug('Data: ', e.data.data)
};
```

Or using CORS:

```javascript
var source = new EventSource('/events?token=ecd589e4e01912cf3c4035afad73426dbb8dba75', {withCredentials: true});
```

It is also possible to consume the stream via the shell.

Records are separated by blank lines; the `data:` and `tag:` prefixes will need to be removed manually before attempting to unserialize the JSON.

curl's `-N` flag turns off input buffering which is required to process the stream incrementally.

Here is a basic example of printing each event as it comes in:

```bash
curl -NsS localhost:8000/events |
  while IFS= read -r line ; do
echo $line
done
```

Here is an example of using awk to filter events based on tag:

```bash
curl -NsS localhost:8000/events |
  awk 'BEGIN { RS=""; FS="\n" } $1 ~ /^tag: salt/job/\[0-9]+\$/ { print $0 }',
tag: salt/job/20140112010149808995/new
data: {"tag": "salt/job/20140112010149808995/new", "data": {"tgt_type": "glob", "jid": "20140112010149808995"}}
tag: salt/job/20140112010149808995/ret/jerry
data: {"tag": "salt/job/20140112010149808995/ret/jerry", "data": {"jid": "20140112010149808995"}}
```

/hook

class salt.netapi.rest_cherrypy.app.Webhook
A generic web hook entry point that fires an event on Salt's event bus

External services can POST data to this URL to trigger an event in Salt. For example, Amazon SNS, Jenkins-CI or Travis-CI, or GitHub web hooks.
Note: Be mindful of security
Salt's Reactor can run any code. A Reactor SLS that responds to a hook event is responsible for validating that the event came from a trusted source and contains valid data.

This is a generic interface and securing it is up to you!
This URL requires authentication however not all external services can be configured to authenticate. For this reason authentication can be selectively disabled for this URL. Follow best practices -- always use SSL, pass a secret key, configure the firewall to only allow traffic from a known source, etc.

The event data is taken from the request body. The Content-Type header is respected for the payload.
The event tag is prefixed with salt/netapi/hook and the URL path is appended to the end. For example, a POST request sent to /hook/mycompany/myapp/mydata will produce a Salt event with the tag salt/netapi/hook/mycompany/myapp/mydata.
The following is an example .travis.yml file to send notifications to Salt of successful test runs:

```yaml
language: python
script: python -m unittest tests
after_success:
  - |
    curl -sSk https://saltapi-url.example.com:8000/hook/travis/build/success -d branch="${TRAVIS_BRANCH}" -d commit="${TRAVIS_COMMIT}"`n
```

See also:
- events
- reactor

**POST** (*args, **kwargs)
Fire an event in Salt with a custom event tag and data

**POST /hook**
Status Codes
- **200** -- success
- **401** -- authentication required
- **406** -- requested Content-Type not available
- **413** -- request body is too large

Example request:

```bash
curl -sS localhost:8000/hook -d foo='Foo!' -d bar='Bar!'
```

Example response:

```
HTTP/1.1 200 OK
Content-Length: 14
Content-Type: application/json

{"success": true}
```

As a practical example, an internal continuous-integration build server could send an HTTP POST request to the URL https://localhost:8000/hook/mycompany/build/success which contains
the result of a build and the SHA of the version that was built as JSON. That would then produce the
following event in Salt that could be used to kick off a deployment via Salt’s Reactor:

```
Event fired at Fri Feb 14 17:40:11 2014
*************************
Tag: salt/netapi/hook/mycompany/build/success
Data:
{'_stamp': '2014-02-14_17:40:11.440996',
 'headers': {
   'X-My-Secret-Key': 'F0fAgoQjIT@W',
   'Content-Length': '37',
   'Content-Type': 'application/json',
   'Host': 'localhost:8000',
   'Remote-Addr': '127.0.0.1'},
'post': {'revision': 'aa22a3c4b2e7', 'result': True}}
```

Salt’s Reactor could listen for the event:

```
reactor:
  - 'salt/netapi/hook/mycompany/build/*':
    - /srv/reactor/react_ci_builds.sls
```

And finally deploy the new build:

```
{% set secret_key = data.get('headers', {}).get('X-My-Secret-Key') %}
{% set build = data.get('post', {}) %}
{% if secret_key == 'F0fAgoQjIT@W' and build.result == True %}
deploy_my_app:
  cmd.state.sls:
    - tgt: 'application*' 
    - arg:
      - myapp.deploy 
      - kwarg:
        pillar:
          revision: {{ revision }}
{% endif %}
```

/keys

class salt.netapi.rest_cherrypy.app.Keys
Convenience URLs for working with minion keys

New in version 2014.7.0.

These URLs wrap the functionality provided by the key wheel module functions.

**GET (mid=None)**
Show the list of minion keys or detail on a specific key

New in version 2014.7.0.

**GET /keys/ (mid)**
List all keys or show a specific key

**Status Codes**
- **200** -- success
- **401** -- authentication required
- **406** -- requested Content-Type not available
Example request:

curl -i localhost:8000/keys

GET /keys HTTP/1.1
Host: localhost:8000
Accept: application/x-yaml

Example response:

HTTP/1.1 200 OK
Content-Length: 165
Content-Type: application/x-yaml

return:
  local:
    - master.pem
    - master.pub
  minions:
    - jerry
  minions_pre: []
  minions_rejected: []

Example request:

curl -i localhost:8000/keys/jerry

GET /keys/jerry HTTP/1.1
Host: localhost:8000
Accept: application/x-yaml

Example response:

HTTP/1.1 200 OK
Content-Length: 73
Content-Type: application/x-yaml

return:
  minions:

POST (mid, keysize=None, force=None, **kwargs)
Easily generate keys for a minion and auto-accept the new key

New in version 2014.7.0.

Example partial kickstart script to bootstrap a new minion:

%post
mkdir -p /etc/salt/pki/minion
curl -sSk https://localhost:8000/keys \
  -d mid=jerry \
  -d username=kickstart \
  -d password=kickstart \
  -d eauth=pam \
  | tar -C /etc/salt/pki/minion -xf -

mkdir -p /etc/salt/minion.d
printf 'master: 10.0.0.5\nid: jerry' > /etc/salt/minion.d/id.conf
%end
**POST /keys**

Generate a public and private key and return both as a tarball

Authentication credentials must be passed in the request.

**Status Codes**

- **200** -- success
- **401** -- authentication required
- **406** -- requested Content-Type not available

**Example request:**

```
curl -sSk https://localhost:8000/keys \
    -d mid=jerry \
    -d username=kickstart \
    -d password=kickstart \
    -d eauth=pam \
    -o jerry-salt-keys.tar
```

**POST /keys** HTTP/1.1
Host: localhost:8000

**Example response:**

```
HTTP/1.1 200 OK
Content-Length: 10240
Content-Disposition: attachment; filename="saltkeys-jerry.tar"
Content-Type: application/x-tar

jerry.pub00006440000000000000000000000703000000000010730 0ustar 00000000000000
```

/\s

`class salt.netapi.rest_cherrypy.app.WebsocketEndpoint`

Open a WebSocket connection to Salt's event bus

The event bus on the Salt master exposes a large variety of things, notably when executions are started on the master and also when minions ultimately return their results. This URL provides a real-time window into a running Salt infrastructure. Uses websocket as the transport mechanism.

**See also:**

- `events`

**GET**(token=None, **kwargs)

Return a websocket connection of Salt's event stream

```python
GET /ws/(token)
```

**Query format_events** The event stream will undergo server-side formatting if the `format_events` parameter is included in the request. This can be useful to avoid formatting on the client-side:

```
curl -NsS \...
```

**Reqheader X-Auth-Token** an authentication token from `Login`.

**Status 101** switching to the websockets protocol

**Status 401** authentication required
Status 406  requested Content-Type not available

Example request:

```
   -H 'Sec-WebSocket-Key: ''$(echo -n $RANDOM | base64)''localhost:8000/ws
GET /ws HTTP/1.1
Connection: Upgrade
Upgrade: websocket
Host: localhost:8000
Origin: https://localhost:8000
Sec-WebSocket-Version: 13
Sec-WebSocket-Key: s65VsgHigh7v/Jcf4nXHnA==
X-Auth-Token: ffedf49d
```

Example response:

```
HTTP/1.1 101 Switching Protocols
Upgrade: websocket
Connection: Upgrade
Sec-WebSocket-Accept: mWZjBV9FCglzn1rIKJAxrTFlnJE=
Sec-WebSocket-Version: 13
```

An authentication token may optionally be passed as part of the URL for browsers that cannot be configured to send the authentication header or cookie:

```
curl -NsS <...snip...> localhost:8000/ws/ffedf49d
```

The event stream can be easily consumed via JavaScript:

```
// Note, you must be authenticated!
var source = new Websocket('ws://localhost:8000/ws/d0ce6c1a');
source.onerror = function(e) { console.debug('error!', e); };
source.onmessage = function(e) { console.debug(e.data); };

source.send('websocket client ready')

source.close();
```

Or via Python, using the Python module websocket-client for example.

```
# Note, you must be authenticated!

from websocket import create_connection

ws = create_connection('ws://localhost:8000/ws/d0ce6c1a')
ws.send('websocket client ready')

# Look at https://pypi.python.org/pypi/websocket-client/ for more examples.
while listening_to_events:
    print ws.recv()

ws.close()
```

Above examples show how to establish a websocket connection to Salt and activating real time updates from Salt's event stream by signaling websocket client ready.
/stats

class salt.netapi.rest_cherrypy.app.Stats
    Expose statistics on the running CherryPy server

    GET()
        Return a dump of statistics collected from the CherryPy server

    GET /stats
        Request Headers
            • X-Auth-Token -- a session token from Login.
            • Accept -- the desired response format.
        Response Headers
            • Content-Type -- the format of the response body; depends on the Accept request header.
        Status Codes
            • 200 -- success
            • 401 -- authentication required
            • 406 -- requested Content-Type not available

31.17.2 rest_tornado

A non-blocking REST API for Salt

depends
    • tornado Python module

configuration
    All authentication is done through Salt’s external auth system which requires additional configuration not described here.

In order to run rest_tornado with the salt-master add the following to the Salt master config file.

rest_tornado:
    # can be any port
    port: 8000
    # address to bind to (defaults to 0.0.0.0)
    address: 0.0.0.0
    # socket backlog
    backlog: 128
    ssl_crt: /etc/pki/api/certs/server.crt
    # no need to specify ssl_key if cert and key # are in one single file
    ssl_key: /etc/pki/api/certs/server.key
    debug: False
    disable_ssl: False
    webhook_disable_auth: False

Authentication

Authentication is performed by passing a session token with each request. Tokens are generated via the SaltAuthHandler URL.

The token may be sent in one of two ways:
    • Include a custom header named X-Auth-Token.
• Sent via a cookie. This option is a convenience for HTTP clients that automatically handle cookie support (such as browsers).

See also:

You can bypass the session handling via the RunSaltAPIHandler URL.

Usage

Commands are sent to a running Salt master via this module by sending HTTP requests to the URLs detailed below.

Content negotiation

This REST interface is flexible in what data formats it will accept as well as what formats it will return (e.g., JSON, YAML, x-www-form-urlencoded).

• Specify the format of data in the request body by including the Content-Type header.
• Specify the desired data format for the response body with the Accept header.

Data sent in POST and PUT requests must be in the format of a list of lowstate dictionaries. This allows multiple commands to be executed in a single HTTP request.

lowstate  A dictionary containing various keys that instruct Salt which command to run, where that command lives, any parameters for that command, any authentication credentials, what returner to use, etc.

Salt uses the lowstate data format internally in many places to pass command data between functions. Salt also uses lowstate for the LocalClient() Python API interface.

The following example (in JSON format) causes Salt to execute two commands:

```
[{
   "client": "local",
   "tgt": "*",
   "fun": "test.fib",
   "arg": ["10"]
},
{
   "client": "runner",
   "fun": "jobs.lookup_jid",
   "jid": "20130603122505459265"
}]
```

Multiple commands in a Salt API request will be executed in serial and makes no guarantees that all commands will run. Meaning that if test.fib (from the example above) had an exception, the API would still execute `jobs.lookup_jid`.

Responses to these lowstates are an in-order list of dicts containing the return data, a yaml response could look like:

```
- ms-1: true
  ms-2: true
- ms-1: foo
  ms-2: bar
```

In the event of an exception while executing a command the return for that lowstate will be a string, for example if no minions matched the first lowstate we would get a return like:

```
- No minions matched the target. No command was sent, no jid was assigned.
  - ms-1: true
    ms-2: true
```
x-www-form-urlencoded

Sending JSON or YAML in the request body is simple and most flexible, however sending data in urlencoded format is also supported with the caveats below. It is the default format for HTML forms, many JavaScript libraries, and the `curl` command.

For example, the equivalent to running `salt '*' test.ping` is sending `fun=test.ping&arg&client=local&tgt=*` in the HTTP request body.

Caveats:

- Only a single command may be sent per HTTP request.
- Repeating the `arg` parameter multiple times will cause those parameters to be combined into a single list.

Note, some popular frameworks and languages (notably jQuery, PHP, and Ruby on Rails) will automatically append empty brackets onto repeated parameters. E.g., `arg=one, arg=two` will be sent as `arg[]=one, arg[]=two`. This is not supported; send JSON or YAML instead.

A Websockets add-on to saltnado

depends
  - tornado Python module

In order to enable saltnado_websockets you must add websockets: True to your saltnado config block.

```yaml
rest_tornado:
  # can be any port
  port: 8000
  ssl_crt: /etc/pki/api/certs/server.crt
  # no need to specify ssl_key if cert and key
  # are in one single file
  ssl_key: /etc/pki/api/certs/server.key
  debug: False
  disable_ssl: False
  websockets: True
```

All Events

Exposes all `"real-time"` events from Salt's event bus on a websocket connection. It should be noted that `"Real-time"` here means these events are made available to the server as soon as any salt related action (changes to minions, new jobs etc) happens. Clients are however assumed to be able to tolerate any network transport related latencies. Functionality provided by this endpoint is similar to the `/events` end point.

The event bus on the Salt master exposes a large variety of things, notably when executions are started on the master and also when minions ultimately return their results. This URL provides a real-time window into a running Salt infrastructure. Uses websocket as the transport mechanism.

Exposes GET method to return websocket connections. All requests should include an auth token. A way to obtain obtain authentication tokens is shown below.

```bash
% curl -si localhost:8000/login \
  -H "Accept: application/json" \
  -d username='salt' \
  -d password='salt' \
  -d eauth='pam'
```
Which results in the response

```json
{
    "return": {
        "perms": [".*", "@runner", "@wheel"],
        "start": 1400556492.277421,
        "token": "d0ce6c1a37e99dccc0374392f272fe19c0090cca7",
        "expire": 1400599692.277422,
        "user": "salt",
        "eauth": "pam"
    }
}
```

In this example the `token` returned is `d0ce6c1a37e99dccc0374392f272fe19c0090cca7` and can be included in subsequent websocket requests (as part of the URL).

The event stream can be easily consumed via JavaScript:

```javascript
// Note, you must be authenticated!
// Get the Websocket connection to Salt
var source = new WebSocket('wss://localhost:8000/all_events/d0ce6c1a37e99dccc0374392f272fe19c0090cca7');

// Get Salt's "real time" event stream.
source.onopen = function() { source.send('websocket client ready'); };

// Other handlers
source.onerror = function(e) { console.debug('error!', e); };

// e.data represents Salt's "real time" event data as serialized JSON.
source.onmessage = function(e) { console.debug(e.data); };

// Terminates websocket connection and Salt's "real time" event stream on the server.
source.close();
```

Or via Python, using the Python module `websocket-client` for example. Or the `tornado` client.

```python
# Note, you must be authenticated!

from websocket import create_connection

# Get the Websocket connection to Salt
ws = create_connection('wss://localhost:8000/all_events/d0ce6c1a37e99dccc0374392f272fe19c0090cca7')

# Get Salt's "real time" event stream.
ws.send('websocket client ready')

# Simple listener to print results of Salt's "real time" event stream.
# Look at https://pypi.python.org/pypi/websocket-client/ for more examples.
while listening_to_events:
    print ws.recv()  # Salt's "real time" event data as serialized JSON.

# Terminates websocket connection and Salt's "real time" event stream on the server.
ws.close()

# Please refer to https://github.com/liris/websocket-client/issues/81 when using a self signed cert
```

Above examples show how to establish a websocket connection to Salt and activating real time updates from Salt's event stream by signaling `websocket client ready`.
Formatted Events

Exposes formatted "real-time" events from Salt's event bus on a websocket connection. It should be noted that "Real-time" here means these events are made available to the server as soon as any salt related action (changes to minions, new jobs etc) happens. Clients are however assumed to be able to tolerate any network transport related latencies. Functionality provided by this endpoint is similar to the /events end point.

The event bus on the Salt master exposes a large variety of things, notably when executions are started on the master and also when minions ultimately return their results. This URL provides a real-time window into a running Salt infrastructure. Uses websocket as the transport mechanism.

Formatted events parses the raw "real time" event stream and maintains a current view of the following:

- minions
- jobs

A change to the minions (such as addition, removal of keys or connection drops) or jobs is processed and clients are updated. Since we use salt's presence events to track minions, please enable presence_events and set a small value for the loop_interval in the salt master config file.

Exposes GET method to return websocket connections. All requests should include an auth token. A way to obtain authentication tokens is shown below.

```bash
% curl -s localhost:8000/login \
   -H "Accept: application/json" \
   -d username='salt' \
   -d password='salt' \
   -d eauth='pam'
```

Which results in the response

```json
{
   "return": [{
      "perms": [".*", "@runner", "@wheel"],
      "start": 1400556492.277421,
      "token": "d0ce6c1a37e99dcc0374392f272fe19c0090cca7",
      "expire": 1400599692.277422,
      "user": "salt",
      "eauth": "pam"
   }]
}
```

In this example the token returned is d0ce6c1a37e99dcc0374392f272fe19c0090cca7 and can be included in subsequent websocket requests (as part of the URL).

The event stream can be easily consumed via JavaScript:

```javascript
// Note, you must be authenticated!

// Get the Websocket connection to Salt
var source = new WebSocket('wss://localhost:8000/formatted_events/d0ce6c1a37e99dcc0374392f272fe19c0090cca7');

// Get Salt's "real time" event stream.
source.onopen = function() { source.send('websocket client ready'); }; 

// Other handlers
source.onerror = function(e) { console.debug('error!', e); }; 

// e.data represents Salt's "real time" event data as serialized JSON.
```
source.onmessage = function(e) { console.debug(e.data); }; 

// Terminates websocket connection and Salt's "real time" event stream on the server.
source.close();

Or via Python, using the Python module websocket-client for example. Or the tornado client.

```python
from websocket import create_connection

# Get the Websocket connection to Salt
ws = create_connection('wss://localhost:8000/formatted_events/d0ce6c1a37e99dcc0374392f272fe19c0090cc2f8')

# Get Salt's "real time" event stream.
ws.send('websocket client ready')

# Simple listener to print results of Salt's "real time" event stream.
# Look at https://pypi.python.org/pypi/websocket-client/ for more examples.
while listening_to_events:
    print ws.recv() # Salt's "real time" event data as serialized JSON.

# Terminates websocket connection and Salt's "real time" event stream on the server.
ws.close()

# Please refer to https://github.com/liris/websocket-client/issues/81 when using a self signed cert
```

Above examples show how to establish a websocket connection to Salt and activating real time updates from Salt's event stream by signaling websocket client ready.

Example responses

Minion information is a dictionary keyed by each connected minion's id (mid), grains information for each minion is also included.

Minion information is sent in response to the following minion events:

- connection drops
  - requires running manage.present periodically every loop_interval seconds
- minion addition
- minion removal

```json
# Not all grains are shown
data: {
  "minions": {
    "minion1": {
      "id": "minion1",
      "grains": {
        "kernel": "Darwin",
        "domain": "local",
        "zmqversion": "4.0.3",
        "kernelrelease": "13.2.0"
      }
    }
  }
}
```
Job information is also tracked and delivered.

Job information is also a dictionary in which each job's information is keyed by salt's jid.

```json
data: {
    "jobs": {
        "20140609153646699137": {
            "tgt_type": "glob",
            "jid": "20140609153646699137",
            "tgt": "*",
            "start_time": "2014-06-09T15:36:46.700315",
            "state": "complete",
            "fun": "test.ping",
            "minions": {
                "minion1": {
                    "return": true,
                    "retcode": 0,
                    "success": true
                }
            }
        }
    }
}
```

Setup

31.17.3 rest_wsgi

A minimalist REST API for Salt

This rest_wsgi module provides a no-frills REST interface for sending commands to the Salt master. There are no dependencies.

Extra care must be taken when deploying this module into production. Please read this documentation in entirety.

All authentication is done through Salt’s external auth system.

Usage

- All requests must be sent to the root URL (/).
- All requests must be sent as a POST request with JSON content in the request body.
- All responses are in JSON.

See also:

rest_cherrypy

The rest_cherrypy module is more full-featured, production-ready, and has builtin security features.
Deployment

The rest_wsgi netapi module is a standard Python WSGI app. It can be deployed one of two ways.

Using a WSGI-compliant web server

This module may be run via any WSGI-compliant production server such as Apache with mod_wsgi or Nginx with FastCGI.

It is strongly recommended that this app be used with a server that supports HTTPS encryption since raw Salt authentication credentials must be sent with every request. Any apps that access Salt through this interface will need to manually manage authentication credentials (either username and password or a Salt token). Tread carefully.

salt-api using a development-only server

If run directly via the salt-api daemon it uses the wsgiref.simple_server() that ships in the Python standard library. This is a single-threaded server that is intended for testing and development. This server does not use encryption; please note that raw Salt authentication credentials must be sent with every HTTP request.

Running this module via salt-api is not recommended!

In order to start this module via the salt-api daemon the following must be put into the Salt master config:

```
rest_wsgi:
  port: 8001
```

Usage examples

**POST /**

Example request for a basic `test.ping`:

```
% curl -sS -i \
    -H 'Content-Type: application/json' \
    -d '[["eauth":"pam","username":"saltdev","password":"saltdev","client":"local","tgt":"*"}}'
```

Example response:

```
HTTP/1.0 200 OK
Content-Length: 89
Content-Type: application/json

{"return": [{"ms--4": true, "ms--3": true, "ms--2": true, "ms--1": true, "ms--0": true}]}```

Example request for an asynchronous `test.ping`:

```
% curl -sS -i \
    -H 'Content-Type: application/json' \
    -d '[["eauth":"pam","username":"saltdev","password":"saltdev","client":"local_async","tgt":"*"}}'
```

Example response:

```
HTTP/1.0 200 OK
Content-Length: 103
Content-Type: application/json

{"return": [{"jid": "20130412192112593739", "minions": ["ms--4", "ms--3", "ms--2", "ms--1", "ms--0"]}]}```

31.17. Full list of netapi modules 1431
Example request for looking up a job ID:

% curl -sS -i \
   -H 'Content-Type: application/json' \
   -d '{"eauth":"pam","username":"saltdev","password":"saltdev","client":"runner","fun":"jobs.lookup_jid","jid":"20130412192112593739"}' localhost:8001

Example response:

HTTP/1.0 200 OK
Content-Length: 89
Content-Type: application/json

{"return": [{"ms--4": true, "ms--3": true, "ms--2": true, "ms--1": true, "ms--0": true}]}

form lowstate A list of lowstate data appropriate for the client interface you are calling.

status 200 success
status 401 authentication required

31.18 Full list of builtin output modules

Follow one of the below links for further information and examples

<table>
<thead>
<tr>
<th>Module</th>
<th>Description</th>

</table>

31.18.1 salt.output.compact

Display compact output data structure

Example output: `saltdev`: ['test_|-always-passes_|-foo_|-succeed_without_changes': {'comment': 'Success!', 'name': 'foo', 'start_time': '05:16:26.118141', 'result': True, 'duration': 1, '__run_num__': 0, 'changes': {}}, 'test_|-my-custom-combo_|-foo_|-configurable_test_state': {'comment': 'bar.baz', 'name': 'foo', 'start_time': '05:16:26.117177', 'result': False, 'duration': 1, '__run_num__': 4, 'changes': {'testing': {'new': 'Something pretended to change', 'old': 'Unchanged'}}}, 'test_|-always-fails_|-foo_|-fail_without_changes': {'comment': 'Failure!', 'name': 'foo', 'start_time': '05:16:26.113124', 'result': False, 'duration': 1, '__run_num__': 1, 'changes': {}}, 'test_|-always-changes-and-succeeds_|-foo_|-succeed_with_changes': {'comment': 'Success!', 'name': 'foo', 'start_time': '05:16:26.114570', 'result': True, 'duration': 0, '__run_num__': 2, 'changes': {'testing': {'new': 'Something pretended to change', 'old': 'Unchanged'}}}, 'test_|-always-changes-and-fails_|-foo_|-fail_with_changes': {'comment': 'Failure!', 'name': 'foo', 'start_time': '05:16:26.113124', 'result': False, 'duration': 1, '__run_num__': 1, 'changes': {}}, 'test_|-always-fails_|-foo_|-fail_without_changes': {'comment': 'Failure!', 'name': 'foo', 'start_time': '05:16:26.113124', 'result': False, 'duration': 1, '__run_num__': 1, 'changes': {}}, 'test_|-always-changes-and-succeeds_|-foo_|-succeed_with_changes': {'comment': 'Success!', 'name': 'foo', 'start_time': '05:16:26.114570', 'result': True, 'duration': 0, '__run_num__': 2, 'changes': {'testing': {'new': 'Something pretended to change', 'old': 'Unchanged'}}}, 'test_|-always-changes-and-fails_|-foo_|-fail_with_changes': {'comment': 'Failure!'}}

1432 Chapter 31. Reference
31.18.2 salt.output.highstate

Outputter for displaying results of state runs

The return data from the Highstate command is a standard data structure which is parsed by the highstate outputter to deliver a clean and readable set of information about the HighState run on minions.

Two configurations can be set to modify the highstate outputter. These values can be set in the master config to change the output of the salt command or set in the minion config to change the output of the salt-call command.

state_verbose: By default state_verbose is set to True, setting this to False will instruct the highstate outputter to omit displaying anything in green, this means that nothing with a result of True and no changes will not be printed

state_output: The highstate outputter has five output modes, full, terse, mixed, changes and filter.

- The default is set to full, which will display many lines of detailed information for each executed chunk.
- If terse is used, then the output is greatly simplified and shown in only one line.
- If mixed is used, then terse output will be used unless a state failed, in which case full output will be used.
- If changes is used, then terse output will be used if there was no error and no changes, otherwise full output will be used.
- If filter is used, then either or both of two different filters can be used: exclude or terse. These can be set as such from the command line, or in the Salt config as state_output_exclude or state_output_terse, respectively. The values to exclude must be a comma-separated list of True, False and/or None. Because of parsing nuances, if only one of these is used, it must still contain a comma. For instance: exclude=True,

state_tabular: If state_output uses the terse output, set this to True for an aligned output format. If you wish to use a custom format, this can be set to a string.

Example output:

myminion:
----------
ID: test.ping
Function: module.run
Result: True
Comment: Module function test.ping executed
Changes:
--------
ret:
    True
Summary for myminion
----------
Succeeded: 1
Failed: 0
The HighState Outputer is only meant to be used with the state.highstate function, or a function that returns highstate return data.

**31.18.3 salt.output.json_out**

Display return data in JSON format

configuration The output format can be configured in two ways: Using the --out-indent CLI flag and specifying a positive integer or a negative integer to group JSON from each minion to a single line.

Or setting the output_indent setting in the Master or Minion configuration file with one of the following values:

- Null: put each minion return on a single line.
- pretty: use four-space indents and sort the keys.
- An integer: specify the indentation level.

Salt's outputters operate on a per-minion basis. Each minion return will be output as a single JSON object once it comes in to the master.

Some JSON parsers can guess when an object ends and a new one begins but many cannot. A good way to differentiate between each minion return is to use the single-line output format and to parse each line individually. Example output (truncated):

```json
{"dave": {"en0": {"hwaddr": "02:b0:26:32:4c:69", ...}}}
{"jerry": {"en0": {"hwaddr": "02:26:ab:0d:b9:0d", ...}}}
{"kevin": {"en0": {"hwaddr": "02:6d:7f:ce:9f:ee", ...}}}
{"mike": {"en0": {"hwaddr": "02:48:a2:4b:70:a0", ...}}}
{"phill": {"en0": {"hwaddr": "02:1d:cc:a2:33:55", ...}}}
{"stuart": {"en0": {"hwaddr": "02:9a:eo:ea:9e:3c", ...}}}
```

Print the output data in JSON

**31.18.4 salt.output.key**

Display salt-key output

The salt-key command makes use of this outputter to format its output.

Read in the dict structure generated by the salt key API methods and print the structure.

**31.18.5 salt.output.nested**

Recursively display nested data

This is the default outputter for most execution functions.
Example output:

```
myminion:
    foo:
    bar:
    dictionary:
        abc: 123
        def: 456
    list:
        - Hello
        - World
```

class salt.output.nested.NestDisplay
Manage the nested display contents

```
    display(ret, indent, prefix, out)
    Recursively iterate down through data structures to determine output
```

```
    ustring(indent, color, msg, prefix='`', suffix='`', endc=None)
```

salt.output.nested.output(ret)
Display ret data

31.18.6 salt.output.newline_values_only

Display values only, separated by newlines

New in version 2015.5.0.

This outputer is designed for Salt CLI return data. It will do the following to the return dict:

1. Get just the values (ignoring the minion IDs).
2. Each value, if it is iterable, is split a separate line.
3. Each minion's values are separated by newlines.

This results in a single string of return data containing all the values from the various minions.

**Warning:** As noted above, this outputer will discard the minion ID. If the minion ID is important, then an outputer that returns the full return dictionary in a parsable format (such as json, pprint, or yaml) may be more suitable.

Example 1

**Input**

```
{
    'myminion': ['127.0.0.1', '10.0.0.1'],
    'second-minion': ['127.0.0.1', '10.0.0.2']
}
```
Output

```
127.0.0.1
10.0.0.1
127.0.0.1
10.0.0.2
```

Example 2

Input

```
{
    'myminion': 8,
    'second-minion': 10
}
```

Output

```
8
10
```

```
salt.output.newline_values_only.output(data)
    Display modified ret data
```

31.18.7 salt.output.no_out

Display no output

No output is produced when this outputer is selected

```
salt.output.no_out.output(ret)
    Don't display data. Used when you only are interested in the return.
```

31.18.8 salt.output.no_return

Display output for minions that did not return

This outputer is used to display notices about which minions failed to return when a salt function is run with -v or --verbose. It should not be called directly from the CLI.

Example output:

```
virtucentos:
    Minion did not return
```

```
class salt.output.no_return.NestDisplay
    Create generator for nested output
        display(ret, indent, prefix, out)
            Recursively iterate down through data structures to determine output
salt.output.no_return.output(ret)
    Display ret data
```
31.18.9 salt.output.overstatestage

Display clean output of an overstate stage

This outputer is used to display OverState stages, and should not be called directly.

```python
salt.output.overstatestage.output(data)
```

Format the data for printing stage information from the overstate system

31.18.10 salt.output.pprint_out

Python pretty-print (pprint)

The python pretty-print system was once the default outputter. It simply passes the return data through to `pprint.pformat` and prints the results.

Example output:

```python
{'saltmine': {'foo': {'bar': 'baz',
                      'dictionary': {'abc': 123, 'def': 456},
                      'list': ['Hello', 'World']}}}
```

```python
salt.output.pprint_out.output(data)
```

Print out via pretty print

31.18.11 salt.output.progress

Display return data as a progress bar

```python
salt.output.progress.output(ret, bar)
```

Update the progress bar

```python
salt.output.progress.progress_iter(progress)
```

Initialize and return a progress bar iter

31.18.12 salt.output.raw

Display raw output data structure

This outputer simply displays the output as a python data structure, by printing a string representation of it. It is similar to the pprint outputter, only the data is not nicely formatted/indented.

This was the original outputter used by Salt before the outputter system was developed.

Example output:

```python
{'myminion': {'foo': {'list': ['Hello', 'World'], 'bar': 'baz', 'dictionary': {'abc': 123, 'def': 456}}}}
```

```python
salt.output.raw.output(data)
```

Rather basic....
31.18.13 salt.output.txt

Simple text outputter

The txt outputter has been developed to make the output from shell commands on minions appear as they do when the command is executed on the minion.

```
salt.output.txt.output(data)
Output the data in lines, very nice for running commands
```

31.18.14 salt.output.virt_query

virt.query outputter

Used to display the output from the virt.query runner.

```
salt.output.virt_query.output(data)
Display output for the salt-run virt.query function
```

31.18.15 salt.output.yaml_out

Display return data in YAML format

This outputter defaults to printing in YAML block mode for better readability.

Example output:
```
saltmine:
  foo:
    bar: baz
dictionary:
  abc: 123
def: 456
list:
  - Hello
  - World
```

```
salt.output.yaml_out.output(data)
Print out YAML using the block mode
```

31.19 Peer Communication

Salt 0.9.0 introduced the capability for Salt minions to publish commands. The intent of this feature is not for Salt minions to act as independent brokers one with another, but to allow Salt minions to pass commands to each other.

In Salt 0.10.0 the ability to execute runners from the master was added. This allows for the master to return collective data from runners back to the minions via the peer interface.

The peer interface is configured through two options in the master configuration file. For minions to send commands from the master the peer configuration is used. To allow for minions to execute runners from the master the peer_run configuration is used.
Since this presents a viable security risk by allowing minions access to the master publisher the capability is turned off by default. The minions can be allowed access to the master publisher on a per minion basis based on regular expressions. Minions with specific ids can be allowed access to certain Salt modules and functions.

31.19.1 Peer Configuration

The configuration is done under the `peer` setting in the Salt master configuration file, here are a number of configuration possibilities.

The simplest approach is to enable all communication for all minions, this is only recommended for very secure environments.

```
peer:
  .*:
    - .*
```

This configuration will allow minions with IDs ending in example.com access to the test, ps, and pkg module functions.

```
peer:
  .*example.com:
    - test.*
    - ps.*
    - pkg.*
```

The configuration logic is simple, a regular expression is passed for matching minion ids, and then a list of expressions matching minion functions is associated with the named minion. For instance, this configuration will also allow minions ending with foo.org access to the publisher.

```
peer:
  .*example.com:
    - test.*
    - ps.*
    - pkg.*
  .*foo.org:
    - test.*
    - ps.*
    - pkg.*
```

31.19.2 Peer Runner Communication

Configuration to allow minions to execute runners from the master is done via the `peer_run` option on the master. The `peer_run` configuration follows the same logic as the `peer` option. The only difference is that access is granted to runner modules.

To open up access to all minions to all runners:

```
peer_run:
  .*:
    - .*
```

This configuration will allow minions with IDs ending in example.com access to the manage and jobs runner functions.

```
peer_run:
  .*example.com:
    - manage.*
    - jobs.*
```
31.19.3 Using Peer Communication

The publish module was created to manage peer communication. The publish module comes with a number of functions to execute peer communication in different ways. Currently there are three functions in the publish module. These examples will show how to test the peer system via the salt-call command.

To execute test.ping on all minions:

```
# salt-call publish.publish \* test.ping
```

To execute the manage.up runner:

```
# salt-call publish.runner manage.up
```

To match minions using other matchers, use `expr_form`:

```
# salt-call publish.publish 'webserv* and not G@os:Ubuntu' test.ping expr_form='compound'
```

31.20 Pillars

Salt includes a number of built-in external pillars, listed at Full list of builtin pillar modules.

You may also wish to look at the standard pillar documentation, at Pillar Configuration.

The source for the built-in Salt pillars can be found here: https://github.com/saltstack/salt/blob/develop/salt/pillar

31.21 Full list of builtin pillar modules

<table>

<td>Copy pillar data from a bucket in Amazon S3</td>
</tr>
<tr>
<td>svn_pillar</td>
<td>Clone a remote SVN repository and use the filesystem as a Pillar source</td>
</tr>
</tbody>
</table>

Continued on next page
31.21.1 salt.pillar.cmd_json

Execute a command and read the output as JSON. The JSON data is then directly overlaid onto the minion’s Pillar data.

```
salt.pillar.cmd_json.ext_pillar(minion_id, pillar, command)
```

Execute a command and read the output as JSON

31.21.2 salt.pillar.cmd_yaml

Execute a command and read the output as YAML. The YAML data is then directly overlaid onto the minion’s Pillar data.

```
salt.pillar.cmd_yaml.ext_pillar(minion_id, pillar, command)
```

Execute a command and read the output as YAML

31.21.3 salt.pillar.cmd_yamllex

Execute a command and read the output as YAMLEX. The YAMLEX data is then directly overlaid onto the minion’s Pillar data.

```
salt.pillar.cmd_yamllex.ext_pillar(minion_id, pillar, command)
```

Execute a command and read the output as YAMLEX

31.21.4 salt.pillar.cobbler

A module to pull data from Cobbler via its API into the Pillar dictionary

Configuring the Cobbler ext_pillar

The same cobbler:* parameters are used for both the Cobbler tops and Cobbler pillar modules.

```
ext_pillar:
  - cobbler:
      key: cobbler # Nest results within this key. By default, values are not nested.
      only: [parameters] # Add only these keys to pillar.

cobbler.url: https://example.com/cobbler_api #default is http://localhost/cobbler_api

cobbler.user: username # default is no username

cobbler.password: password # default is no password
```

Module Documentation

```
salt.pillar.cobbler.ext_pillar(minion_id, pillar, key=None, only=())
```

Read pillar data from Cobbler via its API.
31.21.5 salt.pillar.django_orm

Generate Pillar data from Django models through the Django ORM

maintainer Micah Hausler <micah.hausler@gmail.com>
maturity new

Configuring the django_orm ext_pillar

To use this module, your Django project must be on the salt master server with database access. This assumes you are using virtualenv with all the project's requirements installed.

```yaml
ext_pillar:
  - django_or
    pillar_name: my_application
    project_path: /path/to/project/
    settings_module: my_application.settings
    env_file: /path/to/env/file.sh
    # Optional: If your project is not using the system python, 
    # add your virtualenv path below.
    env: /path/to/virtualenv/

django_app:

  # Required: the app that is included in INSTALLED_APPS
  my_application.clients:

    # Required: the model name
    Client:

      # Required: model field to use as the key in the rendered
      # Pillar. Must be unique; must also be included in the
      # ``fields`` list below.
      name: shortname

      # Optional:
      # See Django's QuerySet documentation for how to use .filter()
      filter: {'kw': 'args'}

      # Required: a list of field names
      # List items will be used as arguments to the .values() method.
      # See Django's QuerySet documentation for how to use .values()
      fields:
        - field_1
        - field_2
```

This would return pillar data that would look like

```yaml
my_application:
  my_application.clients:
    Client:
      client_1:
        field_1: data_from_field_1
        field_2: data_from_field_2
      client_2:
        field_1: data_from_field_1
        field_2: data_from_field_2
```
As another example, data from multiple database tables can be fetched using Django's regular lookup syntax. Note, using ManyToManyFields will not currently work since the return from values() changes if a ManyToMany is present.

```
ext_pillar:
  - django_orm:
      pillar_name: djangotutorial
      project_path: /path/to/mysite
      settings_module: mysite.settings

  django_app:
    mysite.polls:
      Choices:
        name: poll__question
      fields:
        - poll__question
        - poll__id
        - choice_text
        - votes
```

**Module Documentation**

`salt.pillar.django_orm.ext_pillar` *(minion_id, pillar, pillar_name, project_path, settings_module, django_app, env=None, env_file=None, *args, **kwargs)*

Connect to a Django database through the ORM and retrieve model fields

**Parameters**

- **pillar_name** *(str)* -- The name of the pillar to be returned
- **project_path** *(str)* -- The full path to your Django project (the directory manage.py is in)
- **settings_module** *(str)* -- The settings module for your project. This can be found in your manage.py file
- **django_app** *(str)* -- A dictionary containing your apps, models, and fields
- **env** *(str)* -- The full path to the virtualenv for your Django project
- **env_file** *(str)* -- An optional bash file that sets up your environment. The file is run in a subprocess and the changed variables are then added

**31.21.6 salt.pillar.ec2_pillar**

Retrieve EC2 instance data for minions.

The minion id must be the instance-id retrieved from AWS. As an option, use_grain can be set to True. This allows the use of an instance-id grain instead of the minion-id. Since this is a potential security risk, the configuration can be further expanded to include a list of minions that are trusted to only allow the alternate id of the instances to specific hosts. There is no glob matching at this time.

```
ext_pillar:
  - ec2_pillar:
      use_grain: True
      minion_ids:
        - trusted-minion-1
        - trusted-minion-2
        - trusted-minion-3
```
This is a very simple pillar that simply retrieves the instance data from AWS. Currently the only portion implemented are EC2 tags, which returns a list of key/value pairs for all of the EC2 tags assigned to the instance.

```
salt.pillar.ec2_pillar.ext_pillar(minion_id, pillar, use_grain=False, minion_ids=None)
```

Execute a command and read the output as YAML

### 31.21.7 salt.pillar.etcd_pillar

Use etcd data as a Pillar source

New in version 2014.7.0.

```
depends
    - python-etcd
```

In order to use an etcd server, a profile must be created in the master configuration file:

```
my_etcd_config:
    etcd.host: 127.0.0.1
    etcd.port: 4001
```

After the profile is created, configure the external pillar system to use it. Optionally, a root may be specified.

```
ext_pillar:
    - etcd: my_etcd_config
```

```
ext_pillar:
    - etcd: my_etcd_config root=/salt
```

Using these configuration profiles, multiple etcd sources may also be used:

```
ext_pillar:
    - etcd: my_etcd_config
    - etcd: my_other_etcd_config
```

The `minion_id` may be used in the `root` path to expose minion-specific information stored in etcd.

```
ext_pillar:
    - etcd: my_etcd_config root=/salt/%(minion_id)s
```

Minion-specific values may override shared values when the minion-specific root appears after the shared root:

```
ext_pillar:
    - etcd: my_etcd_config root=/salt-shared
    - etcd: my_other_etcd_config root=/salt-private/%(minion_id)s
```

Using the configuration above, the following commands could be used to share a key with all minions but override its value for a specific minion:

```
etcdctl set /salt-shared/mykey my_value
netcdctl set /salt-private/special_minion_id/mykey my_other_value
```

```
salt.pillar.etcd_pillar.ext_pillar(minion_id, pillar, conf)
```

Check etcd for all data

### 31.21.8 salt.pillar.file_tree

Recursively iterate over directories and add all files as Pillar data.
Example configuration:

```yaml
ext_pillar:
  - file_tree:
      root_dir: /path/to/root/directory
      follow_dir_links: False
      raw_data: False
```

The `root_dir` parameter is required and points to the directory where files for each host are stored. The `follow_dir_links` parameter is optional and defaults to False. If `follow_dir_links` is set to True, file_tree will follow symbolic links to other directories. Be careful when using `follow_dir_links`, the current implementation is dumb and will run into infinite recursion if a recursive symlink chain exists in the `root_dir`!

If `raw_data` is set to True, it will revert the behavior of the python open() function, which adds a line break character at the end of the file, in this case, the pillar data.

To fill pillar data for each host, file_tree recursively iterates over `root_dir/hosts/id` (where `id` is a minion ID), and constructs the same directory tree with contents of all the files inside the pillar tree.

For example, the following `root_dir` tree:

```
./hosts/
./hosts/test-host/
./hosts/test-host/files/
./hosts/test-host/files/testdir/
./hosts/test-host/files/testdir/file1.txt
./hosts/test-host/files/testdir/file2.txt
./hosts/test-host/files/another-testdir/
./hosts/test-host/files/another-testdir/symlink-to-file1.txt
```

will result in the following pillar tree for minion with ID `test-host`:

```
test-host:
  ----------
  files:
  """"""
  another-testdir:
    ----------
    symlink-to-file1.txt:
      Contents of file #1.
  testdir:
    ----------
    file1.txt:
      Contents of file #1.
    file2.txt:
    """
    """
```

To fill pillar data for minion in a node group, file_tree recursively iterates over `root_dir/nodegroups/nodegroup` (where `nodegroup` is a minion node group), and constructs the same directory tree with contents of all the files inside the pillar tree. **IMPORTANT:** The host data take precedence over the node group data.

For example, the following `root_dir` tree:

```
./nodegroups/
./nodegroups/test-group/
./nodegroups/test-group/files/
./nodegroups/test-group/files/testdir/
./nodegroups/test-group/files/testdir/file1.txt
```

31.21. Full list of builtin pillar modules
will result in the following pillar tree for minion in the node group `test-group`:

```
**test-host**
  
  **files**
  
  **another-testdir**
    
    **symlink-to-file1.txt**
      Contents of file #1.

  **testdir**
    
    **file1.txt**
      Contents of file #1.
    
    **file2.txt**
      Contents of file #2.
```

_**salt.pillar.file_tree.ext_pillar**_ (minion_id, pillar, root_dir=None, follow_dir_links=False, de-
bug=False, raw_data=False)

Find pillar data for specified ID.

### 31.21.9 salt.pillar.foreman

A module to pull data from Foreman via its API into the Pillar dictionary

#### Configuring the Foreman ext_pillar

Set the following Salt config to setup Foreman as external pillar source:

```
ext_pillar:
  - foreman:
    key: foreman # Nest results within this key
    only: ['hostgroup_name', 'parameters'] # Add only these keys to pillar

foreman.url: https://example.com/foreman_api
foreman.user: username # default is admin
foreman.password: password # default is changeme
```

The following options are optional:

```
foreman.api: apiversion # default is 2 (1 is not supported yet)
foreman.verifyssl: False # default is True
foreman.certfile: /etc/ssl/certs/mycert.pem # default is None
foreman.keyfile: /etc/ssl/private/mykey.pem # default is None
foreman.cafile: /etc/ssl/certs/mycert.ca.pem # default is None
foreman.lookup_parameters: True # default is True
```

An alternative would be to use the Foreman modules integrating Salt features in the Smart Proxy and the webinterface.

Further information can be found on [GitHub](https://github.com/saltstack/salt/tree/master/salt/modules/foreman).
Module Documentation

salt.pillar.foreman.ext_pillar(minion_id, pillar, key=None, only=())
Read pillar data from Foreman via its API.

31.21.10 salt.pillar.git_pillar

Use a git repository as a Pillar source

Note: This external pillar has been rewritten for the 2015.8.0 release. The old method of configuring this external pillar will be maintained for a couple releases, allowing time for configurations to be updated to reflect the new usage.

This external pillar allows for a Pillar top file and Pillar SLS files to be sourced from a git repository. However, since git_pillar does not have an equivalent to the pillar_roots parameter, configuration is slightly different. The Pillar top file must still contain the relevant environment, like so:

```
base:
  '*':
    - foo
```

The branch/tag which maps to that environment must then be specified along with the repo's URL. Configuration details can be found below.

Configuring git_pillar for Salt releases before 2015.8.0

For Salt releases earlier than 2015.8.0, GitPython is the only supported provider for git_pillar. Individual repositories can be configured under the ext_pillar configuration parameter like so:

```
ext_pillar:
  - git: master https://gitserver/git-pillar.git root=subdirectory
```

The repository is specified in the format `<branch> <repo_url>`, with an optional root parameter (added in the 2014.7.0 release) which allows the pillar SLS files to be served up from a subdirectory (similar to gitfs_root in gitfs).

To use more than one branch from the same repo, multiple lines must be specified under ext_pillar:

```
ext_pillar:
  - git: master https://gitserver/git-pillar.git
  - git: dev https://gitserver/git-pillar.git
```

To remap a specific branch to a specific Pillar environment, use the format `<branch>:<env>`:

```
ext_pillar:
  - git: develop:dev https://gitserver/git-pillar.git
  - git: master:prod https://gitserver/git-pillar.git
```

In this case, the develop branch would need its own top.sls with a dev section in it, like this:

```
develop:
  '*':
    - bar
```

The master branch would need its own top.sls with a prod section in it:
If `__env__` is specified as the branch name, then git_pillar will use the branch specified by `gitfs_base`:

```
ext_pillar:
  - git: __env__ https://gitserver/git-pillar.git root=pillar
```

The corresponding Pillar top file would look like this:

```
{{env}}:
  '*':
    - bar
```

### Configuring git_pillar for Salt releases 2015.8.0 and later

**Note:** In version 2015.8.0, the method of configuring git external pillars has changed, and now more closely resembles that of the [Git Fileserver Backend](https://github.com/saltstack/salt/tree/master/doc/channels). If Salt detects the old configuration schema, it will use the pre-2015.8.0 code to compile the external pillar. A warning will also be logged.

Beginning with Salt version 2015.8.0, [pygit2](https://pypi.python.org/pypi/pygit2) is now supported in addition to [GitPython](https://pypi.python.org/pypi/GitPython) (**Dulwich** will not be supported for the foreseeable future). The requirements for [GitPython](https://pypi.python.org/pypi/GitPython) and [pygit2](https://pypi.python.org/pypi/pygit2) are the same as for `gitfs`, as described [here](https://github.com/saltstack/salt/tree/master/doc/channels).

Here is an example git_pillar configuration.

```
ext_pillar:
  - git:
      # Use 'prod' instead of the branch name 'production' as the environment
      - production https://gitserver/git-pillar.git:
        - env: prod
      # Use 'dev' instead of the branch name 'develop' as the environment
      - develop https://gitserver/git-pillar.git:
        - env: dev
      # No per-remote config parameters (and no trailing colon), 'qa' will
      # be used as the environment
      - qa https://gitserver/git-pillar.git
      # SSH key authentication
      - master git@other-git-server:pillardata-ssh.git:
        # Pillar SLS files will be read from the 'pillar' subdirectory in
        # this repository
        - root: pillar
        - privkey: /path/to/key
        - pubkey: /path/to/key.pub
        - passphrase: CorrectHorseBatteryStaple
      # HTTPS authentication
      - master https://other-git-server/pillardata-https.git:
        - user: git
        - password: CorrectHorseBatteryStaple
```

The main difference between this and the old way of configuring `git_pillar` is that multiple remotes can be configured under one `git` section under `ext_pillar`. More than one `git` section can be used, but it is not necessary. Remotes will be evaluated sequentially.

Per-remote configuration parameters are supported (similar to `gitfs`), and global versions of the `git_pillar` configuration parameters can also be set.
With the addition of `pygit2` support, git_pillar can now interact with authenticated remotes. Authentication works just like in gitfs (as outlined in the `Git Fileserver Backend Walkthrough`), only with the global authentication parameter names prefixed with `git_pillar` instead of `gitfs` (e.g. `git_pillar_pubkey`, `git_pillar_privkey`, `git_pillar_passphrase`, etc.).

A full list of the `git_pillar` configuration options can be found [here](#).

```python
salt.pillar.git_pillar.ext_pillar(minion_id, repo, pillar_dirs)
```

Checkout the ext_pillar sources and compile the resulting pillar SLS

### 31.21.11 salt.pillar.hg_pillar

Use remote Mercurial repository as a Pillar source.

New in version 2015.8.0.

The module depends on the `hglib` python module being available. This is the same requirement as for `hgfs_` so should not pose any extra hurdles.

This external Pillar source can be configured in the master config file as such:

```yaml
ext_pillar:
  - hg: ssh://hg@example.co/user/repo
```

```python
class salt.pillar.hg_pillar.Repo(repo_uri)
    Deal with remote hg (mercurial) repository for Pillar
    close()
        Cleanup mercurial command server
    pull()
    update(branch='default')
        Ensure we are using the latest revision in the hg repository

salt.pillar.hg_pillar.ext_pillar(minion_id, pillar, repo, branch='default', root=None)
    Extract pillar from an hg repository

salt.pillar.hg_pillar.update(repo_uri)
    Execute an hg pull on all the repos
```

### 31.21.12 salt.pillar.hiera

Use hiera data as a Pillar source

```python
salt.pillar.hiera.ext_pillar(minion_id, pillar, conf)
    Execute hiera and return the data
```

### 31.21.13 salt.pillar.libvirt

Load up the libvirt keys into Pillar for a given minion if said keys have been generated using the libvirt key runner

```python
salt.pillar.libvirt.ext_pillar(minion_id, pillar, command)
    Read in the generated libvirt keys

salt.pillar.libvirt.gen_hyper_keys(minion_id, country='US', state='Utah', locality='Salt Lake City', organization='Salted')
    Generate the keys to be used by libvirt hypervisors, this routine gens the keys and applies them to the pillar for the hypervisor minions
```

31.21. Full list of builtin pillar modules
31.21.14 salt.pillar.mongo

Read Pillar data from a mongodb collection

depends pymongo (for salt-master)

This module will load a node-specific pillar dictionary from a mongo collection. It uses the node's id for lookups and can load either the whole document, or just a specific field from that document as the pillar dictionary.

Salt Master Mongo Configuration

The module shares the same base mongo connection variables as salt.returners.mongo_return. These variables go in your master config file.

- **mongo.db** - The mongo database to connect to. Defaultsto 'salt'.
- **mongo.host** - The mongo host to connect to. Supports replica sets by specifying all hosts in the set, comma-delimited. Defaultsto 'salt'.
- **mongo.port** - The port that the mongo database is running on. Defaultsto 27017.
- **mongo.user** - The username for connecting to mongo. Only required if you are using mongo authentication. Defaultsto ''. 
- **mongo.password** - The password for connecting to mongo. Only required if you are using mongo authentication. Defaultsto ''. 

Configuring the Mongo ext_pillar

The Mongo ext_pillar takes advantage of the fact that the Salt Master configuration file is yaml. It uses a sub-dictionary of values to adjust specific features of the pillar. This is the explicit single-line dictionary notation for yaml. One may be able to get the easier-to-read multi-line dict to work correctly with some experimentation.

```yaml
ext_pillar:
  - mongo: {collection: vm, id_field: name, re_pattern: \.example\..com, fields: [customer_id, software, apache_vhosts]}
```

In the example above, we've decided to use the *vm* collection in the database to store the data. Minion ids are stored in the name field on documents in that collection. And, since minion ids are FQDNs in most cases, we'll need to trim the domain name in order to find the minion by hostname in the collection. When we find a minion, return only the customer_id, software, and apache_vhosts fields, as that will contain the data we want for a given node. They will be available directly inside the pillar dict in your SLS templates.

Module Documentation

salt.pillar.mongo.ext_pillar *(minion_id, pillar, collection='pillar', id_field='_id', re_pattern=None, re_replace='\:', fields=None)*

Connect to a mongo database and read per-node pillarcollection.

Parameters:

- **collection**: The mongodb collection to read data from. Defaultsto 'pillar'.
- **id_field**: The field in the collection that represents an individual minion id. Defaultsto '_id'.
- **re_pattern**: If your naming convention in the collection is shorter than the minion id, you can use this to trim the name. **re_pattern** will be used to match the name, and **re_replace** will be used to replace it. Backrefs are supported as they are in the Python standard library. If **None**, no mangling
of the name will be performed - the collection will be searched with the entire minion id. Defaults to None.

- `re_replace`: Use as the replacement value in node ids matched with `re_pattern`. Defaults to `. Feel free to use backreferences here.

- `fields`: The specific fields in the document to use for the pillar data. If None, will use the entire document. If using the entire document, the `_id` field will be converted to string. Be careful with other fields in the document as they must be string serializable. Defaults to None.

### 31.21.15 salt.pillar.mysql

Retrieve Pillar data by doing a MySQL query

MariaDB provides Python support through the MySQL Python package. Therefore, you may use this module with both MySQL or MariaDB.

This module is a concrete implementation of the sql_base ext_pillar for MySQL.

```python
maturity new
depends python-mysqldb
platform all
```

**Legacy compatibility**

This module has an extra addition for backward compatibility.

If there's a keyword arg of mysql_query, that'll go first before other args. This legacy compatibility translates to depth 1.

We do this so that it's backward compatible with older configs. This is deprecated and slated to be removed in Boron.

**Configuring the mysql ext_pillar**

Use the `mysql` key under ext_pillar for configuration of queries.

MySQL configuration of the MySQL returner is being used (mysql.db, mysql.user, mysql.pass, mysql.port, mysql.host) for database connection info.

Required python modules: MySQLdb

**Complete example**

```python
mysql:
    user: 'salt'
    pass: 'super_secret_password'
    db: 'salt_db'

ext_pillar:
    - mysql:
        fromdb:
            query: 'SELECT col1,col2,col3,col4,col5,col6,col7
                    FROM some_random_table
                    WHERE minion_pattern LIKE %s
            depth: 5
```

31.21. Full list of builtin pillar modules
as_list: True
with_lists: [1,3]

class salt.pillar.mysql.MySQLExtPillar
    This class receives and processes the database rows from MySQL.

    extract_queries(args, kwargs)
    This function normalizes the config block into a set of queries we can use. The return is a list of consistently laid out dicts.

salt.pillar.mysql.ext_pillar(minion_id, pillar, *args, **kwargs)
    Execute queries against MySQL, merge and return as a dict

31.21.16 salt.pillar.pepa

Pepa

Configuration templating for SaltStack using Hierarchical substitution and Jinja.

Configuring Pepa

extension_modules: /srv/salt/ext

ext_pillar:
    - pepa:
        resource: host
        sequence:
            - hostname:
                name: input
                base_only: True
            - default:
                - environment:
                    - location..region:
                        name: region
                    - location..country:
                        name: country
                    - location..datacenter:
                        name: datacenter
            - roles:
            - osfinger:
                name: os
            - hostname:
                name: override
                base_only: True
subkey: True
subkey_only: True
pepa_roots:
    base: /srv/pepa/base
    dev: /srv/pepa/base
    qa: /srv/pepa/qa
    prod: /srv/pepa/prod

# Use a different delimiter for nested dictionaries, defaults to '..' since some keys may use '.' in names
#pepa_delimiter: ..
# Supply Grains for Pepa, this should **ONLY** be used for testing or validation
#pepa_grains:
# environment: dev

# Supply Pillar for Pepa, this should **ONLY** be used for testing or validation
#pepa_pillars:
# saltversion: 0.17.4

# Enable debug for Pepa, and keep Salt on warning
#log_level: debug

#log_granular_levels:
# salt: warning
# salt.loaded.ext.pillar.pepa: debug

Pepa can also be used in Master-less SaltStack setup.

## Command line

```
hostname
```

### positional arguments:

- **hostname**

### optional arguments:

- **-h, --help** show this help message and exit
- **-c CONFIG, --config CONFIG** Configuration file
- **-d, --debug** Print debug info
- **-g GRAINS, --grains GRAINS** Input Grains as YAML
- **-p PILLAR, --pillar PILLAR** Input Pillar as YAML
- **-n, --no-color** No color output
- **-v, --validate** Validate output

## Templates

Templates is configuration for a host or software, that can use information from Grains or Pillars. These can then be used for hierarchically substitution.

**Example File:** host/input/test_example_com.yaml

```
location..region: emea
location..country: nl
location..datacenter: foobar
environment: dev
roles:
  - salt.master
network..gateway: 10.0.0.254
network..interfaces..eth0..hwaddr: 00:20:26:a1:12:12
network..interfaces..eth0..dhcp: False
network..interfaces..eth0..ipv4: 10.0.0.3
network..interfaces..eth0..netmask: 255.255.255.0
```

31.21. Full list of builtin pillar modules
network..interfaces..eth0..fqdn: {{ hostname }}
cobbler..profile: fedora-19-x86_64

As you see in this example you can use Jinja directly inside the template.

Example File: host/region/amer.yaml

```yaml
network..dns..servers:
  - 10.0.0.1
  - 10.0.0.2
time..ntp..servers:
  - ntp1.amer.example.com
  - ntp2.amer.example.com
  - ntp3.amer.example.com
time..timezone: America/Chihuahua
yum..mirror: yum.amer.example.com
```

Each template is named after the value of the key using lowercase and all extended characters are replaced with underscore.

Example:

osfinger: Fedora-19

Would become:

fedora_19.yaml

**Nested dictionaries**

In order to create nested dictionaries as output you can use double dot ".." as a delimiter. You can change this using "pepa_delimiter" we choose double dot since single dot is already used by key names in some modules, and using ":" requires quoting in the YAML.

Example:

```yaml
network..dns..servers:
  - 10.0.0.1
  - 10.0.0.2
network..dns..options:
  - timeout:2
  - attempts:1
  - ndots:1
network..dns..search:
  - example.com
```

Would become:

```yaml
network:
  dns:
    servers:
      - 10.0.0.1
      - 10.0.0.2
    options:
      - timeout:2
      - attempts:1
      - ndots:1
    search:
      - example.com
```
Operators

Operators can be used to merge/unset a list/hash or set the key as immutable, so it can’t be changed.

<table>
<thead>
<tr>
<th>Operator</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>merge()</td>
<td>Merge list or hash</td>
</tr>
<tr>
<td>unset()</td>
<td>Unset key</td>
</tr>
<tr>
<td>immutable()</td>
<td>Set the key as immutable, so it can’t be changed</td>
</tr>
<tr>
<td>imerge()</td>
<td>Set immutable and merge</td>
</tr>
<tr>
<td>iunset()</td>
<td>Set immutable and unset</td>
</tr>
</tbody>
</table>

Example:

```yaml
network..dns..search..merge():
    - foobar.com
    - dummy.nl
owner..immutable(): Operations
host..printers..unset():
```

Validation

Since it’s very hard to test Jinja as is, the best approach is to run all the permutations of input and validate the output, i.e. Unit Testing.

To facilitate this in Pepa we use YAML, Jinja and Cerberus <https://github.com/nicolaiarocci/cerberus>.

Schema

So this is a validation schema for network configuration, as you see it can be customized with Jinja just as Pepa templates.

This was designed to be run as a build job in Jenkins or similar tool. You can provide Grains/Pillar input using either the config file or command line arguments.

File Example: host/validation/network.yaml

```yaml
network..dns..search:
    type: list
    allowed:
        - example.com

network..dns..options:
    type: list
    allowed: ['timeout:2', 'attempts:1', 'ndots:1']

network..dns..servers:
    type: list
    schema:
        regex: ^([0-9]{1,3}\.){3}[0-9]{1,3}$

network..gateway:
    type: string
    regex: ^([0-9]{1,3}\.){3}[0-9]{1,3}$

{% if network.interfaces is defined %}
{% for interface in network.interfaces %}
```

31.21. Full list of builtin pillar modules
network..interfaces..{{ interface }}..dhcp:
  type: boolean

network..interfaces..{{ interface }}..fqdn:
  type: string
  regex: ^([a-z0-9](\[a-z0-9-]{0,61}[a-z0-9])?\.)+[a-zA-Z]{2,6}$

network..interfaces..{{ interface }}..hwaddr:
  type: string
  regex: ^([0-9a-f]{1,2}:){5}[0-9a-f]{1,2}$

network..interfaces..{{ interface }}..ipv4:
  type: string
  regex: ^([0-9]{1,3}\.){3}[0-9]{1,3}$

network..interfaces..{{ interface }}..netmask:
  type: string
  regex: ^([0-9]{1,3}\.){3}[0-9]{1,3}$

{% endfor %}
{% endif %}

salt.pillar.pepa.ext_pillar(minion_id, pillar, resource, sequence, subkey=False, subkey_only=False)

Evaluate Pepa templates

salt.pillar.pepa.key_value_to_tree(data)

Convert key/value to tree

salt.pillar.pepa.validate(output, resource)

Validate Pepa templates

31.21.17 salt.pillar.pillar_ldap

Use LDAP data as a Pillar source

This pillar module executes a series of LDAP searches. Data returned by these searches are aggregated, whereby data returned by later searches override data by previous searches with the same key.

The final result is merged with existing pillar data.

The configuration of this external pillar module is done via an external file which provides the actual configuration for the LDAP searches.

Configuring the LDAP ext_pillar

The basic configuration is part of the master configuration.

ext_pillar:
  - pillar_ldap: /etc/salt/master.d/pillar_ldap.yaml
Note: When placing the file in the master.d directory, make sure its name doesn't end in .conf, otherwise the salt-master process will attempt to parse its content.

**Warning:** Make sure this file has very restrictive permissions, as it will contain possibly sensitive LDAP credentials!

The only required key in the master configuration is pillar_ldap pointing to a file containing the actual configuration.

**Configuring the LDAP searches**

The file is processed using *Salt's Renderers* `<renderers>` which makes it possible to reference grains within the configuration.

**Warning:** When using Jinja in this file, make sure to do it in a way which prevents leaking sensitive information. A rogue minion could send arbitrary grains to trick the master into returning secret data. Use only the `id` grain which is verified through the minion's key/cert.

**Map Mode**  The `it-admins` configuration below returns the Pillar `it-admins` by:

- filtering for:
  - members of the group `it-admins`
  - objects with `objectclass=user`
- returning the data of users (mode: `map`), where each user is a dictionary containing the configured string or list attributes.

**Configuration:**

```yaml
salt-users:
  server: ldap.company.tld
  port: 389
  tls: true
  dn: 'dc=company,dc=tld'
  binddn: 'cn=salt-pillars,ou=users,dc=company,dc=tld'
  bindpw: bi7ieBai5Ano
  referrals: false
  anonymous: false
  mode: map
  dn: 'ou=users,dc=company,dc=tld'
  filter: '(&(memberof=cn=it-admins,ou=groups,dc=company,dc=tld)(objectclass=user))'
  attrs:
    - cn
    - displayName
    - givenName
    - sn
  lists:
    - memberOf

**Result:**

31.21. Full list of builtin pillar modules
salt-users:
- cn: cn=johndoe,ou=users,dc=company,dc=tld
  displayName: John Doe
  givenName: John
  sn: Doe
  memberOf:
    - cn=it-admins,ou=groups,dc=company,dc=tld
    - cn=team01,ou=groups,dc=company
- cn: cn=janedoe,ou=users,dc=company,dc=tld
  displayName: Jane Doe
  givenName: Jane
  sn: Doe
  memberOf:
    - cn=it-admins,ou=groups,dc=company,dc=tld
    - cn=team02,ou=groups,dc=company

List Mode  TODO: see also _result_to_dict() documentation

salt.pillar.pillar_ldap.ext_pillar(minion_id, pillar, config_file)
Execute LDAP searches and return the aggregated data

31.21.18 salt.pillar.puppet

Execute an unmodified puppet_node_classifier and read the output as YAML. The YAML data is then directly overlaid onto the minion’s Pillar data.

salt.pillar.puppet.ext_pillar(minion_id, pillar, command)
Execute an unmodified puppet_node_classifier and read the output as YAML

31.21.19 salt.pillar.reclass_adapter

Use the `reclass` database as a Pillar source

This ext_pillar plugin provides access to the reclass database, such that Pillar data for a specific minion are fetched using reclass.

You can find more information about reclass at http://reclass.pantsfullofunix.net.

To use the plugin, add it to the ext_pillar list in the Salt master config and tell reclass by way of a few options how and where to find the inventory:

```
ext_pillar:
  - reclass:
      storage_type: yaml_fs
      inventory_base_uri: /srv/salt
```

This would cause reclass to read the inventory from YAML files in /srv/salt/nodes and /srv/salt/classes.

If you are also using reclass as master_tops plugin, and you want to avoid having to specify the same information for both, use YAML anchors (take note of the differing data types for ext_pillar and master_tops):

```
reclass: &reclass
  storage_type: yaml_fs
  inventory_base_uri: /srv/salt
reclass_source_path: ~/code/reclass
```
If you want to run reclass from source, rather than installing it, you can either let the master know via the PYTHONPATH environment variable, or by setting the configuration option, like in the example above.

```python
salt.pillar.reclass_adapter.\texttt{ext\_pillar}(\texttt{minion\_id}, \texttt{pillar}, **\texttt{kwargs})
```

Obtain the Pillar data from reclass for the given `minion_id`.

### 31.21.20 salt.pillar.redismod

**Read pillar data from a Redis backend**

New in version 2014.7.0.

```python
depends
    * redis Python module (on master)
```

#### Salt Master Redis Configuration

The module shares the same base Redis connection variables as `salt.returners.redis_return`. These variables go in your master config file.

- `redis.db` - The Redis database to use. Defaults to 0.
- `redis.host` - The Redis host to connect to. Defaults to 'salt'.
- `redis.port` - The port that the Redis database is listening on. Defaults to 6379.
- `redis.password` - The password for authenticating with Redis. Only required if you are using master auth. Defaults to None.

#### Configuring the Redis ext_pillar

```python
ext_pillar:
    - redis: {\texttt{function: key\_value}}
```

```
salt.pillar.redismod.\texttt{ext\_pillar}(\texttt{minion\_id}, \texttt{pillar}, \texttt{function}, **\texttt{kwargs})
```

Grabs external pillar data based on configured function

```
salt.pillar.redismod.\texttt{key\_json}(\texttt{minion\_id}, \texttt{pillar}, \texttt{pillar\_key=\texttt{None}})
```

Pulls a string from redis and deserializes it from json. Deserialized dictionary data loaded directly into top level if `pillar_key` is not set.

- `pillar_key` Pillar key to return data into

```
salt.pillar.redismod.\texttt{key\_value}(\texttt{minion\_id}, \texttt{pillar}, \texttt{pillar\_key=\texttt{redis\_pillar}})
```

Looks for key in redis matching `minion_id`, returns a structure based on the data type of the redis key. String for string type, dict for hash type and lists for lists, sets and sorted sets.

- `pillar_key` Pillar key to return data into
31.21.21 salt.pillar.s3

Copy pillar data from a bucket in Amazon S3

The S3 pillar can be configured in the master config file with the following options:

```
ext_pillar:
  - s3:
      bucket: my.fancy.pillar.bucket
      keyid: KASKFJWAKJASJDKAJSKSD
      key: ksladfDLKDALSFKSD93q032sdDasdfasdfsadksdf
      multiple_env: False
      environment: base
      prefix: somewhere/overthere
      verify_ssl: True
      service_url: s3.amazonaws.com
      s3_cache_expire: 30
      s3_sync_on_update: True
```

The `bucket` parameter specifies the target S3 bucket. It is required.

The `keyid` parameter specifies the key id to use when access the S3 bucket. If it is not provided, an attempt to fetch it from EC2 instance meta-data will be made.

The `key` parameter specifies the key to use when access the S3 bucket. If it is not provided, an attempt to fetch it from EC2 instance meta-data will be made.

The `multiple_env` defaults to False. It specifies whether the pillar should interpret top level folders as pillar environments (see mode section below).

The `environment` defaults to `base`. It specifies which environment the bucket represents when in single environments mode (see mode section below). It is ignored if multiple_env is True.

The `prefix` defaults to `. It specifies a key prefix to use when searching for data in the bucket for the pillar. It works when multiple_env is True or False. Essentially it tells ext_pillar to look for your pillar data in a 'subdirectory' of your S3 bucket.

The `verify_ssl` parameter defaults to True. It specifies whether to check for valid S3 SSL certificates. NOTE If you use bucket names with periods, this must be set to False else an invalid certificate error will be thrown (issue #12200).

The `service_url` parameter defaults to `s3.amazonaws.com`. It specifies the base url to use for accessing S3.

The `s3_cache_expire` parameter defaults to 30s. It specifies expiration time of S3 metadata cache file.

The `s3_sync_on_update` parameter defaults to True. It specifies if cache is synced on update rather than jit.

This pillar can operate in two modes, single environment per bucket or multiple environments per bucket.

Single environment mode must have this bucket structure:

```
  s3://<bucket name>/prefix/files
```

Multiple environment mode must have this bucket structure:

```
  s3://<bucket name>/prefix/environment/files
```

If you wish to define your pillar data entirely within S3 it’s recommended that you use the `prefix=` parameter and specify one entry in ext_pillar for each environment rather than specifying multiple_env. This is due to issue #22471 (https://github.com/saltstack/salt/issues/22471)

class salt.pillar.s3.S3Credentials(key, keyid, bucket, service_url, verify_ssl, location)
salt.pillar.s3.<strong>ext_pillar</strong>(minion_id, pillar, bucket, key=None, keyid=None, verify_ssl=True, location=None, multiple_env=False, environment='base', prefix='', service_url=None, s3_cache_expire=30, s3_sync_on_update=True)

Execute a command and read the output as YAML

### 31.21.22 salt.pillar.svn_pillar

Clone a remote SVN repository and use the filesystem as a Pillar source

This external Pillar source can be configured in the master config file like so:

```python
ext_pillar:
    - svn: trunk svn://svnserver/repo root=subdirectory
```

The `root=` parameter is optional and used to set the subdirectory from where to look for Pillar files (such as `top.sls`).

Changed in version 2014.7.0: The optional `root` parameter will be added.

Note that this is not the same thing as configuring pillar data using the `pillar_roots` parameter. The branch referenced in the `ext_pillar` entry above (`master`), would evaluate to the `base` environment, so this branch needs to contain a `top.sls` with a `base` section in it, like this:

```yaml
base:
    '!*':
        - foo
```

To use other environments from the same SVN repo as `svn_pillar` sources, just add additional lines, like so:

```python
ext_pillar:
    - svn: trunk svn://svnserver/repo
    - svn: dev svn://svnserver/repo
```

In this case, the `dev` branch would need its own `top.sls` with a `dev` section in it, like this:

```yaml
dev:
    '!*':
        - bar
```

class salt.pillar.svn_pillar.<strong>SvnPillar</strong>(branch, repo_location, root, opts)

Deal with the remote SVN repository for Pillar

```python
pillar_dir()
```

Returns the directory of the pillars (repo cache + branch + root)

```python
update()
```

salt.pillar.svn_pillar.<strong>ext_pillar</strong>(minion_id, pillar, repo_string)

Execute a command and read the output as YAML

### 31.21.23 salt.pillar.varstack_pillar

Use Varstack data as a Pillar source

**Configuring Varstack**

Using varstack in Salt is fairly simple. Just put the following into the config file of your master:
ext_pillar:
- varstack: /etc/varstack.yaml

Varstack will then use /etc/varstack.yaml to determine which configuration data to return as pillar information. From there you can take a look at the README of varstack on how this file is evaluated.
salt.pillar.varstack_pillar.ext_pillar(minion_id, pillar, conf)
    Parse varstack data and return the result

31.21.24 salt.pillar.virtkey

Accept a key from a hypervisor if the virt runner has already submitted an authorization request

salt.pillar.virtkey.ext_pillar(hyper_id, pillar, name, key)
    Accept the key for the VM on the hyper, if authorized.

31.22 Renderers

The Salt state system operates by gathering information from common data types such as lists, dictionaries, and strings that would be familiar to any developer.

SLS files are translated from whatever data templating format they are written in back into Python data types to be consumed by Salt.

By default SLS files are rendered as Jinja templates and then parsed as YAML documents. But since the only thing the state system cares about is raw data, the SLS files can be any structured format that can be dreamed up.

Currently there is support for Jinja + YAML, Mako + YAML, Wempy + YAML, Jinja + json, Mako + json and Wempy + json.

Renderers can be written to support any template type. This means that the Salt states could be managed by XML files, HTML files, Puppet files, or any format that can be translated into the Pythonic data structure used by the state system.

31.22.1 Multiple Renderers

A default renderer is selected in the master configuration file by providing a value to the renderer key.

When evaluating an SLS, more than one renderer can be used.

When rendering SLS files, Salt checks for the presence of a Salt-specific shebang line.

The shebang line directly calls the name of the renderer as it is specified within Salt. One of the most common reasons to use multiple renderers is to use the Python or py renderer.

Below, the first line is a shebang that references the py renderer.

```python
#!py
def run():
    '''
    Install the python-mako package
    '''
    return {'include': ['python'],
            'python-mako': {'pkg': ['installed']}}
```
31.22.2 Composing Renderers

A renderer can be composed from other renderers by connecting them in a series of pipes (|).

In fact, the default Jinja + YAML renderer is implemented by connecting a YAML renderer to a Jinja renderer. Such renderer configuration is specified as: jinja | yaml.

Other renderer combinations are possible:

- **yaml** i.e. just YAML, no templating.
- **mako | yaml** pass the input to the mako renderer, whose output is then fed into the yaml renderer.
- **jinja | mako | yaml** This one allows you to use both jinja and mako templating syntax in the input and then parse the final rendered output as YAML.

The following is a contrived example SLS file using the jinja | mako | yaml renderer:

```yaml
#!jinja|mako|yaml
An Example:
- name: |
  - echo "Using Salt ${grains['saltversion']}" \ 
    "from path {{grains['saltpath']}}." 
- cwd: /

<%doc> ${...} is Mako's notation, and so is this comment. </%doc>
{%# Similarly, {{...}} is Jinja's notation, and so is this comment. %}
```

For backward compatibility, jinja | yaml can also be written as yaml_jinja, and similarly, the yaml_mako, yaml_wempy, json_jinja, json_mako, and json_wempy renderers are all supported.

Keep in mind that not all renderers can be used alone or with any other renderers. For example, the template renderers shouldn’t be used alone as their outputs are just strings, which still need to be parsed by another renderer to turn them into highstate data structures.

For example, it doesn’t make sense to specify yaml | jinja because the output of the YAML renderer is a highstate data structure (a dict in Python), which cannot be used as the input to a template renderer. Therefore, when combining renderers, you should know what each renderer accepts as input and what it returns as output.

31.22.3 Writing Renderers

A custom renderer must be a Python module placed in the renderers directory and the module implement the render function.

The render function will be passed the path of the SLS file as an argument.

The purpose of the render function is to parse the passed file and to return the Python data structure derived from the file.

Custom renderers must be placed in a `_renderers` directory within the file_roots specified by the master config file.

Custom renderers are distributed when any of the following are run: state.highstate

```
saltutil.sync_renderers
saltutil.sync_all
```

Any custom renderers which have been synced to a minion, that are named the same as one of Salt’s default set of renderers, will take the place of the default renderer with the same name.
31.22.4 Examples

The best place to find examples of renderers is in the Salt source code. Documentation for renderers included with Salt can be found here:

https://github.com/saltstack/salt/blob/develop/salt/renderers

Here is a simple YAML renderer example:

```python
import yaml
def render(yaml_data, env='', sls='', **kws):
    if not isinstance(yaml_data, basestring):
        yaml_data = yaml_data.read()
    data = yaml.load(yaml_data)
    return data if data else {}
```

31.22.5 Full List of Renderers

```
salt.renderers.cheetah

Cheetah Renderer for Salt

salt.renderers.cheetah.render(cheetah_data, saltenv='base', sls='', method='xml', **kws)

    Render a Cheetah template.

    **Return type** A Python data structure

salt.renderers.genshi

Genshi Renderer for Salt

salt.renderers.genshi.render(genshi_data, saltenv='base', sls='', method='xml', **kws)

    Render a Genshi template. A method should be passed in as part of the kwargs. If no method is passed in, xml is assumed. Valid methods are:
```
Note that the text method will call NewTextTemplate. If oldtext is desired, it must be called explicitly

**Return type**  A Python data structure

**salt.renderers.gpg**

Renderer that will decrypt GPG ciphers

Any key in the SLS file can be a GPG cipher, and this renderer will decrypt it before passing it off to Salt. This allows you to safely store secrets in source control, in such a way that only your Salt master can decrypt them and distribute them only to the minions that need them.

The typical use-case would be to use ciphers in your pillar data, and keep a secret key on your master. You can put the public key in source control so that developers can add new secrets quickly and easily.

This renderer requires the python-gnupg package. Be careful to install the python-gnupg package, not the gnupg package, or you will get errors.

To set things up, you will first need to generate a keypair. On your master, run:

```
# gpg --gen-key --homedir /etc/salt/gpgkeys
```

Do not supply a password for your keypair, and use a name that makes sense for your application. Be sure to back up your gpg directory someplace safe!

**Note:** Unfortunately, there are some scenarios - for example, on virtual machines which don’t have real hardware - where insufficient entropy causes key generation to be extremely slow. If you come across this problem, you should investigate means of increasing the system entropy. On virtualised Linux systems, this can often be achieved by installing the rng-tools package.

To retrieve the public key:

```
# gpg --armor --homedir /etc/salt/gpgkeys --armor --export <KEY-NAME> > exported_pubkey.gpg
```

Now, to encrypt secrets, copy the public key to your local machine and run:

```
$ gpg --import exported_pubkey.gpg
```

To generate a cipher from a secret:

```
$ echo -n "supersecret" | gpg --homedir ~/.gnupg --armor --encrypt -r <KEY-name>
```

There are two ways to configure salt for the usage of this renderer:

1. **Set up the renderer on your master by adding something like this line to your config:**

   ```
   renderer: jinja | yaml | gpg
   ```

   This will apply the renderers to all pillars and states while requiring python-gnupg to be installed on all minions since the decryption will happen on the minions.

2. **To apply the renderer on a file-by-file basis add the following line to the top of any pillar with gpg data in it:**

   ```
   #!yaml|gpg
   ```

Now with your renderers configured, you can include your ciphers in your pillar data like so:
salt.renderers.gpg.decrypt_ciphertext(cypher, gpg, safe=False)

Given a block of ciphertext as a string, and a gpg object, try to decrypt the cipher and return the decrypted string. If the cipher cannot be decrypted, log the error, and return the ciphertext back out.

Parameters safe -- Raise an exception on failure instead of returning the ciphertext

salt.renderers.gpg.decrypt_object(obj, gpg)

Recurrsively try to decrypt any object. If the object is a string, and it contains a valid GPG header, decrypt it, otherwise keep going until a string is found.

salt.renderers.gpg.render(gpg_data, saltenv='base', sls='`, argline='`, **kwargs)

Create a gpg object given a gpg_keydir, and then use it to try to decrypt the data to be rendered.

salt.renderers.hjson

Hjson Renderer for Salt http://laktak.github.io/hjson/

salt.renderers.hjson.render(hjson_data, saltenv='base', sls='`, `kws)

Accepts HJSON as a string or as a file object and runs it through the HJSON parser.

Return type A Python data structure

salt.renderers.jinja

Jinja loading util to enable a more powerful backend for jinja templates

Jinja in States The most basic usage of Jinja in state files is using control structures to wrap conditional or redundant state elements:

```jinja
{% if grains['os'] != 'FreeBSD' %}
tcs:
    pkg:
        - installed
{% endif %}

motd:
    file.managed:
        {% if grains['os'] == 'FreeBSD' %}
            - name: /etc/motd
        {% elif grains['os'] == 'Debian' %}
            - name: /etc/motd.tail
        {% endif %}
```
In this example, the first if block will only be evaluated on minions that aren't running FreeBSD, and the second block changes the file name based on the os grain.

Writing if-else blocks can lead to very redundant state files however. In this case, using pillars, or using a previously defined variable might be easier:

```py
{% set motd = ['/etc/motd'] %}
{% if grains['os'] == 'Debian' %}
    {% set motd = ['/etc/motd.tail', '/var/run/motd'] %}
{% endif %}

{% for motdfile in motd %}
    {{ motdfile }}:
        file.managed:
            - source: salt://motd
{% endfor %}
```

Using a variable set by the template, the for loop will iterate over the list of MOTD files to update, adding a state block for each file.

**Include and Import** Includes and imports can be used to share common, reusable state configuration between state files and between files.

```py
{% from 'lib.sls' import test %}
```

This would import the test template variable or macro, not the test state element, from the file lib.sls. In the case that the included file performs checks again grains, or something else that requires context, passing the context into the included file is required:

```py
{% from 'lib.sls' import test with context %}
```

**Macros** Macros are helpful for eliminating redundant code, however stripping whitespace from the template block, as well as contained blocks, may be necessary to emulate a variable return from the macro.

```py
# init.sls
{% from 'lib.sls' import pythonpkg with context %}

python-virtualenv:
    pkg.installed:
        - name: {{ pythonpkg('virtualenv') }}

python-fabric:
    pkg.installed:
        - name: {{ pythonpkg('fabric') }}

# lib.sls
{% macro pythonpkg(pkg) -%}
    {%- if grains['os'] == 'FreeBSD' -%}
        py27-{{ pkg }}
    {%- elif grains['os'] == 'Debian' -%}
        python-{{ pkg }}
    {%- endif -%}
{%- endmacro %}
```

31.22. Renderers
This would define a macro that would return a string of the full package name, depending on the packaging system’s naming convention. The whitespace of the macro was eliminated, so that the macro would return a string without line breaks, using whitespace control.

Template Inheritance  Template inheritance works fine from state files and files. The search path starts at the root of the state tree or pillar.

Filters  Saltstack extends builtin filters with these custom filters:

strftime  Converts any time related object into a time based string. It requires a valid strftime directives. An exhaustive list can be found in the official Python documentation.

```%
% set curtime = None | strftime() %

Fuzzy dates require the timelib Python module is installed.

```{% %
{{ "2002/12/25|strftime("%y") }}
{{ "1040814000|strftime("%Y-%m-%d") }}
{{ datetime|strftime("%u") }}
{{ "tomorrow|strftime" }}

sequence  Ensure that parsed data is a sequence.

yaml_encode  Serializes a single object into a YAML scalar with any necessary handling for escaping special characters. This will work for any scalar YAML data type: ints, floats, timestamps, booleans, strings, unicode. It will not work for multi-objects such as sequences or maps.

```{%-% %
{%- set bar = 7 %}
{%- set baz = none %}
{%- set zip = true %}
{%- set zap = 'The word of the day is "salty"' %}

{%- load_yaml as foo %}
bar: {{ bar|yaml_encode }}
baz: {{ baz|yaml_encode }}
baz: {{ zip|yaml_encode }}
baz: {{ zap|yaml_encode }}
{%- endload %}

In the above case ''{{ bar }}'' and ''{{ foo.bar }}'' should be identical and ''{{ baz }}'' and ''{{ foo.baz }}'' should be identical.

yaml_dquote  Serializes a string into a properly-escaped YAML double-quoted string. This is useful when the contents of a string are unknown and may contain quotes or unicode that needs to be preserved. The resulting string will be emitted with opening and closing double quotes.

```{%-% %
{%- set bar = "The quick brown fox . . ." %}
{%- set baz = 'The word of the day is "salty".' %}

{%- load_yaml as foo %}
bar: {{ bar|yaml_dquote }}
baz: {{ baz|yaml_dquote }}
{%- endload %}

In the above case ''{{ bar }}'' and ''{{ foo.bar }}'' should be identical and ''{{ baz }}'' and ''{{ foo.baz }}'' should be identical. If variable contents are not guaranteed to be a string
then it is better to use `yaml_encode` which handles all YAML scalar types.

**yaml_squote** Similar to the `yaml_dquote` filter but with single quotes. Note that YAML only allows special escapes inside double quotes so `yaml_squote` is not nearly as useful (viz. you likely want to use `yaml_encode` or `yaml_dquote`).

### Jinja in Files

Jinja can be used in the same way in managed files:

```bash
# redis.sls
/etc/redis/redis.conf:
  file.managed:
    - source: salt://redis.conf
    - template: jinja
    - context:
      bind: 127.0.0.1

# lib.sls
{% set port = 6379 %}

# redis.conf
{% from 'lib.sls' import port with context %}
port {{ port }}
bind {{ bind }}
```

As an example, configuration was pulled from the file context and from an external template file.

**Note:** Macros and variables can be shared across templates. They should not be starting with one or more underscores, and should be managed by one of the following tags: `macro`, `set`, `load_yaml`, `load_json`, `import_yaml` and `import_json`.

### Calling Salt Functions

The Jinja renderer provides a shorthand lookup syntax for the `salt` dictionary of execution function.

New in version 2014.7.0.

```bash
# The following two function calls are equivalent.
{{ salt['cmd.run']('whoami') }}
{{ salt.cmd.run('whoami') }}
```

### Debugging

The `show_full_context` function can be used to output all variables present in the current Jinja context.

New in version 2014.7.0.

```python
Context is: {{ show_full_context() }}
```

```python
salt.renderers.jinja.render(template_file, saltenv='base', sls='', argline='', context=None, tmplpath=None, **kws)
```

Render the template_file, passing the functions and grains into the Jinja rendering system.

**Return type** string

class salt.utils.jinja.SerializerExtension(environment)

Yaml and Json manipulation.
Format filters

Allows to jsonify or yamlify any data structure. For example, this dataset:

```python
data = {
    'foo': True,
    'bar': 42,
    'baz': [1, 2, 3],
    'qux': 2.0
}
```

yaml = {{ data|yaml }}
jjson = {{ data|json }}
python = {{ data|python }}

will be rendered as:

```yaml
yaml = {bar: 42, baz: [1, 2, 3], foo: true, qux: 2.0}
jjson = {'baz': [1, 2, 3], 'foo': true, 'bar': 42, 'qux': 2.0}
python = {'bar': 42, 'baz': [1, 2, 3], 'foo': True, 'qux': 2.0}
```

The yaml filter takes an optional flow_style parameter to control the default-flow-style parameter of the YAML dumper.

```python
{{ data|yaml(False) }}
```

will be rendered as:

```yaml
bar: 42
baz:
  - 1
  - 2
  - 3
foo: true
qux: 2.0
```

Load filters

Strings and variables can be deserialized with load_yaml and load_json tags and filters. It allows one to manipulate data directly in templates, easily:

```python
{% set yaml_src = "[foo: it works]|load_yaml %}  
{% set json_src = "[bar: 'for real']|load_json %}  
Dude, {{ yaml_src.foo }} {{ json_src.bar }}!
```

will be rendered as:

Dude, it works for real!

Load tags

Salt implements import_yaml and import_json tags. They work like the import tag, except that the document is also deserialized.

Syntaxes are [% load_yaml as [VARIABLE] %][YOUR DATA][% endload %] and [% load_json as [VARIABLE] %][YOUR DATA][% endload %]

For example:

```python
{% load_yaml as yaml_src %}  
foo: it works
```
Dude, {{ yaml_src.foo }} {{ json_src.bar }}!

will be rendered as:

Dude, it works for real!

Import tags

External files can be imported and made available as a Jinja variable.

Catalog

`import_*` and `load_` tags will automatically expose their target variable to import. This feature makes catalog of data to handle.

for example:

```
# doc1.sls
{% load_yaml as var1 %}
  foo: it works
{% endload %}
{% load_yaml as var2 %}
  bar: for real
{% endload %}
```

```
# doc2.sls
{% from "doc1.sls" import var1, var2 as local2 %}
  {{ var1.foo }} {{ local2.bar }}
```

salt.renderers.json

JSON Renderer for Salt

`salt.renderers.json.render(json_data, saltenv='base', sls='`, **kws)`

Accepts JSON as a string or as a file object and runs it through the JSON parser.

Return type A Python data structure

salt.renderers.mako

Mako Renderer for Salt

`salt.renderers.mako.render(template_file, saltenv='base', sls='`, context=None, tmplpath=None, **kws)`

Render the template_file, passing the functions and grains into the Mako rendering system.

Return type string
salt.renderers.msgpack

salt.renderers.msgpack.render(msgpack_data, saltenv='base', sls='*', **kws)

Accepts a message pack string or a file object, renders said data back to a Python dict.

Return type  A Python data structure

salt.renderers.py

Pure python state renderer

The SLS file should contain a function called run which returns high state data.

In this module, a few objects are defined for you, giving access to Salt’s execution functions, grains, pillar, etc. They are:

• __salt__ - Execution functions (i.e. __salt__['test.echo']('foo'))
• __grains__ - Grains (i.e. __grains__['os'])
• __pillar__ - Pillar data (i.e. __pillar__['foo'])
• __opts__ - Minion configuration options
• __env__ - The effective salt fileserver environment (i.e. base). Also referred to as a ‘saltenv’. __env__ should not be modified in a pure python SLS file. To use a different environment, the environment should be set when executing the state. This can be done in a couple different ways:
  - Using the saltenv argument on the salt CLI (i.e. salt '*' state.sls foo.bar.baz saltenv=env_name).
  - By adding a saltenv argument to an individual state within the SLS file. In other words, adding a line like this to the state’s data structure: {'saltenv': 'env_name'}
• __sls__ - The SLS path of the file. For example, if the root of the base environment is /srv/salt, and the SLS file is /srv/salt/foo/bar/baz.sls, then __sls__ in that file will be foo.bar.baz.

```python
# !/py

def run():
    config = {}

    if __grains__['os'] == 'Ubuntu':
        user = 'ubuntu'
        group = 'ubuntu'
        home = '/home/{}'.format(user)
    else:
        user = 'root'
        group = 'root'
        home = '/root/'

    config['s3cmd'] = {
        'pkg': [
            'installed',
            {'name': 's3cmd'},
        ],
    }

    config[home + '/.s3cfg'] = {
        'file.managed': [
```
salt.renderers.pydsl

A Python-based DSL

maintainer  Jack Kuan <kjkuan@gmail.com>
maturity   new
platform   all

The pydsl renderer allows one to author salt formulas (.sls files) in pure Python using a DSL that's easy to write and easy to read. Here's an example:

```python
# !pydsl

apache = state('apache')
apache.pkg.installed()
apache.service.running()
state('/var/www/index.html') |
  .file('managed',
      source='salt://webserver/index.html') |
  .require(pkg='apache')
```

Notice that any Python code is allow in the file as it's really a Python module, so you have the full power of Python at your disposal. In this module, a few objects are defined for you, including the usual (with __ added) __salt__ dictionary, __grains__, __pillar__, __opts__, __env__, and __sls__, plus a few more:

```
__file__
    local file system path to the sls module.

__pydsl__
    Salt PyDSL object, useful for configuring DSL behavior per sls rendering.
include
    Salt PyDSL function for creating Include declaration's.
extend
```
Salt PyDSL function for creating `Extend declaration`'s.

state

Salt PyDSL function for creating `ID declaration`'s.

A state `ID declaration` is created with a `state(id)` function call. Subsequent `state(id)` call with the same id returns the same object. This singleton access pattern applies to all declaration objects created with the DSL.

```
state('example')
assert state('example') is state('example')
assert state('example').cmd is state('example').cmd
assert state('example').cmd.running is state('example').cmd.running
```

The `id` argument is optional. If omitted, an UUID will be generated and used as the `id`.

```
state(id) returns an object under which you can create a State declaration object by accessing an attribute named after any state module available in Salt.
```

```
state('example').cmd
state('example').file
state('example').pkg
...
```

Then, a Function declaration object can be created from a State declaration object by one of the following two ways:

1. by calling a method named after the state function on the State declaration object.

```
state('example').file.managed(...)
```

2. by directly calling the attribute named for the State declaration, and supplying the state function name as the first argument.

```
state('example').file('managed', ...)
```

With either way of creating a Function declaration object, any Function arg declaration's can be passed as keyword arguments to the call. Subsequent calls of a Function declaration will update the arg declarations.

```
state('example').file('managed', source='salt://webserver/index.html')
state('example').file.managed(source='salt://webserver/index.html')
```

As a shortcut, the special `name` argument can also be passed as the first or second positional argument depending on the first or second way of calling the State declaration object. In the following two examples `ls -la` is the `name` argument.

```
state('example').cmd.run('ls -la', cwd='/')
state('example').cmd('run', 'ls -la', cwd='/')
```

Finally, a Requisite declaration object with its Requisite reference's can be created by invoking one of the requisite methods (see State Requisites) on either a Function declaration object or a State declaration object. The return value of a requisite call is also a Function declaration object, so you can chain several requisite calls together.

Arguments to a requisite call can be a list of State declaration objects and/or a set of keyword arguments whose names are state modules and values are IDs of ID declaration's or names of Name declaration's.

```
apache2 = state('apache2')
apache2.pkg.installed()
state('libapache2-mod-wsgi').pkg.installed()

# you can call requisites on function declaration
apache2.service.running() \
```

...
.require(apache2.pkg, pkg='libapache2-mod-wsgi') \
.watch(file='/etc/apache2/httpd.conf')

# or you can call requisites on state declaration.
# this actually creates an anonymous function declaration object
# to add the requisites.
apache2.service.require(state('libapache2-mod-wsgi').pkg, pkg='apache2') \n.watch(file='/etc/apache2/httpd.conf')

# we still need to set the name of the function declaration.
apache2.service.running()

Include declaration objects can be created with the include function, while Extend declaration objects can be created with the extend function, whose arguments are just Function declaration objects.

include('edit.vim', 'http.server')
extend(state('apache2')).service.watch(file='/etc/httpd/httpd.conf')

The include function, by default, causes the included sls file to be rendered as soon as the include function is called. It returns a list of rendered module objects; sls files not rendered with the pydsl renderer return None’s. This behavior creates no Include declaration’s in the resulting high state data structure.

import types

# including multiple sls returns a list.
_, mod = include('a-non-pydsl-sls', 'a-pydsl-sls')

assert _ is None
assert isinstance(slsmods[1], types.ModuleType)

# including a single sls returns a single object
mod = include('a-pydsl-sls')

# myfunc is a function that calls state(...) to create more states.
mod.myfunc(1, 2, "three")

Notice how you can define a reusable function in your pydsl sls module and then call it via the module returned by include.

It's still possible to do late includes by passing the delayed=True keyword argument to include.

include('edit.vim', 'http.server', delayed=True)

Above will just create a Include declaration in the rendered result, and such call always returns None.

Special integration with the cmd state Taking advantage of rendering a Python module, PyDSL allows you to declare a state that calls a pre-defined Python function when the state is executed.

greeting = "hello world"
def helper(something, *args, **kws):
    print greeting  # hello world
    print something, args, kws  # test123 ['a', 'b', 'c'] {'x': 1, 'y': 2}

state().cmd.call(helper, "test123", 'a', 'b', 'c', x=1, y=2)
The `cmd.call` state function takes care of calling our helper function with the arguments we specified in the states, and translates the return value of our function into a structure expected by the state system. See `salt.states.cmd.call()` for more information.

**Implicit ordering of states** Salt states are explicitly ordered via `Requisite declaration`'s. However, with `pydsl` it's possible to let the renderer track the order of creation for `Function declaration` objects, and implicitly add `require` requisites for your states to enforce the ordering. This feature is enabled by setting the `ordered` option on `__pydsl__`.

Note: this feature is only available if your minions are using Python >= 2.7.

```python
include('some.sls.file')
A = state('A').cmd.run(cwd='/var/tmp')
extend(A)
__pydsl__.set(ordered=True)
for i in range(10):
    i = str(i)
    state(i).cmd.run('echo '+i, cwd='/')
state('1').cmd.run('echo one')
state('2').cmd.run(name='echo two')
```

Notice that the `ordered` option needs to be set after any `extend` calls. This is to prevent `pydsl` from tracking the creation of a state function that's passed to an `extend` call.

Above example should create states from 0 to 9 that will output 0, one, two, 3, ... 9, in that order.

It's important to know that `pydsl` tracks the `creations of Function declaration` objects, and automatically adds a `require` requisite to a `Function declaration` object that requires the last `Function declaration` object created before it in the sls file.

This means later calls (perhaps to update the function's `Function arg declaration`) to a previously created function declaration will not change the order.

**Render time state execution** When Salt processes a salt formula file, the file is rendered to Salt's high state data representation by a renderer before the states can be executed. In the case of the `pydsl` renderer, the `sls` file is executed as a python module as it is being rendered which makes it easy to execute a state at render time. In `pydsl`, executing one or more states at render time can be done by calling a configured `ID declaration` object.

```bash
#!pydsl
s = state()  # save for later invocation
# configure it
s.cmd.run('echo at render time', cwd='/')
s.file.managed('target.txt', source='salt://source.txt')
```

Once an `ID declaration` is called at render time it is detached from the sls module as if it was never defined.

Note: If `implicit ordering` is enabled (i.e., via `__pydsl__.set(ordered=True)) then the first invocation of a `ID declaration` object must be done before a new `Function declaration` is created.
Integration with the stateconf renderer  The `salt.renderers.stateconf` renderer offers a few interesting features that can be leveraged by the `pydsl` renderer. In particular, when using with the `pydsl` renderer, we are interested in `stateconf`’s sls namespaces feature (via dot-prefixed id declarations), as well as, the automatic `start` and `goal` states generation.

Now you can use `pydsl` with `stateconf` like this:

```python
#pydsl|stateconf -ps
include('xxx', 'yyy')
# ensure that states in xxx run BEFORE states in this file.
extend(state('start').stateconf.require(stateconf='xxx::goal'))
# ensure that states in yyy run AFTER states in this file.
extend(state('goal').stateconf.require_in(stateconf='yyy::start'))
__pydsl__.set(ordered=True)
```

`-s` enables the generation of a stateconf `start` state, and `-p` lets us pipe high state data rendered by `pydsl` to `stateconf`. This example shows that by `require-ing` or `require_in-ing` the included sls' `start` or `goal` states, it’s possible to ensure that the included sls files can be made to execute before or after a state in the including sls file.

Importing custom Python modules  To use a custom Python module inside a PyDSL state, place the module somewhere that it can be loaded by the Salt loader, such as `_modules` in the `/srv/salt` directory.

Then, copy it to any minions as necessary by using `saltutil.sync_modules`.

To import into a PyDSL SLS, one must bypass the Python importer and insert it manually by getting a reference from Python’s `sys.modules` dictionary.

For example:

```python
#pydsl|stateconf -ps
def main():
  my_mod = sys.modules['salt.loaded.ext.module.my_mod']
salt.renderers.pydsl.render(template, saltenv='base', sls='''), tmplpath=None, rendered_sls=None, **kws)
```

`salt.renderers.pyobjects`

Python renderer that includes a Pythonic Object based interface

```python
maintainer  Evan Borgstrom <evan@borgstrom.ca>
```

Let's take a look at how you use `pyobjects` in a state file. Here's a quick example that ensures the `/tmp` directory is in the correct state.

```python
#pyobjects
File.managed("/tmp", user='root', group='root', mode='1777')
```

Nice and Pythonic!
By using the "shebang" syntax to switch to the pyobjects renderer we can now write our state data using an object based interface that should feel at home to python developers. You can import any module and do anything that you’d like (with caution, importing sqlalchemy, django or other large frameworks has not been tested yet). Using the pyobjects renderer is exactly the same as using the built-in Python renderer with the exception that pyobjects provides you with an object based interface for generating state data.

Creating state data  Pyobjects takes care of creating an object for each of the available states on the minion. Each state is represented by an object that is the CamelCase version of its name (i.e. File, Service, User, etc), and these objects expose all of their available state functions (i.e. File.managed, Service.running, etc).

The name of the state is split based upon underscores (_), then each part is capitalized and finally the parts are joined back together.

Some examples:
- postgres_user becomes PostgresUser
- ssh_known_hosts becomes SshKnownHosts

Context Managers and requisites  How about something a little more complex. Here we’re going to get into the core of how to use pyobjects to write states.

```python
# pyobjects

with Pkg.installed("nginx"):  
    Service.running("nginx", enable=True)

with Service("nginx", "watch_in"):  
    File.managed("/etc/nginx/conf.d/mysite.conf",  
                owner='root', group='root', mode='0444',  
                source='salt://nginx/mysite.conf')
```

The objects that are returned from each of the magic method calls are setup to be used a Python context managers (with) and when you use them as such all declarations made within the scope will automatically use the enclosing state as a requisite!

The above could have also been written use direct requisite statements as.

```python
# pyobjects

Pkg.installed("nginx")  
Service.running("nginx", enable=True, require=Pkg("nginx"))
File.managed("/etc/nginx/conf.d/mysite.conf",  
            owner='root', group='root', mode='0444',  
            source='salt://nginx/mysite.conf')
watch_in=Service("nginx")
```

You can use the direct requisite statement for referencing states that are generated outside of the current file.

```python
# pyobjects

# some-other-package is defined in some other state file
Pkg.installed("nginx", require=Pkg("some-other-package"))
```

The last thing that direct requisites provide is the ability to select which of the SaltStack requisites you want to use (require, require_in, watch, watch_in, use & use_in) when using the requisite as a context manager.
with Service("my-service", "watch_in"):
...

The above example would cause all declarations inside the scope of the context manager to automatically have their `watch_in` set to `Service("my-service")`.

Including and Extending To include other states use the `include()` function. It takes one name per state to include.

To extend another state use the `extend()` function on the name when creating a state.

```python
include('http', 'ssh')
Service.running(extend('apache'),
          watch=[File('/etc/httpd/extra/httpd-vhosts.conf')])
```

Importing from other state files Like any Python project that grows you will likely reach a point where you want to create reusability in your state tree and share objects between state files, Map Data (described below) is a perfect example of this.

To facilitate this Python's `import` statement has been augmented to allow for a special case when working with a Salt state tree. If you specify a Salt url (`salt://...`) as the target for importing from then the pyobjects renderer will take care of fetching the file for you, parsing it with all of the pyobjects features available and then place the requested objects in the global scope of the template being rendered.

This works for all types of import statements; `import X`, `from X import Y`, and `from X import Y as Z`.

```python
import salt://myfile.sls
from salt://something/data.sls import Object
from salt://something/data.sls import Object as Other
```

See the Map Data section for a more practical use.

Caveats:

- Imported objects are ALWAYS put into the global scope of your template, regardless of where your import statement is.

Salt object In the spirit of the object interface for creating state data pyobjects also provides a simple object interface to the `_salt_` object.

A function named `salt` exists in scope for your sls files and will dispatch its attributes to the `_salt_` dictionary.

The following lines are functionally equivalent:

```python
ret = salt.cmd.run(bar)
ret = __salt__['cmd.run'](bar)
```
Pillar, grain, mine & config data  Pyobjects provides shortcut functions for calling pillar.get, grains.get, mine.get & config.get on the __salt__ object. This helps maintain the readability of your state files.

Each type of data can be accessed by a function of the same name: pillar(), grains(), mine() and config().

The following pairs of lines are functionally equivalent:

```python
# !pyobjects
value = pillar('foo:bar:baz', 'qux')
value = __salt__['pillar.get']('foo:bar:baz', 'qux')
value = grains('pkg:apache')
value = __salt__['grains.get']('pkg:apache')
value = mine('os:Fedora', 'network.interfaces', 'grain')
value = __salt__['mine.get']('os:Fedora', 'network.interfaces', 'grain')
value = config('foo:bar:baz', 'qux')
value = __salt__['config.get']('foo:bar:baz', 'qux')
```

Map Data  When building complex states or formulas you often need a way of building up a map of data based on grain data. The most common use of this is tracking the package and service name differences between distributions.

To build map data using pyobjects we provide a class named Map that you use to build your own classes with inner classes for each set of values for the different grain matches.

```python
# !pyobjects
class Samba(Map):
    merge = 'samba:lookup'

    class Debian:
        server = 'samba'
        client = 'samba-client'
        service = 'samba'

    class Ubuntu:
        __grain__ = 'os'
        service = 'smbd'

    class RedHat:
        server = 'samba'
        client = 'samba'
        service = 'smb'
```

To use this new data you can import it into your state file and then access your attributes. To access the data in the map you simply access the attribute name on the base class that is extending Map. Assuming the above Map was in the file samba/map.sls, you could do the following.

```python
# !pyobjects
from salt://samba/map.sls import Samba
with Pkg.installed("samba", names=[Samba.server, Samba.client]):
    Service.running("samba", name=Samba.service)
```

TODO
• Interface for working with reactor files

salt.renderers.pyobjects.load_states()
   This loads our states into the salt __context__

salt.renderers.pyobjects.render(template, saltenv='base', sls='`, salt_data=True, **kwargs)

salt.renderers.stateconf

   maintainer  Jack Kuan <kjkuan@gmail.com>
   maturity   new
   platform   all

This module provides a custom renderer that processes a salt file with a specified templating engine (e.g. Jinja) and a chosen data renderer (e.g. YAML), extracts arguments for any stateconf.set state, and provides the extracted arguments (including Salt-specific args, such as require, etc) as template context. The goal is to make writing reusable/configurable/parameterized salt files easier and cleaner.

To use this renderer, either set it as the default renderer via the renderer option in master/minion's config, or use the shebang line in each individual sls file, like so: !stateconf. Note, due to the way this renderer works, it must be specified as the first renderer in a render pipeline. That is, you cannot specify !mako|yaml|stateconf, for example. Instead, you specify them as renderer arguments: !stateconf mako . yaml.

Here's a list of features enabled by this renderer.

• Prefixes any state id (declaration or reference) that starts with a dot (.) to avoid duplicated state ids when the salt file is included by other salt files.

   For example, in the salt://some/file.sls, a state id such as .sls_params will be turned into some.file::sls_params. Example:

   ```
   #!stateconf yaml . jinja
   .vim:
      pkg.installed
   ```

   Above will be translated into:

   ```
   some.file::vim:
      pkg.installed:
         - name: vim
   ```

   Notice how that if a state under a dot-prefixed state id has no name argument then one will be added automatically by using the state id with the leading dot stripped off.

The leading dot trick can be used with extending state ids as well, so you can include relatively and extend relatively. For example, when extending a state in salt://some/other_file.sls, e.g:

   ```
   #!stateconf yaml . jinja
   include:
      - .file

   extend:
      .file::sls_params:
         stateconf.set:
            - name1: something
   ```
Above will be pre-processed into:

```python
include:
  - some.file

extend:
  some.file::sls_params:
    stateconf.set:
      - name1: something
```

- Adds a `sls_dir` context variable that expands to the directory containing the rendering salt file. So, you can write `salt://{{sls_dir}}/...` to reference templates files used by your salt file.

- Recognizes the special state function, `stateconf.set`, that configures a default list of named arguments usable within the template context of the salt file. Example:

```python
#!stateconf yaml . jinja

.sls_params:
  stateconf.set:
    - name1: value1
    - name2: value2
    - name3:
      - value1
      - value2
      - value3
    - require_in:
      - cmd: output

# --- end of state config ---

.output:
  cmd.run:
    - name: |
      echo 'name1={{sls_params.name1}}
      name2={{sls_params.name2}}
      name3[1]={{sls_params.name3[1]}}'
```

This even works with `include + extend` so that you can override the default configured arguments by including the salt file and then extend the `stateconf.set` states that come from the included salt file. (*IMPORTANT: Both the included and the extending sls files must use the stateconf renderer for this `extend` to work!*)

Notice that the end of configuration marker (# --- end of state config --) is needed to separate the use of `stateconf.set` form the rest of your salt file. The regex that matches such marker can be configured via the `stateconf_end_marker` option in your master or minion config file.

Sometimes, it is desirable to set a default argument value that’s based on earlier arguments in the same `stateconf.set`. For example, it may be tempting to do something like this:

```python
#!stateconf yaml . jinja

.apache:
  stateconf.set:
    - host: localhost
    - port: 1234
    - url: 'http://{{host}}:{{port}}/'

# --- end of state config ---
```
However, this won't work. It can however be worked around like so:

```python
# !stateconf yaml . jinja

.apache:
    stateconf.set:
        - host: localhost
        - port: 1234
        {# - url: 'http://{{host}}:{{port}}/' #}

# --- end of state config ---
# {{ apache.setdefault('url', "http://%(host)s:%(port)s/" % apache) }}

.test:
    cmd.run:
        - name: echo '{{apache.url}}'
        - cwd: /
```

- Adds support for relative include and exclude of .sls files. Example:

```python
# !stateconf yaml . jinja

include:
    - .apache
    - .db.mysql
    - ..app.django

exclude:
    - sls: .users
```

If the above is written in a salt file at `salt://some/where.sls` then it will include `salt://some/apache.sls`, `salt://some/db/mysql.sls` and `salt://app/django.sls`, and exclude `salt://some/users.sls`. Actually, it does that by rewriting the above include and exclude into:

```python
include:
    - some.apache
    - some.db.mysql
    - app.django

exclude:
    - sls: some.users
```

- Optionally (enabled by default, `disable` via the `-G` renderer option, e.g. in the shebang line: `#!stateconf -G`), generates a `stateconf.set` goal state (state id named as `.goal` by default, configurable via the master/minion config option, `stateconf_goal_state`) that requires all other states in the salt file. Note, the `.goal` state id is subject to dot-prefix rename rule mentioned earlier.

Such goal state is intended to be required by some state in an including salt file. For example, in your webapp salt file, if you include a sls file that is supposed to setup Tomcat, you might want to make sure that all states in the Tomcat sls file will be executed before some state in the webapp sls file.

- Optionally (enable via the `-o` renderer option, e.g. in the shebang line: `#!stateconf -o`), orders the states in a sls file by adding a `require` requisite to each state such that every state requires the state defined just before it. The order of the states here is the order they are defined in the sls file. (Note: this feature is only available if
your minions are using Python >= 2.7. For Python2.6, it should also work if you install the `ordereddict` module from PyPI

By enabling this feature, you are basically agreeing to author your sls files in a way that gives up the explicit (or implicit?) ordering imposed by the use of `require`, `watch`, `require_in` or `watch_in` requisites, and instead, you rely on the order of states you define in the sls files. This may or may not be a better way for you. However, if there are many states defined in a sls file, then it tends to be easier to see the order they will be executed with this feature.

You are still allowed to use all the requisites, with a few restrictions. You cannot `require` or `watch` a state defined after the current state. Similarly, in a state, you cannot `require_in` or `watch_in` a state defined before it. Breaking any of the two restrictions above will result in a state loop. The renderer will check for such incorrect uses if this feature is enabled.

Additionally, `names` declarations cannot be used with this feature because the way they are compiled into low states make it impossible to guarantee the order in which they will be executed. This is also checked by the renderer. As a workaround for not being able to use `names`, you can achieve the same effect, by generate your states with the template engine available within your sls file.

Finally, with the use of this feature, it becomes possible to easily make an included sls file execute all its states after some state (say, with id `X`) in the including sls file. All you have to do is to make state, `X`, `require_in` the first state defined in the included sls file.

When writing sls files with this renderer, one should avoid using what can be defined in a `name` argument of a state as the state's id. That is, avoid writing states like this:

```
/path/to/some/file:
  file.managed:
    - source: salt://some/file

cp /path/to/some/file file2:
  cmd.run:
    - cwd: /
    - require:
      - file: /path/to/some/file
```

Instead, define the state id and the `name` argument separately for each state. Also, the ID should be something meaningful and easy to reference within a requisite (which is a good habit anyway, and such extra indirection would also makes the sls file easier to modify later). Thus, the above states should be written like this:

```
add-some-file:
  file.managed:
    - name: /path/to/some/file
    - source: salt://some/file

copy-files:
  cmd.run:
    - name: cp /path/to/some/file file2
    - cwd: /
    - require:
      - file: add-some-file
```

Moreover, when referencing a state from a requisite, you should reference the state's id plus the state name rather than the state name plus its `name` argument. (Yes, in the above example, you can actually `require` the file: `/path/to/some/file`, instead of the file: `add-some-file`). The reason is that this renderer will re-write or rename state id's and their references for state id's prefixed with .. So, if you reference `name` then there's no way to reliably rewrite such reference.
salt.renderers.wempy

salt.renderers.wempy.render(template_file, saltenv='base', sls='`, argline='`, context=None, **kws)

    Render the data passing the functions and grains into the rendering system

    Return type  string

salt.renderers.yaml

Understanding YAML  The default renderer for SLS files is the YAML renderer. YAML is a markup language with many powerful features. However, Salt uses a small subset of YAML that maps over very commonly used data structures, like lists and dictionaries. It is the job of the YAML renderer to take the YAML data structure and compile it into a Python data structure for use by Salt.

Though YAML syntax may seem daunting and terse at first, there are only three very simple rules to remember when writing YAML for SLS files.

**Rule One: Indentation**  YAML uses a fixed indentation scheme to represent relationships between data layers. Salt requires that the indentation for each level consists of exactly two spaces. Do not use tabs.

**Rule Two: Colons**  Python dictionaries are, of course, simply key-value pairs. Users from other languages may recognize this data type as hashes or associative arrays.

Dictionary keys are represented in YAML as strings terminated by a trailing colon. Values are represented by either a string following the colon, separated by a space:

my_key: my_value

In Python, the above maps to:

`{my_key: 'my_value'}`

Dictionaries can be nested:

first_level_dict_key:
    second_level_dict_key: value_in_second_level_dict

And in Python:

`{first_level_dict_key: {second_level_dict_key: 'value_in_second_level_dict' }}`

**Rule Three: Dashes**  To represent lists of items, a single dash followed by a space is used. Multiple items are a part of the same list as a function of their having the same level of indentation.

- list_value_one
- list_value_two
- list_value_three

Lists can be the value of a key-value pair. This is quite common in Salt:

my_dictionary:
    - list_value_one
    - list_value_two
    - list_value_three
YAML Renderer for Salt

```python
salt.renderers.yaml.get_yaml_loader(argline)
```

Return the ordered dict yaml loader

```python
salt.renderers.yaml.render(yaml_data, saltenv='base', sls='`, argline='`, **kws)
```

Accepts YAML as a string or as a file object and runs it through the YAML parser.

**Return type** A Python data structure

YAMLEX Renderer is a replacement of the YAML renderer. It’s 100% YAML with a pinch of Salt magic:

- All mappings are automatically OrderedDict
- All strings are automatically str obj
- data aggregation with !aggregation yaml tag, based on the `salt.utils.aggregation` module.
- data aggregation over documents for pillar

Instructed aggregation within the !aggregation and the !reset tags:

```yaml
#!yamlex
foo: !aggregate first
foo: !aggregate second
bar: !aggregate {first: foo}
bar: !aggregate {second: bar}
baz: !aggregate 42
qux: !aggregate default
!reset qux: !aggregate my custom data
```

is roughly equivalent to

```python
foo: [first, second]
bar: {first: foo, second: bar}
baz: [42]
qux: [my custom data]
```

By default the return values of the commands sent to the Salt minions are returned to the Salt master, however anything at all can be done with the results data.

By using a Salt returner, results data can be redirected to external data stores for analysis and archival.

Returners pull their configuration values from the Salt minions. Returners are only configured once, which is generally at load time.

The returner interface allows the return data to be sent to any system that can receive data. This means that return data can be sent to a Redis server, a MongoDB server, a MySQL server, or any system.
See also:

*Full list of builtin returners*

### 31.23.1 Using Returners

All Salt commands will return the command data back to the master. Specifying returners will ensure that the data is also sent to the specified returner interfaces.

Specifying what returners to use is done when the command is invoked:

```
salt '*' test.ping --return redis_return
```

This command will ensure that the redis_return returner is used.

It is also possible to specify multiple returners:

```
salt '*' test.ping --return mongo_return,redis_return,cassandra_return
```

In this scenario all three returners will be called and the data from the test.ping command will be sent out to the three named returners.

### 31.23.2 Writing a Returner

A returner is a Python module containing at minimum a `returner` function. Other optional functions can be included to add support for `master_job_cache`, `external_job_cache`, and `Event Returners`. Salt’s `master_job_cache` allows returners to be used as a pluggable replacement for the Default Job Cache. In order to do so, a returner must implement the following functions:

```python
import redis
import json

def returner(ret):
    ":"""
    Return information to a redis server
    ":"""
    # Get a redis connection
    serv = redis.Redis(
        host='redis-serv.example.com',
        port=6379,
        db=0
    )
    serv.sadd("%(id)s:jobs" % ret, ret['jid'])
    serv.set("%(jid)s:%(id)s" % ret, json.dumps(ret['return']))
    serv.sadd('jobs', ret['jid'])
    serv.sadd(ret['jid'], ret['id'])
```

The above example of a returner set to send the data to a Redis server serializes the data as JSON and sets it in redis.

**Master Job Cache Support**

*master_job_cache*, *external_job_cache*, and *Event Returners*. Salt’s `master_job_cache` allows returners to be used as a pluggable replacement for the Default Job Cache. In order to do so, a returner must implement the following functions:
Note: The code samples contained in this section were taken from the cassandra_cql returner.

**prep_jid** Ensures that job ids (jid) don’t collide, unless passed_jid is provided.

nochache is an optional boolean that indicates if return data should be cached. passed_jid is a caller provided jid which should be returned unconditionally.

```python
def prep_jid(nocache, passed_jid=None):  # pylint: disable=unused-argument
    Do any work necessary to prepare a JID, including sending a custom id
    
    return passed_jid if passed_jid is not None else salt.utils.jid.gen_jid()
```

**save_load** Save job information. The jid is generated by prep_jid and should be considered a unique identifier for the job. The jid, for example, could be used as the primary/unique key in a database. The load is what is returned to a Salt master by a minion. The following code example stores the load as a JSON string in the salt.jids table.

```python
def save_load(jid, load):
    
    Save the load to the specified jid id
    
    query = '''INSERT INTO salt.jids (jid, load)
      ) VALUES (
        '{0}', '{1}'
      );'''.format(jid, json.dumps(load))

    # cassandra_cql.cql_query may raise a CommandExecutionError
    try:
      __salt__['cassandra_cql.cql_query'](query)
    except CommandExecutionError:
      log.critical('Could not save load in jids table.
    raise
    except Exception as e:
      log.critical('Unexpected error while inserting into jids: {0}''.format(str(e)))
    raise
```

**get_load** must accept a job id (jid) and return the job load stored by save_load, or an empty dictionary when not found.

```python
def get_load(jid):
    
    Return the load data that marks a specified jid
    
    query = '''SELECT load FROM salt.jids WHERE jid = '{0}';'''.format(jid)
    
    ret = {}

    # cassandra_cql.cql_query may raise a CommandExecutionError
    try:
      data = __salt__['cassandra_cql.cql_query'](query)
      if data:
        load = data[0].get('load')
        if load:
          ret = json.loads(load)
    except CommandExecutionError:
      ```
Salt Documentation, Release 2015.8.0

$\log$.critical('Could not get load from jids table.')
$\raise$
$\except$ Exception as e:
$log$.critical('Could not get load from jids: {0}'.format(str(e))
$\raise$

return ret

### External Job Cache Support

Salt's external_job_cache extends the master_job_cache. External Job Cache support requires the following functions in addition to what is required for Master Job Cache support:

**get_jid** Return a dictionary containing the information (load) returned by each minion when the specified job id was executed.

Sample:

```python
{
    "local": {
        "master_minion": {
            "fun_args": [],
            "jid": "20150330121011408195",
            "return": true,
            "retcode": 0,
            "success": true,
            "cmd": "_return",
            "stamp": "2015-03-30T12:10:12.708663",
            "fun": "test.ping",
            "id": "master_minion"
        }
    }
}
```

**get_fun** Return a dictionary of minions that called a given Salt function as their last function call.

Sample:

```python
{
    "local": {
        "minion1": "test.ping",
        "minion3": "test.ping",
        "minion2": "test.ping"
    }
}
```

**get_jids** Return a list of all job ids.

Sample:

```python
{
    "local": [
        "20150330121011408195",
        "20150330195922139916"
    ]
}
```

**get_minions** Returns a list of minions
Sample:

```json
{
    "local": [
        "minion3",
        "minion2",
        "minion1",
        "master_minion"
    ]
}
```

Please refer to one or more of the existing returners (i.e. mysql, cassandra_cql) if you need further clarification.

### Event Support

An `event_return` function must be added to the returner module to allow events to be logged from a master via the returner. A list of events are passed to the function by the master.

The following example was taken from the MySQL returner. In this example, each event is inserted into the `salt_events` table keyed on the event tag. The tag contains the jid and therefore is guaranteed to be unique.

```python
def event_return(events):
    
    Return event to mysql server

    Requires that configuration be enabled via 'event_return'
    option in master config.

    with _get_serv(events, commit=True) as cur:
        for event in events:
            tag = event.get('tag', '')
            data = event.get('data', '')
            sql = '''INSERT INTO `salt_events` (`tag`, `data`, `master_id` )
                VALUES (%s, %s, %s)'''
            cur.execute(sql, (tag, json.dumps(data), __opts__['id']))
```

### Custom Returners

Place custom returners in a `_returners` directory within the `file_roots` specified by the master config file.

Custom returners are distributed when any of the following are called: `state.highstate`

- `saltutil.sync_returners`
- `saltutil.sync_all`

Any custom returners which have been synced to a minion that are named the same as one of Salt's default set of returners will take the place of the default returner with the same name.

### Naming the Returner

Note that a returner's default name is its filename (i.e. `foo.py` becomes returner `foo`), but that its name can be overridden by using a `__virtual__` function. A good example of this can be found in the `redis` returner, which is named `redis_return.py` but is loaded as simply `redis`: 
try:
    import redis
    HAS_REDIS = True
except ImportError:
    HAS_REDIS = False
__virtualname__ = 'redis'

def __virtual__():
    if not HAS_REDIS:
        return False
    return __virtualname__

Testing the Returner

The returner, prep_jid, save_load, get_load, and event_return functions can be tested by configuring the master_job_cache and Event Returners in the master config file and submitting a job to test.ping each minion from the master.

Once you have successfully exercised the Master Job Cache functions, test the External Job Cache functions using the ret execution module.

    salt-call ret.get_jids cassandra_cql --output=json
    salt-call ret.get_fun cassandra_cql test.ping --output=json
    salt-call ret.get_minions cassandra_cql --output=json
    salt-call ret.get_jid cassandra_cql 20150330121011408195 --output=json

31.23.3 Event Returners

For maximum visibility into the history of events across a Salt infrastructure, all events seen by a salt master may be logged to a returner.

To enable event logging, set the event_return configuration option in the master config to returner which should be designated as the handler for event returns.

Note: Not all returners support event returns. Verify a returner has an event_return() function before using.

Note: On larger installations, many hundreds of events may be generated on a busy master every second. Be certain to closely monitor the storage of a given returner as Salt can easily overwhelm an underpowered server with thousands of returns.

<tr>
<td>xmpp_return</td>
<td>Return salt data via xmpp</td>
</tr>
</tbody>
</table>

**salt.returners.carbon_return**

Take data from salt and "return" it into a carbon receiver.

Add the following configuration to the minion configuration file:

```yaml
 carbon.host: <server ip address>
carbon.port: 2003
```

Errors when trying to convert data to numbers may be ignored by setting `carbon.skip_on_error` to `True`:

```
carbon.skip_on_error: True
```

By default, data will be sent to carbon using the plaintext protocol. To use the pickle protocol, set `carbon.mode` to `pickle`:

```
carbon.mode: pickle
```

You can also specify the pattern used for the metric base path (except for virt modules metrics):

```
carbon.metric_base_pattern: carbon.[minion_id].[module].[function]
```

**These tokens can used:** module, salt module, function, salt function, minion id, minion id

**Default is:** carbon.metric_base_pattern: [module],[function],[minion_id]

Carbon settings may also be configured as:
carbon:
  host: <server IP or hostname>
  port: <carbon port>
  skip_on_error: True
  mode: (pickle|text)
  metric_base_pattern: <pattern> | [module].[function].[minion_id]

Alternative configuration values can be used by prefacing the configuration. Any values not found in the alternative configuration will be pulled from the default location:

alternative.carbon:
  host: <server IP or hostname>
  port: <carbon port>
  skip_on_error: True
  mode: (pickle|text)

To use the carbon returner, append `--return carbon` to the salt command.

\texttt{salt '* test.ping --return carbon}

To use the alternative configuration, append `--return_config alternative` to the salt command.

New in version 2015.5.0.

\texttt{salt '* test.ping --return carbon --return_config alternative}

\begin{Verbatim}
\texttt{salt.returners.carbon_return.event_return(events)}
\end{Verbatim}

Return event data to remote carbon server

\begin{Verbatim}
\texttt{salt.returners.carbon_return.prep_jid(nocache=False, passed_jid=None)}
\end{Verbatim}

Do any work necessary to prepare a JID, including sending a custom id

\begin{Verbatim}
\texttt{salt.returners.carbon_return.returner(ret)}
\end{Verbatim}

Return data to a remote carbon server using the text metric protocol

Each metric will look like:

\begin{Verbatim}
[module].[function].[minion_id].[metric path [...]].[metric name]
\end{Verbatim}

\begin{Verbatim}
\texttt{salt.returners.cassandra_cql_return}
\end{Verbatim}

Return data to a cassandra server

New in version 2015.5.0.

\begin{itemize}
  \item \textbf{maintainer} Corin Kochenower<ckochenower@saltstack.com>
  \item \textbf{maturity} new as of 2015.2
  \item \textbf{depends} salt.modules.cassandra_cql
  \item \textbf{depends} DataStax Python Driver for Apache Cassandra [https://github.com/datastax/python-driver]
  \item install cassandra-driver
  \item \textbf{platform} all
  \item \textbf{configuration} To enable this returner, the minion will need the DataStax Python Driver for Apache Cassandra ([https://github.com/datastax/python-driver](https://github.com/datastax/python-driver)) installed and the following values configured in the minion or master config. The list of cluster IPs must include at least one cassandra node
\end{itemize}
IP address. No assumption or default will be used for the cluster IPs. The cluster IPs will be tried in the order listed. The port, username, and password values shown below will be the assumed defaults if you do not provide values:

```yaml
cassandra:
  cluster:
  - 192.168.50.11
  - 192.168.50.12
  - 192.168.50.13
  port: 9042
  username: salt
  password: salt
```

Use the following cassandra database schema:

```sql
CREATE KEYSPACE IF NOT EXISTS salt
  WITH replication = {'class': 'SimpleStrategy', 'replication_factor' : 1};
CREATE USER IF NOT EXISTS salt WITH PASSWORD 'salt' NOSUPERUSER;
GRANT ALL ON KEYSPACE salt TO salt;
USE salt;
CREATE TABLE IF NOT EXISTS salt.salt_returns (
  jid text,
  minion_id text,
  fun text,
  alter_time timestamp,
  full_ret text,
  return text,
  success boolean,
  PRIMARY KEY (jid, minion_id, fun)
) WITH CLUSTERING ORDER BY (minion_id ASC, fun ASC);
CREATE TABLE IF NOT EXISTS salt.jids (jid text PRIMARY KEY,
  load text);
CREATE TABLE IF NOT EXISTS salt.minions (minion_id text PRIMARY KEY,
  last_fun text);
CREATE INDEX IF NOT EXISTS minions_last_fun ON salt.minions (last_fun);
CREATE TABLE IF NOT EXISTS salt.salt_events (id timeuuid,
  tag text,
  alter_time timestamp,
  data text,
  master_id text,
  PRIMARY KEY (id, tag)
) WITH CLUSTERING ORDER BY (tag ASC);
CREATE INDEX tag ON salt.salt_events (tag);
```

Required python modules: cassandra-driver
To use the cassandra returner, append `--return cassandra' to the salt command. ex:

```bash
salt '*' test.ping --return cassandra
```

salt.returners.cassandra_cql_return.event_return(events)
Return event to one of potentially many clustered cassandra nodes

Requires that configuration be enabled via 'event_return' option in master config.

Cassandra does not support an auto-increment feature due to the highly inefficient nature of creating a mono-
tonically increasing number across all nodes in a distributed database. Each event will be assigned a uuid by
the connecting client.

salt.returners.cassandra_cql_return.get_fun(fun)
Return a dict of the last function called for all minions

salt.returners.cassandra_cql_return.get_jid(jid)
Return the information returned when the specified job id was executed

salt.returners.cassandra_cql_return.get_jids()
Return a list of all job ids

salt.returners.cassandra_cql_return.get_load(jid)
Return the load data that marks a specified jid

salt.returners.cassandra_cql_return.get_minions()
Return a list of minions

salt.returners.cassandra_cql_return.prep_jid(nocache=False, passed_jid=None)
Do any work necessary to prepare a JID, including sending a custom id

salt.returners.cassandra_cql_return.returner(ret)
Return data to one of potentially many clustered cassandra nodes

salt.returners.cassandra_cql_return.save_load(jid, load)
Save the load to the specified jid id

salt.returners.cassandra_return

Return data to a Cassandra ColumnFamily

Here's an example Keyspace / ColumnFamily setup that works with this returner:

```sql
create keyspace salt;
use salt;
create column family returns
    with key_validation_class='UTF8Type'
    and comparator='UTF8Type'
    and default_validation_class='UTF8Type';
```

Required python modules: pycassa

To use the cassandra returner, append `--return cassandra' to the salt command. ex:

```bash
salt '*' test.ping --return cassandra
```

salt.returners.cassandra_cql_return.prep_jid(nocache=False, passed_jid=None)
Do any work necessary to prepare a JID, including sending a custom id

salt.returners.cassandra_cql_return.returner(ret)
Return data to a Cassandra ColumnFamily
salt.returners.couchbase_return

Simple returner for Couchbase. Optional configuration settings are listed below, along with sane defaults.

couchbase.host: 'salt'
couchbase.port: 8091
couchbase.bucket: 'salt'
couchbase.skip_verify_views: False

To use the couchbase returner, append `--return couchbase` to the salt command. Example:

```bash
salt '*' test.ping --return couchbase
```

All of the return data will be stored in documents as follows:

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>JID</td>
<td>load: load obj tgt_minions: list of minions targeted nocache: should we not cache the return data</td>
</tr>
<tr>
<td>JID/MINION_ID</td>
<td>return: return_data out: out_data</td>
</tr>
</tbody>
</table>

salt.returners.couchbase_return.get_jid(jid)

Return the information returned when the specified job id was executed

salt.returners.couchbase_return.get_jids()

Return a list of all job ids

salt.returners.couchbase_return.get_load(jid)

Return the load data that marks a specified jid

salt.returners.couchbase_return.prep_jid(nocache=False, passed_jid=None)

Return a job id and prepare the job id directory. This is the function responsible for making sure jids don't collide (unless its passed a jid) So do what you have to do to make sure that stays the case.

salt.returners.couchbase_return.returner(load)

Return data to the local job cache

salt.returners.couchbase_return.save_load(jid, clear_load)

Save the load to the specified jid

salt.returners.couchdb_return

Simple returner for CouchDB. Optional configuration settings are listed below, along with sane defaults:

couchdb.db: 'salt'
couchdb.url: 'http://salt:5984/'

Alternative configuration values can be used by prefacing the configuration. Any values not found in the alternative configuration will be pulled from the default location:

alternative.couchdb.db: 'salt'
alternative.couchdb.url: 'http://salt:5984/'

To use the couchdb returner, append `--return couchdb` to the salt command. Example:

```bash
salt '*' test.ping --return couchdb
```

To use the alternative configuration, append `--return_config alternative` to the salt command. New in version 2015.5.0.

```bash
salt '*' test.ping --return couchdb --return_config alternative
```
On concurrent database access  As this returner creates a couchdb document with the salt job id as document id and as only one document with a given id can exist in a given couchdb database, it is advised for most setups that every minion be configured to write to its own database (the value of couchdb.db may be suffixed with the minion id), otherwise multi-minion targetting can lead to losing output:

- the first returning minion is able to create a document in the database
- other minions fail with {'error': 'HTTP Error 409: Conflict'}

salt.returners.couchdb_return.ensure_views()
This function makes sure that all the views that should exist in the design document do exist.

salt.returners.couchdb_return.get_fun(fun)
Return a dict with key being minion and value being the job details of the last run of function `fun`.

salt.returners.couchdb_return.get_jid(jid)
Get the document with a given JID.

salt.returners.couchdb_return.get_jids()
List all the jobs that we have.

salt.returners.couchdb_return.get_minions()
Return a list of minion identifiers from a request of the view.

salt.returners.couchdb_return.get_valid_salt_views()
Returns a dict object of views that should be part of the salt design document.

salt.returners.couchdb_return.prep_jid(nocache=False, passed_jid=None)
Do any work necessary to prepare a JID, including sending a custom id

salt.returners.couchdb_return.returner(ret)
Take in the return and shove it into the couchdb database.

salt.returners.couchdb_return.set_salt_view()
Helper function that sets the salt design document. Uses get_valid_salt_views and some hardcoded values.

salt.returners.django_return

A returner that will inform a Django system that returns are available using Django’s signal system.

https://docs.djangoproject.com/en/dev/topics/signals/

It is up to the Django developer to register necessary handlers with the signals provided by this returner and process returns as necessary.

The easiest way to use signals is to import them from this returner directly and then use a decorator to register them.

An example Django module that registers a function called `returner_callback` with this module’s `returner` function:

```python
import salt.returners.django_return
from django.dispatch import receiver

@receiver(salt.returners.django_return, sender=returner)
def returner_callback(sender, ret):
    print('I received {0} from {1}'.format(ret, sender))

salt.returners.django_return.prep_jid(nocache=False, passed_jid=None)
    Do any work necessary to prepare a JID, including sending a custom ID

salt.returners.django_return.returner(ret)
    Signal a Django server that a return is available
```
salt.returners.django_return.save_load(jid, load)

Save the load to the specified jid

salt.returners.elasticsearch_return

Return data to an elasticsearch server for indexing.

maintainer Jurnell Cockhren <jurnell.cockhren@sophicware.com>, Arnold Bechtoldt
<mail@arnoldbechtoldt.com>
maturity New
depends elasticsearch-py
platform all

To enable this returner the elasticsearch python client must be installed on the desired minions (all or some subset).
Please see documentation of elasticsearch execution module for a valid connection configuration.

Warning: The index that you wish to store documents will be created by Elasticsearch automatically if doesn’t exist yet. It is highly recommended to create predefined index templates with appropriate mapping(s) that will be used by Elasticsearch upon index creation. Otherwise you will have problems as described in #20826.

To use the returner per salt call:

```
salt '*' test.ping --return elasticsearch
```

In order to have the returner apply to all minions:

```
ext_job_cache: elasticsearch
```

salt.returners.elasticsearch_return.get_load(jid)

Return the load data that marks a specified jid

salt.returners.elasticsearch_return.prep_jid(nocache=False, passed_jid=None)

Do any work necessary to prepare a JID, including sending a custom id

salt.returners.elasticsearch_return.returner(ret)

Process the return from Salt

salt.returners.elasticsearch_return.save_load(jid, load)

Save the load to the specified jid id

salt.returners.etcd_return

Return data to an etcd server or cluster

depends

• python-etcd

In order to return to an etcd server, a profile should be created in the master configuration file:
my_etcd_config:
  etcd.host: 127.0.0.1
  etcd.port: 4001

It is technically possible to configure etcd without using a profile, but this is not considered to be a best practice, especially when multiple etcd servers or clusters are available.

Additionally, two more options must be specified in the top-level configuration in order to use the etcd returner:

etcd.host: 127.0.0.1
etcd.port: 4001

e etcd.returner: my_etcd_config
etcd.returner_root: /salt/return

The `etcd.returner` option specifies which configuration profile to use. The `etcd.returner_root` option specifies the path inside etcd to use as the root of the returner system.

Once the etcd options are configured, the returner may be used:

CLI Example:

```
salt '*' test.ping --return etcd
```

```
salt.returners.etcd_return.get_fun()
  Return a dict of the last function called for all minions
```

```
salt.returners.etcd_return.get_jid(jid)
  Return the information returned when the specified job id was executed
```

```
salt.returners.etcd_return.get_jids()
  Return a list of all job ids
```

```
salt.returners.etcd_return.get_load(jid)
  Return the load data that marks a specified jid
```

```
salt.returners.etcd_return.get_minions()
  Return a list of minions
```

```
salt.returners.etcd_return.prep_jid(nocache=False, passed_jid=None)
  Do any work necessary to prepare a JID, including sending a custom id
```

```
salt.returners.etcd_return.returner(ret)
  Return data to an etcd server or cluster
```

```
salt.returners.etcd_return.save_load(jid, load)
  Save the load to the specified jid
```

salt.returners.hipchat_return

Return salt data via hipchat.

New in version 2015.5.0.

The following fields can be set in the minion conf file:

```
hipchat.room_id (required)
hipchat.api_key (required)
hipchat.api_version (required)
hipchat.from_name (required)
hipchat.color (optional)
```

31.23. Returners
hipchat.notify (optional)
hipchat.profile (optional)

Alternative configuration values can be used by prefacing the configuration. Any values not found in the alternative configuration will be pulled from the default location:

- `hipchat.room_id`
- `hipchat.api_key`
- `hipchat.api_version`
- `hipchat.from_name`

Hipchat settings may also be configured as:

```yaml
hipchat:
  room_id: RoomName
  api_key: xxxxxxxxxxxxxxxxxxxxxxxxxxxx
  api_version: v1
  from_name: user@email.com

alternative.hipchat:
  room_id: RoomName
  api_key: xxxxxxxxxxxxxxxxxxxxxxxxxxxx
  api_version: v1
  from_name: user@email.com

hipchat_profile:
  api_key: xxxxxxxxxxxxxxxxxxxxxxxxxxxx
  api_version: v1
  from_name: user@email.com

hipchat:
  profile: hipchat_profile
  room_id: RoomName

alternative.hipchat:
  profile: hipchat_profile
  room_id: RoomName
```

To use the HipChat returner, append `--return hipchat` to the salt command.

```bash
salt '*' test.ping --return hipchat
```

To use the alternative configuration, append `--return_config alternative` to the salt command.

New in version 2015.5.0.

```bash
salt '*' test.ping --return hipchat --return_config alternative
```

salt.returners.hipchat_return.event_return(events)
   Return event data to hipchat

salt.returners.hipchat_return.returner(ret)
   Send an hipchat message with the return data from a job

salt.returners.influxdb_return

Return data to an influxdb server.

New in version 2015.8.0.
To enable this returner the minion will need the python client for influxdb installed and the following values configured in the minion or master config, these are the defaults:

```
influxdb.db: 'salt'
influxdb.user: 'salt'
influxdb.password: 'salt'
influxdb.host: 'localhost'
influxdb.port: 8086
```

Alternative configuration values can be used by prefacing the configuration. Any values not found in the alternative configuration will be pulled from the default location:

```
alternative.influxdb.db: 'salt'
alternative.influxdb.user: 'salt'
alternative.influxdb.password: 'salt'
alternative.influxdb.host: 'localhost'
alternative.influxdb.port: 6379
```

To use the influxdb returner, append `--return influxdb` to the salt command.

```
salt '*' test.ping --return influxdb
```

To use the alternative configuration, append `--return_config alternative` to the salt command.

```
salt '*' test.ping --return influxdb --return_config alternative
```

```
salt.returners.influxdb_return.get_fun(fun)
    Return a dict of the last function called for all minions

salt.returners.influxdb_return.get_jid(jid)
    Return the information returned when the specified job id was executed

salt.returners.influxdb_return.get_jids()
    Return a list of all job ids

salt.returners.influxdb_return.get_load(jid)
    Return the load data that marks a specified jid

salt.returners.influxdb_return.get_minions()
    Return a list of minions

salt.returners.influxdb_return.prep_jid(nocache=False, passed_jid=None)
    Do any work necessary to prepare a JID, including sending a custom id

salt.returners.influxdb_return.returner(ret)
    Return data to a influxdb data store

salt.returners.influxdb_return.save_load(jid, load)
    Save the load to the specified jid
```

```
salt.returners.kafka_return
```

Return data to a Kafka topic

- maintainer Chris ter Edwards (christer.edwards@gmail.com)
- maturity 0.1
- depends kafka-python
- platform all
To enable this returner install kafka-python and enable the following settings in the minion config:

```python
returner.kafka.hostnames:
    - "server1"
    - "server2"
    - "server3"

returner.kafka.topic: 'topic'
```

To use the kafka returner, append `--return kafka` to the Salt command, eg:

```bash
salt '*' test.ping --return kafka
```

salt.returners.kafka_return

Return information to a Kafka server

salt.returners.local

The local returner is used to test the returner interface, it just prints the return data to the console to verify that it is being passed properly.

To use the local returner, append `--return local` to the salt command. ex:

```bash
salt '*' test.ping --return local
```

salt.returners.local.event_return

Print event return data to the terminal to verify functionality

salt.returners.local.returner

Print the return data to the terminal to verify functionality

salt.returners.local_cache

Return data to local job cache

salt.returners.local_cache.clean_old_jobs()

Clean out the old jobs from the job cache

salt.returners.local_cache.get_endtime(jid)

Retrieve the stored endtime for a given job

Returns False if no endtime is present

salt.returners.local_cache.get_jid(jid)

Return the information returned when the specified job id was executed

salt.returners.local_cache.get_jids()

Return a dict mapping all job ids to job information

salt.returners.local_cache.get_jids_filter(count, filter_find_job=True)

Return a list of all jobs information filtered by the given criteria.

- param int count: show not more than the count of most recent jobs
- param bool filter_find_jobs: filter out `saltutil.find_job` jobs

salt.returners.local_cache.get_load(jid)

Return the load data that marks a specified jid

salt.returners.local_cache.prep_jid(nocache=False, passed_jid=None, recurse_count=0)

Return a job id and prepare the job id directory. This is the function responsible for making sure jids don’t collide (unless its passed a jid.) So do what you have to do to make sure that stays the case
salt.returners.local_cache.returner(load)
    Return data to the local job cache

salt.returners.local_cache.save_load(jid, clear_load)
    Save the load to the specified jid

salt.returners.local_cache.update_endtime(jid, time)
    Update (or store) the end time for a given job
    Endtime is stored as a plain text string

salt.returners.memcache_return

Return data to a memcache server

To enable this returner the minion will need the python client for memcache installed and the following values
configured in the minion or master config, these are the defaults.

<table>
<thead>
<tr>
<th>memcache.host: 'localhost'</th>
</tr>
</thead>
<tbody>
<tr>
<td>memcache.port: '11211'</td>
</tr>
</tbody>
</table>

Alternative configuration values can be used by prefacing the configuration. Any values not found in the alternative
configuration will be pulled from the default location.

<table>
<thead>
<tr>
<th>alternative.memcache.host: 'localhost'</th>
</tr>
</thead>
<tbody>
<tr>
<td>alternative.memcache.port: '11211'</td>
</tr>
</tbody>
</table>

python2-memcache uses 'localhost' and '11211' as syntax on connection.

To use the memcache returner, append `--return memcache` to the salt command.

```bash
salt '*' test.ping --return memcache
```

To use the alternative configuration, append `--return_config alternative` to the salt command.

New in version 2015.5.0.

```bash
salt '*' test.ping --return memcache --return_config alternative
```

salt.returners.memcache_return.get_fun(fun)
    Return a dict of the last function called for all minions

salt.returners.memcache_return.get_jid(jid)
    Return the information returned when the specified job id was executed

salt.returners.memcache_return.get_jids()
    Return a list of all job ids

salt.returners.memcache_return.get_load(jid)
    Return the load data that marks a specified jid

salt.returners.memcache_return.get_minions()
    Return a list of minions

salt.returners.memcache_return.prep_jid(nocache=False, passed_jid=None)
    Do any work necessary to prepare a JID, including sending a custom id

salt.returners.memcache_return.returner(ret)
    Return data to a memcache data store

salt.returners.memcache_return.save_load(jid, load)
    Save the load to the specified jid
salt.returners.mongo_future_return

Return data to a mongodb server

Required python modules: pymongo

This returner will send data from the minions to a MongoDB server. To configure the settings for your MongoDB server, add the following lines to the minion config files:

```
    mongo.db: <database name>
    mongo.host: <server ip address>
    mongo.user: <MongoDB username>
    mongo.password: <MongoDB user password>
    mongo.port: 27017
```

You can also ask for indexes creation on the most common used fields, which should greatly improve performance. Indexes are not created by default.

```
    mongo.indexes: true
```

Alternative configuration values can be used by prefacing the configuration. Any values not found in the alternative configuration will be pulled from the default location:

```
    alternative.mongo.db: <database name>
    alternative.mongo.host: <server ip address>
    alternative.mongo.user: <MongoDB username>
    alternative.mongo.password: <MongoDB user password>
    alternative.mongo.port: 27017
```

This mongo returner is being developed to replace the default mongodb returner in the future and should not be considered API stable yet.

To use the mongo returner, append `--return mongo` to the salt command.

```
salt '*' test.ping --return mongo
```

To use the alternative configuration, append `--return_config alternative` to the salt command.

New in version 2015.5.0.

```
salt '*' test.ping --return mongo --return_config alternative
```

salt.returners.mongo_future_return.get_fun(fun)

Return the most recent jobs that have executed the named function

salt.returners.mongo_future_return.get_jid(jid)

Return the return information associated with a jid

salt.returners.mongo_future_return.get_jids()

Return a list of jid ids

salt.returners.mongo_future_return.get_load(jid)

Return the load associated with a given job id

salt.returners.mongo_future_return.get_minions()

Return a list of minions

salt.returners.mongo_future_return.prep_jid(nocache=False, passed_jid=None)

Do any work necessary to prepare a JID, including sending a custom id

salt.returners.mongo_future_return.returner(ret)

Return data to a mongodb server
salt.returners.mongo_future_return.save_load(jid, load)
Save the load for a given job id

salt.returners.mongo_return

Return data to a mongodb server
Required python modules: pymongo
This returner will send data from the minions to a MongoDB server. To configure the settings for your MongoDB server, add the following lines to the minion config files.

mongo.db: <database name>
mongo.host: <server ip address>
mongo.user: <MongoDB username>
mongo.password: <MongoDB user password>
mongo.port: 27017

Alternative configuration values can be used by prefacing the configuration. Any values not found in the alternative configuration will be pulled from the default location.

alternative.mongo.db: <database name>
alternative.mongo.host: <server ip address>
alternative.mongo.user: <MongoDB username>
alternative.mongo.password: <MongoDB user password>
alternative.mongo.port: 27017

To use the mongo returner, append `--return mongo` to the salt command.

salt '*' test.ping --return mongo_return

To use the alternative configuration, append `--return_config alternative` to the salt command.
New in version 2015.5.0.
salt '*' test.ping --return mongo_return --return_config alternative

salt.returners.mongo_return.get_fun(fun)
Return the most recent jobs that have executed the named function

salt.returners.mongo_return.get_jid(jid)
Return the return information associated with a jid

salt.returners.mongo_return.prep_jid(nocache=False, passed_jid=None)
Do any work necessary to prepare a JID, including sending a custom id

salt.returners.mongo_return.returner(ret)
Return data to a mongodb server

salt.returners.multi_returner

Read/Write multiple returners

salt.returners.multi_returner.clean_old_jobs()
Clean out the old jobs from all returners (if you have it)
salt.returners.multi_returner.get_jid(jid)
Merge the return data from all returners
salt.returners.multi_returner.get_jids()
    Return all job data from all returners

salt.returners.multi_returner.get_load(jid)
    Merge the load data from all returners

salt.returners.multi_returner.prep_jid(nocache=False, passed_jid=None)
    Call both with prep_jid on all returners in multi_returner
    TODO: finish this, what do do when you get different jids from 2 returners... since our jids are time based, this
    make this problem hard, because they aren't unique, meaning that we have to make sure that no one else got
    the jid and if they did we spin to get a new one, which means ``locking`` the jid in 2 returners is non-trivial

salt.returners.multi_returner.returner(load)
    Write return to all returners in multi_returner

salt.returners.multi_returner.save_load(jid, clear_load)
    Write load to all returners in multi_returner

salt.returners.mysql

Return data to a mysql server

    maintainer  Dave Boucha <dave@saltstack.com>, Seth House <shouse@saltstack.com>
    maturity    new
    depends     python-mysqldb
    platform    all

To enable this returner, the minion will need the python client for mysql installed and the following values configured
in the minion or master config. These are the defaults:

<p>| | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>mysql.host</td>
<td>'salt'</td>
</tr>
<tr>
<td>mysql.user</td>
<td>'salt'</td>
</tr>
<tr>
<td>mysql.pass</td>
<td>'salt'</td>
</tr>
<tr>
<td>mysql.db</td>
<td>'salt'</td>
</tr>
<tr>
<td>mysql.port</td>
<td>3306</td>
</tr>
</tbody>
</table>

SSL is optional. The defaults are set to None. If you do not want to use SSL, either exclude these options or set them
to None.

<p>| | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>mysql.ssl_ca</td>
<td>None</td>
</tr>
<tr>
<td>mysql.ssl_cert</td>
<td>None</td>
</tr>
<tr>
<td>mysql.ssl_key</td>
<td>None</td>
</tr>
</tbody>
</table>

Alternative configuration values can be used by prefacing the configuration with `alternative`. Any values not found in
the alternative configuration will be pulled from the default location. As stated above, SSL configuration is optional.
The following ssl options are simply for illustration purposes:

<p>| | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>alternative.mysql.host</td>
<td>'salt'</td>
</tr>
<tr>
<td>alternative.mysql.user</td>
<td>'salt'</td>
</tr>
<tr>
<td>alternative.mysql.pass</td>
<td>'salt'</td>
</tr>
<tr>
<td>alternative.mysql.db</td>
<td>'salt'</td>
</tr>
<tr>
<td>alternative.mysql.port</td>
<td>3306</td>
</tr>
<tr>
<td>alternative.mysql.ssl_ca</td>
<td>'/etc/pki/mysql/certs/localhost.pem'</td>
</tr>
<tr>
<td>alternative.mysql.ssl_cert</td>
<td>'/etc/pki/mysql/certs/localhost.crt'</td>
</tr>
<tr>
<td>alternative.mysql.ssl_key</td>
<td>'/etc/pki/mysql/certs/localhost.key'</td>
</tr>
</tbody>
</table>
Use the following mysql database schema:

```
CREATE DATABASE `salt`
    DEFAULT CHARACTER SET utf8
    DEFAULT COLLATE utf8_general_ci;

USE `salt`;

-- Table structure for table `jids`
--

DROP TABLE IF EXISTS `jids`;
CREATE TABLE `jids` (  
jid varchar(255) NOT NULL,  
load mediumtext NOT NULL,  
UNIQUE KEY `jid` (`jid`)  
) ENGINE=InnoDB DEFAULT CHARSET=utf8;
CREATE INDEX jid ON jids(jid) USING BTREE;

-- Table structure for table `salt_returns`
--

DROP TABLE IF EXISTS `salt_returns`;
CREATE TABLE `salt_returns` (  
fun varchar(50) NOT NULL,  
jid varchar(255) NOT NULL,  
return mediumtext NOT NULL,  
id varchar(255) NOT NULL,  
success varchar(10) NOT NULL,  
full_ret mediumtext NOT NULL,  
alter_time TIMESTAMP DEFAULT CURRENT_TIMESTAMP,  
KEY `id` (`id`),  
KEY `jid` (`jid`),  
KEY `fun` (`fun`)  
) ENGINE=InnoDB DEFAULT CHARSET=utf8;

-- Table structure for table `salt_events`
--

DROP TABLE IF EXISTS `salt_events`;
CREATE TABLE `salt_events` (  
id BIGINT NOT NULL AUTO_INCREMENT,  
tag varchar(255) NOT NULL,  
data varchar(1024) NOT NULL,  
alter_time TIMESTAMP DEFAULT CURRENT_TIMESTAMP,  
master_id varchar(255) NOT NULL,  
PRIMARY KEY (`id`),  
KEY `tag` (`tag`)  
) ENGINE=InnoDB DEFAULT CHARSET=utf8;
```

Required python modules: MySQLdb

To use the mysql returner, append `--return mysql` to the salt command.

```
salt '*' test.ping --return mysql
```

To use the alternative configuration, append `--return_config alternative` to the salt command.
New in version 2015.5.0.

```
salt '*' test.ping --return mysql --return_config alternative
```

```
salt.returners.mysql.event_return(events)
    Return event to mysql server
    Requires that configuration be enabled via `event_return' option in master config.
```

```
salt.returners.mysql.get_fun(fun)
    Return a dict of the last function called for all minions
```

```
salt.returners.mysql.get_jid(jid)
    Return the information returned when the specified job id was executed
```

```
salt.returners.mysql.get_jids()
    Return a list of all job ids
```

```
salt.returners.mysql.get_jids_filter(count, filter_find_job=True)
    Return a list of all job ids :param int count: show not more than the count of most recent jobs :param bool filter_find_jobs: filter out `saltutil.find_job' jobs
```

```
salt.returners.mysql.get_load(jid)
    Return the load data that marks a specified jid
```

```
salt.returners.mysql.get_minions()
    Return a list of minions
```

```
salt.returners.mysql.prep_jid(nocache=False, passed_jid=None)
    Do any work necessary to prepare a JID, including sending a custom id
```

```
salt.returners.mysql.returner(ret)
    Return data to a mysql server
```

```
salt.returners.mysql.save_load(jid, load)
    Save the load to the specified jid id
```

```
salt.returners.nagios_return
```

Return salt data to Nagios

The following fields can be set in the minion conf file:

```
nagios.url (required)
nagios.token (required)
nagios.service (optional)
nagios.check_type (optional)
```

Alternative configuration values can be used by prefacing the configuration. Any values not found in the alternative configuration will be pulled from the default location:

```
nagios.url
nagios.token
nagios.service
```

Nagios settings may also be configured as:

```
nagios:
    url: http://localhost/nrdp
    token: r4nd0mt0k3n
    service: service-check
```
alternative.nagios:
  url: http://localhost/nrdp
  token: r4nd0mt0k3n
  service: another-service-check

To use the Nagios returner, append ' --return nagios' to the salt command. ex:

```bash
.. code-block:: bash
  salt '*' test.ping --return nagios
```

To use the alternative configuration, append ' --return_config alternative' to the salt command. ex:

```bash
  salt '*' test.ping --return nagios --return_config alternative
```

salt.returners.nagios_return.**returner**(ret)

Send a message to Nagios with the data

**salt.returners.odbc**

Return data to an ODBC compliant server. This driver was developed with Microsoft SQL Server in mind, but theoretically could be used to return data to any compliant ODBC database as long as there is a working ODBC driver for it on your minion platform.

**maintainer**

3. (a) Oldham (cr@saltstack.com)

**maturity** New

**depends** unixodbc, pyodbc, freetds (for SQL Server)

**platform** all

To enable this returner the minion will need

On Linux:

On Windows:

TBD

unixODBC and FreeTDS need to be configured via /etc/odbcinst.ini and /etc/odbc.ini.

/etc/odbcinst.ini:

```
[TDS]
Description=TDS
Driver=/usr/lib/x86_64-linux-gnu/odbc/libtdsodbc.so
```

(Note the above Driver line needs to point to the location of the FreeTDS shared library. This example is for Ubuntu 14.04.)

/etc/odbc.ini:

```
[TS]
Description = "Salt Returner"
Driver=TDS
```

31.23. **Returners**
Server = <your server ip or fqdn>
Port = 1433
Database = salt
Trace = No

Also you need the following values configured in the minion or master config. Configure as you see fit:

returner.odbc.dsn: 'TS'
returner.odbc.user: 'salt'
returner.odbc.passwd: 'salt'

Alternative configuration values can be used by prefacing the configuration. Any values not found in the alternative configuration will be pulled from the default location:

alternative.returner.odbc.dsn: 'TS'
alternative.returner.odbc.user: 'salt'
alternative.returner.odbc.passwd: 'salt'

Running the following commands against Microsoft SQL Server in the desired database as the appropriate user should create the database tables correctly. Replace with equivalent SQL for other ODBC-compliant servers

```sql
--
-- Table structure for table 'jids'
--

if OBJECT_ID('dbo.jids', 'U') IS NOT NULL
    DROP TABLE dbo.jids

CREATE TABLE dbo.jids (    jid varchar(255) PRIMARY KEY,    load varchar(MAX) NOT NULL)
;

--
-- Table structure for table 'salt_returns'
--

IF OBJECT_ID('dbo.salt_returns', 'U') IS NOT NULL
    DROP TABLE dbo.salt_returns;

CREATE TABLE dbo.salt_returns (    added datetime not null default (getdate()),    fun varchar(100) NOT NULL,    jid varchar(255) NOT NULL,    retval varchar(MAX) NOT NULL,    id varchar(255) NOT NULL,    success bit default(0) NOT NULL,    full_ret varchar(MAX)
);

CREATE INDEX salt_returns_added on dbo.salt_returns(added);
CREATE INDEX salt_returns_id on dbo.salt_returns(id);
CREATE INDEX salt_returns_jid on dbo.salt_returns(jid);
CREATE INDEX salt_returns_fun on dbo.salt_returns(fun);

To use this returner, append '--return odbc' to the salt command.

.. code-block:: bash

    salt '*' status.diskusage --return odbc
To use the alternative configuration, append `--return_config alternative` to the salt command.

.. versionadded:: 2015.5.0

.. code-block:: bash

    salt '*' test.ping --return odbc --return_config alternative

salt.returners.odbc.get_fun(fun)
    Return a dict of the last function called for all minions

salt.returners.odbc.get_jid(jid)
    Return the information returned when the specified job id was executed

salt.returners.odbc.get_jids()
    Return a list of all job ids

salt.returners.odbc.get_load(jid)
    Return the load data that marks a specified jid

salt.returners.odbc.get_minions()
    Return a list of minions

salt.returners.odbc.prep_jid(nocache=False, passed_jid=None)
    Do any work necessary to prepare a JID, including sending a custom id

salt.returners.odbc.returner(ret)
    Return data to an odbc server

salt.returners.odbc.save_load(jid, load)
    Save the load to the specified jid id

salt.returners.pgjsonb

Return data to a PostgreSQL server with json data stored in Pg's jsonb data type

maintainer  Dave Boucha <dave@saltstack.com>, Seth House <shouse@saltstack.com>, C. R. Oldham <cr@saltstack.com>

maturity  new

depends  python-psycopg2

platform  all

To enable this returner, the minion will need the python client for PostgreSQL installed and the following values configured in the minion or master config. These are the defaults:

returner.pgjsonb.host: 'salt'
returner.pgjsonb.user: 'salt'
returner.pgjsonb.pass: 'salt'
returner.pgjsonb.db: 'salt'
returner.pgjsonb.port: 5432

SSL is optional. The defaults are set to None. If you do not want to use SSL, either exclude these options or set them to None.

returner.pgjsonb.ssl_ca: None
returner.pgjsonb.ssl_cert: None
returner.pgjsonb.ssl_key: None
Alternative configuration values can be used by prefacing the configuration with `alternative`. Any values not found in the alternative configuration will be pulled from the default location. As stated above, SSL configuration is optional.

The following SSL options are simply for illustration purposes:

```plaintext
alternative.pgjsonb.host: 'salt'
alternative.pgjsonb.user: 'salt'
alternative.pgjsonb.pass: 'salt'
alternative.pgjsonb.db: 'salt'
alternative.pgjsonb.port: 5432
alternative.pgjsonb.ssl_ca: '/etc/pki/mysql/certs/localhost.pem'
alternative.pgjsonb.ssl_cert: '/etc/pki/mysql/certs/localhost.crt'
alternative.pgjsonb.ssl_key: '/etc/pki/mysql/certs/localhost.key'
```

Use the following Pg database schema:

```sql
CREATE DATABASE salt
    WITH ENCODING 'utf-8';

-- Table structure for table `jids`
--
DROP TABLE IF EXISTS jids;
CREATE OR REPLACE TABLE jids (  jid varchar(255) NOT NULL primary key
    load jsonb NOT NULL
);
CREATE INDEX idx_jids_jsonb on jids
    USING gin (load)
    WITH (fastupdate=on);

-- Table structure for table `salt_returns`
--
DROP TABLE IF EXISTS salt_returns;
CREATE TABLE salt_returns (  fun varchar(50) NOT NULL,
    jid varchar(255) NOT NULL,
    return jsonb NOT NULL,
    id varchar(255) NOT NULL,
    success varchar(10) NOT NULL,
    full_ret jsonb NOT NULL,
    alter_time TIMESTAMP WITH TIME ZONE DEFAULT NOW()));
CREATE INDEX idx_salt_returns_id ON salt_returns (id);
CREATE INDEX idx_salt_returns_jid ON salt_returns (jid);
CREATE INDEX idx_salt_returns_fun ON salt_returns (fun);
CREATE INDEX idx_salt_returns_return ON salt_returns
    USING gin (return) with (fastupdate=on);
CREATE INDEX idx_salt_returns_full_ret ON salt_returns
    USING gin (full_ret) with (fastupdate=on);

-- Table structure for table `salt_events`
--
DROP TABLE IF EXISTS salt_events;
DROP SEQUENCE IF EXISTS seq_salt_events_id;
CREATE SEQUENCE seq_salt_events_id;
```
CREATE TABLE salt_events (  
id BIGINT NOT NULL UNIQUE DEFAULT nextval('seq_salt_events_id'),  
tag varchar(255) NOT NULL,  
data jsonb NOT NULL,  
alter_time TIMESTAMPTZ WITH TIME ZONE DEFAULT NOW(),  
master_id varchar(255) NOT NULL);

CREATE INDEX idx_salt_events_tag on salt_events (tag);
CREATE INDEX idx_salt_events_data ON salt_events  
USING gin (data) with (fastupdate=on);

Required python modules: Psycopg2

To use this returner, append `--return pgjsonb` to the salt command.

salt '*' test.ping --return pgjsonb

To use the alternative configuration, append `--return_config alternative` to the salt command.

New in version 2015.5.0.

salt '*' test.ping --return pgjsonb --return_config alternative

salt.returners.pgjsonb.event_return(events)  
Return event to Pg server

  Requires that configuration be enabled via `event_return` option in master config.

salt.returners.pgjsonb.get_fun(fun)  
Return a dict of the last function called for all minions

salt.returners.pgjsonb.get_jid(jid)  
Return the information returned when the specified job id was executed

salt.returners.pgjsonb.get_jids()  
Return a list of all job ids

salt.returners.pgjsonb.get_load(jid)  
Return the load data that marks a specified jid

salt.returners.pgjsonb.get_minions()  
Return a list of minions

salt.returners.pgjsonb.prep_jid(nocache=False, passed_jid=None)  
Do any work necessary to prepare a JID, including sending a custom id

salt.returners.pgjsonb.returner(ret)  
Return data to a Pg server

salt.returners.pgjsonb.save_load(jid, load)  
Save the load to the specified jid id

salt.returners.postgres

Return data to a postgresql server

  maintainer None
  maturity New
  depends psycopg2
platform all

To enable this returner the minion will need the psycopg2 installed and the following values configured in the minion or master config:

```python
returner.postgres.host: 'salt'
returner.postgres.user: 'salt'
returner.postgrespasswd: 'salt'
returner.postgres.db: 'salt'
returner.postgres.port: 5432
```

Alternative configuration values can be used by prefacing the configuration. Any values not found in the alternative configuration will be pulled from the default location:

```python
alternative.returner.postgres.host: 'salt'
alternative.returner.postgres.user: 'salt'
alternative.returner.postgrespasswd: 'salt'
alternative.returner.postgres.db: 'salt'
alternative.returner.postgres.port: 5432
```

Running the following commands as the postgres user should create the database correctly:

```
psql << EOF
CREATE ROLE salt WITH PASSWORD 'salt';
CREATE DATABASE salt WITH OWNER salt;
EOF

psql -h localhost -U salt << EOF
--
-- Table structure for table 'jids'
--

DROP TABLE IF EXISTS jids;
CREATE TABLE jids (jid varchar(20) PRIMARY KEY, load text NOT NULL);
--
-- Table structure for table 'salt_returns'
--

DROP TABLE IF EXISTS salt_returns;
CREATE TABLE salt_returns (added TIMESTAMP WITH TIME ZONE DEFAULT now(), fun text NOT NULL, jid varchar(20) NOT NULL, return text NOT NULL, id text NOT NULL, success boolean);
CREATE INDEX ON salt_returns (added);
CREATE INDEX ON salt_returns (id);
CREATE INDEX ON salt_returns (jid);
CREATE INDEX ON salt_returns (fun);
EOF
```

Required python modules: psycopg2

To use the postgres returner, append `--return postgres` to the salt command.
salt '*' test.ping --return postgres

To use the alternative configuration, append `--return_config alternative' to the salt command.

New in version 2015.5.0.

```
salt '*' test.ping --return postgres --return_config alternative
```

```
salt.returners.postgres.get_fun(fun)
   Return a dict of the last function called for all minions

salt.returners.postgres.get_jid(jid)
   Return the information returned when the specified job id was executed

salt.returners.postgres.get_jids()
   Return a list of all job ids

salt.returners.postgres.get_load(jid)
   Return the load data that marks a specified jid

salt.returners.postgres.get_minions()
   Return a list of minions

salt.returners.postgres.prep_jid(nocache=False, passed_jid=None)
   Do any work necessary to prepare a JID, including sending a custom id

salt.returners.postgres.returner(ret)
   Return data to a postgres server

salt.returners.postgres.save_load(jid, load)
   Save the load to the specified jid id
```

```
salt.returners.postgres_local_cache
```

Use a postgresql server for the master job cache. This helps the job cache to cope with scale.

```
maintainer  gjredelinghuys@gmail.com
maturity    New
depends     psycopg2
platform    all
```

To enable this returner the minion will need the psycopg2 installed and the following values configured in the master config:

```
master_job_cache: postgres_local_cache
master_job_cache.postgres.host: 'salt'
master_job_cache.postgres.user: 'salt'
master_job_cache.postgres.passwd: 'salt'
master_job_cache.postgres.db: 'salt'
master_job_cache.postgres.port: 5432
```

Running the following command as the postgres user should create the database correctly:

```
psql << EOF
CREATE ROLE salt WITH PASSWORD 'salt';
CREATE DATABASE salt WITH OWNER salt;
EOF
```
and then:

```bash
psql -h localhost -U salt << EOF
```

```sql
-- Table structure for table 'jids'
```

```sql
DROP TABLE IF EXISTS jids;
CREATE TABLE jids (
  jid       varchar(20) PRIMARY KEY,
  started    TIMESTAMP WITH TIME ZONE DEFAULT now(),
  tgt_type   text NOT NULL,
  cmd        text NOT NULL,
  tgt        text NOT NULL,
  kwargs     text NOT NULL,
  ret        text NOT NULL,
  username   text NOT NULL,
  arg        text NOT NULL,
  fun        text NOT NULL
);

-- Table structure for table 'salt_returns'
```

```sql
DROP TABLE IF EXISTS salt_returns;
CREATE TABLE salt_returns (
  added    TIMESTAMP WITH TIME ZONE DEFAULT now(),
  fun       text NOT NULL,
  jid       varchar(20) NOT NULL,
  return    text NOT NULL,
  id        text NOT NULL,
  success   boolean
);
CREATE INDEX ON salt_returns (added);
CREATE INDEX ON salt_returns (id);
CREATE INDEX ON salt_returns (jid);
CREATE INDEX ON salt_returns (fun);
```

EOF

Required python modules: psycopg2

```python
salt.returners.postgres_local_cache.clean_old_jobs()
```

Clean out the old jobs from the job cache

```python
salt.returners.postgres_local_cache.get_jid(jid)
```

Return the information returned when the specified job id was executed

```python
salt.returners.postgres_local_cache.get_jids()
```

Return a list of all job ids. For master job cache this also formats the output and returns a string

```python
salt.returners.postgres_local_cache.get_load(jid)
```

Return the load data that marks a specified jid

```python
salt.returners.postgres_local_cache.prep_jid(nocache=False, passed_jid=None)
```

Return a job id and prepare the job id directory. This is the function responsible for making sure jids don't collide (unless its passed a jid). So do what you have to do to make sure that stays the case

```python
salt.returners.postgres_local_cache.returner(load)
```

Return data to a postgres server
salt.returners.postgres_local_cache.save_load(jid, clear_load)

Save the load to the specified jid id

salt.returners.pushover_returner

Return salt data via pushover (http://www.pushover.net)

New in version Boron.

The following fields can be set in the minion conf file:

```
pushover.user (required)
pushover.token (required)
pushover.title (optional)
pushover.device (optional)
pushover.priority (optional)
pushover.expire (optional)
pushover.retry (optional)
pushover.profile (optional)
```

Alternative configuration values can be used by prefacing the configuration. Any values not found in the alternative configuration will be pulled from the default location:

```
alternative.pushover.user
alternative.pushover.token
alternative.pushover.title
alternative.pushover.device
alternative.pushover.priority
alternative.pushover.expire
alternative.pushover.retry
```

PushOver settings may also be configured as:

```
pusher:
  user: xxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx
  token: xxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx
  title: Salt Returner
  device: phone
  priority: -1
  expire: 3600
  retry: 5

alternative.pushover:
  user: xxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx
  token: xxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx
  title: Salt Returner
  device: phone
  priority: 1
  expire: 4800
  retry: 2

pushover_profile:
  token: xxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

pushover:
  user: xxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx
  profile: pushover_profile
```
alternative.pushover:
  user: xxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx
  profile: pushover_profile

To use the PushOver returner, append `--return pushover` to the salt command. ex:
.. code-block:: bash
   
salt '*' test.ping --return pushover

To use the alternative configuration, append `--return_config alternative` to the salt command. ex:
   
salt '*' test.ping --return pushover --return_config alternative

salt.returners.pushover_returner.returner(ret)
  Send an PushOver message with the data

salt.returners.redis_return

Return data to a redis server

To enable this returner the minion will need the python client for redis installed and the following values configured in the minion or master config, these are the defaults:

redis.db: '0'
redis.host: 'salt'
redis.port: 6379

Alternative configuration values can be used by prefacing the configuration. Any values not found in the alternative configuration will be pulled from the default location:

alternative.redis.db: '0'
alternative.redis.host: 'salt'
alternative.redis.port: 6379

To use the redis returner, append `--return redis` to the salt command.

salt '*' test.ping --return redis

To use the alternative configuration, append `--return_config alternative` to the salt command.

New in version 2015.5.0.

salt '*' test.ping --return redis --return_config alternative

salt.returners.redis_return.get_fun(fun)
  Return a dict of the last function called for all minions

salt.returners.redis_return.get_jid(jid)
  Return the information returned when the specified job id was executed

salt.returners.redis_return.get_jids()
  Return a list of all job ids

salt.returners.redis_return.get_load(jid)
  Return the load data that marks a specified jid

salt.returners.redis_return.get_minions()
  Return a list of minions
salt.returners.redis_return.prep_jid(nocache=False, passed_jid=None)
Do any work necessary to prepare a JID, including sending a custom id

salt.returners.redis_return.returner(ret)
Return data to a redis data store

salt.returners.redis_return.save_load(jid, load)
Save the load to the specified jid

class salt.returners.sentry_return

Salt returner that report execution results back to sentry. The returner will inspect the payload to identify errors and flag them as such.

Pillar needs something like:
raven:
    servers:
    - http://192.168.1.1
    - https://sentry.example.com
    public_key: deadbeefdeadbeefdeadbeefdeadbeef
    secret_key: beefdeadbeefdeadbeefdeadbeefdeadbeefdead
    project: 1
    tags:
    - os
    - master
    - saltversion
    - cpuarch

and https://pypi.python.org/pypi/raven installed

The tags list (optional) specifies grains items that will be used as sentry tags, allowing tagging of events in the sentry UI.

salt.returners.sentry_return.prep_jid(nocache=False, passed_jid=None)
Do any work necessary to prepare a JID, including sending a custom id

salt.returners.sentry_return.returner(ret)
Log outcome to sentry. The returner tries to identify errors and report them as such. All other messages will be reported at info level.

class salt.returners.slack_returner

Return salt data via slack

New in version 2015.5.0.

The following fields can be set in the minion conf file:

slack.channel (required)
slack.api_key (required)
slack.username (required)
slack.as_user (required to see the profile picture of your bot)
slack.profile (optional)

Alternative configuration values can be used by prefacing the configuration. Any values not found in the alternative configuration will be pulled from the default location:
Slack settings may also be configured as:

```python
slack:
    channel: RoomName
    api_key: xxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx
    username: user
    as_user: true

alternative.slack:
    room_id: RoomName
    api_key: xxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx
    from_name: user@email.com

slack_profile:
    api_key: xxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx
    from_name: user@email.com

slack:
    profile: slack_profile
    channel: RoomName

alternative.slack:
    profile: slack_profile
    channel: RoomName
```

To use the Slack returner, append `--return slack` to the salt command.

```bash
salt '*' test.ping --return slack
```

To use the alternative configuration, append `--return_config alternative` to the salt command.

```bash
salt '*' test.ping --return slack --return_config alternative
```

`salt.returners.slack_returner.returner(ret)`

Send an slack message with the data

`salt.returners.sms_return`

Return data by SMS.

New in version 2015.5.0.

- **maintainer**  Damian Myerscough
- **maturity**  new
- **depends**  twilio
- **platform**  all

To enable this returner the minion will need the python twilio library installed and the following values configured in the minion or master config:
twilio.sid: 'XXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXX'
twilio.token: 'XXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXX'
twilio.to: '+1415XXXXXXX'
twilio.from: '+1650XXXXXXX'

To use the sms returner, append `--return sms` to the salt command.

```shell
salt '*' test.ping --return sms
```

```python
salt.returners.sms_return.returner(ret)

Return a response in an SMS message
```

```python
salt.returners.smtp_return

Return salt data via email
```

The following fields can be set in the minion conf file:

- smtp.from (required)
- smtp.to (required)
- smtp.host (required)
- smtp.port (optional, defaults to 25)
- smtp.username (optional)
- smtp.password (optional)
- smtp.tls (optional, defaults to False)
- smtp.subject (optional, but helpful)
- smtp.gpgowner (optional)
- smtp.fields (optional)
- smtp.template (optional)
- smtp.renderer (optional)

Alternative configuration values can be used by prefacing the configuration. Any values not found in the alternative configuration will be pulled from the default location:

```python
alternative.smtp.from
alternative.smtp.to
alternative.smtp.host
alternative.smtp.port
alternative.smtp.username
alternative.smtp.password
alternative.smtp.tls
alternative.smtp.subject
alternative.smtp.gpgowner
alternative.smtp.fields
alternative.smtp.template
alternative.smtp.renderer
```

There are a few things to keep in mind:

- If a username is used, a password is also required. It is recommended (but not required) to use the TLS setting when authenticating.
- You should at least declare a subject, but you don’t have to.
- The use of encryption, i.e. setting gpgowner in your settings, requires python-gnupg to be installed.
- The field gpgowner specifies a user’s ~/.gpg directory. This must contain a gpg public key matching the address the mail is sent to. If left unset, no encryption will be used.
Smtp Documentation, Release 2015.8.0

- smtp.fields lets you include the value(s) of various fields in the subject line of the email. These are comma-delimited. For instance:

```bash
smtp.fields: id,fun
```

...will display the id of the minion and the name of the function in the subject line. You may also use `jid` (the job id), but it is generally recommended not to use `return`, which contains the entire return data structure (which can be very large). Also note that the subject is always unencrypted.

To use the SMTP returner, append `--return smtp` to the salt command.

```bash
salt '*' test.ping --return smtp
```

To use the alternative configuration, append `--return_config alternative` to the salt command.

New in version 2015.5.0.

```bash
salt '*' test.ping --return smtp --return_config alternative
```

salt.returners.smtp_return.prep_jid(nocache=False, passed_jid=None)
Do any work necessary to prepare a JID, including sending a custom id

salt.returners.smtp_return.returner(ret)
Send an email with the data

salt.returners.sqlite3

Insert minion return data into a sqlite3 database

 maintainer Mickey Malone <mickey.malone@gmail.com>
maturity New
depends None
platform All

SQLite is a serverless database that lives in a single file. In order to use this returner the database file must exist, have the appropriate schema defined, and be accessible to the user whom the minion process is running as. This returner requires the following values configured in the master or minion config:

```bash
returner.sqlite3.database: /usr/lib/salt/salt.db
returner.sqlite3.timeout: 5.0
```

Alternative configuration values can be used by prefacing the configuration. Any values not found in the alternative configuration will be pulled from the default location:

```bash
alternative.returner.sqlite3.database: /usr/lib/salt/salt.db
alternative.returner.sqlite3.timeout: 5.0
```

Use the commands to create the sqlite3 database and tables:

```bash
sqlite3 /usr/lib/salt/salt.db << EOF
CREATE TABLE jids (   jid TEXT PRIMARY KEY,   load TEXT NOT NULL
```

1522 Chapter 31. Reference
```sql
CREATE TABLE salt_returns (
    fun TEXT KEY,
    jid TEXT KEY,
    id TEXT KEY,
    fun_args TEXT,
    date TEXT NOT NULL,
    full_ret TEXT NOT NULL,
    success TEXT NOT NULL
);
EOF
```

To use the sqlite returner, append `--return sqlite3` to the salt command.

```
salt '*' test.ping --return sqlite3
```

To use the alternative configuration, append `--return_config alternative` to the salt command.

New in version 2015.5.0.

```
salt '*' test.ping --return sqlite3 --return_config alternative
```

```
salt.returners.sqlite3_return.get_fun(fun)
    Return a dict of the last function called for all minions

salt.returners.sqlite3_return.get_jid(jid)
    Return the information returned from a specified jid

salt.returners.sqlite3_return.get_jids()
    Return a list of all job ids

salt.returners.sqlite3_return.get_load(jid)
    Return the load from a specified jid

salt.returners.sqlite3_return.get_minions()
    Return a list of minions

salt.returners.sqlite3_return.prep_jid(nocache=False, passed_jid=None)
    Do any work necessary to prepare a JID, including sending a custom id

salt.returners.sqlite3_return.returner(ret)
    Insert minion return data into the sqlite3 database

salt.returners.sqlite3_return.save_load(jid, load)
    Save the load to the specified jid

salt.returners.syslog_return

Return data to the host operating system's syslog facility

Required python modules: syslog, json

The syslog returner simply reuses the operating system's syslog facility to log return data

To use the syslog returner, append `--return syslog` to the salt command.
"salt '*' test.ping --return syslog"

**Note:** Syslog server implementations may have limits on the maximum record size received by the client. This may lead to job return data being truncated in the syslog server's logs. For example, for rsyslog on RHEL-based systems, the default maximum record size is approximately 2KB (which return data can easily exceed). This is configurable in rsyslog.conf via the $MaxMessageSize config parameter. Please consult your syslog implementation's documentation to determine how to adjust this limit.

```python
salt.returners.syslog_return.prep_jid(nocache=False, passed_jid=None)
```

Do any work necessary to prepare a JID, including sending a custom id

```python
salt.returners.syslog_return.returner(ret)
```

Return data to the local syslog

**salt.returners.xmpp_return**

Return salt data via xmpp

The following fields can be set in the minion conf file:

- `xmpp.jid` (required)
- `xmpp.password` (required)
- `xmpp.recipient` (required)
- `xmpp.profile` (optional)

Alternative configuration values can be used by prefacing the configuration. Any values not found in the alternative configuration will be pulled from the default location:

- `xmpp.jid`
- `xmpp.password`
- `xmpp.recipient`
- `xmpp.profile`

XMPP settings may also be configured as:

```python
xmpp:
  jid: user@xmpp.domain.com/resource
  password: password
  recipient: user@xmpp.example.com
```

```python
alternative.xmpp:
  jid: user@xmpp.domain.com/resource
  password: password
  recipient: someone@xmpp.example.com
```

```python
xmpp_profile:
  jid: user@xmpp.domain.com/resource
  password: password
```

```python
xmpp:
  profile: xmpp_profile
  recipient: user@xmpp.example.com
```

```python
alternative.xmpp:
  profile: xmpp_profile
  recipient: someone-else@xmpp.example.com
```
To use the XMPP returner, append `--return xmpp` to the salt command.

```bash
salt '*' test.ping --return xmpp
```

To use the alternative configuration, append `--return_config alternative` to the salt command.

New in version 2015.5.0.

```bash
salt '*' test.ping --return xmpp --return_config alternative
```

class `salt.returners.xmpp_return`.SendMsgBot(jid, password, recipient, msg)

```python
start(event)
```

class `salt.returners.xmpp_return`.returner(ret)

Send an xmpp message with the data

### 31.24 Full list of builtin roster modules

<table>
<thead>
<tr>
<th>Module</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ansible</td>
<td>Read in an Ansible inventory file or script</td>
</tr>
<tr>
<td>cache</td>
<td>Use the minion cache on the master to derive IP addresses based on minion ID.</td>
</tr>
<tr>
<td>cloud</td>
<td>Use the cloud cache on the master to derive IPv4 addresses based on minion ID.</td>
</tr>
<tr>
<td>clustershell</td>
<td>This roster resolves hostname in a pdsh/clustershell style.</td>
</tr>
<tr>
<td>flat</td>
<td>Read in the roster from a flat file using the renderer system</td>
</tr>
<tr>
<td>scan</td>
<td>Scan a netmask or ipaddr for open ssh ports</td>
</tr>
</tbody>
</table>

#### 31.24.1 salt.roster.ansible

Read in an Ansible inventory file or script

Flat inventory files should be in the regular ansible inventory format.

```
[servers]
salt.gtmanfred.com ansible_ssh_user=gtmanfred ansible_ssh_host=127.0.0.1 ansible_ssh_port=22 ansible_ssh_pass='password'

[desktop]
home ansible_ssh_user=gtmanfred ansible_ssh_host=12.34.56.78 ansible_ssh_port=23 ansible_ssh_pass='password'

[computers:children]
desktop
servers

[names:vars]
http_port=80
```

then salt-ssh can be used to hit any of them

```
[~]# salt-ssh all test.ping
salt.gtmanfred.com: True
desktop: True
home: True

[~]# salt-ssh desktop test.ping
home: True
```

31.24. Full list of builtin roster modules
There is also the option of specifying a dynamic inventory, and generating it on the fly

```bash
#!/bin/bash
echo '{
  "servers": {
    "hosts": [
      "salt.gtmanfred.com"
    ],
  },
  "desktop": {
    "hosts": [
      "home"
    ],
  },
  "computers": {
    "hosts":{},
    "children": [
      "desktop",
      "servers"
    ],
  },
  "_meta": {
    "hostvars": {
      "salt.gtmanfred.com": {
        "ansible_ssh_user": "gtmanfred",
        "ansible_ssh_host": "127.0.0.1",
        "ansible_sudo_pass": "password",
        "ansible_ssh_port": 22
      },
      "home": {
        "ansible_ssh_user": "gtmanfred",
        "ansible_ssh_host": "12.34.56.78",
        "ansible_sudo_pass": "password",
        "ansible_ssh_port": 23
      }
    }
  }
}'
```

This is the format that an inventory script needs to output to work with ansible, and thus here.

Any of the [groups] or direct hostnames will return. The `all' is special, and returns everything.

```python
class salt.roster.ansible.Inventory(tgt, tgt_type='glob', inventory_file='/etc/salt/roster')
    Matcher for static inventory files
class salt.roster.ansible.Script(tgt, tgt_type='glob', inventory_file='/etc/salt/roster')
```
Matcher for Inventory scripts

class salt.roster.ansible.Target

    get_glob()
    Return minions that match via glob

targets()
    Execute the correct tgt_type routine and return

salt.roster.ansible.targets(tgt, tgt_type='glob', **kwargs)
    Return the targets from the ansible inventory file Default: /etc/salt/roster

31.24.2 salt.roster.cache

Use the minion cache on the master to derive IP addresses based on minion ID.
Currently only contains logic to return an IPv4 address; does not handle IPv6, or authentication (passwords, keys, etc).

It is possible to configure this roster to prefer a particular type of IP over another. To configure the order, set the roster_order in the master config file. The default for this is:

    roster_order:
    - public
    - private
    - local

    salt.roster.cache.extract_ipv4(roster_order, ipv4)
    Extract the preferred IP address from the ipv4 grain

    salt.roster.cache.targets(tgt, tgt_type='glob', **kwargs)
    Return the targets from the flat yaml file, checks opts for location but defaults to /etc/salt/roster

31.24.3 salt.roster.cloud

Use the cloud cache on the master to derive IPv4 addresses based on minion ID.

This roster requires that the minion in question was created using at least the 2015.5.0 version of Salt Cloud. Starting with the 2015.5.0 release, Salt Cloud maintains an index of minions that it creates and deletes. This index tracks the provider and profile configuration used to provision the minion, including authentication information. So long as this configuration remains current, it can be used by Salt SSH to log into any minion in the index.

    salt.roster.cloud.extract_ipv4(roster_order, ipv4)
    Extract the preferred IP address from the ipv4 grain

    salt.roster.cloud.targets(tgt, tgt_type='glob', **kwargs)
    Return the targets from the flat yaml file, checks opts for location but defaults to /etc/salt/roster

31.24.4 salt.roster.clustershell

This roster resolves hostname in a pdsh/clustershell style.

    depends clustershell, https://github.com/cea-hpc/clustershell

When you want to use host globs for target matching, use --roster clustershell. For example:
salt-ssh --roster clustershell 'server_[1-10,21-30],test_server[5,7,9]' test.ping

salt.roster.clustershell.targets(tgt, tgt_type='glob', **kwargs)
    Return the targets

31.24.5 salt.roster.flat

Read from the roster file using the renderers system

class salt.roster.flat.RosterMatcher (raw, tgt, tgt_type, ipv='ipv4')
    Matcher for the roster data structure

    get_data (minion)
        Return the configured ip

    ret_glob_minions()
        Return minions that match via glob

    ret_list_minions()
        Return minions that match via list

    ret_pcre_minions()
        Return minions that match via pcre

    targets()
        Execute the correct tgt_type routine and return

salt.roster.flat.targets(tgt, tgt_type='glob', **kwargs)
    Return the targets from the flat yaml file, checks opts for location but defaults to /etc/salt/roster

31.24.6 salt.roster.scan

Scan a netmask or ipaddr for open ssh ports

class salt.roster.scan.RosterMatcher (tgt, tgt_type)
    Matcher for the roster data structure

    targets()
        Return ip addrs based on netmask, sitting in the `glob` spot because it is the default

salt.roster.scan.targets(tgt, tgt_type='glob', **kwargs)
    Return the targets from the flat yaml file, checks opts for location but defaults to /etc/salt/roster

31.25 Salt Runners

Salt runners are convenience applications executed with the salt-run command.
Salt runners work similarly to Salt execution modules however they execute on the Salt master itself instead of remote Salt minions.
A Salt runner can be a simple client call or a complex application.

<td>test</td>
<td>This runner is used only for test purposes and servers no production purpose</td>
</tr>
<tr>
<td>thin</td>
<td>The thin runner is used to manage the salt thin systems.</td>
</tr>
<tr>
<td>virt</td>
<td>Control virtual machines via Salt</td>
</tr>
<tr>
<td>winrepo</td>
<td>Runner to manage Windows software repo</td>
</tr>
</tbody>
</table>

#### salt.runners.cache

Return cached data from minions

- `salt.runners.cache.clear_all(tgt=None, expr_form='glob')`
  - Clear the cached pillar, grains, and mine data of the targeted minions
  - CLI Example:
    ```
    salt-run cache.clear_all
    ```

- `salt.runners.cache.clear_grains(tgt=None, expr_form='glob')`
  - Clear the cached grains data of the targeted minions
  - CLI Example:
    ```
    salt-run cache.clear_grains
    ```

- `salt.runners.cache.clear_mine(tgt=None, expr_form='glob')`
  - Clear the cached mine data of the targeted minions
  - CLI Example:
salt-run cache.clear_mine

salt.runners.cache.clear_mine_func(tgt=None, expr_form='glob', clear_mine_func_flag=None)
    Clear the cached mine function data of the targeted minions
    CLI Example:
    
salt-run cache.clear_mine_func tgt='*' clear_mine_func='network.interfaces'

salt.runners.cache.clear_pillar(tgt=None, expr_form='glob')
    Clear the cached pillar data of the targeted minions
    CLI Example:
    
salt-run cache.clear_pillar

salt.runners.cache.grains(tgt=None, expr_form='glob', outputter=None, **kwargs)
    Return cached grains of the targeted minions
    CLI Example:
    
salt-run cache.grains

salt.runners.cache.mine(tgt=None, expr_form='glob', outputter=None, **kwargs)
    Return cached mine data of the targeted minions
    CLI Example:
    
salt-run cache.mine

salt.runners.cache.pillar(tgt=None, expr_form='glob', outputter=None, **kwargs)
    Return cached pillars of the targeted minions
    CLI Example:
    
salt-run cache.pillar

salt.runners.cloud

The Salt Cloud Runner

This runner wraps the functionality of salt cloud making salt cloud routines available to all internal apis via the runner system

salt.runners.cloud.action(func=None, cloudmap=None, instances=None, provider=None, instance=None, **kwargs)
    Execute a single action on the given map/provider-instance

salt.runners.cloud.create(provider, instances, **kwargs)
    Create an instance using Salt Cloud
    CLI Example:
    
salt-run cloud.create my-ec2-config myinstance image=ami-1624987f size=t1.micro

salt.runners.cloud.destroy(instances)
    Destroy the named vm(s)

salt.runners.cloud.full_query(query_type='list_nodes_full')
    List all available cloud provider data
salt.runners.cloud.list_images(provider='all')
List cloud provider images for the given providers

salt.runners.cloud.list_locations(provider='all')
List cloud provider sizes for the given providers

salt.runners.cloud.list_sizes(provider='all')
List cloud provider sizes for the given providers

salt.runners.cloud.map_run(path, **kwargs)
Execute a salt cloud map file

salt.runners.cloud.profile(prof=None, instances=None, **kwargs)
Create a cloud vm with the given profile and instances, instances can be a list or comma-delimited string

CLI Example:
```bash
salt-run cloud.profile prof=my-ec2 instances=node1,node2,node3
```

salt.runners.cloud.query(query_type='list_nodes')
List cloud provider data for all providers

salt.runners.cloud.select_query(query_type='list_nodes_select')
List selected nodes

salt.runners.doc

A runner module to collect and display the inline documentation from the various module types

salt.runners.doc.execution()
Collect all the sys.doc output from each minion and return the aggregate

CLI Example:
```bash
salt-run doc.execution
```

salt.runners.doc.runner()
Return all inline documentation for runner modules

CLI Example:
```bash
salt-run doc.runner
```

salt.runners.doc.wheel()
Return all inline documentation for wheel modules

CLI Example:
```bash
salt-run doc.wheel
```

salt.runners.drac

Manage Dell DRAC from the Master
The login credentials need to be configured in the Salt master configuration file.

salt.runners.drac.poweroff(hostname, timeout=20)
Power server off

CLI Example:
salt.run drac.poweroff example.com

salt.runners.drac.poweron(hostname, timeout=20)
  Power server on
  CLI Example:
      salt-run drac.poweron example.com

salt.runners.drac.pxe(hostname, timeout=20)
  Connect to the Dell DRAC and have the boot order set to PXE and power cycle the system to PXE boot
  CLI Example:
      salt-run drac.pxe example.com

salt.runners.drac.reboot(hostname, timeout=20)
  Reboot a server using the Dell DRAC
  CLI Example:
      salt-run drac.reboot example.com

salt.runners.drac.version(hostname, timeout=20)
  Display the version of DRAC
  CLI Example:
      salt-run drac.version example.com

salt.runners.error

Error generator to enable integration testing of salt runner error handling
salt.runners.error.error(name=None, message='')
  If name is None Then return empty dict
  Otherwise raise an exception with __name__ from name, message from message
  CLI Example:
      salt-run error
      salt-run error.error name="Exception" message="This is an error."

salt.runners.f5

Runner to provide F5 Load Balancer functionality

  depends
    • pycontrol Python module

  configuration In order to connect to a F5 Load Balancer, you must specify in the Salt master configuration the currently available load balancers

      load_balancers:
        bigip1.example.com
        username: admin
        password: secret
bigip2.example.com:
  username: admin
  password: secret

class salt.runners.f5.F5Mgmt(lb, username, password)

  add_pool_member(name, port, pool_name)
  Add a node to a pool

  check_member_pool(member, pool_name)
  Check a pool member exists in a specific pool

  check_pool(name)
  Check to see if a pool exists

  check_virtualserver(name)
  Check to see if a virtual server exists

  create_pool(name, method='ROUND_ROBIN')
  Create a pool on the F5 load balancer

  create_vs(name, ip, port, protocol, profile, pool_name)
  Create a virtual server

  lbmethods()
  List all the load balancer methods

salt.runners.f5.add_pool_member(lb, name, port, pool_name)
  Add a node to a pool

  CLI Examples:
  
  salt-run f5.add_pool_member load_balancer 10.0.0.1 80 my_pool

salt.runners.f5.check_member_pool(lb, member, pool_name)
  Check a pool member exists in a specific pool

  CLI Examples:
  
  salt-run f5.check_member_pool load_balancer 10.0.0.1 my_pool

salt.runners.f5.check_pool(lb, name)
  Check to see if a pool exists

  CLI Examples:
  
  salt-run f5.check_pool load_balancer pool_name

salt.runners.f5.check_virtualserver(lb, name)
  Check to see if a virtual server exists

  CLI Examples:
  
  salt-run f5.check_virtualserver load_balancer virtual_server

salt.runners.f5.create_pool(lb, name, method='ROUND_ROBIN')
  Create a pool on the F5 load balancer

  CLI Examples:
  
  salt-run f5.create_pool load_balancer pool_name loadbalance_method
  salt-run f5.create_pool load_balancer my_pool ROUND_ROBIN
salt.runners.f5.create_vs(lb, name, ip, port, protocol, profile, pool_name)

Create a virtual server

CLI Examples:

```
salt-run f5.create_vs lb balancer vs_name 10.0.0.1 80 tcp http poolname
```

salt.runners.fileserver

Directly manage the Salt fileserver plugins

salt.runners.fileserver.clear_cache(backend=None)

New in version 2015.5.0.

Clear the fileserver cache from VCS fileserver backends (git, hg, svn). Executing this runner with no arguments will clear the cache for all enabled VCS fileserver backends, but this can be narrowed using the backend argument.

**backend** Only clear the update lock for the specified backend(s). If all passed backends start with a minus sign (-), then these backends will be excluded from the enabled backends. However, if there is a mix of backends with and without a minus sign (ex: backend=-roots,git) then the ones starting with a minus sign will be disregarded.

CLI Example:

```
salt-run fileserver.clear_cache
salt-run fileserver.clear_cache backend=git,hg
salt-run fileserver.clear_cache hg
salt-run fileserver.clear_cache -roots
```

salt.runners.fileserver.clear_lock(backend=None, remote=None)

New in version 2015.5.0.

Clear the fileserver update lock from VCS fileserver backends (git, hg, svn). This should only need to be done if a fileserver update was interrupted and a remote is not updating (generating a warning in the Master's log file). Executing this runner with no arguments will remove all update locks from all enabled VCS fileserver backends, but this can be narrowed by using the following arguments:

**backend** Only clear the update lock for the specified backend(s).

**remote** If not None, then any remotes which contain the passed string will have their lock cleared. For example, a remote value of github will remove the lock from all github.com remotes.

CLI Example:

```
salt-run fileserver.clear_lock
salt-run fileserver.clear_lock backend=git,hg
salt-run fileserver.clear_lock backend=git remote=github
salt-run fileserver.clear_lock remote=bitbucket
```

salt.runners.fileserver.dir_list(saltenv='base', backend=None, outputter=None)

Return a list of directories in the given environment

**saltenv** [base] The salt fileserver environment to be listed

**backend** Narrow fileserver backends to a subset of the enabled ones. If all passed backends start with a minus sign (-), then these backends will be excluded from the enabled backends. However, if there is a mix of backends with and without a minus sign (ex: backend=-roots,git) then the ones starting with a minus sign will be disregarded.

New in version 2015.5.0.
CLI Example:

```bash
salt-run fileserver.dir_list
salt-run fileserver.dir_list saltenv=prod
salt-run fileserver.dir_list saltenv=dev backend=git
salt-run fileserver.dir_list base hg,roots
salt-run fileserver.dir_list -git
```

**salt.runners.fileserver.empty_dir_list**

New in version 2015.5.0.

Return a list of empty directories in the given environment

**saltenv** [base] The salt fileserver environment to be listed

**backend** Narrow fileserver backends to a subset of the enabled ones. If all passed backends start with a minus sign (\(-\)), then these backends will be excluded from the enabled backends. However, if there is a mix of backends with and without a minus sign (ex: `backend=-roots,git`) then the ones starting with a minus sign will be disregarded.

**Note:** Some backends (such as `git` and `hg`) do not support empty directories. So, passing `backend=git` or `backend=hg` will result in an empty list being returned.

CLI Example:

```bash
salt-run fileserver.empty_dir_list
salt-run fileserver.empty_dir_list saltenv=prod
salt-run fileserver.empty_dir_list backend=roots
```

**salt.runners.fileserver.envs**

Return the available fileserver environments. If no backend is provided, then the environments for all configured backends will be returned.

**backend** Narrow fileserver backends to a subset of the enabled ones.

Changed in version 2015.5.0: If all passed backends start with a minus sign (\(-\)), then these backends will be excluded from the enabled backends. However, if there is a mix of backends with and without a minus sign (ex: `backend=-roots,git`) then the ones starting with a minus sign will be disregarded.

Additionally, fileserver backends can now be passed as a comma-separated list. In earlier versions, they needed to be passed as a python list (ex: `backend=[\'roots\', \'git\']")

CLI Example:

```bash
salt-run fileserver.envs
salt-run fileserver.envs backend=roots,git
salt-run fileserver.envs git
```

**salt.runners.fileserver.file_list**

Return a list of files from the salt fileserver

**saltenv** [base] The salt fileserver environment to be listed

**backend** Narrow fileserver backends to a subset of the enabled ones. If all passed backends start with a minus sign (\(-\)), then these backends will be excluded from the enabled backends. However, if there is a mix of backends with and without a minus sign (ex: `backend=-roots,git`) then the ones starting with a minus sign will be disregarded.

New in version 2015.5.0.

CLI Examples:
salt-run fileserver.file_list
salt-run fileserver.file_list saltenv=prod
salt-run fileserver.file_list saltenv=dev backend=git
salt-run fileserver.file_list base hg,roots
salt-run fileserver.file_list -git

salt.runners.fileserver.lock(backend=None, remote=None)

New in version 2015.5.0.

Set a fileserver update lock for VCS fileserver backends (git, hg, svn).

Note: This will only operate on enabled backends (those configured in fileserver_backend).

backend Only set the update lock for the specified backend(s).
remote If not None, then any remotes which contain the passed string will have their lock cleared. For example, a remote value of *github.com* will remove the lock from all github.com remotes.

CLI Example:

salt-run fileserver.lock
salt-run fileserver.lock backend=git,hg
salt-run fileserver.lock backend=git remote='*github.com*'
salt-run fileserver.lock remote=bitbucket

salt.runners.fileserver.symlink_list(saltenv='base', backend=None, outputter=None)

Return a list of symlinked files and dirs

saltenv [base] The salt fileserver environment to be listed

backend Narrow fileserver backends to a subset of the enabled ones. If all passed backends start with a minus sign (-), then these backends will be excluded from the enabled backends. However, if there is a mix of backends with and without a minus sign (ex: backend=-roots,git) then the ones starting with a minus sign will be disregarded.

New in version 2015.5.0.

CLI Example:

salt-run fileserver.symlink_list
salt-run fileserver.symlink_list saltenv=prod
salt-run fileserver.symlink_list saltenv=dev backend=git
salt-run fileserver.symlink_list base hg,roots
salt-run fileserver.symlink_list -git

salt.runners.fileserver.update(backend=None)

Update the fileserver cache. If no backend is provided, then the cache for all configured backends will be updated.

backend Narrow fileserver backends to a subset of the enabled ones.

Changed in version 2015.5.0: If all passed backends start with a minus sign (-), then these backends will be excluded from the enabled backends. However, if there is a mix of backends with and without a minus sign (ex: backend=-roots,git) then the ones starting with a minus sign will be disregarded.

Additionally, fileserver backends can now be passed as a comma-separated list. In earlier versions, they needed to be passed as a python list (ex: backend=['roots', 'git'])

CLI Example:
salt-run fileserver.update
salt-run fileserver.update backend=roots,git

**salt.runners.git_pillar**

Directly manage the salt git_pillar plugin

```python
salt.runners.git_pillar.update(branch, repo)
    Execute an update for the configured git fileserver backend for Pillar
```

**CLI Example:**

```bash
salt-run git_pillar.update branch='branch' repo='location'
```

**salt.runners.http**

Module for making various web calls. Primarily designed for webhooks and the like, but also useful for basic http testing.

New in version 2015.5.0.

```python
salt.runners.http.query(url, output=True, **kwargs)
    Query a resource, and decode the return data
```

**CLI Example:**

```bash
salt-run http.query http://somelink.com/
salt-run http.query http://somelink.com/ method=POST params='key1=val1&key2=val2'
salt-run http.query http://somelink.com/ method=POST data='<xml>somecontent</xml>'
```

**salt.runners.http.update_ca_bundle**  
(target=None, source=None, merge_files=None)

Update the local CA bundle file from a URL

New in version 2015.5.0.

**CLI Example:**

```bash
salt-run http.update_ca_bundle
tsalt-run http.update_ca_bundle target=/path/to/cacerts.pem
tsalt-run http.update_ca_bundle source=https://example.com/cacerts.pem
```

If the `target` is not specified, it will be pulled from the `ca_cert` configuration variable available to the master. If it cannot be found there, it will be placed at `<<FILE_ROOTS>>/cacerts.pem`.

If the `source` is not specified, it will be pulled from the `ca_cert_url` configuration variable available to the master. If it cannot be found, it will be downloaded from the cURL website, using an http (not https) URL. **USING THE DEFAULT URL SHOULD BE AVOIDED!**

`merge_files` may also be specified, which includes a string or list of strings representing a file or files to be appended to the end of the CA bundle, once it is downloaded.

**CLI Example:**

```bash
salt-run http.update_ca_bundle merge_files=/path/to/mycert.pem
```
salt.runners.jobs

A convenience system to manage jobs, both active and already run

salt.runners.jobs.active(outputter=None, display_progress=False)
Return a report on all actively running jobs from a job id centric perspective
CLI Example:
salt-run jobs.active

salt.runners.jobs.last_run(ext_source=None, outputter=None, metadata=None, function=None, target=None, display_progress=False)
List all detectable jobs and associated functions
New in version 2015.8.0.
CLI Example:
salt-run jobs.last_run
salt-run jobs.last_run target=nodename
data-run jobs.last_run function='cmd.run'
salt-run jobs.last_run metadata="{'foo': 'bar'}"

salt.runners.jobs.list_job(jid, ext_source=None, outputter=None)
List a specific job given by its jid
CLI Example:
salt-run jobs.list_job 20130916125524463507

salt.runners.jobs.list_jobs(ext_source=None, outputter=None, search_metadata=None, search_function=None, search_target=None, start_time=None, end_time=None, display_progress=False)
List all detectable jobs and associated functions
ext_source The external job cachet to use. Default: None.
search_metadata Search the metadata of a job for the provided string of dictionary. Default: 'None'.
search_function Search the function of a job for the provided string. Default: 'None'.
search_target Search the target of a job for the provided minion name. Default: 'None'.
start_time Search for jobs where the start time of the job is greater than or equal to the provided time stamp. Any timestamp supported by the Dateutil (required) module can be used. Default: 'None'.
end_time Search for jobs where the start time of the job is less than or equal to the provided time stamp. Any timestamp supported by the Dateutil (required) module can be used. Default: 'None'.

CLI Example:
salt-run jobs.list_jobs
salt-run jobs.list_jobs search_function='test.*' search_target='localhost' search_metadata='"{"bar": "foo"}"'
salt-run jobs.list_jobs start_time='2015, Mar 16 19:00' end_time='2015, Mar 18 22:00'"'

salt.runners.jobs.list_jobs_filter(count, filter_find_job=True, ext_source=None, outputter=None, display_progress=False)
List all detectable jobs and associated functions
The external job cache to use. Default: None.

CLI Example:
```
salt-run jobs.list_jobs_filter 50
salt-run jobs.list_jobs_filter 100 filter_find_job=False
```

salt.runners.jobs.lookup_jid(jid, ext_source=None, returned=True, missing=False, outputter=None, display_progress=False)

Return the printout from a previously executed job.

**jid** The jid to look up.

**ext_source** The external job cache to use. Default: None.

**returned** When set to True, adds the minions that did return from the command. Default: True.

New in version 2015.8.0.

**missing** When set to True, adds the minions that did NOT return from the command. Default: False.

**display_progress** Displays progress events when set to True. Default: False.

New in version 2015.5.0.

CLI Example:
```
salt-run jobs.lookup_jid 20130916125524463507
salt-run jobs.lookup_jid 20130916125524463507 outputter=highstate
```

salt.runners.jobs.print_job(jid, ext_source=None, outputter=None)

Print a specific job's detail given by it's jid, including the return data.

CLI Example:
```
salt-run jobs.print_job 20130916125524463507
```

**salt.runners.launchd**

Manage launchd plist files.

salt.runners.launchd.write_launchd_plist(program)

Write a launchd plist for managing salt-master or salt-minion

CLI Example:
```
salt-run launchd.write_launchd_plist salt-master
```

**salt.runners.lxc**

Control Linux Containers via Salt

**depends** lxc execution module

salt.runners.lxc.cloud_init(names, host=None, quiet=False, **kwargs)

Wrapper for using lxc.init in saltcloud compatibility mode.

**names** Name of the containers, supports a single name or a comma delimited list of names.

**host** Minion to start the container on. Required.
**path** path to the container parent default: `/var/lib/lxc` (system default)

New in version 2015.8.0.

**saltcloud_mode** init the container with the saltcloud opts format instead

```python
salt.runners.lxc.find_guest(name, quiet=False, path=None)
```

Returns the host for a container.

**path** path to the container parent default: `/var/lib/lxc` (system default)

New in version 2015.8.0.

```python
salt-run lxc.find_guest name
```

```python
salt.runners.lxc.find_guests(names, path=None)
```

Return a dict of hosts and named guests

**path** path to the container parent default: `/var/lib/lxc` (system default)

New in version 2015.8.0.

```python
salt-run lxc.find_guests name
```

```python
salt.runners.lxc.freeze(name, quiet=False, path=None)
```

Freeze the named container

**path** path to the container parent default: `/var/lib/lxc` (system default)

New in version 2015.8.0.

```python
salt-run lxc.freeze name
```

```python
salt.runners.lxc.info(name, quiet=False, path=None)
```

Returns information about a container.

**path** path to the container parent default: `/var/lib/lxc` (system default)

New in version 2015.8.0.

```python
salt-run lxc.info name
```

```python
salt.runners.lxc.init(names, host=None, saltcloud_mode=False, quiet=False, **kwargs)
```

Initialize a new container

```python
salt-run lxc.init name host=minion_id [cpuset=cgroups_cpuset] \n[cpushare=cgroups_cpushare] [memory=cgroups_memory] \n[template=lxc_template_name] [clone=original name] \n[profile=lxc_profile] [network_profile=network_profile] \n[nic=network_profile] [nic_opts=nic_opts] \n[start=(true|false)] [seed=(true|false)] \n[install=(true|false)] [config=minion_config] \n[snapshot=(true|false)]
```

**names** Name of the containers, supports a single name or a comma delimited list of names.

**host** Minion on which to initialize the container (required)

**path** path to the container parent default: `/var/lib/lxc` (system default)

New in version 2015.8.0.

**saltcloud_mode** init the container with the saltcloud opts format instead See lxc.init_interface module documentation

**cpuset** cgroups cpuset.
cpushare  cgroups cpu shares.

memory  cgroups memory limit, in MB

Changed in version 2015.5.0: If no value is passed, no limit is set. In earlier Salt versions, not passing this value causes a 1024MB memory limit to be set, and it was necessary to pass `memory=0` to set no limit.

template  Name of LXC template on which to base this container

clone  Clone this container from an existing container

profile  A LXC profile (defined in config or pillar).

network_profile  Network profile to use for the container

New in version 2015.5.2.

nic  Deprecated since version 2015.5.0: Use `network_profile` instead

nic_opts  Extra options for network interfaces. E.g.:

```json
{"eth0": {"mac": "aa:bb:cc:dd:ee:ff", "ipv4": "10.1.1.1", "ipv6": "2001:db8::ff00:42:8329"}}
```

start  Start the newly created container.

seed  Seed the container with the minion config and autsign its key. Default: true

install  If salt-minion is not already installed, install it. Default: true

config  Optional config parameters. By default, the id is set to the name of the container.

```
salt.runners.lxc.list(host=None, quiet=False, path=None)
List defined containers (running, stopped, and frozen) for the named (or all) host(s).

path  path to the container parent default: /var/lib/lxc (system default)

New in version 2015.8.0.

salt-run lxc.list [host=minion_id]
```

```
salt.runners.lxc.purge(name, delete_key=True, quiet=False, path=None)
Purge the named container and delete its minion key if present. WARNING: Destroys all data associated with the container.

path  path to the container parent default: /var/lib/lxc (system default)

New in version 2015.8.0.

salt-run lxc.purge name
```

```
salt.runners.lxc.start(name, quiet=False, path=None)
Start the named container.

path  path to the container parent default: /var/lib/lxc (system default)

New in version 2015.8.0.

salt-run lxc.start name
```

```
salt.runners.lxc.stop(name, quiet=False, path=None)
Stop the named container.

path  path to the container parent default: /var/lib/lxc (system default)

New in version 2015.8.0.
```
salt runners.lxc.unfreeze(name, quiet=False, path=None)

Unfreeze the named container.

path: path to the container parent default: /var/lib/lxc (system default)

New in version 2015.8.0.

salt runners.lxc.unfreeze name

salt runners.manage

General management functions for salt, tools like seeing what hosts are up and what hosts are down.

salt runners.manage.alived(subset=None, show_ipv4=False)

New in version 2015.8.0.

Print a list of all minions that are up according to Salt's presence detection (no commands will be sent to minions).

subset [None] Pass a CIDR range to filter minions by IP address.

show_ipv4 [False] Also show the IP address each minion is connecting from.

CLI Example:
salt-run manage.alived

salt runners.manage.allowed(subset=None, show_ipv4=False)

New in version 2015.8.0.

Print a list of all minions that are up according to Salt's presence detection (no commands will be sent to minions).

subset [None] Pass a CIDR range to filter minions by IP address.

show_ipv4 [False] Also show the IP address each minion is connecting from.

CLI Example:
salt-run manage.allowed

salt runners.manage.bootstrap(version='develop', script=None, hosts=' ', root_user=True)

Bootstrap minions with salt-bootstrap.

version [develop] Git tag of version to install

script [https://bootstrap.saltstack.com] Script to execute

hosts Comma-separated hosts [example: hosts='host1.local,host2.local']

root_user [True] Prepend root@ to each host.

CLI Example:
salt-run manage.bootstrap hosts='host1,host2'
salt-run manage.bootstrap hosts='host1,host2' version='v0.17'
salt-run manage.bootstrap hosts='host1,host2' version='v0.17' script='https://bootstrap.saltstack.com/develop'
salt-run manage.bootstrap hosts='ec2-user@host1,ec2-user@host2' root_user=False
salt.runners.manage.bootstrap_psexec(hosts=’, master=None, version=None, arch='win32', installer_url=None, username=None, password=None)

Bootstrap Windows minions via PsExec.

**hosts** Comma separated list of hosts to deploy the Windows Salt minion.

**master** Address of the Salt master passed as an argument to the installer.

**version** Point release of installer to download. Defaults to the most recent.

**arch** Architecture of installer to download. Defaults to win32.

**installer_url** URL of minion installer executable. Defaults to the latest version from https://repo.saltstack.com/windows/

**username** Optional user name for login on remote computer.

**password** Password for optional username. If omitted, PsExec will prompt for one to be entered for each host.

CLI Example:

```bash
salt-run manage.bootstrap_psexec hosts='host1,host2'
salt-run manage.bootstrap_psexec hosts='host1,host2' version='0.17' username='DOMAIN\Administrator'
salt-run manage.bootstrap_psexec hosts='host1,host2' installer_url='http://exampledomain/salt-installer.exe'
```

salt.runners.manage.down(removekeys=False)

Print a list of all the down or unresponsive salt minions Optionally remove keys of down minions

CLI Example:

```bash
salt-run manage.down
salt-run manage.down removekeys=True
```

salt.runners.manage.get_stats(estate=None, stack='road')

Print the stack stats

**estate** [None] The name of the target estate. Master stats would be requested by default

**stack** ['road'] Show stats on either road or lane stack Allowed values are `road` or `lane`.

CLI Example:

```bash
salt-run manage.get_stats [estate=alpha_minion] [stack=lane]
```

salt.runners.manage.joined(subset=None, show_ipv4=False)

New in version 2015.8.0.

Print a list of all minions that are up according to Salt’s presence detection (no commands will be sent to minions)

**subset** [None] Pass in a CIDR range to filter minions by IP address.

**show_ipv4** [False] Also show the IP address each minion is connecting from.

CLI Example:

```bash
salt-run manage.joined
```

salt.runners.manage.key_regen()

This routine is used to regenerate all keys in an environment. This is invasive! ALL KEYS IN THE SALT ENVIRONMENT WILL BE REGENERATED‼

The key_regen routine sends a command out to minions to revoke the master key and remove all minion keys, it then removes all keys from the master and prompts the user to restart the master. The minions will all reconnect and keys will be placed in pending.
After the master is restarted and minion keys are in the pending directory execute a `salt-key -A` command to accept the regenerated minion keys.

The master must be restarted within 60 seconds of running this command or the minions will think there is something wrong with the keys and abort.

Only Execute this runner after upgrading minions and master to 0.15.1 or higher!

CLI Example:

```
salt-run manage.key_regen
```

```
salt.runners.manage.lane_stats(estate=None)
Print the estate manor lane stack stats

estate [None] The name of the target estate. Master stats would be requested by default

CLI Example:

```
salt-run manage.lane_stats [estate=alpha_minion]
```

```
salt.runners.manage.list_not_state(subset=None, show_ipv4=False, state=None)
New in version 2015.8.0.
Print a list of all minions that are NOT up according to Salt’s presence detection (no commands will be sent to minions)

subset [None] Pass in a CIDR range to filter minions by IP address.
show_ipv4 [False] Also show the IP address each minion is connecting from.
state ['available'] Show minions being in specific state that is one of 'available', 'joined', 'allowed', 'alived' or 'reaped'.

CLI Example:

```
salt-run manage.list_not_state
```

```
salt.runners.manage.list_state(subset=None, show_ipv4=False, state=None)
New in version 2015.8.0.
Print a list of all minions that are up according to Salt’s presence detection (no commands will be sent to minions)

subset [None] Pass in a CIDR range to filter minions by IP address.
show_ipv4 [False] Also show the IP address each minion is connecting from.
state ['available'] Show minions being in specific state that is one of 'available', 'joined', 'allowed', 'alived' or 'reaped'.

CLI Example:

```
salt-run manage.list_state
```

```
salt.runners.manage.not_alived(subset=None, show_ipv4=False)
New in version 2015.8.0.
Print a list of all minions that are NOT up according to Salt’s presence detection (no commands will be sent)

subset [None] Pass in a CIDR range to filter minions by IP address.
show_ipv4 [False] Also show the IP address each minion is connecting from.

CLI Example:

```
salt-run manage.not_alived

salt.runners.manage.not_allowed(subset=None, show_ipv4=False)

New in version 2015.8.0.
Print a list of all minions that are NOT up according to Salt's presence detection (no commands will be sent)

subset [None] Pass in a CIDR range to filter minions by IP address.
show_ipv4 [False] Also show the IP address each minion is connecting from.

CLI Example:
salt-run manage.not_allowed

salt.runners.manage.not_joined(subset=None, show_ipv4=False)

New in version 2015.8.0.
Print a list of all minions that are NOT up according to Salt's presence detection (no commands will be sent)

subset [None] Pass in a CIDR range to filter minions by IP address.
show_ipv4 [False] Also show the IP address each minion is connecting from.

CLI Example:
salt-run manage.not_joined

salt.runners.manage.not_present(subset=None, show_ipv4=False)

New in version 2015.5.0.
Print a list of all minions that are NOT up according to Salt's presence detection (no commands will be sent)

subset [None] Pass in a CIDR range to filter minions by IP address.
show_ipv4 [False] Also show the IP address each minion is connecting from.

CLI Example:
salt-run manage.not_present

salt.runners.manage.not_reaped(subset=None, show_ipv4=False)

New in version 2015.8.0.
Print a list of all minions that are NOT up according to Salt's presence detection (no commands will be sent)

subset [None] Pass in a CIDR range to filter minions by IP address.
show_ipv4 [False] Also show the IP address each minion is connecting from.

CLI Example:
salt-run manage.not_reaped

salt.runners.manage.present(subset=None, show_ipv4=False)

Print a list of all minions that are up according to Salt's presence detection (no commands will be sent to minions)

subset [None] Pass in a CIDR range to filter minions by IP address.
show_ipv4 [False] Also show the IP address each minion is connecting from.

CLI Example:
salt-run manage.present

salt.runners.manage.reaped(subset=None, show_ipv4=False)
   New in version 2015.8.0.
   Print a list of all minions that are up according to Salt’s presence detection (no commands will be sent to minions)
   subset [None] Pass in a CIDR range to filter minions by IP address.
   show_ipv4 [False] Also show the IP address each minion is connecting from.
   CLI Example:
   salt-run manage.reaped

salt.runners.manage.road_stats(estate=None)
   Print the estate road stack stats
   estate [None] The name of the target estate. Master stats would be requested by default
   CLI Example:
   salt-run manage.road_stats [estate=alpha_minion]

salt.runners.manage.safe_accept(target, expr_form='glob')
   Accept a minion’s public key after checking the fingerprint over salt-ssh
   CLI Example:
   salt-run manage.safe_accept my_minion
   salt-run manage.safe_accept minion1,minion2 expr_form=list

salt.runners.manage.status(output=True)
   Print the status of all known salt minions
   CLI Example:
   salt-run manage.status

salt.runners.manage.up()
   Print a list of all of the minions that are up
   CLI Example:
   salt-run manage.up

salt.runners.manage.versions()
   Check the version of active minions
   CLI Example:
   salt-run manage.versions

salt.runners.mine
A runner to access data from the salt mine

salt.runners.mine.get(tgt, fun, tgt_type='glob')
   Gathers the data from the specified minions’ mine, pass in the target, function to look up and the target type
   CLI Example:
salt-run mine.get 

### salt.runners.nacl

This runner helps create encrypted passwords that can be included in pillars.

**depends** libnacl, https://github.com/saltstack/libnacl

This is often useful if you wish to store your pillars in source control or share your pillar data with others that you trust. I don't advise making your pillars public regardless if they are encrypted or not.

The following configurations can be defined in the master config so your users can create encrypted passwords using the runner nacl:

```bash
cat /etc/salt/master.d/nacl.conf
nacl.config:
  key: None
  keyfile: /root/.nacl
```

Now with the config in the master you can use the runner nacl like:

```bash
salt-run nacl.enc 'data'
```

**salt.runners.nacl.dec(data, **kwargs)**

Takes a key generated from `nacl.keygen` and decrypt some data.

CLI Examples:

```bash
salt-run nacl.dec pEXHQM6cuaF7A=
salt-run nacl.dec data='pEXHQM6cuaF7A=' keyfile=/root/.nacl
salt-run nacl.dec data='pEXHQM6cuaF7A=' key='cKEzd4kXsbeCE7/nLTIqXwnU1ulg4NoeeYcCFpd9k='
```

**salt.runners.nacl.enc(data, **kwargs)**

Takes a key generated from `nacl.keygen` and encrypt some data.

CLI Examples:

```bash
salt-run nacl.enc datatoenc
salt-run nacl.enc datatoenc keyfile=/root/.nacl
salt-run nacl.enc datatoenc key='cKEzd4kXsbeCE7/nLTIqXwnU1ulg4NoeeYcCFpd9k='
```

**salt.runners.nacl.keygen(keyfile=None)**

Use libnacl to generate a private key

CLI Examples:

```bash
salt-run nacl.keygen
salt-run nacl.keygen keyfile=/root/.nacl
salt-run --out=newline_values_only nacl.keygen > /root/.nacl
```

### salt.runners.network

Network tools to run from the Master

**salt.runners.network.wol(mac, bcast='255.255.255.255', destport=9)**

Send a ”Magic Packet” to wake up a Minion

CLI Example:
salt.runners.network.wollist(\texttt{maclist, bcast=`255.255.255.255', destport=9})

Send a "Magic Packet" to wake up a list of Minions. This list must contain one MAC hardware address per line

CLI Example:

\begin{verbatim}
salt-run network.wollist `/path/to/maclist'
salt-run network.wollist `/path/to/maclist' 255.255.255.255 7
salt-run network.wollist `/path/to/maclist' 255.255.255.255 7
\end{verbatim}

salt.runners.pagerduty

Runner Module for Firing Events via PagerDuty

New in version 2014.1.0.

\textbf{configuration} This module can be used by specifying the name of a configuration profile in the master config.

For example:

\begin{verbatim}
my-pagerduty-account:
pagerduty.api_key: F3RbyjIVE43RFfWf2214
pagerduty.subdomain: mysubdomain
\end{verbatim}

salt.runners.pagerduty.create_event(service_key=None, description=None, details=None, incident_key=None, profile=None)

Create an event in PagerDuty. Designed for use in states.

CLI Example:

\begin{verbatim}
salt-run pagerduty.create_event <service_key> <description> <details> profile=my-pagerduty-account
\end{verbatim}

The following parameters are required:

\textbf{service_key} This key can be found by using pagerduty.list_services.

\textbf{description} This is a short description of the event.

\textbf{details} This can be a more detailed description of the event.

\textbf{profile} This refers to the configuration profile to use to connect to the PagerDuty service.

salt.runners.pagerduty.list_escalation_policies(profile=None, api_key=None)

List escalation policies belonging to this account

CLI Example:

\begin{verbatim}
salt-run pagerduty.list_policies my-pagerduty-account
salt-run pagerduty.list_escalation_policies my-pagerduty-account
\end{verbatim}

salt.runners.pagerduty.list_incidents(profile=None, api_key=None)

List incidents belonging to this account

CLI Example:

\begin{verbatim}
salt-run pagerduty.list_incidents my-pagerduty-account
\end{verbatim}
salt.runners.pagerduty.list_maintenance_windows(\texttt{profile=None, api\_key=None})
\begin{itemize}
\item List maintenance windows belonging to this account
\end{itemize}

CLI Example:
\begin{verbatim}
salt-run pagerduty.list_windows my-pagerduty-account
salt-run pagerduty.list_maintenance_windows my-pagerduty-account
\end{verbatim}

salt.runners.pagerduty.list_policies(\texttt{profile=None, api\_key=None})
\begin{itemize}
\item List escalation policies belonging to this account
\end{itemize}

CLI Example:
\begin{verbatim}
salt-run pagerduty.list_policies my-pagerduty-account
salt-run pagerduty.list_escalation_policies my-pagerduty-account
\end{verbatim}

salt.runners.pagerduty.list_schedules(\texttt{profile=None, api\_key=None})
\begin{itemize}
\item Listschedulesbelongingtothisaccount
\end{itemize}

CLI Example:
\begin{verbatim}
salt-run pagerduty.list_schedules my-pagerduty-account
\end{verbatim}

salt.runners.pagerduty.list_services(\texttt{profile=None, api\_key=None})
\begin{itemize}
\item Listservicesbelongingtothisaccount
\end{itemize}

CLI Example:
\begin{verbatim}
salt-run pagerduty.list_services my-pagerduty-account
\end{verbatim}

salt.runners.pagerduty.list_users(\texttt{profile=None, api\_key=None})
\begin{itemize}
\item Listusersbelongingtothisaccount
\end{itemize}

CLI Example:
\begin{verbatim}
salt-run pagerduty.list_users my-pagerduty-account
\end{verbatim}

salt.runners.pagerduty.list_windows(\texttt{profile=None, api\_key=None})
\begin{itemize}
\item List maintenance windows belonging to this account
\end{itemize}

CLI Example:
\begin{verbatim}
salt-run pagerduty.list_windows my-pagerduty-account
salt-run pagerduty.list_maintenance_windows my-pagerduty-account
\end{verbatim}

\textbf{salt.runners.pillar}

Functions to interact with the pillar compiler on the master

salt.runners.pillar.show_pillar(\texttt{minion='*', **kwargs})
\begin{itemize}
\item Returns the compiled pillar either of a specific minion or just the global available pillars. This function assumes that no minion has the id *.
\end{itemize}

CLI Example:
\begin{verbatim}
shows minion specific pillar:
salt-run pillar.show_pillar 'www.example.com'
\end{verbatim}

shows global pillar:
\begin{verbatim}
salt-run pillar.show_pillar
\end{verbatim}

shows global pillar for `dev' pillar environment:
API Example:

```python
import salt.config
import salt.runner
opts = salt.config.master_config('/etc/salt/master')
runner = salt.runner.RunnerClient(opts)
pillar = runner.cmd('pillar.show_pillar', [])
print(pillar)
```

```
salt.runners.pillar.show_top(minion=None, saltenv='base')
```

Returns the compiled top data for pillar for a specific minion. If no minion is specified, we use the first minion we find.

CLI Example:

```
salt-run pillar.show_top
```

---

**salt.runners.pkg**

Package helper functions using `salt.modules.pkg`

New in version 2015.8.0.

```
salt.runners.pkg.list_upgrades(jid, style='group', outputter='nested', ext_source=None)
```

Show list of available pkg upgrades using a specified format style

CLI Example:

```
salt-run pkg.list_upgrades jid=20141120114114417719 style=group
```

---

**salt.runners.queue**

General management and processing of queues.

This runner facilitates interacting with various queue backends such as the included sqlite3 queue or the planned AWS SQS and Redis queues.

The queue functions such as `insert`, `delete`, and `pop` can be used for typical management of the queue.

The `process_queue` function pops the requested number of items from the queue and creates a Salt Event that can then be processed by a Reactor. The `process_queue` function can be called manually, or can be configured to run on a schedule with the Salt Scheduler or regular system cron. It is also possible to use the peer system to allow a minion to call the runner.

This runner, as well as the Queues system, is not api stable at this time.

There are many things that could potentially be done with queues within Salt. For the time being the focus will be on queueing infrastructure actions on specific minions. The queues generally will be populated with minion IDs. When the `process_queue` runner function is called events are created on the Salt Event bus that indicate the queue and a list of one or more minion IDs. The reactor is set up to match on event tags for a specific queue and then take infrastructure actions on those minion IDs. These actions might be to delete the minion’s key from the master, use salt-cloud to destroy the vm, or some other custom action.

```
salt.runners.queue.delete(queue, items, backend='sqlite')
```

Delete an item or items from a queue

CLI Example:
<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
<th>CLI Example</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>salt-run queue.delete myqueue myitem</code></td>
<td>Delete an item from a queue.</td>
<td><code>salt-run queue.delete myqueue myitem</code></td>
</tr>
<tr>
<td><code>salt-run queue.delete myqueue myitem backend=sqlite</code></td>
<td>Delete an item from a queue with a specific backend.</td>
<td><code>salt-run queue.delete myqueue myitem backend=sqlite</code></td>
</tr>
<tr>
<td><code>salt-run queue.delete myqueue myitem backend=sqlite</code></td>
<td>Delete all items from a queue with a specific backend.</td>
<td><code>salt-run queue.delete myqueue myitem backend=sqlite</code></td>
</tr>
<tr>
<td><code>salt-run queue.insert myqueue myitem</code></td>
<td>Add an item or items to a queue.</td>
<td><code>salt-run queue.insert myqueue myitem</code></td>
</tr>
<tr>
<td><code>salt-run queue.insert myqueue myitem backend=sqlite</code></td>
<td>Add an item or items to a queue with a specific backend.</td>
<td><code>salt-run queue.insert myqueue myitem backend=sqlite</code></td>
</tr>
<tr>
<td><code>salt-run queue.insert myqueue myitem backend=sqlite</code></td>
<td>Add an item or items to a queue with a specific backend.</td>
<td><code>salt-run queue.insert myqueue myitem backend=sqlite</code></td>
</tr>
<tr>
<td><code>salt-run queue.list_items myqueue backend=sqlite</code></td>
<td>List contents of a queue.</td>
<td><code>salt-run queue.list_items myqueue backend=sqlite</code></td>
</tr>
<tr>
<td><code>salt-run queue.list_length myqueue backend=sqlite</code></td>
<td>Provide the number of items in a queue.</td>
<td><code>salt-run queue.list_length myqueue backend=sqlite</code></td>
</tr>
<tr>
<td><code>salt-run queue.pop myqueue</code></td>
<td>Pop one or more items from a queue.</td>
<td><code>salt-run queue.pop myqueue</code></td>
</tr>
<tr>
<td><code>salt-run queue.pop myqueue quantity=1 backend=sqlite</code></td>
<td>Pop one item from a queue with a specific backend.</td>
<td><code>salt-run queue.pop myqueue quantity=1 backend=sqlite</code></td>
</tr>
<tr>
<td><code>salt-run queue.pop myqueue quantity=1 backend=sqlite</code></td>
<td>Pop one item from a queue with a specific backend.</td>
<td><code>salt-run queue.pop myqueue quantity=1 backend=sqlite</code></td>
</tr>
<tr>
<td><code>salt-run queue.pop myqueue quantity=6 backend=sqlite</code></td>
<td>Pop six items from a queue with a specific backend.</td>
<td><code>salt-run queue.pop myqueue quantity=6 backend=sqlite</code></td>
</tr>
<tr>
<td><code>salt-run queue.pop myqueue quantity=all backend=sqlite</code></td>
<td>Pop all items from a queue with a specific backend.</td>
<td><code>salt-run queue.pop myqueue quantity=all backend=sqlite</code></td>
</tr>
<tr>
<td><code>salt-run queue.pop myqueue quantity=all backend=sqlite</code></td>
<td>Pop all items from a queue with a specific backend.</td>
<td><code>salt-run queue.pop myqueue quantity=all backend=sqlite</code></td>
</tr>
<tr>
<td><code>salt-run queue.process_queue myqueue</code></td>
<td>Pop items from a queue and create an event on the Salt event bus.</td>
<td><code>salt-run queue.process_queue myqueue</code></td>
</tr>
<tr>
<td><code>salt-run queue.process_queue myqueue quantity=1 backend=sqlite</code></td>
<td>Pop items from a queue and create an event on the Salt event bus with a specific backend.</td>
<td><code>salt-run queue.process_queue myqueue quantity=1 backend=sqlite</code></td>
</tr>
<tr>
<td><code>salt-run queue.process_queue myqueue quantity=6 backend=sqlite</code></td>
<td>Pop items from a queue and create an event on the Salt event bus with a specific backend.</td>
<td><code>salt-run queue.process_queue myqueue quantity=6 backend=sqlite</code></td>
</tr>
<tr>
<td><code>salt-run queue.pop myqueue quantity=all backend=sqlite</code></td>
<td>Pop items from a queue and create an event on the Salt event bus with a specific backend.</td>
<td><code>salt-run queue.pop myqueue quantity=all backend=sqlite</code></td>
</tr>
</tbody>
</table>
salt.runners.sdb

Runner for setting and querying data via the sdb API on the master

**salt.runners.sdb.get(uri)**

Get a value from a db, using a uri in the form of sdb://<profile>/<key>. If the uri provided does not start with sdb://, then it will be returned as-is.

CLI Example:
```
salt '*' sdb.get sdb://mymemcached/foo
```

**salt.runners.sdb.set(uri, value)**

Set a value in a db, using a uri in the form of sdb://<profile>/<key>. If the uri provided does not start with sdb:// or the value is not successfully set, return False.

CLI Example:
```
salt '*' sdb.set sdb://mymemcached/foo bar
```

salt.runners.ssh

A Runner module interface on top of the salt-ssh Python API.

This allows for programmatic use from salt-api, the Reactor, Orchestrate, etc.

**salt.runners.ssh.cmd(tgt, fun, arg=(), timeout=None, expr_form='glob', kwarg=None)**

Execute a single command via the salt-ssh subsystem and return all routines at once

New in version 2015.2.

A wrapper around the SSHClient.cmd method.

salt.runners.search

Runner frontend to search system

**salt.runners.search.query(term)**

Query the search system

CLI Example:
```
salt-run search.query foo
```

salt.runners.state

Execute orchestration functions

**salt.runners.state.event(tagmatch='*', count=-1, quiet=False, sock_dir=None, pretty=False)**

Watch Salt’s event bus and block until the given tag is matched

New in version 2014.7.0.

This is useful for utilizing Salt’s event bus from shell scripts or for taking simple actions directly from the CLI.

Enable debug logging to see ignored events.

**Parameters**
• **tagmatch** -- the event is written to stdout for each tag that matches this pattern; uses the same matching semantics as Salt's Reactor.

• **count** -- this number is decremented for each event that matches the `tagmatch` parameter; pass -1 to listen forever.

• **quiet** -- do not print to stdout; just block

• **sock_dir** -- path to the Salt master's event socket file.

• **pretty** -- Output the JSON all on a single line if False (useful for shell tools); pretty-print the JSON output if True.

CLI Examples:

```
# Reboot a minion and run highstate when it comes back online
salt 'jerry' system.reboot &&
    salt-run state.event 'salt/minion/jerry/start' count=1 quiet=True &&
    salt 'jerry' state.highstate
# Reboot multiple minions and run highstate when all are back online
salt -L 'kevin,stewart,dave' system.reboot &&
    salt-run state.event 'salt/minion/*/start' count=3 quiet=True &&
    salt -L 'kevin,stewart,dave' state.highstate
# Watch the event bus forever in a shell while-loop.
salt-run state.event | while read -r tag data; do
echo $tag
    echo $data | jq -colour-output .
done
```

See also:

See https://github.com/saltstack/salt/blob/develop/tests/eventlisten.sh for an example of usage within a shell script.

salt.runners.state.orchestratemotionds, saltenv='base', test=None, exclude=None, pillar=None)

New in version 0.17.0.

Execute a state run from the master, used as a powerful orchestration system.

See also:

More Orchestratedocumentation

• [Full Orchestrator Tutorial](#)

• Docs for the master-side state module

CLI Examples:

```
salt-run state.orchestraterunserver
salt-run state.orchestraterunserver saltenv=dev test=True
```

Changed in version 2014.1.1: Runner renamed from state.sls to state.orchestraterun

Changed in version 2014.7.0: Runner uses the pillar variable

salt.runners.state.orchestraterunhigh(data, test=None, queue=False, pillar=None, **kwargs)

Execute a single state orchestration routine

New in version 2015.5.0.

CLI Example:
salt-run state.orchestrate_high '{
  stage_one:
    {salt.state: [{tgt: "db*"}, {sls: postgres_setup}]},
  stage_two:
    {salt.state: [{tgt: "web*"}, {sls: apache_setup}, {
      require: [[salt: stage_one]],
    }],}
}'

salt.runners.state.orchestrate_single(fun, name, test=None, queue=False, pillar=None, **kwargs)

Execute a single state orchestration routine

New in version 2015.5.0.

CLI Example:

```
salt-run state.orchestrate_single fun=salt.wheel name=key.list_all
```

salt.runners.survey

A general map/reduce style salt runner for aggregating results returned by several different minions.

New in version 2014.7.0.

Aggregated results are sorted by the size of the minion pools which returned matching results.

Useful for playing the game: "some of these things are not like the others..." when identifying discrepancies in a large infrastructure managed by salt.

salt.runners.survey.diff(*args, **kwargs)

Return the DIFFERENCE of the result sets returned by each matching minion pool

New in version 2014.7.0.

These pools are determined from the aggregated and sorted results of a salt command. This command displays the "difs" as a series of 2-way differences-- namely the difference between the FIRST displayed minion pool (according to sort order) and EACH SUBSEQUENT minion pool result set. Differences are displayed according to the Python `difflib.unified_diff()` as in the case of the salt execution module `file.get_diff`.

This command is submitted via a salt runner using the general form:

```
salt-run survey.diff [survey_sort=up/down] <target> <salt-execution-module> <salt-execution-module parameters>
```

Optionally accept a `survey_sort=" parameter. Default: `survey_sort=down``

CLI Example #1: (Example to display the "differences of files")

```
salt-run survey.diff survey_sort=up "*" cp.get_file_str file:///etc/hosts
```

salt.runners.survey.hash(*args, **kwargs)

Return the MATCHING minion pools from the aggregated and sorted results of a salt command

New in version 2014.7.0.

This command is submitted via a salt runner using the general form:

```
salt-run survey.hash [survey_sort=up/down] <target> <salt-execution-module> <salt-execution-module parameters>
```
Optionally accept a `survey_sort=` parameter. Default: `survey_sort=down`

CLI Example #1: (functionally equivalent to `salt-run manage.up`)

```
salt-run survey.hash "*" test.ping
```

CLI Example #2: (find an `outlier` minion config file)

```
salt-run survey.hash "*" file.get_hash /etc/salt/minion survey_sort=up
```

**salt.runners.test**

This runner is used only for test purposes and servers no production purpose

```
salt.runners.test.arg(*args, **kwargs)
```

Output the given args and kwargs

Kwargs will be filtered for `private` keynames.

```
salt.runners.test.raw_arg(*args, **kwargs)
```

Output the given args and kwargs

```
salt.runners.test.sleep(s_time=10)
```

Sleep t seconds, then return True

```
salt.runners.test.stdout_print()
```

Print `foo` and return `bar`

```
salt.runners.test.stream()
```

Return True

**salt.runners.thin**

The thin runner is used to manage the salt thin systems.

Salt Thin is a transport-less version of Salt that can be used to run routines in a standalone way. This runner has tools which generate the standalone salt system for easy consumption.

```
salt.runners.thin.generate(extra_mods='', overwrite=False, so_mods='')
```

Generate the salt-thin tarball and print the location of the tarball Optional additional mods to include (e.g. mako) can be supplied as a comma delimited string. Permits forcing an overwrite of the output file as well.

CLI Example:

```
salt-run thin.generate
salt-run thin.generate mako
salt-run thin.generate mako,wempy 1
salt-run thin.generate overwrite=1
```

**salt.runners.virt**

Control virtual machines via Salt

```
salt.runners.virt.force_off(name)
```

Force power down the named virtual machine

```
salt.runners.virt.hyper_info(hyper=None)
```

Return information about the hypervisors connected to this master
salt.runners.virt.init(name, cpu, mem, image, hyper=``None``, seed=``True``, nic=``'default'``, install=``True``)
This routine is used to create a new virtual machine. This routine takes a number of options to determine what the newly created virtual machine will look like.

**name**  The mandatory name of the new virtual machine. The name option is also the minion id, all minions must have an id.

**cpu**  The number of cpus to allocate to this new virtual machine.

**mem**  The amount of memory to allocate to this virtual machine. The number is interpreted in megabytes.

**image**  The network location of the virtual machine image, commonly a location on the salt fileserver, but http, https and ftp can also be used.

**hyper**  The hypervisor to use for the new virtual machine, if this is omitted Salt will automatically detect what hypervisor to use.

**seed**  Set to False to prevent Salt from seeding the new virtual machine.

**nic**  The nic profile to use, defaults to the `default` nic profile which assumes a single network interface per vm associated with the `br0` bridge on the master.

**install**  Set to False to prevent Salt from installing a minion on the new vm before it spins up.

salt.runners.virt.list(hyper=``None``, quiet=``False``)
List the virtual machines on each hyper, this is a simplified query, showing only the virtual machine names belonging to each hypervisor. A single hypervisor can be passed in to specify an individual hypervisor to list.

salt.runners.virt.migrate(name, target='``
Migrate a vm from one hypervisor to another. This routine will just start the migration and display information on how to look up the progress.

salt.runners.virt.next_hyper()
Return the hypervisor to use for the next autodeployed vm. This queries the available hypervisors and executes some math the determine the most `available` next hypervisor.

salt.runners.virt.pause(name)
Pause the named vm

salt.runners.virt.purge(name, delete_key=``True``)
Destroy the named vm

salt.runners.virt.query(hyper=``None``, quiet=``False``)
Query the virtual machines. When called without options all hypervisors are detected and a full query is returned. A single hypervisor can be passed in to specify an individual hypervisor to query.

salt.runners.virt.reset(name)
Force power down and restart an existing vm

salt.runners.virt.resume(name)
Resume a paused vm

salt.runners.virt.start(name)
Start a named virtual machine

salt.runners.virt.vm_info(name, quiet=``False``)
Return the information on the named vm

salt.runners.winrepo
Runner to manage Windows software repo
salt.runners.winrepo.genrepo(*opts=None, fire_event=True*)
Generate winrepo_cachefile based on sls files in the winrepo_dir

- **opts** Specify an alternate opts dict. Should not be used unless this function is imported into an execution module.
- **fire_event** [True] Fire an event on failure. Only supported on the master.

CLI Example:
```
salt-run winrepo.genrepo
```

salt.runners.winrepo.update_git_repos(*opts=None, clean=False, masterless=False*)
Checkout git repos containing Windows Software Package Definitions

- **opts** Specify an alternate opts dict. Should not be used unless this function is imported into an execution module.
- **clean** [False] Clean repo cachedirs which are not configured under `winrepo_remotes`.

**Warning**: This argument should not be set to True if a mix of git and non-git repo definitions are being used, as it will result in the non-git repo definitions being removed.

New in version 2015.8.0.

CLI Examples:
```
salt-run winrepo.update_git_repos
salt-run winrepo.update_git_repos clean=True
```

### 31.25.2 Writing Salt Runners

A Salt runner is written in a similar manner to a Salt execution module. Both are Python modules which contain functions and each public function is a runner which may be executed via the `salt-run` command.

For example, if a Python module named `test.py` is created in the runners directory and contains a function called `foo`, the `test` runner could be invoked with the following command:

```
# salt-run test.foo
```

Runners have several options for controlling output.

Any `print` statement in a runner is automatically also fired onto the master event bus where. For example:

```python
def a_runner(outputter=None, display_progress=False):
    print('Hello world')
    ...
```

The above would result in an event fired as follows:

```
Event fired at Tue Jan 13 15:26:45 2015
*************************
Tag: salt/run/20150113152644070246/print
Data:
{'_stamp': '2015-01-13T15:26:45.078707',
'data': 'hello',
'outputter': 'pprint'}
```
A runner may also send a progress event, which is displayed to the user during runner execution and is also passed across the event bus if the `display_progress` argument to a runner is set to True.

A custom runner may send its own progress event by using the `__jid_event__.fire_event()` method as shown here:

```python
if display_progress:
    __jid_event__.fire_event({'message': 'A progress message', 'progress'}
```

The above would produce output on the console reading: A progress message as well as an event on the event similar to:

```
Event fired at Tue Jan 13 15:21:20 2015
************************************************
Tag: salt/run/20150113152118341421/progress
Data:
'message': "A progress message"}
```

A runner could use the same approach to send an event with a customized tag onto the event bus by replacing the second argument (`progress`) with whatever tag is desired. However, this will not be shown on the command-line and will only be fired onto the event bus.

### 31.25.3 Synchronous vs. Asynchronous

A runner may be fired asynchronously which will immediately return control. In this case, no output will be display to the user if `salt-run` is being used from the command-line. If used programatically, no results will be returned. If results are desired, they must be gathered either by firing events on the bus from the runner and then watching for them or by some other means.

**Note:** When running a runner in asynchronous mode, the `--progress` flag will not deliver output to the salt-run CLI. However, progress events will still be fired on the bus.

In synchronous mode, which is the default, control will not be returned until the runner has finished executing.

To add custom runners, put them in a directory and add it to `runner_dirs` in the master configuration file.

### 31.25.4 Examples

Examples of runners can be found in the Salt distribution:

https://github.com/saltstack/salt/blob/develop/salt/runners

A simple runner that returns a well-formatted list of the minions that are responding to Salt calls could look like this:

```python
# Import salt modules
import salt.client

def up():
    '''
    Print a list of all of the minions that are up
    '''
    client = salt.client.LocalClient(__opts__['conf_file'])
    minions = client.cmd('!', 'test.ping', timeout=1)
    for minion in sorted(minions):
        print minion
```
31.26 State Enforcement

Salt offers an optional interface to manage the configuration or "state" of the Salt minions. This interface is a fully capable mechanism used to enforce the state of systems from a central manager.

31.26.1 Mod Aggregate State Runtime Modifications

New in version 2014.7.0.

The mod_aggregate system was added in the 2014.7.0 release of Salt and allows for runtime modification of the executing state data. Simply put, it allows for the data used by Salt’s state system to be changed on the fly at runtime, kind of like a configuration management JIT compiler or a runtime import system. All in all, it makes Salt much more dynamic.

How it Works

The best example is the pkg state. One of the major requests in Salt has long been adding the ability to install all packages defined at the same time. The mod_aggregate system makes this a reality. While executing Salt’s state system, when a pkg state is reached the mod_aggregate function in the state module is called. For pkg this function scans all of the other states that are slated to run, and picks up the references to name and pkgs, then adds them to pkgs in the first state. The result is a single call to yum, apt-get, pacman, etc as part of the first package install.

How to Use it

Note: Since this option changes the basic behavior of the state runtime, after it is enabled states should be executed using test=True to ensure that the desired behavior is preserved.

In config files

The first way to enable aggregation is with a configuration option in either the master or minion configuration files. Salt will invoke mod_aggregate the first time it encounters a state module that has aggregate support.

If this option is set in the master config it will apply to all state runs on all minions, if set in the minion config it will only apply to said minion.

Enable for all states:

```
state_aggregate: True
```

Enable for only specific state modules:

```
state_aggregate:
  - pkg
```

In states

The second way to enable aggregation is with the state-level aggregate keyword. In this configuration, Salt will invoke the mod_aggregate function the first time it encounters this keyword. Any additional occurrences of the keyword will be ignored as the aggregation has already taken place.
The following example will trigger `mod_aggregate` when the `lamp_stack` state is processed resulting in a single call to the underlying package manager.

```yaml
lamp_stack:
  pkg.installed:
    - php
    - mysql-client
    - aggregate: True

memcached:
  pkg.installed:
    - name: memcached
```

## Adding `mod_aggregate` to a State Module

Adding a `mod_aggregate` routine to an existing state module only requires adding an additional function to the state module called `mod_aggregate`.

The `mod_aggregate` function just needs to accept three parameters and return the low data to use. Since `mod_aggregate` is working on the state runtime level it does need to manipulate low data.

The three parameters are `low`, `chunks`, and `running`. The `low` option is the low data for the state execution which is about to be called. The `chunks` is the list of all of the low data dictionaries which are being executed by the runtime and the `running` dictionary is the return data from all of the state executions which have already be executed.

This example, simplified from the pkg state, shows how to create `mod_aggregate` functions:

```python
def mod_aggregate(low, chunks, running):
    # The `mod_aggregate` function which looks up all packages in the available
    # low chunks and merges them into a single pkgs ref in the present low data
    pkgs = []
    # What functions should we aggregate?
    agg_enabled = ['installed',
                   'latest',
                   'removed',
                   'purged',
                   ]
    # The `low` data is just a dict with the state, function (fun) and
    # arguments passed in from the sls
    if low.get('fun') not in agg_enabled:
        return low
    # Now look into what other things are set to execute
    for chunk in chunks:
        # The state runtime uses "tags" to track completed jobs, it may
        # look familiar with the _|-_
        tag = salt.utils.gen_state_tag(chunk)
        if tag in running:
            # Already ran the pkg state, skip aggregation
            continue
        if chunk.get('state') == 'pkg':
            if '__agg__' in chunk:
                continue
        # Check for the same function
        if chunk.get('fun') != low.get('fun'):
            continue
```
```python
        continue
    # Pull out the pkg names!
    if 'pkgs' in chunk:
        pkgs.extend(chunk['pkgs'])
        chunk['__agg__'] = True
    elif 'name' in chunk:
        pkgs.append(chunk['name'])
        chunk['__agg__'] = True
    if pkgs:
        if 'pkgs' in low:
            low['pkgs'].extend(pkgs)
        else:
            low['pkgs'] = pkgs
    # The low has been modified and needs to be returned to the state
    # runtime for execution
    return low
```

31.26.2 Altering States

Note: This documentation has been moved [here](#).

31.26.3 File State Backups

In 0.10.2 a new feature was added for backing up files that are replaced by the file.managed and file.recurse states. The new feature is called the backup mode. Setting the backup mode is easy, but it can be set in a number of places. The backup_mode can be set in the minion config file:

```
backup_mode: minion
```

Or it can be set for each file:

```
/etc/ssh/sshd_config:
    file.managed:
        - source: salt://ssh/sshd_config
        - backup: minion
```

Backed-up Files

The files will be saved in the minion cachedir under the directory named file_backup. The files will be in the location relative to where they were under the root filesystem and be appended with a timestamp. This should make them easy to browse.

Interacting with Backups

Starting with version 0.17.0, it will be possible to list, restore, and delete previously-created backups.

Listing

The backups for a given file can be listed using `file.list_backups`: 

31.26. State Enforcement
# salt foo.bar.com file.list_backups /tmp/foo.txt

foo.bar.com:

0:

---

Backup Time: 
Sat Jul 27 2013 17:48:41.738027
Location: 
/var/cache/salt/minion/file_backup/tmp/foo.txt_Sat_Jul_27_17:48:41_738027_2013
Size:
13

1:

---

Backup Time: 
Sat Jul 27 2013 17:48:28.369804
Location: 
Size:
35

Restoring

Restoring is easy using `file.restore_backup`, just pass the path and the numeric id found with `file.list_backups`:

# salt foo.bar.com file.restore_backup /tmp/foo.txt 1

foo.bar.com:

---

comment: 
Successfully restored /var/cache/salt/minion/file_backup/tmp/foo.txt_Sat_Jul_27_17:48:28_369804_2013 to /tmp/foo.txt
result: 
True

The existing file will be backed up, just in case, as can be seen if `file.list_backups` is run again:

# salt foo.bar.com file.list_backups /tmp/foo.txt

foo.bar.com:

0:

---

Backup Time: 
Sat Jul 27 2013 18:00:19.822550
Location: 
/var/cache/salt/minion/file_backup/tmp/foo.txt_Sat_Jul_27_18:00:19_822550_2013
Size:
53

1:

---

Backup Time: 
Sat Jul 27 2013 17:48:41.738027
Location: 
/var/cache/salt/minion/file_backup/tmp/foo.txt_Sat_Jul_27_17:48:41_738027_2013
Size:
13

2:

---

Backup Time:
Deleting backups can be done using `file.delete_backup`:

```
# salt foo.bar.com file.delete_backup /tmp/foo.txt 0
```

foo.bar.com:

```
----------
comment:  Successfully removed /var/cache/salt/minion/file_backup/tmp/foo.txt_Sat_Jul_27_18:00:19_822550_2013
result:   True
```

31.26.4 Understanding State Compiler Ordering

**Note:** This tutorial is an intermediate level tutorial. Some basic understanding of the state system and writing Salt Formulas is assumed.

Salt’s state system is built to deliver all of the power of configuration management systems without sacrificing simplicity. This tutorial is made to help users understand in detail just how the order is defined for state executions in Salt.

This tutorial is written to represent the behavior of Salt as of version 0.17.0.

**Compiler Basics**

To understand ordering in depth some very basic knowledge about the state compiler is very helpful. No need to worry though, this is very high level!

**High Data and Low Data**

When defining Salt Formulas in YAML the data that is being represented is referred to by the compiler as High Data. When the data is initially loaded into the compiler it is a single large python dictionary, this dictionary can be viewed raw by running:

```
salt '*' state.show_highstate
```

This "High Data" structure is then compiled down to "Low Data". The Low Data is what is matched up to create individual executions in Salt’s configuration management system. The low data is an ordered list of single state calls to execute. Once the low data is compiled the evaluation order can be seen.

The low data can be viewed by running:
salt '*' state.show_lowstate

Note: The state execution module contains MANY functions for evaluating the state system and is well worth a read! These routines can be very useful when debugging states or to help deepen one's understanding of Salt's state system.

As an example, a state written thusly:

```
apache:
pkg.installed:
  - name: httpd
service.running:
  - name: httpd
  - watch:
    - file: apache_conf
    - pkg: apache

apache_conf:
file.managed:
  - name: /etc/httpd/conf.d/httpd.conf
  - source: salt://apache/httpd.conf
```

Will have High Data which looks like this represented in json:

```
{
  "apache": {
    "pkg": [
      {
        "name": "httpd",
        "installed",
        {
          "order": 10000
        }
      },
      "service": [
        {
          "name": "httpd",
          {
            "watch": [
              {
                "file": "apache_conf"
              },
              {
                "pkg": "apache"
              }
            ]
          },
          "running",
          {
            "order": 10001
          }
        },
        "__sls__": "blah",
        "__env__": "base"
      },
      "apache_conf": {
```
The subsequent Low Data will look like this:

```
[
    {
      "name": "httpd",
      "state": "pkg",
      "__id__": "apache",
      "fun": "installed",
      "__env__": "base",
      "__sls__": "blah",
      "order": 10000
    },
    {
      "name": "apache",
      "watch": [
        {
          "file": "apache_conf"
        },
        {
          "pkg": "apache"
        }
      ],
      "state": "service",
      "__id__": "apache",
      "fun": "running",
      "__env__": "base",
      "__sls__": "blah",
      "order": 10001
    },
    {
      "name": "/etc/httpd/conf.d/httpd.conf",

This tutorial discusses the Low Data evaluation and the state runtime.
Ordering Layers

Salt defines 2 order interfaces which are evaluated in the state runtime and defines these orders in a number of passes.

Definition Order

---

**Note:** The Definition Order system can be disabled by turning the option `state_auto_order` to `False` in the master configuration file.

---

The top level of ordering is the **Definition Order**. The Definition Order is the order in which states are defined in salt formulas. This is very straightforward on basic states which do not contain `include` statements or a `top` file, as the states are just ordered from the top of the file, but the include system starts to bring in some simple rules for how the Definition Order is defined.

Looking back at the 'Low Data' and 'High Data' shown above, the order key has been transparently added to the data to enable the Definition Order.

**The Include Statement** Basically, if there is an include statement in a formula, then the formulas which are included will be run BEFORE the contents of the formula which is including them. Also, the include statement is a list, so they will be loaded in the order in which they are included.

In the following case:

```yaml
foo.sls
  include:
    - bar
    - baz

bar.sls
  include:
    - quo

baz.sls
  include:
    - qux
```

In the above case if `state.sls foo` were called then the formulas will be loaded in the following order:

1. quo
2. bar
3. qux
4. baz
5. foo

**The order Flag**

The Definition Order happens transparently in the background, but the ordering can be explicitly overridden using the `order` flag in states:
This order flag will over ride the definition order, this makes it very simple to create states that are always executed first, last or in specific stages, a great example is defining a number of package repositories that need to be set up before anything else, or final checks that need to be run at the end of a state run by using `order: last` or `order: -1`.

When the order flag is explicitly set the Definition Order system will omit setting an order for that state and directly use the order flag defined.

**Lexicographical Fall-back**

Salt states were written to ALWAYS execute in the same order. Before the introduction of Definition Order in version 0.17.0 everything was ordered lexicographically according to the name of the state, then function then id.

This is the way Salt has always ensured that states always run in the same order regardless of where they are deployed, the addition of the Definition Order method makes this finite ordering easier to follow.

The lexicographical ordering is still applied but it only has any effect when two order statements collide. This means that if multiple states are assigned the same order number that they will fall back to lexicographical ordering to ensure that every execution still happens in a finite order.

---

**Note:** If running with `state_auto_order: False` the `order` key is not set automatically, since the Lexicographical order can be derived from other keys.

---

**Requisite Ordering**

Salt states are fully declarative, in that they are written to declare the state in which a system should be. This means that components can require that other components have been set up successfully. Unlike the other ordering systems, the Requisite system in Salt is evaluated at runtime.

The requisite system is also built to ensure that the ordering of execution never changes, but is always the same for a given set of states. This is accomplished by using a runtime that processes states in a completely predictable order instead of using an event loop based system like other declarative configuration management systems.

---

**Runtime Requisite Evaluation**

The requisite system is evaluated as the components are found, and the requisites are always evaluated in the same order. This explanation will be followed by an example, as the raw explanation may be a little dizzying at first as it creates a linear dependency evaluation sequence.

The `Low Data` is an ordered list or dictionaries, the state runtime evaluates each dictionary in the order in which they are arranged in the list. When evaluating a single dictionary it is checked for requisites, requisites are evaluated in order, `require` then `watch` then `prereq`.

---

**Note:** If using requisite in statements like `require_in` and `watch_in` these will be compiled down to `require` and `watch` statements before runtime evaluation.

---

Each requisite contains an ordered list of requisites, these requisites are looked up in the list of dictionaries and then executed. Once all requisites have been evaluated and executed then the requiring state can safely be run (or not run if requisites have not been met).
This means that the requisites are always evaluated in the same order, again ensuring one of the core design principals of Salt's State system to ensure that execution is always finite is intact.

**Simple Runtime Evaluation Example**

Given the above `Low Data` the states will be evaluated in the following order:

1. The pkg.installed is executed ensuring that the apache package is installed, it contains no requisites and is therefore the first defined state to execute.
2. The service.running state is evaluated but NOT executed, a watch requisite is found, therefore they are read in order, the runtime first checks for the file, sees that it has not been executed and calls for the file state to be evaluated.
3. The file state is evaluated AND executed, since it, like the pkg state does not contain any requisites.
4. The evaluation of the service state continues, it next checks the pkg requisite and sees that it is met, with all requisites met the service state is now executed.

**Best Practice**

The best practice in Salt is to choose a method and stick with it, official states are written using requisites for all associations since requisites create clean, traceable dependency trails and make for the most portable formulas. To accomplish something similar to how classical imperative systems function all requisites can be omitted and the failhard option then set to True in the master configuration, this will stop all state runs at the first instance of a failure.

In the end, using requisites creates very tight and fine grained states, not using requisites makes full sequence runs and while slightly easier to write, and gives much less control over the executions.

### 31.26.5 Extending External SLS Data

Sometimes a state defined in one SLS file will need to be modified from a separate SLS file. A good example of this is when an argument needs to be overwritten or when a service needs to watch an additional state.

**The Extend Declaration**

The standard way to extend is via the extend declaration. The extend declaration is a top level declaration like include and encapsulates ID declaration data included from other SLS files. A standard extend looks like this:

```yaml
include:
  - http
  - ssh

extend:
  apache:
    file:
      - name: /etc/httpd/conf/httpd.conf
      - source: salt://http/httpd2.conf
  ssh-server:
    service:
      - watch:
        - file: /etc/ssh/banner
```
/etc/ssh/banner:
  file.managed:
    - source: salt://ssh/banner

A few critical things happened here, first off the SLS files that are going to be extended are included, then the extend dec is defined. Under the extend dec 2 IDs are extended, the apache ID's file state is overwritten with a new name and source. Than the ssh server is extended to watch the banner file in addition to anything it is already watching.

**Extend is a Top Level Declaration**

This means that extend can only be called once in an sls, if if is used twice then only one of the extend blocks will be read. So this is WRONG:

```yaml
include:
  - http
  - ssh

extend:
  apache:
    file:
      - name: /etc/httpd/conf/httpd.conf
      - source: salt://http/httpd2.conf
# Second extend will overwrite the first!! Only make one
extend:
  ssh-server:
    service:
      - watch:
        - file: /etc/ssh/banner
```

**The Requisite ``in'' Statement**

Since one of the most common things to do when extending another SLS is to add states for a service to watch, or anything for a watcher to watch, the requisite in statement was added to 0.9.8 to make extending the watch and require lists easier. The ssh-server extend statement above could be more cleanly defined like so:

```yaml
include:
  - ssh

/etc/ssh/banner:
  file.managed:
    - source: salt://ssh/banner
    - watch_in:
      - service: ssh-server
```

**Rules to Extend By**

There are a few rules to remember when extending states:

1. Always include the SLS being extended with an include declaration
2. Requisites (watch and require) are appended to, everything else is overwritten
3. extend is a top level declaration, like an ID declaration, cannot be declared twice in a single SLS
4. Many IDs can be extended under the extend declaration
31.26.6 Failhard Global Option

Normally, when a state fails Salt continues to execute the remainder of the defined states and will only refuse to execute states that require the failed state.

But the situation may exist, where you would want all state execution to stop if a single state execution fails. The capability to do this is called failing hard.

State Level Failhard

A single state can have a failhard set, this means that if this individual state fails that all state execution will immediately stop. This is a great thing to do if there is a state that sets up a critical config file and setting a require for each state that reads the config would be cumbersome. A good example of this would be setting up a package manager early on:

```bash
/etc/yum.repos.d/company.repo:
    file.managed:
        - source: salt://company/yumrepo.conf
        - user: root
        - group: root
        - mode: 644
        - order: 1
        - failhard: True
```

In this situation, the yum repo is going to be configured before other states, and if it fails to lay down the config file, than no other states will be executed.

Global Failhard

It may be desired to have failhard be applied to every state that is executed, if this is the case, then failhard can be set in the master configuration file. Setting failhard in the master configuration file will result in failing hard when any minion gathering states from the master have a state fail.

This is NOT the default behavior, normally Salt will only fail states that require a failed state.

Using the global failhard is generally not recommended, since it can result in states not being executed or even checked. It can also be confusing to see states failhard if an admin is not actively aware that the failhard has been set.

To use the global failhard set failhard: True in the master configuration file.

31.26.7 Global State Arguments

Note: This documentation has been moved here.

31.26.8 Highstate data structure definitions

The Salt State Tree

A state tree is a collection of SLS files and directories that live under the directory specified in file_roots.

Note: Directory names or filenames in the state tree cannot contain a period, with the exception of the period in the .sls file suffix.
Top file

The main state file that instructs minions what environment and modules to use during state execution. Configurable via state_top.

See also:

*A detailed description of the top file*

Include declaration

Defines a list of Module reference strings to include in this SLS. Occurs only in the top level of the highstate structure.

Example:

```
include:
  - edit.vim
  - http.server
```

Module reference

The name of a SLS module defined by a separate SLS file and residing on the Salt Master. A module named edit.vim is a reference to the SLS file *salt://edit/vim.sls*.

ID declaration

Defines an individual highstate component. Always references a value of a dictionary containing keys referencing State declaration and Requisite declaration. Can be overridden by a Name declaration or a Names declaration. Occurs on the top level or under the Extend declaration.

Must be unique across entire state tree. If the same ID declaration is used twice, only the first one matched will be used. All subsequent ID declarations with the same name will be ignored.

Note: Naming gotchas

In Salt versions earlier than 0.9.7, ID declarations containing dots would result in unpredictable highstate output.

Extend declaration

Extends a Name declaration from an included SLS module. The keys of the extend declaration always refer to an existing ID declaration which have been defined in included SLS modules. Occurs only in the top level and defines a dictionary.

States cannot be extended more than once in a single state run.

Extend declarations are useful for adding-to or overriding parts of a State declaration that is defined in another SLS file. In the following contrived example, the shown mywebsite.sls file is include -ing and extend
-ing the apache.sls module in order to add a watch declaration that will restart Apache whenever the Apache configuration file, mywebsite changes.

```
include:
  - apache

extend:
  apache:
    service:
      - watch:
        - file: mywebsite

mywebsite:
  file.managed:
    - name: /var/www/mysite
```

See also:

watch_in and require_in

Sometimes it is more convenient to use the watch_in or require_in syntax instead of extending another SLS file.

**State Requisites**

**State declaration**

A list which contains one string defining the Function declaration and any number of Function arg declaration dictionaries.

Can, optionally, contain a number of additional components like the name override components — name and names. Can also contain requisite declarations.

Occurs under an ID declaration.

**Requisite declaration**

A list containing requisite references.

Used to build the action dependency tree. While Salt states are made to execute in a deterministic order, this order is managed by requiring and watching other Salt states.

Occurs as a list component under a State declaration or as a key under an ID declaration.

**Requisite reference**

A single key dictionary. The key is the name of the referenced State declaration and the value is the ID of the referenced ID declaration.

Occurs as a single index in a Requisite declaration list.

**Function declaration**

The name of the function to call within the state. A state declaration can contain only a single function declaration.

For example, the following state declaration calls the installed function in the pkg state module:
The function can be declared inline with the state as a shortcut. The actual data structure is compiled to this form:

```yaml
httpd:
  pkg:
    - installed
```

Where the function is a string in the body of the state declaration. Technically when the function is declared in dot notation the compiler converts it to be a string in the state declaration list. Note that the use of the first example more than once in an ID declaration is invalid yaml.

Invalid:

```yaml
httpd:
  pkg.installed
  service.running
```

When passing a function without arguments and another state declaration within a single ID declaration, then the long or "standard" format needs to be used since otherwise it does not represent a valid data structure.

Valid:

```yaml
httpd:
  pkg.installed: []
  service.running: []
```

Occurs as the only index in the `State declaration` list.

**Function arg declaration**

A single key dictionary referencing a Python type which is to be passed to the named `Function declaration` as a parameter. The type must be the data type expected by the function.

Occurs under a `Function declaration`.

For example in the following state declaration `user`, `group`, and `mode` are passed as arguments to the `managed` function in the `file` state module:

```yaml
/etc/http/conf/http.conf:
  file.managed:
    - user: root
    - group: root
    - mode: 644
```

**Name declaration**

Overrides the `name` argument of a `State declaration`. If `name` is not specified the `ID declaration` satisfies the `name` argument.

The name is always a single key dictionary referencing a string.

Overriding `name` is useful for a variety of scenarios.

For example, avoiding clashing ID declarations. The following two state declarations cannot both have `/etc/motd` as the ID declaration:
motd_perms:
  file.managed:
    - name: /etc/motd
    - mode: 644

motd_quote:
  file.append:
    - name: /etc/motd
    - text: "Of all smells, bread; of all tastes, salt."

Another common reason to override name is if the ID declaration is long and needs to be referenced in multiple places. In the example below it is much easier to specify mywebsite than to specify /etc/apache2/sites-available/mywebsite.com multiple times:

mywebsite:
  file.managed:
    - name: /etc/apache2/sites-available/mywebsite.com
    - source: salt://mywebsite.com

a2ensite mywebsite.com:
  cmd.wait:
    - unless: test -L /etc/apache2/sites-enabled/mywebsite.com
    - watch:
      - file: mywebsite

apache2:
  service.running:
    - watch:
      - file: mywebsite

Names declaration

Expands the contents of the containing State declaration into multiple state declarations, each with its own name.

For example, given the following state declaration:

```
python-pkgs:
  pkg.installed:
    - names: 
      - python-django
      - python-crypto
      - python-yaml
```

Once converted into the lowstate data structure the above state declaration will be expanded into the following three state declarations:

```
python-django:
  pkg.installed

python-crypto:
  pkg.installed

python-yaml:
  pkg.installed
```

Other values can be overridden during the expansion by providing an additional dictionary level.

New in version 2014.7.0.
**ius:**

pkgrepo.managed:
- humanname: IUS Community Packages for Enterprise Linux 6 - $basearch
- gpgcheck: 1
- gpgkey: http://dl.iuscommunity.org/pub/ius/IUS-COMMUNITY-GPG-KEY
- names:
  - ius
  - ius-devel:
    - baseurl: http://mirror.rackspace.com/ius/development/CentOS/6/$basearch

**Large example**

Here is the layout in yaml using the names of the highdata structure components.

```
<Include Declaration>:
  - <Module Reference>
  - <Module Reference>

<Extend Declaration>:
  <ID Declaration>:
    [<overrides>] 

# standard declaration

<ID Declaration>:
  <State Module>:
    - <Function>
    - <Function Arg>
    - <Function Arg>
    - <Function Arg>
    - <Name>: <name>
    - <Requisite Declaration>:
      - <Requisite Reference>
      - <Requisite Reference>

# inline function and names

<ID Declaration>:
  <State Module>.<Function>:
    - <Function Arg>
    - <Function Arg>
    - <Function Arg>
    - <Names>:
      - <name>
      - <name>
      - <name>
      - <Requisite Declaration>:
        - <Requisite Reference>
        - <Requisite Reference>

# multiple states for single id

<ID Declaration>:
```

31.26. State Enforcement 1575
31.26.9 Include and Exclude

Salt SLS files can include other SLS files and exclude SLS files that have been otherwise included. This allows for an SLS file to easily extend or manipulate other SLS files.

Include

When other SLS files are included, everything defined in the included SLS file will be added to the state run. When including define a list of SLS formulas to include:

```yaml
include:
  - http
  - libvirt
```

The include statement will include SLS formulas from the same environment that the including SLS formula is in. But the environment can be explicitly defined in the configuration to override the running environment, therefore if an SLS formula needs to be included from an external environment named `dev` the following syntax is used:

```yaml
include:
  - dev: http
```

NOTE: include does not simply inject the states where you place it in the SLS file. If you need to guarantee order of execution, consider using requisites.

Do not use dots in SLS file names or their directories

The initial implementation of top.sls and Include declaration followed the python import model where a slash is represented as a period. This means that a SLS file with a period in the name (besides the suffix period) can not be referenced. For example, webserver_1.0.sls is not referenceable because webserver_1.0 would refer to the directory/file webserver_1/0.sls

The same applies for any subdirectories, this is especially `tricky' when git repos are created. Another command that typically can't render it's output is `state.show_sls` of a file in a path that contains a dot.

Relative Include

In Salt 0.16.0, the capability to include SLS formulas which are relative to the running SLS formula was added. Simply precede the formula name with a .:
In Salt 2015.8, the ability to include SLS formulas which are relative to the parents of the running SLS formula was added. In order to achieve this, precede the formula name with more than one . (dot). Much like Python’s relative import abilities, two or more leading dots represent a relative include of the parent or parents of the current package, with each . representing one level after the first.

The following SLS configuration, if placed within example.dev.virtual, would result in example.http and base being included respectively:

```
include:
- ..http
- ...base
```

**Exclude**

The exclude statement, added in Salt 0.10.3, allows an SLS to hard exclude another SLS file or a specific id. The component is excluded after the high data has been compiled, so nothing should be able to override an exclude.

Since the exclude can remove an id or an SLS the type of component to exclude needs to be defined. An exclude statement that verifies that the running highstate does not contain the http SLS and the /etc/vimrc id would look like this:

```
exclude:
- sls: http
- id: /etc/vimrc
```

### 31.26.10 State System Layers

The Salt state system is comprised of multiple layers. While using Salt does not require an understanding of the state layers, a deeper understanding of how Salt compiles and manages states can be very beneficial.

**Function Call**

The lowest layer of functionality in the state system is the direct state function call. State executions are executions of single state functions at the core. These individual functions are defined in state modules and can be called directly via the `state.single` command.

```
salt '*' state.single pkg.installed name='vim'
```

**Low Chunk**

The low chunk is the bottom of the Salt state compiler. This is a data representation of a single function call. The low chunk is sent to the state caller and used to execute a single state function.

A single low chunk can be executed manually via the `state.low` command.

```
salt '*' state.low '{name: vim, state: pkg, fun: installed}'
```

The passed data reflects what the state execution system gets after compiling the data down from sls formulas.
Low State

The Low State layer is the list of low chunks ``evaluated'' in order. To see what the low state looks like for a highstate, run:

```shell
salt '*' state.show_lowstate
```

This will display the raw lowstate in the order which each low chunk will be evaluated. The order of evaluation is not necessarily the order of execution, since requisites are evaluated at runtime. Requisite execution and evaluation is finite; this means that the order of execution can be ascertained with 100% certainty based on the order of the low state.

High Data

High data is the data structure represented in YAML via SLS files. The High data structure is created by merging the data components rendered inside sls files (or other render systems). The High data can be easily viewed by executing the `state.show_highstate` or `state.show_sls` functions. Since this data is a somewhat complex data structure, it may be easier to read using the json, yaml, or pprint outputters:

```shell
salt '*' state.show_highstate --out yaml
salt '*' state.show_sls edit.vim --out pprint
```

SLS

Above ``High Data'', the logical layers are no longer technically required to be executed, or to be executed in a hierarchy. This means that how the High data is generated is optional and very flexible. The SLS layer allows for many mechanisms to be used to render sls data from files or to use the fileservice backend to generate sls and file data from external systems.

The SLS layer can be called directly to execute individual sls formulas.

Note: SLS Formulas have historically been called ``SLS files''. This is because a single SLS was only constituted in a single file. Now the term ``SLS Formula'' better expresses how a compartmentalized SLS can be expressed in a much more dynamic way by combining pillar and other sources, and the SLS can be dynamically generated.

To call a single SLS formula named `edit.vim`, execute `state.sls`:

```shell
salt '*' state.sls edit.vim
```

HighState

Calling SLS directly logically assigns what states should be executed from the context of the calling minion. The Highstate layer is used to allow for full contextual assignment of what is executed where to be tied to groups of, or individual, minions entirely from the master. This means that the environment of a minion, and all associated execution data pertinent to said minion, can be assigned from the master without needing to execute or configure anything on the target minion. This also means that the minion can independently retrieve information about its complete configuration from the master.

To execute the High State call `state.highstate`:

```shell
salt '*' state.highstate
```
OverState

The overstate layer expresses the highest functional layer of Salt’s automated logic systems. The Overstate allows for stateful and functional orchestration of routines from the master. The overstate defines in data execution stages which minions should execute states, or functions, and in what order using requisite logic.

31.26.11 The Orchestrate Runner

Note: This documentation has been moved here.

31.26.12 Ordering States

The way in which configuration management systems are executed is a hotly debated topic in the configuration management world. Two major philosophies exist on the subject, to either execute in an imperative fashion where things are executed in the order in which they are defined, or in a declarative fashion where dependencies need to be mapped between objects.

Imperative ordering is finite and generally considered easier to write, but declarative ordering is much more powerful and flexible but generally considered more difficult to create.

Salt has been created to get the best of both worlds. States are evaluated in a finite order, which guarantees that states are always executed in the same order, and the states runtime is declarative, making Salt fully aware of dependencies via the requisite system.

State Auto Ordering

Salt always executes states in a finite manner, meaning that they will always execute in the same order regardless of the system that is executing them. But in Salt 0.17.0, the state_auto_order option was added. This option makes states get evaluated in the order in which they are defined in sls files.

The evaluation order makes it easy to know what order the states will be executed in, but it is important to note that the requisite system will override the ordering defined in the files, and the order option described below will also override the order in which states are defined in sls files.

If the classic ordering is preferred (lexicographic), then set state_auto_order to False in the master configuration file.

Requisite Statements

Note: This document represents behavior exhibited by Salt requisites as of version 0.9.7 of Salt.

Often when setting up states any single action will require or depend on another action. Salt allows for the building of relationships between states with requisite statements. A requisite statement ensures that the named state is evaluated before the state requiring it. There are three types of requisite statements in Salt, require, watch, and prereq.

These requisite statements are applied to a specific state declaration:

```
httpd:
  pkg.installed: []
  file.managed:
    - name: /etc/httpd/conf/httpd.conf
```
In this example, the require requisite is used to declare that the file /etc/httpd/conf/httpd.conf should only be set up if the pkg state executes successfully.

The requisite system works by finding the states that are required and executing them before the state that requires them. Then the required states can be evaluated to see if they have executed correctly.

Require statements can refer to any state defined in Salt. The basic examples are pkg, service, and file, but any used state can be referenced.

In addition to state declarations such as pkg, file, etc., sls type requisites are also recognized, and essentially allow ‘chaining’ of states. This provides a mechanism to ensure the proper sequence for complex state formulas, especially when the discrete states are split or groups into separate sls files:

```yaml
include:
  - network

httpd:
  pkg.installed: []
  service.running:
    - require:
      - pkg: httpd
      - sls: network
```

In this example, the httpd service running state will not be applied (i.e., the httpd service will not be started) unless both the httpd package is installed AND the network state is satisfied.

**Note:** Requisite matching

Requisites match on both the ID Declaration and the name parameter. Therefore, if using the pkgs or sources argument to install a list of packages in a pkg state, it’s important to note that it is impossible to match an individual package in the list, since all packages are installed as a single state.

**Multiple Requisites**

The requisite statement is passed as a list, allowing for the easy addition of more requisites. Both requisite types can also be separately declared:

```yaml
httpd:
  pkg.installed: []
  service.running:
    - enable: True
    - watch:
      - file: /etc/httpd/conf/httpd.conf
        require:
          - pkg: httpd
          - user: httpd
          - group: httpd
  file.managed:
    - name: /etc/httpd/conf/httpd.conf
      source: salt://httpd/httpd.conf
      require:
        - pkg: httpd
```
user.present: []
group.present: []

In this example, the httpd service is only going to be started if the package, user, group, and file are executed successfully.

Requisite Documentation

For detailed information on each of the individual requisites, please look here.

The Order Option

Before using the order option, remember that the majority of state ordering should be done with a Requisite declaration, and that a requisite declaration will override an order option, so a state with order option should not require or required by other states.

The order option is used by adding an order number to a state declaration with the option order:

```
vim:
  pkg.installed:
    - order: 1
```

By adding the order option to 1 this ensures that the vim package will be installed in tandem with any other state declaration set to the order 1.

Any state declared without an order option will be executed after all states with order options are executed.

But this construct can only handle ordering states from the beginning. Certain circumstances will present a situation where it is desirable to send a state to the end of the line. To do this, set the order to last:

```
vim:
  pkg.installed:
    - order: last
```

31.26.13 OverState System

Note: This documentation has been moved here.

31.26.14 State Providers

New in version 0.9.8.

Salt predetermines what modules should be mapped to what uses based on the properties of a system. These determinations are generally made for modules that provide things like package and service management.

Sometimes in states, it may be necessary to use an alternative module to provide the needed functionality. For instance, an older Arch Linux system may not be running systemd, so instead of using the systemd service module, you can revert to the default service module:

```
httpd:
  service.running:
    - enable: True
    - provider: service
```
In this instance, the basic `service` module (which manages `sysvinit`-based services) will replace the `systemd` module which is used by default on Arch Linux.

However, if it is necessary to make this override for most or every service, it is better to just override the provider in the minion config file, as described in the section below.

**Setting a Provider in the Minion Config File**

Sometimes, when running Salt on custom Linux spins, or distribution that are derived from other distributions, Salt does not successfully detect providers. The providers which are most likely to be affected by this are:

- `pkg`
- `service`
- `user`
- `group`

When something like this happens, rather than specifying the provider manually in each state, it easier to use the `providers` parameter in the minion config file to set the provider.

If you end up needing to override a provider because it was not detected, please let us know! File an issue on the [issue tracker](#), and provide the output from the `grains.items` function, taking care to sanitize any sensitive information.

Below are tables that should help with deciding which provider to use if one needs to be overridden.

**Provider: pkg**

<table>
<thead>
<tr>
<th>Execution Module</th>
<th>Used for</th>

</tr>
<tr>
<td>win_groupadd</td>
<td>Windows</td>
</tr>
</tbody>
</table>

**Arbitrary Module Redirects**

The provider statement can also be used for more powerful means, instead of overwriting or extending the module used for the named service an arbitrary module can be used to provide certain functionality.

```
emacs:
  pkg.installed:
```
In this example, the state is being instructed to use a custom module to invoke commands. Arbitrary module redirects can be used to dramatically change the behavior of a given state.

### 31.26.15 Requisites and Other Global State Arguments

#### Fire Event Notifications

New in version 2015.8.0.

The `fire_event` option in a state will cause the minion to send an event to the Salt Master upon completion of that individual state.

The following example will cause the minion to send an event to the Salt Master with a tag of `salt/state_result/20150505121517276431/dasalt/nano` and the result of the state will be the data field of the event. Notice that the name of the state gets added to the tag.

```yaml
nano_stuff:
  pkg.installed:
    - name: nano
    - fire_event: True
```

In the following example instead of setting `fire_event` to `True`, `fire_event` is set to an arbitrary string, which will cause the event to be sent with this tag: `salt/state_result/20150505121725642845/dasalt/custom/tag/nano/finished`

```yaml
nano_stuff:
  pkg.installed:
    - name: nano
    - fire_event: custom/tag/nano/finished
```

#### Requisites

The Salt requisite system is used to create relationships between states. The core idea being that, when one state is dependent somehow on another, that inter-dependency can be easily defined.

Requisites come in two types: Direct requisites (such as `require`), and requisite_ins (such as `require_in`). The relationships are directional: a direct requisite requires something from another state. However, a requisite_in inserts a requisite into the targeted state pointing to the targeting state. The following example demonstrates a direct requisite:

```yaml
vim:
  pkg.installed: []

/etc/vimrc:
  file.managed:
    - source: salt://edit/vimrc
    - require:
      - pkg: vim
```

In the example above, the file `/etc/vimrc` depends on the vim package.

Requisite_in statements are the opposite. Instead of saying ```"I depend on something"``` requisite_ins say ```"Someone depends on me"```:
vim:
  pkg.installed:
    - require_in:
      - file: /etc/vimrc

/etc/vimrc:
  file.managed:
    - source: salt://edit/vimrc

So here, with a requisite_in, the same thing is accomplished as in the first example, but the other way around. The vim package is saying `~/etc/vimrc depends on me`. This will result in a `require` being inserted into the `/etc/vimrc` state which targets the `vim` state.

In the end, a single dependency map is created and everything is executed in a finite and predictable order.

Note: Requisite matching

Requisites match on both the ID Declaration and the `name` parameter. This means that, in the example above, the `require_in` requisite would also have been matched if the `/etc/vimrc` state was written as follows:

vimrc:
  file.managed:
    - name: /etc/vimrc
    - source: salt://edit/vimrc

Direct Requisite and Requisite_in types

There are several direct requisite statements that can be used in Salt:

- `require`
- `watch`
- `prereq`
- `use`
- `onchanges`
- `onfail`

Each direct requisite also has a corresponding requisite_in:

- `require_in`
- `watch_in`
- `prereq_in`
- `use_in`
- `onchanges_in`
- `onfail_in`

All of the requisites define specific relationships and always work with the dependency logic defined above.

`require` The use of `require` demands that the dependent state executes before the depending state. The state containing the `require` requisite is defined as the depending state. The state specified in the `require` statement is defined as the dependent state. If the dependent state’s execution succeeds, the depending state will then execute.
If the dependent state's execution fails, the depending state will not execute. In the first example above, the file `/etc/vimrc` will only execute after the `vim` package is installed successfully.

**Require an entire sls file**  As of Salt 0.16.0, it is possible to require an entire sls file. Do this first by including the sls file and then setting a state to `require` the included sls file:

```
include:
  - foo

bar:
  pkg.installed:
    - require:
      - sls: foo
```

**watch**  `watch` statements are used to add additional behavior when there are changes in other states.

**Note:** If a state should only execute when another state has changes, and otherwise do nothing, the new `on-changes` requisite should be used instead of `watch`. `watch` is designed to add *additional* behavior when there are changes, but otherwise execute normally.

The state containing the `watch` requisite is defined as the watching state. The state specified in the `watch` statement is defined as the watched state. When the watched state executes, it will return a dictionary containing a key named `'changes'`. Here are two examples of state return dictionaries, shown in json for clarity:

```json
"local": {
  "file_|-/tmp/foo_|-/tmp/foo_|-directory": {
    "comment": "Directory /tmp/foo updated",
    "__run_num__": 0,
    "changes": {
      "user": "bar"
    },
    "name": "/tmp/foo",
    "result": true
  }
}

"local": {
  "pkgrepo_|-salt-minion_|-salt-minion_|-managed": {
    "comment": "Package repo 'salt-minion' already configured",
    "__run_num__": 0,
    "changes": {},
    "name": "salt-minion",
    "result": true
  }
}
```

If the `"result"` of the watched state is `true`, the watching state will *execute normally*. This part of `watch` mirrors the functionality of the `require` requisite. If the `"result"` of the watched state is `false`, the watching state will never run, nor will the watching state's `mod_watch` function execute.

However, if the `"result"` of the watched state is `true`, and the `"changes"` key contains a populated dictionary (changes occurred in the watched state), then the `watch` requisite can add additional behavior. This additional behavior is defined by the `mod_watch` function within the watching state module. If the `mod_watch` function exists in the watching state module, it will be called *in addition* to the normal watching state. The return data from the `mod_watch` function is what will be returned to the master in this case; the return data from the main watching function is discarded.
If the "changes" key contains an empty dictionary, the watch requisite acts exactly like the require requisite (the watching state will execute if "result" is True, and fail if "result" is False in the watched state).

**Note:** Not all state modules contain mod_watch. If mod_watch is absent from the watching state module, the watch requisite behaves exactly like a require requisite.

A good example of using watch is with a service.running state. When a service watches a state, then the service is reloaded/restarted when the watched state changes, in addition to Salt ensuring that the service is running.

```
ntpd:
  service.running:
    - watch:
      - file: /etc/ntp.conf
  file.managed:
    - name: /etc/ntp.conf
    - source: salt://ntp/files/ntp.conf
```

prereq  New in version 0.16.0.

prereq allows for actions to be taken based on the expected results of a state that has not yet been executed. The state containing the prereq requisite is defined as the pre-requiring state. The state specified in the prereq statement is defined as the pre-required state.

When a prereq requisite is evaluated, the pre-required state reports if it expects to have any changes. It does this by running the pre-required single state as a test-run by enabling test=True. This test-run will return a dictionary containing a key named "changes". (See the watch section above for examples of "changes" dictionaries.)

If the "changes" key contains a populated dictionary, it means that the pre-required state expects changes to occur when the state is actually executed, as opposed to the test-run. The pre-requiring state will now actually run. If the pre-requiring state executes successfully, the pre-required state will then execute. If the pre-requiring state fails, the pre-required state will not execute.

If the "changes" key contains an empty dictionary, this means that changes are not expected by the pre-required state. Neither the pre-required state nor the pre-requiring state will run.

The best way to define how prereq operates is displayed in the following practical example: When a service should be shut down because underlying code is going to change, the service should be off-line while the update occurs. In this example, graceful-down is the pre-requiring state and site-code is the pre-required state.

```
graceful-down:
  cmd.run:
    - name: service apache graceful
    - prereq:
      - file: site-code

site-code:
  file.recurse:
    - name: /opt/site_code
    - source: salt://site/code
```

In this case the apache server will only be shutdown if the site-code state expects to deploy fresh code via the file.recurse call. The site-code deployment will only be executed if the graceful-down run completes successfully.

onfail  New in version 2014.7.0.

The onfail requisite allows for reactions to happen strictly as a response to the failure of another state. This can be used in a number of ways, such as executing a second attempt to set up a service or begin to execute a separate
thread of states because of a failure.

The onfail requisite is applied in the same way as require as watch:

```yaml
primary_mount:
  mount.mounted:
    - name: /mnt/share
    - device: 10.0.0.45:/share
    - fstype: nfs

backup_mount:
  mount.mounted:
    - name: /mnt/share
    - device: 192.168.40.34:/share
    - fstype: nfs
    - onfail:
      - mount: primary_mount
```

onchanges  New in version 2014.7.0.

The onchanges requisite makes a state only apply if the required states generate changes, and if the watched state's `result` is True. This can be a useful way to execute a post hook after changing aspects of a system.

If a state has multiple onchanges requisites then the state will trigger if any of the watched states changes.

use  The use requisite is used to inherit the arguments passed in another id declaration. This is useful when many files need to have the same defaults.

```yaml
/etc/foo.conf:
  file.managed:
    - source: salt://foo.conf
    - template: jinja
    - mkdirs: True
    - user: apache
    - group: apache
    - mode: 755

/etc/bar.conf
  file.managed:
    - source: salt://bar.conf
    - use:
      - file: /etc/foo.conf
```

The use statement was developed primarily for the networking states but can be used on any states in Salt. This makes sense for the networking state because it can define a long list of options that need to be applied to multiple network interfaces.

The use statement does not inherit the requisites arguments of the targeted state. This means also a chain of use requisites would not inherit inherited options.

The _in versions of requisites  All of the requisites also have corresponding requisite_in versions, which do the reverse of their normal counterparts. The examples below all use require_in as the example, but note that all of the _in requisites work the same way: They result in a normal requisite in the targeted state, which targets the state which has defines the requisite_in. Thus, a require_in causes the target state to require the targeting state. Similarly, a watch_in causes the target state to watch the targeting state. This pattern continues for the rest of the requisites.
If a state declaration needs to be required by another state declaration then `require_in` can accommodate it. Therefore, these two sls files would be the same in the end:

Using `require`

```yaml
httpd:
  pkg.installed: []
  service.running:
    - require:
      - pkg: httpd
```

Using `require_in`

```yaml
httpd:
  pkg.installed:
    - require_in:
      - service: httpd
  service.running: []
```

The `require_in` statement is particularly useful when assigning a require in a separate sls file. For instance it may be common for `httpd` to require components used to set up PHP or mod_python, but the HTTP state does not need to be aware of the additional components that require it when it is set up:

```yaml
http.sls
httpd:
  pkg.installed: []
  service.running:
    - require:
      - pkg: httpd
```

```yaml
php.sls
include:
  - http

php:
  pkg.installed:
    - require_in:
      - service: httpd
```

```yaml
mod_python.sls
include:
  - http

mod_python:
  pkg.installed:
    - require_in:
      - service: httpd
```

Now the `httpd` server will only start if `php` or `mod_python` are first verified to be installed. Thus allowing for a requisite to be defined `after the fact`.

**Altering States**

The state altering system is used to make sure that states are evaluated exactly as the user expects. It can be used to double check that a state preformed exactly how it was expected to, or to make 100% sure that a state only runs
under certain conditions. The use of unless or onlyif options help make states even more stateful. The check_cmds option helps ensure that the result of a state is evaluated correctly.

**Unless**

New in version 2014.7.0.

The `unless` requisite specifies that a state should only run when any of the specified commands return `False`. The `unless` requisite operates as NOR and is useful in giving more granular control over when a state should execute.

**NOTE:** Under the hood `unless` calls `cmd.retcode` with `python_shell=True`. This means the commands referenced by unless will be parsed by a shell, so beware of side-effects as this shell will be run with the same privileges as the salt-minion.

```plaintext
deploy_app:
  cmd.run:
    - names:
      - first_deploy_cmd
      - second_deploy_cmd
      - unless: ls /usr/bin/vim
```

In the example above, the state will only run if either the vim-enhanced package is not installed (returns `False`) or if `/usr/bin/vim` does not exist (returns `False`). The state will run if both commands return `False`.

However, the state will not run if both commands return `True`.

**NOTE:** Under the hood `unless` calls `cmd.retcode` with `python_shell=True`. This means the commands referenced by unless will be parsed by a shell, so beware of side-effects as this shell will be run with the same privileges as the salt-minion.

```plaintext
deploy_app:
  cmd.run:
    - names:
      - first_deploy_cmd
      - second_deploy_cmd
      - unless: ls /usr/bin/vim
```

In the above case, `some_check` will be run prior to `_each_ name` -- once for `first_deploy_cmd` and a second time for `second_deploy_cmd`.

**Onlyif**

New in version 2014.7.0.

`onlyif` is the opposite of `unless`. If all of the commands in `onlyif` return `True`, then the state is run. If any of the specified commands return `False`, the state will not run.

**NOTE:** Under the hood `onlyif` calls `cmd.retcode` with `python_shell=True`. This means the commands referenced by unless will be parsed by a shell, so beware of side-effects as this shell will be run with the same privileges as the salt-minion.

```plaintext
stop-volume:
  module.run:
    - name: glusterfs.stop_volume
    - m_name: work
    - onlyif:
      - gluster volume status work
    - order: 1
```
```
remove-volume:
  module.run:
    - name: glusterfs.delete
    - m_name: work
    - onlyif:
      - gluster volume info work
    - watch:
      - cmd: stop-volume
```

The above example ensures that the stop_volume and delete modules only run if the gluster commands return a 0 ret value.

### Listen/Listen_in

New in version 2014.7.0.

listen and its counterpart listen_in trigger mod_wait functions for states, when those states succeed and result in changes, similar to how watch its counterpart watch_in. Unlike watch and watch_in, listen, and listen_in will not modify the order of states and can be used to ensure your states are executed in the order they are defined. All listen/listen_in actions will occur at the end of a state run, after all states have completed.

```
restart-apache2:
  service.running:
    - name: apache2
    - listen:
      - file: /etc/apache2/apache2.conf

configure-apache2:
  file.managed:
    - name: /etc/apache2/apache2.conf
    - source: salt://apache2/apache2.conf
```

This example will cause apache2 to be restarted when the apache2.conf file is changed, but the apache2 restart will happen at the end of the state run.

```
restart-apache2:
  service.running:
    - name: apache2

configure-apache2:
  file.managed:
    - name: /etc/apache2/apache2.conf
    - source: salt://apache2/apache2.conf
    - listen_in:
      - service: apache2
```

This example does the same as the above example, but puts the state argument on the file resource, rather than the service resource.

### check_cmd

New in version 2014.7.0.

Check Command is used for determining that a state did or did not run as expected.
NOTE: Under the hood check_cmd calls cmd.retcode with python_shell=True. This means the commands referenced by unless will be parsed by a shell, so beware of side-effects as this shell will be run with the same privileges as the salt-minion.

```
comment-repo:
  file.replace:
    - name: /etc/yum.repos.d/fedora.repo
      pattern: ^enabled=0
      repl: enabled=1
      check_cmd:
        - grep 'enabled=0' /etc/yum.repos.d/fedora.repo && return 1 || return 0
```

This will attempt to do a replace on all enabled=0 in the .repo file, and replace them with enabled=1. The check_cmd is just a bash command. It will do a grep for enabled=0 in the file, and if it finds any, it will return a 0, which will prompt the && portion of the command to return a 1, causing check_cmd to set the state as failed. If it returns a 1, meaning it didn't find any `enabled=0' it will hit the || portion of the command, returning a 0, and declaring the function succeeded.

Overriding Checks

There are two commands used for the above checks.

mod_run_check is used to check for onlyif and unless. If the goal is to override the global check for these to variables, include a mod_run_check in the salt/states/ file.

mod_run_check_cmd is used to check for the check_cmd options. To override this one, include a mod_run_check_cmd in the states file for the state.

31.26.16 Startup States

Sometimes it may be desired that the salt minion execute a state run when it is started. This alleviates the need for the master to initiate a state run on a new minion and can make provisioning much easier.

As of Salt 0.10.3 the minion config reads options that allow for states to be executed at startup. The options are startup_states, sls_list, and top_file.

The startup_states option can be passed one of a number of arguments to define how to execute states. The available options are:

highstate Execute state.highstate

sls Read in the sls_list option and execute the named sls files

top Read in the top_file option and execute states based on that top file on the Salt Master

Examples:

Execute state.highstate when starting the minion:

```
startup_states: highstate
```

Execute the sls files edit.vim and hyper:

```
startup_states: sls

sls_list:
```
31.26.17 State Testing

Executing a Salt state run can potentially change many aspects of a system and it may be desirable to first see what a state run is going to change before applying the run.

Salt has a test interface to report on exactly what will be changed, this interface can be invoked on any of the major state run functions:

```bash
salt '*' state.highstate test=True
salt '*' state.sls test=True
salt '*' state.single test=True
```

The test run is mandated by adding the `test=True` option to the states. The return information will show states that will be applied in yellow and the result is reported as `None`.

Default Test

If the value `test` is set to `True` in the minion configuration file then states will default to being executed in test mode. If this value is set then states can still be run by calling `test=False`:

```bash
salt '*' state.highstate test=False
salt '*' state.sls test=False
salt '*' state.single test=False
```

31.26.18 The Top File

Introduction

Most infrastructures are made up of groups of machines, each machine in the group performing a role similar to others. Those groups of machines work in concert with each other to create an application stack.

To effectively manage those groups of machines, an administrator needs to be able to create roles for those groups. For example, a group of machines that serve front-end web traffic might have roles which indicate that those machines should all have the Apache webserver package installed and that the Apache service should always be running.

In Salt, the file which contains a mapping between groups of machines on a network and the configuration roles that should be applied to them is called a top file.

Top files are named `top.sls` by default and they are so-named because they always exist in the ```top``` of a directory hierarchy that contains state files. That directory hierarchy is called a state tree.

A Basic Example

Top files have three components:

- Environment: A state tree directory containing a set of state files to configure systems.
- Target: A grouping of machines which will have a set of states applied to them.
- State files: A list of state files to apply to a target. Each state file describes one or more states to be configured and enforced on the targeted machines.
The relationship between these three components is nested as follows:

- Environments contain targets
- Targets contain states

Putting these concepts together, we can describe a scenario in which all minions with an ID that begins with `web` have an `apache` state applied to them:

```
base: # Apply SLS files from the directory root for the 'base' environment
    'web*': # All minions with a minion_id that begins with 'web'
        - apache # Apply the state file named 'apache.sls'
```

## Environments

Environments are directory hierarchies which contain a top files and a set of state files.

Environments can be used in many ways, however there is no requirement that they be used at all. In fact, the most common way to deploy Salt is with a single environment, called `base`. It is recommended that users only create multiple environments if they have a use case which specifically calls for multiple versions of state trees.

### Getting Started with Top Files

Each environment is defined inside a salt master configuration variable called, `file_roots`.

In the most common single-environment setup, only the `base` environment is defined in `file_roots` along with only one directory path for the state tree.

```
file_roots:
    base:
        - /srv/salt
```

In the above example, the top file will only have a single environment to pull from.

Next is a simple single-environment top file placed in `/srv/salt/top.sls`, illustrating that for the environment called `base`, all minions will have the state files named `core.sls` and `edit.sls` applied to them.

```
base:
    '*':
        - core
        - edit
```

Assuming the `file_roots` configuration from above, Salt will look in the `/srv/salt` directory for `core.sls` and `edit.sls`.

### Multiple Environments

In some cases, teams may wish to create versioned state trees which can be used to test Salt configurations in isolated sets of systems such as a staging environment before deploying states into production.

For this case, multiple environments can be used to accomplish this task.

To create multiple environments, the `file_roots` option can be expanded:

```
file_roots:
    dev:
        - /srv/salt/dev
    qa:
```

1594 Chapter 31. Reference
In the above, we declare three environments: dev, qa and prod. Each environment has a single directory assigned to it.

Our top file references the environments:

```bash
dev:
  'webserver*':
    - webserver
  'db*':
    - db
qa:
  'webserver*':
    - webserver
  'db*':
    - db
prod:
  'webserver*':
    - webserver
  'db*':
    - db
```

As seen above, the top file now declares the three environments and for each, targets are defined to map globs of minion IDs to state files. For example, all minions which have an ID beginning with the string webserver will have the webserver state from the requested environment assigned to it.

In this manner, a proposed change to a state could first be made in a state file in /srv/salt/dev and the applied to development web servers before moving the state into QA by copying the state file into /srv/salt/qa.

Choosing an Environment to Target

The top file is used to assign a minion to an environment unless overridden using the methods described below. The environment in the top file must match an environment in file_roots in order for any states to be applied to that minion. The states that will be applied to a minion in a given environment can be viewed using the state.show_top execution function.

Minions may be pinned to a particular environment by setting the environment value in the minion configuration file. In doing so, a minion will only request files from the environment to which it is assigned.

The environment to use may also be dynamically selected at the time that a salt, salt-call or salt-ssh by passing passing a flag to the execution module being called. This is most commonly done with functions in the state module by using the saltenv= argument. For example, to run a highstate on all minions, using the state files in the prod state tree, run: salt '*' state.highstate saltenv=prod.

Note: Not all functions accept saltenv as an argument. See individual function documentation to verify.

Shorthand

If you assign only one SLS to a system, as in this example, a shorthand is also available:

```bash
base:
  '*': global
dev:
```
Advanced Minion Targeting

In addition to globs, minions can be specified in top files a few other ways. Some common ones are compound matches and node groups.

Below is a slightly more complex top file example, showing the different types of matches you can perform:

```
# All files will be taken from the file path specified in the base
# environment in the `file_roots` configuration value.

base:
  # All minions get the following three state files applied
  '*':
  - ldap-client
  - networking
  - salt.minion

  # All minions which have an ID that begins with the phrase
  # 'salt-master' will have an SLS file applied that is named
  # 'master.sls' and is in the 'salt' directory, underneath
  # the root specified in the `base` environment in the
  # configuration value for `file_roots`.

  'salt-master*':
  - salt.master

  # Minions that have an ID matching the following regular
  # expression will have the state file called 'web.sls' in the
  # nagios/mon directory applied. Additionally, minions matching
  # the regular expression will also have the 'server.sls' file
  # in the apache/ directory applied.

  # NOTE!
  #
  # Take note of the 'match' directive here, which tells Salt
  # to treat the target string as a regex to be matched!

  '^\(memcache\|web\).\(qa\|prod\).\(loc\)\$':
  - match: pcre
  - nagios.mon.web
  - apache.server

  # Minions that have a grain set indicating that they are running
  # the Ubuntu operating system will have the state file called
  # 'ubuntu.sls' in the 'repos' directory applied.

  #
  # Again take note of the 'match' directive here which tells
```
# Salt to match against a grain instead of a minion ID.

'os:Ubuntu':
  - match: grain
  - repos.ubuntu

# Minions that are either RedHat or CentOS should have the 'epel.sls' # state applied, from the 'repos/' directory.

'os:(RedHat|CentOS)'
  - match: grain_pcre
  - repos.epel

# The three minions with the IDs of 'foo', 'bar' and 'baz' should # have 'database.sls' applied.

'foo,bar,baz:
  - match: list
  - database

# Any minion for which the pillar key 'somekey' is set and has a value # of that key matching 'abc' will have the 'xyz.sls' state applied.

'somekey:abc':
  - match: pillar
  - xyz

# All minions which begin with the strings 'nag1' or any minion with # a grain set called 'role' with the value of 'monitoring' will have # the 'server.sls' state file applied from the 'nagios/' directory.

'nag1* or G@role:monitoring':
  - match: compound
  - nagios.server

---

How Top Files Are Compiled

When using multiple environments, it is not necessary to create a top file for each environment. The most common approach, and the easiest to maintain, is to use a single top file placed in only one environment.

However, some workflows do call for multiple top files. In this case, top files may be merged together to create high data for the state compiler to use as a source to compile states on a minion.

For the following discussion of top file compilation, assume the following configuration:

/etc/salt/master
/srv/salt/first/top.sls: ...

```yaml
first_env:
  '*':
    - first

second_env:
  '*':
    - second
```
The astute reader will ask how the state compiler resolves which should be an obvious conflict if a minion is not pinned to a particular environment and if no environment argument is passed into a state function.

Given the above, it is initially unclear whether `first.sls` will be applied or whether `second.sls` will be applied in a `salt '*' state.highstate` command.

When conflicting keys arise, there are several configuration options which control the behaviour of salt:

- **env_order** Setting `env_order` will set the order in which environments are processed by the state compiler.

- **top_file_merging_strategy** Can be set to `same`, which will process only the top file from the environment that the minion belongs to via the environment configuration setting or the environment that is requested via the `saltenv` argument supported by some functions in the `state` module.

  Can also be set to `merge`. This is the default. When set to `merge`, top files will be merged together. The order in which top files are merged together can be controlled with `env_order`.

- **default_top** If `top_file_merging_strategy` is set to `same` and an environment does not contain a top file, the top file in the environment specified by `default_top` will be used instead.

### 31.26.19 SLS Template Variable Reference

The template engines available to sls files and file templates come loaded with a number of context variables. These variables contain information and functions to assist in the generation of templates. See each variable below for its availability -- not all variables are available in all templating contexts.

**Salt**

The `salt` variable is available to abstract the salt library functions. This variable is a python dictionary containing all of the functions available to the running salt minion. It is available in all salt templates.

```python
{% for file in salt['cmd.run']('ls -1 /opt/to_remove').splitlines() %}
/opt/to_remove/{{ file }}:
   file.absent
{% endfor %}
```

**Opts**

The `opts` variable abstracts the contents of the minion’s configuration file directly to the template. The `opts` variable is a dictionary. It is available in all templates.

```python
{{ opts['cachedir'] }}
```

The `config.get` function also searches for values in the `opts` dictionary.

**Pillar**

The `pillar` dictionary can be referenced directly, and is available in all templates:

```python
{{ pillar['key'] }}
```

Using the `pillar.get` function via the `salt` variable is generally recommended since a default can be safely set in the event that the value is not available in pillar and dictionaries can be traversed directly:
Grains

The grains dictionary makes the minion's grains directly available, and is available in all templates:

```yaml
{{ grains['os'] }}
```

The grains.get function can be used to traverse deeper grains and set defaults:

```yaml
{{ salt['grains.get']('os') }}
```

env

The env variable is available in only in sls files when gathering the sls from an environment.

```yaml
{{ env }}
```

sls

The sls variable contains the sls reference value, and is only available in the actual SLS file (not in any files referenced in that SLS). The sls reference value is the value used to include the sls in top files or via the include option.

```yaml
{{ sls }}
```

31.26.20 State Modules

State Modules are the components that map to actual enforcement and management of Salt states.

States are Easy to Write!

State Modules should be easy to write and straightforward. The information passed to the SLS data structures will map directly to the states modules.

Mapping the information from the SLS data is simple, this example should illustrate:

```
/etc/salt/master: # maps to "name"
file.managed: # maps to <filename>.<function> - e.g. "managed" in https://github.com/saltstack/salt/tree/develop/salt/states/file.py
- user: root # one of many options passed to the manage function
- group: root
- mode: 644
- source: salt://salt/master
```

Therefore this SLS data can be directly linked to a module, function, and arguments passed to that function.

This does issue the burden, that function names, state names and function arguments should be very human readable inside state modules, since they directly define the user interface.

Keyword Arguments

Salt passes a number of keyword arguments to states when rendering them, including the environment, a unique identifier for the state, and more. Additionally, keep in mind that the requisites for a state are part of the keyword arguments.
arguments. Therefore, if you need to iterate through the keyword arguments in a state, these must be considered
and handled appropriately. One such example is in the pkgrepo.managed state, which needs to be able to handle
arbitrary keyword arguments and pass them to module execution functions. An example of how these keyword
arguments can be handled can be found here.

Using Custom State Modules

Place your custom state modules inside a _states directory within the file_roots specified by the master
config file. These custom state modules can then be distributed in a number of ways. Custom state modules
are distributed when state.highstate is run, or by executing the saltutil.sync_states or
saltutil.sync_all functions.

Any custom states which have been synced to a minion, that are named the same as one of Salt’s default set of
states, will take the place of the default state with the same name. Note that a state’s default name is its filename (i.e.
foo.py becomes state foo), but that its name can be overridden by using a __virtual__ function.

Cross Calling Execution Modules from States

As with Execution Modules, State Modules can also make use of the __salt__ and __grains__ data. See cross
calling execution modules.

It is important to note that the real work of state management should not be done in the state module unless it is
needed. A good example is the pkg state module. This module does not do any package management work, it just
calls the pkg execution module. This makes the pkg state module completely generic, which is why there is only one
pkg state module and many backend pkg execution modules.

On the other hand some modules will require that the logic be placed in the state module, a good example of this
is the file module. But in the vast majority of cases this is not the best approach, and writing specific execution
modules to do the backend work will be the optimal solution.

Cross Calling State Modules

All of the Salt state modules are available to each other and state modules can call functions available in other state
modules.

The variable __states__ is packed into the modules after they are loaded into the Salt minion.

The __states__ variable is a Python dictionary containing all of the state modules. Dictionary keys are strings
representing the names of the modules and the values are the functions themselves.

Salt state modules can be cross-called by accessing the value in the __states__ dict:

```python
ret = __states__['file.managed'](name='/tmp/myfile', source='salt://myfile')
```

This code will call the managed function in the file state module and pass the arguments name and source to it.

Return Data

A State Module must return a dict containing the following keys/values:

- **name**: The same value passed to the state as `name`.
- **changes**: A dict describing the changes made. Each thing changed should be a key, with its value being another
dict with keys called `old` and `new` containing the old/new values. For example, the pkg state’s changes
dict has one key for each package changed, with the "old" and "new" keys in its sub-dict containing the old and new versions of the package.

- **result**: A tristate value. `True` if the action was successful, `False` if it was not, or `None` if the state was run in test mode, `test=True`, and changes would have been made if the state was not run in test mode.

<table>
<thead>
<tr>
<th></th>
<th>live mode</th>
<th>test mode</th>
</tr>
</thead>
<tbody>
<tr>
<td>no changes</td>
<td><code>True</code></td>
<td><code>True</code></td>
</tr>
<tr>
<td>successful</td>
<td><code>True</code></td>
<td><code>None</code></td>
</tr>
<tr>
<td>changes</td>
<td><code>False</code></td>
<td><code>None</code></td>
</tr>
</tbody>
</table>

**Note**: Test mode does not predict if the changes will be successful or not.

- **comment**: A string containing a summary of the result.

**Test State**

All states should check for and support `test` being passed in the options. This will return data about what changes would occur if the state were actually run. An example of such a check could look like this:

```python
# Return comment of changes if test.
if __opts__['test']:
    ret['result'] = None
    ret['comment'] = 'State Foo will execute with param {0}'.format(bar)
    return ret
```

Make sure to test and return before performing any real actions on the minion.

**Watcher Function**

If the state being written should support the watch requisite then a watcher function needs to be declared. The watcher function is called whenever the watch requisite is invoked and should be generic to the behavior of the state itself.

The watcher function should accept all of the options that the normal state functions accept (as they will be passed into the watcher function).

A watcher function typically is used to execute state specific reactive behavior, for instance, the watcher for the service module restarts the named service and makes it useful for the watcher to make the service react to changes in the environment.

The watcher function also needs to return the same data that a normal state function returns.

**Mod_init Interface**

Some states need to execute something only once to ensure that an environment has been set up, or certain conditions global to the state behavior can be predefined. This is the realm of the mod_init interface.

A state module can have a function called `mod_init` which executes when the first state of this type is called. This interface was created primarily to improve the pkg state. When packages are installed the package metadata needs to be refreshed, but refreshing the package metadata every time a package is installed is wasteful. The `mod_init` function for the pkg state sets a flag down so that the first, and only the first, package installation attempt will refresh the package database (the package database can of course be manually called to refresh via the `refresh` option in the pkg state).

The `mod_init` function must accept the [Low State Data](#) for the given executing state as an argument. The low state data is a dict and can be seen by executing the state.show_lowstate function. Then the `mod_init` function must return
a bool. If the return value is True, then the mod_init function will not be executed again, meaning that the needed behavior has been set up. Otherwise, if the mod_init function returns False, then the function will be called the next time.

A good example of the mod_init function is found in the pkg state module:

```python
def mod_init(low):
    '''
    Refresh the package database here so that it only needs to happen once
    '''
    if low['fun'] == 'installed' or low['fun'] == 'latest':
        rtag = __gen_rtag()
        if not os.path.exists(rtag):
            open(rtag, 'w+').write('')
        return True
    else:
        return False
```

The mod_init function in the pkg state accepts the low state data as low and then checks to see if the function being called is going to install packages, if the function is not going to install packages then there is no need to refresh the package database. Therefore if the package database is prepared to refresh, then return True and the mod_init will not be called the next time a pkg state is evaluated, otherwise return False and the mod_init will be called next time a pkg state is evaluated.

**Log Output**

You can call the logger from custom modules to write messages to the minion logs. The following code snippet demonstrates writing log messages:

```python
import logging

log = logging.getLogger(__name__)

log.info('Here is Some Information')
log.warning('You Should Not Do That')
log.error('It Is Busted')
```

**Full State Module Example**

The following is a simplistic example of a full state module and function. Remember to call out to execution modules to perform all the real work. The state module should only perform ``before`` and ``after`` checks.

1. Make a custom state module by putting the code into a file at the following path: `/srv/salt/_states/my_custom_state.py`.
2. Distribute the custom state module to the minions:

```bash
salt '*' saltutil.sync_states
```
3. Write a new state to use the custom state by making a new state file, for instance `/srv/salt/my_custom_state.sls`.
4. Add the following SLS configuration to the file created in Step 3:

```yaml
human_friendly_state_id:  # An arbitrary state ID declaration.
    my_custom_state:      # The custom state module name.
        - enforce_custom_thing  # The function in the custom state module.
```
Example state module

```python
import salt.exceptions

def enforce_custom_thing(name, foo, bar=True):
    
    Enforce the state of a custom thing

    This state module does a custom thing. It calls out to the execution module `my_custom_module` in order to check the current system and perform any needed changes.

    name
        The thing to do something to
    foo
        A required argument
    bar : True
        An argument with a default value
    
    ret = {'name': name, 'changes': {}, 'result': False, 'comment': ''}

    # Start with basic error-checking. Do all the passed parameters make sense and agree with each-other?
    if bar == True and foo.startswith('Foo'):
        raise salt.exceptions.SaltInvocationError('Argument "foo" cannot start with "Foo" if argument "bar" is True."

    # Check the current state of the system. Does anything need to change?
    current_state = __salt__['my_custom_module.current_state'](name)

    if current_state == foo:
        ret['result'] = True
        ret['comment'] = 'System already in the correct state'
        return ret

    # The state of the system does need to be changed. Check if we're running in ``test=true`` mode.
    if __opts__['test'] == True:
        ret['comment'] = 'The state of "{0}" will be changed.'.format(name)
        ret['changes'] = {
            'old': current_state,
            'new': 'Description, diff, whatever of the new state',
        }

        # Return ``None`` when running with ``test=true``.
        ret['result'] = None

        return ret

    # Finally, make the actual change and return the result.
    new_state = __salt__['my_custom_module.change_state'](name, foo)
```

```
- name: a_value  # Maps to the ``name`` parameter in the custom function.
- foo: Foo       # Specify the required ``foo`` parameter.
- bar: False     # Override the default value for the ``bar`` parameter.
```
State management, also frequently called Software Configuration Management (SCM), is a program that puts and keeps a system into a predetermined state. It installs software packages, starts or restarts services or puts configuration files in place and watches them for changes.

Having a state management system in place allows one to easily and reliably configure and manage a few servers or a few thousand servers. It allows configurations to be kept under version control.

Salt States is an extension of the Salt Modules that we discussed in the previous remote execution tutorial. Instead of calling one-off executions the state of a system can be easily defined and then enforced.

### 31.26.22 Understanding the Salt State System Components

The Salt state system is comprised of a number of components. As a user, an understanding of the SLS and renderer systems are needed. But as a developer, an understanding of Salt states and how to write the states is needed as well.

**Note:** States are compiled and executed only on minions that have been targeted. To execute functions directly on masters, see runners.

#### Salt SLS System

The primary system used by the Salt state system is the SLS system. SLS stands for Salt State.

The Salt States are files which contain the information about how to configure Salt minions. The states are laid out in a directory tree and can be written in many different formats.

The contents of the files and the way they are laid out is intended to be as simple as possible while allowing for maximum flexibility. The files are laid out in states and contains information about how the minion needs to be configured.

#### SLS File Layout

SLS files are laid out in the Salt file server.

A simple layout can look like this:

```
top.sls
ssh.sls
sshd_config
users/init.sls
users/admin.sls
```
The `top.sls` file is a key component. The `top.sls` files is used to determine which SLS files should be applied to which minions.

The rest of the files with the `.sls` extension in the above example are state files.

Files without a `.sls` extensions are seen by the Salt master as files that can be downloaded to a Salt minion.

States are translated into dot notation. For example, the `ssh.sls` file is seen as the ssh state and the `users/admin.sls` file is seen as the users.admin state.

Files named `init.sls` are translated to be the state name of the parent directory, so the `web/init.sls` file translates to the `web` state.

In Salt, everything is a file; there is no "magic translation" of files and file types. This means that a state file can be distributed to minions just like a plain text or binary file.

### SLS Files

The Salt state files are simple sets of data. Since SLS files are just data they can be represented in a number of different ways.

The default format is YAML generated from a Jinja template. This allows for the states files to have all the language constructs of Python and the simplicity of YAML.

State files can then be complicated Jinja templates that translate down to YAML, or just plain and simple YAML files.

The State files are simply common data structures such as dictionaries and lists, constructed using a templating language such as YAML.

Here is an example of a Salt State:

```bash
vim:
  pkg.installed: []
salt:
  pkg.latest:
    - name: salt
  service.running:
    - names:
      - salt-master
      - salt-minion
    - require:
      - pkg: salt
    - watch:
      - file: /etc/salt/minion

/etc/salt/minion:
  file.managed:
    - source: salt://salt/minion
    - user: root
    - group: root
    - mode: 644
    - require:
      - pkg: salt
```
This short stanza will ensure that vim is installed, Salt is installed and up to date, the salt-master and salt-minion daemons are running and the Salt minion configuration file is in place. It will also ensure everything is deployed in the right order and that the Salt services are restarted when the watched file updated.

**The Top File**

The top file controls the mapping between minions and the states which should be applied to them.

The top file specifies which minions should have which SLS files applied and which environments they should draw those SLS files from.

The top file works by specifying environments on the top-level.

Each environment contains globs to match minions. Finally, each glob contains a list of lists of Salt states to apply to matching minions:

```
base:
  '*':
    - salt
    - users
    - users.admin
  'saltmaster.*':
    - match: pcre
    - salt.master
```

This above example uses the base environment which is built into the default Salt setup.

The base environment has two globs. First, the "*" glob contains a list of SLS files to apply to all minions.

The second glob contains a regular expression that will match all minions with an ID matching saltmaster.* and specifies that for those minions, the salt.master state should be applied.

**Reloading Modules**

Some Salt states require that specific packages be installed in order for the module to load. As an example the pip state module requires the pip package for proper name and version parsing.

In most of the common cases, Salt is clever enough to transparently reload the modules. For example, if you install a package, Salt reloads modules because some other module or state might require just that package which was installed.

On some edge-cases salt might need to be told to reload the modules. Consider the following state file which we'll call pep8.sls:

```python
python-pip:
  cmd.run:
    - name: |
      easy_install --script-dir=/usr/bin -U pip
    - cwd: /

pep8:
  pip.installed:
    - require:
      - cmd: python-pip
```

The above example installs pip using easy_install from setuptools and installs pep8 using pip, which, as told earlier, requires pip to be installed system-wide. Let's execute this state:
salt-call state.sls pep8

The execution output would be something like:

```
----------
State: - pip
Name:  pep8
Function: installed
        Result: False
        Comment: State pip.installed found in sls pep8 is unavailable

Changes:

Summary
--------
Succeeded: 1
Failed:  1
--------
Total:   2
```

If we executed the state again the output would be:

```
----------
State: - pip
Name:  pep8
Function: installed
        Result: True
        Comment: Package was successfully installed
Changes: pep8==1.4.6: Installed

Summary
--------
Succeeded: 2
Failed:  0
--------
Total:   2
```

Since we installed pip using cmd, Salt has no way to know that a system-wide package was installed.

On the second execution, since the required pip package was installed, the state executed correctly.

**Note:** Salt does not reload modules on every state run because doing so would greatly slow down state execution.

So how do we solve this *edge-case*? **reload_modules**!

**reload_modules** is a boolean option recognized by salt on all available states which forces salt to reload its modules once a given state finishes.

The modified state file would now be:

```
python-pip:
    cmd.run:
        - name: |
          easy_install --script-dir=/usr/bin -U pip
        - cwd: /
          - reload_modules: true

pep8:
    pip.installed:
```
- require:
  - cmd: python-pip

Let's run it, once:

```
salt-call state.sls pep8
```

The output is:

```
---------
State: - pip
Name:   pep8
Function: installed
  Result: True
  Comment: Package was successfully installed
  Changes: pep8==1.4.6: Installed

Summary
---------
Succeeded: 2
Failed: 0
---------
Total: 2
```

31.27.1 salt.states.alias

Configuration of email aliases

The mail aliases file can be managed to contain definitions for specific email aliases:

<table>
<thead>
<tr>
<th>username</th>
<th>alias.present</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>- target: <a href="mailto:user@example.com">user@example.com</a></td>
</tr>
<tr>
<td>thomas</td>
<td>alias.present</td>
</tr>
<tr>
<td></td>
<td>- target: <a href="mailto:thomas@example.com">thomas@example.com</a></td>
</tr>
</tbody>
</table>

salt.states.alias.absent(name)

Ensure that the named alias is absent

name The alias to remove

salt.states.alias.present(name, target)

Ensures that the named alias is present with the given target or list of targets. If the alias exists but the target differs from the previous entry, the target(s) will be overwritten. If the alias does not exist, the alias will be created.

name The local user/address to assign an alias to
target The forwarding address

31.27.2 salt.states.alternatives

Configuration of the alternatives system

Control the alternatives system

{% set my_hadoop_conf = '/opt/hadoop/conf' %}

{{ my_hadoop_conf }}:
file.directory

hadoop-0.20-conf:
alternatives.install:
- name: hadoop-0.20-conf
- link: /etc/hadoop-0.20/conf
- path: {{ my_hadoop_conf }}
- priority: 30
- require:
  - file: {{ my_hadoop_conf }}

hadoop-0.20-conf:
alternatives.remove:
  - name: hadoop-0.20-conf
  - path: {{ my_hadoop_conf }}

salt.states.alternatives.auto(name)
New in version 0.17.0.
Instructions alternatives to use the highest priority path for <name>

name is the master name for this link group (e.g. pager)

salt.states.alternatives.install(name, link, path, priority)
Install new alternative for defined <name>

name is the master name for this link group (e.g. pager)
link is the symlink pointing to /etc/alternatives/<name>. (e.g. /usr/bin/pager)
path is the location of the new alternative target. NB: This file / directory must already exist. (e.g. /usr/bin/less)
priority is an integer; options with higher numbers have higher priority in automatic mode.

salt.states.alternatives.remove(name, path)
Removes installed alternative for defined <name> and <path> or fallback to default alternative, if some defined before.

name is the master name for this link group (e.g. pager)
path is the location of one of the alternative target files. (e.g. /usr/bin/less)

salt.states.alternatives.set(name, path)
New in version 0.17.0.
Sets alternative for <name> to <path>, if <path> is defined as an alternative for <name>.

name is the master name for this link group (e.g. pager)
path is the location of one of the alternative target files. (e.g. /usr/bin/less)

31.27.3 salt.states.apache

Apache state
New in version 2014.7.0.
Allows for inputting a yaml dictionary into a file for apache configuration files.
The variable this is special and signifies what should be included with the above word between angle brackets (<>).

```
/etc/httpd/conf.d/website.com.conf:
apache.configfile:
  - config:
    VirtualHost:
      this: '*:80'
    ServerName:
      - website.com
    ServerAlias:
      - www.website.com
      - dev.website.com
    ErrorLog: logs/website.com-error_log
    CustomLog: logs/website.com-access_log combined
    DocumentRoot: /var/www/vhosts/website.com
    Directory:
```
this: /var/www/vhosts/website.com
Order: Deny,Allow
Deny from: all
Allow from:
- 127.0.0.1
- 192.168.100.0/24
Options:
- +Indexes
- FollowSymlinks
AllowOverride: All

salt.states.apache.configfile(name, config)

31.27.4 salt.states.apache_module

Manage Apache Modules

New in version 2014.7.0.

Enable and disable apache modules.

Enable cgi module:
  apache_module.enable:
    - name: cgi

Disable cgi module:
  apache_module.disable:
    - name: cgi

salt.states.apache_module.disable(name)
  Ensure an Apache module is disabled.
  
  name  Name of the Apache module

salt.states.apache_module.enable(name)
  Ensure an Apache module is enabled.
  
  name  Name of the Apache module

31.27.5 salt.states.aptpkg

Package management operations specific to APT- and DEB-based systems

salt.states.aptpkg.held(name)
  Set package in `hold' state, meaning it will not be upgraded.
  
  name  The name of the package, e.g., `tmux'

31.27.6 salt.states.archive

Extract an archive

New in version 2014.1.0.
salt.states.archive.extracted(name, source, archive_format, archive_user=None, user=None, group=None, tar_options=None, source_hash=None, if_missing=None, keep=False)

New in version 2014.1.0.

State that make sure an archive is extracted in a directory. The downloaded archive is erased if successfully extracted. The archive is downloaded only if necessary.

**Note:** If `if_missing` is not defined, this state will check for `name` instead. If `name` exists, it will assume the archive was previously extracted successfully and will not extract it again.

Example, tar with flag for lmza compression:

```yaml
graylog2-server:
  archive.extracted:
    - name: /opt/
    - source: https://github.com/downloads/Graylog2/graylog2-server/graylog2-server-0.9.6p1.tar.lzma
    - source_hash: md5=499ae16dca71eeb7c3a38c75ea7a1a6
    - tar_options: J
    - archive_format: tar
    - if_missing: /opt/graylog2-server-0.9.6p1/
```

Example, tar with flag for verbose output:

```yaml
graylog2-server:
  archive.extracted:
    - name: /opt/
    - source: https://github.com/downloads/Graylog2/graylog2-server/graylog2-server-0.9.6p1.tar.gz
    - source_hash: md5=499ae16dca71eeb7c3a38c75ea7a1a6
    - archive_format: tar
    - tar_options: v
    - user: root
    - group: root
    - if_missing: /opt/graylog2-server-0.9.6p1/
```

**name** Directory name where to extract the archive

**source** Archive source, same syntax as file.managed source argument.

**source_hash** Hash of source file, or file with list of hash-to-file mappings. It uses the same syntax as the file.managed source_hash argument.

**archive_format** tar, zip or rar

**archive_user** The user to own each extracted file.

Deprecation since version 2014.7.2: replaced by standardized `user` parameter.

**user** The user to own each extracted file.

**group** The group to own each extracted file.

**if_missing** Some archives, such as tar, extract themselves in a subfolder. This directive can be used to validate if the archive had been previously extracted.

**tar_options** Required if used with `archive_format`: tar, otherwise optional. It needs to be the tar argument specific to the archive being extracted, such as ‘J’ for LZMA or ‘v’ to verbosely list files processed. Using this option means that the tar executable on the target will be used, which is less platform independent. Main operators like ‘x’, ‘-extract’, ‘--get’, ‘-c’ and ‘-f’/’--file should not be used here. If `archive_format` is zip or rar and this option is not set, then the Python tarfile module is used. The tarfile module supports gzip and bzip2 in Python 2.
keep  Keep the archive in the minion's cache

### 31.27.7  salt.states.artifactory

This state downloads artifacts from artifactory.

**salt.states.artifactory.downloaded**(name, artifact, target_dir='/tmp', target_file=None)

Ensures that the artifact from artifactory exists at given location. If it doesn't exist, then it will be downloaded. It it already exists then the checksum of existing file is checked against checksum in artifactory. If it is different then the step will fail.

**artifact:**

Details of the artifact to be downloaded from artifactory.

- artifact_url: URL of the artifactory instance
- repository: Repository in artifactory
- artifact_id: Artifact ID
- group_id: Group ID
- packaging: Packaging
- classifier: Classifier
- version: Version
- username: Artifactory username
- password: Artifactory password

**target_dir:** Directory where the artifact should be downloaded. By default it is downloaded to /tmp directory.

**target_file:** Target file to download artifact to. By default file name is resolved by artifactory.

Example:: Download artifact to a specific file:

```yaml
jboss_module_downloaded:
    artifactory.downloaded:
      - artifact:
          artifact_url: http://artifactory.intranet.company.com/artifactory
          repository: 'libs-release-local'
          artifact_id: 'module'
          group_id: 'com.company.module'
          packaging: 'jar'
          classifier: 'sources'
          version: '1.0'
          target_file: /opt/jboss7/modules/com/company/lib/module.jar
```

Download artifact to the folder (automatically resolves file name):

```yaml
jboss_module_downloaded:
    artifactory.downloaded:
      - artifact:
          artifact_url: http://artifactory.intranet.company.com/artifactory
          repository: 'libs-release-local'
          artifact_id: 'module'
          group_id: 'com.company.module'
          packaging: 'jar'
          classifier: 'sources'
```
31.27.8 salt.states.at

Configuration disposable regularly scheduled tasks for at.

The at state can be add disposable regularly scheduled tasks for your system.

salt.states.at.absent(name, jobid=None, **kwargs)
Remove a job from queue. The `kwargs` can include hour, minute, day, month, year

- limit Target range
- tag Job's tag
- runas Runs user-specified jobs

example1:
  at.absent:
    - limit: all

example2:
  at.absent:
    - limit: all
    - year: 13

example3:
  at.absent:
    - limit: all
    - tag: rose
    - runas: jim

example4:
  at.absent:
    - limit: all
    - tag: rose
    - day: 13
    - hour: 16

salt.states.at.present(name, timespec, tag=None, user=None, job=None)
Add a job to queue.

- job Command to run.
- timespec The `timespec` follows the format documented in the at(1) manpage.
- tag Make a tag for the job.
- user The user to run the at job

rose:
  at.present:
    - job: 'echo "I love saltstack" > love'
    - timespec: '9:09 11/09/13'
    - tag: love
    - user: jam
31.27.9 salt.states.augeas

Configuration management using Augeas

New in version 0.17.0.

This state requires the augeas Python module.

Augeas can be used to manage configuration files.

**Warning:** Minimal installations of Debian and Ubuntu have been seen to have packaging bugs with python-augeas, causing the augeas module to fail to import. If the minion has the augeas module installed, and the state fails with a comment saying that the state is unavailable, first restart the salt-minion service. If the problem persists past that, the following command can be run from the master to determine what is causing the import to fail:

```bash
salt minion-id cmd.run 'python -c "from augeas import Augeas"'
```

For affected Debian/Ubuntu hosts, installing libpython2.7 has been known to resolve the issue.

salt.states.augeas.change(name, context=None, changes=None, lens=None, **kwargs)

New in version 2014.7.0.

This state replaces setvalue().

Issue changes to Augeas, optionally for a specific context, with a specific lens.

- **name** State name

  A file path, prefixed by `/files`. Should resolve to an actual file (not an arbitrary augeas path).

  This is used to avoid duplicating the file name for each item in the changes list (for example, set bind 0.0.0.0 in the example below operates on the file specified by context). If context is not specified, a file path prefixed by `/files` should be included with the set command.

  The file path is examined to determine if the specified changes are already present.

  ```
  redis-conf:
  augeas.change:
  - context: /files/etc/redis/redis.conf
  - changes:
    - set bind 0.0.0.0
    - set maxmemory 1G
  ```

  **changes** List of changes that are issued to Augeas. Available commands are set, setm, mv/move, ins/insert, and rm/remove.

  **lens** The lens to use, needs to be suffixed with `.lns`, e.g.: `Nginx.lns`. See the list of stock lenses shipped with Augeas.

Usage examples:

Set the bind parameter in `/etc/redis/redis.conf`:

```
redis-conf:
 augeas.change:
  - changes:
    - set /files/etc/redis/redis.conf/bind 0.0.0.0
```

**Note:** Use the context parameter to specify the file you want to manipulate. This way you don't have to include this in the changes every time:
Augeas is aware of a lot of common configuration files and their syntax. It knows the difference between for example ini and yaml files, but also files with very specific syntax, like the hosts file. This is done with lenses, which provide mappings between the Augeas tree and the file.

There are many preconfigured lenses that come with Augeas by default, and they specify the common locations for configuration files. So most of the time Augeas will know how to manipulate a file. In the event that you need to manipulate a file that Augeas doesn’t know about, you can specify the lens to use like this:

```
redis-conf:
  augeas.change:
    - lens: redis
      context: /files/etc/redis/redis.conf
      changes:
        - set bind 0.0.0.0
```

Note: Even though Augeas knows that /etc/redis/redis.conf is a Redis configuration file and knows how to parse it, it is recommended to specify the lens anyway. This is because by default, Augeas loads all known lenses and their associated file paths. All these files are parsed when Augeas is loaded, which can take some time. When specifying a lens, Augeas is loaded with only that lens, which speeds things up quite a bit.

A more complex example, this adds an entry to the services file for Zabbix, and removes an obsolete service:

```
zabbix-service:
  augeas.change:
    - lens: services
      context: /files/etc/services
      changes:
        - ins service-name after service-name[last()]
        - set service-name[last()] zabbix-agent
        - set service-name[. = 'zabbix-agent']/#comment "Zabbix Agent service"
        - set service-name[. = 'zabbix-agent']/port 10050
        - set service-name[. = 'zabbix-agent']/protocol tcp
        - rm service-name[. = 'im-obsolete']
        - unless: grep "zabbix-agent" /etc/services
```

Warning: Don’t forget the unless here, otherwise a new entry will be added every time this state is run.

### 31.27.10 salt.states.aws_sqs

Manage SQS Queues

Create and destroy SQS queues. Be aware that this interacts with Amazon’s services, and so may incur charges.

This module uses the awsccli tool provided by Amazon. This can be downloaded from pip. Also check the documentation for awsccli for configuration information.
myqueue:
  aws_sqs.exists:
    - region: eu-west-1

salt.states.aws_sqs.absent(name, region, user=None, opts=False)
  Remove the named SQS queue if it exists.

    name  Name of the SQS queue.
    region  Region to remove the queue from
    user  Name of the user performing the SQS operations
    opts  Include additional arguments and options to the aws command line

salt.states.aws_sqs.exists(name, region, user=None, opts=False)
  Ensure the SQS queue exists.

    name  Name of the SQS queue.
    region  Region to create the queue
    user  Name of the user performing the SQS operations
    opts  Include additional arguments and options to the aws command line

31.27.11 salt.states.beacon

Management of the Salt beacons

New in version 2015.8.0.

ps:
  beacon.present:
    - enable: False
    - salt-master: running
    - apache2: stopped

sh:
  beacon.present:

load:
  beacon.present:
    - 1m:
      - 0.0
      - 2.0
    - 5m:
      - 0.0
      - 1.5
    - 15m:
      - 0.1
      - 1.0

salt.states.beacon.absent(name, **kwargs)
  Ensure beacon is absent.

    name  The name of the beacon ensured absent.
	salt.states.beacon.disabled(name, **kwargs)
  Disable a beacon.
**name**  The name of the beacon to enable.

```python
salt.states.beacon.enabled(name, **kwargs)
```
Enable a beacon.

**name**  The name of the beacon to enable.

```python
salt.states.beacon.present(name, **kwargs)
```
Ensure beacon is configured with the included beacon data.

**name**  The name of the beacon ensure is configured.

## 31.27.12 salt.states.bigip

A state module designed to enforce load-balancing configurations for F5 Big-IP entities.

**maturity**  develop

**platform**  f5_bigip_11.6

```python
salt.states.bigip.add_pool_member(hostname, username, password, name, member)
```
A function to connect to a bigip device and add a new member to an existing pool.

**Parameters:**
- hostname: The host/address of the bigip device
- username: The iControl REST username
- password: The iControl REST password
- name: The name of the pool to modify
- member: The member to add to the pool

```python
salt.states.bigip.create_monitor(hostname, username, password, monitor_type, name, **kwargs)
```
A function to connect to a bigip device and create a monitor.

**Parameters:**
- hostname: The host/address of the bigip device
- username: The iControl REST username
- password: The iControl REST password
- monitor_type: The type of monitor to create
- name: The name of the monitor to create

**Keyword Args:**  
`[arg=val]...` Consult F5 BIGIP user guide for specific options for each monitor type. Typically, tmsh arg names are used.

```python
salt.states.bigip.create_node(hostname, username, password, name, address)
```
Create a new node if it does not already exist.

**Parameters:**
- hostname: The host/address of the bigip device
- username: The iControl REST username
- password: The iControl REST password
- name: The name of the node to create
- address: The address of the node

```python
salt.states.bigip.create_pool(hostname, username, password, name, members=None, allow_nat=None, allow_snat=None, description=None, gateway_failsafe_device=None, ignore_persisted_weight=None, ip_tos_to_client=None, ip_tos_to_server=None, link_qos_to_client=None, link_qos_to_server=None, load_balancing_mode=None, min_active_members=None, min_up_members=None, min_up_members_action=None, min_up_members_checking=None, monitor=None, profiles=None, queue_depth_limit=None, queue_on_connection_limit=None, queue_time_limit=None, reselect_tries=None, service_down_action=None, slow_ramp_time=None)
```
Create a new node if it does not already exist.

**Parameters:**
- hostname: The host/address of the bigip device
- username: The iControl REST username
- password: The iControl REST password
- name: The name of the pool to create
- members: List of members to be added to the pool

salt.states.bigip.create_profile(hostname, username, password, profile_type, name, **kwargs)
A function to connect to a bigip device and create a profile.

Parameters:
hostname: The host/address of the bigip device username: The iControl REST username password: The iControl REST password profile_type: The type of profile to create name: The name of the profile to create

Keyword Args: [arg=val]...
Consult F5 BIGIP user guide for specific options for each profile type. Typically, tmsh arg names are used.

Special Characters: |, and [must be escaped using \ when used] within strings.

salt.states.bigip.create_virtual(hostname, username, password, name, destination, pool=None, address_status=None, auto_lasthop=None, bwc_policy=None, cmp_enabled=None, connection_limit=None, dhcp_relay=None, description=None, fallback_persistence=None, flow_eviction_policy=None, gtm_score=None, ip_forward=None, ip_protocol=None, internal=None, twelve_forward=None, last_hop_pool=None, mask=None, mirror=None, nat64=None, persist=None, profiles=None, policies=None, rate_class=None, rate_limit=None, rate_limit_mode=None, rate_limit_dst=None, rate_limit_src=None, rules=None, related_rules=None, reject=None, source=None, source_address_translation=None, source_port=None, virtual_state=None, traffic_classes=None, translate_address=None, translate_port=None, vlans=None)
A function to connect to a bigip device and create a virtual server if it does not already exists.

Parameters:
hostname: The host/address of the bigip device username: The iControl REST username password: The iControl REST password name: The name of the virtual to create destination: [ [virtual_address_name:port] | [ipv4:port] | [ipv6:port] ]

salt.states.bigip.delete_monitor( hostname, username, password, monitor_type, name)
Modify an existing monitor. If it does exist, only the parameters specified will be enforced.

Parameters: hostname: The host/address of the bigip device username: The iControl REST username password: The iControl REST password monitor_type: The type of monitor to create name: The name of the monitor to create

Keyword Args: [arg=val]... Consult F5 BIGIP user guide for specific options for each monitor type. Typically, tmsh arg names are used.

salt.states.bigip.delete_node( hostname, username, password, name)
Delete an existing node.

Parameters: hostname: The host/address of the bigip device username: The iControl REST username password: The iControl REST password name: The name of the node which will be deleted.

salt.states.bigip.delete_pool( hostname, username, password, name)
Delete an existing pool.

Parameters: hostname: The host/address of the bigip device username: The iControl REST username password: The iControl REST password name: The name of the pool which will be deleted

salt.states.bigip.delete_pool_member( hostname, username, password, name, member)
Delete an existing pool member.

Parameters: hostname: The host/address of the bigip device username: The iControl REST username password: The iControl REST password name: The name of the pool to be modified member: The name of the member to delete from the pool

salt.states.bigip.delete_profile( hostname, username, password, profile_type, name)
Modify an existing profile. If it does exist, only the parameters specified will be enforced.

Parameters: hostname: The host/address of the bigip device username: The iControl REST username password: The iControl REST password profile_type: The type of profile to create name: The name of the profile to create

Keyword Args: [arg=val]... Consult F5 BIGIP user guide for specific options for each profile type. Typically, tmsh arg names are used.

salt.states.bigip.delete_virtual( hostname, username, password, name)
Delete an existing virtual.

Parameters: hostname: The host/address of the bigip device username: The iControl REST username password: The iControl REST password name: The name of the virtual which will be deleted

salt.states.bigip.list_monitor( hostname, username, password, monitor_type, name)
A function to list an existing monitor.

Parameters: hostname: The host/address of the bigip device username: The iControl REST username password: The iControl REST password monitor_type: The type of monitor to list name: The name of the monitor to list

salt.states.bigip.list_node( hostname, username, password, name)
A function to connect to a bigip device and list a specific node.
Parameters: hostname: The host/address of the bigip device username: The iControl REST username password: The iControl REST password name: The name of the node to list.

```python
salt.states.bigip.list_pool(hostname, username, password, name)
```
A function to connect to a bigip device and list a specific pool.

Parameters: hostname: The host/address of the bigip device username: The iControl REST username password: The iControl REST password name: The name of the pool to list.

```python
salt.states.bigip.list_profile(hostname, username, password, profile_type, name)
```
A function to list an existing profile.

Parameters: hostname: The host/address of the bigip device username: The iControl REST username password: The iControl REST password profile_type: The type of profile to list name: The name of the profile to list

```python
salt.states.bigip.list_virtual(hostname, username, password, name)
```
A function to list a specific virtual.

Parameters: hostname: The host/address of the bigip device username: The iControl REST username password: The iControl REST password name: The name of the virtual to list

```python
salt.states.bigip.manage_monitor(hostname, username, password, monitor_type, name, **kwargs)
```
Create a new monitor if a monitor of this type and name does not already exists. If it does exists, only the parameters specified will be enforced.

Parameters: hostname: The host/address of the bigip device username: The iControl REST username password: The iControl REST password monitor_type: The type of monitor to create name: The name of the monitor to create

Keyword Args: [arg=val] ... Consult F5 BIGIP user guide for specific options for each monitor type. Typically, tmsh arg names are used.

```python
salt.states.bigip.manage_node(hostname, username, password, name, address, connection_limit=None, description=None, dynamic_ratio=None, logging=None, monitor=None, rate_limit=None, ratio=None, session=None, node_state=None)
```
Manages a node of a given bigip device. If the node does not exist it will be created, otherwise, only the properties which are different than the existing will be updated.

```python
salt.states.bigip.manage_pool(hostname, username, password, name, allow_nat=None, allow_snat=None, description=None, gateway_failsafe_device=None, ignore_persisted_weight=None, ip_tos_to_client=None, ip_tos_to_server=None, link_qos_to_client=None, link_qos_to_server=None, load_balancing_mode=None, min_active_members=None, min_up_members=None, min_up_members_action=None, min_up_members_checking=None, monitor=None, profiles=None, queue_depth_limit=None, queue_on_connection_limit=None, queue_time_limit=None, reselect_tries=None, service_down_action=None, slow_ramp_time=None)
```
Create a new pool if it does not already exist. Pool members are managed separately. Only the parameters
specifying are enforced.

**Parameters:**
- **hostname:** The host/address of the bigip device
- **username:** The iControl REST username
- **password:** The iControl REST password
- **name:** The name of the pool to create

- **allowNat:** [yes \ or \ no]
- **allowSnat:** [yes \ or \ no]
- **description:** [string]
- **gatewayFailsafeDevice:** [string]
- **ignorePersistedWeight:** [enabled \ or \ disabled]
- **ipToSsClient:** [pass-through \ or \ [integer]]
- **ipToSsServer:** [pass-through \ or \ [integer]]
- **linkQosToClient:** [pass-through \ or \ [integer]]
- **linkQosToServer:** [pass-through \ or \ [integer]]
- **loadBalancingMode:** [dynamic-ratio-member \ or \ dynamic-ratio-node]
  - **fastest-app-response**
  - **fastest-node**
  - **least-connections-members**
  - **least-connections-node**
  - **least-connections**
  - **least-member**
  - **least-node**
  - **least-sessions**
  - **observed-member**
  - **observed-node**
  - **predictive-member**
  - **predictive-node**
  - **ratio-least-connections-member**
  - **ratio-least-connections-node**
  - **ratio-member**
  - **ratio-node**
  - **ratio-session**
  - **round-robin**
  - **weighted-least-connections-member**
  - **weighted-least-connections-node**

- **minActiveMembers:** [integer]
- **minUpMembers:** [integer]
- **minUpMembersAction:** [failover \ or \ reboot \ or \ restart-all]
- **minUpMembersChecking:** [enabled \ or \ disabled]
- **monitor:** [name]
- **profiles:** [none \ or \ profile-name]
- **queueDepthLimit:** [integer]
- **queueOnConnectionLimit:** [enabled \ or \ disabled]
- **queueTimeLimit:** [integer]
- **reselectTries:** [integer]
- **serviceDownAction:** [drop \ or \ none \ or \ reselect \ or \ reset]
- **slowRampTime:** [integer]

### salt.states.bigip.manage_pool_members

Manage the members of an existing pool. This function replaces all current pool members. Only the parameters specified are enforced.

**Parameters:**
- **hostname:** The host/address of the bigip device
- **username:** The iControl REST username
- **password:** The iControl REST password
- **name:** The name of the pool to modify
- **members:** list of pool members to manage.

### salt.states.bigip.manage_profile

Create a new profile if a monitor of this type and name does not already exists. If it does exists, only the parameters specified will be enforced.

**Parameters:**
- **hostname:** The host/address of the bigip device
- **username:** The iControl REST username
- **password:** The iControl REST password
- **profileType:** The type of profile to create
- **name:** The name of the profile to create
- **kwargs:** [arg=val]...

Consult F5 BIGIP user guide for specific options for each profile type. Typically, tmsh arg names are used.

### salt.states.bigip.manage_virtual

Manage a virtual server. If a virtual does not exist it will be created, otherwise only the parameters specified will be enforced.

**Parameters:**
- **hostname:** The host/address of the bigip device
- **username:** The iControl REST username
- **password:** The iControl REST password
- **name:** The name of the virtual to create
- **destination:** [virtual]
- **pool:** [None]
- **addressStatus:** [None]
- **autoLastHop:** [None]
- **bwcPolicy:** [None]
- **cmpEnabled:** [None]
- **connectionLimit:** [None]
- **dhcpRelay:** [None]
- **description:** [None]
- **fallbackPersistence:** [None]
- **flowEvictionPolicy:** [None]
- **gtmScore:** [None]
- **ipForward:** [None]
- **ipProtocol:** [None]
- **internal:** [None]
- **twelveForward:** [None]
- **lastHopPool:** [None]
- **mask:** [None]
- **mirror:** [None]
- **nat64:** [None]
- **persist:** [None]
- **profiles:** [None]
- **policies:** [None]
- **rateClass:** [None]
- **rateLimit:** [None]
- **rateLimitMode:** [None]
- **rateLimitDst:** [None]
- **rateLimitSrc:** [None]
- **relatedRules:** [None]
- **reject:** [None]
- **source:** [None]
- **sourceAddressTranslation:** [None]
- **sourcePort:** [None]
- **virtualState:** [None]
- **trafficClasses:** [None]
- **translateAddress:** [None]
- **translatePort:** [None]
- **vlans:** [None]
salt.states.bigip.modify_monitor

Modify an existing monitor. If it does exists, only the parameters specified will be enforced.

Parameters:
- **hostname**: The host/address of the bigip device
- **username**: The iControl REST username
- **password**: The iControl REST password
- **monitor_type**: The type of monitor to create name: The name of the monitor to create

Keyword Args: [arg=val]... Consult F5 BIGIP user guide for specific options for each monitor type. Typically, tmsh arg names are used.

salt.states.bigip.modify_node

Modify an existing node. Only a node which already exists will be modified and only the parameters specified will be enforced.

Parameters:
- **hostname**: The host/address of the bigip device username: The iControl REST username password: The iControl REST password
- **name**: The name of the node to modify

salt.states.bigip.modify_pool

Modify an existing pool. Pool members are managed separately. Only the parameters specified are enforced.

Parameters:
- **hostname**: The host/address of the bigip device
- **username**: The iControl REST username
- **password**: The iControl REST password
- **name**: The name of the pool to modify
Parameters: hostname: The host/address of the bigip device username: The iControl REST username password: The iControl REST password name: The name of the pool to create

salt.states.bigip.modify_pool_member(hostname, username, password, name, member, connection_limit=None, description=None, dynamic_ratio=None, inherit_profile=None, logging=None, monitor=None, priority_group=None, profiles=None, rate_limit=None, ratio=None, session=None, member_state=None)

A function to connect to a bigip device and modify a member of an existing pool.

Parameters: hostname: The host/address of the bigip device username: The iControl REST username password: The iControl REST password name: The name of the pool to modify member: The member modify

salt.states.bigip.modify_profile(hostname, username, password, profile_type, name, **kwargs)

Modify an existing profile. If it does exists, only the parameters specified will be enforced.

Parameters: hostname: The host/address of the bigip device username: The iControl REST username password: The iControl REST password profile_type: The type of profile to create name: The name of the profile to create

Keyword Args: [arg=val] ... Consult F5 BIGIP user guide for specific options for each monitor type. Typically, tmsh arg names are used.

salt.states.bigip.modify_virtual(hostname, username, password, name, destination, pool=None, address_status=None, auto_lasthop=None, bwc_policy=None, cmp_enabled=None, connection_limit=None, dhcp_relay=None, description=None, fallback_persistence=None, flow_eviction_policy=None, gtm_score=None, ip_forward=None, ip_protocol=None, internal=None, twelve_forward=None, last_hop_pool=None, mask=None, mirror=None, nat64=None, persist=None, profiles=None, policies=None, rate_class=None, rate_limit=None, rate_limit_mode=None, rate_limit_dst=None, rate_limit_src=None, rules=None, related_rules=None, reject=None, source=None, source_address_translation=None, source_port=None, virtual_state=None, traffic_classes=None, translate_address=None, translate_port=None, vlans=None)
Modify an virtual server. modify an existing virtual. Only parameters specified will be enforced.

**Parameters:**
- hostname: The host/address of the bigip device
- username: The iControl REST username
- password: The iControl REST password
- name: The name of the virtual to create
- destination: [ [virtual_address_name:port] | [ipv4:port] | [ipv6:port] ]
- pool: [ [pool_name] | none] address_status: [yes | no]
- auto_lasthop: [default | enabled | disabled]
- bwc_policy: [none | string]
- cmp_enabled: [yes | no]
- dhcp_relay: [yes | no]
- connection_limit: [integer]
- description: [string]
- state: [disabled | enabled]
- fallback_persistence: [none | [profile name]]
- flow_eviction_policy: [none | [eviction policy name]]
- gtm_score: [integer]
- ip_forward: [yes | no]
- ip_protocol: [any | protocol]
- internal: [yes | no]
- twelve_forward(12-forward): [yes | no]
- last_hop_pool: [ [pool_name] | none]
- mask: { [ipv4] | [ipv6] }
- mirror: { [disabled | enabled | none] }
- nat64: [enabled | disabled]
- persist: [list]
- profiles: [none | default | list]
- policies: [none | default | list]
- rate_class: [name]
- rate_limit: [integer]
- rate_limit_mode: [destination | object | object-destination]
- object-source | object-source-destination | source | source-destination
- rate_limit_dst: [integer]
- rate_limit_src: [integer]
- rules: [none | list]
- relatedrules: [none | list]
- reject: [yes | no]
- source: { [ipv4[/prefixlen]] | [ipv6[/prefixlen]] }
- source_address_translation: [none | snat:pool_name | lsn | automap | dictionary]
- source_port: [change | preserve | preserve-strict]
- state: [enabled | disabled]
- traffic_classes: [none | default | list]
- translate_address: [enabled | disabled]
- translate_port: [enabled | disabled]
- vlans: [none | default | dictionary]
- vlan_ids: [list]
- enabled: [true | false]

31.27.13 salt.states.blockdev

Management of Block Devices

A state module to manage blockdevices

```
/dev/sda:
    blockdev.tuned:
        - read-only: True

master-data:
    blockdev.tuned::
         - name : /dev/vg/master-data
         - read-only: True
         - read-ahead: 1024
```

New in version 2014.7.0.

salt.states.blockdev.formatted(name, fs_type='ext4', **kwargs)
Manage filesystems of partitions.

- name The name of the block device
- fs_type The filesystem it should be formatted as

salt.states.blockdev.tuned(name, **kwargs)
Manage options of block device

- name The name of the block device

- opts:
  - read-ahead Read-ahead buffer size
  - filesystem-read-ahead Filesystem Read-ahead buffer size
  - read-only Set Read-Only
• read-write Set Read-Write

31.27.14 salt.states.boto_asg

Manage Autoscale Groups

New in version 2014.7.0.

Create and destroy autoscale groups. Be aware that this interacts with Amazon’s services, and so may incur charges.

This module uses boto, which can be installed via package, or pip.

This module accepts explicit autoscale credentials but can also utilize IAM roles assigned to the instance through Instance Profiles. Dynamic credentials are then automatically obtained from AWS API and no further configuration is necessary. More Information available at:

If IAM roles are not used you need to specify them either in a pillar or in the minion's config file:

```yaml
asg.keyid: GKTADJGHEIQSXMKKRBJ08H
asg.key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
```

It's also possible to specify key, keyid and region via a profile, either as a passed in dict, or as a string to pull from pillars or minion config:

```yaml
myprofile:
  keyid: GKTADJGHEIQSXMKKRBJ08H
  key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
  region: us-east-1
```

Ensure myasg exists:

```yaml
boto_asg.present:
  - name: myasg
    - launch_config_name: mylc
    - availability_zones:
      - us-east-1a
      - us-east-1b
    - min_size: 1
    - max_size: 1
    - desired_capacity: 1
    - load_balancers:
      - myelb
    - suspended_processes:
      - AddToLoadBalancer
      - AlarmNotification
    - scaling_policies
      - name: ScaleDown
        - scaling_adjustment: -1
    - region: us-east-1
    - keyid: GKTADJGHEIQSXMKKRBJ08H
    - key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
```

31.27. Full list of builtin state modules
# Using a profile from pillars.
Ensure myasg exists:
```
boto_asg.present:
  - name: myasg
    - launch_config_name: mylc
    - availability_zones:
        - us-east-1a
        - us-east-1b
    - min_size: 1
    - max_size: 1
    - desired_capacity: 1
    - load_balancers:
        - myelb
    - profile: myprofile
```

# Passing in a profile.
Ensure myasg exists:
```
boto_asg.present:
  - name: myasg
    - launch_config_name: mylc
    - availability_zones:
        - us-east-1a
        - us-east-1b
    - min_size: 1
    - max_size: 1
    - desired_capacity: 1
    - load_balancers:
        - myelb
    - profile:
        - keyid: GKTADJGHEIQSXMKKRBJ08H
        - key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
        - region: us-east-1
```

# Deleting an autoscale group with running instances.
Ensure myasg is deleted:
```
boto_asg.absent:
  - name: myasg
    # If instances exist, we must force the deletion of the asg.
    - force: True
```

It's possible to specify cloudwatch alarms that will be setup along with the ASG. Note the alarm name will be the
name attribute defined, plus the ASG resource name.
```
Ensure myasg exists:
  boto_asg.present:
    - name: myasg
    - launch_config_name: mylc
    - availability_zones:
        - us-east-1a
        - us-east-1b
    - min_size: 1
    - max_size: 1
    - desired_capacity: 1
    - load_balancers:
        - myelb
    - profile:
        - myprofile
    - alarms:
        - CPU:
```
You can also use alarms from pillars, and override values from the pillar alarms by setting overrides on the resource. Note that `boto_asg_alarms` will be used as a default value for all resources, if defined and can be used to ensure alarms are always set for an ASG resource.

Setting the alarms in a pillar:

```yaml
my_asg_alarm:
  CPU:
    name: 'ASG CPU **MANAGED BY SALT**'
    attributes:
      metric: CPUUtilization
      namespace: AWS/EC2
      statistic: Average
      comparison: '>=
      threshold: 65.0
      period: 60
      evaluation_periods: 30
      unit: null
      description: 'ASG CPU'
      alarm_actions: [ 'arn:aws:sns:us-east-1:12345:myalarm' ]
      insufficient_data_actions: []
      ok_actions: [ 'arn:aws:sns:us-east-1:12345:myalarm' ]
```

Overriding the alarm values on the resource:

```yaml
Ensure myasg exists:
boto_asg.present:
  - name: myasg
  - launch_config_name: mylc
  - availability_zones:
    - us-east-1a
    - us-east-1b
  - min_size: 1
  - max_size: 1
  - desired_capacity: 1
  - load_balancers:
    - myelb
  - profile: myprofile
  - alarms_from_pillar: my_asg_alarm
# override CPU:attributes:threshold
  - alarms:
    CPU:
      attributes:
        threshold: 50.0
```
salt.states.boto_asg.absent(name, force=False, region=None, key=None, keyid=None, profile=None)

Ensure the named autoscale group is deleted.

- **name**: Name of the autoscale group.
- **force**: Force deletion of autoscale group.
- **region**: The region to connect to.
- **key**: Secret key to be used.
- **keyid**: Access key to be used.
- **profile**: A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

salt.states.boto_asg.present(name, launch_config_name=None, availability_zones=None, min_size=None, max_size=None, launch_config=None, desired_capacity=None, load_balancers=None, default_cooldown=None, health_check_type=None, health_check_period=None, placement_group=None, vpc_zone_identifier=None, tags=None, termination_policies=None, suspended_processes=None, scaling_policies=None, scaling_policies_from_pillar='boto_asg_scaling_policies', alarms=None, alarms_from_pillar='boto_asg_alarms', region=None, key=None, keyid=None, profile=None, notification_arn=None, notification_arn_from_pillar='boto_asg_notification_arn', notification_types=None, notification_types_from_pillar='boto_asg_notification_types')

Ensure the autoscale group exists.

- **name**: Name of the autoscale group.
- **launch_config_name**: Name of the launch config to use for the group. Or, if launch_config is specified, this will be the launch config name's prefix. (see below)
- **launch_config**: A dictionary of launch config attributes. If specified, a launch config will be used or created, matching this set of attributes, and the autoscale group will be set to use that launch config. The launch config name will be the launch_config_name followed by a hyphen followed by a hash of the launch_config dict contents.
- **availability_zones**: List of availability zones for the group.
- **min_size**: Minimum size of the group.
- **max_size**: Maximum size of the group.
- **desired_capacity**: The desired capacity of the group.
- **load_balancers**: List of load balancers for the group. Once set this can not be updated (Amazon restriction).
- **default_cooldown**: Number of seconds after a Scaling Activity completes before any further scaling activities can start.
- **health_check_type**: The service you want the health status from, Amazon EC2 or Elastic Load Balancer (EC2 or ELB).
- **health_check_period**: Length of time in seconds after a new EC2 instance comes into service that Auto Scaling starts checking its health.
- **placement_group**: Physical location of your cluster placement group created in Amazon EC2. Once set this can not be updated (Amazon restriction).
- **vpc_zone_identifier**: A list of the subnet identifiers of the Virtual Private Cloud.
tags

A list of tags. Example:

- key: 'key' value: 'value' propagate_at_launch: true

termination_policies A list of termination policies. Valid values are: "OldestInstance", "NewestInstance", "OldestLaunchConfiguration", "ClosestToNextInstanceHour", "Default". If no value is specified, the "Default" value is used.

scaling_policies List of scaling policies. Each policy is a dict of key-values described by boto autoscale policy.

scaling_policies_from_pillar: name of pillar dict that contains scaling policy settings. Scaling policies defined for this specific state will override those from pillar.

alarms: a dictionary of name- boto cloudwatch alarm sections to be associated with this ASG. All attributes should be specified except for dimension which will be automatically set to this ASG. See the boto_cloudwatch_alarm state for information about these attributes.

alarms_from_pillar: name of pillar dict that contains alarm settings. Alarms defined for this specific state will override those from pillar.

region The region to connect to.

key Secret key to be used.

keyid Access key to be used.

profile A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

notification_arn The aws arn that notifications will be sent to

notification_arn_from_pillar: name of the pillar dict that contains notification_arn settings. A notification_arn defined for this specific state will override the one from pillar.

notification_types A list of event names that will trigger a notification. The list of valid notification types is:

```
`autoscaling:EC2_INSTANCE_LAUNCH`, `autoscaling:EC2_INSTANCE_LAUNCH_ERROR`,
`autoscaling:EC2_INSTANCE_TERMINATE`, `autoscaling:EC2_INSTANCE_TERMINATE_ERROR`,
`autoscaling:TEST_NOTIFICATION`
```

notification_types_from_pillar name of the pillar dict that contains notification_types settings. Notification_types defined for this specific state will override those from the pillar.

31.27.15 salt.states.boto_cfn

Connection module for Amazon Cloud Formation

New in version 2015.8.0.

depends boto

configuration This module accepts explicit AWS credentials but can also utilize IAM roles assigned to the instance through Instance Profiles. Dynamic credentials are then automatically obtained from AWS API and no further configuration is necessary. More Information available at [http://docs.aws.amazon.com/AWSEC2/latest/UserGuide/iam-roles-for-amazon-ec2.html](http://docs.aws.amazon.com/AWSEC2/latest/UserGuide/iam-roles-for-amazon-ec2.html)

If IAM roles are not used you need to specify them either in a pillar or in the minion's config file:
keyid: GKTADJGHEIQSXMKKRBJ08H
key: askdjghsdfjkghWupUjasdflkdfklgjsdfajkghs

stack-present:
boto_cfn.present:
  - name: mystack
  - template_body: salt://base/mytemplate.json
  - disable_rollback: true
  - region: eu-west-1
  - keyid: 'AKIAJHTMIQ2ASDFLASDF'
  - key: 'fdkjsafkljsASSADFalkfjasdf'

stack-absent:
boto_cfn.absent:
  - name: mystack

salt.states.boto_cfn.absent(name, region=None, key=None, keyid=None, profile=None)
Ensure cloud formation stack is absent.

  name (string) – The name of the stack to delete.
  region (string) - Region to connect to.
  key (string) - Secret key to be used.
  keyid (string) - Access key to be used.
  profile (dict) - A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

salt.states.boto_cfn.present(name, template_body=None, template_url=None, parameters=None, notification_arns=None, disable_rollback=None, timeout_in_minutes=None, capabilities=None, tags=None, on_failure=None, stack_policy_body=None, stack_policy_url=None, use_previous_template=None, stack_policy_during_update_body=None, stack_policy_during_update_url=None, region=None, key=None, keyid=None, profile=None)
Ensure cloud formation stack is present.

  name (string) - Name of the stack.
  template_body (string) – Structure containing the template body. Can also be loaded from a file by using salt://.
  template_url (string) – Location of file containing the template body. The URL must point to a template located in an S3 bucket in the same region as the stack.
  parameters (list) – A list of key/value tuples that specify input parameters for the stack. A 3-tuple (key, value, bool) may be used to specify the UsePreviousValue option.
  notification_arns (list) – The Simple Notification Service (SNS) topic ARNs to publish stack related events. You can find your SNS topic ARNs using the `SNS console`_ or your Command Line Interface (CLI).
  disable_rollback (bool) – Indicates whether or not to rollback on failure.
  timeout_in_minutes (integer) – The amount of time that can pass before the stack status becomes CREATE_FAILED; if DisableRollback is not set or is set to False, the stack will be rolled back.
  capabilities (list) – The list of capabilities you want to allow in the stack. Currently, the only valid capability is 'CAPABILITY_IAM'.

_1634 Chapter 31. Reference
tags (dict) – A set of user-defined Tags to associate with this stack, represented by key/value pairs. Tags defined for the stack are propagated to EC2 resources that are created as part of the stack. A maximum number of 10 tags can be specified.

on_failure (string) – Determines what action will be taken if stack creation fails. This must be one of: DO_NOTHING, ROLLBACK, or DELETE. You can specify either OnFailure or DisableRollback, but not both.

stack_policy_body (string) – Structure containing the stack policy body. Can also be loaded from a file by using salt://.

stack_policy_url (string) – Location of a file containing the stack policy. The URL must point to a policy (max size: 16KB) located in an S3 bucket in the same region as the stack. If you pass StackPolicyBody and StackPolicyURL, only StackPolicyBody is used.

use_previous_template (boolean) – Used only when templates are not the same. Set to True to use the previous template instead of uploading a new one via TemplateBody or TemplateURL.

stack_policy_during_update_body (string) – Used only when templates are not the same. Structure containing the temporary overriding stack policy body. If you pass StackPolicyDuringUpdateBody and StackPolicyDuringUpdateURL, only StackPolicyDuringUpdateBody is used. Can also be loaded from a file by using salt://.

stack_policy_during_update_url (string) – Used only when templates are not the same. Location of a file containing the temporary overriding stack policy. The URL must point to a policy (max size: 16KB) located in an S3 bucket in the same region as the stack. If you pass StackPolicyDuringUpdateBody and StackPolicy-DuringUpdateURL, only StackPolicyDuringUpdateBody is used.

region (string) - Region to connect to.
key (string) - Secret key to be used.
keyid (string) - Access key to be used.
profile (dict) - A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

### 31.27.16 salt.states.boto_cloudwatch_alarm

Manage Cloudwatch alarms

New in version 2014.7.0.

Create and destroy cloudwatch alarms. Be aware that this interacts with Amazon’s services, and so may incur charges.

This module uses boto, which can be installed via package, or pip.

This module accepts explicit credentials but can also utilize IAM roles assigned to the instance trough Instance Profiles. Dynamic credentials are then automatically obtained from AWS API and no further configuration is necessary. More Information available at:

If IAM roles are not used you need to specify them either in a pillar or in the minion’s config file:

```bash
cloudwatch.keyid: GKTADJGHEIQSXMKKRBJ08H
cloudwatch.key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
```

It’s also possible to specify key, keyid and region via a profile, either as a passed in dict, or as a string to pull from pillars or minion config:

---

31.27. Full list of builtin state modules 1635
myprofile:
  keyid: GKTADJGHEIQSXMKKRBJ08H
  key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
  region: us-east-1

my test alarm:
  boto_cloudwatch_alarm.present:
    - name: my test alarm
    - attributes:
        metric: ApproximateNumberOfMessagesVisible
        namespace: AWS/SQS
        statistic: Average
        comparison: ">="
        threshold: 20000.0
        period: 60
        evaluation_periods: 1
        description: test alarm via salt
        dimensions:
          QueueName:
            - the-sqs-queue-name
        alarm_actions:
          - arn:aws:sns:us-east-1:111111111111:myalerting-action

salt.states.boto_cloudwatch_alarm.absent(name, region=None, key=None, keyid=None, profile=None)

Ensure the named cloudwatch alarm is deleted.

  name  Name of the alarm.
  region  Region to connect to.
  key  Secret key to be used.
  keyid  Access key to be used.
  profile  A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.
	salt.states.boto_cloudwatch_alarm.present(name, attributes, region=None, key=None, keyid=None, profile=None)

Ensure the cloudwatch alarm exists.

  name  Name of the alarm
  attributes  A dict of key/value cloudwatch alarm attributes.
  region  Region to connect to.
  key  Secret key to be used.
  keyid  Access key to be used.
  profile  A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

31.27.17 salt.states.boto_dynamodb

Manage DynamoDB Tables

New in version 2015.5.0.
Create and destroy DynamoDB tables. Be aware that this interacts with Amazon's services, and so may incur charges.

This module uses boto, which can be installed via package, or pip.

This module accepts explicit DynamoDB credentials but can also utilize IAM roles assigned to the instance through Instance Profiles. Dynamic credentials are then automatically obtained from AWS API and no further configuration is necessary. More information available [here](#).

If IAM roles are not used you need to specify them either in a pillar file or in the minion's config file:

```yaml
keyid: GKTADJGHEIQSXMKKRBJ08H
key: askdjghsdfjkgWupUjasdfklkdgjsdfjajkghs
region: us-east-1
```

It's also possible to specify `key`, `keyid` and `region` via a profile, either passed in as a dict, or as a string to pull from pillars or minion config:

```yaml
myprofile:
  keyid: GKTADJGHEIQSXMKKRBJ08H
  key: askdjghsdfjkgWupUjasdfklkdgjsdfjajkghs
  region: us-east-1
```

Ensure DynamoDB table does not exist:

```yaml
salt.states.boto_dynamodb.absent:
  - table_name: new_table
  - keyid: GKTADJGHEIQSXMKKRBJ08H
  - key: askdjghsdfjkgWupUjasdfklkdgjsdfjajkghs
  - region: us-east-1
```

Ensure DynamoDB table exists:

```yaml
salt.states.boto_dynamodb.present:
  - table_name: new_table
  - read_capacity_units: 1
  - write_capacity_units: 2
  - hash_key: primary_id
  - hash_key_data_type: N
  - range_key: start_timestamp
  - range_key_data_type: N
  - keyid: GKTADJGHEIQSXMKKRBJ08H
  - key: askdjghsdfjkgWupUjasdfklkdgjsdfjajkghs
  - region: us-east-1
  - local_indexes:
    - index:
      - name: "primary_id_end_timestamp_index"
      - hash_key: primary_id
      - hash_key_data_type: N
      - range_key: end_timestamp
      - range_key_data_type: N
  - global_indexes:
    - index:
      - name: "name_end_timestamp_index"
      - hash_key: name
      - hash_key_data_type: S
      - range_key: end_timestamp
      - range_key_data_type: N
      - read_capacity_units: 3
      - write_capacity_units: 4
```

salt.states.boto_dynamodb.absent(table_name, region=None, key=None, keyid=None, profile=None)
Ensure the DynamoDB table does not exist.

**table_name**  Name of the DynamoDB table.

**region**  Region to connect to.

**key**  Secret key to be used.

**keyid**  Access key to be used.

**profile**  A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

```python
salt.states.boto_dynamodb.present(table_name, region=None, key=None, keyid=None, profile=None, read_capacity_units=None, write_capacity_units=None, hash_key=None, hash_key_data_type=None, range_key=None, range_key_data_type=None, local_indexes=None, global_indexes=None)
```

Ensure the DynamoDB table exists. Note: all properties of the table can only be set during table creation. Adding or changing indexes or key schema cannot be done after table creation.

**table_name**  Name of the DynamoDB table

**region**  Region to connect to.

**key**  Secret key to be used.

**keyid**  Access key to be used.

**profile**  A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

**read_capacity_units**  The read throughput for this table

**write_capacity_units**  The write throughput for this table

**hash_key**  The name of the attribute that will be used as the hash key for this table

**hash_key_data_type**  The DynamoDB datatype of the hash key

**range_key**  The name of the attribute that will be used as the range key for this table

**range_key_data_type**  The DynamoDB datatype of the range key

**local_indexes**  The local indexes you would like to create

**global_indexes**  The local indexes you would like to create

### 31.27.18  salt.states.boto_ec2

Manage EC2

New in version 2015.8.0.

This module provides an interface to the Elastic Compute Cloud (EC2) service from AWS.

The below code creates a key pair:

```yaml
create-key-pair:
  boto_ec2.key_present:
    - name: mykeypair
    - save_private: /root/
    - region: eu-west-1
```
import-key-pair:
    boto_ec2.key_present:
        name: mykeypair
        upload_public: 'ssh-rsa AAAA'
        keyid: GKTADJGHEIQSXMKKRBJ08H
        key: askdjghsdfjkghWupUjasdfklkdfklglgsdfjajkgghs

You can also use salt:// in order to define the public key.

import-key-pair:
    boto_ec2.key_present:
        name: mykeypair
        upload_public: salt://mybase/public_key.pub
        keyid: GKTADJGHEIQSXMKKRBJ08H
        key: askdjghsdfjkghWupUjasdfklkdfklglgsdfjajkgghs

The below code deletes a key pair:

delete-key-pair:
    boto_ec2.key_absent:
        name: mykeypair
        region: eu-west-1
        keyid: GKTADJGHEIQSXMKKRBJ08H
        key: askdjghsdfjkghWupUjasdfklkdfklglgsdfjajkgghs

salt.states.boto_ec2.key_absent(name, region=None, key=None, keyid=None, profile=None)

Deletes a key pair

salt.states.boto_ec2.key_present(name, save_private=None, upload_public=None, region=None,
    key=None, keyid=None, profile=None)

Ensure key pair is present.

31.27.19 salt.states.boto_elasticache

Manage Elasticache

replication_group_description .. versionadded:: 2014.7.0

Create, destroy and update Elasticache clusters. Be aware that this interacts with Amazon’s services, and so may
incur charges.

Note: This module currently only supports creation and deletion of elasticache resources and will not modify clusters
when their configuration changes in your state files.

This module uses boto, which can be installed via package, or pip.

This module accepts explicit elasticache credentials but can also utilize IAM roles assigned to the instance through
Instance Profiles. Dynamic credentials are then automatically obtained from AWS API and no further configuration
is necessary. More information available here.

If IAM roles are not used you need to specify them either in a pillar file or in the minion's config file:

elasticache.keyid: GKTADJGHEIQSXMKKRBJ08H
elasticsearch.key: askdjghsdfjkghWupUjasdfklkdfklglgsdfjajkgghs
It's also possible to specify `key`, `keyid` and `region` via a profile, either passed in as a dict, or as a string to pull from pillars or minion config:

```yaml
myprofile:
  keyid: GKTADJGHEIQXSXMKKRBJ08H
  key: askdjghsdfjghWupUjasdflkdfklgjsdfjajkghs
  region: us-east-1
```

Ensure `myelasticache` exists:
```yaml
boto_elasticache.present:
  - name: myelasticache
  - engine: redis
  - cache_node_type: cache.t1.micro
  - num_cache_nodes: 1
  - region: us-east-1
  - keyid: GKTADJGHEIQXSXMKKRBJ08H
  - key: askdjghsdfjghWupUjasdflkdfklgjsdfjajkghs
```

# Using a profile from pillars
Ensure `myelasticache` exists:
```yaml
boto_elasticache.present:
  - name: myelasticache
  - engine: redis
  - cache_node_type: cache.t1.micro
  - num_cache_nodes: 1
  - region: us-east-1
  - profile: myprofile
```

# Passing in a profile
Ensure `myelasticache` exists:
```yaml
boto_elasticache.present:
  - name: myelasticache
  - engine: redis
  - cache_node_type: cache.t1.micro
  - num_cache_nodes: 1
  - region: us-east-1
  - profile: {keyid: GKTADJGHEIQXSXMKKRBJ08H,
              key: askdjghsdfjghWupUjasdflkdfklgjsdfjajkghs}
```

salt.states.boto_elasticache.absent(name, wait=True, region=None, key=None, keyid=None, profile=None)

Ensure the named elasticache cluster is deleted.

- **name** Name of the cache cluster.
- **wait** Boolean. Wait for confirmation from boto that the cluster is in the deleting state.
- **region** Region to connect to.
- **key** Secret key to be used.
- **keyid** Access key to be used.
- **profile** A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.
salt.states.boto_elasticache.creategroup(name, primary_cluster_id, replication_group_description, wait=None, region=None, key=None, keyid=None, profile=None)

Ensure the replication group is created.

- **name** Name of the replication group
- **wait** Waits for the group to be available
- **primary_cluster_id** Name of the master cache node
- **replication_group_description** Description for the group
- **region** Region to connect to.
- **key** Secret key to be used.
- **keyid** Access key to be used.
- **profile** A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

salt.states.boto_elasticache.present(name, engine=None, cache_node_type=None, num_cache_nodes=None, preferred_availability_zone=None, port=None, cache_parameter_group_name=None, cache_security_group_names=None, replication_group_id=None, auto_minor_version_upgrade=True, security_group_ids=None, cache_subnet_group_name=None, engine_version=None, notification_topic_arn=None, preferred_maintenance_window=None, wait=None, region=None, key=None, keyid=None, profile=None)

Ensure the cache cluster exists.

- **name** Name of the cache cluster (cache cluster id).
- **engine** The name of the cache engine to be used for this cache cluster. Valid values are memcached or redis.
- **cache_node_type** The compute and memory capacity of the nodes in the cache cluster. `cache.t1.micro`, `cache.m1.small`, etc. See: http://boto.readthedocs.org/en/latest/ref/elasticache.html#boto.elasticache.layer1.ElastiCacheConnection.create_cache_cluster
- **num_cache_nodes** The number of cache nodes that the cache cluster will have.
- **preferred_availability_zone** The EC2 Availability Zone in which the cache cluster will be created. All cache nodes belonging to a cache cluster are placed in the preferred availability zone.
- **port** The port number on which each of the cache nodes will accept connections.
- **cache_parameter_group_name** The name of the cache parameter group to associate with this cache cluster. If this argument is omitted, the default cache parameter group for the specified engine will be used.
- **cache_security_group_names** A list of cache security group names to associate with this cache cluster. Use this parameter only when you are creating a cluster outside of a VPC.
- **replication_group_id** The replication group to which this cache cluster should belong. If this parameter is specified, the cache cluster will be added to the specified replication group as a read replica; otherwise, the cache cluster will be a standalone primary that is not part of any replication group.
- **auto_minor_version_upgrade** Determines whether minor engine upgrades will be applied automatically to the cache cluster during the maintenance window. A value of True allows these upgrades to occur; False disables automatic upgrades.
security_group_ids One or more VPC security groups associated with the cache cluster. Use this parameter only when you are creating a cluster in a VPC.

cache_subnet_group_name The name of the cache subnet group to be used for the cache cluster. Use this parameter only when you are creating a cluster in a VPC.

engine_version The version number of the cache engine to be used for this cluster.

notification_topic_arn The Amazon Resource Name (ARN) of the Amazon Simple Notification Service (SNS) topic to which notifications will be sent. The Amazon SNS topic owner must be the same as the cache cluster owner.

preferred_maintenance_window The weekly time range (in UTC) during which system maintenance can occur. Example: sun:05:00-sun:09:00

wait Boolean. Wait for confirmation from boto that the cluster is in the available state.

region Region to connect to.

key Secret key to be used.

keyid Access key to be used.

profile A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

salt.states.boto_elasticache.subnet_group_absent(name, tags=None, region=None, key=None, keyid=None, profile=None)

salt.states.boto_elasticache.subnet_group_present(name, subnet_ids, description, tags=None, region=None, key=None, keyid=None, profile=None)

Ensure ElastiCache subnet group exists.

New in version 2015.8.0.

name The name for the ElastiCache subnet group. This value is stored as a lowercase string.

subnet_ids A list of VPC subnet IDs for the cache subnet group.

description Subnet group description.

tags A list of tags.

region Region to connect to.

key Secret key to be used.

keyid Access key to be used.

profile A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

31.27.20 salt.states.boto_elb

Manage ELBs

New in version 2014.7.0.

Create and destroy ELBs. Be aware that this interacts with Amazon's services, and so may incur charges.

This module uses boto, which can be installed via package, or pip.
This module accepts explicit elb credentials but can also utilize IAM roles assigned to the instance through Instance Profiles. Dynamic credentials are then automatically obtained from AWS API and no further configuration is necessary. More information available here.

If IAM roles are not used you need to specify them either in a pillar file or in the minion's config file:

```yaml
elb.keyid: GKTADJGHEIQSXMKKRBJ08H
elb.key: askdjghsdfjkgHwUpUJasdfsflkdfklgjsdfjajkghs
```

It's also possible to specify `key`, `keyid` and `region` via a profile, either passed in as a dict, or as a string to pull from pillars or minion config:

```yaml
myprofile:
  keyid: GKTADJGHEIQSXMKKRBJ08H
  key: askdjghsdfjkgHwUpUJasdfsflkdfklgjsdfjajkghs
  region: us-east-1
```

Ensure myelb ELB exists:

```yaml
boto_elb.present:
  - name: myelb
  - region: us-east-1
  - availability_zones:
    - us-east-1a
    - us-east-1c
    - us-east-1d
  - keyid: GKTADJGHEIQSXMKKRBJ08H
  - key: askdjghsdfjkgHwUpUJasdfsflkdfklgjsdfjajkghs
  - listeners:
    - elb_port: 443
      instance_port: 80
      elb_protocol: HTTPS
      instance_protocol: HTTP
      certificate: 'arn:aws:iam::1111111:server-certificate/mycert'
    - elb_port: 8210
      instance_port: 8210
      elb_protocol: TCP
  - health_check:
    - target: 'HTTP:80/'
  - attributes:
    - cross_zone_load_balancing:
      enabled: true
    - access_log:
      enabled: true
    - s3_bucket_name: 'mybucket'
    - s3_bucket_prefix: 'my-logs'
    - emit_interval: 5
  - cnames:
    - name: mycname.example.com.
      zone: example.com.
      ttl: 60
    - name: myothercname.example.com.
      zone: example.com.
```

# Using a profile from pillars
Ensure myelb ELB exists:

```yaml
boto_elb.present:
  - name: myelb
  - region: us-east-1
  - profile: myelbprofile
```
# Passing in a profile

Ensure myelb ELB exists:

```yaml
boto_elb.present:
  - name: myelb
  - region: us-east-1
  - profile:
      keyid: GKTADJGHEIQXSXMKKRBJ08H
      key: askdjghsdfkjghWuupUjasdflkdflkgjsdfjajgks
```

It's possible to specify attributes from pillars by specifying a pillar. You can override the values defined in the pillard by setting the attributes on the resource. The module will use the default pillar key `boto_elb_attributes`, which allows you to set default attributes for all ELB resources.

Setting the attributes pillar:

```yaml
my_elb_attributes:
  cross_zone_load_balancing:
    enabled: true
  connection_draining:
    enabled: true
  timeout: 20
  access_log:
    enabled: true
  s3_bucket_name: 'mybucket'
  s3_bucket_prefix: 'my-logs'
  emit_interval: 5
```

Overriding the attribute values on the resource:

Ensure myelb ELB exists:

```yaml
boto_elb.present:
  - name: myelb
  - region: us-east-1
  - attributes_from_pillar: my_elb_attributes
# override cross_zone_load_balancing:enabled
  - attributes:
      cross_zone_load_balancing:
        enabled: false
  - profile: myelbprofile
```

It's possible to specify cloudwatch alarms that will be setup along with the ELB. Note the alarm name will be defined by the name attribute provided, plus the ELB resource name.

Ensure myelb ELB exists:

```yaml
boto_elb.present:
  - name: myelb
  - region: us-east-1
  - profile: myelbprofile
  - alarms:
      UnHealthyHostCount:
        name: 'ELB UnHealthyHostCount **MANAGED BY SALT**'
        attributes:
          metric: UnHealthyHostCount
          namespace: AWS/ELB
          statistic: Average
          comparison: '>='
          threshold: 1.0
          period: 600
```
You can also use alarms from pillars, and override values from the pillar alarms by setting overrides on the resource. Note that `boto_elb_alarms` will be used as a default value for all resources, if defined and can be used to ensure alarms are always set for a resource.

Setting the alarms in a pillar:

```yaml
my_elb_alarm:
  UnHealthyHostCount:
    name: 'ELB UnHealthyHostCount **MANAGED BY SALT**'
    attributes:
      metric: UnHealthyHostCount
      namespace: AWS/ELB
      statistic: Average
      comparison: '>='
      threshold: 1.0
      period: 600
      evaluation_periods: 6
      unit: null
    description: ELB UnHealthyHostCount
    insufficient_data_actions: []
    ok_actions: ['arn:aws:sns:us-east-1:12345:myalarm']
```

Overriding the alarm values on the resource:

```yaml
Ensure myelb ELB exists:
  boto_elb.present:
    - name: myelb
    - region: us-east-1
    - profile: myelbprofile
    - alarms_from_pillar: my_elb_alarm
      # override UnHealthyHostCount:attributes:threshold
      - alarms:
          UnHealthyHostCount:
            attributes:
              threshold: 2.0
```

salt.states.boto_elb.absent
(name, region=None, key=None, keyid=None, profile=None)

salt.states.boto_elb.present
(name, listeners, availability_zones=None, subnets=None, security_groups=None, scheme='internet-facing', health_check=None, attributes=None, attributes_from_pillar='boto_elb_attributes', cnames=None, alarms=None, alarms_from_pillar='boto_elb_alarms', region=None, key=None, keyid=None, profile=None, wait_for_sync=True)

Ensure the IAM role exists.

name  Name of the IAM role.

availability_zones  A list of availability zones for this ELB.

listeners  A list of listener lists; example:
[`443`, `HTTPS`, `arn:aws:iam::1111111:server-certificate/mycert`], ```8443, `80`, `HTTPS`, `HTTP', `arn:aws:iam::1111111:server-certificate/mycert' ```

```subnets``` A list of subnet IDs in your VPC to attach to your LoadBalancer.

```security_groups``` The security groups assigned to your LoadBalancer within your VPC.

```scheme``` The type of a LoadBalancer. internet-facing or internal. Once set, can not be modified.

```health_check``` A dict defining the health check for this ELB.

```attributes``` A dict defining the attributes to set on this ELB.

```attributes_from_pillar``` name of pillar dict that contains attributes. Attributes defined for this specific state will override those from pillar.

```cnames``` A list of cname dicts with attributes: name, zone, ttl, and identifier. See the boto_route53 state for information about these attributes.

```alarms``` a dictionary of name->boto_cloudwatch_alarm sections to be associated with this ELB. All attributes should be specified except for dimension which will be automatically set to this ELB. See the boto_cloudwatch_alarm state for information about these attributes.

```alarms_from_pillar``` name of pillar dict that contains alarm settings. Alarms defined for this specific state will override those from pillar.

```region``` Region to connect to.

```key``` Secret key to be used.

```keyid``` Access key to be used.

```profile``` A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

```wait_for_sync``` Wait for an INSYNC change status from Route53.

```salt.states.boto_elb.register_instances``` (**name**, **instances**, **region=NONE**, **key=NONE**, **keyid=NONE**, **profile=NONE**) 

Add instance/s to load balancer

New in version 2015.8.0.

```add-instances:
  boto_elb.register_instances:
    - name: myloadbalancer
    - instances:
      - instance-id1
      - instance-id2

31.27.21 salt.states.boto_iam

Manage IAM roles.

New in version 2015.8.0.

This module uses boto, which can be installed via package, or pip.
This module accepts explicit IAM credentials but can also utilize IAM roles assigned to the instance through Instance Profiles. Dynamic credentials are then automatically obtained from AWS API and no further configuration is necessary. More information available [here](#).

It's also possible to specify `key`, `keyid` and `region` via a profile, either passed in as a dict, or as a string to pull from pillars or minion config:

```yaml
delete-user:
  - boto_iam.user_absent:
    - name: myuser
    - delete_keys: true

delete-keys:
  - boto_iam.keys_absent:
    - access_keys:

salt.states.boto_iam.account_policy(allow_users_to_change_password=None,
    hard_expiry=None, max_password_age=None,
    minimum_password_length=None, password_reuse_prevention=None,
    require_lowercase_characters=None, require_numbers=None,
    require_symbols=None, require_uppercase_characters=None,
    region=None, key=None, keyid=None, profile=None)

Change account policy.

allow_users_to_change_password (bool) Allows all IAM users in your account to use the AWS Management Console to change their own passwords.

hard_expiry (bool) Prevents IAM users from setting a new password after their password has expired.

max_password_age (int) The number of days that an IAM user password is valid.

minimum_password_length (int) The minimum number of characters allowed in an IAM user password.

password_reuse_prevention (int) Specifies the number of previous passwords that IAM users are prevented from reusing.

require_lowercase_characters (bool) Specifies whether IAM user passwords must contain at least one lowercase character from the ISO basic Latin alphabet (a to z).

require_numbers (bool) Specifies whether IAM user passwords must contain at least one numeric character (0 to 9).
**require_symbols (bool)** Specifies whether IAM user passwords must contain at least one of the following non-alphanumeric characters: ! @ # $ % ^ & ( ) _ + - = [ ] { } ` | 

**require_uppercase_characters (bool)** Specifies whether IAM user passwords must contain at least one uppercase character from the ISO basic Latin alphabet (A to Z).

**region (string)** Region to connect to.

**key (string)** Secret key to be used.

**keyid (string)** Access key to be used.

**profile (dict)** A dict with region, key and keyid, or a pillar key (string)

```python
salt.states.boto_iam.group_present(name, policies=None, policies_from_pillars=None, users=None, region=None, key=None, keyid=None, profile=None)
```

Ensure the IAM group is present

**name (string)** The name of the new group.

**policies (dict)** A dict of IAM group policy documents.

**policies_from_pillars (list)** A list of pillars that contain role policy dicts. Policies in the pillars will be merged in the order defined in the list and key conflicts will be handled by later defined keys overriding earlier defined keys. The policies defined here will be merged with the policies defined in the policies argument. If keys conflict, the keys in the policies argument will override the keys defined in policies_from_pillars.

**users (list)** A list of users to be added to the group.

**region (string)** Region to connect to.

**key (string)** Secret key to be used.

**keyid (string)** Access key to be used.

**profile (dict)** A dict with region, key and keyid, or a pillar key (string)

```python
salt.states.boto_iam.keys_absent(access_keys, user_name, region=None, key=None, keyid=None, profile=None)
```

Ensure the IAM user access_key_id is absent.

**access_key_id (list)** A list of access key ids

**user_name (string)** The username of the user

**region (string)** Region to connect to.

**key (string)** Secret key to be used.

**keyid (string)** Access key to be used.

**profile (dict)** A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

```python
salt.states.boto_iam.keys_present(name, number, save_dir, region=None, key=None, keyid=None, profile=None)
```

Ensure the IAM access keys are present.

**name (string)** The name of the new user.

**number (int)** Number of keys that user should have.

**save_dir (string)** The directory that the key/keys will be saved. Keys are saved to a file named according to the username provided.
**Salt Documentation, Release 2015.8.0**

region (string) Region to connect to.
key (string) Secret key to be used.
keyid (string) Access key to be used.
profile (dict) A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

```python
salt.states.boto_iam.server_cert_absent(name, region=None, key=None, keyid=None, profile=None)
```

Deletes a server certificate.

name (string) The name for the server certificate. Do not include the path in this value.
region (string) The name of the region to connect to.
key (string) The key to be used in order to connect
keyid (string) The keyid to be used in order to connect
profile (string) The profile that contains a dict of region, key, keyid

```python
salt.states.boto_iam.server_cert_present(name, public_key, private_key, cert_chain=None, path=None, region=None, key=None, keyid=None, profile=None)
```

Creates a server certificate.

name (string) The name for the server certificate. Do not include the path in this value.
public_key (string) The contents of the public key certificate in PEM-encoded format.
private_key (string) The contents of the private key in PEM-encoded format.
cert_chain (string) The contents of the certificate chain. This is typically a concatenation of the PEM-encoded public key certificates of the chain.
path (string) The path for the server certificate.
region (string) The name of the region to connect to.
key (string) The key to be used in order to connect
keyid (string) The keyid to be used in order to connect
profile (string) The profile that contains a dict of region, key, keyid

```python
salt.states.boto_iam.user_absent(name, delete_keys=None, region=None, key=None, keyid=None, profile=None)
```

Ensures the IAM user is absent. User cannot be deleted if it has keys.

name (string) The name of the new user.
delete_keys (bool) Delete all keys from user.
region (string) Region to connect to.
key (string) Secret key to be used.
keyid (string) Access key to be used.
profile (dict) A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

```python
salt.states.boto_iam.user_present(name, policies=None, policies_from_pillars=None, password=None, path=None, region=None, key=None, keyid=None, profile=None)
```

Ensures the IAM user is present.
name (string)  The name of the new user.

policies (dict)  A dict of IAM group policy documents.

policies_from_pillars (list)  A list of pillars that contain role policy dicts. Policies in the pillars will be merged in the order defined in the list and key conflicts will be handled by later defined keys overriding earlier defined keys. The policies defined here will be merged with the policies defined in the policies argument. If keys conflict, the keys in the policies argument will override the keys defined in policies_from_pillars.

password (string)  The password for the new user. Must comply with account policy.

path (string)  The path of the user. Default is `/'

region (string)  Region to connect to.

key (string)  Secret key to be used.

keyid (string)  Access key to be used.

profile (dict)  A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

31.27.22  salt.states.boto_iam_role

Manage IAM roles

New in version 2014.7.0.

This module uses boto, which can be installed via package, or pip.

This module accepts explicit IAM credentials but can also utilize IAM roles assigned to the instance through Instance Profiles. Dynamic credentials are then automatically obtained from AWS API and no further configuration is necessary. More information available [here](#).

If IAM roles are not used you need to specify them either in a pillar file or in the minion's config file:

```
iam.keyid: GKTADJGHEIQSXMKKRBJ08H
iam.key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
```

It's also possible to specify key, keyid and region via a profile, either passed in as a dict, or as a string to pull from pillars or minion config:

```
myprofile:
    keyid: GKTADJGHEIQSXMKKRBJ08H
    key: askjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
    region: us-east-1
```

Creating a role will automatically create an instance profile and associate it with the role. This is the default behavior of the AWS console.

```
myrole:
    boto_iam_role.present:
      - region: us-east-1
      - key: GKTADJGHEIQSXMKKRBJ08H
      - keyid: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
      - policies_from_pillars:
          - shared_iam_bootstrap_policy
          - policies:
              MySQSPolicy:
                Statement:
                  - Action:  
```
- sqs:*  
  Effect: Allow  
  Resource:  
    - arn:aws:sqs:*::*:*  
  Sid: MyPolicySQS1  

MyS3Policy:  
  Statement:  
    - Action:  
      - s3:GetObject  
    Effect: Allow  
    Resource:  
      - arn:aws:s3::*::*:mybucket/*

# Using a credentials profile from pillars  
myrole:  
  boto_iam_role.present:  
    - region: us-east-1  
    - profile: myiamprofile

# Passing in a credentials profile  
myrole:  
  boto_iam_role.present:  
    - region: us-east-1  
    - profile:  
      key: GKTADJGHEIQSXMKKRBJ08H  
      keyid: askdjghsdfjkghWupUjasdfdklfdklgjsdfjajkghs

If delete_policies: False is specified, existing policies that are not in the given list of policies will not be deleted. This allows manual modifications on the IAM role to be persistent. This functionality was added in 2015.8.0.

salt.states.boto_iam_role.absent(name, region=None, key=None, keyid=None, profile=None)  
Ensure the IAM role is deleted.  

name Name of the IAM role.  

region Region to connect to.  

key Secret key to be used.  

keyid Access key to be used.  

profile A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

salt.states.boto_iam_role.present(name, policy_document=None, path=None, policies=None, policies_from_pillars=None, create_instance_profile=True, region=None, key=None, keyid=None, profile=None, delete_policies=True)  
Ensure the IAM role exists.  

name Name of the IAM role.  

policy_document The policy that grants an entity permission to assume the role. (See http://boto.readthedocs.org/en/latest/ref/iam.html#boto.iam.connection.IAMConnection.create_role)  

path The path to the role/instance profile. (See http://boto.readthedocs.org/en/latest/ref/iam.html#boto.iam.connection.IAMConnection.create_role)  

policies A dict of IAM role policies.  

policies_from_pillars A list of pillars that contain role policy dicts. Policies in the pillars will be merged in the order defined in the list and key conflicts will be handled by later defined keys overriding earlier defined
keys. The policies defined here will be merged with the policies defined in the policies argument. If keys conflict, the keys in the policies argument will override the keys defined in policies_from_pillars.

create_instance_profile A boolean of whether or not to create an instance profile and associate it with this role.

region Region to connect to.

key Secret key to be used.

keyid Access key to be used.

profile A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

delete_policies Deletes existing policies that are not in the given list of policies. Default value is True. If False is specified, existing policies will not be deleted allowing manual modifications on the IAM role to be persistent.

New in version 2015.8.0.

31.27.23 salt.states.boto_kms

Manage KMS keys, key policies and grants.

New in version 2015.8.0.

Be aware that this interacts with Amazon's services, and so may incur charges.

This module uses boto, which can be installed via package, or pip.

This module accepts explicit kms credentials but can also utilize IAM roles assigned to the instance through Instance Profiles. Dynamic credentials are then automatically obtained from AWS API and no further configuration is necessary. More information available here.

If IAM roles are not used you need to specify them either in a pillar file or in the minion's config file:

```yaml
elb.keyid: GKTADJGHEIQSXMKKRBJ08H
elb.key: askdjghsdfjkgWupUjasdfklgjsdfjajkghs
```

It's also possible to specify key, keyid and region via a profile, either passed in as a dict, or as a string to pull from pillars or minion config:

```yaml
myprofile:
  keyid: GKTADJGHEIQSXMKKRBJ08H
  key: askdjghsdfjkgWupUjasdfklgjsdfjajkghs
  region: us-east-1
```

Ensure mykey key exists:

```yaml
boto_kms.key_present:
  - name: mykey
  - region: us-east-1
```

# Using a profile from pillars

Ensure mykey key exists:

```yaml
boto_kms.key_present:
  - name: mykey
  - region: us-east-1
  - profile: myprofile
```

# Passing in a profile
Ensure mykey key exists:

```yaml
boto_key.key_present:
  - name: mykey
  - region: us-east-1
  - profile:
    keyid: GKTADJGHEIQSXMKKRBJ08H
    key: asldgjhsfjkgWupUjasdfklkdfklgjsdfjajkghs
```

salt.states.boto_kms.key_present(name, policy, description=None, key_usage=None, grants=None, manage_grants=False, key_rotation=False, enabled=True, region=None, key=None, keyid=None, profile=None)

Ensure the KMS key exists. KMS keys can not be deleted, so this function must be used to ensure the key is enabled or disabled.

- **name** Name of the key.
- **policy** Key usage policy.
- **description** Description of the key.
- **key_usage** Specifies the intended use of the key. Can only be set on creation, defaults to ENCRYPT_DECRYPT, which is also the only supported option.
- **grants** A list of grants to apply to the key. Not currently implemented.
- **manage_grants** Whether or not to manage grants. False by default, which will not manage any grants.
- **key_rotation** Whether or not key rotation is enabled for the key. False by default.
- **enabled** Whether or not the key is enabled. True by default.
- **region** Region to connect to.
- **key** Secret key to be used.
- **keyid** Access key to be used.
- **profile** A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

### 31.27.24 salt.states.boto_lc

Manage Launch Configurations

New in version 2014.7.0.

Create and destroy Launch Configurations. Be aware that this interacts with Amazon’s services, and so may incur charges.

A limitation of this module is that you can not modify launch configurations once they have been created. If a launch configuration with the specified name exists, this module will always report success, even if the specified configuration doesn’t match. This is due to a limitation in Amazon’s launch configuration API, as it only allows launch configurations to be created and deleted.

Also note that a launch configuration that’s in use by an autoscale group can not be deleted until the autoscale group is no longer using it. This may affect the way in which you want to order your states.

This module uses boto, which can be installed via package, or pip.
This module accepts explicit autoscale credentials but can also utilize IAM roles assigned to the instance through Instance Profiles. Dynamic credentials are then automatically obtained from AWS API and no further configuration is necessary. More information available here.

If IAM roles are not used you need to specify them either in a pillar file or in the minion’s config file:

```
asg.keyid: GKTADJGHEIQSXMKKRBJ08H
asg.key: askdjghsdfjkgWupUjasdfklgjsdfjajkghs
```

It’s also possible to specify `key`, `keyid` and `region` via a profile, either passed in as a dict, or as a string to pull from pillars or minion config:

```
myprofile:
  keyid: GKTADJGHEIQSXMKKRBJ08H
  key: askdjghsdfjkgWupUjasdfklgjsdfjajkghs
  region: us-east-1
```

Credential information is shared with autoscale groups as launch configurations and autoscale groups are completely dependent on each other.

Ensure mylc exists:

```
boto_lc.present:
  - name: mylc
  - image_id: ami-0b9c9f62
  - key_name: mykey
  - security_groups:
    - mygroup
  - instance_type: m1.small
  - instance_monitoring: true
  - block_device_mappings:
    - '/dev/sda1':
      size: 20
  - cloud_init:
    scripts:
      'run_salt.sh': |
      #!/bin/bash
      add-apt-repository -y ppa:saltstack/salt
      apt-get update
      apt-get install -y salt-minion
      salt-call state.highstate
  - region: us-east-1
  - keyid: GKTADJGHEIQSXMKKRBJ08H
  - key: askdjghsdfjkgWupUjasdfklgjsdfjajkghs
```

# Using a profile from pillars.
Ensure mylc exists:

```
boto_lc.present:
  - name: mylc
  - image_id: ami-0b9c9f62
  - profile: myprofile
```

# Passing in a profile.
Ensure mylc exists:

```
boto_lc.present:
  - name: mylc
  - image_id: ami-0b9c9f62
  - profile:
    keyid: GKTADJGHEIQSXMKKRBJ08H
```

31.27. Full list of builtin state modules
salt.states.boto_lc.absent(name, region=None, key=None, keyid=None, profile=None)

Ensure the named launch configuration is deleted.

name Name of the launch configuration.
region The region to connect to.
key Secret key to be used.
keyid Access key to be used.
profile A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

salt.states.boto_lc.present(name, image_id, key_name=None, security_groups=None, user_data=None, cloud_init=None, instance_type='m1.small', kernel_id=None, ramdisk_id=None, block_device_mappings=None, instance_monitoring=False, spot_price=None, instance_profile_name=None, ebs_optimized=False, associate_public_ip_address=None, volume_type=None, delete_on_termination=True, iops=None, use_block_device_types=False, region=None, key=None, keyid=None, profile=None)

Ensure the launch configuration exists.

name Name of the launch configuration.
image_id AMI to use for instances. AMI must exist or creation of the launch configuration will fail.
key_name Name of the EC2 key pair to use for instances. Key must exist or creation of the launch configuration will fail.
security_groups List of Names or security group id’s of the security groups with which to associate the EC2 instances or VPC instances, respectively. Security groups must exist, or creation of the launch configuration will fail.
user_data The user data available to launched EC2 instances.
cloud_init A dict of cloud_init configuration. Currently supported values: scripts, cloud-config. Mutually exclusive with user_data.
instance_type The instance type. ex: m1.small.
kernel_id The kernel id for the instance.
ramdisk_id The RAM disk ID for the instance.
block_device_mappings A dict of block device mappings.
instance_monitoring Whether instances in group are launched with detailed monitoring.
spot_price The spot price you are bidding. Only applies if you are building an autoscaling group with spot instances.
instance_profile_name The name or the Amazon Resource Name (ARN) of the instance profile associated with the IAM role for the instance. Instance profile must exist or the creation of the launch configuration will fail.
ebs_optimized Specifies whether the instance is optimized for EBS I/O (true) or not (false).
The `associate_public_ip_address` parameter is used for Auto Scaling groups that launch instances into an Amazon Virtual Private Cloud. It specifies whether to assign a public IP address to each instance launched in an Amazon VPC.

- `volume_type`: Undocumented in boto.
- `delete_on_termination`: Undocumented in boto.
- `iops`: Undocumented in boto.
- `use_block_device_types`: Undocumented in boto.
- `region`: The region to connect to.
- `key`: Secret key to be used.
- `keyid`: Access key to be used.
- `profile`: A dict with region, key, and keyid, or a pillar key (string) that contains a dict with region, key, and keyid.

### 31.27.25 salt.states.boto_rds

#### Manage RDSs

New in version 2015.8.0.

Create and destroy RDS instances. Be aware that this interacts with Amazon's services, and so may incur charges. This module uses boto, which can be installed via package, or pip.

This module accepts explicit rds credentials but can also utilize IAM roles assigned to the instance through Instance Profiles. Dynamic credentials are then automatically obtained from AWS API and no further configuration is necessary. More information available [here](#).

If IAM roles are not used you need to specify them either in a pillar file or in the minion's config file:

```bash
rds.keyid: GKTADJGHEIQSXMKKRBJ08H
rds.key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
```

It's also possible to specify `key`, `keyid` and `region` via a profile, either passed in as a dict, or as a string to pull from pillars or minion config:

```bash
myprofile:
    keyid: GKTADJGHEIQSXMKKRBJ08H
    key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
    region: us-east-1
```

Ensure myrds RDS exists:

```bash
boto_rds.present:
    - name: myrds
    - allocated_storage: 5
    - storage_type: gp2
    - db_instance_class: db.t2.micro
    - engine: MySQL
    - master_username: myuser
    - master_user_password: mypass
    - region: us-east-1
    - keyid: GKTADJGHEIQSXMKKRBJ08H
    - key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
```

---

**31.27. Full list of builtin state modules** 1657
salt.states.boto_rds.absent

```
(name, skip_final_snapshot=None, final_db_snapshot_identifier=None, tags=None, region=None, key=None, keyid=None, profile=None)
```

Ensure RDS instance exists.

**name** Name of the RDS instance.

**allocated_storage** The amount of storage (in gigabytes) to be initially allocated for the database instance.

**storage_type** The storage type you want to use, available: standard, gp2 and io1

**db_instance_class** The compute and memory capacity of the Amazon RDS DB instance.

**engine** The name of the database engine to be used for this instance.

**master_username** The name of master user for the client DB instance.

**master_user_password** The password for the master database user. Can be any printable ASCII character except ‘/’, ‘‘’, or ‘@’.

**db_name** The database name for the restored DB instance.

**db_security_groups** A list of DB security groups to associate with this DB instance.

**vpc_security_group_ids** A list of EC2 VPC security groups to associate with this DB instance.

**availability_zone** The EC2 Availability Zone that the database instance will be created in.

**db_subnet_group_name** A DB subnet group to associate with this DB instance.

**preferred_maintenance_window** The weekly time range (in UTC) during which system maintenance can occur.

**backup_retention_period** The number of days for which automated backups are retained.

**preferred_backup_window** The daily time range during which automated backups are created if automated backups are enabled.

**port** The port number on which the database accepts connections.

**multi_az** Specifies if the DB instance is a Multi-AZ deployment. You cannot set the AvailabilityZone parameter if the MultiAZ parameter is set to true.

**engine_version** The version number of the database engine to use.

**auto_minor_version_upgrade** Indicates that minor engine upgrades will be applied automatically to the DB instance during the maintenance window.

**license_model** License model information for this DB instance.

**iops** The amount of Provisioned IOPS (input/output operations per second) to be initially allocated for the DB instance.

**option_group_name** Indicates that the DB instance should be associated with the specified option group.
character_set_name For supported engines, indicates that the DB instance should be associated with the specified CharacterSet.

publicly_accessible Specifies the accessibility options for the DB instance. A value of true specifies an Internet-facing instance with a publicly resolvable DNS name, which resolves to a public IP address. A value of false specifies an internal instance with a DNS name that resolves to a private IP address.

wait_status Wait for the RDS instance to reach a desired status before finishing the state. Available states: available, modifying, backing-up

tags A list of tags.

region Region to connect to.

key Secret key to be used.

keyid Access key to be used.

profile A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

```
salt.states.boto_rds.replica_present(name, source, db_instance_class=None, availability_zone=None, port=None, auto_minor_version_upgrade=None, iops=None, option_group_name=None, publicly_accessible=None, tags=None, region=None, key=None, keyid=None, profile=None)
```

Ensure RDS replica exists.

```
Ensure myrds replica RDS exists:
    boto_rds.create_replica:
        - name: myreplica
        - source: mydb
```

```
salt.states.boto_rds.subnet_group_absent(name, tags=None, region=None, key=None, keyid=None, profile=None)
```

```
salt.states.boto_rds.subnet_group_present(name, subnet_ids, description, tags=None, region=None, key=None, keyid=None, profile=None)
```

Ensure DB subnet group exists.

name The name for the DB subnet group. This value is stored as a lowercase string.

subnet_ids The EC2 Subnet IDs for the DB subnet group.

description Subnet group description.

tags A list of tags.

region Region to connect to.

key Secret key to be used.

keyid Access key to be used.

profile A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

31.27.26 salt.states.boto_route53

Manage Route53 records
New in version 2014.7.0.

Create and delete Route53 records. Be aware that this interacts with Amazon's services, and so may incur charges.

This module uses boto3, which can be installed via package, or pip.

This module accepts explicit route53 credentials but can also utilize IAM roles assigned to the instance through Instance Profiles. Dynamic credentials are then automatically obtained from AWS API and no further configuration is necessary. More information available here.

If IAM roles are not used you need to specify them either in a pillar file or in the minion's config file:

```
route53.keyid: GKTADJGHEIQSXMKKRBJ08H
route53.key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
```

It's also possible to specify key, keyid and region via a profile, either passed in as a dict, or as a string to pull from pillars or minion config:

```
myprofile:
    keyid: GKTADJGHEIQSXMKKRBJ08H
    key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
    region: us-east-1
```

```
myrecord:
    boto_route53.present:
        name: test.example.com.
        value: my-elb.us-east-1.elb.amazonaws.com.
        zone: example.com.
        ttl: 60
        record_type: CNAME
        region: us-east-1
        keyid: GKTADJGHEIQSXMKKRBJ08H
        key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
```

```
# Using a profile from pillars
myarecord:
    boto_route53.present:
        name: test.example.com.
        value: 1.1.1.1
        zone: example.com.
        ttl: 60
        record_type: A
        region: us-east-1
        profile: myprofile
```

```
# Passing in a profile
myarecord:
    boto_route53.present:
        name: test.example.com.
        value: 1.1.1.1
        zone: example.com.
        ttl: 60
        record_type: A
        region: us-east-1
        profile:
            keyid: GKTADJGHEIQSXMKKRBJ08H
            key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
```

salt.states.boto_route53.absent(name, zone, record_type, identifier=None, region=None, key=None, keyid=None, profile=None, wait_for_sync=True, split_dns=False, private_zone=False)

Ensure the Route53 record is deleted.

name Name of the record.
zone The zone to delete the record from.
record_type The record type (A, NS, MX, TXT, etc.)
identifier An identifier to match for deletion.
region The region to connect to.
key Secret key to be used.
keyid Access key to be used.
profile A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.
wait_for_sync Wait for an INSYNC change status from Route53.
split_dns Route53 supports a public and private DNS zone with the same names.
private_zone If using split_dns, specify if this is the private zone.

salt.states.boto_route53.present(name, value, zone, record_type, ttl=None, identifier=None, region=None, key=None, keyid=None, profile=None, wait_for_sync=True, split_dns=False, private_zone=False)

Ensure the Route53 record is present.

name Name of the record.
value Value of the record.
zone The zone to create the record in.
record_type The record type (A, NS, MX, TXT, etc.)
ttl The time to live for the record.
identifier The unique identifier to use for this record.
region The region to connect to.
key Secret key to be used.
keyid Access key to be used.
profile A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.
wait_for_sync Wait for an INSYNC change status from Route53.
split_dns Route53 supports a public and private DNS zone with the same names.
private_zone If using split_dns, specify if this is the private zone.

31.27.27 salt.states.boto_secgroup

Manage Security Groups

New in version 2014.7.0.
Create and destroy Security Groups. Be aware that this interacts with Amazon's services, and so may incur charges. This module uses boto, which can be installed via package, or pip.

This module accepts explicit EC2 credentials but can also utilize IAM roles assigned to the instance through Instance Profiles. Dynamic credentials are then automatically obtained from AWS API and no further configuration is necessary. More information available here.

If IAM roles are not used you need to specify them either in a pillar file or in the minion's config file:

```
secgroup.keyid: GKTADJGHEIQSXMKKRBJ08H
secgroup.key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
```

It's also possible to specify key, keyid and region via a profile, either passed in as a dict, or as a string to pull from pillars or minion config:

```
myprofile:
  keyid: GKTADJGHEIQSXMKKRBJ08H
  key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
  region: us-east-1
```

Ensure mysecgroup exists:
```
boto_secgroup.present:
  - name: mysecgroup
  - description: My security group
  - rules:
    - ip_protocol: tcp
      from_port: 80
      to_port: 80
      cidr_ip:
        - 10.0.0.0/0
        - 192.168.0.0/0
    - ip_protocol: icmp
      from_port: -1
      to_port: -1
      source_group_name: mysecgroup
  - rules_egress:
    - ip_protocol: all
      from_port: -1
      to_port: -1
      cidr_ip:
        - 10.0.0.0/0
        - 192.168.0.0/0
    - region: us-east-1
    - keyid: GKTADJGHEIQSXMKKRBJ08H
    - key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
```

# Using a profile from pillars
Ensure mysecgroup exists:
```
boto_secgroup.present:
  - name: mysecgroup
  - description: My security group
  - region: us-east-1
  - profile: myprofile
```

# Passing in a profile
Ensure mysecgroup exists:
```
boto_secgroup.present:
  - name: mysecgroup
  - description: My security group
```

1662 Chapter 31. Reference
salt.states.boto_secgroup.absent(name, vpc_id=None, region=None, key=None, keyid=None, profile=None)

Ensure a security group with the specified name does not exist.

- name: Name of the security group.
- vpc_id: The ID of the VPC to create the security group in, if any.
- region: Region to connect to.
- key: Secret key to be used.
- keyid: Access key to be used.
- profile: A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

salt.states.boto_secgroup.present(name, description, vpc_id=None, rules=None, rules_egress=None, region=None, key=None, keyid=None, profile=None)

Ensure the security group exists with the specified rules.

- name: Name of the security group.
- description: A description of this security group.
- vpc_id: The ID of the VPC to create the security group in, if any.
- rules: A list of ingress rule dicts.
- rules_egress: A list of egress rule dicts.
- region: Region to connect to.
- key: Secret key to be used.
- keyid: Access key to be used.
- profile: A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

31.27.28 salt.states.boto_sns

Manage SNS Topics

Create and destroy SNS topics. Be aware that this interacts with Amazon's services, and so may incur charges.

This module uses boto, which can be installed via package, or pip.

This module accepts explicit AWS credentials but can also utilize IAM roles assigned to the instance through Instance Profiles. Dynamic credentials are then automatically obtained from AWS API and no further configuration is necessary. More information available here.

If IAM roles are not used you need to specify them either in a pillar file or in the minion's config file:

```
sns.keyid: GKTADJGHEIQSXMKKRBJ08H
sns.key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
```
It's also possible to specify `key`, `keyid` and `region` via a profile, either passed in as a dict, or as a string to pull from pillars or minion config:

```yaml
define myprofile:
    keyid: GKTADJGHEIQSXMKKRBJ08H
    key: askdjghsdfjkgWupUjasdklfklgjsdfjajkghs
    region: us-east-1

mytopic:
    boto_sns.present:
        - region: us-east-1
        - keyid: GKTADJGHEIQSXMKKRBJ08H
        - key: askdjghsdfjkgWupUjasdklfklgjsdfjajkghs

# Using a profile from pillars
mytopic:
    boto_sns.present:
        - region: us-east-1
        - profile: mysnsprofile

# Passing in a profile
mytopic:
    boto_sns.present:
        - region: us-east-1
        - profile:
            keyid: GKTADJGHEIQSXMKKRBJ08H
            key: askdjghsdfjkgWupUjasdklfklgjsdfjajkghs

salt.states.boto_sns.absent(name, region=None, key=None, keyid=None, profile=None)
Ensure the named sns topic is deleted.

- name Name of the SNS topic.
- region Region to connect to.
- key Secret key to be used.
- keyid Access key to be used.
- profile A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

salt.states.boto_sns.present(name, subscriptions=None, region=None, key=None, keyid=None, profile=None)
Ensure the SNS topic exists.

- name Name of the SNS topic.
- subscriptions List of SNS subscriptions.

Each subscription is a dictionary with a protocol and endpoint key:

```yaml
[
    {'protocol': 'https', 'endpoint': 'https://www.example.com/sns-endpoint'},
    {'protocol': 'sqs', 'endpoint': 'arn:aws:sqs:us-west-2:123456789012:MyQueue'}
]
```

- region Region to connect to.
- key Secret key to be used.
- keyid Access key to be used.
profile  A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

31.27.29  salt.states.boto_sqs

Manage SQS Queues

New in version 2014.7.0.

Create and destroy SQS queues. Be aware that this interacts with Amazon's services, and so may incur charges.

This module uses boto, which can be installed via package, or pip.

This module accepts explicit SQS credentials but can also utilize IAM roles assigned to the instance through Instance Profiles. Dynamic credentials are then automatically obtained from AWS API and no further configuration is necessary. More information available here.

If IAM roles are not used you need to specify them either in a pillar file or in the minion's config file:

```py
sqs.keyid: GKTADJGHEIQSXMKKRBJ08H
sqs.key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
```

It's also possible to specify key, keyid and region via a profile, either passed in as a dict, or as a string to pull from pillars or minion config:

```py
myprofile:
    keyid: GKTADJGHEIQSXMKKRBJ08H
    key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
    region: us-east-1

myqueue:
    boto_sqs.present:
        - region: us-east-1
        - keyid: GKTADJGHEIQSXMKKRBJ08H
        - key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
        - attributes:
            ReceiveMessageWaitTimeSeconds: 20
```

# Using a profile from pillars

```py
myqueue:
    boto_sqs.present:
        - region: us-east-1
        - profile: mysqsprofile
```

# Passing in a profile

```py
myqueue:
    boto_sqs.present:
        - region: us-east-1
        - profile:
            keyid: GKTADJGHEIQSXMKKRBJ08H
            key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
```

salt.states.boto_sqs.absent(name, region=, key=, keyid=, profile=)

Ensure the named sqs queue is deleted.

name  Name of the SQS queue.

region  Region to connect to.

key  Secret key to be used.
keyid  Access key to be used.

profile  A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

```
salt.states.boto_sqs.present(name, attributes=None, region=None, key=None, keyid=None, profile=None)
```

Ensure the SQS queue exists.

- name  Name of the SQS queue.
- attributes  A dict of key/value SQS attributes.
- region  Region to connect to.
- key  Secret key to be used.
- keyid  Access key to be used.
- profile  A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

### 31.27.30  salt.states.boto_vpc

**Manage VPCs**

New in version 2015.8.0.

Create and destroy VPCs. Be aware that this interacts with Amazon's services, and so may incur charges.

This module uses boto, which can be installed via package, or pip.

This module accepts explicit vpc credentials but can also utilize IAM roles assigned to the instance through Instance Profiles. Dynamic credentials are then automatically obtained from AWS API and no further configuration is necessary. More information available here.

If IAM roles are not used you need to specify them either in a pillar file or in the minion's config file:

```
vpc.keyid: GKTADJGHEIQSXMKKRBJ08H
vpc.key: askdjghsdfjkghWupUjasdflkdfklgjhsdkfjajkghs
```

It's also possible to specify key, keyid and region via a profile, either passed in as a dict, or as a string to pull from pillars or minion config:

```
myprofile:
  keyid: GKTADJGHEIQSXMKKRBJ08H
  key: askdjghsdfjkghWupUjasdflkdfklgjhsdkfjajkghs
  region: us-east-1
```

Ensure VPC exists:

```
boto_vpc.present:
  - name: myvpc
  - cidr_block: 10.10.11.0/24
  - dns_hostnames: True
  - region: us-east-1
  - keyid: GKTADJGHEIQSXMKKRBJ08H
  - key: askdjghsdfjkghWupUjasdflkdfklgjhsdkfjajkghs
```

Ensure subnet exists:

```
boto_vpc.subnet_present:
  - name: mysubnet
```
- vpc_id: vpc-123456
- cidr_block: 10.0.0.0/16
- region: us-east-1
- keyid: GKTADJGHEIQSXMKKRBJ08H
- key: askdjghsdfjkghWupUjasdflkdfklgjsdfajkghs

Ensure internet gateway exists:

```python
boto_vpc.internet_gateway_present:
- name: myigw
- vpc_name: myvpc
- region: us-east-1
- keyid: GKTADJGHEIQSXMKKRBJ08H
- key: askdjghsdfjkghWupUjasdflkdfklgjsdfajkghs
```

Ensure route table exists:

```python
boto_vpc.route_table_present:
- name: my_route_table
- vpc_id: vpc-123456
- routes:
  - destination_cidr_block: 0.0.0.0/0
  - instance_id: i-123456
  - interface_id: eni-123456
- subnets:
  - name: subnet1
  - name: subnet2
- region: us-east-1
- keyid: GKTADJGHEIQSXMKKRBJ08H
- key: askdjghsdfjkghWupUjasdflkdfklgjsdfajkghs
```

```python
salt.states.boto_vpc.absent(name, tags=None, region=None, key=None, keyid=None, profile=None)

Ensure VPC with passed properties is absent.

name Name of the VPC.

tags A list of tags. All tags must match.

region Region to connect to.

key Secret key to be used.

keyid Access key to be used.

profile A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.
```

```python
salt.states.boto_vpc.internet_gateway_absent(name, detach=False, region=None, key=None, keyid=None, profile=None)

Ensure the named internet gateway is absent.

name Name of the internet gateway.

detach First detach the internet gateway from a VPC, if attached.

region Region to connect to.

key Secret key to be used.

keyid Access key to be used.

profile A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.
```
Ensure an internet gateway exists.

- **name**: Name of the internet gateway.
- **vpc_name**: Name of the VPC to which the internet gateway should be attached.
- **vpc_id**: Id of the VPC to which the internet_gateway should be attached. Only one of vpc_name or vpc_id may be provided.
- **tags**: A list of tags.
- **region**: Region to connect to.
- **key**: Secret key to be used.
- **keyid**: Access key to be used.
- **profile**: A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

Ensure VPC exists.

- **name**: Name of the VPC.
- **cidr_block**: The range of IPs in CIDR format, for example: 10.0.0.0/24. Block size must be between /16 and /28 netmask.
- **instance_tenancy**: Instances launched in this VPC will be single-tenant or dedicated hardware.
- **dns_support**: Indicates whether the DNS resolution is supported for the VPC.
- **dns_hostnames**: Indicates whether the instances launched in the VPC get DNS hostnames.
- **tags**: A list of tags.
- **region**: Region to connect to.
- **key**: Secret key to be used.
- **keyid**: Access key to be used.
- **profile**: A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

Ensure the named route table is absent.

- **name**: Name of the route table.
- **region**: Region to connect to.
- **key**: Secret key to be used.
- **keyid**: Access key to be used.
- **profile**: A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.
salt.states.boto_vpc.route_table_present(name, vpc_name=None, vpc_id=None, routes=None, subnet_ids=None, subnet_names=None, tags=None, region=None, key=None, keyid=None, profile=None)

Ensure route table with routes exists and is associated to a VPC.

Example:

```yaml
.. code-block:: yaml

   boto_vpc.route_table_present:
     - name: my_route_table
     - vpc_id: vpc-123456
     - routes: - destination_cidr_block: 0.0.0.0/0
       instance_id: i-123456 interface_id: eni-123456
     - subnet_names: - subnet1 - subnet2

name  Name of the route table.

vpc_name  Name of the VPC with which the route table should be associated.

vpc_id  Id of the VPC with which the route table should be associated. Either vpc_name or vpc_id must be provided.

routes  A list of routes.

subnet_ids  A list of subnet ids to associate

subnet_names  A list of subnet names to associate

tags  A list of tags.

region  Region to connect to.

key  Secret key to be used.

keyid  Access key to be used.

profile  A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

salt.states.boto_vpc.subnet_absent(name=None, subnet_id=None, region=None, key=None, keyid=None, profile=None)

Ensure subnet with passed properties is absent.

name  Name of the subnet.

region  Region to connect to.

key  Secret key to be used.

keyid  Access key to be used.

profile  A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

cidr_block  Cidr block of the subnet.

salt.states.boto_vpc.subnet_present(name, cidr_block, vpc_name=None, vpc_id=None, availability_zone=None, tags=None, region=None, key=None, keyid=None, profile=None)

Ensure a subnet exists.
name  Name of the subnet.

cidr_block  The range of IPs for the subnet, in CIDR format. For example: 10.0.0.0/24. Block size must be between /16 and /28 netmask.

vpc_name  Name of the VPC in which the subnet should be placed. Either vpc_name or vpc_id must be provided.

vpc_id  Id of the VPC in which the subnet should be placed. Either vpc_name or vpc_id must be provided.

availability_zone  AZ in which the subnet should be placed.

tags  A list of tags.

region  Region to connect to.

key  Secret key to be used.

keyid  Access key to be used.

profile  A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

### 31.27.31 salt.states.bower

**Installation of Bower Packages**

These states manage the installed packages using Bower. Note that npm, git and bower must be installed for these states to be available, so bower states should include requisites to pkg.installed states for the packages which provide npm and git (simply npm and git in most cases), and npm.installed state for the package which provides bower.

Example:

```
npm:
    pkg.installed
git:
    pkg.installed
bower:
    npm.installed
    require:
        - pkg: npm
        - pkg: git

underscore:
    bower.installed:
        - dir: /path/to/project
        - require:
            - npm: bower
```

**salt.states.bower.bootstrap**(name, user=None)

Bootstraps a frontend distribution.

- user  The user to run Bower with

**salt.states.bower.installed**(name, dir, pkgs=None, user=None, env=None)

Verify that the given package is installed and is at the correct version (if specified).
underscore:
  bower.installed:
    - dir: /path/to/project
    - user: someuser

jquery#2.0:
  bower.installed:
    - dir: /path/to/project

name  The package to install

dir  The target directory in which to install the package

pkgs  A list of packages to install with a single Bower invocation; specifying this argument will ignore the
       name argument

user  The user to run Bower with

env  A list of environment variables to be set prior to execution. The format is the same as the cmd.run
     state function.

salt.states.bower.removed(name, dir, user=None)
Verify that the given package is not installed.

dir  The target directory in which to install the package

user  The user to run Bower with

31.27.32  salt.states.cabal

Installation of Cabal Packages

New in version 2015.8.0.

These states manage the installed packages for Haskell using cabal. Note that cabal-install must be installed for these
states to be available, so cabal states should include a requisite to a pkg.installed state for the package which provides
cabal (cabal-install in case of Debian based distributions). Example:

.. code-block:: yaml

  cabal-install: pkg.installed

  ShellCheck:
    cabal.installed:
      - require: - pkg: cabal-install

salt.states.cabal.installed(name, pkgs=None, user=None, install_global=False, env=None)
Verify that the given package is installed and is at the correct version (if specified).

ShellCheck-0.3.5:
  cabal:
    - installed:

name  The package to install

user  The user to run cabal install with

install_global  Install package globally instead of locally
env  A list of environment variables to be set prior to execution. The format is the same as the cmd.run.

statefunction.

salt.states.cabal.removed(name, user=None, env=None)
Verify that given package is not installed.

31.27.33  salt.states.chef

Execute Chef client runs

Run chef-client or chef-solo

my-chef-run:
  chef.client:
    - override-runlist: 'demo1,demo2'
    - server: 'https://chef.domain.com'

default-chef-run:
  chef.client: []

my-solo-run:
  chef.solo:
    - environment: dev

salt.states.chef.client(name, **kwargs)

  name  Unique identifier for the state. Does not affect the Chef run.
  server  The chef server URL
  client_key  Set the client key file location
  config  The configuration file to use
  config-file-jail  Directory under which config files are allowed to be loaded (no client.rb or knife.rb outside this path will be loaded).
  environment  Set the Chef Environment on the node
  group  Group to set privilege to
  json-attributes  Load attributes from a JSON file or URL
  localmode  Point chef-client at local repository if True
  log_level  Set the log level (debug, info, warn, error, fatal)
  logfile  Set the log file location
  node-name  The node name for this client
  override-runlist  Replace current run list with specified items for a single run
  pid  Set the PID file location, defaults to /tmp/chef-client.pid
  run-lock-timeout  Set maximum duration to wait for another client run to finish, default is indefinitely.
  runlist  Permanently replace current run list with specified items
  user  User to set privilege to
  validation_key  Set the validation key file location, used for registering new clients

salt.states.chef.solo(name, **kwargs)
name  Unique identifier for the state. Does not affect the Chef run.
config  The configuration file to use
environment  Set the Chef Environment on the node
group  Group to set privilege to
json-attributes  Load attributes from a JSON file or URL
log_level  Set the log level (debug, info, warn, error, fatal)
logfile  Set the log file location
node-name  The node name for this client
override-runlist  Replace current run list with specified items for a single run
recipe-url  Pull down a remote gzipped tarball of recipes and untar it to the cookbook cache
run-lock-timeout  Set maximum duration to wait for another client run to finish, default is indefinitely.
user  User to set privilege to

31.27.34  salt.states.cloud

Using states instead of maps to deploy clouds

New in version 2014.1.0.

Use this minion to spin up a cloud instance:

my-ec2-instance:
    cloud.profile:
        my-ec2-config

salt.states.cloud.absent(name, onlyif=None, unless=None)
Ensure that no instances with the specified names exist.

    name  The name of the instance to destroy
    onlyif  Do run the state only if is unless succeed
    unless  Do not run the state at least unless succeed

salt.states.cloud.present(name, cloud_provider, onlyif=None, unless=None, **kwargs)
Spin up a single instance on a cloud provider, using salt-cloud. This state does not take a profile argument; rather, it takes the arguments that would normally be configured as part of the state.

    name  The name of the instance to create
    cloud_provider  The name of the cloud provider to use
    onlyif  Do run the state only if is unless succeed
    unless  Do not run the state at least unless succeed

31.27.  Full list of builtin state modules  1673
salt.states.cloud.profile(name, profile, onlyif=None, unless=None, **kwargs)

Create a single instance on a cloud provider, using a salt-cloud profile.

Note that while profiles used this function do take any configuration argument that would normally be used to create an instance using a profile, this state will not verify the state of any of those arguments on an existing instance. Stateful properties of an instance should be configured using their own individual state (i.e., cloud.tagged, cloud.untagged, etc).

- **name**: The name of the instance to create
- **profile**: The name of the cloud profile to use
- **onlyif**: Do run the state only if is unless succeed
- **unless**: Do not run the state at least unless succeed
- **kwargs**: Any profile override or addition

salt.states.cloud.volume_absent(name, provider=None, **kwargs)

Check that a block volume exists.

salt.states.cloud.volume_attached(name, server_name, provider=None, **kwargs)

Check if a block volume is attached.

salt.states.cloud.volume_detached(name, server_name=None, provider=None, **kwargs)

Check if a block volume is attached.

Returns True if server or Volume do not exist.

salt.states.cloud.volume_present(name, provider=None, **kwargs)

Check that a block volume exists.

### 31.27.35 salt.states.cmd

**Execution of arbitrary commands**

The cmd state module manages the enforcement of executed commands, this state can tell a command to run under certain circumstances.

A simple example to execute a command:

date > /tmp/salt-run:

    cmd.run

Only run if another execution failed, in this case truncate syslog if there is no disk space:

> /var/log/messages:

    cmd.run:
        - unless: echo 'foo' > /tmp/.test && rm -f /tmp/.test

Only run if the file specified by creates does not exist, in this case touch /tmp/foo if it does not exist.

    touch /tmp/foo:

    cmd.run:
        - creates: /tmp/foo

**Note**: The creates option was added to version 2014.7.0

Salt determines whether the cmd state is successfully enforced based on the exit code returned by the command. If the command returns a zero exit code, then salt determines that the state was successfully enforced. If the script
returns a non-zero exit code, then salt determines that it failed to successfully enforce the state. If a command returns a non-zero exit code but you wish to treat this as a success, then you must place the command in a script and explicitly set the exit code of the script to zero.

Please note that the success or failure of the state is not affected by whether a state change occurred nor the stateful argument.

When executing a command or script, the state (i.e., changed or not) of the command is unknown to Salt's state system. Therefore, by default, the `cmd` state assumes that any command execution results in a changed state.

This means that if a `cmd` state is watched by another state then the state that's watching will always be executed due to the `changed` state in the `cmd` state.

Many state functions in this module now also accept a `stateful` argument. If `stateful` is specified to be true then it is assumed that the command or script will determine its own state and communicate it back by following a simple protocol described below:

1. **If there's nothing in the stdout of the command, then assume no changes.** Otherwise, the stdout must be either in JSON or its last non-empty line must be a string of key=value pairs delimited by spaces (no spaces on either side of =).

2. **If it's JSON then it must be a JSON object (e.g., {}).** If it's key=value pairs then quoting may be used to include spaces. (Python's `shlex` module is used to parse the key=value string)

   Two special keys or attributes are recognized in the output:

<table>
<thead>
<tr>
<th>Key</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>changed:</td>
<td>bool (i.e., 'yes', 'no', 'true', 'false', case-insensitive)</td>
</tr>
<tr>
<td>comment:</td>
<td>str (i.e., any string)</td>
</tr>
</tbody>
</table>

   So, only if `changed` is `True` then assume the command execution has changed the state, and any other key values or attributes in the output will be set as part of the changes.

3. **If there's a comment then it will be used as the comment of the state.**

   Here's an example of how one might write a shell script for use with a stateful command:

   ```bash
   #!/bin/bash
   
   # working hard...
   
   # writing the state line
   echo # an empty line here so the next line will be the last.
   echo "changed=yes comment='something has changed' whatever=123"
   
   And an example SLS file using this module:
   
   Run myscript:
   cmd.run:
     - name: /path/to/myscript
     - cwd: /
     - stateful: True
   
   Run only if myscript changed something:
   cmd.wait:
     - name: echo hello
     - cwd: /
     - watch:
       - cmd: Run myscript
   
   Note that if the `cmd.wait` state also specifies `stateful`: True it can then be watched by some other states as well.
4. The stateful argument can optionally include a test_name parameter.

This is used to specify a command to run in test mode. This command should return stateful data for changes that would be made by the command in the name parameter.

New in version 2015.2.0.

```yaml
Run myscript:
  cmd.run:
    - name: /path/to/myscript
    - cwd: /
    - stateful:
      - test_name: /path/to/myscript test

Run masterscript:
  cmd.script:
    - name: masterscript
    - source: salt://path/to/masterscript
    - cwd: /
    - stateful:
      - test_name: masterscript test
```

`cmd.wait` is not restricted to watching only `cmd` states. For example it can also watch a git state for changes

```yaml
# Watch for changes to a git repo and rebuild the project on updates
my-project:
  git.latest:
    - name: git@github.com/repo/foo
    - target: /opt/foo
    - rev: master
  cmd.wait:
    - name: make install
    - cwd: /opt/foo
    - watch:
      - git: my-project
```

**Should I use `cmd.run` or `cmd.wait`?**

These two states are often confused. The important thing to remember about them is that `cmd.run` states are run each time the SLS file that contains them is applied. If it is more desirable to have a command that only runs after some other state changes, then `cmd.wait` does just that. `cmd.wait` is designed to `watch` other states, and is executed when the state it is watching changes. Example:

```
/usr/local/bin/postinstall.sh:
  cmd.wait:
    - watch:
      - pkg: mycustompkg
  file.managed:
    - source: salt://utils/scripts/postinstall.sh

mycustompkg:
  pkg.installed:
    - require:
      - file: /usr/local/bin/postinstall.sh
```
How do I create an environment from a pillar map?

The map that comes from a pillar cannot be directly consumed by the env option. To use it one must convert it to a list. Example:

```python
printenv:
    cmd.run:
        - env:
            {% for key, value in pillar['keys'].iteritems() %}
                -('{{ key }}': '{{ value }}')
            {% endfor %}

salt.states.cmd.call(name, func, args=(), kws=None, onlyif=None, unless=None, creates=None, output_loglevel='debug', use_vt=False, **kwargs)

Invoke a pre-defined Python function with arguments specified in the state declaration. This function is mainly used by the salt.renderers.pydsl renderer.

The interpretation of onlyif and unless arguments are identical to those of cmd.run, and all other arguments(cwd, runas, ...) allowed by cmd.run are allowed here, except that their effects apply only to the commands specified in onlyif and unless rather than to the function to be invoked.

In addition, the stateful argument has no effects here.

The return value of the invoked function will be interpreted as follows.

If it’s a dictionary then it will be passed through to the state system, which expects it to have the usual structure returned by any salt state function.

Otherwise, the return value (denoted as result in the code below) is expected to be a JSON serializable object, and this dictionary is returned:

```python
{
    'name': name,
    'changes': {'retval': result},
    'result': True if result is None else bool(result),
    'comment': result if isinstance(result, string_types) else ''
}
```

salt.states.cmd.mod_run_check(cmd_kwargs, onlyif, unless, group, creates)

Execute the onlyif and unless logic. Return a result dict if: *group is not available* only if: failed (onlyif != 0) *unless succeeded (unless == 0) else return True

salt.states.cmd.mod_watch(name, **kwargs)

Execute a cmd function based on a watch call

salt.states.cmd.run(name, onlyif=None, unless=None, creates=None, cwd=None, user=None, group=None, shell=None, env=None, stateful=False, umask=None, output_loglevel='debug', quiet=False, timeout=None, ignore_timeout=False, use_vt=False, **kwargs)

Run a command if certain circumstances are met. Use cmd.wait if you want to use the watch requisite.

name  The command to execute, remember that the command will execute with the path and permissions of the salt-minion.

onlyif  A command to run as a check, run the named command only if the command passed to the onlyif option returns true

unless  A command to run as a check, only run the named command if the command passed to the unless option returns false

cwd  The current working directory to execute the command in, defaults to /root
user  The user name to run the command as

group  The group context to run the command as

shell  The shell to use for execution, defaults to the shell grain

env  A list of environment variables to be set prior to execution. Example:

```yaml
script-foo:
    cmd.run:
        - env:
            - BATCH: 'yes'
```

**Warning:** The above illustrates a common PyYAML pitfall, that yes, no, on, off, true, and false are all loaded as boolean True and False values, and must be enclosed in quotes to be used as strings. More info on this (and other) PyYAML idiosyncrasies can be found [here](#).

Variables as values are not evaluated. So $PATH in the following example is a literal `\$PATH`:

```yaml
script-bar:
    cmd.run:
        - env: "PATH=/some/path:$PATH"
```

One can still use the existing $PATH by using a bit of Jinja:

```python
{% set current_path = salt['environ.get']('PATH', '/bin:/usr/bin') %}

mycommand:
    cmd.run:
        - name: ls -l /
        - env:
            - PATH: {{ current_path, '/my/special/bin'|join(':') }}
```

stateful  The command being executed is expected to return data about executing a state

umask  The umask (in octal) to use when running the command.

output_loglevel  Control the loglevel at which the output from the command is logged. Note that the command being run will still be logged (loglevel: DEBUG) regardless, unless quiet is used for this value.

quiet  The command will be executed quietly, meaning no log entries of the actual command or its return data. This is deprecated as of the 2014.1.0 release, and is being replaced with output_loglevel: quiet.

timeout  If the command has not terminated after timeout seconds, send the subprocess sigterm, and if sigterm is ignored, follow up with sigkill

ignore_timeout  Ignore the timeout of commands, which is useful for running nohup processes.

    New in version 2015.8.0.

creates  Only run if the file specified by creates does not exist.

    New in version 2014.7.0.

use_vt  Use VT utils (saltstack) to stream the command output more interactively to the console and the logs. This is experimental.

    Note: cmd.run supports the usage of reload_modules. This functionality allows you to force Salt to reload all modules. You should only use reload_modules if your cmd.run does some sort of installation (such as pip), if you do not reload the modules future items in your state which rely on the software being installed will fail.
getpip:
  cmd.run:
    - name: /usr/bin/python /usr/local/sbin/get-pip.py
    - unless: which pip
    - require:
      - pkg: python
      - file: /usr/local/sbin/get-pip.py
      - reload_modules: True

salt.states.cmd.script(name, source=None, template=None, onlyif=None, unless=None, creates=None, cwd=None, user=None, group=None, shell=None, env=None, stateful=False, umask=None, timeout=None, use_vt=False, output_loglevel='debug', **kwargs)
Download a script and execute it with specified arguments.

source The location of the script to download. If the file is located on the master in the directory named spam, and is called eggs, the source string is salt://spam/eggs

template If this setting is applied then the named templating engine will be used to render the downloaded file. Currently jinja, mako, and weppy are supported

name Either `cmd arg1 arg2 arg3...` (cmd is not used) or a source `salt://...`.

onlyif Run the named command only if the command passed to the onlyif option returns true

unless Run the named command only if the command passed to the unless option returns false

cwd The current working directory to execute the command in, defaults to /root

user The name of the user to run the command as

group The group context to run the command as

shell The shell to use for execution. The default is set in grains['shell']

env A list of environment variables to be set prior to execution. Example:

salt://scripts/foo.sh:
  cmd.script:
    - env:
      - BATCH: 'yes'

Warning: The above illustrates a common PyYAML pitfall, that yes, no, on, off, true, and false are all loaded as boolean True and False values, and must be enclosed in quotes to be used as strings. More info on this (and other) PyYAML idiosyncrasies can be found here.

Variables as values are not evaluated. So $PATH in the following example is a literal `$PATH`:

salt://scripts/bar.sh:
  cmd.script:
    - env: "PATH=/some/path:$PATH"

One can still use the existing $PATH by using a bit of Jinja:

{% set current_path = salt['environ.get']('PATH', '/bin:/usr/bin') %}

mycommand:
  cmd.run:
    - name: ls -l /
- env:
  - PATH: {{ [current_path, '/my/special/bin']|join(':') }}

**umask**  The umask (in octal) to use when running the command.

**stateful**  The command being executed is expected to return data about executing a state

**timeout**  If the command has not terminated after timeout seconds, send the subprocess sigterm, and if sigterm is ignored, follow up with sigkill

**args**  String of command line args to pass to the script. Only used if no args are specified as part of the name argument. To pass a string containing spaces in YAML, you will need to doubly-quote it: `arg1 `arg two`arg3``

**creates**  Only run if the file specified by creates does not exist.

New in version 2014.7.0.

**use_vt**  Use VT utils (saltstack) to stream the command output more interactively to the console and the logs.

This is experimental.

**output_loglevel**  Control the loglevel at which the output from the command is logged. Note that the command being run will still be logged (loglevel: DEBUG) regardless, unless quiet is used for this value.

```
salt.states.cmd.wait(name, onlyif=None, unless=None, creates=None, cwd=None, user=None, 
group=None, shell=None, env=(), stateful=False, umask=None, output_loglevel='debug', use_vt=False, **kwargs)
```

Run the given command only if the watch statement calls it

**name**  The command to execute, remember that the command will execute with the path and permissions of the salt-minion.

**onlyif**  A command to run as a check, run the named command only if the command passed to the onlyif option returns true

**unless**  A command to run as a check, only run the named command if the command passed to the unless option returns false

**cwd**  The current working directory to execute the command in, defaults to /root

**user**  The user name to run the command as

**group**  The group context to run the command as

**shell**  The shell to use for execution, defaults to /bin/sh

**env**  A list of environment variables to be set prior to execution. Example:

```
script-foo:
  cmd.wait:
    - env:
      - BATCH: 'yes'
```

**Warning**: The above illustrates a common PyYAML pitfall, that yes, no, on, off, true, and false are all loaded as boolean True and False values, and must be enclosed in quotes to be used as strings. More info on this (and other) PyYAML idiosyncrasies can be found [here](#).

Variables as values are not evaluated. So $PATH in the following example is a literal `$PATH`:

```
script-bar:
  cmd.wait:
    - env: "PATH=/some/path:$PATH"
```
One can still use the existing $PATH by using a bit of Jinja:

```python
{% set current_path = salt['environ.get']('PATH', '/bin:/usr/bin') %}

mycommand:
  cmd.run:
    - name: ls -l /
    - env:
      - PATH: {{ [current_path, '/my/special/bin']|join(':') }}
```

**umask**  The umask (in octal) to use when running the command.

**stateful**  The command being executed is expected to return data about executing a state

**creates**  Only run if the file specified by creates does not exist.

  New in version 2014.7.0.

**output_loglevel**  Control the loglevel at which the output from the command is logged. Note that the command being run will still be logged (loglevel: DEBUG) regardless, unless quiet is used for this value.

**use_vt**  Use VT utils (saltstack) to stream the command output more interactively to the console and the logs. This is experimental.

```python
salt.states.cmd.wait_call(name, func, args=(), kws=None, onlyif=None, unless=None, creates=None, stateful=False, use_vt=False, output_loglevel='debug', **kwargs)
```

```python
salt.states.cmd.wait_script(name, source=None, template=None, onlyif=None, unless=None, cwd=None, user=None, group=None, shell=None, env=None, stateful=False, umask=None, use_vt=False, output_loglevel='debug', **kwargs)
```

Download a script from a remote source and execute it only if a watch statement calls it.

**source**  The source script being downloaded to the minion, this source script is hosted on the salt master server. If the file is located on the master in the directory named spam, and is called eggs, the source string is `salt://spam/eggs`

**template**  If this setting is applied then the named templating engine will be used to render the downloaded file, currently jinja, mako, and wempy are supported

**name**  The command to execute, remember that the command will execute with the path and permissions of the salt-minion.

**onlyif**  A command to run as a check, run the named command only if the command passed to the onlyif option returns true

**unless**  A command to run as a check, only run the named command if the command passed to the unless option returns false

**cwd**  The current working directory to execute the command in, defaults to /root

**user**  The user name to run the command as

**group**  The group context to run the command as

**shell**  The shell to use for execution, defaults to the shell grain

**env**  A list of environment variables to be set prior to execution. Example:

```python
salt://scripts/foo.sh:
  cmd.wait_script:
    - env:
      - BATCH: 'yes'
```
Warning: The above illustrates a common PyYAML pitfall, that yes, no, on, off, true, and false are all loaded as boolean True and False values, and must be enclosed in quotes to be used as strings. More info on this (and other) PyYAML idiosyncrasies can be found here.

Variables as values are not evaluated. So $PATH in the following example is a literal `$PATH':

```
salt://scripts/bar.sh:
  cmd.wait_script:
    - env: "PATH=/some/path:$PATH"
```

One can still use the existing $PATH by using a bit of Jinja:

```
{% set current_path = salt['environ.get']('PATH', '/bin:/usr/bin') %}

mycommand:
  cmd.run:
    - name: ls -l /
    - env:
      - PATH: {{ [current_path, '/my/special/bin']|join(':') }}
```

**umask**  The umask (in octal) to use when running the command.

**stateful**  The command being executed is expected to return data about executing a state

**use_vt**  Use VT utils (saltstack) to stream the command output more interactively to the console and the logs. This is experimental.

**output_loglevel**  Control the loglevel at which the output from the command is logged. Note that the command being run will still be logged (loglevel: DEBUG) regardless, unless quiet is used for this value.

### 31.27.36  salt.states.composer

**Installation of Composer Packages**

These states manage the installed packages for composer for PHP. Note that either composer is installed and accessible via a bin directory or you can pass the location of composer in the state.

**get-composer:**

```
get-composer:
  cmd.run:
    - name: 'CURL=`which curl`; $CURL -sS https://getcomposer.org/installer | php'
    - unless: test -f /usr/local/bin/composer
    - cwd: /root/
```

**install-composer:**

```
install-composer:
  cmd.wait:
    - name: mv /root/composer.phar /usr/local/bin/composer
    - cwd: /root/
    - watch:
      - cmd: get-composer
```

**/path/to/project:**

```yaml
composer.installed:
  - no_dev: true
  - require:
```

```
```
# Without composer installed in your PATH
# Note: composer.phar must be executable for state to work properly
/path/to/project:
  composer.installed:
    - composer: /path/to/composer.phar
    - php: /usr/local/bin/php
    - no_dev: true

salt.states.composer.installed(
    name, composer=None, php=None, user=None, prefer_source=None, prefer_dist=None, no_scripts=None, no_plugins=None, optimize=None, no_dev=None, quiet=False, composer_home='/root', always_check=True)

Verify that the correct versions of composer dependencies are present.

dir Directory location of the composer.json file.

composer Location of the composer.phar file. If not set composer will just execute `composer` as if it is installed globally. (i.e. /path/to/composer.phar)

php Location of the php executable to use with composer. (i.e. /usr/bin/php)

user Which system user to run composer as.

    New in version 2014.1.4.

prefer_source --prefer-source option of composer.

prefer_dist --prefer-dist option of composer.

no_scripts --no-scripts option of composer.

no_plugins --no-plugins option of composer.

optimize --optimize-autoloader option of composer. Recommended for production.

no_dev --no-dev option for composer. Recommended for production.

quiet --quiet option for composer. Whether or not to return output from composer.

composer_home $COMPOSER_HOME environment variable

always_check If True, _always_ run composer install in the directory. This is the default behavior. If False, only run composer install if there is no vendor directory present.

salt.states.composer.update(
    name, composer=None, php=None, user=None, prefer_source=None, prefer_dist=None, no_scripts=None, no_plugins=None, optimize=None, no_dev=None, quiet=False, composer_home='/root')

Composer update the directory to ensure we have the latest versions of all project dependencies.

dir Directory location of the composer.json file.

composer Location of the composer.phar file. If not set composer will just execute `composer` as if it is installed globally. (i.e. /path/to/composer.phar)

php Location of the php executable to use with composer. (i.e. /usr/bin/php)

user Which system user to run composer as.

    New in version 2014.1.4.

prefer_source --prefer-source option of composer.

prefer_dist --prefer-dist option of composer.
no_scripts  --no-scripts option of composer.
no_plugins  --no-plugins option of composer.
optimize   --optimize-autoloader option of composer. Recommended for production.
no_dev      --no-dev option for composer. Recommended for production.
quiet       --quiet option for composer. Whether or not to return output from composer.
composer_home  $COMPOSER_HOME environment variable

31.27.37  salt.states.cron

Management of cron, the Unix command scheduler

Cron declarations require a number of parameters. The following are the parameters used by Salt to define the various timing values for a cron job:

- minute
- hour
- daymonth
- month
- dayweek (0 to 6 are Sunday through Saturday, 7 can also be used for Sunday)

Warning: Any timing arguments not specified take a value of *. This means that setting hour to 5, while not defining the minute param, will result in Salt adding a job that will execute every minute between 5 and 6 A.M.!
Additionally, the default user for these states is root. Therefore, if the cron job is for another user, it is necessary to specify that user with the user parameter.

A long time ago (before 2014.2), when making changes to an existing cron job, the name declaration is the parameter used to uniquely identify the job, so if an existing cron that looks like this:

```
date > /tmp/crontest:
  cron.present:
    - user: root
    - minute: 5
```

Is changed to this:

```
date > /tmp/crontest:
  cron.present:
    - user: root
    - minute: 7
    - hour: 2
```

Then the existing cron will be updated, but if the cron command is changed, then a new cron job will be added to the user's crontab.

The current behavior is still relying on that mechanism, but you can also specify an identifier to identify your crontabs:

```
date > /tmp/crontest:
  cron.present:
    - identifier: SUPERCRON
    - user: root
```
New in version 2014.1.2.

And, some months later, you modify it:

```
superscript > /tmp/crontest:
cron.present:
  - identifier: SUPERCRON
  - user: root
  - minute: 3
  - hour: 4
```

New in version 2014.1.2.

The old `date > /tmp/crontest` will be replaced by `superscript > /tmp/crontest`.

Additionally, Salt also supports running a cron every x minutes very similarly to the Unix convention of using `*/5` to have a job run every five minutes. In Salt, this looks like:

```
date > /tmp/crontest:
cron.present:
  - user: root
  - minute: '*/5'
```

The job will now run every 5 minutes.

Additionally, the temporal parameters (minute, hour, etc.) can be randomized by using `random` instead of using a specific value. For example, by using the `random` keyword in the `minute` parameter of a cron state, the same cron job can be pushed to hundreds or thousands of hosts, and they would each use a randomly-generated minute. This can be helpful when the cron job accesses a network resource, and it is not desirable for all hosts to run the job concurrently.

```
/path/to/cron/script:
cron.present:
  - user: root
  - minute: random
  - hour: 2
```

New in version 0.16.0.

Since Salt assumes a value of * for unspecified temporal parameters, adding a parameter to the state and setting it to `random` will change that value from * to a randomized numeric value. However, if that field in the cron entry on the minion already contains a numeric value, then using the `random` keyword will not modify it.

```
salt.states.cron.absent(name, user='root', identifier=False, **kwargs)
```

Verifies that the specified cron job is absent for the specified user; only the name is matched when removing a cron job.

- `name` The command that should be absent in the user crontab.
- `user` The name of the user whose crontab needs to be modified, defaults to the root user
- `identifier` Custom-defined identifier for tracking the cron line for future crontab edits. This defaults to the state id

```
salt.states.cron.env_absent(name, user='root')
```

Verifies that the specified environment variable is absent from the crontab for the specified user

- `name` The name of the environment variable to remove from the user crontab
- `user` The name of the user whose crontab needs to be modified, defaults to the root user
salt.states.cron.env_present(name, value=None, user='root')
Verifies that the specified environment variable is present in the crontab for the specified user.

- **name** The name of the environment variable to set in the user crontab
- **user** The name of the user whose crontab needs to be modified, defaults to the root user
- **value** The value to set for the given environment variable

salt.states.cron.file(name, source_hash='`', user='root', template=None, context=None, replace=True, defaults=None, env=None, backup='`', **kwargs)
Provides file.managed-like functionality (templating, etc.) for a pre-made crontab file, to be assigned to a given user.

- **name** The source file to be used as the crontab. This source file can be hosted on either the salt master server, or on an HTTP or FTP server. For files hosted on the salt file server, if the file is located on the master in the directory named spam, and is called eggs, the source string is `salt://spam/eggs`

  If the file is hosted on a HTTP or FTP server then the source_hash argument is also required

- **source_hash** This can be either a file which contains a source hash string for the source, or a source hash string. The source hash string is the hash algorithm followed by the hash of the file:
  
  ```
  md5=e138491e9d5b97023cea823fe17bac22
  ```

- **user** The user to whom the crontab should be assigned. This defaults to root.
- **template** If this setting is applied then the named templating engine will be used to render the downloaded file. Currently, jinja and mako are supported.
- **context** Overrides default context variables passed to the template.
- **replace** If the crontab should be replaced, if False then this command will be ignored if a crontab exists for the specified user. Default is True.
- **defaults** Default context passed to the template.
- **backup** Overrides the default backup mode for the user’s crontab.

salt.states.cron.present(name, user='root', minute='*', hour='*', daymonth='*', month='*', dayweek='*', comment=None, identifier=False)
Verifies that the specified cron job is present for the specified user. For more advanced information about what exactly can be set in the cron timing parameters, check your cron system’s documentation. Most Unix-like systems’ cron documentation can be found via the crontab man page: `man 5 crontab`.

- **name** The command that should be executed by the cron job.
- **user** The name of the user whose crontab needs to be modified, defaults to the root user
- **minute** The information to be set into the minute section, this can be any string supported by your cron system’s the minute field. Default is *
- **hour** The information to be set in the hour section. Default is *
- **daymonth** The information to be set in the day of month section. Default is *
- **month** The information to be set in the month section. Default is *
- **dayweek** The information to be set in the day of week section. Default is *
- **comment** User comment to be added on line previous the cron job
- **identifier** Custom-defined identifier for tracking the cron line for future crontab edits. This defaults to the state id
31.27.38 salt.states.cyg

Installation of Cygwin packages.
A state module to manage cygwin packages. Packages can be installed or removed.

dos2unix:
  cyg.installed

class salt.states.cyg.DictDiffer(current_dict, past_dict)
  Calculate the difference between two dictionaries.
  1. items added
  2. items removed
  3. keys same in both but changed values
  4. keys same in both and unchanged values

  added()
  Return a set of additions to past_dict.

  changed()
  Return a set of the keys with changed values.

  removed()
  Return a set of things removed from past_dict.

  same()
  True if the two dicts are the same.

  unchanged()
  Return a set of the keys with unchanged values.

salt.states.cyg.installed(name, cyg_arch='x86_64', mirrors=None)
  Make sure that a package is installed.

  name  The name of the package to install

  cyg_arch  [x86_64] The cygwin architecture to install the package into. Current options are x86 and x86_64

  mirrors  [None] List of mirrors to check. None will use a default mirror (kernel.org)

  CLI Example:
  rsync:
    cyg.installed:
      - mirrors:
        - http://mirror/without/public/key: ""

salt.states.cyg.removed(name, cyg_arch='x86_64', mirrors=None)
  Make sure that a package is not installed.

  name  The name of the package to uninstall

  cyg_arch  [x86_64] The cygwin architecture to remove the package from. Current options are x86 and x86_64

  mirrors  [None] List of mirrors to check. None will use a default mirror (kernel.org)

  CLI Example:
rsync:
  cyg.removed:
  - mirrors:
    - http://mirror/without/public/key: ""

salt.states.cyg.updated(name=None, cyg_arch='x86_64', mirrors=None)
Make sure all packages are up to date.

name [None] No affect, salt fails poorly without the arg available
cyg_arch [x86_64] The cygwin architecture to update. Current options are x86 and x86_64
mirrors [None] List of mirrors to check. None will use a default mirror (kernel.org)

CLI Example:

rsync:
  cyg.updated:
  - mirrors:
    - http://mirror/without/public/key: ""

31.27.39 salt.states.ddns

Dynamic DNS updates

Ensure a DNS record is present or absent utilizing RFC 2136 type dynamic updates. Requires dnspython module.

webserver:
  ddns.present:
    - zone: example.com
    - ttl: 60
    - data: 111.222.333.444
    - nameserver: 123.234.345.456
    - keyfile: /srv/salt/tsig_key.txt

salt.states.ddns.absent(name, zone, data=None, rdtype=None, **kwargs)

Ensures that the named DNS record is absent.

name The host portion of the DNS record, e.g., `webserver`
zone The zone to check
data Data for the DNS record. E.g., the IP address for an A record. If omitted, all records matching name (and rdtype, if provided) will be purged.
rdtype DNS resource type. If omitted, all types will be purged.
**kwargs Additional arguments the ddns.delete function may need (e.g. nameserver, keyfile, keyname).

salt.states.ddns.present(name, zone, ttl, data, rdtype='A', **kwargs)

Ensures that the named DNS record is present with the given ttl.

name The host portion of the DNS record, e.g., `webserver`
zone The zone to check/update
ttl TTL for the record
data Data for the DNS record. E.g., the IP address for an A record.
**rdtype** DNS resource type. Default `A`.

**kwargs** Additional arguments the ddns.update function may need (e.g. nameserver, keyfile, keyname).

### 31.27.40 salt.states.debconfmod

**Management of debconf selections**

**depends**
- debconf-utils package

The debconfmod state module manages the enforcement of debconf selections, this state can set those selections prior to package installation.

**Available Functions**

The debconfmod state has two functions, the `set` and `set_file` functions

**set** Set debconf selections from the state itself

**set_file** Set debconf selections from a file

```yaml
nullmailer-debconf:
    debconf.set:
    - name: nullmailer
    - data:
      'shared/mailname': {'type': 'string', 'value': 'server.domain.tld'}
      'nullmailer/relayhost': {'type': 'string', 'value': 'mail.domain.tld'}

ferm-debconf:
    debconf.set:
    - name: ferm
    - data:
      'ferm/enable': {'type': 'boolean', 'value': True}
```

**Note:** Due to how PyYAML imports nested dicts (see here), the values in the `data` dict must be indented four spaces instead of two.

```yaml
salt.states.debconfmod.set(name, data)

Set debconf selections
```

```yaml
    <state_id>:
    debconf.set:
    - name: <name>
    - data:
      <question>: {'type': <type>, 'value': <value>}
      <question>: {'type': <type>, 'value': <value>}

    <state_id>:
    debconf.set:
    - name: <name>
    - data:
      <question>: {'type': <type>, 'value': <value>}
      <question>: {'type': <type>, 'value': <value>}
```

**name:** The package name to set answers for.
data: A set of questions/answers for debconf. Note that everything under this must be indented twice.

question: The question the is being pre-answered

type: The type of question that is being asked (string, boolean, select, etc.)

value: The answer to the question

salt.states.debconfmod.set_file(name, source, template=None, context=None, defaults=None, **kwargs)

Set debconf selections from a file or a template

```
<state_id>:
    debconf.set_file:
        - source: salt://path/to/pkg.selections

<state_id>:
    debconf.set_file:
        - source: salt://path/to/pkg.selections?saltenv=myenvironment

<state_id>:
    debconf.set_file:
        - source: salt://path/to/pkg.selections.jinja2
        - template: jinja
        - context:
            some_value: "false"
```

source: The location of the file containing the package selections

template If this setting is applied then the named templating engine will be used to render the package selections file, currently jinja, mako, and wempy are supported

context Overrides default context variables passed to the template.

defaults Default context passed to the template.

31.27.41 salt.states.disk

Disk monitoring state

Monitor the state of disk resources

salt.states.disk.status(name, maximum=None, minimum=None)

Return the current disk usage stats for the named mount point

31.27.42 salt.states.dockerio

Manage Docker containers

Docker is a lightweight, portable, self-sufficient software container wrapper. The base supported wrapper type is LXC, cgroups, and the Linux Kernel.

Note: This state module requires docker-py which supports Docker Remote API version 1.6.
Available Functions

- **built**
  
  ```
  corp/mysuperdocker_img:
  docker.built:
  - path: /path/to/dir/container
  ```

- **pulled**
  
  ```
  ubuntu:
  docker.pulled:
  - tag: latest
  ```

- **pushed**
  
  ```
  corp/mysuperdocker_img:
  docker.pushed
  ```

- **installed**
  
  ```
  mysuperdocker-container:
  docker.installed:
  - name: mysuperdocker
  - hostname: superdocker
  - image: corp/mysuperdocker_img
  ```

- **loaded**
  
  ```
  mysuperdocker-file:
  docker.loaded:
  - name: mysuperdocker
  - source: salt://_files/tmp/docker_image.tar
  ```

- **running**
  
  ```
  my_service:
  docker.running:
  - container: mysuperdocker
  - image: corp/mysuperdocker_img
  - port_bindings:
    - "5000/tcp":
      HostIp: ""
      HostPort: "5000"
  ```

  **Note:** The `port_bindings` argument above is a dictionary. The double indentation is required for PyYAML to load the data structure properly as a python dictionary. More information can be found [here](#).

- **absent**
  
  ```
  mys_olduperdocker:
  docker.absent
  ```

- **run**
  
  ```
  /finish-install.sh:
  docker.run:
  - cid: mysuperdocker
  ```
Use Cases

Ensures the container is running with the latest image available

```yaml
my-service-image:
docker.pulled:
  - name: registry/my-service:latest
  - force: true

my-service-container:
docker.installed:
  - image: registry/my-service:latest
  - watch:
    - docker: my-service-image

my-service:
docker.running:
  - container: my-service-container
  - watch:
    - docker: my-service-container
```

Note: The docker modules are named `dockerio` because the name `docker` would conflict with the underlying docker-py library.

`salt.states.dockerio.absent(name)`
Ensure that the container is absent; if not, it will be killed and destroyed. (docker inspect)

- **name**: Either the container name or id

`salt.states.dockerio.built(name, tag='latest', path=None, quiet=False, nocache=False, rm=True, force=False, timeout=None, **kwargs)`
Build a docker image from a path or URL to a dockerfile. (docker build)

- **name**: Name of the image
- **tag**: tag of the image (defaults to `latest`)
- **path**: URL (e.g. url/branch/docker_dir/dockerfile) or filesystem path to the dockerfile

`salt.states.dockerio.installed(name, image, tag='latest', command=None, hostname=None, user=None, detach=True, stdin_open=False, tty=False, mem_limit=None, ports=None, environment=None, dns=None, volumes=None, volumes_from=None, cpu_shares=None, cpuset=None, **kwargs)`
Ensure that a container with the given name exists; if not, build a new container from the specified image. (docker run)

- **name**: Name for the container
- **image**: Image from which to build this container
- **tag**: tag of the image (defaults to `latest`)
- **environment**: Environment variables for the container, either

---

salt Documentation, Release 2015.8.0

```bash
- unless: grep -q something /var/log/foo
- docker_unless: grep -q done /install_log
```
• a mapping of key, values
• a list of mappings of key, values

ports

List of ports definitions, either:
• a port to map
• a mapping of mapping portInHost : PortInContainer

volumes List of volumes (see notes for the running function)

For other parameters, see absolutely first the salt.modules.dockerio execution module and the docker-py python bindings for docker documentation `<https://github.com/dotcloud/docker-py#api>`_ for *docker.create_container*.

**Note:** This command does not verify that the named container is running the specified image.

```python
salt.states.dockerio.loaded(name, tag='latest', source=None, source_hash='`', force=False)
```

Load an image into the local docker registry (*docker load*)

*name* Name of the docker image

*tag* tag of the image (defaults to `latest`)

*source* The source .tar file to download to the minion, created by docker save this source file can be hosted on
either the salt master server, or on an HTTP or FTP server.

If the file is hosted on a HTTP or FTP server then the source_hash argument is also required

**Note:** See first the documentation for *salt file.managed* `<http://docs.saltstack.com/en/latest/ref/states/all/_salt.states.file.html#salt.states.file.managed>`

*source_hash*

This can be one of the following:

1. a source hash string
2. the URI of a file that contains source hash strings

**Note:** See first the documentation for *salt file.managed* `<http://docs.saltstack.com/en/latest/ref/states/all/_salt.states.file.html#salt.states.file.managed>`

*force* Load even if the image exists

```python
salt.states.dockerio.mod_watch(name, sfun=None, *args, **kw)
```

```python
salt.states.dockerio.present(name, image=None, tag='latest', is_latest=False)
```

If a container with the given name is not present, this state will fail. Supports optionally checking for specific
image/tag (*docker inspect*)

*name:* container id

*image:* image the container should be running (defaults to any)

*tag:* tag of the image (defaults to `latest`)

*is_latest:* also check if the container runs the latest version of the image ( latest defined as the latest pulled
onto the local machine)
**Pull an image from a docker registry** *(docker pull)*

```python
salt.states.dockerio.pulled(name, tag='latest', force=False, insecure_registry=False, *args, **kwargs)
```

Pull an image from a docker registry. *(docker pull)*

**Note:** See first the documentation for docker login, docker pull, docker push, and docker.import_image (docker import). NOTE that we added in SaltStack a way to authenticate yourself with the Docker Hub Registry by supplying your credentials (username, email & password) using pillars. For more information, see salt.modules.dockerio execution module.

- **name** Name of the image
- **tag** Tag of the image
- **force** Pull even if the image is already pulled
- **insecure_registry** Set to True to allow connections to non-HTTPS registries. Default False.

**Push an image from a docker registry** *(docker push)*

```python
salt.states.dockerio.pushed(name, tag='latest', insecure_registry=False)
```

Push an image from a docker registry. *(docker push)*

**Note:** See first the documentation for docker login, docker pull, docker push, and docker.import_image (docker import). NOTE that we added in SaltStack a way to authenticate yourself with the Docker Hub Registry by supplying your credentials (username, email & password) using pillars. For more information, see salt.modules.dockerio execution module.

- **name** Name of the image
- **tag** Tag of the image [Optional]
- **insecure_registry** Set to True to allow connections to non-HTTPS registries. Default False.

**Run a command in a specific container**

```python
salt.states.dockerio.run(name, cid=None, hostname=None, onlyif=None, unless=None, docked_onlyif=None, docked_unless=None, *args, **kwargs)
```

Run a command in a specific container

You can match by either name or hostname

- **name** command to run in the container
- **cid** Container id or name
- **state_id** state_id
- **onlyif** Only execute cmd if statement on the host returns 0
- **unless** Do not execute cmd if statement on the host returns 0
- **docked_onlyif** Only execute cmd if statement in the container returns 0
- **docked_unless** Do not execute cmd if statement in the container returns 0

**Ensure that a container is running**

```python
salt.states.dockerio.running(name, image, tag='latest', container=None, command=None, hostname=None, user=None, detach=True, stdin_open=False, tty=False, mem_limit=None, ports=None, environment=None, dns=None, volumes=None, volumes_from=None, start=True, cap_drop=None, privileged=None, publish_all_ports=False, network_mode=None, check_is_running=True, publish_all_ports=False, links=None, restart_policy=None, cpu_shares=None, cpuset=None, kill_signal=None, *args, **kwargs)
```

Ensure that a container is running. If the container does not exist, it will be created from the specified image.
(docker run)

**name/container**  Name for the container

**image**  Image from which to build this container

**tag**  tag of the image (defaults to "latest")

**environment**

Environment variables for the container, either

- a mapping of key, values
- a list of mappings of key, values

**ports**

List of ports definitions, either:

- a port to map
- a mapping of mapping portInHost: PortInContainer

```
- ports:
  - "5000/tcp":
    HostIp: ""
    HostPort: "5000"
```

**publish_all_ports**  Publish all ports from the port list (default is false, only meaningful if port does not contain portinhost:portincontainer mapping)

**volumes**  List of volumes to mount or create in the container (like `\-v` of docker run command), mapping host directory to container directory.

To specify a volume in the container in terse list format:

```
- volumes:
  - "/var/log/service" # container-only volume
  - "/srv/timezone:/etc/timezone" # bound volume
  - "/usr/local/etc/passwd:/etc/passwd:ro" # read-only bound volume
```

You can also use the short dictionary form (note that the notion of source:target from docker is preserved):

```
- volumes:
  - /var/log/service: /var/log/service # mandatory read-write implied
```

Or, alternatively, to specify read-only mounting, use the extended form:

```
- volumes:
  - /home/user1:
    bind: /mnt/vol2
    ro: True
  - /var/www:
    bind: /mnt/vol1
    ro: False
```

Or (for backwards compatibility) another dict style:

```
- volumes:
  - /home/user1:
    bind: /mnt/vol2
    ro: True
  - /var/www:
```

---

31.27. Full list of builtin state modules
bind: /mnt/vol1
ro: False

volumes_from  List of containers to share volumes with
dns  List of DNS servers.
    - dns:
        - 127.0.0.1

network_mode
    • `bridge`: creates a new network stack for the container on the docker bridge
    • `none`: no networking for this container
    • `container:[name|id]`: reuses another container network stack
    • `host`: use the host network stack inside the container
    - network_mode: host

restart_policy  Restart policy to apply when a container exits (no, on-failure[:max-retry], always)
    - restart_policy:
        MaximumRetryCount: 5
        Name: on-failure

cap_add  List of capabilities to add in a container.
cap_drop  List of capabilities to drop in a container.
check_is_running  Enable checking if a container should run or not. Useful for data-only containers that must be linked to another one. e.g. nginx <- static-files
cpu_shares  CPU shares (relative weight)
    - cpu_shares: 2

cpuset  CPUs in which to allow execution (`0-3` or `0,1`)
    - cpuset: '0-3'
kill_signal  If defined, its value will be sent as a kill signal to the running container. i.e. It will use client.kill(signal=kill_signal) instead of client.restart(), when the state is triggered by a watcher requisite.
    possible use case: Soft reload of nginx

nginx:
    docker.running:
        - image: some-fictional-registry.com/nginx
        - tag: latest
        - kill_signal: SIGHUP
        - watch:
            - file: /etc/nginx/nginx.conf

This state will ask nginx to reload (instead of restart) each time the /etc/nginx/nginx.conf is modified.

New in version 2015.8.0.

For other parameters, see salt.modules.dockerio execution module and the docker-py python bindings for docker documentation <https://github.com/dotcloud/docker-py#api> for docker.create_container.
Note: This command does not verify that the named container is running the specified image.

```python
salt.states.dockerio.script(*args, **kw)
```
Place holder function for a cmd.script alike.

Note: Not yet implemented. Its implementation might be very similar from salt.states.dockerio.run

### 31.27.43 `salt.states.dockerng`

Management of Docker containers

New in version 2015.8.0.

This is the state module to accompany the `dockerng` execution module.

Note: To pull from a Docker registry, authentication must be configured. See here for more information on how to configure access to docker registries in Pillar data.

```python
salt.states.dockerng.absent(name, force=False)
```
Ensure that a container is absent

- **name**: Name of the container
- **force**: [False] Set to True to remove the container even if it is running

Usage Examples:

```
mycontainer:
  dockerng.absent

multiple_containers:
  dockerng.absent:
    - names:
      - foo
      - bar
      - baz
```

```python
salt.states.dockerng.image_absent(name=None, images=None, force=False)
```
Ensure that an image is absent from the Minion. Image names can be specified either using repo:tag notation, or just the repo name (in which case a tag of latest is assumed).

- **images**: Run this state on more than one image at a time. The following two examples accomplish the same thing:

  ```
  remove_images:
    dockerng.image_absent:
      - names:
        - busybox
        - centos:6
        - nginx
  ```

  ```
  remove_images:
    dockerng.image_absent:
      - images:
        - busybox
        - centos:6
        - nginx
  ```
However, the second example will be a bit quicker since Salt will do all the deletions in a single run, rather than executing the state separately on each image (as it would in the first example).

**force** [False] Salt will fail to remove any images currently in use by a container. Set this option to true to remove the image even if it is already present.

**Note:** This option can also be overridden by Pillar data. If the Minion has a pillar variable named `dockerng.running.force` which is set to True, it will turn on this option. This pillar variable can even be set at runtime. For example:

```
salt myminion state.sls docker_stuff pillar="{dockerng.force: True}"
```

If this pillar variable is present and set to False, then it will turn off this option.

For more granular control, setting a pillar variable named `dockerng.force.image_name` will affect only the named image.

```python
salt.states.dockerng.image_present(name, build=None, load=None, force=False, insecure_registry=False, client_timeout=60)
```

Ensure that an image is present. The image can either be pulled from a Docker registry, built from a Dockerfile, or loaded from a saved image. Image names can be specified either using `repo:tag` notation, or just the repo name (in which case a tag of `latest` is assumed).

If neither of the `build` or `load` arguments are used, then Salt will pull from the configured registries. If the specified image already exists, it will not be pulled unless `force` is set to True. Here is an example of a state that will pull an image from the Docker Hub:

```salt
myuser/myimage:mytag:

dockerng.image_present
```

**build** Path to directory on the Minion containing a Dockerfile

```salt
myuser/myimage:mytag:

dockerng.image_present:
  - build: /home/myuser/docker/myimage
```

The image will be built using `dockerng.build` and the specified image name and tag will be applied to it.

**load** Loads a tar archive created with `dockerng.load` (or the `docker load` Docker CLI command), and assigns it the specified repo and tag.

```salt
myuser/myimage:mytag:

dockerng.image_present:
  - load: salt://path/to/image.tar
```

**force** [False] Set this parameter to True to force Salt to pull/build/load the image even if it is already present.

**client_timeout** Timeout in seconds for the Docker client. This is not a timeout for the state, but for receiving a response from the API.

```salt
salt.states.dockerng.mod_watch(name, sfun=None, **kwargs)
salt.states.dockerng.running(name, image=None, force=False, stop_timeout=10, validate_ip_addrs=True, watch_action='force', client_timeout=60, start=True, **kwargs)
```

Ensure that a container with a specific configuration is present and running.
name  Name of the container

image  Image to use for the container. Image names can be specified either using repo:tag notation, or just the repo name (in which case a tag of latest is assumed).

Note: This state will pull the image if it is not present. However, if the image needs to be built from a Dockerfile or loaded from a saved image, or if you would like to use requisites to trigger a replacement of the container when the image is updated, then the dockerng.image_present should be used to manage the image.

force  [False] Set this parameter to True to force Salt to re-create the container irrespective of whether or not it is configured as desired.

stop_timeout  [10] If the container needs to be replaced, the container will be stopped using dockerng.stop. The value of this parameter will be passed to dockerng.stop as the timeout value, telling Docker how long to wait for a graceful shutdown before killing the container.

validate_ip_addrs  [True] For parameters which accept IP addresses as input, IP address validation will be performed. To disable, set this to False.

watch_action  [force] Control what type of action is taken when this state watches another state that has changes. The default action is force, which runs the state with force set to True, triggering a rebuild of the container.

If any other value is passed, it will be assumed to be a kill signal. If the container matches the specified configuration, and is running, then the action will be to send that signal to the container. Kill signals can be either strings or numbers, and are defined in the Standard Signals section of the signal(7) manpage. Run man 7 signal on a Linux host to browse this manpage. For example:

```
mycontainer:
    dockerng.running:
        - image: busybox
        - watch_action: SIGHUP
        - watch:
            - file: some_file
```

Note: If the container differs from the specified configuration, or is not running, then instead of sending a signal to the container, the container will be re-created/started and no signal will be sent.

client_timeout  Timeout in seconds for the Docker client. This is not a timeout for this function, but for receiving a response from the API.

Note: This is only used if Salt needs to pull the requested image.

CONTAINER CONFIGURATION PARAMETERS

command  Command to run in the container

```
foo:
    dockerng.running:
        - image: bar/baz:latest
        - command: bash
```

hostname  Hostname of the container. If not provided, and if a name has been provided, the hostname will default to the name that was passed.

```
foo:
    dockerng.running:
```

- image: bar/baz:latest
- hostname: web1

**Warning:** hostname cannot be set if network_mode is set to host. The below example will result in an error:

```yaml
foo:
docker.run:
  - image: bar/baz:latest
  - hostname: web1
  - network_mode: host
```

domainname  Domain name of the container

```yaml
foo:
docker.run:
  - image: bar/baz:latest
  - hostname: domain.tld
```

**interactive**  [False] Leave stdin open

```yaml
foo:
docker.run:
  - image: bar/baz:latest
  - interactive: True
```

**tty**  [False] Attach TTYs

```yaml
foo:
docker.run:
  - image: bar/baz:latest
  - tty: True
```

detach  [True] If True, run command in the background (daemon mode)

```yaml
foo:
docker.run:
  - image: bar/baz:latest
  - detach: False
```

**user**  User under which to run docker

```yaml
foo:
docker.run:
  - image: bar/baz:latest
  - user: foo
```

**memory**  [0] Memory limit. Can be specified in bytes or using single-letter units (i.e. 512M, 2G, etc.). A value of 0 (the default) means no memory limit.

```yaml
foo:
docker.run:
  - image: bar/baz:latest
  - memory: 512M
```

**memory_swap**  [-1] Total memory limit (memory plus swap). Set to -1 to disable swap. A value of 0 means no swap limit.
foo:
dockerng.running:
  - image: bar/baz:latest
  - memory_swap: 1G

mac_address  MAC address to use for the container. If not specified, a random MAC address will be used.

foo:
dockerng.running:
  - image: bar/baz:latest
  - mac_address: 01:23:45:67:89:0a

network_disabled  [False] If True, networking will be disabled within the container.

foo:
dockerng.running:
  - image: bar/baz:latest
  - network_disabled: True

working_dir  Working directory inside the container.

foo:
dockerng.running:
  - image: bar/baz:latest
  - working_dir: /var/log/nginx

entrypoint  Entrypoint for the container.

foo:
dockerng.running:
  - image: bar/baz:latest
  - entrypoint:
    - mycmd
    - --arg1
    - --arg2

The entrypoint can also be specified as a list of arguments:

foo:
dockerng.running:
  - image: bar/baz:latest
  - entrypoint:
    - mycmd
    - --arg1
    - --arg2

environment  Either a list of variable/value mappings, or a list of strings in the format VARNAME=value.
The below two examples are equivalent:

foo:
dockerng.running:
  - image: bar/baz:latest
  - environment:
    - VAR1: value
    - VAR2: value

foo:
dockerng.running:
  - image: bar/baz:latest
  - environment:
    - VAR1=value
    - VAR2=value
ports  A list of ports to expose on the container. Can either be a comma-separated list or a YAML list. If the protocol is omitted, the port will be assumed to be a TCP port. The below two examples are equivalent:

```yaml
foo:
  docker.ng.running:
    - image: bar/baz:latest
    - ports: 1111,2222/udp
```

```
foo:
  docker.ng.running:
    - image: bar/baz:latest
    - ports:
      - 1111
      - 2222/udp
```

volumes  [None] List of directories to expose as volumes. Can either be a comma-separated list or a YAML list. The below two examples are equivalent:

```yaml
foo:
  docker.ng.running:
    - image: bar/baz:latest
    - volumes: /mnt/vol1,/mnt/vol2
```

```
foo:
  docker.ng.running:
    - image: bar/baz:latest
    - volumes:
      - /mnt/vol1
      - /mnt/vol2
```

cpu_shares  CPU shares (relative weight)

```yaml
foo:
  docker.ng.running:
    - image: bar/baz:latest
    - cpu_shares: 0.5
```

cpuset  CPUs on which which to allow execution, specified as a string containing a range (e.g. 0–3) or a comma-separated list of CPUs (e.g. 0,1).

```yaml
foo:
  docker.ng.running:
    - image: bar/baz:latest
    - cpuset: "0,1"
```

binds  Files/directories to bind mount. Each bind mount should be passed in the format `<host_path>:<container_path>:<read_only>`, where `<read_only>` is one of `rw` (for read-write access) or `ro` (for read-only access).

```yaml
foo:
  docker.ng.running:
    - image: bar/baz:latest
    - binds: /srv/www:/var/www:ro,
```

Binds can be passed as a YAML list instead of a comma-separated list:
```yaml
foo:
dockerNG.running:
  - image: bar/baz:latest
  - binds:
    - /srv/www:/var/www:ro
    - /home/myuser/conf/foo.conf:/etc/foo.conf:rw

Optionally, the read-only information can be left off the end and the bind mount will be assumed to be read-write. The example below is equivalent to the one above:

```yaml
foo:
dockerNG.running:
  - image: bar/baz:latest
  - binds:
    - /srv/www:/var/www:ro
    - /home/myuser/conf/foo.conf
```

**port_bindings** Bind exposed ports. Port bindings should be passed in the same way as the `--publish` argument to the `docker run` CLI command:

- `ip:hostPort:containerPort` - Bind a specific IP and port on the host to a specific port within the container.
- `ip::containerPort` - Bind a specific IP and an ephemeral port to a specific port within the container.
- `hostPort:containerPort` - Bind a specific port on all of the host's interfaces to a specific port within the container.
- `containerPort` - Bind an ephemeral port on all of the host's interfaces to a specific port within the container.

Multiple bindings can be separated by commas, or passed as a Python list. The below two examples are equivalent:

```yaml
foo:
dockerNG.running:
  - image: bar/baz:latest
  - port_bindings: "5000:5000,2123:2123/udp,8080"
```

```yaml
foo:
dockerNG.running:
  - image: bar/baz:latest
  - port_bindings:
    - 5000:5000
    - 2123:2123/udp
    - 8080
```

**Note:** When configuring bindings for UDP ports, the protocol must be passed in the `containerPort` value, as seen in the examples above.

**lxc_conf** Additional LXC configuration parameters to set before starting the container.

```yaml
foo:
dockerNG.running:
  - image: bar/baz:latest
  - lxc_conf:
    - lxc.utsname: docker
```
Note: These LXC configuration parameters will only have the desired effect if the container is using the LXC execution driver, which has not been the default for some time.

**publish_all_ports** [False] Allocates a random host port for each port exposed using the `ports` parameter.

```yaml
foo:
  dockerng.running:
    - image: bar/baz:latest
    - ports: 8080
    - publish_all_ports: True
```

**links** Link this container to another. Links should be specified in the format `<container_name_or_id>:<link_alias>`. Multiple links can be passed, either as a comma-separated list or a YAML list. The below two examples are equivalent:

```yaml
foo:
  dockerng.running:
    - image: bar/baz:latest
    - links: web1:link1,web2:link2

foo:
  dockerng.running:
    - image: bar/baz:latest
    - links:
      - web1:link1
      - web2:link2
```

**dns** List of DNS nameservers. Can be passed as a comma-separated list or a YAML list. The below two examples are equivalent:

```yaml
foo:
  dockerng.running:
    - image: bar/baz:latest
    - dns: 8.8.8.8,8.8.4.4

foo:
  dockerng.running:
    - image: bar/baz:latest
    - dns:
      - 8.8.8.8
      - 8.8.4.4
```

Note: To skip IP address validation, use `validate_ip_addrs=False`

**dns_search** List of DNS search domains. Can be passed as a comma-separated list or a YAML list. The below two examples are equivalent:

```yaml
foo:
  dockerng.running:
    - image: bar/baz:latest
    - dns_search: foo1.domain.tld,foo2.domain.tld

foo:
  dockerng.running:
    - image: bar/baz:latest
    - dns_search:
```
volumes_from  Container names or IDs from which the container will get volumes. Can be passed as a comma-separated list or a YAML list. The below two examples are equivalent:

```yaml
foo:
  dockerng.running:
    - image: bar/baz:latest
    - volumes_from: foo
```

```yaml
foo:
  dockerng.running:
    - image: bar/baz:latest
    - volumes_from:
        - foo
```

network_mode  [bridge] One of the following:

- bridge - Creates a new network stack for the container on the docker bridge
- null - No networking (equivalent of the Docker CLI argument --net=none)
- container:<name_or_id> - Reuses another container's network stack
- host - Use the host's network stack inside the container

**Warning:** Using host mode gives the container full access to the host's system's services (such as D-bus), and is therefore considered insecure.

```yaml
foo:
  dockerng.running:
    - image: bar/baz:latest
    - network_mode: null
```

restart_policy  Set a restart policy for the container. Must be passed as a string in the format policy[:retry_count] where policy is one of always or on-failure, and retry_count is an optional limit to the number of retries. The retry count is ignored when using the always restart policy.

```yaml
foo:
  dockerng.running:
    - image: bar/baz:latest
    - restart_policy: on-failure:5

bar:
  dockerng.running:
    - image: bar/baz:latest
    - restart_policy: always
```

cap_add  List of capabilities to add within the container. Can be passed as a comma-separated list or a Python list. The below two examples are equivalent:

```yaml
foo:
  dockerng.running:
    - image: bar/baz:latest
    - cap_add: SYS_ADMIN,MKNOD
```
foo:
dockerng.running:
- image: bar/baz:latest
- cap_add:
  - SYS_ADMIN
  - MKNOD

**Note:** This option requires Docker 1.2.0 or newer.

**cap_drop** List of capabilities to drop within the container. Can be passed as a comma-separated list or a Python list. The below two examples are equivalent:

```
foo:
dockerng.running:
- image: bar/baz:latest
- cap_drop: SYS_ADMIN,MKNOD
```

```
foo:
dockerng.running:
- image: bar/baz:latest
- cap_drop:
  - SYS_ADMIN
  - MKNOD
```

**Note:** This option requires Docker 1.2.0 or newer.

**extra_hosts** Additional hosts to add to the container’s /etc/hosts file. Can be passed as a comma-separated list or a Python list. The below two examples are equivalent:

```
foo:
dockerng.running:
- image: bar/baz:latest
- extra_hosts: web1:10.9.8.7,web2:10.9.8.8
```

```
foo:
dockerng.running:
- image: bar/baz:latest
- extra_hosts:
  - web1:10.9.8.7
  - web2:10.9.8.8
```

**Note:** To skip IP address validation, use `validate_ip_addrs=False`

**Note:** This option requires Docker 1.3.0 or newer.

**pid_mode** Set to `host` to use the host container’s PID namespace within the container

```
foo:
dockerng.running:
- image: bar/baz:latest
- pid_mode: host
```

**Note:** This option requires Docker 1.5.0 or newer.
**start** [True] Set to False to suppress starting of the container if it exists, matches the desired configuration, but is not running. This is useful for data-only containers, or for non-daemonized container processes, such as the django migrate and collectstatic commands. In instances such as this, the container only needs to be started the first time.

```
salt.states.dockerng.stopped(name=None, containers=None, stop_timeout=10, unpause=False, error_on_absent=True)
```

Ensure that a container (or containers) is stopped

**name** Name or ID of the container

**containers** Run this state on more than one container at a time. The following two examples accomplish the same thing:

```
stopped_containers:
  dockerng.stopped:
    - names:
      - foo
      - bar
      - baz
```

```
stopped_containers:
  dockerng.stopped:
    - containers:
      - foo
      - bar
      - baz
```

However, the second example will be a bit quicker since Salt will stop all specified containers in a single run, rather than executing the state separately on each image (as it would in the first example).

**stop_timeout** [10] Timeout for graceful shutdown of the container. If this timeout is exceeded, the container will be killed.

**unpause** [False] Set to True to unpause any paused containers before stopping. If unset, then an error will be raised for any container that was paused.

**error_on_absent** [True] By default, this state will return an error if any of the specified containers are absent. Set this to False to suppress that error.

### 31.27.44 salt.states.drac

Management of Dell DRAC

The DRAC module is used to create and manage DRAC cards on Dell servers

Ensure the user damian is present

```
damian:
  drac.present:
    - name: damian
    - password: secret
    - permission: login,test_alerts,clear_logs
```

Ensure the user damian does not exist

```
damian:
  drac.absent:
    - name: damian
```

Ensure DRAC network is in a consistent state
my_network:
  drac.network:
    - ip: 10.225.108.29
    - netmask: 255.255.255.224
    - gateway: 10.225.108.1

salt.states.drac.absent(name)
  Ensure a user does not exist on the Dell DRAC
  name: The users username

salt.states.drac.network(ip, netmask, gateway)
  Ensure the DRAC network settings are consistent

salt.states.drac.present(name, password, permission)
  Ensure the user exists on the Dell DRAC
  name: The users username
  password: The password used to authenticate
  permission: The permissions that should be assigned to a user

31.27.45 salt.states.elasticsearch_index

State module to manage Elasticsearch indices
New in version 2015.8.0.

salt.states.elasticsearch_index.absent(name)
  Ensure that the named index is absent

salt.states.elasticsearch_index.present(name, definition)
  Ensure that the named index is present

31.27.46 salt.states.elasticsearch_index_template

State module to manage Elasticsearch index templates
New in version 2015.8.0.

salt.states.elasticsearch_index_template.absent(name)
  Ensure that the named index template is absent

salt.states.elasticsearch_index_template.present(name, definition=None)
  Ensure that the named index template is present

31.27.47 salt.states.environ

Support for getting and setting the environment variables of the current salt process.

salt.states.environ.setenv(name, value, false_unsets=False, clear_all=False, update_minion=False)
  Set the salt process environment variables.
  name: The environment key to set. Must be a string.
  value: Either a string or dict. When string, it will be the value set for the environment key of `name` above.
    When a dict, each key/value pair represents an environment variable to set.
false_unsets If a key's value is False and false_unsets is True, then the key will be removed from the salt processes environment dict entirely. If a key's value is False and false_unsets is not True, then the key's value will be set to an empty string. Default: False

clear_all USE WITH CAUTION! This option can unset environment variables needed for salt to function properly. If clear_all is True, then any environment variables not defined in the environ dict will be deleted. Default: False

update_minion If True, apply these environ changes to the main salt-minion process. If False, the environ changes will only affect the current salt subprocess. Default: False

Example:

```python
a_string_env:
environ.setenv:
  - name: foo
  - value: bar
  - update_minion: True

a_dict_env:
environ.setenv:
  - name: does_not_matter
  - value:
    foo: bar
    baz: quux
```

31.27.48 salt.states.eselect

Management of Gentoo configuration using eeselect

A state module to manage Gentoo configuration via eeselect

```yaml
profile:
  eselect.set:
    target: hardened/linux/amd64

salt.states.eselect.set(name, target, module_parameter=None, action_parameter=None)
  Verify that the given module is set to the given target

name  The name of the module
target The target to be set for this module
module_parameter additional params passed to the defined module
action_parameter additional params passed to the defined action
```

31.27.49 salt.states.etcd_mod

Manage etcd Keys

New in version 2015.8.0.

```yaml
defends
  - python-etcd
```

This state module supports setting and removing keys from etcd.
Salt Master Configuration

To work with an etcd server you must configure an etcd profile in the Salt Master configuration, for example:

You can also configure etcd without a profile however it is recommended that you use profiles:

Available Functions

- **set**
  This will set a value to a key in etcd. Changes will be returned if the key has been created or the value of the key has been updated. This means you can watch these states for changes.

- **wait_set**
  Performs the same functionality as `set` but only if a watch requisite is True.

```
/some/file.txt:
  file.managed:
    - source: salt://file.txt

/foo/bar/baz:
  etcd.wait_set:
    - value: foo
    - profile: my_etcd_config
    - watch:
      - file: /some/file.txt
```

- **rm**
  This will delete a key from etcd. If the key exists then changes will be returned and thus you can watch for changes on the state, if the key does not exist then no changes will occur.

- **wait_rm**
  Performs the same functionality as `rm` but only if a watch requisite is True.

```
/some/file.txt:
  file.managed:
    - source: salt://file.txt

/foo/bar/baz:
  etcd.wait_rm:
    - profile: my_etcd_config
    - watch:
      - file: /some/file.txt
```

**salt.states.etcd_mod.mod_watch(name, **kwargs)**
Execute an etcd function based on a watch call requisite.

**salt.states.etcd_mod.rm(name, recurse=False, profile=None)**
Deletes a key from etcd. This function is also aliased as `rm`.

- **name** The etcd key name to remove, for example `/foo/bar/baz`.
- **requeue** Optional, defaults to `False`. If `True` performs a recursive delete.
- **profile** Optional, defaults to `None`. Sets the etcd profile to use which has been defined in the Salt Master config.
salt.states.etcd_mod.set(name, value, profile=None)
Set a key in etcd and can be called as set.

name The etcd key name, for example: /foo/bar/baz.
value The value the key should contain.
profile Optional, defaults to None. Sets the etcd profile to use which has been defined in the Salt Master config.

salt.states.etcd_mod.wait_rm(name, recurse=False, profile=None)
Deletes a key from etcd only if the watch statement calls it. This function is also aliased as wait_rm.

name The etcd key name to remove, for example /foo/bar/baz.
recurse Optional, defaults to False. If True performs a recursive delete, see: https://python-etcd.readthedocs.org/en/latest/#delete-a-key.
profile Optional, defaults to None. Sets the etcd profile to use which has been defined in the Salt Master config.

salt.states.etcd_mod.wait_set(name, value, profile=None)
Set a key in etcd only if the watch statement calls it. This function is also aliased as wait_set.

name The etcd key name, for example: /foo/bar/baz.
value The value the key should contain.
profile The etcd profile to use that has been configured on the Salt Master, this is optional and defaults to None.

31.27.50 salt.states.event

Send events through Salt’s event system during state runs

salt.states.event.send(name, data=None, preload=None, with_env=False, with_grains=False, with_pillar=False, **kwargs)
Send an event to the Salt Master

New in version 2014.7.0.

Accepts the same arguments as the event.send execution module of the same name.

Example:

```
# ...snip bunch of states above

mycompany/mystaterun/status/update:
  event.send:
    - data:
      status: "Half-way through the state run!"

# ...snip bunch of states below
```

salt.states.event.wait(name, sfun=None)
Fire an event on the Salt master event bus if called from a watch statement

New in version 2014.7.0.

Example:
# Stand up a new web server.
apache:
  pkg:
    - installed
    - name: httpd
  service:
    - running
    - enable: True
    - name: httpd

# Notify the load balancer to update the pool once Apache is running.
refresh_pool:
  event:
    - wait
    - name: mycompany/loadbalancer/pool/update
    - data:
      - new_web_server_ip: {{ grains['ipv4'] | first() }}
  watch:
    - pkg: apache

31.27.51 salt.states.file

Operations on regular files, special files, directories, and symlinks

Salt States can aggressively manipulate files on a system. There are a number of ways in which files can be managed. Regular files can be enforced with the file.managed state. This state downloads files from the salt master and places them on the target system. Managed files can be rendered as a jinja, mako, or wempy template, adding a dynamic component to file management. An example of file.managed which makes use of the jinja templating system would look like this:

/etc/http/conf/http.conf:
    file.managed:
        - source: salt://apache/http.conf
        - user: root
        - group: root
        - mode: 644
        - template: jinja
        - defaults:
            - custom_var: "default value"
            - other_var: 123
{% if grains['os'] == 'Ubuntu' %}
        - context:
            - custom_var: "override"
{% endif %}

It is also possible to use the py renderer as a templating option. The template would be a Python script which would need to contain a function called run(), which returns a string. All arguments to the state will be made available to the Python script as globals. The returned string will be the contents of the managed file. For example:

def run():
    lines = ['foo', 'bar', 'baz']
    lines.extend([source, name, user, context])  # Arguments as globals
    return '

'.join(lines)

Note: The defaults and context arguments require extra indentation (four spaces instead of the normal two)
in order to create a nested dictionary. More information.

If using a template, any user-defined template variables in the file defined in source must be passed in using the defaults and/or context arguments. The general best practice is to place default values in defaults, with conditional overrides going into context, as seen above.

The template will receive a variable custom_var, which would be accessed in the template using {{ custom_var }}. If the operating system is Ubuntu, the value of the variable custom_var would be override, otherwise it is the default default value.

The source parameter can be specified as a list. If this is done, then the first file to be matched will be the one that is used. This allows you to have a default file on which to fall back if the desired file does not exist on the salt fileserver. Here’s an example:

```yaml
/etc/foo.conf:
  file.managed:
    - source:
      - salt://foo.conf{{ grains['fqdn'] }}
      - salt://foo.conf.fallback
      - user: foo
      - group: users
      - mode: 644
      - backup: minion
```

Note: Salt supports backing up managed files via the backup option. For more details on this functionality please review the backup_mode documentation.

The source parameter can also specify a file in another Salt environment. In this example foo.conf in the dev environment will be used instead.

```yaml
/etc/foo.conf:
  file.managed:
    - source:
      - salt://foo.conf?saltenv=dev
      - user: foo
      - group: users
      - mode: 0644
```

Warning: When using a mode that includes a leading zero you must wrap the value in single quotes. If the value is not wrapped in quotes it will be read by YAML as an integer and evaluated as an octal.

Special files can be managed via the mknod function. This function will create and enforce the permissions on a special file. The function supports the creation of character devices, block devices, and fifo pipes. The function will create the directory structure up to the special file if it is needed on the minion. The function will not overwrite or operate on (change major/minor numbers) existing special files with the exception of user, group, and permissions. In most cases the creation of some special files require root permissions on the minion. This would require that the minion to be run as the root user. Here is an example of a character device:

```yaml
/var/named/chroot/dev/random:
  file.mknod:
    - ntype: c
    - major: 1
    - minor: 8
    - user: named
    - group: named
    - mode: 660
```
Here is an example of a block device:

```
/var/named/chroot/dev/loop0:
  file.mknod:
    - ntype: b
    - major: 7
    - minor: 0
    - user: named
    - group: named
    - mode: 660
```

Here is an example of a fifo pipe:

```
/var/named/chroot/var/log/logfifo:
  file.mknod:
    - ntype: p
    - user: named
    - group: named
    - mode: 660
```

Directories can be managed via the `directory` function. This function can create and enforce the permissions on a directory. A directory statement will look like this:

```
/srv/stuff/substuff:
  file.directory:
    - user: fred
    - group: users
    - mode: 755
    - makedirs: True
```

If you need to enforce user and/or group ownership or permissions recursively on the directory's contents, you can do so by adding a `recurse` directive:

```
/srv/stuff/substuff:
  file.directory:
    - user: fred
    - group: users
    - mode: 755
    - makedirs: True
    - recurse:
      - user
      - group
      - mode
```

As a default, `mode` will resolve to `dir_mode` and `file_mode`, to specify both directory and file permissions, use this form:

```
/srv/stuff/substuff:
  file.directory:
    - user: fred
    - group: users
    - file_mode: 744
    - dir_mode: 755
    - makedirs: True
    - recurse:
      - user
      - group
      - mode
```

Symlinks can be easily created; the symlink function is very simple and only takes a few arguments:
Recursive directory management can also be set via the `recurse` function. Recursive directory management allows for a directory on the salt master to be recursively copied down to the minion. This is a great tool for deploying large code and configuration systems. A state using `recurse` would look something like this:

```
/etc/grub.conf:
  file.symlink:
    - target: /boot/grub/grub.conf

A more complex `recurse` example:

```{%
{% set site_user = 'testuser' %}
{% set site_name = 'test_site' %}
{% set project_name = 'test_proj' %}
{% set sites_dir = 'test_dir' %}

django-project:
  file.recurse:
    - name: {{ sites_dir }}/{{ site_name }}/{{ project_name }}
    - user: {{ site_user }}
    - dir_mode: 2775
    - file_mode: '0644'
    - template: jinja
    - source: salt://project/templates_dir
    - include_empty: True
```

salt.states.file.absent(name)

Make sure that the named file or directory is absent. If it exists, it will be deleted. This will work to reverse any of the functions in the file state module.

name The path which should be deleted

salt.states.file.accumulated(name, filename, text, **kwargs)

Prepare accumulator which can be used in template in file.managed state. Accumulator dictionary becomes available in template. It can also be used in file.blockreplace.

name Accumulator name
filename Filename which would receive this accumulator (see file.managed state documentation about name)
text String or list for adding in accumulator
require_in / watch_in One of them required for sure we fill up accumulator before we manage the file. Probably the same as filename

Example:

Given the following:

```animals_doing_things:
  file.accumulated:
    - filename: /tmp/animal_file.txt
    - text: 'jumps over the lazy dog.'
    - require_in:
      - file: animal_file

animal_file:
```
file.managed:
- name: /tmp/animal_file.txt
- source: salt://animal_file.txt
- template: jinja

One might write a template for animal_file.txt like the following:

The quick brown fox{% for animal in accumulator['animals_doing_things'] %}{{ animal }}{% endfor %}

Collectively, the above states and template file will produce:

The quick brown fox jumps over the lazy dog.

Multiple accumulators can be `chained` together.

Note: The `accumulator` data structure is a Python dictionary. Do not expect any loop over the keys in a deterministic order!

salt.states.file.append(name, text=None, makedirs=False, source=None, source_hash=None, template='jinja', sources=None, source_hashes=None, defaults=None, context=None)

Ensure that some text appears at the end of a file.

The text will not be appended if it already exists in the file. A single string of text or a list of strings may be appended.

name The location of the file to append to.

text The text to be appended, which can be a single string or a list of strings.

makedirs If the file is located in a path without a parent directory, then the state will fail. If makedirs is set to True, then the parent directories will be created to facilitate the creation of the named file. Defaults to False.

source A single source file to append. This source file can be hosted on either the salt master server, or on an HTTP or FTP server. Both HTTPS and HTTP are supported as well as downloading directly from Amazon S3 compatible URLs with both pre-configured and automatic IAM credentials (see s3.get state documentation). File retrieval from Openstack Swift object storage is supported via swift://container/object_path URLs (see swift.get documentation).

For files hosted on the salt file server, if the file is located on the master in the directory named spam, and is called eggs, the source string is salt://spam/eggs.

If the file is hosted on an HTTP or FTP server, the source_hash argument is also required.

source_hash

This can be one of the following:

1. a source hash string
2. the URI of a file that contains source hash strings

The function accepts the first encountered long unbroken alphanumeric string of correct length as a valid hash, in order from most secure to least secure:

<table>
<thead>
<tr>
<th>Type</th>
<th>Length</th>
</tr>
</thead>
<tbody>
<tr>
<td>sha512</td>
<td>128</td>
</tr>
<tr>
<td>sha384</td>
<td>96</td>
</tr>
<tr>
<td>sha256</td>
<td>64</td>
</tr>
</tbody>
</table>
The file can contain several checksums for several files. Each line must contain both the file name and the hash. If no file name is matched, the first hash encountered will be used, otherwise the most secure hash with the correct source file name will be used.

Debian file type *.dsc is supported.

Examples:

```
/etc/rc.conf ef6e82e4006dee563d98ada2a2a80a27
sha254c8525aee419eb649f0233be91c151178b30f0dff8ebbdcc8de71b1d5c8bcc06a /etc/resolv.conf
```

**Known issues:** If the remote server URL has the hash file as an apparent sub-directory of the source file, the module will discover that it has already cached a directory where a file should be cached. For example:

```
tomdroid-src-0.7.3.tar.gz:
  file.managed:
    - name: /tmp/tomdroid-src-0.7.3.tar.gz
    - source: https://launchpad.net/tomdroid/beta/0.7.3/+download/tomdroid-src-0.7.3.tar.gz
    - source_hash: https://launchpad.net/tomdroid/beta/0.7.3/+download/tomdroid-src-0.7.3.tar.gz/+md5
```

**template** [jinja] The named templating engine will be used to render the appended-to file. Defaults to jinja.

**sources** A list of source files to append. If the files are hosted on an HTTP or FTP server, the source_hashes argument is also required.

**source_hashes** A list of source_hashes corresponding to the sources list specified in the sources argument.

**defaults** Default context passed to the template.

**context** Overrides default context variables passed to the template.

Multi-line example:

```
/etc/motd:
  file.append:
    - text: |
      Thou hadst better eat salt with the Philosophers of Greece,
      than sugar with the Courtiers of Italy.
      - Benjamin Franklin
```

Multiple lines of text:

```
/etc/motd:
  file.append:
    - text:
      - Trust no one unless you have eaten much salt with him.
      - "Salt is born of the purest of parents: the sun and the sea."
```

Gather text from multiple template files:

```
/etc/motd:
  file:
    - append
    - template: jinja
```
- sources:
  - salt://motd/devops-messages.tmpl
  - salt://motd/hr-messages.tmpl
  - salt://motd/general-messages.tmpl

New in version 0.9.5.

salt.states.file.blockreplace(name, marker_start='#-- start managed zone --', marker_end='##-- end managed zone --', source=None, source_hash=None, template='jinja', sources=None, source_hashes=None, defaults=None, context=None, content='``', append_if_not_found=False, prepend_if_not_found=False, backup='.bak', show_changes=True)

Maintain an edit in a file in a zone delimited by two line markers

New in version 2014.1.0.

A block of content delimited by comments can help you manage several lines entries without worrying about old entries removal. This can help you maintaining an un-managed file containing manual edits. Note: this function will store two copies of the file in-memory (the original version and the edited version) in order to detect changes and only edit the targeted file if necessary.

**name**  Filesystem path to the file to be edited

**marker_start** The line content identifying a line as the start of the content block. Note that the whole line containing this marker will be considered, so whitespace or extra content before or after the marker is included in final output

**marker_end** The line content identifying a line as the end of the content block. Note that the whole line containing this marker will be considered, so whitespace or extra content before or after the marker is included in final output. Note: you can use file.accumulated and target this state. All accumulated data dictionaries content will be added as new lines in the content

**content** The content to be used between the two lines identified by marker_start and marker_end

**source** The source file to download to the minion, this source file can be hosted on either the salt master server, or on an HTTP or FTP server. Both HTTPS and HTTP are supported as well as downloading directly from Amazon S3 compatible URLs with both pre-configured and automatic IAM credentials. (see s3.get state documentation) File retrieval from Openstack Swift object storage is supported via swift://container/object_path URLs, see swift.get documentation. For files hosted on the salt file server, if the file is located on the master in the directory named spam, and is called eggs, the source string is salt://spam/eggs. If source is left blank or None (use ~ in YAML), the file will be created as an empty file and the content will not be managed

If the file is hosted on a HTTP or FTP server then the source_hash argument is also required

A list of sources can also be passed in to provide a default source and a set of fallbacks. The first source in the list that is found to exist will be used and subsequent entries in the list will be ignored.

**source_hash**

This can be one of the following:

1. a source hash string
2. the URI of a file that contains source hash strings
The function accepts the first encountered long unbroken alphanumeric string of correct length as a valid hash, in order from most secure to least secure:

<table>
<thead>
<tr>
<th>Type</th>
<th>Length</th>
</tr>
</thead>
<tbody>
<tr>
<td>sha512</td>
<td>128</td>
</tr>
<tr>
<td>sha384</td>
<td>96</td>
</tr>
<tr>
<td>sha256</td>
<td>64</td>
</tr>
<tr>
<td>sha224</td>
<td>56</td>
</tr>
<tr>
<td>sha1</td>
<td>40</td>
</tr>
<tr>
<td>md5</td>
<td>32</td>
</tr>
</tbody>
</table>

Using a Source Hash File  The file can contain several checksums for several files. Each line must contain both the file name and the hash. If no file name is matched, the first hash encountered will be used, otherwise the most secure hash with the correct source file name will be used.

When using a source hash file the source_hash argument needs to be a url, the standard download urls are supported, ftp, http, salt etc:

Example:

tomdroid-src-0.7.3.tar.gz:

```yaml
file.managed:
  - name: /tmp/tomdroid-src-0.7.3.tar.gz
  - source: https://launchpad.net/tomdroid/beta/0.7.3/+download/tomdroid-src-0.7.3.tar.gz
  - source_hash: https://launchpad.net/tomdroid/beta/0.7.3/+download/tomdroid-src-0.7.3.hash
```

The following is an example of the supported source_hash format:

```
/etc/rc.conf ef6e82e4006dee563d98ada2a2a80a27
sha254c8525aee419eb649f0233be91c151178b30f0dff8ebbdcc8de71b1d5c8bcc06a /etc/resolv.conf
ead48423703509d37c4a90e6a0d53e1e43b6fc268
```

Debian file type *.dsc files are also supported.

Inserting the Source Hash in the sls Data  Examples:

```
tomdroid-src-0.7.3.tar.gz:

file.managed:
  - name: /tmp/tomdroid-src-0.7.3.tar.gz
  - source: https://launchpad.net/tomdroid/beta/0.7.3/+download/tomdroid-src-0.7.3.tar.gz
  - source_hash: md5=79eef25f9b0b2c642c62b7f737d4f53f
```

- **template**  If this setting is applied then the named templating engine will be used to render the downloaded file, currently jinja, mako, and wempy are supported

- **context**  Overrides default context variables passed to the template.

- **defaults**  Default context passed to the template.

- **append_if_not_found**  If markers are not found and set to True then the markers and content will be appended to the file. Default is False

- **prepend_if_not_found**  If markers are not found and set to True then the markers and content will be prepended to the file. Default is False

- **backup**  The file extension to use for a backup of the file if any edit is made. Set this to False to skip making a backup.

- **dry_run**  Don’t make any edits to the file
show_changes  Output a unified diff of the old file and the new file. If False return a boolean if any changes were made.

Example of usage with an accumulator and with a variable:

```python
{% set myvar = 42 %}
hosts-config-block-{{ myvar }}:
    file.blockreplace:
    - name: /etc/hosts
    - marker_start: "# START managed zone {{ myvar }} -DO-NOT-EDIT-
    - marker_end: "# END managed zone {{ myvar }} --"
    - content: 'First line of content'
    - append_if_not_found: True
    - backup: '.bak'
    - show_changes: True

hosts-config-block-{{ myvar }}-accumulated1:
    file.accumulated:
    - filename: /etc/hosts
    - name: my-accumulator-{{ myvar }}
    - text: "text 2"
    - require_in:
        - file: hosts-config-block-{{ myvar }}

hosts-config-block-{{ myvar }}-accumulated2:
    file.accumulated:
    - filename: /etc/hosts
    - name: my-accumulator-{{ myvar }}
    - text: |
        text 3
        text 4
    - require_in:
        - file: hosts-config-block-{{ myvar }}
```

will generate and maintain a block of content in /etc/hosts:

```
# START managed zone 42 -DO-NOT-EDIT-
First line of content
text 2
text 3
text 4
# END managed zone 42 --
```

salt.states.file.comment(name, regex, char='#', backup='.bak')

Comment out specified lines in a file.

name  The full path to the file to be edited
regex A regular expression used to find the lines that are to be commented; this pattern will be wrapped in parenthesis and will move any preceding/trailing ^ or $ characters outside the parenthesis (e.g., the pattern ^foo$ will be rewritten as ^\(foo\)$) Note that you _need_ the leading ^, otherwise each time you run highstate, another comment char will be inserted.
char  [#] The character to be inserted at the beginning of a line in order to comment it out
backup  [.bak] The file will be backed up before edit with this file extension

**Warning:** This backup will be overwritten each time sed / comment / uncomment is called. Meaning the backup will only be useful after the first invocation.
Usage:

```
/etc/fstab:
file.comment:
    - regex: ^bind 127.0.0.1
```

New in version 0.9.5.

```python
salt.states.file.copy(name, source, force=False, makedirs=False, preserve=False, user=None, group=None, mode=None, subdir=False, **kwargs)
```

If the source file exists on the system, copy it to the named file. The named file will not be overwritten if it already exists unless the force option is set to True.

- **name**  The location of the file to copy to
- **source**  The location of the file to copy to the location specified with name
- **force**  If the target location is present then the file will not be moved, specify ``force: True`` to overwrite the target file
- **makedirs**  If the target subdirectories don’t exist create them
- **preserve**  New in version 2015.5.0.
  - Set preserve: True to preserve user/group ownership and mode after copying. Default is False. If preserve is set to True, then user/group/mode attributes will be ignored.
- **user**  New in version 2015.5.0.
  - The user to own the copied file, this defaults to the user salt is running as on the minion. If preserve is set to True, then this will be ignored
- **group**  New in version 2015.5.0.
  - The group to own the copied file, this defaults to the group salt is running as on the minion. If preserve is set to True or on Windows this will be ignored
- **mode**  New in version 2015.5.0.
  - The permissions to set on the copied file, aka 644, `0775`, `'4664`. If preserve is set to True, then this will be ignored. Not supported on Windows
- **subdir**  New in version 2015.5.0.
  - If the name is a directory then place the file inside the named directory

```python
salt.states.file.directory(name, user=None, group=None, recurse=None, dir_mode=None, file_mode=None, makedirs=False, clean=False, require=None, exclude_pat=None, follow_symlinks=False, force=False, backup_name=None, allow_symlink=True, **kwargs)
```

Ensure that a named directory is present and has the right perms

- **name**  The location to create or manage a directory
- **user**  The user to own the directory; this defaults to the user salt is running as on the minion
- **group**  The group ownership set for the directory; this defaults to the group salt is running as on the minion. On Windows, this is ignored
- **recurse**  Enforce user/group ownership and mode of directory recursively. Accepts a list of strings representing what you would like to recurse. If mode is defined, will recurse on both file_mode and dir_mode if they are defined. If ignore_files or ignore_dirs is included, files or directories will be left unchanged respectively. Example:
Leave files or directories unchanged:

```
/var/log/httpd:
  file.directory:
  - user: root
  - group: root
  - dir_mode: 755
  - file_mode: 644
  - recurse:
    - user
    - group
    - mode
```

New in version 2015.5.0.

**dir_mode / mode** The permissions mode to set any directories created. Not supported on Windows

**file_mode** The permissions mode to set any files created if `mode` is run in `recurse`. This defaults to dir_mode. Not supported on Windows

**mkdirs** If the directory is located in a path without a parent directory, then the state will fail. If mkdirs is set to True, then the parent directories will be created to facilitate the creation of the named file.

**clean** Make sure that only files that are set up by salt and required by this function are kept. If this option is set then everything in this directory will be deleted unless it is required.

**require** Require other resources such as packages or files

**exclude_pat** When `clean` is set to True, exclude this pattern from removal list and preserve in the destination.

**follow_symlinks** [False] If the desired path is a symlink (or recurse is defined and a symlink is encountered while recursing), follow it and check the permissions of the directory/file to which the symlink points.

New in version 2014.1.4.

**force** If the name of the directory exists and is not a directory and force is set to False, the state will fail. If force is set to True, the file in the way of the directory will be deleted to make room for the directory,
unless backupname is set, then it will be renamed.

New in version 2014.7.0.

**backupname** If the name of the directory exists and is not a directory, it will be renamed to the backupname.
If the backupname already exists and force is False, the state will fail. Otherwise, the backupname will be removed first.

New in version 2014.7.0.

**allow_symlink** [True] If allow_symlink is True and the specified path is a symlink, it will be allowed to remain if it points to a directory. If allow_symlink is False then the state will fail, unless force is also set to True, in which case it will be removed or renamed, depending on the value of the backupname argument.

New in version 2014.7.0.

**salt.states.file.exists(name)**
Verify that the named file or directory is present or exists. Ensures pre-requisites outside of Salt’s purview (e.g., keytabs, private keys, etc.) have been previously satisfied before deployment.

**name** Absolute path which must exist

**salt.states.file.line(name, content, match=None, mode=None, location=None, before=None, after=None, show_changes=True, backup=False, quiet=False, indent=True)**
Line-based editing of a file.

New in version 2015.8.0.

Params are identical to the remote execution function **file.line**.

**salt.states.file.managed(name, source=None, source_hash='`, user=None, group=None, mode=None, template=None, makedirs=False, dir_mode=None, context=None, replace=True, defaults=None, env=None, backup='`, show_diff=True, create=True, contents=None, contents_pillar=None, contents_grains=None, contents_newline=True, follow_symlinks=True, check_cmd=None, **kwargs)**
Manage a given file, this function allows for a file to be downloaded from the salt master and potentially run through a templating system.

**name** The location of the file to manage

**source** The source file to download to the minion, this source file can be hosted on either the salt master server, or on an HTTP or FTP server. Both HTTPS and HTTP are supported as well as downloading directly from Amazon S3 compatible URLs with both pre-configured and automatic IAM credentials. (see s3.get state documentation) File retrieval from Openstack Swift object storage is supported via swift://container/object_path URLs, see swift.get documentation. For files hosted on the salt file server, if the file is located on the master in the directory named spam, and is called eggs, the source string is salt://spam/eggs. If source is left blank or None (use ~ in YAML), the file will be created as an empty file and the content will not be managed

If the file is hosted on a HTTP or FTP server then the source_hash argument is also required

A list of sources can also be passed in to provide a default source and a set of fallbacks. The first source in the list that is found to exist will be used and subsequent entries in the list will be ignored.

```yaml
file_override_example:
  file.managed:
    - source:
      - salt://file_that_does_not_exist
      - salt://file_that_exists
```

**source_hash**
This can be one of the following:

1. a source hash string
2. the URI of a file that contains source hash strings

The function accepts the first encountered long unbroken alphanumeric string of correct length as a valid hash, in order from most secure to least secure:

<table>
<thead>
<tr>
<th>Type</th>
<th>Length</th>
</tr>
</thead>
<tbody>
<tr>
<td>sha512</td>
<td>128</td>
</tr>
<tr>
<td>sha384</td>
<td>96</td>
</tr>
<tr>
<td>sha256</td>
<td>64</td>
</tr>
<tr>
<td>sha224</td>
<td>56</td>
</tr>
<tr>
<td>sha1</td>
<td>40</td>
</tr>
<tr>
<td>md5</td>
<td>32</td>
</tr>
</tbody>
</table>

Using a Source Hash File  The file can contain several checksums for several files. Each line must contain both the file name and the hash. If no file name is matched, the first hash encountered will be used, otherwise the most secure hash with the correct source file name will be used.

When using a source hash file the source_hash argument needs to be a url, the standard download urls are supported, ftp, http, salt etc:

Example:

```yaml
tomdroid-src-0.7.3.tar.gz:
  file.managed:
    - name: /tmp/tomdroid-src-0.7.3.tar.gz
    - source: https://launchpad.net/tomdroid/beta/0.7.3/+download/tomdroid-src-0.7.3.tar.gz
    - source_hash: https://launchpad.net/tomdroid/beta/0.7.3/+download/tomdroid-src-0.7.3.hash
```

The following is an example of the supported source_hash format:

```
/etc/rc.conf ef6e82e4006dee563d98ada2a2a80a27
sha254c8525aee419eb649f0233be91c151178b30f0dff8e8e6addcc8de71b1d5c8b06a /etc/resolv.conf
ea48423703509d37c4a90e6a0d53e143b6fc268
```

Debian file type *.dsc files are also supported.

Inserting the Source Hash in the sls Data  Examples:

```yaml
tomdroid-src-0.7.3.tar.gz:
  file.managed:
    - name: /tmp/tomdroid-src-0.7.3.tar.gz
    - source: https://launchpad.net/tomdroid/beta/0.7.3/+download/tomdroid-src-0.7.3.tar.gz
    - source_hash: md5=79eef25f9b0b2c642c62b7f737df53f
```

Known issues: If the remote server URL has the hash file as an apparent sub-directory of the source file, the module will discover that it has already cached a directory where a file should be cached. For example:

```yaml
tomdroid-src-0.7.3.tar.gz:
  file.managed:
    - name: /tmp/tomdroid-src-0.7.3.tar.gz
    - source: https://launchpad.net/tomdroid/beta/0.7.3/+download/tomdroid-src-0.7.3.tar.gz
    - source_hash: https://launchpad.net/tomdroid/beta/0.7.3/+download/tomdroid-src-0.7.3.hash
```

1724 Chapter 31. Reference
user  The user to own the file, this defaults to the user salt is running as on the minion

group  The group ownership set for the file, this defaults to the group salt is running as on the minion On Windows, this is ignored

mode  The permissions to set on this file, aka 644, 0775, 4664. Not supported on Windows

template  If this setting is applied then the named templating engine will be used to render the downloaded file, currently jinja, mako, and wempy are supported

makedirs  If the file is located in a path without a parent directory, then the state will fail. If makedirs is set to True, then the parent directories will be created to facilitate the creation of the named file.

dir_mode  If directories are to be created, passing this option specifies the permissions for those directories. If this is not set, directories will be assigned permissions from the `mode' argument.

replace  If this file should be replaced. If false, this command will not overwrite file contents but will enforce permissions if the file exists already. Default is True.

context  Overrides default context variables passed to the template.

defaults  Default context passed to the template.

backup  Overrides the default backup mode for this specific file.

show_diff  If set to False, the diff will not be shown.

create  Default is True, if create is set to False then the file will only be managed if the file already exists on the system.

contents  Default is None. If specified, will use the given string as the contents of the file. Should not be used in conjunction with a source file of any kind. Ignores hashes and does not use a templating engine.

contents_pillar  New in version 0.17.0.

Operates like contents, but draws from a value stored in pillar, using the pillar path syntax used in pillar.get. This is useful when the pillar value contains newlines, as referencing a pillar variable using a jinja/mako template can result in YAML formatting issues due to the newlines causing indentation mismatches.

For example, the following could be used to deploy an SSH private key:

```
/home/deployer/.ssh/id_rsa:
  file.managed:
    - user: deployer
    - group: deployer
    - mode: 600
    - contents_pillar: userdata:deployer:id_rsa
```

This would populate /home/deployer/.ssh/id_rsa with the contents of pillar['userdata']['deployer']['id_rsa']. An example of this pillar setup would be like so:

```
userdata:
  deployer:
    id_rsa: |
      -----BEGIN RSA PRIVATE KEY-----
      MIIEowIBAAKCAQEAoQiwQ3Jn87uP5aAQF9p1LZNXv1YMIswrMe2HcWVBgh+hY
      U7sCwa/dH6+vWnmqmoqMnP=8gTPKGl1vgA0bJAnMT623dMxjVknwEagZPRJ1x
      B/HaAre9EuNiV3L1zBtWRseMfT+rWxIKVbpwlGrgfaz70mQpx+UyFbAGLIn+
      GpxzZAmFp2w4s61lRuissX7j/sHpQb8p9M5e04Z3rjkCPlcxI
      -----END RSA PRIVATE KEY-----
```

31.27. Full list of builtin state modules 1725
**Note:** The private key above is shortened to keep the example brief, but shows how to do multiline string in YAML. The key is followed by a pipe character, and the multiline string is indented two more spaces.

**contents_grains** New in version 2014.7.0.

Same as contents_pillar, but with grains

**contents_newline** New in version 2014.7.0.

When using contents, contents_pillar, or contents_grains, this option ensures the file will have a newline at the end. When loading some data this newline is better left off. Setting contents_newline to False will omit this final newline.

**follow_symlinks** [True] New in version 2014.7.0.

If the desired path is a symlink follow it and make changes to the file to which the symlink points.

**check_cmd** New in version 2014.7.0.

The specified command will be run with the managed file as an argument. If the command exits with a nonzero exit code, the command will not be run.

**salt.states.file.missing(name)**

Verify that the named file or directory is missing, this returns True only if the named file is missing but does not remove the file if it is present.

**name** Absolute path which must NOT exist

**salt.states.file.mknod(name, ntype, major=0, minor=0, user=None, group=None, mode='0600')**

Create a special file similar to the `nix mknod command. The supported device types are p (fifo pipe), c (character device), and b (block device). Provide the major and minor numbers when specifying a character device or block device. A fifo pipe does not require this information. The command will create the necessary dirs if needed. If a file of the same name not of the same type/major/minor exists, it will not be overwritten or unlinked (deleted). This is logically in place as a safety measure because you can really shoot yourself in the foot here and it is the behavior of `nix mknod. It is also important to note that not just anyone can create special devices. Usually this is only done as root. If the state is executed as none other than root on a minion, you may receive a permission error.

**name** name of the file

**ntype** node type `p` (fifo pipe), `c` (character device), or `b` (block device)

**major** major number of the device does not apply to a fifo pipe

**minor** minor number of the device does not apply to a fifo pipe

**user** owning user of the device/pipe

**group** owning group of the device/pipe

**mode** permissions on the device/pipe

Usage:

```
/dev/chr:
  file.mknod:
    - ntype: c
    - major: 180
    - minor: 31
    - user: root
    - group: root
```
New in version 0.17.0.

`salt.states.file.mod_run_check_cmd(cmd, filename, **check_cmd_opts)`

Execute the check_cmd logic.

Return a result dict if check_cmd succeeds (check_cmd == 0) otherwise return True

`salt.states.file.patch(name, source=None, hash=None, options='`, dry_run_first=True, env=None, **kwargs)`

Apply a patch to a file.

**Note:** A suitable patch executable must be available on the minion when using this state function.

- **name** The file to with the patch will be applied.
- **source** The source patch to download to the minion, this source file must be hosted on the salt master server. If the file is located in the directory named spam, and is called eggs, the source string is `salt://spam/eggs`. A source is required.
- **hash** Hash of the patched file. If the hash of the target file matches this value then the patch is assumed to have been applied. The hash string is the hash algorithm followed by the hash of the file: `md5=e138491e9d5b97023cea823fe17bac22`
- **options** Extra options to pass to patch.
- **dry_run_first** `[True]` Run patch with `--dry-run` first to check if it will apply cleanly.
- **env** Specify the environment from which to retrieve the patch file indicated by the `source` parameter. If not provided, this defaults to the environment from which the state is being executed.

**Usage:**

```
# Equivalent to `\patch --forward /opt/file.txt file.patch`

/opt/file.txt:
  file.patch:
    - source: salt://file.patch
    - hash: md5=e138491e9d5b97023cea823fe17bac22
```

`salt.states.file.prepend(name, text=None, makedirs=False, source=None, source_hash=None, template='jinja', sources=None, source_hashes=None, defaults=None, context=None)`

Ensure that some text appears at the beginning of a file
The text will not be prepended again if it already exists in the file. You may specify a single line of text or a list of lines to append.

Multi-line example:

```
/etc/motd:
  file.prepend:
    - text:
        Thou hadst better eat salt with the Philosophers of Greece, 
        than sugar with the Courtiers of Italy.
        - Benjamin Franklin
```

Multiple lines of text:

```
/etc/motd:
  file.prepend:
    - text:
        Trust no one unless you have eaten much salt with him.
        - "Salt is born of the purest of parents: the sun and the sea."
```

Gather text from multiple template files:

```
/etc/motd:
  file:
    - prepend
    - template: jinja
    - sources:
        - salt://motd/devops-messages.tmpl
        - salt://motd/hr-messages.tmpl
        - salt://motd/general-messages.tmpl
```

New in version 2014.7.0.

```
salt.states.file.recurse(name, source, clean=False, require=None, user=None, group=None, dir_mode=None, file_mode=None, sym_mode=None, template=None, context=None, defaults=None, env=None, include_empty=False, **kwargs)
```

Recurse through a subdirectory on the master and copy said subdirectory over to the specified path.

- **name**  The directory to set the recursion in
- **source**  The source directory, this directory is located on the salt master file server and is specified with the salt:// protocol. If the directory is located on the master in the directory named spam, and is called eggs, the source string is salt://spam/eggs
- **clean**  Make sure that only files that are set up by salt and required by this function are kept. If this option is set then everything in this directory will be deleted unless it is required.
- **require**  Require other resources such as packages or files
- **user**  The user to own the directory. This defaults to the user salt is running as on the minion
- **group**  The group ownership set for the directory. This defaults to the group salt is running as on the minion. On Windows, this is ignored
- **dir_mode**  The permissions mode to set on any directories created. Not supported on Windows
- **file_mode**  The permissions mode to set on any files created. Not supported on Windows
- **sym_mode**  The permissions mode to set on any symlink created. Not supported on Windows
**template** If this setting is applied then the named templating engine will be used to render the downloaded file. Supported templates are: *jinja, mako* and *wempy*.

**Note:** The template option is required when recursively applying templates.

**context** Overrides default context variables passed to the template.

**defaults** Default context passed to the template.

**include_empty** Set this to True if empty directories should also be created (default is False)

**include_pat** When copying, include only this pattern from the source. Default is glob match; if prefixed with 'E@', then regexp match. Example:

- include_pat: hello* :: glob matches 'hello01', 'hello02'  
  ... but not 'otherhello'
- include_pat: E@hello :: regexp matches 'otherhello',  
  'hello01' ...

**exclude_pat** Exclude this pattern from the source when copying. If both *include_pat* and *exclude_pat* are supplied, then it will apply conditions cumulatively. i.e. first select based on include_pat, and then within that result apply exclude_pat.

Also, when `clean=True`, exclude this pattern from the removal list and preserve in the destination. Example:

- exclude_pat: APPDATA* :: glob matches APPDATA.01,  
  APPDATA.02,.. for exclusion
- exclude_pat: E@(APPDATA)|(TEMPDATA) :: regexp matches APPDATA  
  or TEMPDATA for exclusion

**maxdepth** When copying, only copy paths which are of depth *maxdepth* from the source path. Example:

- maxdepth: 0 :: Only include files located in the source directory
- maxdepth: 1 :: Only include files located in the source directory  
  or immediate subdirectories

**keep_symlinks** Keep symlinks when copying from the source. This option will cause the copy operation to terminate at the symlink. If desire behavior similar to rsync, then set this to True.

**force_symlinks** Force symlink creation. This option will force the symlink creation. If a file or directory is obstructing symlink creation it will be recursively removed so that symlink creation can proceed. This option is usually not needed except in special circumstances.

**salt.states.file.rename(name, source, force=False, makedirs=False)**

If the source file exists on the system, rename it to the named file. The named file will not be overwritten if it already exists unless the force option is set to True.

**name** The location of the file to rename to

**source** The location of the file to move to the location specified with name

**force** If the target location is present then the file will not be moved, specify `force: True` to overwrite the target file

**makedirs** If the target subdirectories don’t exist create them
salt.states.file.replace(name, pattern, repl, count=0, flags=0, bufsize=1, append_if_not_found=False, prepend_if_not_found=False, not_found_content=None, backup='.bak', show_changes=True)

Maintain an edit in a file.

New in version 0.17.0.

**name**  Filesystem path to the file to be edited.

**pattern**  Python's regular expression search.

**repl**  The replacement text.

**count**  Maximum number of pattern occurrences to be replaced.

**flags**  A list of flags defined in the `re` module documentation. Each list item should be a string that will correlate to the human-friendly flag name. E.g., ['IGNORECASE', 'MULTILINE']. Note: multiline searches must specify `file` as the `bufsize` argument below. Defaults to 0 and can be a list or an int.

**bufsize**  How much of the file to buffer into memory at once. The default value 1 processes one line at a time. The special value `file` may be specified which will read the entire file into memory before processing. Note: multiline searches must specify `file` buffering. Can be an int or a str.

**append_if_not_found**  If pattern is not found and set to `True` then, the content will be appended to the file.

New in version 2014.7.0.

**prepend_if_not_found**  If pattern is not found and set to `True` then, the content will be prepended to the file.

New in version 2014.7.0.

**not_found_content**  Content to use for append/prepend if not found. If `None` (default), uses `repl`. Useful when `repl` uses references to group in pattern.

New in version 2014.7.0.

**backup**  The file extension to use for a backup of the file before editing. Set to `False` to skip making a backup.

**show_changes**  Output a unified diff of the old file and the new file. If `False` return a boolean if any changes were made. Returns a boolean or a string.

For complex regex patterns it can be useful to avoid the need for complex quoting and escape sequences by making use of YAML's multiline string syntax.

```yaml
complex_search_and_replace:
  file.replace:  # <...snip...>
    - pattern: |
        CentOS \(2.6.32[^\n]+\n\s+root[^\n]+\)+
```

**Note:**  When using YAML multiline string syntax in `pattern`, make sure to also use that syntax in the `repl` part, or you might lose line feeds.

salt.states.file.serialize(name, dataset=None, dataset_pillar=None, user=None, group=None, mode=None, env=None, backup='', makedirs=False, show_diff=True, create=True, merge_if_exists=False, **kwargs)

Serializes dataset and store it into managed file. Useful for sharing simple configuration files.

**name**  The location of the file to create

**dataset**  The dataset that will be serialized

**dataset_pillar**  Operates like `dataset`, but draws from a value stored in pillar, using the pillar path syntax used in `pillar.get`. This is useful when the pillar value contains newlines, as referencing a pillar
variable using a jinja/mako template can result in YAML formatting issues due to the newlines causing indentation mismatches.

New in version FIXME.

**formatter** Write the data as this format. Supported output formats:

- JSON
- YAML
- Python (via pprint.pformat)

**user** The user to own the directory, this defaults to the user salt is running as on the minion

**group** The group ownership set for the directory, this defaults to the group salt is running as on the minion

**mode** The permissions to set on this file, aka 644, 0775, 4664

**backup** Overrides the default backup mode for this specific file.

**makedirs** Create parent directories for destination file.

New in version 2014.1.3.

**show_diff** If set to False, the diff will not be shown.

**create** Default is True, if create is set to False then the file will only be managed if the file already exists on the system.

**merge_if_exists** Default is False, if merge_if_exists is True then the existing file will be parsed and the dataset passed in will be merged with the existing content.

New in version 2014.7.0.

For example, this state:

```yaml
/etc/dummy/package.json:
  file.serialize:
    - dataset:
        name: naive
        description: A package using naive versioning
        author: A confused individual <iam@confused.com>
        dependencies:
          express: &gt;= 1.2.0
          optimist: &gt;= 0.1.0
          engine: node 0.4.1
        - formatter: json
```

will manage the file `/etc/dummy/package.json:

```yaml
{
    "author": "A confused individual <iam@confused.com>",
    "dependencies": {
      "express": ">= 1.2.0",
      "optimist": ">= 0.1.0"
    },
    "description": "A package using naive versioning",
    "engine": "node 0.4.1",
    "name": "naive"
}
```

salt.states.file.symlink(name, target, force=False, backupname=None, makedirs=False, user=None, group=None, mode=None, **kwargs)

Create a symlink
If the file already exists and is a symlink pointing to any location other than the specified target, the symlink will be replaced. If the symlink is a regular file or directory then the state will return False. If the regular file or directory is desired to be replaced with a symlink pass force: True, if it is to be renamed, pass a backupname.

**name**  The location of the symlink to create

**target**  The location that the symlink points to

**force**  If the name of the symlink exists and is not a symlink and force is set to False, the state will fail. If force is set to True, the file or directory in the way of the symlink file will be deleted to make room for the symlink, unless backupname is set, when it will be renamed

**backupname**  If the name of the symlink exists and is not a symlink, it will be renamed to the backupname. If the backupname already exists and force is False, the state will fail. Otherwise, the backupname will be removed first.

**makedirs**  If the location of the symlink does not already have a parent directory then the state will fail, setting makedirs to True will allow Salt to create the parent directory

**user**  The user to own the file, this defaults to the user salt is running as on the minion

**group**  The group ownership set for the file, this defaults to the group salt is running as on the minion. On Windows, this is ignored

**mode**  The permissions to set on this file, aka 644, 0775, 4664. Not supported on Windows

```
salt.states.file.touch(name, atime=None, mtime=None, makedirs=False)
```

Replicate the `nix``touch'' command to create a new empty file or update the atime and mtime of an existing file.

Note that if you just want to create a file and don't care about atime or mtime, you should use file.managed instead, as it is more feature-complete. (Just leave out the source/template/contents arguments, and it will just create the file and/or check its permissions, without messing with contents)

**name**  name of the file

**atime**  atime of the file

**mtime**  mtime of the file

**makedirs**  whether we should create the parent directory/directories in order to touch the file

Usage:

```
/var/log/httpd/logrotate.empty:
  file.touch
```

New in version 0.9.5.

```
salt.states.file.uncomment(name, regex, char='#', backup='.bak')
```

Uncomment specified commented lines in a file

**name**  The full path to the file to be edited

**regex**  A regular expression used to find the lines that are to be uncommented. This regex should not include the comment character. A leading ^ character will be stripped for convenience (for easily switching between comment() and uncomment()). The regex will be searched for from the beginning of the line, ignoring leading spaces (we prepend "^[ t]"")

**char**  [#] The character to remove in order to uncomment a line

**backup**  [.bak] The file will be backed up before edit with this file extension;
Warning: This backup will be overwritten each time `sed / comment / uncomment` is called. Meaning the backup will only be useful after the first invocation.

Usage:
```
/etc/adduser.conf:
  file.uncomment:
    - regex: EXTRA_GROUPS
```

New in version 0.9.5.

### 31.27.52 salt.states.firewalld

Management of firewalld

New in version 2015.8.0.

The following example applies changes to the public zone, blocks echo-reply and echo-request packets, does not set the zone to be the default, enables masquerading, and allows ports 22/tcp and 25/tcp.

```
public:
  - name: public
  - block_icmp
    - echo-reply
    - echo-request
  - default: False
  - masquerade: True
  - ports:
    - 22/tcp
    - 25/tcp
```

The following example applies changes to the public zone, enables masquerading and configures port forwarding TCP traffic from port 22 to 2222, and forwards TCP traffic from port 80 to 443 at 192.168.0.1.

```
my_zone:
  firewalld.present:
    - name: public
    - masquerade: True
    - port_fwd:
      - 22:2222:tcp
      - 80:443:tcp:192.168.0.1
```

```
salt.states.firewalld.present(name, block_icmp=None, default=None, masquerade=False, ports=None, port_fwd=None, services=None)
```

Ensure a zone has specific attributes

### 31.27.53 salt.states.gem

Installation of Ruby modules packaged as gems

A state module to manage rubygems. Gems can be set up to be installed or removed. This module will use RVM or rbenv if they are installed. In that case, you can specify what ruby version and gemset to target.

```
addressable:
  gem.installed:
```

31.27. Full list of builtin state modules
salt.states.gem.\texttt{installed}(name, \ruby=None, \gem_bin=None, user=None, version=None, rdoc=False, ri=False, pre_releases=False, proxy=None)

Make sure that a gem is installed.

name The name of the gem to install

ruby: \texttt{None} Only for RVM or rbenv installations: the ruby version and gemset to target.

gem_bin: \texttt{None} Custom \texttt{gem} command to run instead of the default. Use this to install gems to a non-default ruby install. If you are using rvm or rbenv use the ruby argument instead.

user: \texttt{None} The user under which to run the \texttt{gem} command

New in version 0.17.0.

version \texttt{[None]} Specify the version to install for the gem. Doesn't play nice with multiple gems at once

rdoc \texttt{[False]} Generate RDoc documentation for the gem(s).

ri \texttt{[False]} Generate RI documentation for the gem(s).

pre_releases \texttt{[False]} Install pre-release version of gem(s) if available.

proxy \texttt{[None]} Use the specified HTTP proxy server for all outgoing traffic. Format: \url{http://hostname[:port]}

salt.states.gem.\texttt{removed}(name, \ruby=None, user=None, \gem_bin=None)

Make sure that a gem is not installed.

name The name of the gem to uninstall

gem_bin \texttt{[None]} Full path to \texttt{gem} binary to use.

ruby \texttt{[None]} If RVM or rbenv are installed, the ruby version and gemset to use. Ignored if \texttt{gem_bin} is specified.

user: \texttt{None} The user under which to run the \texttt{gem} command

New in version 0.17.0.

salt.states.gem.\texttt{sources_add}(name, \ruby=None, user=None)

Make sure that a gem source is added.

name The URL of the gem source to be added

ruby: \texttt{None} For RVM or rbenv installations: the ruby version and gemset to target.

user: \texttt{None} The user under which to run the \texttt{gem} command

New in version 0.17.0.

salt.states.gem.\texttt{sources_remove}(name, \ruby=None, user=None)

Make sure that a gem source is removed.

name The URL of the gem source to be removed

ruby: \texttt{None} For RVM or rbenv installations: the ruby version and gemset to target.

user: \texttt{None} The user under which to run the \texttt{gem} command

New in version 0.17.0.
31.27.54 salt.states.git

States to manage git repositories and git configuration

**Important:** Before using git over ssh, make sure your remote host fingerprint exists in your ~/.ssh/known_hosts file.

`salt.states.git.config_set(name, cwd=None, value=None, multivar=None, repo=None, user=None,**kwargs)`

New in version 2014.7.0.

Changed in version 2015.8.0: Renamed from `git.config` to `git.config_set`. For earlier versions, use `git.config`.

Ensure that a config value is set to the desired value(s)

**name** Name of the git config value to set

**value** Set a single value for the config item

**multivar** Set multiple values for the config item

**Note:** The order matters here, if the same parameters are set but in a different order, they will be removed and replaced in the order specified.

New in version 2015.8.0.

**repo** [None] An optional location of a git repository for local operations

**user** [None] Optional name of a user as whom `git config` will be run

**global** [False] If True, this will set a global git config option

Changed in version 2015.8.0: Option renamed from `is_global` to `global`. For earlier versions, use `is_global`.

Local Config Example:

```
# Single value
mylocalrepo:
git.config_set:
  - name: user.email
    - value: foo@bar.net
  - repo: /path/to/repo
```

```
# Multiple values
mylocalrepo:
git.config_set:
  - name: mysection.myattribute
  - multivar:
    - foo
    - bar
    - baz
  - repo: /path/to/repo
```

Global Config Example (User ``foo``):

```
mylocalrepo:
git.config_set:
  - name: user.name
  - value: Foo Bar
```
salt.states.git.config_unset(name, value_regex=None, repo=None, user=None, **kwargs)

New in version 2015.8.0.

Ensure that the named config key is not present

name  The name of the configuration key to unset. This value can be a regex, but the regex must match the
entire key name. For example, foo\. would not match all keys in the foo section, it would be necessary
to use foo\..+ to do so.

value_regex  Regex indicating the values to unset for the matching key(s)

Note: This option behaves differently depending on whether or not all is set to True. If it is, then all
values matching the regex will be deleted (this is the only way to delete multiple values from a multivar).
If all is set to False, then this state will fail if the regex matches more than one value in a multivar.

all  [False] If True, unset all matches

repo  [None] An optional location of a git repository for local operations

user  [None] Optional name of a user as whom git config will be run

global  [False] If True, this will set a global git config option

Examples:

# Value matching 'baz'
mylocalrepo:
  git.config_unset:
    - name: foo.bar
    - value_regex: 'baz'
    - repo: /path/to/repo

# Ensure entire multivar is unset
mylocalrepo:
  git.config_unset:
    - name: foo.bar
    - all: True

# Ensure all variables in 'foo' section are unset, including multivars
mylocalrepo:
  git.config_unset:
    - name: 'foo\..+'
    - all: True

# Ensure that global config value is unset
mylocalrepo:
  git.config_unset:
    - name: foo.bar
    - global: True

salt.states.git.latest(name, rev='HEAD', target=None, branch=None, user=None,
force_checkout=False, force_clone=False, force_fetch=False, force_reset=False,
submodules=False, bare=False, mirror=False, remote='origin', fetch_tags=True,
deepth=None, identity=None, https_user=None, https_pass=None, onlyif=False,
unless=False, **kwargs)

Make sure the repository is cloned to the given directory and is up-to-date.
name  Address of the remote repository as passed to `git clone`

rev  [HEAD] The remote branch, tag, or revision ID to checkout after clone / before update. If specified, then Salt will also ensure that the tracking branch is set to `<remote>/<rev>`, unless `rev` refers to a tag or SHA1, in which case Salt will ensure that the tracking branch is unset.

If `rev` is not specified, it will be assumed to be HEAD, and Salt will not manage the tracking branch at all.

target  Name of the target directory where repository is about to be cloned

branch  Name of the branch into which to checkout the specified rev. If not specified, then Salt will not care what branch is being used locally and will just use whatever branch is currently there.

| Note:  | If not specified, this means that the local branch name will not be changed if the repository is reset to another branch/tag/SHA1. |

New in version 2015.8.0.

user  User under which to run git commands. By default, commands are run by the user under which the minion is running.

New in version 0.17.0.

force  [False] Deprecated since version 2015.8.0: Use `force_clone` instead. For earlier Salt versions, `force` must be used.

force_checkout  [False] When checking out the local branch, the state will fail if there are unwritten changes. Set this argument to True to discard unwritten changes when checking out.

force_clone  [False] If the `target` directory exists and is not a git repository, then this state will fail. Set this argument to `True` to remove the contents of the target directory and clone the repo into it.

force_fetch  [False] If a fetch needs to be performed, non-fast-forward fetches will cause this state to fail. Set this argument to `True` to force the fetch even if it is a non-fast-forward update.

New in version 2015.8.0.

force_reset  [False] If the update is not a fast-forward, this state will fail. Set this argument to `True` to force a hard-reset to the remote revision in these cases.

submodules  [False] Update submodules on clone or branch change

bare  [False] Set to `True` if the repository is to be a bare clone of the remote repository.

mirror  Set to `True` if the repository is to be a mirror of the remote repository. This implies that `bare` set to `True`, and thus is incompatible with `rev`.

remote  [origin] Git remote to use. If this state needs to clone the repo, it will clone it using this value as the initial remote name. If the repository already exists, and a remote by this name is not present, one will be added.

remote_name  Deprecated since version 2015.8.0: Use `remote` instead. For earlier Salt versions, `remote_name` must be used.

fetch_tags  [True] If `True`, then when a fetch is performed all tags will be fetched, even those which are not reachable by any branch on the remote.

depth  Defines depth in history when git a clone is needed in order to ensure latest. E.g. `depth: 1` is useful when deploying from a repository with a long history. Use `rev` to specify branch. This is not compatible with tags or revision IDs.

identity  A path on the minion server to a private key to use over SSH
https_user  HTTP Basic Auth username for HTTPS (only) clones
   New in version 2015.5.0.
https_pass  HTTP Basic Auth password for HTTPS (only) clones
   New in version 2015.5.0.
onlyif  A command to run as a check, run the named command only if the command passed to the onlyif option returns true
unless  A command to run as a check, only run the named command if the command passed to the unless option returns false

Note: Clashing ID declarations can be avoided when including different branches from the same git repository in the same sls file by using the name declaration. The example below checks out the gh-pages and gh-pages-prod branches from the same repository into separate directories. The example also sets up the ssh_known_hosts ssh key required to perform the git checkout.

gitlab.example.com:
   ssh_known_hosts:
      - present
      - user: root
      - enc: ecdsa

   git-website-staging:
      git.latest:
         - name: git@gitlab.example.com:user/website.git
         - rev: gh-pages
         - target: /usr/share/nginx/staging
         - identity: /root/.ssh/website_id_rsa
         - require:
            - pkg: git
            - ssh_known_hosts: gitlab.example.com

   git-website-prod:
      git.latest:
         - name: git@gitlab.example.com:user/website.git
         - rev: gh-pages-prod
         - target: /usr/share/nginx/prod
         - identity: /root/.ssh/website_id_rsa
         - require:
            - pkg: git
            - ssh_known_hosts: gitlab.example.com

salt.states.git.mod_run_check(cmd_kwargs, onlyif, unless)
   Execute the onlyif and unless logic. Return a result dict if:
      • onlyif failed (onlyif!= 0)
      • unless succeeded (unless == 0)
   Otherwise, returns True

salt.states.git.present(name, force=False, bare=True, template=None, separate_git_dir=False, shared=None, user=None)
   Ensure that a repository exists in the given directory
Warning: If the minion has Git 2.5 or later installed, name points to a worktree, and force is set to True, then the worktree will be deleted. This has been corrected in Salt 2015.8.0.

name  Path to the directory
       Changed in version 2015.8.0: This path must now be absolute

force  [False] If True, and if name points to an existing directory which does not contain a git repository, then the contents of that directory will be recursively removed and a new repository will be initialized in its place.

bare  [True] If True, and a repository must be initialized, then the repository will be a bare repository.

Note: This differs from the default behavior of git.init, make sure to set this value to False if a bare repo is not desired.

template  If a new repository is initialized, this argument will specify an alternate `template directory`

New in version 2015.8.0.

separate_git_dir  If a new repository is initialized, this argument will specify an alternate $GIT_DIR

New in version 2015.8.0.

shared  Set sharing permissions on git repo. See git-init(1) for more details.

New in version 2015.5.0.

user  User under which to run git commands. By default, commands are run by the user under which the minion is running.

New in version 0.17.0.

31.27.55 salt.states.glusterfs

Manage glusterfs pool.

salt.states.glusterfs.add_volume_bricks(name, bricks)
Add brick(s) to an existing volume

name  Volume name

bricks  List of brick(s) to add to the volume

myvolume:
    glusterfs.add_volume_bricks:
        - bricks:
            - host1:/srv/gluster/drive1
            - host2:/srv/gluster/drive2

Replicated Volume:
    glusterfs.add_volume_bricks:
        - name: volume2
          bricks:
            - host1:/srv/gluster/drive2
            - host2:/srv/gluster/drive3

salt.states.glusterfs.created(name, bricks, stripe=False, replica=False, device_vg=False, transport='tcp', start=False, force=False)
Check if volume already exists
name  name of the volume

myvolume:
  glusterfs.created:
    - bricks:
      - host1:/srv/gluster/drive1
      - host2:/srv/gluster/drive2

Replicated Volume:
  glusterfs.created:
    - name: volume2
    - bricks:
      - host1:/srv/gluster/drive2
      - host2:/srv/gluster/drive3
    - replica: 2
    - start: True

salt.states.glusterfs.peered(name)
Check if node is peered.

  name  The remote host with which to peer.

  peer-cluster:
    glusterfs.peered:
      - name: two

  peer-clusters:
    glusterfs.peered:
      - names:
        - one
        - two
        - three
        - four

salt.states.glusterfs.started(name)
Check if volume has been started

  name  name of the volume

mycluster:
  glusterfs.started: []

31.27.56 salt.states.gnomedesktop

Configuration of the GNOME desktop

Control the GNOME settings

localdesktop_wm_prefs:
  gnomedesktop.wm_preferences:
    - user: username
    - audible_bell: false
    - action_double_click_titlebar: 'toggle-maximize'

    name, user=None, automatic_mnemonics=None, buttons_have_icons=None, can_change_accels=None, clock_format=None, clock_show_date=None, clock_show_seconds=None, cursor_blink=None, cursor_blink_time=None, cursor_blink_timeout=None, cursor_size=None, cursor_theme=None, document_font_name=None, enable_animations=None, font_name=None, gtk_color_palette=None, gtk_color_scheme=None, gtk_im_module=None, gtk_im_preedit_style=None, gtk_im_status_style=None, gtk_key_theme=None, gtk_theme=None, gtk_timeout_initial=None, gtk_timeout_repeat=None, icon_theme=None, menubar_accel=None, menubar_detachable=None, menus_have_icons=None, menus_have_tearoff=None, monospace_font_name=None, show_input_method_menu=None, show_unicode_menu=None, show_unace_menu=None, text_scaling_factor=None, toolbar_detachable=None, toolbar_icons_size=None, toolbar_style=None, toolkit_accessibility=None, **kwargs)

desktop_interface: sets values in the org.gnome.desktop.interface schema

salt.states.gnomedesktop.desktop_lockdown
    name, user=None, disable_application_handlers=None, disable_command_line=None, disable_lock_screen=None, disable_log_out=None, disable_print_setup=None, disable_printing=None, disable_save_to_disk=None, disable_user_switching=None, user_administration_disabled=None, **kwargs)

desktop_lockdown: sets values in the org.gnome.desktop.lockdown schema
salt.states.gnomedesktop.wm_preferences(name, user=None, action_double_click_titlebar=None, action_middle_click_titlebar=None, action_right_click_titlebar=None, application_based=None, audible_bell=None, auto_raise=None, auto_raise_delay=None, button_layout=None, disable_workarounds=None, focus_mode=None, focus_new_windows=None, mouse_button_modifier=None, num_workspaces=None, raise_on_click=None, resize_with_right_button=None, theme=None, titlebar_font=None, titlebar_uses_system_font=None, visual_bell=None, visual_bell_type=None, workspace_names=None, **kwargs)

wm_preferences: sets values in the org.gnome.desktop.wm.preferences schema

31.27.57 salt.states.grafana

Manage Grafana Dashboards

This module uses elasticsearch, which can be installed via package, or pip.

You can specify elasticsearch hosts directly to the module, or you can use an elasticsearch profile via pillars:

mygrafanaprofile:
  hosts:
    - es1.example.com:9200
    - es2.example.com:9200
  index: grafana-dash

# Basic usage (uses default pillar profile key 'grafana')
Ensure myservice dashboard is managed:
  grafana.dashboard_present:
    - name: myservice
    - dashboard_from_pillar: default
    - rows_from_pillar:
      - systemhealth
      - requests

# Passing hosts in
Ensure myservice dashboard is managed:
  grafana.dashboard_present:

  type: timepicker
originalTitle: dockerregistry
refresh: 1m
rows: []
sharedCrosshair: false
style: dark
templating:
  enable: true
  list: []
time:
  from: now-2h
  to: now
timezone: browser
- rows_from_pillars:
  - systemhealth
  - requests
- profile: mygrafanaprofile
The behavior of this module is to create dashboards if they do not exist, to add rows if they do not exist in existing dashboards, and to update rows if they exist in dashboards. The module will not manage rows that are not defined, allowing users to manage their own custom rows.

```python
salt.states.grafana.dashboard_absent(name, hosts=None, profile='grafana')
```

Ensure the named grafana dashboard is deleted.

- **name** Name of the grafana dashboard.
- **profile** A pillar key or dict that contains a list of hosts and an elasticsearch index to use.

```python
salt.states.grafana.dashboard_present(name, dashboard=None, dashboard_from_pillar=None, rows=None, rows_from_pillar=None, profile='grafana')
```

Ensure the grafana dashboard exists and is managed.

- **name** Name of the grafana dashboard.
- **dashboard** A dict that defines a dashboard that should be managed.
- **dashboard_from_pillar** A pillar key that contains a grafana dashboard dict. Mutually exclusive with dashboard.
- **rows** A list of grafana rows.
- **rows_from_pillar** A list of pillar keys that contain lists of grafana dashboard rows. Rows defined in the pillars will be appended to the rows defined in the state.
- **profile** A pillar key or dict that contains a list of hosts and an elasticsearch index to use.

### 31.27.58 salt.states.grains

#### Manage grains on the minion

This state allows for grains to be set. Grains set or altered this way are stored in the `grains` file on the minions, by default at: `/etc/salt/grains`

Note: This does not override any grains set in the minion file.

```python
salt.states.grains.absent(name, destructive=False)
```

New in version 2014.7.0.

Delete a grain from the grains config file

- **name** The grain name

  **Parameters** `destructive` -- If destructive is True, delete the entire grain. If destructive is False, set the grain's value to None. Defaults to False.

```python
grain_name:
grains.absent
```

```python
salt.states.grains.append(name, value, convert=False)
```

New in version 2014.7.0.

Append a value to a list in the grains config file

- **name** The grain name
- **value** The value to append
Parameters **convert** -- If convert is True, convert non-list contents into a list. If convert is False and the grain contains non-list contents, an error is given. Defaults to False.

```python
grain_name:
grains.append:
    - value: to_be_appended
```

```python
salt.states.grains.list_absent(name, value)
Delete a value from a grain formed as a list.
New in version 2014.1.0.
name The grain name.
value The value to delete from the grain list.
The grain should be list type
```

```python
roles:
grains.list_absent:
    - value: db
```

For multiple grains, the syntax looks like:

```python
roles:
grains.list_absent:
    - value:
        - web
        - dev
```

```python
salt.states.grains.list_present(name, value)
Ensure the value is present in the list type grain.
New in version 2014.1.0.
name The grain name.
value The value is present in the list type grain.
The grain should be list type
```

```python
roles:
grains.list_present:
    - value: web
```

For multiple grains, the syntax looks like:

```python
roles:
grains.list_present:
    - value:
        - web
        - dev
```

```python
salt.states.grains.present(name, value)
Ensure that a grain is set
name The grain name
value The value to set on the grain
If the grain with the given name exists, its value is updated to the new value. If the grain does not yet exist, a new grain is set to the given value.
```
31.27.59 salt.states.group

Management of user groups

The group module is used to create and manage unix group settings, groups can be either present or absent:

```
cheese:
    group.present:
        - gid: 7648
        - system: True
        - addusers:
            - user1
            - users2
        - delusers:
            - foo

cheese:
    group.present:
        - gid: 7648
        - system: True
        - members:
            - foo
            - bar
            - user1
            - user2
```

**salt.states.group.absent**(name)

Ensure that the named group is absent

- **name** The name of the group to remove

**salt.states.group.present**(name, gid=None, system=False, addusers=None, delusers=None, members=None)

Ensure that a group is present

- **name** The name of the group to manage
- **gid** The group id to assign to the named group; if left empty, then the next available group id will be assigned
- **system** Whether or not the named group is a system group. This is essentially the `-r` option of `groupadd`.
- **addusers** List of additional users to be added as a group members.
- **delusers** Ensure these user are removed from the group membership.
- **members** Replace existing group members with a list of new members.

**Note:** Options `members` and `addusers/delusers` are mutually exclusive and can not be used together.
31.27.60 salt.states.hg

Interaction with Mercurial repositories

Before using hg over ssh, make sure the remote host fingerprint already exists in ~/.ssh/known_hosts, and the remote host has this host's public key.

```
https://bitbucket.org/example_user/example_repo:
  hg.latest:
    - rev: tip
    - target: /tmp/example_repo
```

salt.states.hg.latest(name, rev=None, target=None, clean=False, user=None, identity=None, force=False, opts=False)

Make sure the repository is cloned to the given directory and is up to date

- **name** Address of the remote repository as passed to ```hg clone```
- **rev** The remote branch, tag, or revision hash to clone/pull
- **target** Target destination directory path on minion to clone into
- **clean** Force a clean update with `-C` (Default: False)
- **user** Name of the user performing repository management operations

New in version 0.17.0.

- **identity** Private SSH key on the minion server for authentication (ssh://)

New in version 2015.5.0.

- **force** Force hg to clone into pre-existing directories (deletes contents)
- **opts** Include additional arguments and options to the hg command line

31.27.61 salt.states.hipchat

Send a message to Hipchat

This state is useful for sending messages to Hipchat during state runs.

New in version 2015.5.0.

```
hipchat-message:
  hipchat.send_message:
    - room_id: 123456
    - from_name: SuperAdmin
    - message: 'This state was executed successfully.'
    - api_key: peWcBiMOS9HrZG15peWcBiMOS9HrZG15
    - api_version: v1
```

The api key can be specified in the master or minion configuration like below: .. code-block:: yaml

```
hipchat: api_key: peWcBiMOS9HrZG15peWcBiMOS9HrZG15 api_version: v1
```

salt.states.hipchat.send_message(name, room_id, from_name, message, api_key=None, api_version=None, message_color='yellow', notify=False)

Send a message to a Hipchat room.
```python
hipchat-message:
    hipchat.send_message:
        - room_id: 123456
        - from_name: SuperAdmin
        - message: 'This state was executed successfully.'
        - api_key: peWcBiMOS9HrZG15peWcBiMOS9HrZG15
        - api_version: v1
        - color: green
        - notify: True
```

The following parameters are required:

- **name** The unique name for this event.
- **room_id** The room to send the message to. Can either be the ID or the name.
- **from_name** The name of that is to be shown in the ``from`` field. If not specified, defaults to.
- **message** The message that is to be sent to the Hipchat room.

The following parameters are optional:

- **api_key** The api key for Hipchat to use for authentication, if not specified in the configuration options of master or minion.
- **api_version** The api version for Hipchat to use, if not specified in the configuration options of master or minion.
- **color** The color the Hipchat message should be displayed in. One of the following, default: yellow, red, green, purple, gray, or random.
- **notify** Should a notification in the room be raised.

### 31.27.62 salt.states.host

Management of addresses and names in hosts file

The `/etc/hosts` file can be managed to contain definitions for specific hosts:

```yaml
salt-master:
    host.present:
        - ip: 192.168.0.42
```

Or using the `names` directive, you can put several names for the same IP. (Do not try one name with space-separated values).

```yaml
server1:
    host.present:
        - ip: 192.168.0.42
        - names:
            - server1
            - florida
```

**Note:** Changing the names in `host.present` does not cause an update to remove the old entry.
salt.states.host.absent(name, ip)
Ensure that the named host is absent

name The host to remove
ip The ip addr(s) of the host to remove

salt.states.host.present(name, ip)
Ensures that the named host is present with the given ip

name The host to assign an ip to
ip The ip addr(s) to apply to the host

31.27.63 salt.states.htpasswd

Support for htpasswd module
New in version 2014.7.0.

salt.states.htpasswd.user_exists(name, password=None, htpasswd_file=None, options='d', force=False, runas=None)
Make sure the user is inside the specified htpasswd file

name User name
password User password
htpasswd_file Path to the htpasswd file
options See salt.modules.htpasswd.useradd
force Touch the file even if user already created
runas The system user to run htpasswd command with

31.27.64 salt.states.http

HTTP monitoring states
Perform an HTTP query and statefully return the result
New in version 2015.2.

salt.states.http.query(name, match=None, match_type='string', status=None, **kwargs)
Perform an HTTP query and statefully return the result
New in version 2015.2.
31.27.65 salt.states.ifttt

Trigger an event in IFTTT

This state is useful for trigging events in IFTTT.

New in version 2015.8.0.

```yaml
ifttt-event:
    ifttt.trigger_event:
        - event: TestEvent
        - value1: 'This state was executed successfully.'
        - value2: 'Another value we can send.'
        - value3: 'A third value we can send.'
```

The api key can be specified in the master or minion configuration like below:

```yaml
ifttt: secret_key: bzMRb-KKIAaNOWKEw792J7Eb-B3z7muhdhYblJn4V6
```

```python
salt.states.ifttt.trigger_event(name, event, value1=None, value2=None, value3=None)
```

Trigger an event in IFTTT

```yaml
ifttt-event:
    ifttt.trigger_event:
        - event: TestEvent
        - value1: 'A value that we want to send.'
        - value2: 'A second value that we want to send.'
        - value3: 'A third value that we wan to send.'
```

The following parameters are required:

- **name** The unique name for this event.
- **event** The name of the event to trigger in IFTTT.

The following parameters are optional:

- **value1** One of the values that we can send to IFTTT.
- **value2** One of the values that we can send to IFTTT.
- **value3** One of the values that we can send to IFTTT.

31.27.66 salt.states.incron

Management of incron, the inotify cron

The incron state module allows for user incrontabs to be cleanly managed.

Incron declarations require a number of parameters. The parameters needed to be declared: `path`, `mask`, and `cmd`. The `user` whose incrontab is to be edited also needs to be defined.

When making changes to an existing incron job, the `path` declaration is the unique factor, so if an existing cron that looks like this:

```bash
Watch for modifications in /home/user:
    incron.present:
        - user: root
        - path: /home/user
        - mask:
```

31.27. Full list of builtin state modules
- IN_MODIFY
- cmd: 'echo $$ $$'

Is changed to this:

Watch for modifications and access in /home/user:

```bash
in cron.present:
  - user: root
  - path: /home/user
  - mask:
    - IN_MODIFY
    - IN_ACCESS
  - cmd: 'echo $$ $$'
```

Then the existing cron will be updated, but if the cron command is changed, then a new cron job will be added to the user's crontab.

New in version 0.17.0.

**salt.states.incron.absent** *(name, path, mask, cmd, user='root')*

Verifies that the specified incron job is absent for the specified user; only the name is matched when removing an incron job.

- **name** Unique comment describing the entry
- **path** The path that should be watched
- **user** The name of the user who's crontab needs to be modified, defaults to the root user
- **mask** The mask of events that should be monitored for
- **cmd** The cmd that should be executed

**salt.states.incron.present** *(name, path, mask, cmd, user='root')*

Verifies that the specified incron job is present for the specified user. For more advanced information about what exactly can be set in the cron timing parameters, check your incron system's documentation. Most Unix-like systems' incron documentation can be found via the incrontab man page: `man 5 incrontab`.

- **name** Unique comment describing the entry
- **path** The path that should be watched
- **user** The name of the user who's crontab needs to be modified, defaults to the root user
- **mask** The mask of events that should be monitored for
- **cmd** The cmd that should be executed

### 31.27.67 salt.states.influxdb_database

Management of InfluxDB databases

(compatible with InfluxDB version 0.5+)

New in version 2014.7.0.

**salt.states.influxdb_database.absent** *(name, user=None, password=None, host=None, port=None)*

Ensure that the named database is absent

- **name** The name of the database to remove
- **user** The user to connect as (must be able to remove the database)
password  The password of the user
host  The host to connect to
port  The port to connect to

salt.states.influxdb_database.present(name, user=None, password=None, host=None, port=None)
Ensure that the named database is present
name  The name of the database to create
user  The user to connect as (must be able to remove the database)
password  The password of the user
host  The host to connect to
port  The port to connect to

31.27.68  salt.states.influxdb_user

Management of InfluxDB users
(compatible with InfluxDB version 0.5+)
New in version 2014.7.0.

salt.states.influxdb_user.absent(name, database=None, user=None, password=None, host=None, port=None)
Ensure that the named cluster admin or database user is absent.
name  The name of the user to remove
database  The database to remove the user from
user  The user to connect as (must be able to remove the user)
password  The password of the user
host  The host to connect to
port  The port to connect to

salt.states.influxdb_user.present(name, passwd, database=None, user=None, password=None, host=None, port=None)
Ensure that the cluster admin or database user is present.
name  The name of the user to manage
passwd  The password of the user
database  The database to create the user in
user  The user to connect as (must be able to create the user)
password  The password of the user
host  The host to connect to
port  The port to connect to
31.27.69  salt.states.ini_manage

Manage ini files

maintainer  <akilesh1597@gmail.com>
maturity  new
depends  re
platform  all

use section as DEFAULT_implicit if your ini file does not have any section for example /etc/sysctl.conf

salt.states.ini_manage.options_absent(name, sections=None)

```ini
/home/saltminion/api-paste.ini:
ini.options_present:
  - sections:
    test:
      - testkey
      - secondoption
    test1:
      - testkey1
```

options present in file and not specified in sections dict will be untouched
changes dict will contain the list of changes made

salt.states.ini_manage.options_present(name, sections=None)

```ini
/home/saltminion/api-paste.ini:
ini.options_present:
  - sections:
    test:
      testkey: 'testval'
      secondoption: 'secondvalue'
    test1:
      testkey1: 'testval121'
```

options present in file and not specified in sections dict will be untouched
changes dict will contain the list of changes made

salt.states.ini_manage.sections_absent(name, sections=None)

```ini
/home/saltminion/api-paste.ini:
ini.sections_absent:
  - sections:
    test
    test1
```

options present in file and not specified in sections will be deleted changes dict will contain the sections that changed

salt.states.ini_manage.sections_present(name, sections=None)
/home/saltminion/api-paste.ini:
ini.sections_present:
  - sections:
    test:
      testkey: testval
      secondoption: secondvalue
    test2:
      testkey2: 'testval121'

options present in file and not specified in sections will be deleted changes dict will contain the sections that changed

### 31.27.70 salt.states.ipmi

**Manage IPMI devices over LAN**

The following configuration defaults can be defined in the minion, master config or pillar:

```
ipmi.config:
  api_host: 127.0.0.1
  api_user: admin
  api_pass: apassword
  api_port: 623
  api_kg: None
```

Every call can override the config defaults:

```
ensure myipmi system is set to network boot:
  ipmi.boot_device:
    - name: network
      - api_host: myipmi.hostname.com
      - api_user: root
      - api_pass: apassword
      - api_kg: None

ensure myipmi system is powered on:
  ipmi.power:
    - name: boot
      - api_host: myipmi.hostname.com
      - api_user: root
      - api_pass: apassword
```

**salt.states.ipmi.boot_device** *(name='default', **kwargs)*

Request power state change

- **name** = *default*
  - network -- Request network boot
  - hd -- Boot from hard drive
  - safe -- Boot from hard drive, requesting `safe mode`
  - optical -- boot from CD/DVD/BD drive
  - setup -- Boot into setup utility
  - default -- remove any IPMI directed boot device request

**kwargs**
• api_host=localhost
• api_user=admin
• api_pass=
• api_port=623
• api_kg=None

salt.states.ipmi.power(name='power_on', wait=300, **kwargs)
Request power state change

name
Ensure power state one of:
• power_on -- system turn on
• power_off -- system turn off (without waiting for OS)
• shutdown -- request OS proper shutdown
• reset -- reset (without waiting for OS)
• boot -- If system is off, then `on', else `reset'

wait  wait X seconds for the job to complete before forcing. (defaults to 300 seconds)

kwargs
• api_host=localhost
• api_user=admin
• api_pass=
• api_port=623
• api_kg=None

salt.states.ipmi.user_absent(name, channel=14, **kwargs)
Remove user Delete all user (uid) records having the matching name.

name  string name of user to delete

channel  channel to remove user access from defaults to 14 for auto.

kwargs
• api_host=localhost
• api_user=admin
• api_pass=
• api_port=623
• api_kg=None

salt.states.ipmi.user_present(name, uid, password, channel=14, callback=False, link_auth=True, ipmi_msg=True, privilege_level='administrator', **kwargs)
Ensure IPMI user and user privileges.

name  name of user (limit 16 bytes)

uid  user id number (1 to 7)

password  user password (limit 16 bytes)

channel  ipmi channel defaults to 14 for auto
callback  User Restricted to Callback

False = User Privilege Limit is determined by the User Privilege Limit parameter privilege_level, for both callback and non-callback connections.

True = User Privilege Limit is determined by the privilege_level parameter for callback connections, but is restricted to Callback level for non-callback connections. Thus, a user can only initiate a Callback when they `call in' to the BMC, but once the callback connection has been made, the user could potentially establish a session as an Operator.

link_auth  User Link authentication True/False user name and password information will be used for link authentication, e.g. PPP CHAP) for the given channel. Link authentication itself is a global setting for the channel and is enabled/disabled via the serial/modem configuration parameters.

ipmi_msg  User IPMI Messaging True/False user name and password information will be used for IPMI Messaging. In this case, 'IPMI Messaging' refers to the ability to execute generic IPMI commands that are not associated with a particular payload type. For example, if IPMI Messaging is disabled for a user, but that user is enabled for activating the SOL payload type, then IPMI commands associated with SOL and session management, such as Get SOL Configuration Parameters and Close Session are available, but generic IPMI commands such as Get SEL Time are unavailable.) ipmi_msg

privilege_level

- callback
- user
- operator
- administrator
- proprietary
- no_access

kwargs

- api_host=localhost
- api_user=admin
- api_pass=
- api_port=623
- api_kg=None

31.27.71 salt.states.ipset

Management of ipsets

This is an ipset-specific module designed to manage IPSets for use in IPTables Firewalls.

setname:
  ipset.set_present:
    - set_type: bitmap:ip
    - range: 192.168.0.0/16
    - comment: True

setname:
  ipset.set_absent:
    - set_type: bitmap:ip
- range: 192.168.0.0/16
- comment: True

setname_entries:
ipset.present:
  - set_name: setname
  - entry: 192.168.0.3
  - comment: Hello
  - require:
    - ipset: baz

setname_entries:
ipset.present:
  - set_name: setname
  - entry:
    - 192.168.0.3
    - 192.168.1.3
  - comment: Hello
  - require:
    - ipset: baz

setname_entries:

  - set_name: setname
  - entry:
    - 192.168.0.3
    - 192.168.1.3
  - comment: Hello
  - require:
    - ipset: baz

setname:
ipset.flush:

**salt.states.ipset.absent**(name, entry=None, entries=None, family='ipv4', **kwargs)
New in version 2014.7.0.
Remove a entry or entries from a chain

- **name** A user-defined name to call this entry by in another part of a state or formula. This should not be an actual entry.
- **family** Network family, ipv4 or ipv6.

**salt.states.ipset.flush**(name, family='ipv4', **kwargs)
New in version 2014.7.0.
Flush current ipset set

- **family** Networking family, either ipv4 or ipv6

**salt.states.ipset.present**(name, entry=None, family='ipv4', **kwargs)
New in version 2014.7.0.
Append a entry to a set

- **name** A user-defined name to call this entry by in another part of a state or formula. This should not be an actual entry.
- **entry** A single entry to add to a set or a list of entries to add to a set
- **family** Network family, ipv4 or ipv6.
**salt.states.ipset.set_absent** *(name, family='ipv4'; **kwargs)*

New in version 2014.7.0.

Verify the set is absent.

- **family** Networking family, either ipv4 or ipv6

**salt.states.ipset.set_present** *(name, set_type, family='ipv4'; **kwargs)*

New in version 2014.7.0.

Verify the chain is exist.

- **name** A user-defined set name.
- **set_type** The type for the set
- **family** Networking family, either ipv4 or ipv6

### 31.27.72 salt.states.iptables

**Management of iptables**

This is an iptables-specific module designed to manage Linux firewalls. It is expected that this state module, and other system-specific firewall states, may at some point be deprecated in favor of a more generic firewall state.

```yaml
httpd:
  iptables.append:
  - table: filter
  - chain: INPUT
  - jump: ACCEPT
  - match: state
  - connstate: NEW
  - dport: 80
  - proto: tcp
  - sport: 1025:65535
  - save: True

httpd:
  iptables.append:
  - table: filter
  - chain: INPUT
  - jump: ACCEPT
  - match:
    - state
    - comment
    - comment: "Allow HTTP"
  - connstate: NEW
  - dport: 80
  - proto: tcp
  - sport: 1025:65535
  - save: True

httpd:
  iptables.append:
  - table: filter
  - chain: INPUT
  - jump: ACCEPT
  - match:
    - state
```

**31.27. Full list of builtin state modules**

  - sport: 1025:65535
  - save: True

default to accept:
- iptables.set_policy:
  - chain: INPUT
  - policy: ACCEPT

Note: Various functions of the iptables module use the --check option. If the version of iptables on the target system does not include this option, an alternate version of this check will be performed using the output of iptables-save. This may have unintended consequences on legacy releases of iptables.

salt.states.iptables.append(name, table='filter', family='ipv4', **kwargs)
New in version 0.17.0.

Append a rule to a chain

name A user-defined name to call this rule by in another part of a state or formula. This should not be an actual rule.

table The table that owns the chain which should be modified

family Network family, ipv4 or ipv6.

All other arguments are passed in with the same name as the long option that would normally be used for iptables, with one exception: --state is specified as connstate instead of state (not to be confused with ctstate).

Jump options that doesn’t take arguments should be passed in with an empty string.

salt.states.iptables.chain_absent(name, table='filter', family='ipv4')
New in version 2014.1.0.

Verify the chain is absent.

table The table to remove the chain from

family Networking family, either ipv4 or ipv6

salt.states.iptables.chain_present(name, table='filter', family='ipv4')
New in version 2014.1.0.

Verify the chain is exist.

name A user-defined chain name.
```python
salt.states.iptables.delete(name, table='filter', family='ipv4', **kwargs)
New in version 2014.1.0.
Delete a rule to a chain

name  A user-defined name to call this rule by in another part of a state or formula. This should not be an actual rule.

table  The table that owns the chain that should be modified

family  Networking family, either ipv4 or ipv6

All other arguments are passed in with the same name as the long option that would normally be used for iptables, with one exception: --state is specified as connstate instead of state (not to be confused with ctstate).

Jump options that doesn’t take arguments should be passed in with an empty string.

salt.states.iptables.flush(name, table='filter', family='ipv4', **kwargs)
New in version 2014.1.0.
Flush current iptables state

table  The table that owns the chain that should be modified

family  Networking family, either ipv4 or ipv6

salt.states.iptables.insert(name, table='filter', family='ipv4', **kwargs)
New in version 2014.1.0.
Insert a rule into a chain

name  A user-defined name to call this rule by in another part of a state or formula. This should not be an actual rule.

table  The table that owns the chain that should be modified

family  Networking family, either ipv4 or ipv6

All other arguments are passed in with the same name as the long option that would normally be used for iptables, with one exception: --state is specified as connstate instead of state (not to be confused with ctstate).

Jump options that doesn’t take arguments should be passed in with an empty string.

salt.states.iptables.mod_aggregate(low, chunks, running)
The mod_aggregate function which looks up all rules in the available low chunks and merges them into a single rules ref in the present low data

salt.states.iptables.set_policy(name, table='filter', family='ipv4', **kwargs)
New in version 2014.1.0.
Sets the default policy for iptables firewall tables

table  The table that owns the chain that should be modified

family  Networking family, either ipv4 or ipv6

policy  The requested table policy
```
31.27.73 salt.states.jboss7

Manage JBoss 7 Application Server via CLI interface

New in version 2015.5.0.

This state uses jboss-cli.sh script from JBoss installation and parses its output to determine execution result.

In order to run each state, jboss_config dictionary with the following properties must be passed:

```
jboss:
  cli_path: '/opt/jboss/jboss-7.0/bin/jboss-cli.sh'
  controller: 10.11.12.13:9999
  cli_user: 'jbossadm'
  cli_password: 'jbossadm'
```

If controller doesn’t require password, then passing cli_user and cli_password parameters is not obligatory.

Example of application deployment:

```
application_deployed:
jboss7.deployed:
  - artifact:
      artifact_url: http://artifactory.intranet.company.com/artifactory
      repository: 'ext-release-local'
      artifact_id: 'webcomponent'
      group_id: 'com.company.application'
      packaging: 'war'
      version: '0.1'
      target_dir: '/tmp'
  - jboss_config:
      cli_path: '/opt/jboss/jboss-7.0/bin/jboss-cli.sh'
      controller: 10.11.12.13:9999
      cli_user: 'jbossadm'
      cli_password: 'jbossadm'
```

Since same dictionary with configuration will be used in all the states, it is much more convenient to move jboss configuration and other properties to pillar. For example, configuration of jboss server, artifactory address and application version could be moved to pillars:

```
application_deployed:
jboss7.deployed:
  - artifact:
      artifact_url: {{ pillar['artifactory']['url'] }}
      repository: {{ pillar['artifactory']['repository'] }}
      artifact_id: 'webcomponent'
      group_id: 'com.company.application'
      packaging: 'war'
      version: {{ pillar['webcomponent-artifact']['version'] }}
      latest_snapshot: {{ pillar['webcomponent-artifact']['latest_snapshot'] }}
      repository: {{ pillar['webcomponent-artifact']['repository'] }}
  - jboss_config: {{ pillar['jboss'] }}
```

Configuration in pillars:

```
artifactory:
  url: 'http://artifactory.intranet.company.com/artifactory'
  repository: 'libs-snapshots-local'

webcomponent-artifact:
```
For the sake of brevity, examples for each state assume that jboss_config is moved to pillars.

salt.states.jboss7.bindings_exist(name, jboss_config, bindings)
Ensures that given JNDI binding are present on the server. If a binding doesn’t exist on the server it will be created. If it already exists its value will be changed.

  jboss_config: Dict with connection properties (see state description)
  bindings: Dict with bindings to set.

Example:

jndi_entries_created:
jboss7.bindings_exist:
  - bindings:
      'java:global/sampleapp/environment': 'DEV'
      'java:global/sampleapp/configurationFile': '/var/opt/sampleapp/config.properties'
      jboss_config: {{ pillar['jboss'] }}

salt.states.jboss7.datasource_exists(name, jboss_config, datasource_properties, recreate=False)
Ensures that a datasource with given properties exist on the jboss instance. If datasource doesn’t exist, it is created, otherwise only the properties that are different will be updated.

  name: Datasource property name
  jboss_config: Dict with connection properties (see state description)
  datasource_properties: Dict with datasource properties
  recreate: [False] If set to True and datasource exists it will be removed and created again. However, if there are deployments that depend on the datasource, it will not be possible to remove it.

Example:

sampleDS:
jboss7.datasource_exists:
  - recreate: False
  - datasource_properties:
      driver-name: mysql
      connection-url: 'jdbc:mysql://localhost:3306/sampleDatabase'
      jndi-name: 'java:jboss/datasources/sampleDS'
      user-name: sampleuser
      password: secret
      min-pool-size: 3
      use-java-context: True
  jboss_config: {{ pillar['jboss'] }}

salt.states.jboss7.deployed(name, jboss_config, artifact=None, salt_source=None)
Ensures that the given application is deployed on server.

  jboss_config: Dict with connection properties (see state description)
  artifact:
    If set, the artifact will be fetched from artifactory. This is a Dict object with the following properties:
- artifactory_url: Full url to artifactory instance, for example: http://artifactory.intranet.company.com/artifactory
- repository: One of the repositories, for example: libs-snapshots, ext-release-local, etc..
- artifact_id: Artifact ID of the artifact
- group_id: Group ID of the artifact
- packaging: war/jar/ear, etc...
- version: Artifact version. If latest_snapshot is set to True, the value of this attribute will be ignored, and newest snapshot will be taken instead.
- latest_snapshot: If set to True and repository is a snapshot repository it will automatically select the newest snapshot.
- snapshot_version: Exact version of the snapshot (with timestamp). A snapshot version may have several builds and a way to differentiate is to provide a build timestamp.
- target_dir: Temporary directory on minion where artifacts will be downloaded

salt_source:

If set, the artifact to be deployed will be fetched from salt master. This is a Dict object with the following properties:

- source: File on salt master (eg. salt://application-web-0.39.war)
- target_file: Temporary file on minion to save file to (eg. `/tmp/application-web-0.39.war')
- undeploy: Regular expression to match against existing deployments. If any deployment matches the regular expression then it will be undeployed.

The deployment consists of the following steps:

- Fetch artifact (salt filesystem, artifact or filesystem on minion)
- Check if same artifact is not deployed yet (perhaps with different version)
- Undeploy the artifact if it is already deployed
- Deploy the new artifact

Examples:

Deployment of a file from Salt file system:

```python
application_deployed:
    jboss7_deployed:
        - salt_source:
            source: salt://application-web-0.39.war
            target_file: '/tmp/application-web-0.39.war'
            undeploy: 'application-web-.x'
            - jboss_config: {{ pillar['jboss'] }}
```

Here, application-web-0.39.war file is downloaded from Salt file system to /tmp/application-web-0.39.war file on minion. Existing deployments are checked if any of them matches `application-web-.x` regular expression, and if so then it is undeployed before deploying the application. This is useful to automate deployment of new application versions.

JBoss state is capable of deploying artifacts directly from Artifactory repository. Here are some examples of deployments:

1. Deployment of released version of artifact from Artifactory.
This performs the following operations:

- Download artifact from artifactory. In the example above the artifact will be fetched from: http://artifactory.intranet.company.com/artifactory/ext-release-local/com/company/application/webcomponent/0.1/webcomponent-0.1.war
  
  As a rule, for released versions the artifacts are downloaded from: artifactory_url/repository/group_id_with_slashed_instead_of_dots/artifact_id/version/artifact_id-version.packaging. This follows artifactory convention for artifact resolution. By default the artifact will be downloaded to /tmp directory on minion.

- Connect to JBoss via controller (defined in jboss_config dict) and check if the artifact is not deployed already. In case of artifactory it will check if any deployment's name starts with artifact_id value. If deployment already exists it will be undeployed.

- Deploy the downloaded artifact to JBoss via cli interface.

2. Deployment of last updated version of given SNAPSHOT version of artifact from Artifactory.

Deploying snapshot version involves an additional step of resolving the exact version of the artifact (including the timestamp), which is not necessary when deploying a release. In the example above first a request will be made to retrieve the update timestamp from: http://artifactory.intranet.company.com/artifactory/ext-snapshot-local/com/company/application/webcomponent/0.1-SNAPSHOT/maven-metadata.xml

  Then the artifact will be fetched from: http://artifactory.intranet.company.com/artifactory/ext-snapshot-local/com/company/application/webcomponent/0.1-SNAPSHOT/webcomponent-RESOLVED_SNAPSHOT_VERSION.war

**Note:** In order to perform a snapshot deployment you have to:

- Set repository to a snapshot repository.

- Choose a version that ends with ```SNAPSHOT``` string. Snapshot repositories have a different layout and provide some extra information that is needed for deployment of the last or a specific snapshot.

3. Deployment of SNAPSHOT version (with exact timestamp) of artifact from Artifactory.
If you need to deploy an exact version of the snapshot you may provide snapshot_version parameter.

```yaml
application_deployed:
    jboss7.deployed:
        - artifact:
            artifact_url: http://artifactory.intranet.company.com/artifactory
            repository: 'ext-snapshot-local'
            artifact_id: 'webcomponent'
            group_id: 'com.company.application'
            packaging: 'war'
            version: '0.1-SNAPSHOT'
            snapshot_version: '0.1-20141023.131756-19'
            jboss_config: {{ pillar['jboss'] }}
```

In this example the artifact will be retrieved from: http://artifactory.intranet.company.com/artifactory/ext-snapshot-local/com/company/application/webcomponent/0.1-SNAPSHOT/webcomponent-0.1-20141023.131756-19.war

4. Deployment of latest snapshot of artifact from Artifactory.

```yaml
application_deployed:
    jboss7.deployed:
        - artifact:
            artifact_url: http://artifactory.intranet.company.com/artifactory
            repository: 'ext-snapshot-local'
            artifact_id: 'webcomponent'
            group_id: 'com.company.application'
            packaging: 'war'
            latest_snapshot: True
            jboss_config: {{ pillar['jboss'] }}
```

Instead of providing an exact version of a snapshot it is sometimes more convenient to get the newest version. If artifact.latest_snapshot is set to True, then the newest snapshot will be downloaded from Artifactory. In this case it is not necessary to specify version. This is particularly useful when integrating with CI tools that will deploy the current snapshot to the Artifactory.

```python
salt.states.jboss7.reloaded(name, jboss_config, timeout=60, interval=5)
```

Reloads configuration of jboss server.

**jboss_config**: Dict with connection properties (see state description)

**timeout**: Time to wait until jboss is back in running state. Default timeout is 60s.

**interval**: Interval between state checks. Default interval is 5s. Decreasing the interval may slightly decrease waiting time but be aware that every status check is a call to jboss-cli which is a java process. If interval is smaller than process cleanup time it may easily lead to excessive resource consumption.

This step performs the following operations:

- Ensures that server is in running or reload-required state (by reading server-state attribute)
- Reloads configuration
- Waits for server to reload and be in running state

Example:

```yaml
configuration_reloaded:
    jboss7.reloaded:
        - jboss_config: {{ pillar['jboss'] }}
```
31.27.74 salt.states.keyboard

Management of keyboard layouts

The keyboard layout can be managed for the system:

us:
   keyboard.system

Or it can be managed for XOrg:

us:
   keyboard.xorg

`salt.states.keyboard.system(name)`
Set the keyboard layout for the system

   name  The keyboard layout to use

`salt.states.keyboard.xorg(name)`
Set the keyboard layout for XOrg

   layout  The keyboard layout to use

31.27.75 salt.states.keystone

Management of Keystone users

   depends
      • keystoneclient Python module

   configuration  See `salt.modules.keystone` for setup instructions.

Keystone tenants:
   keystone.tenant_present:
      - names:
         - admin
         - demo
         - service

Keystone roles:
   keystone.role_present:
      - names:
         - admin
         - Member

admin:
   keystone.user_present:
      - password: R00T_4CC3SS
      - email: admin@domain.com
      - roles:
         admin:  # tenants
            - admin  # roles
         service:
            - admin
            - Member
      - require:
         - keystone: Keystone tenants
- keystone: Keystone roles

nova:
  keystone.user_present:
    - password: 'Sup3rn8v4'
    - email: nova@domain.com
    - tenant: service
    - roles:
        service:
          - admin
    - require:
        - keystone: Keystone tenants
        - keystone: Keystone roles

demo:
  keystone.user_present:
    - password: 'd3m0n$trati0n'
    - email: demo@domain.com
    - tenant: demo
    - roles:
        demo:
          - Member
    - require:
        - keystone: Keystone tenants
        - keystone: Keystone roles

nova service:
  keystone.service_present:
    - name: nova
    - service_type: compute
    - description: OpenStack Compute Service

salt.states.keystone.endpoint_absent(name, profile=None, **connection_args)

Ensure that the endpoint for a service doesn't exist in Keystone catalog

name The name of the service whose endpoints should not exist

salt.states.keystone.endpoint_present(name, publicurl=None, internalurl=None, adminurl=None, region='RegionOne', profile=None, **connection_args)

Ensure the specified endpoints exists for service

name The Service name
public url The public url of service endpoint
internal url The internal url of service endpoint
admin url The admin url of the service endpoint
region The region of the endpoint

salt.states.keystone.role_absent(name, profile=None, **connection_args)

Ensure that the keystone role is absent.

name The name of the role that should not exist

salt.states.keystone.role_present(name, profile=None, **connection_args)

Ensure that the keystone role exists

name The name of the role that should be present
salt.states.keystone.**service_absent**(name, profile=None, **connection_args)
Ensure that the service doesn't exist in Keystone catalog

    name  The name of the service that should not exist

salt.states.keystone.**service_present**(name, service_type, description=None, profile=None, **connection_args)
Ensure service present in Keystone catalog

    name  The name of the service
    service_type  The type of Openstack Service
    description (optional)  Description of the service

salt.states.keystone.**tenant_absent**(name, profile=None, **connection_args)
Ensure that the keystone tenant is absent.

    name  The name of the tenant that should not exist

salt.states.keystone.**tenant_present**(name, description=None, enabled=True, profile=None, **connection_args)
Ensures that the keystone tenant exists

    name  The name of the tenant to manage
    description  The description to use for this tenant
    enabled  Availability state for this tenant

salt.states.keystone.**user_absent**(name, profile=None, **connection_args)
Ensure that the keystone user is absent.

    name  The name of the user that should not exist

salt.states.keystone.**user_present**(name, password, email, tenant=None, enabled=True, roles=None, profile=None, **connection_args)
Ensure that the keystone user is present with the specified properties.

    name  The name of the user to manage
    password  The password to use for this user
    email  The email address for this user
    tenant  The tenant for this user
    enabled  Availability state for this user
    roles  The roles the user should have under given tenants. Passed as a dictionary mapping tenant names to a list of roles in this tenant, i.e.:

        roles:
            admin:  # tenant
            - admin  # role
            service:
                - admin
                - Member

---

### 31.27.76 salt.states.kmod

**Loading and unloading of kernel modules**

The Kernel modules on a system can be managed cleanly with the kmod state module:
kvm_amd:
  kmod.present
pcspkr:
  kmod.absent

salt.states.kmod.absent(name, persist=False, comment=True)
  Verify that the named kernel module is not loaded
  name  The name of the kernel module to verify is not loaded
  persist  Delete module from /etc/modules
  comment  Don't remove module from /etc/modules, only comment it

salt.states.kmod.present(name, persist=False)
  Ensure that the specified kernel module is loaded
  name  The name of the kernel module to verify is loaded
  persist  Also add module to /etc/modules

31.27.77 salt.states.layman

Management of Gentoo Overlays using layman

A state module to manage Gentoo package overlays via layman

sunrise:
  layman.present

salt.states.layman.absent(name)
  Verify that the overlay is absent
  name  The name of the overlay to delete

salt.states.layman.present(name)
  Verify that the overlay is present
  name  The name of the overlay to add

31.27.78 salt.states.libvirt

Manage libvirt certificates

This state uses the external pillar in the master to call for the generation and signing of certificates for systems running libvirt:

libvirt_keys:
  libvirt.keys

salt.states.libvirt.keys(name, basepath=/etc/pki)
  Manage libvirt keys.
  name  The name variable used to track the execution
  basepath  Defaults to /etc/pki, this is the root location used for libvirt keys on the hypervisor
31.27.79 salt.states.linux_acl

Linux File Access Control Lists

Ensure a Linux ACL is present

```yaml
class 'root':
    acl.present:
        - name: /root
        - acl_type: users
        - acl_name: damian
        - perms: rwx
```

Ensure a Linux ACL does not exist

```yaml
class 'root':
    acl.absent:
        - name: /root
        - acl_type: user
        - acl_name: damian
        - perms: rwx
```

`salt.states.linux_acl.absent(name, acl_type, acl_name='', perms='', recurse=False)`
Ensure a Linux ACL does not exist

`salt.states.linux_acl.present(name, acl_type, acl_name='', perms='', recurse=False)`
Ensure a Linux ACL is present

31.27.80 salt.states.locale

Management of languages/locales

Manage the available locales and the system default:

```yaml
default_locale:
    locale.system:
        - name: en_US.UTF-8
        - require:
            - locale: us_locale
```

```yaml
us_locale:
    locale.present:
        - name: en_US.UTF-8
```

`salt.states.locale.present(name)`
Generate a locale if it is not present

New in version 2014.7.0.

- `name` The name of the locale to be present. Some distributions require the charmap to be specified as part of the locale at this point.

`salt.states.locale.system(name)`
Set the locale for the system

- `name` The name of the locale to use
31.27.81 salt.states.lvm

Management of Linux logical volumes

A state module to manage LVMs

```
/dev/sda:
    lvm.pv_present

my_vg:
    lvm.vg_present:
        - devices: /dev/sda

lvroot:
    lvm.lv_present:
        - vgname: my_vg
        - size: 10G
        - stripes: 5
        - stripesize: 8K
```

**salt.states.lvm.lv_absent**(name, vgname=None)
Remove a given existing logical volume from a named existing volume group

- `name` The logical volume to remove
- `vgname` The volume group name

**salt.states.lvm.lv_present**(name, vgname=None, size=None, extents=None, snapshot=None, pv=", **kwargs)
Create a new logical volume

- `name` The name of the logical volume
- `vgname` The volume group name for this logical volume
- `size` The initial size of the logical volume
- `extents` The number of logical extents to allocate
- `snapshot` The name of the snapshot
- `pv` The physical volume to use
- `kwargs` Any supported options to lvcreate. See `linux_lvm` for more details.

**salt.states.lvm.pv_absent**(name)
Ensure that a Physical Device is not being used by lvm

- `name` The device name to initialize.

**salt.states.lvm.pv_present**(name, **kwargs)
Set a physical device to be used as an LVM physical volume

- `name` The device name to initialize.
- `kwargs` Any supported options to pvcreate. See `linux_lvm` for more details.

**salt.states.lvm.vg_absent**(name)
Remove an LVM volume group

- `name` The volume group to remove

**salt.states.lvm.vg_present**(name, devices=None, **kwargs)
Create an LVM volume group
name The volume group name to create

devices A list of devices that will be added to the volume group

kwargs Any supported options to vgcreate. See `linux_lvm` for more details.

31.27.82 salt.states.lvs_server

Management of LVS (Linux Virtual Server) Real Server

```
salt.states.lvs_server.absent(name, protocol=None, service_address=None, server_address=None)
```

Ensure the LVS Real Server in specified service is absent.

- **name** The name of the LVS server.
- **protocol** The service protocol (only support `tcp`, `udp` and `fwmark` service).
- **service_address** The LVS service address.
- **server_address** The LVS real server address.

```
salt.states.lvs_server.present(name, protocol=None, service_address=None, server_address=None, packet_forward_method='dr', weight=1)
```

Ensure that the named service is present.

- **name** The LVS server name
- **protocol** The service protocol
- **service_address** The LVS service address
- **server_address** The real server address.
- **packet_forward_method** The LVS packet forwarding method (`dr` for direct routing, `tunnel` for tunneling, `nat` for network access translation).
- **weight** The capacity of a server relative to the others in the pool.

```
.lvrs:
  lvs_server.present:
    - protocol: tcp
    - service_address: 1.1.1.1:80
    - server_address: 192.168.0.11:8080
    - packet_forward_method: dr
    - weight: 10
```

31.27.83 salt.states.lvs_service

Management of LVS (Linux Virtual Server) Service

```
salt.states.lvs_service.absent(name, protocol=None, service_address=None)
```

Ensure the LVS service is absent.

- **name** The name of the LVS service
- **protocol** The service protocol
- **service_address** The LVS service address
salt.states.lvs_service.present(name, protocol=None, service_address=None, scheduler='wlc')

Ensure that the named service is present.

name  The LVS service name
protocol  The service protocol
service_address  The LVS service address
scheduler  Algorithm for allocating TCP connections and UDP datagrams to real servers.

```
lvstest:
  lvs_service.present:
    - service_address: 1.1.1.1:80
    - protocol: tcp
    - scheduler: rr
```

31.27.84 salt.states.lxc

Manage Linux Containers

class lxc_absent:

salt.states.lxc.absent(name, stop=False, path=None)

Ensure a container is not present, destroying it if present

name  Name of the container to destroy
stop  stop before destroying default: false

New in version 2015.5.2.

path  path to the container parent default: /var/lib/lxc (system default)

New in version 2015.8.0.

```
web01:
  lxc.absent
```

class lxc_cloned:

salt.states.lxc.cloned(name, orig, snapshot=True, size=None, vgname=None, path=None, profile=None)

Deprecated since version 2015.5.0: Use lxc.present

salt.states.lxc.created(name, **kwargs)

Deprecated since version 2015.5.0: Use lxc.present

salt.states.lxc.edited_conf(name, lxc_conf=None, lxc_conf_unset=None)

Warning: This state is unsuitable for setting parameters that appear more than once in an LXC config file, or parameters which must appear in a certain order (such as when configuring more than one network interface). It is slated to be replaced, and as of version 2015.5.0 it is deprecated.

Edit LXC configuration options

path  path to the container parent default: /var/lib/lxc (system default)

New in version 2015.8.0.

```
setconf:
  lxc.edited_conf:
    - name: ubuntu
      lxc_conf:
        - network.ipv4.ip: 10.0.3.6
```
- lxc_conf_unset:
  - lxc.utsname

salt.states.lxc.frozen(name, start=True, path=None)

New in version 2015.5.0.
Ensure that a container is frozen

**Note:** This state does not enforce the existence of the named container, it just freezes the container if it is running. To ensure that the named container exists, use `lxc.present`.

<table>
<thead>
<tr>
<th>name</th>
<th>The name of the container</th>
</tr>
</thead>
<tbody>
<tr>
<td>path</td>
<td>path to the container parent default: /var/lib/lxc (system default)</td>
</tr>
<tr>
<td>start</td>
<td>[True] Start container first, if necessary. If False, then this state will fail if the container is not running.</td>
</tr>
</tbody>
</table>

```
web01:
  lxc.frozen
web02:
  lxc.frozen:
    - start: False
```

salt.states.lxc.present(name, running=None, clone_from=None, snapshot=False, profile=None, network_profile=None, template=None, config=None, fstype=None, size=None, backing=None, vgname=None, lvname=None, path=None)

Changed in version 2015.8.0: The `lxc.created` state has been renamed to `lxc.present`, and the `lxc.cloned` state has been merged into this state.

Create the named container if it does not exist

<table>
<thead>
<tr>
<th>name</th>
<th>The name of the container to be created</th>
</tr>
</thead>
<tbody>
<tr>
<td>path</td>
<td>path to the container parent default: /var/lib/lxc (system default)</td>
</tr>
<tr>
<td>running</td>
<td>[False]</td>
</tr>
<tr>
<td></td>
<td>• If True, ensure that the container is running</td>
</tr>
<tr>
<td></td>
<td>• If False, ensure that the container is stopped</td>
</tr>
<tr>
<td></td>
<td>• If None, do nothing with regards to the running state of the container</td>
</tr>
</tbody>
</table>

New in version 2015.8.0.

| clone_from | Create named container as a clone of the specified container |
| snapshot   | [False] Use Copy On Write snapshots (LVM). Only supported with clone_from. |
| profile    | Profile to use in container creation (see the LXC Tutorial for more information). Values in a profile will be overridden by the parameters listed below. |
| network_profile | Network Profile to use in container creation (see the LXC Tutorial for more information). Values in a profile will be overridden by the parameters listed below. |

New in version 2015.5.2.
Container Creation Arguments

**template**  The template to use. E.g., `ubuntu` or `fedora`. Conflicts with the `image` argument.

**Note:** The **download** template requires the following three parameters to be defined in `options`:
- `dist` - The name of the distribution
- `release` - Release name/version
- `arch` - Architecture of the container

The available images can be listed using the `lxc.images` function.

**options**

New in version 2015.5.0.

Template-specific options to pass to the lxc-create command. These correspond to the long options (ones beginning with two dashes) that the template script accepts. For example:

```
web01:
  lxc.present:
    - template: download
    - options:
      dist: centos
      release: 6
      arch: amd64
```

Remember to double-indent the options, due to *how PyYAML works*.

**image**  A tar archive to use as the rootfs for the container. Conflicts with the `template` argument.

**backing**  The type of storage to use. Set to `lvm` to use an LVM group. Defaults to filesystem within `/var/lib/lxc`.

**fstype**  Filesystem type to use on LVM logical volume

**size**  Size of the volume to create. Only applicable if `backing` is set to `lvm`.

**vgname**  [lxc] Name of the LVM volume group in which to create the volume for this container. Only applicable if `backing` is set to `lvm`.

**lvname**  Name of the LVM logical volume in which to create the volume for this container. Only applicable if `backing` is set to `lvm`.

**salt.states.lxc.running(name, restart=False, path=None)**

Changed in version 2015.5.0: The `lxc.started` state has been renamed to `lxc.running`.

Ensure that a container is running

**Note:** This state does not enforce the existence of the named container, it just starts the container if it is not running. To ensure that the named container exists, use `lxc.present`.

**name**  The name of the container

**path**  path to the container parent default: `/var/lib/lxc` (system default)

   New in version 2015.8.0.

**restart**  [False] Restart container if it is already running
salt.states.lxc.set_pass(name, **kwargs)
    Deprecated since version 2015.5.0.
    This state function has been disabled, as it did not conform to design guidelines. Specifically, due to the fact that
    lxc.set_password uses chpasswd(8) to set the password, there was no method to make this action
    idempotent (in other words, the password would be changed every time). This makes this state redundant,
    since the following state will do the same thing:

    ```
    setpass:
        module.run:
            - name: set_pass
            - m_name: root
            - password: secret
    ```

salt.states.lxc.started(name, path=None, restart=False)
    Deprecated since version 2015.5.0: Use lxc.running

salt.states.lxc.stopped(name, kill=False, path=None)
    Ensure that a container is stopped

    **Note:** This state does not enforce the existence of the named container, it just stops the container if it running
    or frozen. To ensure that the named container exists, use lxc.present, or use the lxc.absent state to
    ensure that the container does not exist.

    **name**  The name of the container
    **path**  path to the container parent default: /var/lib/lxc (system default)
      New in version 2015.8.0.
    **kill**  [False] Do not wait for the container to stop, kill all tasks in the container. Older LXC versions will stop
    containers like this irrespective of this argument.
      New in version 2015.5.0.

web01:
    lxc.stopped

31.27.85  salt.states.makeconf

Management of Gentoo make.conf

A state module to manage Gentoo’s make.conf file

makeopts:
    makeconf.present:
        - value: '-j3'

salt.states.makeconf.absent(name)
    Verify that the variable is not in the make.conf.
name  The variable name. This will automatically be converted to upper case since variables in make.conf are in upper case

```
salt.states.makeconf.present(name, value=None, contains=None, excludes=None)
```
Verify that the variable is in the make.conf and has the provided settings. If value is set, contains and excludes will be ignored.

- **name**  The variable name. This will automatically be converted to upper case since variables in make.conf are in upper case
- **value**  Enforce that the value of the variable is set to the provided value
- **contains**  Enforce that the value of the variable contains the provided value
- **excludes**  Enforce that the value of the variable does not contain the provided value.

### 31.27.86  salt.states.mdadm

**Managing software RAID with mdadm**

A state module for creating or destroying software RAID devices.

```
/dev/md0:
    raid.present:
      - level: 5
      - devices:
        - /dev/xvdd
        - /dev/xvde
        - /dev/xvdf
      - chunk: 256
      - run: True
```

```
salt.states.mdadm.absent(name)
```
Verify that the raid is absent

- **name**  The name of raid device to be destroyed

```
/dev/md0:
    raid:
      - absent
```

```
salt.states.mdadm.present(name, level, devices, **kwargs)
```
Verify that the raid is present

Changed in version 2014.7.0.

- **name**  The name of raid device to be created
- **level**  The RAID level to use when creating the raid.
- **devices**  A list of devices used to build the array.

Example:

```
/dev/md0:
    raid.present:
      - level: 5
      - devices:
        - /dev/xvdd
        - /dev/xvde
        - /dev/xvdf
```
31.27.87  salt.states.memcached

States for Management of Memcached Keys

New in version 2014.1.0.

salt.states.memcached.absent(name, value=None, host='127.0.0.1', port=11211, time=0)
   Ensure that a memcached key is not present.
   name  The key
   value [None] If specified, only ensure that the key is absent if it matches the specified value.
   host  The memcached server IP address
   port  The memcached server port

foo:
   memcached.absent

bar:
   memcached.absent:
      - host: 10.0.0.1

salt.states.memcached.managed(name, value=None, host='127.0.0.1', port=11211, time=0, min_compress_len=0)
   Manage a memcached key.
   name  The key to manage
   value  The value to set for that key
   host  The memcached server IP address
   port  The memcached server port

   foo:
      memcached.managed:
         - value: bar

31.27.88  salt.states.modjk

State to control Apache modjk

salt.states.modjk.worker_activated(name, workers=None, profile='default')
   Activate all the workers in the modjk load balancer

   Example:

   loadbalancer:
      modjk.worker_activated:
         - workers:
            - app1
            - app2
salt.states.modjk\texttt{.worker\_disabled}(name, workers=None, profile='default')

Disable all the workers in the modjk load balancer

Example:

```
loadbalancer:
  modjk.worker\_disabled:
    - workers:
      - app1
      - app2
```

salt.states.modjk\texttt{.worker\_recover}(name, workers=None, profile='default')

Recover all the workers in the modjk load balancer

Example:

```
loadbalancer:
  modjk.worker\_recover:
    - workers:
      - app1
      - app2
```

salt.states.modjk\texttt{.worker\_stopped}(name, workers=None, profile='default')

Stop all the workers in the modjk load balancer

Example:

```
loadbalancer:
  modjk.worker\_stopped:
    - workers:
      - app1
      - app2
```

31.27.89 salt.states.modjk\_worker

Manage modjk workers

Send commands to a modjk load balancer via the peer system.

This module can be used with the \texttt{prereq} requisite to remove/add the worker from the load balancer before deploying/restarting service.

Mandatory Settings:

- The minion needs to have permission to publish the \texttt{modjk.*} functions (see \texttt{here} for information on configuring peer publishing permissions)
- The modjk load balancer must be configured as stated in the \texttt{modjk} execution module \texttt{documentation}

salt.states.modjk\_worker\texttt{.activate}(name, lbn, target, profile='default', expr\_form='glob')

Activate the named worker from the lbn load balancers at the targeted minions

Example:

```
disable\_before\_deploy:
  modjk\_worker\_activate:
    - name: {{\ grains['id'] }}
    - lbn: application
    - target: 'roles:balancer'
    - expr\_form: grain
```
salt.states.modjk_worker.enable(name, lbn, target, profile='default', expr_form='glob')

Disable the named worker from the lbn load balancers at the targeted minions. The worker will get traffic only for current sessions and won't get new ones.

Example:

```python
disable-before-deploy:
    modjk_worker.enable:
        - name: {{ grains['id'] }}
        - lbn: application
        - target: 'roles:balancer'
        - expr_form: grain
```

salt.states.modjk_worker.stop(name, lbn, target, profile='default', expr_form='glob')

Stop the named worker from the lbn load balancers at the targeted minions. The worker won't get any traffic from the lbn.

Example:

```python
disable-before-deploy:
    modjk_worker.stop:
        - name: {{ grains['id'] }}
        - lbn: application
        - target: 'roles:balancer'
        - expr_form: grain
```

31.27.90 salt.states.module

Execution of Salt modules from within states

These states allow individual execution module calls to be made via states. To call a single module function use a module.run state:

```python
mine.send:
    module.run:
        - name: network.interfaces
```

Note that this example is probably unnecessary to use in practice, since the mine_functions and mine_interval config parameters can be used to schedule updates for the mine (see here for more info).

It is sometimes desirable to trigger a function call after a state is executed, for this the module.wait state can be used:

```python
mine.send:
    module.wait:
        - name: network.interfaces
        - watch:
            - file: /etc/network/interfaces
```

All arguments that the module state does not consume are passed through to the execution module function being executed:

```python
fetch_out_of_band:
    module.run:
        - name: git.fetch
        - cwd: /path/to/my/repo
        - user: myuser
        - opts: '--all'
```
Due to how the state system works, if a module function accepts an argument called, name, then m_name must be used to specify that argument, to avoid a collision with the name argument.

Here is a list of keywords hidden by the state system, which must be prefixed with m_: * fun * name * names * state

For example:

```yaml
disable_nfs:
  module.run:
    - name: service.disable
    - m_name: nfs
```

Note that some modules read all or some of the arguments from a list of keyword arguments. For example:

```yaml
mine.send:
  module.run:
    - func: network.ip_addrs
    - kwargs:
        interface: eth0
```

cloud.create: module.run: - func: cloud.create - provider: test-provider - m_names:

- test-vlad

salt.states.module.mod_watch(name, **kwargs)
  Run a single module function
  name The module function to execute
  returner Specify the returner to send the return of the module execution to
  **kwargs Pass any arguments needed to execute the function

salt.states.module.run(name, **kwargs)
  Run a single module function
  name The module function to execute
  returner Specify the returner to send the return of the module execution to
  **kwargs Pass any arguments needed to execute the function

salt.states.module.wait(name, **kwargs)
  Run a single module function only if the watch statement calls it
  name The module function to execute
  **kwargs Pass any arguments needed to execute the function

Note: Like the cmd.run state, this state will return True but not actually execute, unless one of the following two things happens:

1. The state has a watch requisite, and the state which it is watching changes.
2. Another state has a watch_in requisite which references this state, and the state wth the watch_in changes.
31.27.91 salt.states.mongodb_database

Management of Mongodb databases

Only deletion is supported, creation doesn't make sense and can be done using mongodb_user.present

```python
salt.states.mongodb_database.absent(name, user=None, password=None, host=None, port=None)
```

Ensure that the named database is absent

- **name**: The name of the database to remove
- **user**: The user to connect as (must be able to create the user)
- **password**: The password of the user
- **host**: The host to connect to
- **port**: The port to connect to

31.27.92 salt.states.mongodb_user

Management of Mongodb users

**Note:** This module requires PyMongo to be installed.

```python
salt.states.mongodb_user.absent(name, user=None, password=None, host=None, port=None, database='admin')
```

Ensure that the named user is absent

- **name**: The name of the user to remove
- **user**: MongoDB user with sufficient privilege to create the user
- **password**: Password for the admin user specified by the **user** parameter
- **host**: The hostname/IP address of the MongoDB server
- **port**: The port on which MongoDB is listening
- **database**: The database from which to remove the user specified by the **name** parameter

```python
salt.states.mongodb_user.present(name, passwd, database='admin', user=None, password=None, host='localhost', port=27017)
```

Ensure that the user is present with the specified properties

- **name**: The name of the user to manage
- **passwd**: The password of the user to manage
- **user**: MongoDB user with sufficient privilege to create the user
- **password**: Password for the admin user specified with the **user** parameter
- **host**: The hostname/IP address of the MongoDB server
- **port**: The port on which MongoDB is listening
- **database**: The database in which to create the user

**Note:** If the database doesn't exist, it will be created.

Example:
mongouser-myapp:
    mongodb_user.present:
    - name: myapp
    - passwd: password-of-myapp
    # Connect as admin:sekrit
    - user: admin
    - password: sekrit

31.27.93  salt.states.monit

Monit state

Manage monit states

monit_enable_service_monitoring:
    monit.monitor:
        - name: service

monit_disable_service_monitoring:
    monit.unmonitor:
        - name: service

Note: Use of these states require that the monit execution module is available.

salt.states.monit.monitor(name)
    Get the summary from module monit and try to see if service is being monitored. If not then monitor the service.
	salt.states.monit.unmonitor(name)
    Get the summary from module monit and try to see if service is being monitored. If it is then stop monitoring the service.

31.27.94  salt.states.mount

Mounting of filesystems

Mount any type of mountable filesystem with the mounted function:

/mnt/sdb:
    mount.mounted:
        - device: /dev/sdb1
        - fstype: ext4
        - mkmnt: True
        - opts: 
            - defaults

/srv/bigdata:
    mount.mounted:
        - device: UUID=066e0200-2867-4ebe-b9e6-f30026ca2314
        - fstype: xfs
        - opts: nobootwait,noatime,nodiratime,nobarrier,logbufs=8
salt.states.mount.mod_watch(name, user=None, **kwargs)
    The mounted watcher, called to invoke the watch command.
    name The name of the mount point

salt.states.mount.mounted(name, device, fstype, mkmnt=False, opts='defaults', dump=0, pass_num=0, config='/etc/fstab', persist=True, mount=True, user=None, match_on='auto')
    Verify that a device is mounted
    name The path to the location where the device is to be mounted
    device The device name, typically the device node, such as /dev/sdb1 or UUID=066e0200-2867-4ebe-b9e6-f30026ca2314 or LABEL=DATA
    fstype The filesystem type, this will be xfs, ext2/3/4 in the case of classic filesystems, and fuse in the case of fuse mounts
    mkmnt If the mount point is not present then the state will fail, set mkmnt: True to create the mount point if it is otherwise not present
    opts A list object of options or a comma delimited list
    dump The dump value to be passed into the fstab, Default is 0
    pass_num The pass value to be passed into the fstab, Default is 0
    config Set an alternative location for the fstab, Default is /etc/fstab
    persist Set if the mount should be saved in the fstab, Default is True
    mount Set if the mount should be mounted immediately, Default is True
    user The user to own the mount; this defaults to the user salt is running as on the minion
    match_on A name or list of fstab properties on which this state should be applied. Default is auto, a special value indicating to guess based on fstype. In general, auto matches on name for recognized special devices and device otherwise.

salt.states.mount.swap(name, persist=True, config='''/etc/fstab''')
    Activates a swap device
    /root/swapfile:
    mount.swap

Note: swap does not currently support LABEL

salt.states.mount.unmounted(name, device, config='''/etc/fstab''', persist=False, user=None)
    New in version 0.17.0.
    Verify that a device is not mounted
    name The path to the location where the device is to be unmounted from
    New in version 2015.5.0.
    device The device to be unmounted.
    config Set an alternative location for the fstab, Default is /etc/fstab
persist Set if the mount should be purged from the fstab, Default is False
user The user to own the mount; this defaults to the user salt is running as on the minion

31.27.95 salt.states.mysql_database

Management of MySQL databases (schemas)

depends
  • MySQLdb Python module

configuration See salt.modules.mysql for setup instructions.

The mysql_database module is used to create and manage MySQL databases. Databases can be set as either absent or present.

frank:
  mysql_database.present

salt.states.mysql_database.absent(name, "connection_args")
  Ensure that the named database is absent
  name The name of the database to remove

salt.states.mysql_database.present(name, "connection_args")
  Ensure that the named database is present with the specified properties
  name The name of the database to manage

31.27.96 salt.states.mysql_grants

Management of MySQL grants (user permissions)

depends
  • MySQLdb Python module

configuration See salt.modules.mysql for setup instructions.

The mysql_grants module is used to grant and revoke MySQL permissions.

The name you pass in purely symbolic and does not have anything to do with the grant itself.

The database parameter needs to specify a `priv_level` in the same specification as defined in the MySQL documentation:

  • *
  • **
  • db_name.*
  • db_name.tbl_name
  • etc...

This state is not able to set password for the permission from the specified host. See salt.states.mysql_user for further instructions.
frank_exampledb:
  mysql_grants.present:
  - grant: select, insert, update
  - database: exampledb.*
  - user: frank
  - host: localhost

frank_otherdb:
  mysql_grants.present:
  - grant: all privileges
  - database: otherdb.*
  - user: frank

restricted_singletable:
  mysql_grants.present:
  - grant: select
  - database: somedb.sometable
  - user: joe

salt.states.mysql_grants.absent(name, grant=None, database=None, user=None, host='localhost',
                                   grant_option=False, escape=True, **connection_args)

Ensure that the grant is absent

name  The name (key) of the grant to add
grant  The grant priv_type (i.e. select, insert, update OR all privileges)
database  The database priv_level (i.e. db.tbl OR db.*)
user  The user to apply the grant to
host  The network/host that the grant should apply to

salt.states.mysql_grants.present(name, grant=None, database=None, user=None, host='localhost',
                                   grant_option=False, escape=True, revoke_first=False, ssl_option=False, **connection_args)

Ensure that the grant is present with the specified properties

name  The name (key) of the grant to add
grant  The grant priv_type (i.e. select, insert, update OR all privileges)
database  The database priv_level (i.e. db.tbl OR db.*)
user  The user to apply the grant to
host  The network/host that the grant should apply to

grant_option  Adds the WITH GRANT OPTION to the defined grant. Default is False
escape  Defines if the database value gets escaped or not. Default is True
revoke_first  By default, MySQL will not do anything if you issue a command to grant privileges that are more restrictive than what’s already in place. This effectively means that you cannot downgrade permissions without first revoking permissions applied to a db.table/user pair first.

To have Salt forcibly revoke perms before applying a new grant, enable the `revoke_first` options.

WARNING: This will remove permissions for a database before attempting to apply new permissions. There is no guarantee that new permissions will be applied correctly which can leave your database security in an unknown and potentially dangerous state. Use with caution!

Default is False
ssl_option  Adds the specified ssl options for the connecting user as requirements for this grant. Value is a list
of single-element dicts corresponding to the list of ssl options to use.

Possible key/value pairings for the dicts in the value:

- SSL: True
- X509: True
- SUBJECT: <subject>
- ISSUER: <issuer>
- CIPHER: <cipher>

The non-boolean ssl options take a string as their values, which should be an appropriate value as specified
by the MySQL documentation for these options.

Default is False (no ssl options will be used)

31.27.97  salt.states.mysql_query

Execution of MySQL queries

New in version 2014.7.0.

depends

- MySQLdb Python module

configuration  See salt.modules.mysql for setup instructions.

The mysql_query module is used to execute queries on MySQL databases. Its output may be stored in a file or in a
grain.

query_id:

```python
mysql_query.run
  - database: my_database
  - query: "SELECT * FROM table;"
  - output: "/tmp/query_id.txt"
```

salt.states.mysql_query.run(name, database, query, output=None, grain=None, key=None, overwrite=True, **connection_args)

Execute an arbitrary query on the specified database

name  Used only as an ID

database  The name of the database to execute the query on

query  The query to execute

output  grain: output in a grain other: the file to store results None: output to the result comment (default)

grain:  grain to store the output (need output=grain)

key:  the specified grain will be treated as a dictionary, the result of this state will be stored under the specified

overwrite:  The file or grain will be overwritten if it already exists (default)
31.27.98  salt.states.mysql_user

Management of MySQL users

depends

- MySQLdb Python module

configuration  See salt.modules.mysql for setup instructions.

frank:
  mysql_user.present:
    - host: localhost
    - password: bobcat

New in version 0.16.2: Authentication overrides have been added.

The MySQL authentication information specified in the minion config file can be overridden in states using the following arguments: `connection_host`, `connection_port`, `connection_user`, `connection_pass`, `connection_db`, `connection_unix_socket`, `connection_default_file` and `connection_charset`.

frank:
  mysql_user.present:
    - host: localhost
    - password: "bob@cat"
    - connection_user: someuser
    - connection_pass: somepass
    - connection_charset: utf8
    - saltenv:
      - LC_ALL: "en_US.utf8"

This state is not able to grant permissions for the user. See salt.states.mysql_grants for further instructions.

salt.states.mysql_user.absent(name, host='localhost', **connection_args)

Ensure that the named user is absent

   name  The name of the user to remove

salt.states.mysql_user.present(name, host='localhost', password=None, password_hash=None, allow_passwordless=False, unix_socket=False, **connection_args)

Ensure that the named user is present with the specified properties. A passwordless user can be configured by omitting `password` and `password_hash`, and setting `allow_passwordless` to True.

   name  The name of the user to manage

   host  Host for which this user/password combo applies

   password  The password to use for this user. Will take precedence over the `password_hash` option if both are specified.

   password_hash  The password in hashed form. Be sure to quote the password because YAML doesn't like the `*`. A password hash can be obtained from the mysql command-line client like so:

```
mysql> SELECT PASSWORD('mypass');
+-------------------------------------------+
| PASSWORD('mypass') |
+-------------------------------------------+
| *6C8989366AEF75BB678AD8EAA7A7FC1176A95CEF4 |
+-------------------------------------------+

1 row in set (0.00 sec)
```
allow_passwordless  If True, then password and password_hash can be omitted to permit a passwordless login.

New in version 0.16.2.

unix_socket  If True and allow_passwordless is True, the unix_socket auth plugin will be used.

31.27.99  salt.states.network

Configuration of network interfaces

The network module is used to create and manage network settings, interfaces can be set as either managed or ignored. By default all interfaces are ignored unless specified.

Note: Prior to version 2014.1.0, only RedHat-based systems (RHEL, CentOS, Scientific Linux, etc.) are supported. Support for Debian/Ubuntu is new in 2014.1.0 and should be considered experimental.

Other platforms are not yet supported.

system:
    network.system:
        - enabled: True
        - hostname: server1.example.com
        - gateway: 192.168.0.1
        - gatewaydev: eth0
        - nozeroconf: True
        - nisdomain: example.com
        - require_reboot: True

eth0:
    network.managed:
        - enabled: True
        - type: eth
        - proto: none
        - ipaddr: 10.1.0.1
        - netmask: 255.255.255.0
        - dns:
            - 8.8.8.8
            - 8.8.4.4

eth0-range0:
    network.managed:
        - type: eth
        - ipaddr_start: 192.168.1.1
        - ipaddr_end: 192.168.1.10
        - clonenum_start: 10
        - mtu: 9000

bond0-range0:
    network.managed:
        - type: eth
        - ipaddr_start: 192.168.1.1
        - ipaddr_end: 192.168.1.10
        - clonenum_start: 10
        - mtu: 9000
eth1.0-range0:
  network.managed:
  - type: eth
  - ipaddr_start: 192.168.1.1
  - ipaddr_end: 192.168.1.10
  - clonenum_start: 10
  - vlan: True
  - mtu: 9000

bond0.1-range0:
  network.managed:
  - type: eth
  - ipaddr_start: 192.168.1.1
  - ipaddr_end: 192.168.1.10
  - clonenum_start: 10
  - vlan: True
  - mtu: 9000

.. note::
  add support of ranged interfaces (vlan, bond and eth) for redhat system,
  Important:type must be eth.

routes:
  network.routes:
  - name: eth0
  - routes:

    - type: bridge
    - proto: dhcp
    - bridge: br0
    - delay: 0
    - ports: eth4
    - bypassfirewall: True
    - use:
      - network: eth4
    - require:
      - network: eth4

system:
  network.system:
    - enabled: True
    - hostname: server1.example.com
    - gateway: 192.168.0.1
    - gatewaydev: eth0
    - nozeroconf: True
    - nisdomain: example.com
    - require_reboot: True
    - apply_hostname: True

.. note::
   Apply changes to hostname immediately.

.. versionadded:: 2015.5.0

Note: When managing bridged interfaces on a Debian or Ubuntu based system, the ports argument is required. Red Hat systems will ignore the argument.

salt.states.network.managed(name, type, enabled=True, **kwargs)
Ensure that the named interface is configured properly.

    name  The name of the interface to manage
    type  Type of interface and configuration.
    enabled  Designates the state of this interface.
    kwargs  The IP parameters for this interface.

salt.states.network.routes(name, **kwargs)
Manage network interface static routes.

    name  Interface name to apply the route to.
    kwargs  Named routes
salt.states.network.system(name, **kwargs)
    Ensure that global network settings are configured properly.
    
    name  Custom name to represent this configuration change.
    
    kwargs  The global parameters for the system.

31.27.100 salt.states.nftables

Management of nftables

This is an nftables-specific module designed to manage Linux firewalls. It is expected that this state module, and other system-specific firewall states, may at some point be deprecated in favor of a more generic firewall state.

httpd:
    nftables.append:
        - table: filter
        - chain: input
        - jump: accept
        - match: state
        - connstate: new
        - dport: 80
        - proto: tcp
        - sport: 1025:65535
        - save: True

httpd:
    nftables.append:
        - table: filter
        - family: ipv6
        - chain: INPUT
        - jump: ACCEPT
        - match: state
        - connstate: NEW
        - dport: 80
        - proto: tcp
        - sport: 1025:65535
        - save: True

httpd:
    nftables.insert:
        - position: 1
        - table: filter
        - chain: INPUT
        - jump: ACCEPT
        - match: state
        - connstate: NEW
        - dport: 80
        - proto: tcp
        - sport: 1025:65535
        - save: True

httpd:
    nftables.insert:
        - position: 1
        - table: filter
        - family: ipv6
        - chain: INPUT
- jump: ACCEPT
  - match: state
  - connstate: NEW
  - dport: 80
  - proto: tcp
  - sport: 1025:65535
  - save: True

httpd:
  nftables.delete:
    - table: filter
    - chain: INPUT
    - jump: ACCEPT
    - match: state
    - connstate: NEW
    - dport: 80
    - proto: tcp
    - sport: 1025:65535
    - save: True

httpd:
  nftables.delete:
    - position: 1
    - table: filter
    - chain: INPUT
    - jump: ACCEPT
    - match: state
    - connstate: NEW
    - dport: 80
    - proto: tcp
    - sport: 1025:65535
    - save: True

httpd:
  nftables.delete:
    - table: filter
    - family: ipv6
    - chain: INPUT
    - jump: ACCEPT
    - match: state
    - connstate: NEW
    - dport: 80
    - proto: tcp
    - sport: 1025:65535
    - save: True

salt.states.nftables.append(name, family='ipv4', **kwargs)

New in version 0.17.0.

Append a rule to a chain

name A user-defined name to call this rule by in another part of a state or formula. This should not be an actual rule.

family Network family, ipv4 or ipv6.

All other arguments are passed in with the same name as the long option that would normally be used for nftables, with one exception: --state is specified as connstate instead of state (not to be confused with ctstate).

salt.states.nftables.chain_absent(name, table='filter', family='ipv4')
New in version 2014.7.0.
Verify the chain is absent.

family Networking family, either ipv4 or ipv6

`salt.states.nftables.chain_present(name, table='filter', table_type=None, hook=None, priority=None, family='ipv4')`

New in version 2014.7.0.
Verify the chain is exist.

name A user-defined chain name.

family Networking family, either ipv4 or ipv6

`salt.states.nftables.delete(name, family='ipv4', **kwargs)`

New in version 2014.7.0.
Delete a rule to a chain

name A user-defined name to call this rule by in another part of a state or formula. This should not be an actual rule.

family Networking family, either ipv4 or ipv6

All other arguments are passed in with the same name as the long option that would normally be used for nftables, with one exception: --state is specified as connstate instead of state (not to be confused with ctstate).

`salt.states.nftables.flush(name, family='ipv4', **kwargs)`

New in version 2014.7.0.
Flush current nftables state

family Networking family, either ipv4 or ipv6

`salt.states.nftables.insert(name, family='ipv4', **kwargs)`

New in version 2014.7.0.
Insert a rule into a chain

name A user-defined name to call this rule by in another part of a state or formula. This should not be an actual rule.

family Networking family, either ipv4 or ipv6

All other arguments are passed in with the same name as the long option that would normally be used for nftables, with one exception: --state is specified as connstate instead of state (not to be confused with ctstate).

31.27.101 salt.states.npm

Installation of NPM Packages

These states manage the installed packages for node.js using the Node Package Manager (npm). Note that npm must be installed for these states to be available, so npm states should include a requisite to a pkg.installed state for the package which provides npm (simply npm in most cases). Example:

```
npm:
  pkg.installed

yaml:
  npm.installed:
```
- require:
  - pkg: npm

salt.states.npm.bootstrap(name, user=None)

  Bootstraps a node.js application.
  
  Will execute `npm install --json` on the specified directory.

  user  The user to run NPM with

    New in version 0.17.0.

salt.states.npm.installed(name, pkgs=None, dir=None, user=None, force_reinstall=False, registry=None, env=None)

  Verify that the given package is installed and is at the correct version (if specified).

  
  coffee-script:
  
    npm.installed:
      - user: someuser

  coffee-script@1.0.1:
    npm.installed: []

  name  The package to install

    Changed in version 2014.7.2: This parameter is no longer lowercased by salt so that case-sensitive NPM package names will work.

  pkgs  A list of packages to install with a single npm invocation; specifying this argument will ignore the name argument

    New in version 2014.7.0.

  dir  The target directory in which to install the package, or None for global installation

  user  The user to run NPM with

    New in version 0.17.0.

  registry  The NPM registry from which to install the package

    New in version 2014.7.0.

  env  A list of environment variables to be set prior to execution. The format is the same as the cmd.run.state function.

    New in version 2014.7.0.

  force_reinstall  Install the package even if it is already installed

salt.states.npm.removed(name, dir=None, user=None)

  Verify that the given package is not installed.

  dir  The target directory in which to install the package, or None for global installation

  user  The user to run NPM with

    New in version 0.17.0.
31.27.102 salt.states.ntp

Management of NTP servers

New in version 2014.1.0.

This state is used to manage NTP servers. Currently only Windows is supported.

```python
win_ntp:
    ntp.managed:
        - servers:
            - pool.ntp.org
            - us.pool.ntp.org
```

```
salt.states.ntp.managed(name, servers=None)

Manage NTP servers

servers  A list of NTP servers
```

31.27.103 salt.states.openstack_config

Manage OpenStack configuration file settings.

```
maintainer  Jeffrey C. Ollie <jeff@ojtech.us>
maturity  new
depsends
platform  linux
```

```
salt.states.openstack_config.absent(name, filename, section, parameter=None)

Ensure a value is not set in an OpenStack configuration file.

filename  The full path to the configuration file
section  The section in which the parameter will be set
parameter (optional)  The parameter to change. If the parameter is not supplied, the name will be used as the parameter.
```

```
salt.states.openstack_config.present(name, filename, section, value, parameter=None)

Ensure a value is set in an OpenStack configuration file.

filename  The full path to the configuration file
section  The section in which the parameter will be set
parameter (optional)  The parameter to change. If the parameter is not supplied, the name will be used as the parameter.
value  The value to set
```

31.27.104 salt.states.pagerduty

Create an Event in PagerDuty

New in version 2014.1.0.

This state is useful for creating events on the PagerDuty service during state runs.
server-warning-message:
pagerduty.create_event:
    - name: 'This is a server warning message'
    - details: 'This is a much more detailed message'
    - service_key: 9abcd123456789efabcde362783cdbus
    - profile: my-pagerduty-account

salt.states.pagerduty.create_event(name, details, service_key, profile)

Create an event on the PagerDuty service

server-warning-message:
pagerduty.create_event:
    - name: 'This is a server warning message'
    - details: 'This is a much more detailed message'
    - service_key: 9abcd123456789efabcde362783cdbus
    - profile: my-pagerduty-account

The following parameters are required:

name  This is a short description of the event.
details  This can be a more detailed description of the event.
service_key  This key can be found by using pagerduty.list_services.
profile  This refers to the configuration profile to use to connect to the PagerDuty service.

31.27.105 salt.states.pagerduty_escalation_policy

Manage PagerDuty escalation policies.

Schedules and users can be referenced by pagerduty ID, or by name, or by email address.

For example:

ensure test escalation policy:
pagerduty_escalation_policy.present:
    - name: bruce test escalation policy
    - escalation_rules:
        - targets:
            - type: schedule
              id: 'bruce test schedule level1'
            - type: user
              id: 'Bruce Sherrod'
              escalation_delay_in_minutes: 15
            - targets:
                - type: schedule
                  id: 'bruce test schedule level2'
                  escalation_delay_in_minutes: 15
                - targets:
                    - type: user
                      id: 'Bruce TestUser1'
                    - type: user
                      id: 'Bruce TestUser2'
                      escalation_delay_in_minutes: 15
                    - type: user
                      id: 'Bruce TestUser3'
                      - type: user
                        id: 'bruce+test4@lyft.com'
                        escalation_delay_in_minutes: 15
salt.states.pagerduty_escalation_policy.absent(profile='pagerduty', subdomain=None, api_key=None, **kwargs)

Ensure that a PagerDuty escalation policy does not exist. Accepts all the arguments that pagerduty_escalation_policy.present accepts; but ignores all arguments except the name.

Name can be the escalation policy id or the escalation policy name.

salt.states.pagerduty_escalation_policy.present(profile='pagerduty', subdomain=None, api_key=None, **kwargs)

Ensure that a pagerduty escalation policy exists. Will create or update as needed.

This method accepts as args everything defined in https://developer.pagerduty.com/documentation/rest/escalation_policies/create. In addition, user and schedule id's will be translated from name (or email address) into PagerDuty unique ids. For example:

```yaml
pagerduty_escalation_policy.present:
  - name: bruce test escalation policy
  - escalation_rules:
    - targets:
      - type: schedule id: `bruce test schedule level1`
      - type: user id: `Bruce Sherrod`

In this example, `Bruce Sherrod` will be looked up and replaced with the PagerDuty id (usually a 7 digit all-caps string, e.g. PX6GQL7)

31.27.106 salt.states.pagerduty_schedule

Manage PagerDuty schedules.

Example:

```yaml
ensure test schedule:
  pagerduty_schedule.present:
    - name: `bruce test schedule level1`
    - schedule: name: `bruce test schedule level1` time_zone: `Pacific Time (US & Canada)`
      schedule_layers:
        - name: `Schedule Layer 1` start: `2015-01-01T00:00:00` users:
          - user: `id`: `Bruce TestUser1`
            member_order: 1
          - user: `id`: `Bruce TestUser2`
            member_order: 2
          - user: `id`: `bruce+test3@lyft.com`
            member_order: 3
```

1802 Chapter 31. Reference
* user: `id': `bruce-test4@lyft.com`

member_order: 4
rotation_virtual_start: `2015-01-01T00:00:00’ priority: 1 rotation_turn_length_seconds: 604800

salt.states.pagerduty_schedule.absent( profile='pagerduty', subdomain=None, api_key=None, **kwargs)

Ensure that a pagerduty schedule does not exist. Name can be pagerduty schedule id or pagerduty schedule name.

salt.states.pagerduty_schedule.present( profile='pagerduty', subdomain=None, api_key=None, **kwargs)

Ensure that a pagerduty schedule exists. This method accepts as args everything defined in https://developer.pagerduty.com/documentation/rest/schedules/create. This means that most arguments are in a dict called `schedule`.

User id's can be pagerduty id, or name, or email address.

31.27.107 salt.states.pagerduty_service

Manage PagerDuty services

Escalation policies can be referenced by pagerduty ID or by namea.

For example:

```

ensure test service

pagerduty_service.present:
  • name: `my service`
  • escalation_policy_id: `my escalation policy'
  • type: nagios

[etc]
```

salt.states.pagerduty_service.absent( profile='pagerduty', subdomain=None, api_key=None, **kwargs)

Ensure a pagerduty service does not exist. Name can be the service name or pagerduty service id.

salt.states.pagerduty_service.present( profile='pagerduty', subdomain=None, api_key=None, **kwargs)

Ensure pagerduty service exists. This method accepts as arguments everything defined in https://developer.pagerduty.com/documentation/rest/services/create

Note that many arguments are mutually exclusive, depending on the `type` argument.

Examples:

```

# create a PagerDuty email service at test-email@DOMAIN.pagerduty.com ensure generic email service exists:

pagerduty_service.present:
  • name: my email service

```

31.27. Full list of builtin state modules 1803
**service**: description: "email service controlled by salt" escalation_policy_id: "my escalation policy" type: "generic_email" service_key: "test-email"

# create a pagerduty service using cloudwatch integration ensure my cloudwatch service exists:

```bash
pagerduty_service.present:
  - name: my cloudwatch service
  - service: escalation_policy_id: "my escalation policy" type: aws_cloudwatch description: "my cloudwatch service controlled by salt"
```

TODO: aws_cloudwatch type should be integrated with boto_sns

### 31.27.108 salt.states.pagerduty_user

Manage PagerDuty users.

Example:

```bash
ensure bruce test user 1:
  pagerduty.user_present:
    - name: 'Bruce TestUser1'
    - email: bruce+test1@lyft.com
    - requester_id: P1GV5NT
```

```bash
salt.states.pagerduty_user.absent(profile='pagerduty', subdomain=None, api_key=None, **kwargs)
```

Ensure pagerduty user does not exist. Name can be pagerduty id, email address, or user name.

```bash
salt.states.pagerduty_user.present(profile='pagerduty', subdomain=None, api_key=None, **kwargs)
```

### 31.27.109 salt.states.pecl

**Installation of PHP Extensions Using pecl**

These states manage the installed pecl extensions. Note that php-pear must be installed for these states to be available, so pecl states should include a requisite to a pkg.installed state for the package which provides pecl (php-pear in most cases). Example:

```bash
php-pear:
  pkg.installed

mongo:
  pecl.installed:
    - require:
      - pkg: php-pear
```

```bash
salt.states.pecl.installed(name, version=None, defaults=False, force=False, preferred_state='stable', **kwargs)
```

New in version 0.17.0.
Make sure that a pecl extension is installed.

**name**  The pecl extension name to install

**version**  The pecl extension version to install. This option may be ignored to install the latest stable version.

**defaults**  Use default answers for extensions such as `pecl_http` which ask questions before installation. Without this option, the `pecl_installed` state will hang indefinitely when trying to install these extensions.

**force**  Whether to force the installed version or not

**preferred_state**  The pecl extension state to install

---

salt.states.pecl.removed(name)

Make sure that a pecl extension is not installed.

**name**  The pecl extension name to uninstall

---

### 31.27.110 salt.states.pip_state

**Installation of Python Packages Using pip**

These states manage system installed python packages. Note that pip must be installed for these states to be available, so pip states should include a requisite to a `pkg.installed` state for the package which provides pip (`python-pip` in most cases). Example:

```
python-pip:
  pkg.installed

virtualenvwrapper:
  pip.installed:
    - require:
      - pkg: python-pip
```

salt.states.pip_state.installed(name, pkgs=None, pip_bin=None, requirements=None, env=None, bin_env=None, use_wheel=False, no_use_wheel=False, log=None, proxy=None, timeout=None, repo=None, editable=None, find_links=None, index_url=None, extra_index_url=None, no_index=False, mirrors=None, build=None, target=None, download=None, download_cache=None, source=None, upgrade=False, force_reinstall=False, ignore_installed=False, exists_action=None, no_deps=False, no_install=False, no_download=False, install_options=None, global_options=None, user=None, no_chown=False, cwd=None, activate=False, pre_releases=False, cert=None, allow_all_external=False, allow_external=None, allow_unverified=False, process_dependency_links=False, env_vars=None, use_vt=False, trusted_host=None)

Make sure the package is installed

---

**Note:** There is a known issue when using pip v1.0 that causes `pip install` to return 1 when executed without arguments. See issue 21845 for details and potential workarounds.

**name**  The name of the python package to install. You can also specify version numbers here using the standard operators `==`, `>`, `<`. If `requirements` is given, this parameter will be ignored.

Example:
django:
  pip.installed:
    - name: django >= 1.6, <= 1.7
    - require:
      - pkg: python-pip

This will install the latest Django version greater than 1.6 but less than 1.7.

requirements Path to a pip requirements file. If the path begins with salt:// the file will be transferred from the master file server.
user The user under which to run pip
use_wheel [False] Prefer wheel archives (requires pip>=1.4)
no_use_wheel [False] Force to not use wheel archives (requires pip>=1.4)
log Log file where a complete (maximum verbosity) record will be kept
proxy Specify a proxy in the form user:passwd@proxy.server:port. Note that the user:password@ is optional and required only if you are behind an authenticated proxy. If you provide user@proxy.server:port then you will be prompted for a password.
timeout Set the socket timeout (default 15 seconds)
editable install something editable (i.e. git+https://github.com/worldcompany/djangoembed.git#egg=djangoembed)
find_links URL to look for packages at
index_url Base URL of Python Package Index
extra_index_url Extra URLs of package indexes to use in addition to index_url
no_index Ignore package index
mirrors Specific mirror URL(s) to query (automatically adds --use-mirrors)
built Unpack packages into build dir
target Install packages into target dir
download Download packages into download instead of installing them
download_cache Cache downloaded packages in download_cache dir
source Check out editable packages into source dir
upgrade Upgrade all packages to the newest available version
force_reinstall When upgrading, reinstall all packages even if they are already up-to-date.
ignore_installed Ignore the installed packages (reinstalling instead)
exists_action Default action when a path already exists: (s)witch, (i)gnore, (w)ipe, (b)ackup
no_deps Ignore package dependencies
no_install Download and unpack all packages, but don't actually install them
no_chOWN When user is given, do not attempt to copy and chown a requirements file
cwd Current working directory to run pip from
activate Activates the virtual environment, if given via bin_env, before running install.

Deprecation since version 2014.7.2: If bin_env is given, pip will already be sourced from that virtualenv, making activate effectively a noop.
pre_releases Include pre-releases in the available versions
cert Provide a path to an alternate CA bundle
allow_all_external Allow the installation of all externally hosted files
allow_external Allow the installation of externally hosted files (comma separated list)
allow_unverified Allow the installation of insecure and unverifiable files (comma separated list)
process_dependency_links Enable the processing of dependency links
bin_env [None] Absolute path to a virtual environment directory or absolute path to a pip executable. The example below assumes a virtual environment has been created at /foo/.virtualenvs/bar.
env_vars Add or modify environment variables. Useful for tweaking build steps, such as specifying INCLUDE or LIBRARY paths in Makefiles, build scripts or compiler calls.
use_vt Use VT terminal emulation (see output while installing)
trusted_host Mark this host as trusted, even though it does not have valid or any HTTPS.
Example:
django:
  pip.installed:
  - name: django >= 1.6, <= 1.7
  - bin_env: /foo/.virtualenvs/bar
  - require:
    - pkg: python-pip

Or
Example:

django:
  pip.installed:
  - name: django >= 1.6, <= 1.7
  - bin_env: /foo/.virtualenvs/bar/bin/pip
  - require:
    - pkg: python-pip

Attention
The following arguments are deprecated, do not use.

pip_bin [None] Deprecated, use bin_env
env [None] Deprecated, use bin_env

Changed in version 0.17.0: use_wheel option added.

install_options
Extra arguments to be supplied to the setup.py install command. If you are using an option with
a directory path, be sure to use absolute path.

Example:

django:
  pip.installed:
  - name: django
  - install_options:
    - --prefix=/blah
  - require:
    - pkg: python-pip

global_options Extra global options to be supplied to the setup.py call before the install command.

    New in version 2014.1.3.

Attention
As of Salt 0.17.0 the pip state needs an importable pip module. This usually means having the system's pip
package installed or running Salt from an active virtualenv.

The reason for this requirement is because pip already does a pretty good job parsing its own requirements.
It makes no sense for Salt to do pip requirements parsing and validation before passing them to the pip
library. It's functionality duplication and it's more error prone.

Attention
Please set reload_modules: True to have the salt minion import this module after installation.
Example:

```python
pyopenssl:
    pip.installed:
        - name: pyOpenSSL
        - reload_modules: True
        - exists_action: i
```

```
salt.states.pip_state.removed(name, requirements=None, bin_env=None, log=None, proxy=None, timeout=None, user=None, cwd=None, use_vt=False)
```

Make sure that a package is not installed.

- **name** The name of the package to uninstall
- **user** The user under which to run pip
- **bin_env** [None] the pip executable or virtualenv to use
- **use_vt** Use VT terminal emulation (see output while installing)

```
salt.states.pip_state.uptodate(name, bin_env=None, user=None, cwd=None, use_vt=False)
```

New in version 2015.5.0.

Verify that the system is completely up to date.

- **name** The name has no functional value and is only used as a tracking reference
- **user** The user under which to run pip
- **bin_env** the pip executable or virtualenv to use
- **use_vt** Use VT terminal emulation (see output while installing)

### 31.27.111 salt.states.pkg

**Installation of packages using OS package managers such as yum or apt-get**

Salt can manage software packages via the pkg state module, packages can be set up to be installed, latest, removed and purged. Package management declarations are typically rather simple:

```
vim:
    pkg.installed
```

A more involved example involves pulling from a custom repository.

```
base:
    pkgrepo.managed:
        - humanname: Logstash PPA
        - name: ppa:wolfnet/logstash
        - dist: precise
        - file: /etc/apt/sources.list.d/logstash.list
        - keyid: 28B04E4A
        - keyserver: keyserver.ubuntu.com

logstash:
    pkg.installed
```

```
    fromrepo: ppa:wolfnet/logstash
```

```
Multiple packages can also be installed with the use of the pkgs state module
```

```
dotdeb.repo:
    pkgrepo.managed:
        - humanname: Dotdeb
```

```
```
- name: deb http://packages.dotdeb.org wheezy-php55 all
- dist: wheezy-php55
- file: /etc/apt/sources.list.d/dotdeb.list
- keyid: 89DF5277
- keyserver: keys.gnupg.net
- refresh_db: true

code

```python
php.packages:
  pkg.installed:
    - fromrepo: wheezy-php55
    - pkgs:
      - php5-fpm
      - php5-cli
      - php5-curl
```

**Warning:** Package names are currently case-sensitive. If the minion is using a package manager which is not case-sensitive (such as `pkng`), then this state will fail if the proper case is not used. This will be addressed in a future release of Salt.

salt.states.pkg.group_installed(name, skip=None, include=None, **kwargs)

New in version 2015.8.0.

Ensure that an entire package group is installed. This state is only supported for the `yum` package manager.

- **skip** Packages that would normally be installed by the package group (``default`` packages), which should not be installed.

  Load Balancer:
  pkg.group_installed:
    - skip:
      - piranha

- **include** Packages which are included in a group, which would not normally be installed by a `yum groupinstall` (``optional`` packages). Note that this will not enforce group membership; if you include packages which are not members of the specified groups, they will still be installed. Can be passed either as a comma-separated list or a python list.

  Load Balancer:
  pkg.group_installed:
    - include:
      - haproxy

**Note:** Because this is essentially a wrapper around `pkg.install`, any argument which can be passed to `pkg.install` may also be included here, and it will be passed along wholesale.

salt.states.pkg.installed(name, version=None, refresh=None, fromrepo=None, skip_verify=False, skip_suggestions=False, pkgs=None, sources=None, allow_updates=False, pkg_verify=False, normalize=True, **kwargs)

Ensure that the package is installed, and that it is the correct version (if specified).

**Parameters**

- **name** *(str)* -- The name of the package to be installed. This parameter is ignored if either `pkgs` or `sources` is used. Additionally, please note that this option can only be used to install packages from a software repository. To install a package file manually, use the `sources` option detailed below.

- **version** *(str)* -- Install a specific version of a package. This option is ignored if either `pkgs` or `sources` is used. Currently, this option is supported for the following pkg providers: `apt`, `ebuild`, `pacman`, `yumpkg`, and `zypper`. The version number
includes the release designation where applicable, to allow Salt to target a specific release of a given version. When in doubt, using the pkg.latest_version function for an uninstalled package will tell you the version available.

```
# salt myminion pkg.latest_version httpd
myminion:
  2.2.15-30.el6.centos
```

Also, while this function is not yet implemented for all pkg frontends, pkg.list_repo_pkgs will show all versions available in the various repositories for a given package, irrespective of whether or not it is installed.

```
# salt myminion pkg.list_repo_pkgs httpd
myminion:
  ----------
  base:
    |_  ----------
    |httpd:
    2.2.15-29.el6.centos
  updates:
    |_  ----------
    |httpd:
    2.2.15-30.el6.centos
```

The version strings returned by either of these functions can be used as version specifiers in pkg states.

- **refresh (bool)** -- Update the repo database of available packages prior to installing the requested package.

- **fromrepo (str)** -- Specify a repository from which to install

**Note:** Distros which use APT (Debian, Ubuntu, etc.) do not have a concept of repositories, in the same way as YUM-based distros do. When a source is added, it is assigned to a given release. Consider the following source configuration:

```
deb http://ppa.launchpad.net/saltstack/salt/ubuntu precise main
```

The packages provided by this source would be made available via the precise release, therefore fromrepo would need to be set to precise for Salt to install the package from this source.

Having multiple sources in the same release may result in the default install candidate being newer than what is desired. If this is the case, the desired version must be specified using the version parameter.

If the pkgs parameter is being used to install multiple packages in the same state, then instead of using version, use the method of version specification described in the Multiple Package Installation Options section below.

Running the shell command `apt-cache policy pkgname` on a minion can help elucidate the APT configuration and aid in properly configuring states:

```
root@saltmaster:~# salt ubuntu01 cmd.run 'apt-cache policy ffmpeg'
ubuntu01:
  ffmpeg:
    Installed: (none)
    Candidate: 7:0.10.11-1~precise1
```
Version table:

- 7:0.10.11-1-precise1 0
  http://ppa.launchpad.net/jon-severinsson/ffmpeg/ubuntu/ precise/main amd64 Packages
- 4:0.8.10-0ubuntu0.12.04.1 0
  http://us.archive.ubuntu.com/ubuntu/ precise-updates/main amd64 Packages
- 4:0.8.1-0ubuntu1 0
  http://us.archive.ubuntu.com/ubuntu/ precise/main amd64 Packages
- 4:0.8.10-0ubuntu0.12.04.1 0
  http://security.ubuntu.com/ubuntu/ precise-security/main amd64 Packages

The release is located directly after the source's URL. The actual release name is the part before the slash, so to install version `4:0.8.10-0ubuntu0.12.04.1` either `precise-updates` or `precise-security` could be used for the `fromrepo` value.

- **skip_verify** *(bool)* -- Skip the GPG verification check for the package to be installed

- **skip_suggestions** *(bool)* -- Force strict package naming. Disables lookup of package alternatives.

  New in version 2014.1.1.

- **pkgs** *(list)* -- A list of packages to install from a software repository. All packages listed under `pkgs` will be installed via a single command.

  Example:

  ```
  mypkgs:
  pkg.installed:
  - pkgs:
    - foo
    - bar
    - baz
    - hold: True
  ```

  **NOTE:** For `apt`, `ebuild`, `pacman`, `yumpkg`, and `zypper`, version numbers can be specified in the `pkgs` argument. For example:

  ```
  mypkgs:
  pkg.installed:
  - pkgs:
    - foo
    - bar: 1.2.3-4
    - baz
  ```

  Additionally, `ebuild`, `pacman` and `zypper` support the `<`, `<=`, `>=`, and `>` operators for more control over what versions will be installed. For example:

  ```
  mypkgs:
  pkg.installed:
  - pkgs:
    - foo
    - bar: '>=1.2.3-4'
    - baz
  ```

  **NOTE:** When using comparison operators, the expression must be enclosed in quotes to avoid a YAML render error.
With `ebuild` is also possible to specify a use flag list and/or if the given packages should be in package.accept_keywords file and/or the overlay from which you want the package to be installed.

For example:

```bash
mypkgs:
pkg.installed:
  - pkgs:
    - foo: '~= '
    - bar: '>=1.2:slot::overlay[use,-otheruse]' 
    - baz
```

Multiple Package Installation Options: (not supported in Windows or pkgng)

- **sources** *(list)* -- A list of packages to install, along with the source URI or local path from which to install each package. In the example below, foo, bar, baz, etc. refer to the name of the package, as it would appear in the output of the `pkg.version` or `pkg.list_pkgs` salt CLI commands.

```bash
mypkgs:
pkg.installed:
  - sources:
    - foo: salt://rpms/foo.rpm
    - bar: http://somesite.org/bar.rpm
    - baz: ftp://someothersite.org/baz.rpm
    - qux: /minion/path/to/qux.rpm
```

- **allow_updates** *(bool)* -- Allow the package to be updated outside Salt's control (e.g. auto updates on Windows). This means a package on the Minion can have a newer version than the latest available in the repository without enforcing a re-installation of the package.

  New in version 2014.7.0.

  Example:

```
httpd:
pkg.installed:
  - fromrepo: mycustomrepo
  - skip_verify: True
  - skip_suggestions: True
  - version: 2.0.6~ubuntu3
  - refresh: True
  - allow_updates: True
  - hold: False
```

- **pkg_verify** *(bool)* -- New in version 2014.7.0.

  For requested packages that are already installed and would not be targeted for upgrade or downgrade, use `pkg.verify` to determine if any of the files installed by the package have been altered. If files have been altered, the reinstall option of `pkg.install` is used to force a reinstall. Types to ignore can be passed to `pkg.verify` (see example below). Currently, this option is supported for the following pkg providers: `yumpkg`.

  Examples:

```
httpd:
pkg.installed:
  - version: 2.2.15-30.el6.centos
  - pkg_verify: True
```
mypkgs:
  pkg.installed:
    - pkgs:
      - foo
      - bar: 1.2.3-4
      - baz
    - pkg_verify:
      - ignore_types: [config, doc]

- **normalize**(bool) -- Normalize the package name by removing the architecture, if the architecture of the package is different from the architecture of the operating system. The ability to disable this behavior is useful for poorly-created packages which include the architecture as an actual part of the name, such as kernel modules which match a specific kernel version.

  New in version 2014.7.0.

  Example:

  gpf.s.gplbin-2.6.32-279.31.1.el6.x86_64:
  pkg.installed:
    - normalize: False

- **kwargs** -- These are specific to each OS. If it does not apply to the execution module for your OS, it is ignored.

  **param bool hold** Force the package to be held at the current installed version. Currently works with YUM & APT based systems.

  New in version 2014.7.0.

  **param list names** A list of packages to install from a software repository. Each package will be installed individually by the package manager.

  **Warning:** Unlike `pkgs`, the `names` parameter cannot specify a version. In addition, it makes a separate call to the package management frontend to install each package, whereas `pkgs` makes just a single call. It is therefore recommended to use `pkgs` instead of `names` to install multiple packages, both for the additional features and the performance improvement that it brings.

  **param bool install_recommends** Whether to install the packages marked as recommended. Default is True. Currently only works with APT-based systems.

  New in version 2015.5.0.

  httpd:
  pkg.installed:
    - install_recommends: False

  **param bool only_upgrade** Only upgrade the packages, if they are already installed. Default is False. Currently only works with APT-based systems.

  New in version 2015.5.0.
Returns A dictionary containing the state of the software installation

Rtype dict

salt.states.pkg.latest(name, refresh=None, fromrepo=None, skip_verify=False, pkgs=None, watch_flags=True, **kwargs)

Ensure that the named package is installed and the latest available package. If the package can be updated, this state function will update the package. Generally it is better for the installed function to be used, as latest will update the package whenever a new package is available.

name The name of the package to maintain at the latest available version. This parameter is ignored if `'pkgs` is used.

fromrepo Specify a repository from which to install

skip_verify Skip the GPG verification check for the package to be installed

refresh Update the repo database of available packages prior to installing the requested package.

Multiple Package Installation Options:

(Not yet supported for: Windows, FreeBSD, OpenBSD, MacOS, and Solaris pkgutil)

pkgs A list of packages to maintain at the latest available version.

mypkgs:
  pkg.latest:
    - pkgs:
      - foo
      - bar
      - baz

install_recommends Whether to install the packages marked as recommended. Default is True. Currently only works with APT-based systems.

New in version 2015.5.0.

httpd:
  pkg.latest:
    - install_recommends: False

only_upgrade Only upgrade the packages, if they are already installed. Default is False. Currently only works with APT-based systems.

New in version 2015.5.0.

httpd:
  pkg.latest:
    - only_upgrade: True

salt.states.pkg.mod_aggregate(low, chunks, running)

The mod_aggregate function which looks up all packages in the available low chunks and merges them into a single pkgs ref in the present low data

salt.states.pkg.purged(name, version=None, pkgs=None, normalize=True, **kwargs)

Verify that a package is not installed, calling pkg.purge if necessary to purge the package. All configuration files are also removed.

name The name of the package to be purged.
version  The version of the package that should be removed. Don't do anything if the package is installed with an unmatching version.

normalize  [True] Normalize the package name by removing the architecture, if the architecture of the package is different from the architecture of the operating system. The ability to disable this behavior is useful for poorly-created packages which include the architecture as an actual part of the name, such as kernel modules which match a specific kernel version.

New in version 2015.8.0.

Multiple Package Options:

pkgs  A list of packages to purge. Must be passed as a python list. The name parameter will be ignored if this option is passed. It accepts version numbers as well.

New in version 0.16.0.

salt.states.pkg.removed(name, version=None, pkgs=None, normalize=True, **kwargs)

Verify that a package is not installed, calling pkg.remove if necessary to remove the package.

name  The name of the package to be removed.

version  The version of the package that should be removed. Don't do anything if the package is installed with an unmatching version.

normalize  [True] Normalize the package name by removing the architecture, if the architecture of the package is different from the architecture of the operating system. The ability to disable this behavior is useful for poorly-created packages which include the architecture as an actual part of the name, such as kernel modules which match a specific kernel version.

New in version 2015.8.0.

Multiple Package Options:

pkgs  A list of packages to remove. Must be passed as a python list. The name parameter will be ignored if this option is passed. It accepts version numbers as well.

New in version 0.16.0.

salt.states.pkg.upodate(name, refresh=False, **kwargs)

Verify that the system is completely up to date.

name  The name has no functional value and is only used as a tracking reference

refresh  refresh the package database before checking for new upgrades

kwargs  Any keyword arguments to pass through to pkg.upgrade.

New in version 2015.5.0.

31.27.112  salt.states.pkgbuild

The pkgbuild state is the front of Salt package building backend. It automatically

New in version 2015.8.0.

salt_2015.5.2:

/tmp/pkg:
  pkgbuild.repo

salt.states.pkgbuild.build(name, runas, dest_dir, spec, sources, template, tgt, deps=None, env=None, results=None, always=False, saltenv='base')

Ensure that the named package is built and exists in the named directory

name The name to track the build, the name value is otherwise unused
runas The user to run the build process as
dest_dir The directory on the minion to place the built package(s)
spec The location of the spec file (used for rpms)
sources The list of package sources
template Set to run the spec file through a templating engine
tgt The target platform to run the build on
deps Packages required to ensure that the named package is built can be hosted on either the salt master server or on an HTTP or FTP server. Both HTTPS and HTTP are supported as well as downloading directly from Amazon S3 compatible URLs with both pre-configured and automatic IAM credentials
env A dictionary of environment variables to be set prior to execution. Example:

  - env:
    DEB_BUILD_OPTIONS: 'nocheck'

Warning: The above illustrates a common PyYAML pitfall, that yes, no, on, off, true, and false are all loaded as boolean True and False values, and must be enclosed in quotes to be used as strings. More info on this (and other) PyYAML idiosyncrasies can be found here.

results The names of the expected rpms that will be built
always Build with every run (good if the package is for continuous or nightly package builds)
saltenv The saltenv to use for files downloaded from the salt fileserver

salt.states.pkgbuild.repo(name, keyid=None, env=None)

Make a package repository, the name is directory to turn into a repo. This state is best used with onchanges linked to your package building states
name The directory to find packages that will be in the repository
keyid Optional Key ID to use in signing repository
env A dictionary of environment variables to be utilized in creating the repository. Example:
31.27.113 salt.states.pkgng

Manage package remote repo using FreeBSD pkgng

Salt can manage the URL pkgng pulls packages from. ATM the state and module are small so use cases are typically rather simple:

```
pkgng_clients:
    pkgng.update_packaging_site:
    - name: "http://192.168.0.2"
```

salt.states.pkgng.update_packaging_site(name)

31.27.114 salt.states.pkgrepo

Management of APT/YUM package repos

Package repositories for APT-based and YUM-based distros can be managed with these states. Here is some example SLS:

```
base:
    pkgrepo.managed:
    - humanname: CentOS-$releasever - Base
    - mirrorlist: http://mirrorlist.centos.org/?release=$releasever&arch=$basearch&repo=os
      comments:
      - '#http://mirror.centos.org/centos/$releasever/os/$basearch/'
    - gpgcheck: 1
    - gpgkey: file:///etc/pki/rpm-gpg/RPM-GPG-KEY-CentOS-6

base:
    pkgrepo.managed:
    - humanname: Logstash PPA
    - name: deb http://ppa.launchpad.net/wolfnet/logstash/ubuntu precise main
tfrequency: precise
    - file: /etc/apt/sources.list.d/logstash.list
    - keyid: 28B04E4A
    - keyserver: keyserver.ubuntu.com
    - require_in:
      - pkg: logstash

pkg.latest:
    - name: logstash
    - refresh: True
```

31.27. Full list of builtin state modules
base:
pkgrepo.managed:
  - humanname: deb-multimedia
  - name: deb http://www.deb-multimedia.org stable main
  - file: /etc/apt/sources.list.d/deb-multimedia.list
  - key_url: salt://deb-multimedia/files/marillat.pub

base:
pkgrepo.managed:
  - humanname: Google Chrome
  - name: deb http://dl.google.com/linux/chrome/deb/ stable main
  - dist: stable
  - file: /etc/apt/sources.list.d/chrome-browser.list
  - require_in:
    - pkg: google-chrome-stable
    - gpgcheck: 1
  - key_url: https://dl-ssl.google.com/linux/linux_signing_key.pub

base:
pkgrepo.managed:
  - ppa: wolfnet/logstash

pkg.latest:
  - name: logstash
  - refresh: True

Note: On Ubuntu systems, the python-software-properties package should be installed for better support of PPA repositories. To check if this package is installed, run `dpkg -l python-software-properties`.

Also, some Ubuntu releases have a bug in their python-software-properties package, a missing dependency on pycurl, so python-pycurl will need to be manually installed if it is not present once python-software-properties is installed.

On Ubuntu & Debian systems, the `python-apt` package is required to be installed. To check if this package is installed, run `dpkg -l python-software-properties`. python-apt will need to be manually installed if it is not present.

salt.states.pkgrepo.absent(name, **kwargs)

This function deletes the specified repo on the system, if it exists. It is essentially a wrapper around `pkg.del_repo`.

name The name of the package repo, as it would be referred to when running the regular package manager commands.

UBUNTU-SPECIFIC OPTIONS

ppa On Ubuntu, you can take advantage of Personal Package Archives on Launchpad simply by specifying the user and archive name.

    logstash-ppa:
    pkgrepo.absent:
      - ppa: wolfnet/logstash

ppa_auth For Ubuntu PPAs there can be private PPAs that require authentication to access. For these PPAs the username/password can be specified. This is required for matching if the name format uses the ppa: specifier and is private (requires username/password to access, which is encoded in the URI).

    logstash-ppa:
    pkgrepo.absent:
- ppa: wolfnet/logstash
- ppa_auth: username:password

```yaml
keyid
If passed, then the GPG key corresponding to the passed KeyID will also be removed.

keyid_ppa [False] If set to True, the GPG key's ID will be looked up from ppa.launchpad.net and removed, and the keyid argument will be ignored.
```

---

**Note:** This option will be disregarded unless the ppa argument is present.

salt.states.pkgrepo.managed(name, **kwargs)
This function manages the configuration on a system that points to the repositories for the system's package manager.

- **name** The name of the package repo, as it would be referred to when running the regular package manager commands.
- **ppa** On Ubuntu, you can take advantage of Personal Package Archives on Launchpad simply by specifying the user and archive name. The keyid will be queried from launchpad and everything else is set automatically. You can override any of the below settings by simply setting them as you would normally. For example:

```yaml
logstash-ppa:
  pkgrepo.managed:
    - ppa: wolfnet/logstash
```

- **ppa_auth** For Ubuntu PPAs there can be private PPAs that require authentication to access. For these PPAs the username/password can be passed as an HTTP Basic style username/password combination.

```yaml
logstash-ppa:
  pkgrepo.managed:
    - ppa: wolfnet/logstash
    - ppa_auth: username:password
```

- **name** On apt-based systems this must be the complete entry as it would be seen in the sources.list file. This can have a limited subset of components (i.e. `main`) which can be added/modified with the ``comps`` option.

```yaml
precise-repo:
  pkgrepo.managed:
    - name: deb http://us.archive.ubuntu.com/ubuntu precise main
```

- **disabled** Toggles whether or not the repo is used for resolving dependencies and/or installing packages.
- **comps** On apt-based systems, comps dictate the types of packages to be installed from the repository (e.g. main, nonfree, ...). For purposes of this, comps should be a comma-separated list.
- **file** The filename for the .list that the repository is configured in. It is important to include the full-path AND make sure it is in a directory that APT will look in when handling packages.
- **dist** This dictates the release of the distro the packages should be built for. (e.g. unstable). This option is rarely
needed.

**keyid**  The KeyID of the GPG key to install. This option also requires the **keyserver** option to be set.

**keyserver**  This is the name of the keys server to retrieve gpg keys from. The **keyid** option must also be set for this option to work.

**key_url**  URL to retrieve a GPG key from. Allows the usage of http://, https:// as well as salt://.

**Note:** Use either **keyid/**keyserver or **key_url**, but not both.

**consolidate**  If set to true, this will consolidate all sources definitions to the sources.list file, cleanup the now unused files, consolidate components (e.g. main) for the same URI, type, and architecture to a single line, and finally remove comments from the sources.list file. The consolidate will run every time the state is processed. The option only needs to be set on one repo managed by salt to take effect.

**clean_file**  If set to true, empty file before config repo, dangerous if use multiple sources in one file.

**refresh_db**  If set to false this will skip refreshing the apt package database on debian based systems.

**require_in**  Set this to a list of pkg.installed or pkg.latest to trigger the running of apt-get update prior to attempting to install these packages. Setting a require in the pkg will not work for this.

### 31.27.115 salt.states.portage_config

**Management of Portage package configuration on Gentoo**

A state module to manage Portage configuration on Gentoo

```Python
salt:
    portage_config.flags:
        - use:
            openssl
```

**salt.states.portage_config.flags**(*name*, *use=None*, *accept_keywords=None*, *env=None*, *license=None*, *properties=None*, *unmask=False*, *mask=False*)

Enforce the given flags on the given package or DEPEND atom.

**Warning:** In most cases, the affected package(s) need to be rebuilt in order to apply the changes.

**name**  The name of the package or its DEPEND atom

**use**  A list of USE flags

**accept_keywords**  A list of keywords to accept. ~ARCH means current host arch, and will be translated into a line without keywords

**env**  A list of environment files

**license**  A list of accepted licenses

**properties**  A list of additional properties

**unmask**  A boolean to unmask the package

**mask**  A boolean to mask the package

### 31.27.116 salt.states.ports

**Manage software from FreeBSD ports**

New in version 2014.1.0.

**Note:** It may be helpful to use a higher timeout when running a **ports.installed** state, since compiling the port may exceed Salt’s timeout.
salt -t 1200 '*' state.highstate

salt.states.ports.installed(name, options=None)
Verify that the desired port is installed, and that it was compiled with the desired options.

options Make sure that the desired non-default options are set

| Warning: Any build options not passed here assume the default values for the port, and are not just differences from the existing cached options from a previous make config. |

Example usage:

```python
security/nmap:
    ports.installed:
        - options:
            - IPV6: off
```

31.27.117 salt.states.postgres_database

Management of PostgreSQL databases

The postgres_database module is used to create and manage Postgres databases. Databases can be set as either absent or present

frank:
    postgres_database.present

salt.states.postgres_database.absent(name, user=None, maintenance_db=None, db_password=None, db_host=None, db_port=None, db_user=None)

Ensure that the named database is absent
name The name of the database to remove
db_user database username if different from config or default
db_password user password if any password for a specified user
db_host Database host if different from config or default
db_port Database port if different from config or default
user System user all operations should be performed on behalf of

New in version 0.17.0.

salt.states.postgres_database.present(name, tablespace=None, encoding=None, lc_collate=None, lc_ctype=None, owner=None, owner_recurse=False, template=None, user=None, maintenance_db=None, db_password=None, db_host=None, db_port=None, db_user=None)

Ensure that the named database is present with the specified properties. For more information about all of these options see man createdb(1)
name The name of the database to manage
tablespace Default tablespace for the database
encoding The character encoding scheme to be used in this database
lc_collate The LC_COLLATE setting to be used in this database
lc_ctype The LC_CTYPE setting to be used in this database
owner The username of the database owner

31.27. Full list of builtin state modules
owner_recurse  Recurse owner change to all relations in the database

**template**  The template database from which to build this database

**user**  System user all operations should be performed on behalf of

**db_user**  database username if different from config or default

**db_password**  user password if any password for a specified user

**db_host**  Database host if different from config or default

**db_port**  Database port if different from config or default

New in version 0.17.0.

### 31.27.118 salt.states.postgres_extension

**Management of PostgreSQL extensions (e.g.: postgis)**

The postgres_extensions module is used to create and manage Postgres extensions.

```
adminpack:
  postgres_extension.present
```

New in version 2014.7.0.

**salt.states.postgres_extension.absent**(name, if_exists=None, restrict=None, cascade=None, user=None, maintenance_db=None, db_password=None, db_host=None, db_port=None, db_user=None)

Ensure that the named extension is absent

**name**  Extension name of the extension to remove

**cascade**  Drop on cascade

**if_exists**  Add if exist slug

**restrict**  Add restrict slug

**maintenance_db**  Database to act on

**user**  System user all operations should be performed on behalf of

**db_user**  database username if different from config or default

**db_password**  user password if any password for a specified user

**db_host**  Database host if different from config or default

**db_port**  Database port if different from config or default

**salt.states.postgres_extension.present**(name, if_not_exists=None, schema=None, ext_version=None, from_version=None, user=None, maintenance_db=None, db_password=None, db_host=None, db_port=None, db_user=None)

Ensure that the named extension is present with the specified privileges

**name**  The name of the extension to manage

**if_not_exists**  Add a if_not_exists switch to the ddl statement

**schema**  Schema to install the extension into

**from_version**  Old extension version if already installed

**ext_version**  version to install

**user**  System user all operations should be performed on behalf of

**maintenance_db**  Database to act on

**db_user**  database username if different from config or default

**db_password**  user password if any password for a specified user

**db_host**  Database host if different from config or default

**db_port**  Database port if different from config or default
31.27.119 salt.states.postgres_group

Management of PostgreSQL groups (roles)

The postgres_group module is used to create and manage Postgres groups.

```
frank:
  postgres_group.present
```

salt.states.postgres_group.absent(name, user=None, maintenance_db=None, db_password=None, db_host=None, db_port=None, db_user=None)

Ensure that the named group is absent

- name: The groupname of the group to remove
- user: System user all operations should be performed on behalf of

New in version 0.17.0.

- `db_user`: database username if different from config or default
- `db_password`: user password if any password for a specified user
- `db_host`: Database host if different from config or default
- `db_port`: Database port if different from config or default

salt.states.postgres_group.present(name, createdb=None, createroles=None, createuser=None, encrypted=None, login=None, superuser=None, inherit=None, replication=None, password=None, refresh_password=None, groups=None, user=None, maintenance_db=None, db_password=None, db_host=None, db_port=None, db_user=None)

Ensure that the named group is present with the specified privileges

Please note that the user/group notion in postgresql is just abstract, we have roles, where users can be seen as roles with the LOGIN privilege and groups the others.

- name: The name of the group to manage
- createdb: Is the group allowed to create databases?
- createroles: Is the group allowed to create other roles/users
- createuser: Alias to create roles, and history problem, in psql normally createuser == superuser
- encrypted: Should the password be encrypted in the system catalog?
- login: Should the group have login perm
- inherit: Should the group inherit permissions
- superuser: Should the new group be a `superuser`
- replication: Should the new group be allowed to initiate streaming replication
- password: The Group's password It can be either a plain string or a md5 postgresql hashed password:

  `'md5(MD5OF({password}{role})`'

If encrypted is None or True, the password will be automatically encrypted to the previous format if it is not already done.

- refresh_password: Password refresh flag

  Boolean attribute to specify whether to password comparison check should be performed.

  If refresh_password is None or False, the password will be automatically updated without extra password change check.

  This behaviour makes it possible to execute in environments without superuser access available, e.g. Amazon RDS for PostgreSQL.

- groups: A string of comma separated groups the group should be in
31.27.120 salt.states.postgres_schema

Management of PostgreSQL schemas

The postgres_schemas module is used to create and manage Postgres schemas.

```python
public:
    postgres_schema.present 'dbname' 'name'
```

salt.states.postgres_schema.absent(dbname, name, db_user=None, db_password=None, db_host=None, db_port=None)

Ensure that the named schema is absent.
dbname The database's name will work on
name The name of the schema to remove
db_user database username if different from config or default
db_password user password if any password for a specified user
db_host Database host if different from config or default
db_port Database port if different from config or default

salt.states.postgres_schema.present(dbname, name, owner=None, db_user=None, db_password=None, db_host=None, db_port=None)

Ensure that the named schema is present in the database.
dbname The database's name will work on
name The name of the schema to manage
db_user database username if different from config or default
db_password user password if any password for a specified user
db_host Database host if different from config or default
db_port Database port if different from config or default

31.27.121 salt.states.postgres_tablespace

Management of PostgreSQL tablespace

The postgres_tablespace module is used to create and manage Postgres tablespaces.

Tablespaces can be set as either absent or present.

New in version 2015.8.0.

salt.states.postgres_tablespace.absent(name, user=None, maintenance_db=None, db_password=None, db_host=None, db_port=None, db_user=None)

Ensure that the named database is absent.
name The name of the database to remove
db_user database username if different from config or default
db_password user password if any password for a specified user
db_host Database host if different from config or default
db_port  Database port if different from config or default
user  System user all operations should be performed on behalf of

salt.states.postgres_tablespace.present(name, directory, options=None, owner=None, user=None, maintenance_db=None, db_password=None, db_host=None, db_port=None, db_user=None)

Ensure that the named tablespace is present with the specified properties. For more information about all of these options see man create_tablespace(1).

name  The name of the tablespace to create/manage.
directory  The directory where the tablespace will be located, must already exist.
options  A dictionary of options to specify for the table. Currently, the only tablespace options supported are
    seq_page_cost - float; default=1.0
    random_page_cost - float; default=4.0
owner  The database user that will be the owner of the tablespace Defaults to the user executing the command
    (i.e. the user option)
db_user  database username if different from config or default
db_password  user password if any password for a specified user
db_host  Database host if different from config or default
db_port  Database port if different from config or default
user  System user all operations should be performed on behalf of

31.27.122 salt.states.postgres_user

Management of PostgreSQL users (roles)

The postgres_user module is used to create and manage Postgres users.

frank:
    postgres_user.present

salt.states.postgres_user.absent(name, user=None, maintenance_db=None, db_password=None, db_host=None, db_port=None, db_user=None)

Ensure that the named user is absent

name  The username of the user to remove
user  System user all operations should be performed on behalf of

    New in version 0.17.0.
db_user  database username if different from config or default
db_password  user password if any password for a specified user
db_host  Database host if different from config or default
db_port  Database port if different from config or default

salt.states.postgres_user.present(name, createdb=None, createroles=None, createuser=None, encrypted=None, superuser=None, replication=None, inherit=None, login=None, password=None, refresh_password=None, groups=None, user=None, maintenance_db=None, db_password=None, db_host=None, db_port=None, db_user=None)

Ensure that the named user is present with the specified privileges Please note that the user/group notion in postgresql is just abstract, we have roles, where users can be seen as roles with the LOGIN privilege and groups the others.

name  The name of the user to manage
createdb  Is the user allowed to create databases?
createroles  Is the user allowed to create other users?
createuser  Alias to create roles

31.27.  Full list of builtin state modules  1825
encrypted Should the password be encrypted in the system catalog?
login Should the group have login perm
inherit Should the group inherit permissions
superuser Should the new user be a "superuser"
replication Should the new user be allowed to initiate streaming replication
password The user’s password It can be either a plain string or a md5 postgresql hashed password:

(md5{MD5OF{{password}{role}}})

If encrypted is None or True, the password will be automatically encrypted to the previous format if it is not already done.

refresh_password Password refresh flag

Boolean attribute to specify whether to password comparison check should be performed.

If refresh_password is None or False, the password will be automatically updated without extra password change check.

This behaviour makes it possible to execute in environments without superuser access available, e.g. Amazon RDS for PostgreSQL.
groups A string of comma separated groups the user should be in
user System user alloperationsshould be performed on behalf of

New in version 0.17.0.
db_user database username if different from config or default
db_password user password if any password for a specified user
db_host Database host if different from config or default
db_port Database port if different from config or default

31.27.123 salt.states.powerpath

Powerpath configuration support

Allows configuration of EMC Powerpath. Currently only addition/deletion of licenses is supported.

key:
  powerpath.license_present: []

salt.states.powerpath.license_absent(name)

Ensures that the specified PowerPath license key is absent on the host.

name The license key to ensure is absent

salt.states.powerpath.license_present(name)

Ensures that the specified PowerPath license key is present on the host.

name The license key to ensure is present

31.27.124 salt.states.process

Process Management

Ensure a process matching a given pattern is absent.
**31.27.125 salt.states.pushover**

Send a message to PushOver

This state is useful for sending messages to PushOver during state runs.

New in version Lithium.

```yaml
pushover-message:
  pushover.post_message:
    - user: xxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx
    - token: xxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx
    - title: Salt Returner
    - device: phone
    - priority: -1
    - expire: 3600
    - retry: 5
    - message: 'This state was executed successfully.'
```

The api key can be specified in the master or minion configuration like below:

```yaml
pushover: token: peWcBiMOS9HrZG15peWcBiMOS9HrZG15
```

**salt.states.pushover.post_message**

```
pushover-message:
  pushover.post_message:
    - user: xxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx
    - token: xxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx
    - title: Salt Returner
    - device: phone
    - priority: -1
    - expire: 3600
    - retry: 5
```

Send a message to a PushOver channel.

The following parameters are required:
- **name** The unique name for this event.
- **user** The user or group of users to send the message to. Must be ID of user, not name or email address.
- **message** The message that is to be sent to the PushOver channel.

The following parameters are optional:
- **title** The title to use for the message.
- **device** The device for the user to send the message to.
- **priority** The priority for the message.
- **expire** The message should expire after specified amount of seconds.
- **retry** The message should be resent this many times.
- **token** The token for PushOver to use for authentication, if not specified in the configuration options of master or minion.
31.27.126 salt.states.pyenv

Managing python installations with pyenv

This module is used to install and manage python installations with pyenv. Different versions of python can be installed, and uninstalled. pyenv will be installed automatically the first time it is needed and can be updated later. This module will not automatically install packages which pyenv will need to compile the versions of python.

If pyenv is run as the root user then it will be installed to /usr/local/pyenv, otherwise it will be installed to the users ~/.pyenv directory. To make pyenv available in the shell you may need to add the pyenv/shims and pyenv/bin directories to the users PATH. If you are installing as root and want other users to be able to access pyenv then you will need to add pyenv_ROOT to their environment.

This is how a state configuration could look like:

```yaml
pyenv-deps:
  pkg.installed:
    - pkgs:
      - make
      - build-essential
      - libssl-dev
      - zlib1g-dev
      - libb2z-dev
      - libreadline-dev
      - libsqlite3-dev
      - wget
      - curl
      - llvm

python-2.6:
  pyenv.absent:
    - require:
      - pkg: pyenv-deps

python-2.7.6:
  pyenv.installed:
    - default: True
    - require:
      - pkg: pyenv-deps
```

**salt.states.pyenv.absent**(name, user=None)

Verify that the specified python is not installed with pyenv. pyenv is installed if necessary.

- **name** The version of python to uninstall
- **user** The user to run pyenv as.

New in version 0.17.0.
New in version 0.16.0.

**salt.states.pyenv.install_pyenv**(name, user=None)

Install pyenv if not installed. Allows you to require pyenv be installed prior to installing the plugins. Useful if you want to install pyenv plugins via the git or file modules and need them installed before installing any rubies.

Use the pyenv.root configuration option to set the path for pyenv if you want a system wide install that is not in a user home dir.

- **user** The user to run pyenv as.

**salt.states.pyenv.installed**(name, default=False, user=None)

Verify that the specified python is installed with pyenv. pyenv is installed if necessary.

- **name** The version of python to install
default  [False] Whether to make this python the default.
user: None  The user to run pyenv as.

New in version 0.17.0.
New in version 0.16.0.

31.27.127 salt.states.pyrax_queues

Manage Rackspace Queues

New in version 2015.5.0.
Create and destroy Rackspace queues. Be aware that this interacts with Rackspace's services, and so may incur charges.
This module uses pyrax, which can be installed via package, or pip. This module is greatly inspired by boto_* modules from SaltStack code source.

myqueue:
    pyrax_queues.present:
        - provider: my-pyrax

myqueue:
    pyrax_queues.absent:
        - provider: my-pyrax

salt.states.pyrax_queues.absent(name, provider)
Ensure the named Rackspace queue is deleted.
name  Name of the Rackspace queue.
provider  Salt Cloud provider

salt.states.pyrax_queues.present(name, provider)
Ensure the RackSpace queue exists.
name  Name of the Rackspace queue.
provider  Salt Cloud Provider

31.27.128 salt.states.quota

Management of POSIX Quotas

The quota can be managed for the system:

/:
    quota.mode:
        mode: off
        quotatypename: user

salt.states.quota.mode(name, mode, quotatypename)
Set the quota for the system
name  The filesystem to set the quota mode on
mode  Whether the quota system is on or off
quotatypename  Must be user or group

31.27. Full list of builtin state modules
31.27.129 salt.states.rabbitmq_cluster

Manage RabbitMQ Clusters

Example:

```text
rabbit@rabbit.example.com:
rabbitmq_cluster.join:
  - user: rabbit
  - host: rabbit.example.com
```

salt.states.rabbitmq_cluster.join(name, host, user='rabbit', ram_node=None, runas='root')

Ensure the current node joined to a cluster with node user@host

- name Irrelevant, not used (recommended: user@host)
- user The user of node to join to (default: rabbit)
- host The host of node to join to
- ram_node Join node as a RAM node
- runas The user to run the rabbitmq command as

salt.states.rabbitmq_cluster.joined(name, host, user='rabbit', ram_node=None, runas='root')

Ensure the current node joined to a cluster with node user@host

- name Irrelevant, not used (recommended: user@host)
- user The user of node to join to (default: rabbit)
- host The host of node to join to
- ram_node Join node as a RAM node
- runas The user to run the rabbitmq command as

31.27.130 salt.states.rabbitmq_plugin

Manage RabbitMQ Plugins

New in version 2014.1.0.

Example:

```text
some_plugin:
rabbitmq_plugin.enabled: []
```

salt.states.rabbitmq_plugin.disabled(name, runas=None)

Ensure the RabbitMQ plugin is disabled.

- name The name of the plugin
- runas The user to run the rabbitmq-plugin command as

salt.states.rabbitmq_plugin.enabled(name, runas=None)

Ensure the RabbitMQ plugin is enabled.

- name The name of the plugin
- runas The user to run the rabbitmq-plugin command as

31.27.131 salt.states.rabbitmq_policy

Manage RabbitMQ Policies

- maintainer Benn Eichhorn <benn@getlocalmeasure.com>
Example:

```yaml
rabbit_policy:
    rabbitmq_policy.present:
    - name: HA
    - pattern: '.*'
    - definition: '{"ha-mode":"all"}'
```

salt.states.rabbitmq_policy.absent(name, vhost='/', runas=None)
Ensure the named policy is absent

- **name** The name of the policy to remove
- **runas** Name of the user to run the command as

salt.states.rabbitmq_policy.present(name, pattern, definition, priority=0, vhost='/', runas=None)
Ensure the RabbitMQ policy exists.

- **name** Policy name
- **pattern** A regex of queues to apply the policy to
- **definition** A json dict describing the policy
- **priority** Priority (defaults to 0)
- **vhost** Virtual host to apply to (defaults to '/')
- **runas** Name of the user to run the command as

31.27.132 salt.states.rabbitmq_user
Manage RabbitMQ Users

Example:

```yaml
rabbit_user:
    rabbitmq_user.present:
    - password: password
    - force: True
    - tags:
        - monitoring
        - user
    - perms:
        - '/':
          - '.*'
          - '.*'  # Add more entries as needed
        - runas: rabbitmq
```

salt.states.rabbitmq_user.absent(name, runas=None)
Ensure the named user is absent

- **name** The name of the user to remove
- **runas** User to run the command as
salt.states.rabbitmq_user.present(name, password=None, force=False, tags=None, perms=(), runas=None)

Ensure the RabbitMQ user exists.

- **name**: User name
- **password**: User's password, if one needs to be set
- **force**: If user exists, forcibly change the password
- **tags**: Optional list of tags for the user
- **perms**: A list of dicts with vhost keys and 3-tuple values
- **runas**: Name of the user to run the command

### 31.27.133 salt.states.rabbitmq_vhost

Manage RabbitMQ Virtual Hosts

Example:

```
virtual_host:
    rabbitmq_vhost.present:
        - user: rabbit_user
        - conf: .*
        - write: .*
        - read: .*
```

salt.states.rabbitmq_vhost.absent(name)

Ensure the RabbitMQ Virtual Host is absent

- **name**: Name of the Virtual Host to remove
- **runas**: User to run the command

Deprecated since version 2015.8.0.

salt.states.rabbitmq_vhost.present(name)

Ensure the RabbitMQ VHost exists.

- **name**: VHost name
- **user**: Initial user permission to set on the VHost, if present

Deprecated since version 2015.8.0.

- **owner**: Initial owner permission to set on the VHost, if present

Deprecated since version 2015.8.0.

- **conf**: Initial conf string to apply to the VHost and user. Defaults to "."

Deprecated since version 2015.8.0.

- **write**: Initial write permissions to apply to the VHost and user. Defaults to "."

Deprecated since version 2015.8.0.

- **read**: Initial read permissions to apply to the VHost and user. Defaults to "."

Deprecated since version 2015.8.0.

- **runas**: Name of the user to run the command

Deprecated since version 2015.8.0.
31.27.134 salt.states.rbenv

Managing Ruby installations with rbenv

This module is used to install and manage ruby installations with rbenv and the ruby-build plugin. Different versions of ruby can be installed, and uninstalled. Rbenv will be installed automatically the first time it is needed and can be updated later. This module will not automatically install packages which rbenv will need to compile the versions of ruby. If your version of ruby fails to install, refer to the ruby-build documentation to verify you are not missing any dependencies: https://github.com/sstephenson/ruby-build/wiki

If rbenv is run as the root user then it will be installed to /usr/local/rbenv, otherwise it will be installed to the users ~/.rbenv directory. To make rbenv available in the shell you may need to add the rbenv/shims and rbenv/bin directories to the users PATH. If you are installing as root and want other users to be able to access rbenv then you will need to add RBENV_ROOT to their environment.

The following state configuration demonstrates how to install Ruby 1.9.x and 2.x using rbenv on Ubuntu/Debian:

```yaml
rbenv-deps:
  pkg.installed:
    - names:
      - bash
      - git
      - openssl
      - libssl-dev
      - make
      - curl
      - autoconf
      - bison
      - build-essential
      - libffi-dev
      - libyaml-dev
      - libreadline6-dev
      - zlib1g-dev
      - libncurses5-dev

ruby-1.9.3-p429:
  rbenv.absent:
    - require:
      - pkg: rbenv-deps

ruby-2.0.0-p598:
  rbenv.installed:
    - default: True
    - require:
      - pkg: rbenv-deps
```

salt.states.rbenv.absent(name, user=None)

Verify that the specified ruby is not installed with rbenv. Rbenv is installed if necessary.

name The version of ruby to uninstall
user: None The user to run rbenv as.

New in version 0.17.0.
New in version 0.16.0.

salt.states.rbenv.install_rbenv(name, user=None)

Install rbenv if not installed. Allows you to require rbenv be installed prior to installing the plugins. Useful if you want to install rbenv plugins via the git or file modules and need them installed before installing any rubies.
Use the `rbenv.root` configuration option to set the path for rbenv if you want a system wide install that is not in a user home dir.

user: None  The user to run rbenv as.

**salt.states.rbenv.installed**(name, default=False, user=None)
Verify that the specified ruby is installed with rbenv. Rbenv is installed if necessary.

name  The version of ruby to install

default [False] Whether to make this ruby the default.

user: None  The user to run rbenv as.

New in version 0.17.0.
New in version 0.16.0.

### 31.27.135 salt.states.rdp

Manage RDP Service on Windows servers

**salt.states.rdp.disabled**(name)
Disable the RDP service

**salt.states.rdp.enabled**(name)
Enable the RDP service and make sure access to the RDP port is allowed in the firewall configuration

### 31.27.136 salt.states.redismod

Management of Redis server

New in version 2014.7.0.

```
    depends
    • redis Python module
```

**configuration** See `salt.modules.redis` for setup instructions.

```plaintext
key_in_redis:
  redis.string:
    - value: string data
```

The redis server information specified in the minion config file can be overridden in states using the following arguments: `host, port, db, password`.

```plaintext
key_in_redis:
  redis.string:
    - value: string data
    - host: localhost
    - port: 6379
    - db: 0
    - password: somuchkittycat
```

**salt.states.redismod.absent**(name, keys=None, **connection_args)**
Ensure key absent from redis

name  Key to ensure absent from redis

keys list of keys to ensure absent, name will be ignored if this is used

**salt.states.redismod.string**(name, value, expire=None, expireat=None, **connection_args)**
Ensure that the key exists in redis with the value specified
name  Redis key to manage  
value  Data to persist in key  
expire  Sets time to live for key in seconds  
expireat  Sets expiration time for key via UNIX timestamp, overrides expire

31.27.137  salt.states.reg

Manage the Windows registry

Many Python developers think of registry keys as if they were Python keys in a dictionary which is not the case. The Windows registry is broken down into the following components:

Hives

This is the top level of the registry. They all begin with HKEY. - HKEY_CLASSES_ROOT (HKCR) - HKEY_CURRENT_USER (HKCU) - HKEY_LOCAL_MACHINE (HKLM) - HKEY_USER (HKU) - HKEY_CURRENT_CONFIG

Keys

Hives contain keys. These are basically the folders beneath the hives. They can contain any number of subkeys.

Values or Entries

Values or Entries are the name/data pairs beneath the keys and subkeys. All keys have a default name/data pair. It is usually ``(Default)''=''(value not set)''. The actual value for the name and the data is Null. The registry editor will display ``(Default)'' and ``(value not set)''.

Example

The following example is taken from the Windows startup portion of the registry:

``
[HKEY_LOCAL_MACHINE\SOFTWARE\Microsoft\Windows\CurrentVersion\Run] "RTHDVCPPL" ="C:\Program Files\Realtek\Audio\HDA\RtkNGUI64.exe" -s
"NvBackend" ="C:\Program Files (x86)\NVIDIA Corporation\Update Core\NvBackend.exe"
"BTMTrayAgent" ="rundll32.exe \"C:\Program Files (x86)\Intel\Bluetooth\btmshellex.dll\",TrayApp"
``

In this example these are the values for each:

Hive: HKEY_LOCAL_MACHINE

Key and subkeys: SOFTWARE\Microsoft\Windows\CurrentVersion\Run

Value:

- There are 3 value names: RTHDVCPPL, NvBackend, and BTMTrayAgent
- Each value name has a corresponding value

salt.states.reg.absent(name, vname=None)

Ensure a registry value is removed. To remove a key use key_absent.

Example:
In the above example the path is interpreted as follows: - HKEY_CURRENT_USER is the hive - SOFTWARE\Salt is the key - version is the value name So the value version will be deleted from the SOFTWARE\Salt key in the HKEY_CURRENT_USER hive.

salt.states.reg.key_absent(name, force=False)

New in version 2015.5.4.

Ensure a registry key is removed. This will remove a key and all value entries it contains. It will fail if the key contains subkeys.

Parameters

- **name (str)** -- A string representing the full path to the key to be removed to include the hive and the keypath. The hive can be any of the following: - HKEY_LOCAL_MACHINE or HKLM - HKEY_CURRENT_USER or HKCU - HKEY_USERS or HKU

- **force (bool)** -- A boolean value indicating that all subkeys should be deleted with the key. If force=False and subkeys exists beneath the key you want to delete, key_absent will fail. Use with caution. The default is False.

Returns

Returns a dictionary showing the results of the registry operation.

Return type dict

The following example will delete the SOFTWARE\Salt key and all subkeys under the HKEY_CURRENT_USER hive.

Example:

```
'HKEY_CURRENT_USER\SOFTWARE\Salt':
  reg.key_absent:
    - force: True
```

In the above example the path is interpreted as follows: - HKEY_CURRENT_USER is the hive - SOFTWARE\Salt is the key

salt.states.reg.present(name, value=None, vname=None, vdata=None, vtype='REG_SZ', reflection=True)

Ensure a registry key or value is present.

Parameters

- **name (str)** -- A string value representing the full path of the key to include the HIVE, Key, and all Subkeys. For example:
  
  HKEY_LOCAL_MACHINE\SOFTWARE\Salt

  Valid hive values include:
  
  - HKEY_CURRENT_USER or HKCU
  
  - HKEY_LOCAL_MACHINE or HKLM
  
  - HKEY_USERS or HKU

- **value (str)** -- Deprecated. Use vname and vdata instead. Included here for backwards compatability.

- **vname (str)** -- The name of the value you'd like to create beneath the Key. If this parameter is not passed it will assume you want to set the (Default) value
• **vdata** (*str*) -- The value you’d like to set for the Key. If a value name (vname) is passed, this will be the data for that value name. If not, this will be the (Default) value for the key.

The type for the (Default) value is always REG_SZ and cannot be changed. This parameter is optional. If not passed, the Key will be created with.

• **vtype** (*str*) -- The value type for the data you wish to store in the registry. Valid values are:
  - REG_BINARY
  - REG_DWORD
  - REG_EXPAND_SZ
  - REG_MULTI_SZ
  - REG_SZ (Default)

• **reflection** (*bool*) -- On 64 bit machines a duplicate value will be created in the Wow6432Node for 32bit programs. This only applies to the SOFTWARE key. This option is ignored on 32bit operating systems. This value defaults to True. Set it to False to disable reflection.

**Returns**  Returns a dictionary showing the results of the registry operation.

**Return type**  dict

The following example will set the (Default) value for the SOFTWARE\Salt key in the HKEY_CURRENT_USER hive to 0.15.3. The value will not be reflected in Wow6432Node:

Example:

```python
HKEY_CURRENT_USER\SOFTWARE\Salt:
  reg.present:
    - vdata: 0.15.3
    - reflection: False
```

The following example will set the value for the version entry under the SOFTWARE\Salt key in the HKEY_CURRENT_USER hive to 0.15.3. The value will be reflected in Wow6432Node:

Example:

```python
HKEY_CURRENT_USER\SOFTWARE\Salt:
  reg.present:
    - vname: version
    - vdata: 0.15.3
```

In the above example the path is interpreted as follows: - HKEY_CURRENT_USER is the hive - SOFTWARE\Salt is the key - vname is the value name (`version`) that will be created under the key - vdata is the data that will be assigned to `version`

### 31.27.138 salt.states.rvm

**Managing Ruby installations and gemsets with Ruby Version Manager (RVM)**

This module is used to install and manage ruby installations and gemsets with RVM, the Ruby Version Manager. Different versions of ruby can be installed and gemsets created. RVM itself will be installed automatically if it’s not present. This module will not automatically install packages that RVM depends on or ones that are needed to build
ruby. If you want to run RVM as an unprivileged user (recommended) you will have to create this user yourself. This is how a state configuration could look like:

```yaml
rvm:
  group.present: []
  user.present:
    - gid: rvm
    - home: /home/rvm
    - require:
      - group: rvm

rvm-deps:
  pkg.installed:
    - pkgs:
      - bash
      - coreutils
      - gzip
      - bzip2
      - gawk
      - sed
      - curl
      - git-core
      - subversion

mri-deps:
  pkg.installed:
    - pkgs:
      - build-essential
      - openssl
      - libreadline6
      - libreadline6-dev
      - curl
      - git-core
      - zlib1g
      - zlib1g-dev
      - libssl-dev
      - libyaml-dev
      - libsqlite3-0
      - libsqlite3-dev
      - sqlite3
      - libxml2-dev
      - libxslt1-dev
      - autoconf
      - libc6-dev
      - libncurses5-dev
      - automake
      - libtool
      - bison
      - subversion
      - ruby

jruby-deps:
  pkg.installed:
    - pkgs:
      - curl
      - g++
      - openjdk-6-jre-headless
```
Ruby

- **salt.states.rvm.gemset_present** *(name, ruby='default', user=None)*
  - Verify that the gemset is present.
  - **name** The name of the gemset.
  - **ruby** default The ruby version this gemset belongs to.
  - **user** None The user to run rvm as.
  - New in version 0.17.0.

- **salt.states.rvm.installed** *(name, default=False, user=None)*
  - Verify that the specified ruby is installed with RVM. RVM is installed when necessary.
  - **name** The version of ruby to install
  - **default** [False] Whether to make this ruby the default.
  - **user** None The user to run rvm as.
  - New in version 0.17.0.

Salt States

31.27.139 salt.states.saltmod

Control the Salt command interface

This state is intended for use from the Salt Master. It provides access to sending commands down to minions as well as access to executing master-side modules. These state functions wrap Salt’s *Python API*.

See also:

More Orchestrate documentation
- **Full Orchestrate Tutorial**
- **The Orchestrate runner**

```python
salt.states.saltmod.function(name, tgt, ssh=False, tgt_type=None, expr_form=None, ret='`,
                              expect_minions=False, fail_minions=None, fail_function=None,
                              arg=None, kwarg=None, timeout=None)
```

Execute a single module function on a remote minion via salt or salt-ssh

**name**  The name of the function to run, aka cmd.run or pkg.install

**tgt**  The target specification, aka `'*' for all minions

**tgt_type | expr_form**  The target type, defaults to glob

**arg**  The list of arguments to pass into the function

**kwarg**  The list of keyword arguments to pass into the function

**ret**  Optionally set as a single or a list of returners to use

**expect_minions**  An optional boolean for failing if some minions do not respond

**fail_minions**  An optional list of targeted minions where failure is an option

**fail_function**  An optional string that points to a salt module that returns True or False based on the returned data dict for individual minions

**ssh**  Set to `True` to use the ssh client instead of the standard salt client

```python
salt.states.saltmod.runner(name, **kwargs)
```

Execute a runner module on the master

New in version 2014.7.

**name**  The name of the function to run

**kwarg**  Any keyword arguments to pass to the runner function

```python
run-manage-up:
salt.runner:
    - name: manage.up
```

```python
salt.states.saltmod.state(name, tgt, ssh=False, tgt_type=None, expr_form=None, ret='`,
                          highstate=None, sls=None, top=None, env=None, test=False, pillar=None,
                          expect_minions=False, fail_minions=None, allow_fail=0, concurrent=False,
                          timeout=None)
```

Invoke a state run on a given target

**name**  An arbitrary name used to track the state execution

**tgt**  The target specification for the state run.

**tgt_type | expr_form**  The target type to resolve, defaults to glob

**ret**  Optionally set a single or a list of returners to use

**highstate**  Defaults to None, if set to True the target systems will ignore any sls references specified in the sls option and call state.highstate on the targeted minions

**top**  Should be the name of a top file. If set state.top is called with this top file instead of state.sls.

**sls**  A group of sls files to execute. This can be defined as a single string containing a single sls file, or a list of sls files

**test**  Pass `test=true` through to the state function

**pillar**  Pass the pillar kwarg through to the state function

**saltenv**  The default salt environment to pull sls files from

**ssh**  Set to `True` to use the ssh client instead of the standard salt client

**roster**  In the event of using salt-ssh, a roster system can be set

**expect_minions**  An optional boolean for failing if some minions do not respond

**fail_minions**  An optional list of targeted minions where failure is an option

**allow_fail**  Pass in the number of minions to allow for failure before setting the result of the execution to False

**concurrent**  Allow multiple state runs to occur at once.

WARNING: This flag is potentially dangerous. It is designed for use when multiple state runs can safely be run at the same Do not use this flag for performance optimization.
Examples:

Run a list of sls files via state.sls on target minions:

webservers:
  salt.state:
    - tgt: 'web*'  
    - sls: 
      - apache 
      - django 
      - core 
      - saltenv: prod

Run a full state.highstate on target minions.

databases:
  salt.state:
    - tgt: role:database
    - tgt_type: grain
    - highstate: True

salt.states.saltmod.wait_for_event(name, id_list, event_id='id', timeout=300)
  Watch Salt’s event bus and block until a condition is met

New in version 2014.7.

name  An event tag to watch for; supports Reactor-style globbing.

id_list A list of event identifiers to watch for -- usually the minion ID. Each time an event tag is matched
  the event data is inspected for event_id, if found it is removed from id_list. When id_list is
  empty this function returns success.

event_id [id] The name of a key in the event data. Default is 'id' for the minion ID, another common value is
  name for use with orchestrating salt-cloud events.

timeout [300] The maximum time in seconds to wait before failing.

The following example blocks until all the listed minions complete a restart and reconnect to the Salt master:

reboot_all_minions:
  salt.function:
    - name: system.reboot
    - tgt: '*'

wait_for_reboots:
  salt.wait_for_event:
    - name: salt/minion/*/start
    - id_list:
      - jerry
      - stuart
      - dave
      - phil
      - kevin
      - mike
    - require:
      - salt: reboot_all_minions

salt.states.saltmod.wheel(name, **kwargs)
  Execute a wheel module on the master

New in version 2014.7.

name  The name of the function to run
kwarg

Any keyword arguments to pass to the wheel function

accept_minion_key:
salt.wheel:
  - name: key.accept
  - match: frank

31.27.140 salt.states.schedule

Management of the Salt scheduler

job3:
schedule.present:
  - function: test.ping
  - seconds: 3600
  - splay: 10

This will schedule the command: test.ping every 3600 seconds
(every hour) splaying the time between 0 and 10 seconds

job2:
schedule.present:
  - function: test.ping
  - seconds: 15
  - splay:
    - start: 10
    - end: 20

This will schedule the command: test.ping every 3600 seconds
(every hour) splaying the time between 10 and 20 seconds

job1:
schedule.present:
  - function: state.sls
  - job_args:
    - httpd
  - job_kwargs:
    test: True
  - when:
    - Monday 5:00pm
    - Tuesday 3:00pm
    - Wednesday 5:00pm
    - Thursday 3:00pm
    - Friday 5:00pm

This will schedule the command: state.sls httpd test=True at 5pm on Monday,
Wednesday and Friday, and 3pm on Tuesday and Thursday. Requires that
python-dateutil is installed on the minion.

job1:
schedule.present:
  - function: state.sls
  - job_args:
    - httpd
  - job_kwargs:
    test: True
- cron: '*/5 * * * *'

Scheduled jobs can also be specified using the format used by cron. This will schedule the command: state.sls httpd test=True to run every 5 minutes. Requires that python-croniter is installed on the minion.

```yaml
job1:
  schedule.present:
    - function: state.sls
      - args:
        - httpd
      - kwargs:
        test: True
      - when:
        - Monday 5:00pm
        - Tuesday 3:00pm
        - Wednesday 5:00pm
        - Thursday 3:00pm
        - Friday 5:00pm
      - returner: xmpp
      - return_config: xmpp_state_run
```

This will schedule the command: state.sls httpd test=True at 5pm on Monday, Wednesday and Friday, and 3pm on Tuesday and Thursday. Using the xmpp returner to return the results of the scheduled job, with the alternative configuration options found in the xmpp_state_run section.

```python
salt.states.schedule.absent(name, **kwargs)
Ensure a job is absent from the schedule
name The unique name that is given to the scheduled job.
persist Whether the job should persist between minion restarts, defaults to True.

salt.states.schedule.disabled(name, **kwargs)
Ensure a job is disabled in the schedule
name The unique name that is given to the scheduled job.
persist Whether the job should persist between minion restarts, defaults to True.

salt.states.schedule.enabled(name, **kwargs)
Ensure a job is enabled in the schedule
name The unique name that is given to the scheduled job.
persist Whether the job should persist between minion restarts, defaults to True.

salt.states.schedule.present(name, **kwargs)
Ensure a job is present in the schedule
name The unique name that is given to the scheduled job.
seconds The scheduled job will be executed after the specified number of seconds have passed.
minutes The scheduled job will be executed after the specified number of minutes have passed.
hours The scheduled job will be executed after the specified number of hours have passed.
days The scheduled job will be executed after the specified number of days have passed.
when This will schedule the job at the specified time(s). The when parameter must be a single value or a dictionary with the date string(s) using the dateutil format. Requires python-dateutil.
cron This will schedule the job at the specified time(s) using the crontab format. Requires python-croniter.
function The function that should be executed by the scheduled job.
job_args The arguments that will be used by the scheduled job.
job_kwargs The keyword arguments that will be used by the scheduled job.
maxrunning Ensure that there are no more than N copies of a particular job running.
jid_include Include the job into the job cache.
```
splay  The amount of time in seconds to splay a scheduled job. Can be specified as a single value in seconds or as a dictionary range with 'start' and 'end' values.
range  This will schedule the command within the range specified. The range parameter must be a dictionary with the date strings using the dateutil format. Requires python-dateutil.
once  This will schedule a job to run once on the specified date.
once_fmt  The default date format is ISO 8601 but can be overridden by also specifying the once_fmt option.
enabled  Whether the job should be enabled or disabled. Value should be a boolean.
return_job  Whether to return information to the Salt master upon job completion.
metadata  Using the metadata parameter special values can be associated with a scheduled job. These values are not used in the execution of the job, but can be used to search for specific jobs later if combined with the return_job parameter. The metadata parameter must be specified as a dictionary, otherwise it will be ignored.
returner  The returner to use to return the results of the scheduled job.
return_config  The alternative configuration to use for returner configuration options.
persist  Whether the job should persist between minion restarts, defaults to True.

31.27.141  salt.states.selinux

Management of SELinux rules

If SELinux is available for the running system, the mode can be managed and booleans can be set.

enforcing:
  selinux.mode

samba_create_home_dirs:
  selinux.boolean:
    - value: True
    - persist: True

Note:  Use of these states require that the selinux execution module is available.

salt.states.selinux.boolean(name, value, persist=False)
  Set up an SELinux boolean
    name  The name of the boolean to set
    value  The value to set on the boolean
    persist  Defaults to False, set persist to true to make the boolean apply on a reboot

salt.states.selinux.mode(name)
  Verifies the mode SELinux is running in, can be set to enforcing or permissive
    name  The mode to run SELinux in, permissive or enforcing

31.27.142  salt.states.serverdensity_device

Monitor Server with Server Density

New in version 2014.7.0.

Server Density  Is a hosted monitoring service.

Warning:  This state module is beta. It might be changed later to include more or less automation.
Note: This state module requires a pillar for authentication with Server Density:

```
serverdensity:
  api_token: "b97da80a41c4f61bff05975ee51eb1aa"
  account_url: "https://your-account.serverdensity.io"
```

Note: Although Server Density allows duplicate device names in its database, this module will raise an exception if you try monitoring devices with the same name.

Example:

```
'server_name':
  serverdensity_device.monitored

salt.states.serverdensity_device.monitored(name, group=None, salt_name=True,
  salt_params=True, **params)
```

Device is monitored with Server Density.

- `name` Device name in Server Density.
- `salt_name` If `True` (default), takes the name from the id grain. If `False`, the provided name is used.
- `group` Group name under with device will appear in Server Density dashboard. Default - `None`.
- `salt_params` If `True` (default), needed config parameters will be sourced from grains and from `sta-
tus.all_status`.
- `params` Add parameters that you want to appear in the Server Density dashboard. Will overwrite the `salt_params` parameters. For more info, see the API docs.

Usage example:

```
'server_name':
  serverdensity_device.monitored

'server_name':
  serverdensity_device.monitored:
    - group: web-servers

'my_special_server':
  serverdensity_device.monitored:
    - salt_name: False
    - group: web-servers
    - cpuCores: 2
    - os: CentOS
```

### 31.27.143 salt.states.service

**Starting or restarting of services and daemons**

Services are defined as system daemons typically started with system init or rc scripts. Services can be defined as running or dead.

Note: The current status of a service is determined by the return code of the init/rc script status command. A status return code of 0 it is considered running. Any other return code is considered dead.
httpd:
  service.running: []

The service can also be set to be started at runtime via the enable option:

openvpn:
  service.running:
    - enable: True

By default if a service is triggered to refresh due to a watch statement the service is by default restarted. If the desired behavior is to reload the service, then set the reload value to True:

redis:
  service.running:
    - enable: True
    - reload: True
    - watch:
      pkg: redis

Note: More details regarding watch can be found in the Requisites documentation.

salt.states.service.dead(name, enable=None, sig=None, **kwargs)
   Ensure that the named service is dead by stopping the service if it is running
   name  The name of the init or rc script used to manage the service
   enable Set the service to be enabled at boot time, True sets the service to be enabled, False sets the named service to be disabled. The default is None, which does not enable or disable anything.
   sig    The string to search for when looking for the service process with ps

salt.states.service.disabled(name, **kwargs)
   Verify that the service is disabled on boot, only use this state if you don't want to manage the running process, remember that if you want to disable a service to use the enable: False option for the running or dead function.
   name  The name of the init or rc script used to manage the service

salt.states.service.enabled(name, **kwargs)
   Verify that the service is enabled on boot, only use this state if you don't want to manage the running process, remember that if you want to enable a running service to use the enable: True option for the running or dead function.
   name  The name of the init or rc script used to manage the service

salt.states.service.mod_watch(name, sfun=None, sig=None, reload=False, full_restart=False, init_delay=None, force=False, **kwargs)
   The service watcher, called to invoke the watch command.
   name  The name of the init or rc script used to manage the service
   sfun   The original function which triggered the mod_watch call (service.running, for example).
   sig    The string to search for when looking for the service process with ps

salt.states.service.running(name, enable=None, sig=None, init_delay=None, **kwargs)
   Verify that the service is running
   name  The name of the init or rc script used to manage the service
   enable Set the service to be enabled at boot time, True sets the service to be enabled, False sets the named service to be disabled. The default is None, which does not enable or disable anything.
   sig    The string to search for when looking for the service process with ps
   init_delay Some services may not be truly available for a short period after their startup script indicates to the system that they are. Provide an `init_delay' to specify that this state should wait an additional given number of seconds after a service has started before returning. Useful for requisite states wherein a dependent state might assume a service has started but is not yet fully initialized.
31.27.144 salt.states.slack

Send a message to Slack

This state is useful for sending messages to Slack during state runs.

New in version 2015.5.0.

```
salt-message:
  slack.post_message:
    - channel: '#general'
    - from_name: SuperAdmin
    - message: 'This state was executed successfully.'
    - api_key: peWcBiMOS9HrZG15peWcBiMOS9HrZG15
```

The api key can be specified in the master or minion configuration like below:

```
salt:
  api_key: peWcBiMOS9HrZG15peWcBiMOS9HrZG15
```

**salt.states.slack.post_message** *(name, channel, from_name, message, api_key= None)*

Send a message to a Slack channel.

```
salt-message:
  slack.post_message:
    - channel: '#general'
    - from_name: SuperAdmin
    - message: 'This state was executed successfully.'
    - api_key: peWcBiMOS9HrZG15peWcBiMOS9HrZG15
```

The following parameters are required:

- **name** The unique name for this event.
- **channel** The channel to send the message to. Can either be the ID or the name.
- **from_name** The name of that is to be shown in the `from` field.
- **message** The message that is to be sent to the Slack channel.

The following parameters are optional:

- **api_key** The api key for Slack to use for authentication, if not specified in the configuration options of master or minion.

31.27.145 salt.states.smtp

Sending Messages via SMTP

New in version 2014.7.0.

This state is useful for firing messages during state runs, using the SMTP protocol.

```
server-warning-message:
  smtp.send_msg:
    - name: 'This is a server warning message'
    - profile: my-smtp-account
    - recipient: admins@example.com
```

31.27. Full list of builtin state modules
salt.states.smtp.send_msg(name, recipient, subject, sender, profile, use_ssl='True')
Send a message via SMTP

```
server-warning-message:
smt...'
- profile: my-smtp-account
- subject: 'Message from Salt'
- recipient: admin@example.com
- sender: admin@example.com
- use_ssl: True
```

name The message to send via SMTP

### 31.27.146 salt.states.splunk_search

Splunk Search State Module

New in version 2015.5.0.

This state is used to ensure presence of splunk searches.

```
salt.states.splunk_search.absent(name, profile='splunk')
Ensure a search is absent
```

API Error Search:
splunk_search.absent

The following parameters are required:
- name This is the name of the search in splunk

```
salt.states.splunk_search.present(name, profile='splunk', **kwargs)
Ensure a search is present
```

API Error Search:
splunk_search.present:
splunk_search.present:
- search: index=main sourcetype=blah
- template: alert_5min

The following parameters are required:
- name This is the name of the search in splunk

### 31.27.147 salt.states.ssh_auth

Control of entries in SSH authorized_key files

The information stored in a user's SSH authorized key file can be easily controlled via the ssh_auth state. Defaults can be set by the enc, options, and comment keys. These defaults can be overridden by including them in the name.
Since the YAML specification limits the length of simple keys to 1024 characters, and since SSH keys are often longer than that, you may have to use a YAML `explicit key', as demonstrated in the second example below.

AAAAB3NzaC1kc3MAACBAL0sQ9fJ5bYTEyY==:
  ssh_auth.present:
    - user: root
    - enc: ssh-dss

? AAAAB3NzaC1kc3MAACBAL0sQ9fJ5bYTEyY==...
: ssh_auth.present:
  - user: root
  - enc: ssh-dss

thatch:
  ssh_auth.present:
    - user: root
    - source: salt://ssh_keys/thatch.id_rsa.pub
    - config: %h/.ssh/authorized_keys

sshkeys:
  ssh_auth.present:
    - user: root
    - enc: ssh-rsa
    - options:
      - option1="value1"
      - option2="value2 flag2"
    - comment: myuser
    - names:
      - AAAAB3NzaC1kc3MAACBAL0sQ9fJ5bYTEyY==
      - ssh-dss AAAAB3NzaCL0sQ9fJ5bYTEyY== user@domain
      - option3="value3" ssh-dss AAAAB3NzaC1kcQ9fJFF435bYTEyY== other@testdomain
      - AAAAB3NzaC1kcQ9fJFF435bYTEyY== newcomment

salt.states.ssh_auth.absent(name, user, enc='ssh-rsa', comment='`, source='`, options=None, config='.`ssh/authorized_keys')

Verifies that the specified SSH key is absent

name  The SSH key to manage
user  The user who owns the SSH authorized keys file to modify
enc  Defines what type of key is being used; can be ed25519, ecdsa, ssh-rsa or ssh-dss
comment  The comment to be placed with the SSH public key
options  The options passed to the key, pass a list object
source  The source file for the key(s). Can contain any number of public keys, in standard ``authorized_keys' format. If this is set, comment, enc and options will be ignored.

New in version 2015.8.0.

config  The location of the authorized keys file relative to the user's home directory, defaults to `.`ssh/authorized_keys`. Token expansion %u and %h for username and home path supported.

salt.states.ssh_auth.present(name, user, enc='ssh-rsa', comment='`, source='`, options=None, config='.`ssh/authorized_keys', **kwargs)

Verifies that the specified SSH key is present for the specified user

name  The SSH key to manage
user  The user who owns the SSH authorized keys file to modify
enc  Defines what type of key is being used; can be ed25519, ecdsa, ssh-rsa or ssh-dss
comment  The comment to be placed with the SSH public key
source  The source file for the key(s). Can contain any number of public keys, in standard ``authorized_keys' format. If this is set, comment and enc will be ignored.
Note: The source file must contain keys in the format `<enc> <key> <comment>`. If you have generated a keypair using PuTTYgen, then you will need to do the following to retrieve an OpenSSH-compatible public key.

1. In PuTTYgen, click Load, and select the private key file (not the public key), and click Open.
2. Copy the public key from the box labeled Public key for pasting into OpenSSH authorized_keys file.
3. Paste it into a new file.

options  The options passed to the key, pass a list object.

config  The location of the authorized keys file relative to the user's home directory, defaults to ".ssh/authorized_keys". Token expansion %u and %h for username and home path supported.

31.27.148 salt.states.ssh_known_hosts

Control of SSH known_hosts entries

Manage the information stored in the known_hosts files.

github.com:
 ssh_known_hosts:
 - present
 - user: root

e.example.com:
 ssh_known_hosts:
 - absent
 - user: root

salt.states.ssh_known_hosts.absent(name, user=None, config=None)
 Verifies that the specified host is not known by the given user.

name  The host name.
user  The user who owns the ssh authorized keys file to modify.
config  The location of the authorized keys file relative to the user's home directory, defaults to ".ssh/known_hosts". If no user is specified, defaults to "/etc/ssh/ssh_known_hosts". If present, must be an absolute path when a user is not specified.

salt.states.ssh_known_hosts.present(name, user=None, fingerprint=None, key=None, port=None, enc=None, config=None, hash_hostname=True)
 Verifies that the specified host is known by the specified user.

On many systems, specifically those running with openssh 4 or older, the enc option must be set, only openssh 5 and above can detect the key type.

name  The name of the remote host (e.g. `github.com`)
user  The user who owns the ssh authorized keys file to modify.
fingerprint  The fingerprint of the key which must be presented in the known_hosts file (optional if key specified).
key  The public key which must be presented in the known_hosts file (optional if fingerprint specified).
port  optional parameter, denoting the port of the remote host, which will be used in case, if the public key will be requested from it. By default the port 22 is used.
enc  Defines what type of key is being used, can be ed25519, ecdsa ssh-rsa or ssh-dss.
config  The location of the authorized keys file relative to the user's home directory, defaults to ".ssh/known_hosts". If no user is specified, defaults to "/etc/ssh/ssh_known_hosts". If present, must...
be an absolute path when a user is not specified.

hash_hostname  [True] Hash all hostnames and addresses in the output.

31.27.149 salt.states.stateconf

Stateconf System

The stateconf system is intended for use only with the stateconf renderer. This State module presents the set function. This function does not execute any functionality, but is used to interact with the stateconf renderer.

salt.states.stateconf.context(name, **kwargs)
   No-op state to support state config via the stateconf renderer.

tsalt.states.stateconf.set(name, **kwargs)
   No-op state to support state config via the stateconf renderer.

31.27.150 salt.states.status

Minion status monitoring

Maps to the status execution module.

salt.states.status.loadavg(name, maximum=None, minimum=None)
   Return the current load average for the specified minion. Available values for name are 1-min, 5-min and
   15-min. minimum and maximum values should be passed in as strings.

tsalt.states.status.process(name)
   Return whether the specified signature is found in the process tree. This differs slightly from the services
   states, in that it may refer to a process that is not managed via the init system.

31.27.151 salt.states.stormpath_account

Support for Stormpath.

New in version 2015.8.0.

salt.states.stormpath_account.absent(name, directory_id=None)
   Ensure that an account associated with the given email address is absent. Will search all directories for the
   account, unless a directory_id is specified.
   name The email address of the account to delete.
   directory_id Optional. The ID of the directory that the account is expected to belong to. If not specified, then a
   list of directories will be retrieved, and each will be scanned for the account. Specifying a directory_id will
   therefore cut down on the number of requests to Stormpath, and increase performance of this state.

tsalt.states.stormpath_account.present(name, **kwargs)
   Ensure that an account is present and properly configured
   name The email address associated with the Stormpath account
   directory_id The ID of a directory which the account belongs to. Required.
   password Required when creating a new account. If specified, it is advisable to reference the password in another
   database using an sdb:// URL. Will NOT update the password if an account already exists.
   givenName Required when creating a new account.
   surname Required when creating a new account.
   username Optional. Must be unique across the owning directory. If not specified, the username will default
to the email field.
   middleName Optional.
status enabled accounts are able to login to their assigned applications, disabled accounts may not login to applications, unverified accounts are disabled and have not verified their email address.
customData. Optional. Must be specified as a dict.

31.27.152 salt.states.supervisord

Interaction with the Supervisor daemon

```python
wsgi_server:
    supervisord.running:
        - require:
        - pkg: supervisor
        - watch:
        - file: /etc/nginx/sites-enabled/wsgi_server.conf

salt.states.supervisord.dead(name, user=None, conf_file=None, bin_env=None)
Ensure the named service is dead (not running).
name Service name as defined in the supervisor configuration file
user Name of the user to run the supervisorctl command

New in version 0.17.0.
conf_file path to supervisorctl config file
bin_env path to supervisorctl bin or path to virtualenv with supervisor installed

salt.states.supervisord.mod_watch(name, restart=True, update=False, user=None, conf_file=None, bin_env=None, **kwargs)
salt.states.supervisord.running(name, restart=False, update=False, user=None, conf_file=None, bin_env=None)
Ensure the named service is running.
name Service name as defined in the supervisor configuration file
restart Whether to force a restart
update Whether to update the supervisor configuration.
user Name of the user to run the supervisorctl command

New in version 0.17.0.
conf_file path to supervisorctl config file
bin_env path to supervisorctl bin or path to virtualenv with supervisor installed

31.27.153 salt.states.svn

Manage SVN repositories

Manage repository checkouts via the svn vcs system:

http://unladen-swallow.googlecode.com/svn/trunk/:
svn.latest:
    - target: /tmp/swallow

salt.states.svn.dirty(name, target, user=None, username=None, password=None, ignore_unversioned=False)
Determine if the working directory has been changed.
salt.states.svn.export

Export a file or directory from an SVN repository

- `name`: Address and path to the file or directory to be exported.
- `target`: Name of the target directory where the checkout will put the working directory
- `rev`: The name revision number to checkout. Enable `force` if the directory already exists.
- `user`: Name of the user performing repository management operations
- `username`: The user to access the name repository with. The svn default is the current user
- `password`: Connect to the Subversion server with this password
- `force`: Continue if conflicts are encountered
- `overwrite`: Overwrite existing target
- `externals`: Change to False to not checkout or update externals
- `trust`: Automatically trust the remote server.

salt.states.svn.latest

Checkout or update the working directory to the latest revision from the remote repository.

- `name`: Address of the name repository as passed to `svn checkout`
- `target`: Name of the target directory where the checkout will put the working directory
- `rev`: The name revision number to checkout. Enable `force` if the directory already exists.
- `user`: Name of the user performing repository management operations
- `username`: The user to access the name repository with. The svn default is the current user
- `password`: Connect to the Subversion server with this password
- `force`: Continue if conflicts are encountered
- `externals`: Change to False to not checkout or update externals
- `trust`: Automatically trust the remote server.

31.27.154 salt.states.sysctl

Configuration of the Linux kernel using sysctl

Control the kernel sysctl system.

```
vm.swappiness:
    sysctl.present:
      - value: 20
```

salt.states.sysctl.present

Ensure that the named sysctl value is set in memory and persisted to the named configuration file. The default sysctl configuration file is `/etc/sysctl.conf`

- `name`: The name of the sysctl value to edit
- `value`: The sysctl value to apply
- `config`: The location of the sysctl configuration file. If not specified, the proper location will be detected based on platform.

31.27.155 salt.states.syslog_ng

State module for syslog_ng

- `maintainer`: Tibor Benke <btibi@sch.bme.hu>
maturity  new
depends  cmd, ps, syslog_ng
platform  all

Users can generate syslog-ng configuration files from YAML format or use plain ones and reload, start, or stop their syslog-ng by using this module.

Details

The service module is not available on all system, so this module includes syslog_ng.reloadd, syslog_ng.stopped, and syslog_ng.started functions. If the service module is available on the computers, users should use that.

Users can generate syslog-ng configuration with syslog_ng.config function. For more information see syslog-ng state usage.

Syslog-ng configuration file format

The syntax of a configuration snippet in syslog-ng.conf:

```
object_type object_id {<options>};
```

These constructions are also called statements. There are options inside of them:

```
option(parameter1, parameter2); option2(parameter1, parameter2);
```

**salt.states.syslog_ng.config**(name, config, write=True)

Builds syslog-ng configuration.

```
name : the id of the Salt document config : the parsed YAML code write : if True, it writes the config into the configuration file, otherwise just returns it
```

**salt.states.syslog_ng.reloaded**(name)

Reloads syslog-ng.

**salt.states.syslog_ng.started**(name=None, user=None, group=None, chroot=None, caps=None, no_caps=False, pidfile=None, enable_core=False, fd_limit=None, verbose=False, debug=False, trace=False, yydebug=False, persist_file=None, control=None, worker_threads=None, *args, **kwargs)

Ensures, that syslog-ng is started via the given parameters.

Users shouldn’t use this function, if the service module is available on their system.

**salt.states.syslog_ng.stopped**(name=None)

Kills syslog-ng.

### 31.27.156 salt.states.sysrc

**salt.states.sysrc.absent**(name, **kwargs)

Ensure a sysrc variable is absent.

```
name  The variable name to set
```
file  (optional) The rc file to add the variable to.
  jail  (option) the name or JID of the jail to set the value in.

salt.states.sysrc.managed(name, value, **kwargs)
  Ensure a sysrc variable is set to a specific value.
  name  The variable name to set
  value  Value to set the variable to
  file  (optional) The rc file to add the variable to.
  jail  (option) the name or JID of the jail to set the value in.

31.27.157  salt.states.test

Test States

Provide test case states that enable easy testing of things to do with state calls, e.g. running, calling, logging, output filtering etc.

always-passes:
  test.succeed_without_changes:
    - name: foo

always-fails:
  test.fail_without_changes:
    - name: foo

always-changes-and-succeeds:
  test.succeed_with_changes:
    - name: foo

always-changes-and-fails:
  test.fail_with_changes:
    - name: foo

my-custom-combo:
  test.configurable_test_state:
    - name: foo
    - changes: True
    - result: False
    - comment: bar.baz

is-pillar-foo-present-and-bar-is-int:
  test.check_pillar:
    - present:
      - foo
    - integer:
      - bar

salt.states.test.check_pillar(name, present=None, boolean=None, integer=None, string=None, listing=None, dictionary=None, verbose=False)
  Checks the presence and, optionally, the type of given keys in Pillar. Supported kwargs for types are: - boolean (bool) - integer (int) - string (str) - listing (list) - dictionary (dict)
  Checking for None type pillars is not implemented yet.

is-pillar-foo-present-and-bar-is-int:
  test.check_pillar:
- present:
  - foo
- integer:
  - bar

```
salt.states.test.configurable_test_state(name, changes=True, result=True, comment='')
```
A configurable test state which determines its output based on the inputs.

- name: A unique string.
- changes: Do we return anything in the changes field? Accepts True, False, and 'Random' Default is True
- result: Do we return successfully or not? Accepts True, False, and 'Random' Default is True
- comment: String to fill the comment field with. Default is ''

```
salt.states.test.fail_with_changes(name)
```
Returns failure and changes is not empty.

- name: A unique string.

```
salt.states.test.fail_without_changes(name)
```
Returns failure.

- name: A unique string.

```
salt.states.test.mod_watch(name, sfun=None, **kwargs)
```
'Call this function via a watch statement

- name: A unique string.
- sfun: None
- **kwargs: Any parameters in the state return dictionary can be customized by adding the keywords result, comment, and changes.

```
this_state_will_return_changes:
  test.succeed_with_changes

this_state_will_NOT_return_changes:
  test.succeed_without_changes

this_state_is_watching_another_state:
  test.succeed_without_changes:
    - comment: 'This is a custom comment'
    - watch:
      - test: this_state_will_return_changes
      - test: this_state_will_NOT_return_changes

this_state_is_also_watching_another_state:
  test.succeed_without_changes:
    - watch:
      - test: this_state_will_NOT_return_changes

salt.states.test.show_notification(name, text=None, **kwargs)
```
Simple notification using text argument.

- name: A unique string.
- text: Text to return in the comment.
salt.states.test.succeed_with_changes(name)
   Returns successful and changes is not empty
   New in version 2014.7.0.
   name: A unique string.

salt.states.test.succeed_without_changes(name)
   Returns successful.
   New in version 2014.7.0.
   name A unique string.

31.27.158 salt.states.timezone

Management of timezones

The timezone can be managed for the system:

America/Denver:
   timezone.system

   The system and the hardware clock are not necessarily set to the same time. By default, the hardware clock is set to localtime, meaning it is set to the same time as the system clock. If utc is set to True, then the hardware clock will be set to UTC, and the system clock will be an offset of that.

America/Denver:
   timezone.system:
   - utc: True

   The Ubuntu community documentation contains an explanation of this setting, as it applies to systems that dual-boot with Windows. This is explained in greater detail here.

salt.states.timezone.system(name, utc=True)
   Set the timezone for the system.
   name The name of the timezone to use (e.g.: America/Denver)
   utc Whether or not to set the hardware clock to UTC (default is True)

31.27.159 salt.states.tls

Enforce state for SSL/TLS

salt.states.tls.valid_certificate(name, weeks=0, days=0, hours=0, minutes=0, seconds=0)
   Verify that a TLS certificate is valid now and (optionally) will be valid for the time specified through weeks, days, hours, minutes, and seconds.

31.27.160 salt.states.tomcat

This state uses the manager webapp to manage Apache tomcat webapps This state requires the manager webapp to be enabled

The following grains/pillar should be set:

   tocat-manager:user: admin user name
   tocat-manager:passwd: password

31.27. Full list of built-in state modules
and also configure a user in the conf/tomcat-users.xml file:

```xml
<?xml version='1.0' encoding='utf-8'?>
<tomcat-users>
    <role rolename="manager-script"/>
    <user username="tomcat" password="tomcat" roles="manager-script"/>
</tomcat-users>
```

Notes:

- Not supported multiple version on the same context path
- if you use only this module for deployments you might want to restrict access to the manager so its only accessible via localhost for more info: [http://tomcat.apache.org/tomcat-7.0-doc/manager-howto.html#Configuring_Manager_Application_Access](http://tomcat.apache.org/tomcat-7.0-doc/manager-howto.html#Configuring_Manager_Application_Access)

- Tested on:
  - JVM Vendor: Sun Microsystems Inc.
  - JVM Version: 1.6.0_43-b01
  - OS Architecture: amd64
  - OS Name: Linux
  - OS Version: 2.6.32-358.el6.x86_64
  - Tomcat Version: Apache Tomcat/7.0.37

salt.states.tomcat.mod_watch(name, url='http://localhost:8080/manager', timeout=180)

The tomcat watcher function. When called it will reload the webapp in question

salt.states.tomcat.undeployed(name, url='http://localhost:8080/manager', timeout=180)

Enforce that the WAR will be un-deployed from the server

name the context path to deploy

url [http://localhost:8080/manager] the URL of the server manager webapp

timeout [180] timeout for HTTP request to the tomcat manager

Example:

```yaml
jenkins:
  tomcat.undeployed:
    - name: /ran
    - require:
      - service: application-service
```

salt.states.tomcat.wait(name, url='http://localhost:8080/manager', timeout=180)

Wait for the tomcat manager to load

Notice that if tomcat is not running we won’t wait for it start and the state will fail. This state can be required in the tomcat.war_deployed state to make sure tomcat is running and that the manager is running as well and ready for deployment

url [http://localhost:8080/manager] the URL of the server manager webapp

timeout [180] timeout for HTTP request to the tomcat manager

Example:

```yaml
tomcat-service:
  service.running:
    - name: tomcat
```
- enable: True

wait-for-tomcatmanager:
  tomcat.wait:
    - timeout: 300
    - require:
      - service: tomcat-service

jenkins:
  tomcat.war_deployed:
    - name: /ran
    - war: salt://jenkins-1.2.4.war
    - require:
      - tomcat: wait-for-tomcatmanager

salt.states.tomcat.
war_deployed( name, war, force=False, url='http://localhost:8080/manager',
  timeout=180, temp_war_location=None )

Enforce that the WAR will be deployed and started in the context path it will make use of WAR versions
for more info: http://tomcat.apache.org/tomcat-7.0-doc/config/context.html#Naming

name the context path to deploy
war absolute path to WAR file (should be accessible by the user running tomcat) or a path supported by the
salt.modules.cp.get_url function
force force deploy even if version strings are the same, False by default.
url [http://localhost:8080/manager] the URL of the server manager webapp
timeout [180] timeout for HTTP request to the tomcat manager
temp_war_location [None] use another location to temporarily copy to war file by default the system's temp
directory is used

Example:

jenkins:
  tomcat.war_deployed:
    - name: /ran
    - war: salt://jenkins-1.2.4.war
    - require:
      - tomcat: wait-for-tomcatmanager

31.27.161 salt.states.trafficserver

Control Apache Traffic Server

New in version 2015.8.0.

salt.states.trafficserver.

bounce_cluster(name)
  Bounce all Traffic Server nodes in the cluster. Bouncing Traffic Server shuts down and immediately restarts
  Traffic Server, node-by-node.

  bounce_ats_cluster:
    trafficserver.bounce_cluster

salt.states.trafficserver.

bounce_local(name, drain=False)
  Bounce Traffic Server on the local node. Bouncing Traffic Server shuts down and immediately restarts the
  Traffic Server node.
This option modifies the behavior of traffic_line -b and traffic_line -L such that traffic_server is not shut down until the number of active client connections drops to the number given by the proxy.config.restart.active_client_threshold configuration variable.

```
bounce_ats_local:
  trafficserver.bounce_local

bounce_ats_local:
  trafficserver.bounce_local
    - drain: True
```

**salt.states.trafficserver.clear_cluster(name)**
Clears accumulated statistics on all nodes in the cluster.

```
clear_ats_cluster:
  trafficserver.clear_cluster
```

**salt.states.trafficserver.clear_node(name)**
Clears accumulated statistics on the local node.

```
clear_ats_node:
  trafficserver.clear_node
```

**salt.states.trafficserver.offline(name, path)**
Mark a cache storage device as offline. The storage is identified by a path which must match exactly a path specified in storage.config. This removes the storage from the cache and redirects requests that would have used this storage to other storage. This has exactly the same effect as a disk failure for that storage. This does not persist across restarts of the traffic_server process.

```
offline_ats_path:
  trafficserver.offline:
    - path: /path/to/cache
```

**salt.states.trafficserver.refresh(name)**
Initiate a Traffic Server configuration file reread. Use this command to update the running configuration after any configuration file modification.

The timestamp of the last reconfiguration event (in seconds since epoch) is published in the proxy.node.config.reconfigure_time metric.

```
refresh_ats:
  trafficserver.refresh
```

**salt.states.trafficserver.restart_cluster(name)**
Restart the traffic_manager process and the traffic_server process on all the nodes in a cluster.

```
restart_ats_cluster:
  trafficserver.restart_cluster
```

**salt.states.trafficserver.restart_local(name, drain=False)**
Restart the traffic_manager and traffic_server processes on the local node.

This option modifies the behavior of traffic_line -b and traffic_line -L such that traffic_server is not shut down until the number of active client connections drops to the number given by the proxy.config.restart.active_client_threshold configuration variable.
restart_ats_local:
    trafficserver.restart_local

restart_ats_local_drain:
    trafficserver.restart_local
    - drain: True

salt.states.trafficserver.set_var(name, value)
Set Traffic Server variable values

proxy.config.proxy_name:
    trafficserver.set_var:
        - value: cdn.site.domain.tld

OR

traffic_server_setting:
    trafficserver.set_var:
        - name: proxy.config.proxy_name
        - value: cdn.site.domain.tld

salt.states.trafficserver.shutdown(name)
Shut down Traffic Server on the local node.

shutdown_ats:
    trafficserver.shutdown

salt.states.trafficserver.startup(name)
Start Traffic Server on the local node.

startup_ats:
    trafficserver.startup

salt.states.trafficserver.zero_cluster(name)
Reset performance statistics to zero across the cluster.

zero_ats_cluster:
    trafficserver.zero_cluster

salt.states.trafficserver.zero_node(name)
Reset performance statistics to zero on the local node.

zero_ats_node:
    trafficserver.zero_node

31.27.162 salt.states.tuned

Interface to Red Hat tuned-adm module

maintainer Syed Ali <alicsyed@gmail.com>
maturity new
depends  cmd.run
platform  Linux

salt.states.tuned.off(name=None)
   Turns 'tuned' off. Example tuned.sls file for turning tuned off:
   tuned: tuned.off: []
   To see a valid list of states call execution module: tuned.list

salt.states.tuned.profile(name)
   This state module allows you to modify system tuned parameters
   Example tuned.sls file to set profile to virtual-guest
   tuned:
       tuned:
           • profile
           • name: virtual-guest
   name  tuned profile name to set the system to
   To see a valid list of states call execution module: tuned.list

31.27.163  salt.states.uptime

Monitor Web Server with Uptime

Uptime is an open source remote monitoring application using Node.js, MongoDB, and Twitter Bootstrap.

Warning:  This state module is beta. It might be changed later to include more or less automation.

Note:  This state module requires a pillar to specify the location of your uptime install

uptime:
    application_url: "http://uptime-url.example.org"

Example:

url:
    uptime.monitored
url/sitemap.xml:
    uptime.monitored:
        - polling: 600  # every hour

salt.states.uptime.monitored(name, **params)
   Makes sure an URL is monitored by uptime. Checks if URL is already monitored, and if not, adds it.

31.27.164  salt.states.user

Management of user accounts

The user module is used to create and manage user settings, users can be set as either absent or present
fred:
user.present:
  - fullname: Fred Jones
  - shell: /bin/zsh
  - home: /home/fred
  - uid: 4000
  - gid: 4000
  - groups:
    - wheel
    - storage
    - games

testuser:
user.absent

salt.states.user.absent(name, purge=False, force=False)
Ensure that the named user is absent
  name The name of the user to remove
  purge Set purge to True to delete all of the user's files as well as the user, Default is False.
  force If the user is logged in, the absent state will fail. Set the force option to True to remove the user even if they are logged in. Not supported in FreeBSD and Solaris, Default is False.

salt.states.user.present(name, uid=None, gid=None, gid_from_name=False, groups=None, optional_groups=None, remove_groups=True, home=None, createhome=True, password=None, enforce_password=True, empty_password=False, shell=None, unique=True, system=False, fullname=None, roomnumber=None, workphone=None, homephone=None, loginclass=None, date=None, mindays=None, maxdays=None, inactdays=None, warndays=None, expire=None, win_homedrive=None, win_profile=None, win_logonscript=None, win_description=None)
Ensure that the named user is present with the specified properties
  name The name of the user to manage
  uid The user id to assign, if left empty then the next available user id will be assigned
  gid The default group id. Also accepts group name.
  gid_from_name If True, the default group id will be set to the id of the group with the same name as the user, Default is False.
  groups A list of groups to assign the user to, pass a list object. If a group specified here does not exist on the minion, the state will fail. If set to the empty list, the user will be removed from all groups except the default group.
  optional_groups A list of groups to assign the user to, pass a list object. If a group specified here does not exist on the minion, the state will silently ignore it.
  NOTE: If the same group is specified in both "groups" and "optional_groups", then it will be assumed to be required and not optional.
  remove_groups Remove groups that the user is a member of that weren't specified in the state, Default is True.
  home The custom login directory of user. Uses default value of underlying system if not set. Notice that this directory does not have to exist. This also the location of the home directory to create if createhome is set to True.
  createhome If False, the home directory will not be created if it doesn’t exist. Please note that directories leading up to the home directory will NOT be created, Default is True.
  password A password hash to set for the user. This field is only supported on Linux, FreeBSD, NetBSD, OpenBSD, and Solaris. For Windows this is the plain text password.
  Changed in version 0.16.0: BSD support added.
  enforce_password Set to False to keep the password from being changed if it has already been set and the password hash differs from what is specified in the "password" field. This option will be ignored if
`password` is not specified, Default is True.

**empty_password** Set to True to enable password-less login for user, Default is False.

**shell** The login shell, defaults to the system default shell

**unique** Require a unique UID, Default is True.

**system** Choose UID in the range of FIRST_SYSTEM_UID and LAST_SYSTEM_UID, Default is False.

**loginclass** The login class, defaults to empty (BSD only)

User comment field (GECOS) support (currently Linux, BSD, and MacOS only):

The below values should be specified as strings to avoid ambiguities when the values are loaded. (Especially the phone and room number fields which are likely to contain numeric data)

**fullname** The user's full name

**roomnumber** The user's room number (not supported in MacOS)

**workphone** The user's work phone number (not supported in MacOS)

**homephone** The user's home phone number (not supported in MacOS)

Changed in version 2014.7.0: Shadow attribute support added.

Shadow attributes support (currently Linux only):

The below values should be specified as integers.

**date** Date of last change of password, represented in days since epoch (January 1, 1970).

**mindays** The minimum number of days between password changes.

**maxdays** The maximum number of days between password changes.

**inactdays** The number of days after a password expires before an account is locked.

**warndays** Number of days prior to maxdays to warn users.

**expire** Date that account expires, represented in days since epoch (January 1, 1970).

The below parameters apply to windows only:

**win_homedrive** (Windows Only) The drive letter to use for the home directory. If not specified the home directory will be a unc path. Otherwise the home directory will be mapped to the specified drive. Must be a letter followed by a colon. Because of the colon, the value must be surrounded by single quotes. ie:

- win_homedrive: `U:

Changed in version 2015.8.0.

**win_profile** (Windows Only) The custom profile directory of the user. Uses default value of underlying system if not set.

Changed in version 2015.8.0.

**win_logonscript** (Windows Only) The full path to the logon script to run when the user logs in.

Changed in version 2015.8.0.

**win_description** (Windows Only) A brief description of the purpose of the users account.

Changed in version 2015.8.0.

### 31.27.165 salt.states.vbox_guest

VirtualBox Guest Additions installer state

salt.states.vbox_guest.additions_installed(name, reboot=False, upgrade_os=False)

Ensure that the VirtualBox Guest Additions are installed. Uses the CD, connected by VirtualBox.

name The name has no functional value and is only used as a tracking reference.

reboot [False] Restart OSto complete installation.

upgrade_os [False] Upgrade OS (to ensure the latests version of kernel and developer tools installed).

salt.states.vbox_guest.additions_removed(name, force=False)

Ensure that the VirtualBox Guest Additions are removed. Uses the CD, connected by VirtualBox.

To connect VirtualBox Guest Additions via VirtualBox graphical interface press `Host+D` (`Host` is usually `Right Ctrl`).

name The name has no functional value and is only used as a tracking reference.

force Force VirtualBox Guest Additions removing.
salt.states.vbox_guest.grant_access_to_shared_folders_to(name, users=None)
Grant access to auto-mounted shared folders to the users.

User is specified by its name. To grant access for several users use argument users.
name Name of the user to grant access to auto-mounted shared folders to.
users List of names of users to grant access to auto-mounted shared folders to. If specified, name will not be taken into account.

31.27.166 salt.states.victorops

Create an Event in VictorOps

New in version 2015.8.0.
This state is useful for creating events on the VictorOps service during state runs.

webserver-warning-message:
    victorops.create_event:
        - message_type: 'CRITICAL'
        - entity_id: 'webserver/diskspace'
        - state_message: 'Webserver diskspace is low.'

salt.states.victorops.create_event(name, message_type, routing_key='everyone', **kwargs)
Create an event on the VictorOps service

webserver-warning-message:
    victorops.create_event:
        - message_type: 'CRITICAL'
        - entity_id: 'webserver/diskspace'
        - state_message: 'Webserver diskspace is low.'

database-server-warning-message:
    victorops.create_event:
        - message_type: 'WARNING'
        - entity_id: 'db_server/load'
        - state_message: 'Database Server load is high.'
        - entity_is_host: True
        - entity_display_name: 'dbdserver.example.com'

The following parameters are required:
name This is a short description of the event.
message_type One of the following values: INFO, WARNING, ACKNOWLEDGEMENT, CRITICAL, RECOVERY.
The following parameters are optional:
routing_key The key for where messages should be routed. By default, sent to `everyone` route.
entity_id The name of alerting entity. If not provided, a random name will be assigned.
timestamp Timestamp of the alert in seconds since epoch. Defaults to the time the alert is received at VictorOps.
timestamp_fmt The date format for the timestamp parameter. Defaults to `\%Y-%m-%dT%H:%M:%S`.
state_start_time The time this entity entered its current state (seconds since epoch). Defaults to the time alert is received.
state_start_time_fmt The date format for the timestamp parameter. Defaults to `%Y-%m-%dT%H:%M:%S'.

state_message Any additional status information from the alert item.

entity_is_host Used within VictorOps to select the appropriate display format for the incident.

entity_display_name Used within VictorOps to display a human-readable name for the entity.

ack_message A user entered comment for the acknowledgment.

ack_author The user that acknowledged the incident.

### 31.27.167 salt.states.virtualenv

**Setup of Python virtualenv sandboxes**

```python
salt.states.virtualenv_mod.managed(name, venv_bin=None, requirements=None, system_site_packages=False, distribute=False, use_wheel=False, clear=False, python=None, extra_search_dir=None, prompt=None, user=None, no_chown=False, cwd=None, index_url=None, extra_index_url=None, pre_releases=False, no_deps=False, pip_download=None, pip_download_cache=None, pip_exists_action=None, proxy=None, use_vt=False, env_vars=None)
```

Create a virtualenv and optionally manage it with pip

- **name** Path to the virtualenv
- **requirements** Path to a pip requirements file. If the path begins with `salt://` the file will be transferred from the master file server.
- **cwd** Path to the working directory where `''pip install''` is executed.
- **user** The user under which to run virtualenv and pip
- **no_chown**: False When user is given, do not attempt to copy and chown a requirements file (needed if the requirements file refers to other files via relative paths, as the copy-and-chown procedure does not account for such files)
- **use_wheel** [False] Prefer wheel archives (requires pip>=1.4)
- **no_deps**: False Pass `--no-deps` to pip.
- **pip_exists_action**: None Default action of pip when a path already exists: (s)witch, (i)gnore, (w)ipe, (b)ackup
- **proxy**: None Proxy address which is passed to `''pip install''`
- **env_vars** Set environment variables that some builds will depend on. For example, a Python C-module may have a Makefile that needs `INCLUDE_PATH` set to pick up a header file while compiling. Also accepts any kwargs that the virtualenv module will.

```
/var/www/myvirtualenv.com:
virtualenv.managed:
    - system_site_packages: False
    - requirements: salt://REQUIREMENTS.txt
```

### 31.27.168 salt.states.win_dacl

**Windows Object Access Control Lists**

Ensure an ACL is present
parameters: name - the path of the object objectType - Registry/File/Directory user - user account for the ace permission - permission for the ace (see module win_acl for available permissions for each objectType) acetype - Allow/Deny propagation - how the ACL should apply to child objects (see module win_acl for available propagation types)

addAcl:
  win_dacl.present:
    - name: HKEY_LOCAL_MACHINE\SOFTWARE\mykey
    - objectType: Registry
    - user: FakeUser
    - permission: FullControl
    - acetype: ALLOW
    - propagation: KEY&SUBKEYS

Ensure an ACL does not exist

parameters: name - the path of the object objectType - Registry/File/Directory user - user account for the ace permission - permission for the ace (see module win_acl for available permissions for each objectType) acetype - Allow/Deny propagation - how the ACL should apply to child objects (see module win_acl for available propagation types)

removeAcl:
  win_dacl.absent:
    - name: HKEY_LOCAL_MACHINE\SOFTWARE\mykey
    - objectType: Registry
    - user: FakeUser
    - permission: FullControl
    - acetype: ALLOW
    - propagation: KEY&SUBKEYS

Ensure an object is inheriting permissions

parameters: name - the path of the object objectType - Registry/File/Directory clear_existing_acl - True/False - when inheritance is enabled, should the existing ACL be kept or cleared out

elInherit:
  win_dacl.enableinheritance:
    - name: HKEY_LOCAL_MACHINE\SOFTWARE\mykey
    - objectType: Registry
    - clear_existing_acl: True

Ensure an object is not inheriting permissions

parameters: name - the path of the object objectType - Registry/File/Directory copy_inherited_acl - True/False - if inheritance is enabled, should the inherited permissions be copied to the ACL when inheritance is disabled
31.27.169 salt.states.win_dns_client

Module for configuring DNS Client on Windows systems

salt.states.win_dns_client.dns_dhcp(name, interface='Local Area Connection')
Configure the DNS server list from DHCP Server

salt.states.win_dns_client.dns_exists(name, servers=None, interface='Local Area Connection', replace=False)
Configure the DNS server list in the specified interface

Example:

```
config_dns_servers:
  win_dns_client.dns_exists:
    - replace: True  # remove any servers not in the "servers" list, default is False
    - servers:
      - 8.8.8.8
      - 8.8.8.9
```

salt.states.win_dns_client.primary_suffix(name, suffix=None, updates=False)
New in version 2014.7.0.
Configure the global primary DNS suffix of a DHCP client.
suffix [None] The suffix which is advertised for this client when acquiring a DHCP lease When none is set, the explicitly configured DNS suffix will be removed.
updates [False] Allow syncing the DNS suffix with the AD domain when the client's AD domain membership changes

```
primary_dns_suffix:
  win_dns_client.primary_suffix:
    - suffix: sub.domain.tld
    - updates: True
```
31.27.170 salt.states.win_firewall

State for configuring Windows Firewall

```python
salt.states.win_firewall.add_rule(name, localport, protocol='tcp', action='allow', dir='in')
```

Add a new firewall rule (Windows only)

```python
salt.states.win_firewall.disabled(name)
```

Disable all the firewall profiles (Windows only)

31.27.171 salt.states.win_network

Configuration of network interfaces on Windows hosts

New in version 2014.1.0.

This module provides the network state(s) on Windows hosts. DNS servers, IP addresses and default gateways can currently be managed.

Below is an example of the configuration for an interface that uses DHCP for both DNS servers and IP addresses:

```
Local Area Connection #2:
    network.managed:
        - dns_proto: dhcp
        - ip_proto: dhcp
```

**Note:** Both the `dns_proto` and `ip_proto` arguments are required.

Static DNS and IP addresses can be configured like so:

```
Local Area Connection #2:
    network.managed:
        - dns_proto: static
        - dns_servers:
            - 8.8.8.8
            - 8.8.4.4
        - ip_proto: static
        - ip_addrs:
            - 10.2.3.4/24
```

**Note:** IP addresses are specified using the format `<ip-address>/<subnet-length>`. Salt provides a convenience function called `ip.get_subnet_length` to calculate the subnet length from a netmask.

Optionally, if you are setting a static IP address, you can also specify the default gateway using the `gateway` parameter:

```
Local Area Connection #2:
    network.managed:
        - dns_proto: static
        - dns_servers:
            - 8.8.8.8
            - 8.8.4.4
        - ip_proto: static
        - ip_addrs:
```
salt.states.win_network.managed

Ensure that the named interface is configured properly.

- **name**: The name of the interface to manage
- **dns_proto**: [None] Set to **static** and use the **dns_servers** parameter to provide a list of DNS nameservers.
  - set to **dhcp** to use DHCP to get the DNS servers.
- **dns_servers**: [None] A list of static DNS servers.
- **ip_proto**: [None] Set to **static** and use the **ip_addrs** and (optionally) **gateway** parameters to provide a list of static IP addresses and the default gateway. Set to **dhcp** to use DHCP.
- **ip_addrs**: [None] A list of static IP addresses.
- **gateway**: [None] A list of static IP addresses.
- **enabled**: [True] Set to **False** to ensure that this interface is disabled.

31.27.172 salt.states.win_path

Manage the Windows System PATH

salt.states.win_path.absent(name)

Remove the directory from the SYSTEM path

- **index**: where the directory should be placed in the PATH (default: 0)

Example:

'C:\sysinternals':
  win_path.absent

salt.states.win_path.exists(name, index=None)

Add the directory to the system PATH at index location

- **index**: where the directory should be placed in the PATH (default: None) [Note: Providing no index will append directory to PATH and will not enforce its location within the PATH.]

Example:

'C:\python27':
  win_path.exists

'C:\sysinternals':
  win_path.exists:
    index: 0

31.27.173 salt.states.win_powercfg

This module allows you to control the power settings of a windows minion via powercfg.

New in version 2015.8.0.

- **monitor**: 10.2.3.4/24
- gateway: 10.2.3.1

monitor:
  powercfg.set_timeout:
    - value: 30
    - power: dc
**salt.states.win_powercfg.set_timeout**(*name*, *value*, *power='ac'*)

Set the sleep timeouts of specific items such as disk, monitor.

CLI Example:

```yaml
monitor:
    powercfg.set_timeout:
      - value: 30
      - power: dc

disk:
    powercfg.set_timeout:
      - value: 12
      - power: ac
```

- **name**: The setting to change, can be one of the following: monitor, disk, standby, hibernate
- **timeout**: The amount of time in minutes before the item will timeout i.e the monitor
- **power**: Should we set the value for AC or DC (battery)? Valid options ac,dc.

### 31.27.174 salt.states.win_servermanager

Manage Windows features via the ServerManager powershell module

**salt.states.win_servermanager.installed**(*name*, *recurse=False*, *force=False*)

Install the windows feature

- **name**: short name of the feature (the right column in win_servermanager.list_available)
- **recurse**: install all sub-features as well
- **force**: if the feature is installed but on of its sub-features are not installed set this to True to force the installation of the sub-features

Note: Some features require reboot after un/installation. If so, until the server is restarted other features cannot be installed!

Example:

Run `salt MinionName win_servermanager.list_available` to get a list of available roles and features. Use the name in the right column. Do not use the role or feature names mentioned in the PKGMGR documentation. In this example for IIS-WebServerRole the name to be used is Web-Server.

```yaml
ISWebserverRole:
    win_servermanager.installed:
      - force: True
      - recurse: True
      - name: Web-Server
```

**salt.states.win_servermanager.removed**(*name*)

Remove the windows feature

- **name**: short name of the feature (the right column in win_servermanager.list_available)

Note: Some features require a reboot after un/installation. If so the feature will not be completely uninstalled until the server is restarted.

Example:

Run `salt MinionName win_servermanager.list_installed` to get a list of all features installed. Use the top name listed for each feature, not the indented one. Do not use the role or feature names mentioned in the PKGMGR documentation.
ISWebserverRole:
    win_servermanager.removed:
        - name: Web-Server

31.27.175 salt.states.win_system

Management of Windows system information

New in version 2014.1.0.
This state is used to manage system information such as the computer name and description.

ERIK-WORKSTATION:
    system.computer_name: []

This is Erik's computer, don't touch!:
    system.computer_desc: []

salt.states.win_system.computer_desc(name)
    Manage the computer's description field
    name  The desired computer description

salt.states.win_system.computer_name(name)
    Manage the computer's name
    name  The desired computer name

31.27.176 salt.states.win_update

Management of the windows update agent

New in version 2014.7.0.
Set windows updates to run by category. Default behavior is to install all updates that do not require user interaction to complete.
Optionally set category to a category of your choice to only install certain updates. Default is to set to install all available updates.
The following example will install all Security and Critical Updates, and download but not install standard updates.

updates:
    win_update.installed:
        - categories:
            - 'Critical Updates'
            - 'Security Updates'
    win_update.downloaded:
        - categories:
            - 'Updates'

You can also specify a number of features about the update to have a fine grain approach to specific types of updates.
These are the following features/states of updates available for configuring:
'UI' - User interaction required, skipped by default
'downloaded' - Already downloaded, skipped by default (downloading)
'present' - Present on computer, included by default (installing)
'installed' - Already installed, skipped by default
'reboot' - Reboot required, included by default
'hidden' - skip those updates that have been hidden.
'software' - Software updates, included by default
'driver' - driver updates, skipped by default

The following example installs all driver updates that don't require a reboot:

gryffindor:
  win_update.installed:
    - includes:
      - driver: True
      - software: False
      - reboot: False

To just update your windows machine, add this your sls:

updates:
  win_update.installed

class salt.states.win_update.PyWinUpdater(categories=None, skipUI=True, skipDownloaded=True, skipInstalled=True, skipReboot=False, skipPresent=True, softwareUpdates=True, driverUpdates=False, skipHidden=True)

salt.states.win_update.downloaded(name, categories=None, includes=None, retries=10)
Cache updates for later install.
  name: if categories is left empty, it will be assumed that you are passing the category option through the name. These are separate because you can only have one name, but can have multiple categories.
categories: the list of categories to be downloaded. These are simply strings in the update's information, so there is no enumeration of the categories available. Some known categories:

  Updates
  Windows 7
  Critical Updates

31.27. Full list of builtin state modules
Security Updates
Update Rollups

**includes**: a list of features of the updates to cull by. Available features:

- 'UI' - User interaction required, skipped by default
- 'downloaded' - Already downloaded, skipped by default (downloading)
- 'present' - Present on computer, included by default (installing)
- 'installed' - Already installed, skipped by default
- 'reboot' - Reboot required, included by default
- 'hidden' - skip those updates that have been hidden.
- 'software' - Software updates, included by default
- 'driver' - driver updates, skipped by default

**retries** Number of retries to make before giving up. This is total, not per step.

salt.states.win_update.**installed**(name, categories=None, includes=None, retries=10)
Install specified windows updates.

- **name**: if categories is left empty, it will be assumed that you are passing the category option through the name. These are separate because you can only have one name, but can have multiple categories.
- **categories**: the list of categories to be downloaded. These are simply strings in the update's information, so there is no enumeration of the categories available. Some known categories:

  - Updates
  - Windows 7
  - Critical Updates
  - Security Updates
  - Update Rollups

**includes**: a list of features of the updates to cull by. Available features:

- 'UI' - User interaction required, skipped by default
- 'downloaded' - Already downloaded, skipped by default (downloading)
- 'present' - Present on computer, included by default (installing)
- 'installed' - Already installed, skipped by default
- 'reboot' - Reboot required, included by default
- 'hidden' - skip those updates that have been hidden.
- 'software' - Software updates, included by default
- 'driver' - driver updates, skipped by default

**retries** Number of retries to make before giving up. This is total, not per step.

### 31.27.177 salt.states.winrepo

Manage Windows Package Repository

salt.states.winrepo.**genrepo**(name, force=False, allow_empty=False)

Refresh the winrepo.p file of the repository (salt-run winrepo.genrepo)

If force is True no checks will be made and the repository will be generated if allow_empty is True then the state will not return an error if there are 0 packages,

**Note**: This state only loads on minions that have the roles: salt-master grain set.

Example:

```
winrepo:
    winrepo.genrepo
```
31.27.178 salt.states.x509

Manage X509 Certificates

New in version 2015.8.0.

This module can enable managing a complete PKI infrastructure including creating private keys, CA’s, certificates and CRLs. It includes the ability to generate a private key on a server, and have the corresponding public key sent to a remote CA to create a CA signed certificate. This can be done in a secure manner, where private keys are always generated locally and never moved across the network.

Here is a simple example scenario. In this example ca is the ca server, and www is a web server that needs a certificate signed by ca.

For remote signing, peers must be permitted to remotely call the sign_remote_certificate function.

/etc/salt/master.d/peer.sls

```
peer:
  .*:
    - x509.sign_remote_certificate
```

/srv/salt/top.sls

```
base:
  '.*':
    - cert
  'ca':
    - ca
  'www':
    - www
```

This state creates the CA key, certificate and signing policy. It also publishes the certificate to the mine where it can be easily retrieved by other minions.

/srv/salt/ca.sls

```
salt-minion:
  service.running:
    - enabled
    - listen:
      - file: /etc/salt/minion.d/signing_policies.conf

/etc/salt/minion.d/signing_policies.conf:
  file.managed:
    - source: salt://signing_policies.conf

/etc/pki:
  file.directory: []

/etc/pki/ca.key:
  x509.private_key_managed:
    - bits: 4096
    - backup: True
    - require:
      - file: /etc/pki

/etc/pki/ca.crt:
  x509.certificate_managed:
```
The signing policy defines properties that override any property requested or included in a CRL. It also can define a restricted list of minions which are allowed to remotely invoke this signing policy.

```
/signing_policies.conf
```

```
x509_signing_policies:
  www:
    - minions: 'www'
    - signing_private_key: /etc/pki/ca.key
    - signing_cert: /etc/pki/ca.crt
    - C: US
    - ST: Utah
    - L: Salt Lake City
    - basicConstraints: "critical CA:false"
    - keyUsage: "critical cRLSign, keyCertSign"
    - subjectKeyIdentifier: hash
    - authorityKeyIdentifier: keyid,issuer:always
    - days_valid: 90
    - copypath: /etc/pki/issued_certs/
```

This state will instruct all minions to trust certificates signed by our new CA. Using jinja to strip newlines from the text avoids dealing with newlines in the rendered yaml, and the `sign_remote_certificate` state will handle properly formatting the text before writing the output.

```
/srv/salt/cert.sls
```

```
/usr/local/share/ca-certificates/intca.crt
```

```
x509.pem_managed:
  - text: "{{ salt['mine.get']('pki', 'x509.get_pem_entries')['pki']["/etc/pki/ca.crt"]|replace('\n', '') }}"
```

This state creates a private key then requests a certificate signed by ca according to the www policy.
salt.states.x509.certificate_managed\(name, days\_remaining=90, backup=False, \*\*kwargs\)

Manage a Certificate

- **name**: Path to the certificate
- **days\_remaining**: The minimum number of days remaining when the certificate should be renewed. Default is 90. A value of 0 disables automatic renewal.
- **backup**: When replacing an existing file, backup the old file on the minion. Default is False.
- **kwargs**: Any arguments supported by x509.create_certificate are supported.

Examples:

```bash
/etc/pki/ca.crt:
    x509.certificate\_managed:
    - signing\_private\_key: /etc/pki/ca.key
    - CN: ca.example.com
    - C: US
    - ST: Utah
    - L: Salt Lake City
    - basic\_Constraints: "critical CA:true"
    - key\_Usage: "critical cRLSign, keyCertSign"
    - subject\_Key\_Identifier: hash
    - authority\_Key\_Identifier: keyid,issuer:always
    - days\_valid: 3650
    - days\_remaining: 0
    - backup: True
```

```bash
/etc/ssl/www.crt:
    x509.certificate\_managed:
    - ca\_server: pki
    - signing\_policy: www
    - public\_key: /etc/ssl/www.key
    - CN: www.example.com
    - days\_valid: 90
    - days\_remaining: 30
    - backup: True
```

salt.states.x509.crl\_managed\(name, signing\_private\_key, signing\_cert=None, revoked=None, days\_valid=100, days\_remaining=30, include\_expired=False, backup=False\)

Manage a Certificate Revocation List

- **name**: Path to the certificate
- **signing\_private\_key**: The private key that will be used to sign this crl. This is usually your CA's private key.
- **signing\_cert**: The certificate of the authority that will be used to sign this crl. This is usually your CA's certificate.
revoked: A list of certificates to revoke. Must include either a serial number or a the certificate itself. Can optionally include the revocation date and notAfter date from the certificate. See example below for details.
days_valid: The number of days the certificate should be valid for. Default is 100.
days_remaining: The crl should be automatically recreated if there are less than days_remaining days until the crl expires. Set to 0 to disable automatic renewal. Default is 30.
include_expired: Include expired certificates in the CRL. Default is False.
backup: When replacing an existing file, backup the old file on the minion. Default is False.

Example:

/etc/pki/ca.crl:
x509.crl_managed:
  - signing_private_key: /etc/pki/myca.key
  - signing_cert: /etc/pki/myca.crt
  - revoked:
    - compromised_Web_key:
      - certificate: /etc/pki/certs/badweb.crt
      - revocation_date: 2015-03-01 00:00:00
      - reason: keyCompromise
    - terminated_vpn_user:
      - serial_number: D6:D2:DC:D8:4D:5C:C0:F4
      - not_after: 2016-01-01 00:00:00
      - revocation_date: 2015-02-25 00:00:00
      - reason: cessationOfOperation

salt.states.x509.csr_managed(name, backup=False, **kwargs)
Manage a Certificate Signing Request
name: Path to the CSR
properties: The properties to be added to the certificate request, including items like subject, extensions and public key. See above for valid properties.

Example:

/etc/pki/mycert.csr:
x509.csr_managed:
  - public_key: /etc/pki/mycert.key
  - CN: www.example.com
  - C: US
  - ST: Utah
  - L: Salt Lake City
  - keyUsage: 'critical dataEncipherment'

salt.states.x509.pem_managed(name, text, backup=False)
Manage the contents of a PEM file directly with the content in text, ensuring correct formatting.
name: The path to the file to manage
text: The PEM formatted text to write.
backup: When replacing an existing file, backup the old file on the minion. Default is False.

salt.states.x509.private_key_managed(name, bits=2048, new=False, backup=False)
Manage a private key’s existence.
name: Path to the private key
bits: Key length in bits. Default 2048.
new: Always create a new key. Defaults to False. Combining new with prereq can allow key rotation whenever a new certificate is generated.
backup: When replacing an existing file, backup the old file on the minion. Default is False.
Example:
The jinja templating in this example ensures a private key is generated if the file doesn’t exist and that a new private key is generated whenever the certificate that uses it is to be renewed.

```yaml
/etc/pki/www.key:
  x509.private_key_managed:
    - bits: 4096
    - new: True
  {% if salt['file.file_exists']('/etc/pki/ca.key') -%}
  - prereq:
    - x509: /etc/pki/www.crt
  {%- endif %}
```

### 31.27.179 salt.states.xmpp

#### Sending Messages over XMPP

New in version 2014.1.0.

This state is useful for firing messages during state runs, using the XMPP protocol

```yaml
server-warning-message:
  xmpp.send_msg:
    - name: 'This is a server warning message'
    - profile: my-xmpp-account
    - recipient: admins@xmpp.example.com/salt
```

**salt.states.xmpp.send_msg**(*name, recipient, profile*)

Send a message to an XMPP user

```yaml
server-warning-message:
  xmpp.send_msg:
    - name: 'This is a server warning message'
    - profile: my-xmpp-account
    - recipient: admins@xmpp.example.com/salt
```

**name** The message to send to the XMPP user

**salt.states.xmpp.send_msg_multi**(*name, profile, recipients=None, rooms=None*)

Send a message to a list of recipients or rooms

```yaml
server-warning-message:
  xmpp.send_msg:
    - name: 'This is a server warning message'
    - profile: my-xmpp-account
    - recipients:
      - admins@xmpp.example.com/salt
    - rooms:
      - qa@conference.xmpp.example.com
```

**name** The message to send to the XMPP user
31.27.180 salt.states.zcbuildout

Management of zc.buildout

This module is inspired from minitage's buildout maker [https://github.com/minitage/minitage/blob/master/src/minitage/core/makers/buildout.py](https://github.com/minitage/minitage/blob/master/src/minitage/core/makers/buildout.py)

New in version Boron.

Note: This state module is beta; the API is subject to change and no promise as to performance or functionality is yet present.

Available Functions

- built

```python
installed1
    buildout.installed:
    - name: /path/to/buildout

installed2
    buildout.installed:
    - name: /path/to/buildout
    - parts:
      - a
      - b
    - python: /path/to/pythonpath/bin/python
    - unless: /bin/test_something_installed
    - onlyif: /bin/test_else_installed
```

```python
salt.states.zcbuildout.installed(name, config='buildout.cfg', quiet=False, parts=None, user=None, env=(), buildout_ver=None, test_release=False, distribute=None, new_st=None, offline=False, newest=False, python='/usr/bin/python2.7', debug=False, verbose=False, unless=None, onlyif=None, use_vt=False, loglevel='debug', **kwargs)
```

Install buildout in a specific directory

It is a thin wrapper to modules.buildout.buildout

- **name** directory to execute in
- **quiet** do not output console & logs
- **config** buildout config to use (default: buildout.cfg)
- **parts** specific buildout parts to run
- **user** user used to run buildout as

New in version 2014.1.4.

- **env** environment variables to set when running
- **buildout_ver** force a specific buildout version (1 | 2)
- **test_release** buildout accept test release
- **new_st** Forcing use of setuptools >= 0.7
- **distribute** use distribute over setuptools if possible
- **offline** does buildout run offline
- **python** python to use
- **debug** run buildout with -D debug flag
onlyif Only execute cmd if statement on the host return 0
unless Do not execute cmd if statement on the host return 0
newest run buildout in newest mode
verbose run buildout in verbose mode (-vvvvv)
use_vt Use the new salt VT to stream output [experimental]
loglevel loglevel for buildout commands

31.27.181 salt.states.zk_concurrency

Control concurrency of steps within state execution using zookeeper

This module allows you to "wrap" a state's execution with concurrency control. This is useful to protect against all hosts executing highstate simultaneously if your services don't all HUP restart. The common way of protecting against this is to run in batch mode, but that doesn't protect from another person running the same batch command (and thereby having 2x the number of nodes deploying at once).

This module will block while acquiring a slot, meaning that however the command gets called it will coordinate with zookeeper to ensure that no more than max_concurrency steps are executing with a single path.

```python
acquire_lock:
  zk_concurrency.lock:
    - name: /trafficeserver
    - zk_hosts: 'zookeeper:2181'
    - max_concurrency: 4
    - prereq:
      - service: trafficserver

trafficserver:
  service.running:
    - watch:
      - file: /etc/trafficserver/records.config

/etc/trafficserver/records.config:
  file.managed:
    - source: salt://records.config

release_lock:
  zk_concurrency.unlock:
    - name: /trafficserver
    - require:
      - service: trafficserver
```

This example would allow the file state to change, but would limit the concurrency of the trafficserver service restart to 4.

```python
salt.states.zk_concurrency.lock(name, zk_hosts=None, identifier=None, max_concurrency=1, timeout=None, ephemeral_lease=False)

Block state execution until you are able to get the lock (or hit the timeout)
```

```python
salt.states.zk_concurrency.min_party(name, zk_hosts, min_nodes)

Ensure that there are min_nodes in the party at name.
```

```python
salt.states.zk_concurrency.unlock(name, zk_hosts=None, identifier=None, max_concurrency=1, ephemeral_lease=False)

Remove lease from semaphore.
```
31.28 Execution Modules

Salt execution modules are the functions called by the `salt` command.

**Note:** Salt execution modules are different from state modules and cannot be called directly within state files. You must use the `module` state module to call execution modules within state runs.

See also:

*Full list of builtin modules*

Salt ships with many modules that cover a wide variety of tasks.

31.28.1 Modules Are Easy to Write!

Writing Salt execution modules is straightforward.

A Salt execution modules is a Python or Cython module placed in a directory called `_modules/` within the `file_roots` as specified by the master config file. By default this is `/srv/salt/_modules` on Linux systems.

Modules placed in `_modules/` will be synced to the minions when any of the following Salt functions are called:

- `state.highstate`
- `saltutil.sync_modules`
- `saltutil.sync_all`

Note that a module's default name is its filename (i.e. `foo.py` becomes module `foo`), but that its name can be overridden by using a `__virtual__` function.

If a Salt module has errors and cannot be imported, the Salt minion will continue to load without issue and the module with errors will simply be omitted.

If adding a Cython module the file must be named `<modulename>.pyx` so that the loader knows that the module needs to be imported as a Cython module. The compilation of the Cython module is automatic and happens when the minion starts, so only the `.pyx` file is required.

31.28.2 Zip Archives as Modules

Python 2.3 and higher allows developers to directly import zip archives containing Python code. By setting `enable_zip_modules` to True in the minion config, the Salt loader will be able to import `.zip` files in this fashion. This allows Salt module developers to package dependencies with their modules for ease of deployment, isolation, etc.

For a user, Zip Archive modules behave just like other modules. When executing a function from a module provided as the file `my_module.zip`, a user would call a function within that module as `my_module.<function>.

Creating a Zip Archive Module

A Zip Archive module is structured similarly to a simple Python package. The `.zip` file contains a single directory with the same name as the module. The module code traditionally in `<module_name>.py` goes in `<module_name>/__init__.py`. The dependency packages are subdirectories of `<module_name>/`.

Here is an example directory structure for the `lumberjack` module, which has two library dependencies (sleep and work) to be included.
The contents of lumberjack/__init__.py show how to import and use these included libraries.

```python
# Libraries included in lumberjack.zip
from lumberjack import sleep, work

def is_ok(person):
    ''' Checks whether a person is really a lumberjack '''
    return sleep.all_night(person) and work.all_day(person)
```

Then, create the zip:

```bash
modules $ ls -R lumberjack
__init__.py    sleep       work
lumberjack/sleep:
    __init__.py
lumberjack/work:
    __init__.py

modules $ zip -r lumberjack lumberjack
  adding: lumberjack/ (stored 0%)
  adding: lumberjack/__init__.py (deflated 39%)
  adding: lumberjack/sleep/ (stored 0%)
  adding: lumberjack/sleep/__init__.py (deflated 7%)
  adding: lumberjack/work/ (stored 0%)
  adding: lumberjack/work/__init__.py (deflated 7%)

modules $ unzip -l lumberjack.zip
Archive: lumberjack.zip

   Length Date Time Name
  -------- ---- ---- ----
0 08-21-15 20:08 lumberjack/
348 08-21-15 20:08 lumberjack/__init__.py
0 08-21-15 19:53 lumberjack/sleep/
83 08-21-15 19:53 lumberjack/sleep/__init__.py
0 08-21-15 19:53 lumberjack/work/
81 08-21-15 19:21 lumberjack/work/__init__.py

512 6 files
```

Once placed in file_roots, Salt users can distribute and use lumberjack.zip like any other module.

```bash
$ sudo salt minion1 saltutil.sync_modules
minion1:
  - modules.lumberjack
$ sudo salt minion1 lumberjack.is_ok 'Michael Palin'
minion1:
  True
```

### 31.28.3 Cross Calling Execution Modules

All of the Salt execution modules are available to each other and modules can call functions available in other execution modules.

The variable __salt__ is packed into the modules after they are loaded into the Salt minion.
The __salt__ variable is a *Python dictionary* containing all of the Salt functions. Dictionary keys are strings representing the names of the modules and the values are the functions themselves.

Salt modules can be cross-called by accessing the value in the __salt__ dict:

```python
def foo(bar):
    return __salt__['cmd.run'](bar)
```

This code will call the *run* function in the *cmd* module and pass the argument `bar` to it.

### 31.28.4 Preloaded Execution Module Data

When interacting with execution modules often it is nice to be able to read information dynamically about the minion or to load in configuration parameters for a module.

Salt allows for different types of data to be loaded into the modules by the minion.

#### Grains Data

The values detected by the Salt Grains on the minion are available in a *dict* named __grains__ and can be accessed from within callable objects in the Python modules.

To see the contents of the grains dictionary for a given system in your deployment run the `grains.items()` function:

```bash
salt 'hostname' grains.items --output=pprint
```

Any value in a grains dictionary can be accessed as any other Python dictionary. For example, the grain representing the minion ID is stored in the `id` key and from an execution module, the value would be stored in __grains__['id'].

#### Module Configuration

Since parameters for configuring a module may be desired, Salt allows for configuration information from the minion configuration file to be passed to execution modules.

Since the minion configuration file is a YAML document, arbitrary configuration data can be passed in the minion config that is read by the modules. It is therefore *strongly* recommended that the values passed in the configuration file match the module name. A value intended for the *test* execution module should be named `test.<value>`.

The test execution module contains usage of the module configuration and the default configuration file for the minion contains the information and format used to pass data to the modules. `salt.modules.test`, `conf/minion`.

### 31.28.5 Printout Configuration

Since execution module functions can return different data, and the way the data is printed can greatly change the presentation, Salt has a printout configuration.

When writing a module the __outputter__ dictionary can be declared in the module. The __outputter__ dictionary contains a mapping of function name to Salt Outputter.

```python
__outputter__ = {
    'run': 'txt'
}
```
This will ensure that the text outputter is used.

### 31.28.6 Virtual Modules

Sometimes an execution module should be presented in a generic way. A good example of this can be found in the package manager modules. The package manager changes from one operating system to another, but the Salt execution module that interfaces with the package manager can be presented in a generic way.

The Salt modules for package managers all contain a `__virtual__` function which is called to define what systems the module should be loaded on.

The `__virtual__` function is used to return either a `string` or `False`. If `False` is returned then the module is not loaded, if a string is returned then the module is loaded with the name of the string.

**Note:** Optionally, modules may additionally return a list of reasons that a module could not be loaded. For example, if a dependency for `my_mod` was not met, a `__virtual__` function could do as follows:

```python
return False, ['My Module must be installed before this module can be used.]
```

This means that the package manager modules can be presented as the `pkg` module regardless of what the actual module is named.

Since `__virtual__` is called before the module is loaded, `__salt__` will be unavailable as it will not have been packed into the module at this point in time.

The package manager modules are among the best example of using the `__virtual__` function. Some examples:

- `pacman.py`
- `yumpkg.py`
- `aptpkg.py`
- `at.py`

**Note:** Modules which return a string from `__virtual__` that is already used by a module that ships with Salt will override the stock module.

### 31.28.7 Documentation

Salt execution modules are documented. The `sys.doc()` function will return the documentation for all available modules:

```bash
salt '*' sys.doc
```

The `sys.doc` function simply prints out the docstrings found in the modules; when writing Salt execution modules, please follow the formatting conventions for docstrings as they appear in the other modules.

**Adding Documentation to Salt Modules**

It is strongly suggested that all Salt modules have documentation added.

To add documentation add a Python docstring to the function.
def spam(eggs):
    '''
    A function to make some spam with eggs!
    CLI Example:::
        salt '*' test.spam eggs
    '''
    return eggs

Now when the sys.doc call is executed the docstring will be cleanly returned to the calling terminal.

Documentation added to execution modules in docstrings will automatically be added to the online web-based documentation.

Add Execution Module Metadata

When writing a Python docstring for an execution module, add information about the module using the following field lists:

```
:maintainer: Thomas Hatch <thatch@saltstack.com, Seth House <shouse@saltstack.com>
:maturity: new
:depends: python-mysqldb
:platform: all
```

The maintainer field is a comma-delimited list of developers who help maintain this module.
The maturity field indicates the level of quality and testing for this module. Standard labels will be determined.
The depends field is a comma-delimited list of modules that this module depends on.
The platform field is a comma-delimited list of platforms that this module is known to run on.

31.28.8 Log Output

You can call the logger from custom modules to write messages to the minion logs. The following code snippet demonstrates writing log messages:

```
import logging

log = logging.getLogger(__name__)

log.info('Here is Some Information')
log.warning('You Should Not Do That')
log.error('It Is Busted')
```

31.28.9 Private Functions

In Salt, Python callable objects contained within an execution module are made available to the Salt minion for use. The only exception to this rule is a callable object with a name starting with an underscore `_`.
Objects Loaded Into the Salt Minion

```python
def foo(bar):
    return bar

class baz:
    def __init__(self, quo):
        pass
```

Objects NOT Loaded into the Salt Minion

```python
def _foobar(baz):  # Preceded with an _
    return baz

cheese = {}  # Not a callable Python object
```

Note: Some callable names also end with an underscore _, to avoid keyword clashes with Python keywords. When using execution modules, or state modules, with these in them the trailing underscore should be omitted.

31.28.10 Useful Decorators for Modules

**Depends Decorator**

When writing execution modules there are many times where some of the module will work on all hosts but some functions have an external dependency, such as a service that needs to be installed or a binary that needs to be present on the system.

Instead of trying to wrap much of the code in large try/except blocks, a decorator can be used.

If the dependencies passed to the decorator don’t exist, then the salt minion will remove those functions from the module on that host.

If a "`fallback_function" is defined, it will replace the function instead of removing it

```python
import logging
from salt.utils.decorators import depends

log = logging.getLogger(__name__)

try:
    import dependency_that_sometimes_exists
except ImportError as e:
    log.trace('Failed to import dependency_that_sometimes_exists: {0}'.format(e))

@depends('dependency_that_sometimes_exists')
def foo():
    '''
    Function with a dependency on the "dependency_that_sometimes_exists" module,
    if the "dependency_that_sometimes_exists" is missing this function will not exist
    '''
    return True
```
```python
def _fallback():
    
    Fallback function for the depends decorator to replace a function with
    
    return "dependency_that_sometimes_exists" needs to be installed for this function to exist

@depends('dependency_that_sometimes_exists', fallback_function=_fallback)
def foo():
    
    Function with a dependency on the "dependency_that_sometimes_exists" module.
    If the "dependency_that_sometimes_exists" is missing this function will be
    replaced with "_fallback"
    
    return True
```

In addition to global dependancies the depends decorator also supports raw booleans.

```python
from salt.utils.decorators import depends
HAS_DEP = False
try:
    import dependency_that_sometimes_exists
    HAS_DEP = True
except ImportError:
    pass

@depends(HAS_DEP)
def foo():
    return True
```

### 31.29 Master Tops

Salt includes a number of built-in subsystems to generate top file data, they are listed listed at Full list of builtin master tops modules.

The source for the built-in Salt master tops can be found here: https://github.com/saltstack/salt/blob/develop/salt/tops

### 31.30 Full list of builtin master tops modules

<table>
<thead>
<tr>
<th>Module</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>cobbler</td>
<td>Cobbler Tops</td>
</tr>
<tr>
<td>ext_nodes</td>
<td>External Nodes Classifier</td>
</tr>
<tr>
<td>mongo</td>
<td>Read tops data from a mongodb collection</td>
</tr>
<tr>
<td>reclass_adapter</td>
<td>Read tops data from a reclass database</td>
</tr>
</tbody>
</table>

### 31.30.1 salt.tops.cobbler

**Cobbler Tops**

Cobbler Tops is a master tops subsystem used to look up mapping information from Cobbler via its API. The same cobbler" parameters are used for both the Cobbler tops and Cobbler pillar modules.
master_tops:
cobbler: {}
cobbler.url: https://example.com/cobbler_api  # default is http://localhost/cobbler_api
cobbler.user: username  # default is no username
cobbler.password: password  # default is no password

Module Documentation

salt.tops.cobbler.top(**kwargs)
Look up top data in Cobbler for a minion.

31.30.2 salt.tops.ext_nodes

External Nodes Classifier

The External Nodes Classifier is a master tops subsystem that retrieves mapping information from major configuration management systems. One of the most common external nodes classifiers system is provided by Cobbler and is called cobbler-ext-nodes.

The cobbler-ext-nodes command can be used with this configuration:

```yaml
master_tops:
    ext_nodes: cobbler-ext-nodes
```

It is noteworthy that the Salt system does not directly ingest the data sent from the cobbler-ext-nodes command, but converts the data into information that is used by a Salt top file.

Any command can replace the call to `cobbler-ext-nodes' above, but currently the data must be formatted in the same way that the standard `cobbler-ext-nodes' does.

See (admittedly degenerate and probably not complete) example:

```yaml
classes:
    - basepackages
    - database
```

The above essentially is the same as a top.sls containing the following:

```yaml
base:
    *:
        - basepackages
        - database

salt.tops.ext_nodes.top(**kwargs)
Run the command configured
```
31.30.3 salt.tops.mongo

Read tops data from a mongod db collection
This module will load tops data from a mongo collection. It uses the node's id for lookups.

Salt Master Mongo Configuration

The module shares the same base mongo connection variables as `salt.returners.mongo_return`. These variables go in your master config file.

- `mongo.db` - The mongo database to connect to. Defaults to 'salt'.
- `mongo.host` - The mongo host to connect to. Supports replica sets by specifying all hosts in the set, comma-delimited. Defaults to 'salt'.
- `mongo.port` - The port that the mongo database is running on. Defaults to 27017.
- `mongo.user` - The username for connecting to mongo. Only required if you are using mongo authentication. Defaults to ''. 
- `mongo.password` - The password for connecting to mongo. Only required if you are using mongo authentication. Defaults to ''. 

Configuring the Mongo Tops Subsystem

```yaml
master_tops:
  mongo:
    collection: tops
    id_field: _id
    re_replace: ""
    re_pattern: \.example\.com
    states_field: states
    environment_field: environment
```

Module Documentation

```python
salt.tops.mongo.top(**kwargs)
```

Connect to a mongo database and read per-node tops data.

Parameters:

- `collection` - The mongodb collection to read data from. Defaults to 'tops'.
- `id_field` - The field in the collection that represents an individual minion id. Defaults to '_id'.
- `re_pattern` - If your naming convention in the collection is shorter than the minion id, you can use this to trim the name. `re_pattern` will be used to match the name, and `re_replace` will be used to replace it. Backrefs are supported as they are in the Python standard library. If None, no mangling of the name will be performed - the collection will be searched with the entire minion id. Defaults to None.
- `re_replace` - Use as the replacement value in node ids matched with `re_pattern`. Defaults to ''. Feel free to use backreferences here.
- `states_field` - The name of the field providing a list of states.
- `environment_field` - The name of the field providing the environment. Defaults to `environment`. 
31.30.4 salt.tops.reclass_adapter

Read tops data from a reclass database

This master_tops plugin provides access to the reclass database, such that state information (top data) are retrieved from reclass.

You can find more information about reclass at http://reclass.pantsfullofunix.net.

To use the plugin, add it to the master_tops list in the Salt master config and tell reclass by way of a few options how and where to find the inventory:

```
master_tops:
  reclass:
    storage_type: yaml_fs
    inventory_base_uri: /srv/salt
```

This would cause reclass to read the inventory from YAML files in /srv/salt/nodes and /srv/salt/classes.

If you are also using reclass as ext_pillar plugin, and you want to avoid having to specify the same information for both, use YAML anchors (take note of the differing data types for ext_pillar and master_tops):

```
reclass: &reclass
  storage_type: yaml_fs
  inventory_base_uri: /srv/salt
reclass_source_path: ~/code/reclass

ext_pillar:
  - reclass: *reclass

master_tops:
  reclass: *reclass
```

If you want to run reclass from source, rather than installing it, you can either let the master know via the PYTHONPATH environment variable, or by setting the configuration option, like in the example above.

```
salt.tops.reclass_adapter.top(**kwargs)
    Query reclass for the top data (states of the minions).
```

31.31 Full list of builtin wheel modules

<table>
<thead>
<tr>
<th>Module</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>config</td>
<td>Manage the master configuration file</td>
</tr>
<tr>
<td>error</td>
<td>Error generator to enable integration testing of salt wheel error handling</td>
</tr>
<tr>
<td>file_roots</td>
<td>Read in files from the file_root and save files to the file root</td>
</tr>
<tr>
<td>key</td>
<td>Wheel system wrapper for key system</td>
</tr>
<tr>
<td>minions</td>
<td>Wheel system wrapper for connected minions</td>
</tr>
<tr>
<td>pillar_roots</td>
<td>The pillar_roots wheel module is used to manage files under the pillar roots directories on the master server.</td>
</tr>
</tbody>
</table>

31.31.1 salt.wheel.config

Manage the master configuration file

```
salt.wheel.config.apply(key, value)
    Set a single key
```
Note: This will strip comments from your config file

```
salt.wheel.config.update_config(file_name, yaml_contents)
```
Update master config with yaml_contents.

Writes yaml_contents to a file named file_name.conf under the folder specified by default_include. This folder is named master.d by default. Please look at include-configuration for more information.

Example low data:

```python
data = {
    'username': 'salt',
    'password': 'salt',
    'fun': 'config.update_config',
    'file_name': 'gui',
    'yaml_contents': {'id': 1},
    'client': 'wheel',
    'eauth': 'pam',
}
```

```
salt.wheel.config.values()
```
Return the raw values of the config file

### 31.3.2 salt.wheel.error

Error generator to enable integration testing of salt wheel error handling

```
salt.wheel.error.error(name=None, message='')
```
If name is None Then return empty dict

Otherwise raise an exception with __name__ from name, message from message

CLI Example:

```
salt-wheel error
salt-wheel error.error name="Exception" message="This is an error."
```

### 31.3.3 salt.wheel.file_roots

Read in files from the file_root and save files to the file root

```
salt.wheel.file_roots.find(path, saltenv='base', env=None)
```
Return a dict of the files located with the given path and environment

```
salt.wheel.file_roots.list_env(saltenv='base', env=None)
```
Return all of the file paths found in an environment

```
salt.wheel.file_roots.list_roots()
```
Return all of the files names in all available environments

```
salt.wheel.file_roots.read(path, saltenv='base', env=None)
```
Read the contents of a text file, if the file is binary then
salt.wheel.file_roots.write(data, path, saltenv='base', index=0, env=None)

Write the named file, by default the first file found is written, but the index of the file can be specified to write to a lower priority file root

31.31.4 salt.wheel.key

Wheel system wrapper for key system

salt.wheel.key.accept(match)
Accept keys based on a glob match

salt.wheel.key.accept_dict(match)
Accept keys based on a dict of keys

salt.wheel.key.delete(match)
Delete keys based on a glob match

salt.wheel.key.delete_dict(match)
Delete keys based on a dict of keys

salt.wheel.key.finger(match)
Return the matching key fingerprints

salt.wheel.key.gen(id_=None, keysize=2048)
Generate a key pair. No keys are stored on the master, a keypair is returned as a dict containing pub and priv keys

salt.wheel.key.gen_accept(id_, keysize=2048, force=False)
Generate a key pair then accept the public key. This function returns the key pair in a dict, only the public key is preserved on the master.

salt.wheel.key.key_str(match)
Return the key strings

salt.wheel.key.list(match)
List all the keys under a named status

salt.wheel.key.list_all()
List all the keys

salt.wheel.key.reject(match)
Reject keys based on a glob match

salt.wheel.key.reject_dict(match)
Reject keys based on a dict of keys

31.31.5 salt.wheel.minions

Wheel system wrapper for connected minions

salt.wheel.minions.connected()
List all connected minions on a salt-master

31.31.6 salt.wheel.pillar_roots

The pillar_roots wheel module is used to manage files under the pillar roots directories on the master server.
salt.wheel.pillar_roots.find(path, saltenv='base', env=None)
    Return a dict of the files located with the given path and environment
salt.wheel.pillar_roots.list_env(saltenv='base', env=None)
    Return all of the file paths found in an environment
salt.wheel.pillar_roots.list_roots()
    Return all of the files names in all available environments
salt.wheel.pillar_roots.read(path, saltenv='base', env=None)
    Read the contents of a text file, if the file is binary then
salt.wheel.pillar_roots.write(data, path, saltenv='base', index=0, env=None)
    Write the named file, by default the first file found is written, but the index of the file can be specified to write
to a lower priority file root

31.32 Full list of builtin beacon modules

<table>
<thead>
<tr>
<th>Beacon</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>btmp</td>
<td>Beacon to fire events at failed login of users</td>
</tr>
<tr>
<td>diskusage</td>
<td>Beacon to monitor disk usage.</td>
</tr>
<tr>
<td>inotify</td>
<td>Watch files and translate the changes into salt events</td>
</tr>
<tr>
<td>journald</td>
<td>A simple beacon to watch journald for specific entries</td>
</tr>
<tr>
<td>load</td>
<td>Beacon to emit system load averages</td>
</tr>
<tr>
<td>network_info</td>
<td>Beacon to monitor statistics from ethernet adapters</td>
</tr>
<tr>
<td>service</td>
<td>Send events covering service status</td>
</tr>
<tr>
<td>sh</td>
<td>Watch the shell commands being executed actively.</td>
</tr>
<tr>
<td>twilio_txt_msg</td>
<td>Beacon to emit Twilio text messages</td>
</tr>
<tr>
<td>wtmp</td>
<td>Beacon to fire events at login of users as registered in the wtmp file</td>
</tr>
</tbody>
</table>

31.32.1 salt.beacons.btmp

Beacon to fire events at failed login of users

beacons:
   btmp: {}

salt.beacons.btmp.beacon(config)
    Read the last btmp file and return information on the failed logins

   beacons:
      btmp: {}

salt.beacons.btmp.validate(config)
    Validate the beacon configuration

31.32.2 salt.beacons.diskusage

Beacon to monitor disk usage.
New in version 2015.5.0.
salt.beacons.diskusage.beacon(config)
Monitor the disk usage of the minion

Specify thresholds for each disk and only emit a beacon if any of them are exceeded.

```yaml
beacons:
  diskusage:
  - /: 63%
  - /mnt/nfs: 50%
```

salt.beacons.diskusage.validate(config)
Validate the beacon configuration

### 31.32.3 salt.beacons.inotify

Watch files and translate the changes into salt events

**depends**

- pyinotify Python module >= 0.9.5

**Caution** Using generic mask options like open, access, ignored, and closed_nowrite with reactors can easily cause the reactor to loop on itself.

salt.beacons.inotify.beacon(config)
Watch the configured files

Example Config

```yaml
beacons:
  inotify:
    /path/to/file/or/dir:
      mask:
      - open
      - create
      - close_write
      recurse: True
      auto_add: True
```

The mask list can contain the following events (the default mask is create, delete, and modify):

- access File accessed
- attrib File metadata changed
- close_nowrite Unwritable file closed
- close_write Writable file closed
- create File created in watched directory
- delete File deleted from watched directory
- delete_self Watched file or directory deleted
- modify File modified
- moved_from File moved out of watched directory
- moved_to File moved into watched directory
- move_self Watched file moved
- open File opened

The mask can also contain the following options:

- dont_follow Don’t dereference symbolic links
- excl_unlink Omit events for children after they have been unlinked
- oneshot Remove watch after one event

31.32. Full list of builtin beacon modules
onlydir Operate only if name is directory

**recurse:** Recursively watch files in the directory
**auto_add:** Automatically start watching files that are created in the watched directory

```python
salt.beacons.inotify.validate(config)
```
Validate the beacon configuration

### 31.32.4 `salt.beacons.journald`

A simple beacon to watch journald for specific entries

```python
salt.beacons.journald.beacon(config)
```
The journald beacon allows for the systemd journal to be parsed and linked objects to be turned into events.

This beacons config will return all sshd journal entries

```python
beacons:
    journald:
        sshd:
            SYSLOG_IDENTIFIER: sshd
            PRIORITY: 6
```

```python
salt.beacons.journald.validate(config)
```
Validate the beacon configuration

### 31.32.5 `salt.beacons.load`

Beacon to emit system load averages

```python
salt.beacons.load.beacon(config)
```
Emit the load averages of this host.

Specify thresholds for each load average and only emit a beacon if any of them are exceeded.

```python
beacons:
    - load:
        - 1m:
            - 0.0
            - 2.0
        - 5m:
            - 0.0
            - 1.5
        - 15m:
            - 0.1
            - 1.0
```

```python
salt.beacons.load.validate(config)
```
Validate the beacon configuration

### 31.32.6 `salt.beacons.network_info`

Beacon to monitor statistics from ethernet adapters

New in version 2015.5.0.
salt.beacons.network_info.beacon(config)

Emit the network statistics of this host.

Specify thresholds for each network stat and only emit a beacon if any of them are exceeded.

Emit beacon when any values are equal to configured values.

beacons:
  network_info:
    eth0:
      - type: equal
      - bytes_sent: 100000
      - bytes_recv: 100000
      - packets_sent: 100000
      - packets_recv: 100000
      - errin: 100
      - errout: 100
      - dropin: 100
      - dropout: 100

Emit beacon when any values are greater than to configured values.

beacons:
  network_info:
    eth0:
      - type: greater
      - bytes_sent: 100000
      - bytes_recv: 100000
      - packets_sent: 100000
      - packets_recv: 100000
      - errin: 100
      - errout: 100
      - dropin: 100
      - dropout: 100

salt.beacons.network_info.validate(config)

Validate the beacon configuration

31.32.7 salt.beacons.service

Send events covering service status

salt.beacons.service.beacon(config)

Scan for the configured services and fire events

Example Config

beacons:
  service:
    salt-master:
    mysql:

The config above sets up beacons to check for the salt-master and mysql services.

The config also supports two other parameters for each service:
onchangeonly: when `onchangeonly` is True the beacon will fire events only when the service status changes. Otherwise, it will fire an event at each beacon interval. The default is False.

uncleanshutdown: If `uncleanshutdown` is present it should point to the location of a pid file for the service. Most services will not clean up this pid file if they are shutdown uncleanly (e.g. via `kill -9`) or if they are terminated through a crash such as a segmentation fault. If the file is present, then the beacon will add `uncleanshutdown: True` to the event. If not present, the field will be False. The field is only added when the service is NOT running. Omitting the configuration variable altogether will turn this feature off.

Here is an example that will fire an event whenever the state of nginx changes and report an unclean shutdown. This example is for Arch, which places nginx’s pid file in `/run`.

```yaml
beacons:
  service:
    nginx:
      onchangeonly: True
      uncleanshutdown: /run/nginx.pid
```

`salt.beacons.service.validate(config)`
Validate the beacon configuration

### 31.32.8 salt.beacons.sh

Watch the shell commands being executed actively. This beacon requires `strace`.

`salt.beacons.sh.beacon(config)`
Scan the shell `execve` routines. This beacon will convert all login shells

```yaml
beacons:
  sh: {}  # Empty dictionary
```

`salt.beacons.sh.validate(config)`
Validate the beacon configuration

### 31.32.9 salt.beacons.twilio_txt_msg

Beacon to emit Twilio text messages

`salt.beacons.twilio_txt_msg.beacon(config)`
Emit a dict name `texts` whose value is a list of texts.

```yaml
beacons:
  twilio_txt_msg:
    account_sid: "<account sid>
    auth_token: "<auth token>
    twilio_number: "+15555555555"
    interval: 10
```

`salt.beacons.twilio_txt_msg.validate(config)`
Validate the beacon configuration
31.32.10 salt.beacons.wtmp

Beacon to fire events at login of users as registered in the wtmp file

```yaml
beacons:
  wtmp: {}

salt.beacons.wtmp.beacon(config)
  Read the last wtmp file and return information on the logins
  beacons:
    wtmp: {}

salt.beacons.wtmp.validate(config)
  Validate the beacon configuration
```

31.33 Full list of builtin engine modules

<table>
<thead>
<tr>
<th>Engine</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>logstash</td>
<td>An engine that reads messages from the salt event bus and pushes them onto a logstash endpoint.</td>
</tr>
<tr>
<td>sqs_events</td>
<td>An engine that continuously reads messages from SQS and fires them as events.</td>
</tr>
<tr>
<td>test</td>
<td>A simple test engine, not intended for real use but as an example</td>
</tr>
</tbody>
</table>

31.33.1 salt.engines.logstash

An engine that reads messages from the salt event bus and pushes them onto a logstash endpoint.

**configuration**

Example configuration

```yaml
environments:
  engines:
    - logstash: host: log.my_network.com port: 5959

depends logstash
```

salt.engines.logstash.start(**host**, **port=5959**, **tag='salt/engine/logstash'**)

Listen to salt events and forward them to logstash

31.33.2 salt.engines.sqs_events

An engine that continuously reads messages from SQS and fires them as events.

Note that long polling is utilized to avoid excessive CPU usage.

New in version 2015.8.0.

**configuration** This engine can be run on the master or on a minion.

Example Config:

```yaml
environments:
  engines:
    - sqs_events: queue: test profile: my-sqs-profile #optional
```
Explicit sqs credentials are accepted but this engine can also utilize IAM roles assigned to the instance through Instance Profiles. Dynamic credentials are then automatically obtained from AWS API and no further configuration is necessary. More Information available at:

If IAM roles are not used you need to specify them either in a pillar or in the config file of the master or minion, as appropriate:

```yaml
sqs.keyid: GKTADJGHEIQSXMKKRBJ08H
sqs.key: askdjghsdfjkgWupUjasdfklkflgjsdfjajkghs
```

A region may also be specified in the configuration:

```yaml
sqs.region: us-east-1
```

If a region is not specified, the default is us-east-1.

It’s also possible to specify key, keyid and region via a profile:

```yaml
myprofile: keyid: GKTADJGHEIQSXMKKRBJ08H key: askdjghsdfjkgWupUjasdfklkflgjsdfjajkghs region: us-east-1
```

```python
salt.engines.sqs_events.start(queue, profile=None, tag='salt/engine/sqs')
```

Listen to events and write them to a log file

### 31.33.3 salt.engines.test

A simple test engine, not intended for real use but as an example

```python
salt.engines.test.start()
```

Listen to events and write them to a log file

### 31.34 Full list of builtin sdb modules

<table>
<thead>
<tr>
<th>sdb Module</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>couchdb</td>
<td>CouchDB sdb Module</td>
</tr>
<tr>
<td>etcd_db</td>
<td>etcd Database Module</td>
</tr>
<tr>
<td>keyring_db</td>
<td>Keyring Database Module</td>
</tr>
<tr>
<td>memcached</td>
<td>Memcached sdb Module</td>
</tr>
<tr>
<td>sqlite3</td>
<td>SQLite sdb Module</td>
</tr>
</tbody>
</table>

#### 31.34.1 salt.sdb.couchdb

CouchDB sdb Module

```python
maintainer SaltStack
maturity New
depends python2-couchdb
platform all
```
This allows interaction between Salt and a CouchDB [couchdb.apache.org] database. It uses Salt's sdb system to allow for inserts and retrievals using the sdb:// prefix in Salt configuration files.

To use the couchbase sdb module, it must first be configured in the Salt master or minion config. The following arguments are required:

```
couchdb_sdb:
    driver: couchdb
    host: localhost
    port: 5984
    database: salt_sdb
```

One could then query the CouchDB instance via an sdb:// URI such as the following:

```
password: sdb://couchdb_sdb/mykey
```

To use this interface, you must track IDs on your own or have another source to do the map-reduce logic necessary to calculate the ID you wish to fetch.

Additional contributions to build true map-reduce functionality into this module would be welcome.

```
salt.sdb.couchdb.get(key, profile=None)
   Get a value from couchdb by id

salt.sdb.couchdb.set(key, value, profile=None)
   Set a key/value pair in couchdb
```

### 31.34.2 salt.sdb.etcd_db

etcd Database Module

- **maintainer** SaltStack
- **maturity** New
- **depends** python-etcd
- **platform** all

New in version 2015.5.0.

This module allows access to the etcd database using an sdb:// URI. This package is located at [https://pypi.python.org/pypi/python-etcd](https://pypi.python.org/pypi/python-etcd).

Like all sdb modules, the etcd module requires a configuration profile to be configured in either the minion or master configuration file. This profile requires very little. In the example:

```
myetcd:
    driver: etcd
    etcd.host: 127.0.0.1
    etcd.port: 4001
```

The **driver** refers to the etcd module, **etcd.host** refers to the host that is hosting the etcd database and **etcd.port** refers to the port on that host.

```
password: sdb://myetcd/mypassword

salt.sdb.etcd_db.get(key, service=None, profile=None)
   Get a value from the etcd service
```
31.34.3 salt.sdb.keyring_db

Keyring Database Module

- maintainer: SaltStack
- maturity: New
- depends: keyring
- platform: all

This module allows access to the keyring package using an sdb:// URI. This package is located at https://pypi.python.org/pypi/keyring.

Care must be taken when using keyring. Not all keyend backends are supported on all operating systems. Also, many backends require an agent to be running in order to work. For instance, the "Secret Service" backend requires a compatible agent such as gnome-keyring-daemon or kwallet to be running. The keyczar backend does not seem to enjoy the benefits of an agent, and so using it will require either that the password is typed in manually (which is unreasonable for the salt-minion and salt-master daemons, especially in production) or an agent is written for it.

Like all sdb modules, the keyring module requires a configuration profile to be configured in either the minion or master configuration file. This profile requires very little. In the example:

```
mykeyring:
  driver: keyring
  service: system
```

The driver refers to the keyring module, service refers to the service that will be used inside of keyring (which may be likened unto a database table) and mykeyring refers to the name that will appear in the URI:

```
password: sdb://mykeyring/mypassword
```

The underlying backend configuration must be configured via keyring itself. For examples and documentation, see keyring:

https://pypi.python.org/pypi/keyring

New in version 2014.1.4.

31.34.4 salt.sdb.memcached

Memcached sdb Module

- maintainer: SaltStack
- maturity: New
- depends: python-memcached
platform  all

This module allows access to memcached using an sdb:// URI. This package is located at https://pypi.python.org/pypi/python-memcached.

Like all sdb modules, the memcached module requires a configuration profile to be configured in either the minion or master configuration file. This profile requires very little. In the example:

```yaml
mymemcache:
    driver: memcached
    host: localhost
    port: 11211
```

The driver refers to the memcached module, host and port the memcached server to connect to (defaults to localhost and 11211, and mymemcached refers to the name that will appear in the URI:

```yaml
password: sdb://mymemcached/mykey
```

```python
salt.sdb.memcached.get(key, profile=None)
    Get a value from memcached

salt.sdb.memcached.set(key, value, profile=None)
    Set a key/value pair in memcached
```

### 31.34.5 salt.sdb.sqlite3

SQLite sdb Module

- maintainer: SaltStack
- maturity: New
- platform: all

This module allows access to sqlite3 using an sdb:// URI

Like all sdb modules, the sqlite3 module requires a configuration profile to be configured in either the minion or master configuration file. This profile requires very little. For example:

```yaml
mysqlite:
    driver: sqlite3
    database: /tmp/sdb.sqlite
    table: sdb
    create_table: True
```

The driver refers to the sqlite3 module, database refers to the sqlite3 database file. table is the table within the db that will hold keys and values (defaults to sdb). The database and table will be created if they do not exist.

**Advanced Usage:**

Instead of a table name, it is possible to provide custom SQL statements to create the table(s) and get and set values.

```python
salt.sdb.sqlite3.get(key, profile=None)
    Get a value from sqlite3

salt.sdb.sqlite3.set(key, value, profile=None)
    Set a key/value pair in sqlite3
```
## 31.35 Full list of built-in serializers

Salt Best Practices

Salt’s extreme flexibility leads to many questions concerning the structure of configuration files. This document exists to clarify these points through examples and code.

### 32.1 General rules

1. Modularity and clarity should be emphasized whenever possible.
2. Create clear relations between pillars and states.
3. Use variables when it makes sense but don’t overuse them.
4. Store sensitive data in pillar.
5. Don’t use grains for matching in your pillar top file for any sensitive pillars.

### 32.2 Structuring States and Formulas

When structuring Salt States and Formulas it is important to begin with the directory structure. A proper directory structure clearly defines the functionality of each state to the user via visual inspection of the state’s name.

Reviewing the MySQL Salt Formula it is clear to see the benefits to the end-user when reviewing a sample of the available states:

```
/srv/salt/mysql/files/
/srv/salt/mysql/client.sls
/srv/salt/mysql/map.jinja
/srv/salt/mysql/python.sls
/srv/salt/mysql/server.sls
```

This directory structure would lead to these states being referenced in a top file in the following way:

```
base:
  'web*':
    - mysql.client
    - mysql.python
  'db*':
    - mysql.server
```
This clear definition ensures that the user is properly informed of what each state will do.

Another example comes from the vim-formula:

```
/srv/salt/vim/files/
/srv/salt/vim/absent.sls
/srv/salt/vim/init.sls
/srv/salt/vim/map.jinja
/srv/salt/vim/nerdtree.sls
/srv/salt/vim/pyflakes.sls
/srv/salt/vim/salt.sls
```

Once again viewing how this would look in a top file:

```
/srv/salt/top.sls:
```
```
base:
    'web*':
      - vim
      - vim.nerdtree
      - vim.pyflakes
      - vim.salt
    'db*':
      - vim.absent
```

The usage of a clear top-level directory as well as properly named states reduces the overall complexity and leads a user to both understand what will be included at a glance and where it is located.

In addition, Formulas should be used as often as possible.

**Note:** Formulas repositories on the saltstack-formulas GitHub organization should not be pointed to directly from systems that automatically fetch new updates such as GitFS or similar tooling. Instead, formulas repositories should be forked on GitHub or cloned locally, where unintended, automatic changes will not take place.

### 32.3 Structuring Pillar Files

**Pillars** are used to store secure and insecure data pertaining to minions. When designing the structure of the `/srv/pillar` directory, the pillars contained within should once again be focused on clear and concise data which users can easily review, modify, and understand.

The `/srv/pillar/` directory is primarily controlled by `top.sls`. It should be noted that the pillar `top.sls` is not used as a location to declare variables and their values. The `top.sls` is used as a way to include other pillar files and organize the way they are matched based on environments or grains.

An example `top.sls` may be as simple as the following:

```
/srv/pillar/top.sls:
```
```
base:
    '*':
      - packages
```

Or much more complicated, using a variety of matchers:

```
/srv/pillar/top.sls:
```
It is clear to see through these examples how the top file provides users with power but when used incorrectly it can lead to confusing configurations. This is why it is important to understand that the top file for pillar is not used for variable definitions.

Each SLS file within the /srv/pillar/ directory should correspond to the states which it matches.

This would mean that the apache pillar file should contain data relevant to Apache. Structuring files in this way once again ensures modularity, and creates a consistent understanding throughout our Salt environment. Users can expect that pillar variables found in an Apache state will live inside of an Apache pillar:

```
/srv/salt/pillar/apache.sls:
```

```
apache:
  lookup:
    name: httpd
    config:
      tmpl: /etc/httpd/httpd.conf
```

While this pillar file is simple, it shows how a pillar file explicitly relates to the state it is associated with.

### 32.4 Variable Flexibility

Salt allows users to define variables in SLS files. When creating a state variables should provide users with as much flexibility as possible. This means that variables should be clearly defined and easy to manipulate, and that sane defaults should exist in the event a variable is not properly defined. Looking at several examples shows how these different items can lead to extensive flexibility.

Although it is possible to set variables locally, this is generally not preferred:

```
/srv/salt/apache/conf.sls:
```

```
{% set name = 'httpd' %}
{% set tmpl = 'salt://apache/files/httpd.conf' %}

include:
  - apache

apache_conf:
  file.managed:
    - name: {{ name }}
    - source: {{ tmpl }}
    - template: jinja
    - user: root
```
When generating this information it can be easily transitioned to the pillar where data can be overwritten, modified, and applied to multiple states, or locations within a single state:

```
/srv/pillar/apache.sls:
```

```
apache:
  lookup:
    name: httpd
    config:
      tmpl: salt://apache/files/httpd.conf
```

```
/srv/salt/apache/conf.sls:
```

```
{% from "apache/map.jinja" import apache with context %}
include:
  - apache

apache_conf:
  file.managed:
    - name: {{ salt['pillar.get']('apache:lookup:name') }}
    - source: {{ salt['pillar.get']('apache:lookup:config:tmpl') }}
    - template: jinja
    - user: root
    - watch_in:
      - service: apache
```

This flexibility provides users with a centralized location to modify variables, which is extremely important as an environment grows.

### 32.5 Modularity Within States

Ensuring that states are modular is one of the key concepts to understand within Salt. When creating a state a user must consider how many times the state could be re-used, and what it relies on to operate. Below are several examples which will iteratively explain how a user can go from a state which is not very modular to one that is:

```
/srv/salt/apache/init.sls:
```

```
httpd:
  pkg.installed: []
  service.running:
    - enable: True
```

```
/etc/httpd/httpd.conf:
  file.managed:
    - source: salt://apache/files/httpd.conf
    - template: jinja
    - watch_in:
      - service: httpd
```
The example above is probably the worst-case scenario when writing a state. There is a clear lack of focus by naming both the pkg/service, and managed file directly as the state ID. This would lead to changing multiple requires within this state, as well as others that may depend upon the state.

Imagine if a require was used for the httpd package in another state, and then suddenly it's a custom package. Now changes need to be made in multiple locations which increases the complexity and leads to a more error-prone configuration.

There is also the issue of having the configuration file located in the init, as a user would be unable to simply install the service and use the default conf file.

Our second revision begins to address the referencing by using `name`, as opposed to direct ID references:

```
/srv/salt/apache/init.sls:

apache:
    pkg.installed:
        - name: httpd
    service.running:
        - name: httpd
        - enable: True

apache_conf:
    file.managed:
        - name: /etc/httpd/httpd.conf
        - source: salt://apache/files/httpd.conf
        - template: jinja
        - watch_in:
            - service: apache
```

The above init file is better than our original, yet it has several issues which lead to a lack of modularity. The first of these problems is the usage of static values for items such as the name of the service, the name of the managed file, and the source of the managed file. When these items are hard coded they become difficult to modify and the opportunity to make mistakes arises. It also leads to multiple edits that need to occur when changing these items (imagine if there were dozens of these occurrences throughout the state!). There is also still the concern of the configuration file data living in the same state as the service and package.

In the next example steps will be taken to begin addressing these issues. Starting with the addition of a map.jinja file (as noted in the `Formula documentation`), and modification of static values:

```
/srv/salt/apache/map.jinja:

{% set apache = salt['grains.filter_by']({
    'Debian': {
        'server': 'apache2',
        'service': 'apache2',
        'conf': '/etc/apache2/apache.conf',
    },
    'RedHat': {
        'server': 'httpd',
        'service': 'httpd',
        'conf': '/etc/httpd/httpd.conf',
    },
}, merge=salt['pillar.get']('apache:lookup')) %}
```

/srv/pillar/apache.sls:

```
The changes to this state now allow us to easily identify the location of the variables, as well as ensuring they are flexible and easy to modify. While this takes another step in the right direction, it is not yet complete. Suppose the user did not want to use the provided conf file, or even their own configuration file, but the default apache conf. With the current state setup this is not possible. To attain this level of modularity this state will need to be broken into two states.

```
/srv/salt/apache/map.jinja:

{% set apache = salt['grains.filter_by']({
    'Debian': {
        'server': 'apache2',
        'service': 'apache2',
        'conf': '/etc/apache2/apache2.conf',
    },
    'RedHat': {
        'server': 'httpd',
        'service': 'httpd',
        'conf': '/etc/httpd/httpd.conf',
    },
}, merge=salt['pillar.get']('apache:lookup'))) %}
```

```
/srv/pillar/apache.sls:

apache:
    lookup:
        config:
            tmpl: salt://apache/files/httpd.conf
```

```
/srv/salt/apache/init.sls:

{% from "apache/map.jinja" import apache with context %}

apache:
    pkg.installed:
        - name: {{ apache.server }}
    service.running:
        - name: {{ apache.service }}
        - enable: True

apache_conf:
    file.managed:
        - name: {{ apache.conf }}
        - source: {{ salt['pillar.get']('apache:lookup:config:tmpl') }}
        - template: jinja
        - user: root
        - watch_in:
            - service: apache
```

/srv/salt/apache/init.sls:
This new structure now allows users to choose whether they only wish to install the default Apache, or if they wish, overwrite the default package, service, configuration file location, or the configuration file itself. In addition to this the data has been broken between multiple files allowing for users to identify where they need to change the associated data.

### 32.6 Storing Secure Data

Secure data refers to any information that you would not wish to share with anyone accessing a server. This could include data such as passwords, keys, or other information.

As all data within a state is accessible by EVERY server that is connected it is important to store secure data within pillar. This will ensure that only those servers which require this secure data have access to it. In this example a use can go from an insecure configuration to one which is only accessible by the appropriate hosts:

```sls
/srv/salt/mysql/testerdb.sls:

testdb:
  mysql_database.present:
    - name: testerdb

/srv/salt/mysql/user.sls:

include:
  - mysql.testerdb

testdb_user:
  mysql_user.present:
    - name: frank
    - password: "test3rdb"
    - host: localhost
```
Many users would review this state and see that the password is there in plain text, which is quite problematic. It results in several issues which may not be immediately visible.

The first of these issues is clear to most users -- the password being visible in this state. This means that any minion will have a copy of this, and therefore the password which is a major security concern as minions may not be locked down as tightly as the master server.

The other issue that can be encountered is access by users on the master. If everyone has access to the states (or their repository), then they are able to review this password. Keeping your password data accessible by only a few users is critical for both security and peace of mind.

There is also the issue of portability. When a state is configured this way it results in multiple changes needing to be made. This was discussed in the sections above but it is a critical idea to drive home. If states are not portable it may result in more work later!

Fixing this issue is relatively simple, the content just needs to be moved to the associated pillar:

```yaml
/srv/pillar/mysql.sls:

mysql:
  lookup:
    name: testerdb
    password: test3rdb
    user: frank
    host: localhost
```

```yaml
/srv/salt/mysql/testerdb.sls:

testdb:
  mysql_database.present:
    - name: {{ salt['pillar.get']('mysql:lookup:name') }}
```

```yaml
/srv/salt/mysql/user.sls:

include:
  - mysql.testerdb

testdb_user:
  mysql_user.present:
    - name: {{ salt['pillar.get']('mysql:lookup:user') }}
    - password: {{ salt['pillar.get']('mysql:lookup:password') }}
    - host: {{ salt['pillar.get']('mysql:lookup:host') }}
    - require:
      - sls: mysql.testerdb
```

Now that the database details have been moved to the associated pillar file, only machines which are targeted via pillar will have access to these details. Access to users who should not be able to review these details can also be prevented while ensuring that they are still able to write states which take advantage of this information.
The intent of the troubleshooting section is to introduce solutions to a number of common issues encountered by users and the tools that are available to aid in developing States and Salt code.

### 33.1 Troubleshooting the Salt Master

If your Salt master is having issues such as minions not returning data, slow execution times, or a variety of other issues, the following links contain details on troubleshooting the most common issues encountered:

#### 33.1.1 Troubleshooting the Salt Master

**Running in the Foreground**

A great deal of information is available via the debug logging system, if you are having issues with minions connecting or not starting run the master in the foreground:

```
# salt-master -l debug
```

Anyone wanting to run Salt daemons via a process supervisor such as `monit`, `runit`, or `supervisord`, should omit the `-d` argument to the daemons and run them in the foreground.

**What Ports does the Master Need Open?**

For the master, TCP ports 4505 and 4506 need to be open. If you've put both your Salt master and minion in debug mode and don't see an acknowledgment that your minion has connected, it could very well be a firewall interfering with the connection. See our firewall configuration page for help opening the firewall on various platforms.

If you've opened the correct TCP ports and still aren't seeing connections, check that no additional access control system such as SELinux or AppArmor is blocking Salt.

**Too many open files**

The salt-master needs at least 2 sockets per host that connects to it, one for the Publisher and one for response port. Thus, large installations may, upon scaling up the number of minions accessing a given master, encounter:
The solution to this would be to check the number of files allowed to be opened by the user running salt-master (root by default):

[root@salt-master ~]# ulimit -n
1024

If this value is not equal to at least twice the number of minions, then it will need to be raised. For example, in an environment with 1800 minions, the nofile limit should be set to no less than 3600. This can be done by creating the file `/etc/security/limits.d/99-salt.conf`, with the following contents:

<table>
<thead>
<tr>
<th>root</th>
<th>hard</th>
<th>nofile</th>
<th>4096</th>
</tr>
</thead>
<tbody>
<tr>
<td>root</td>
<td>soft</td>
<td>nofile</td>
<td>4096</td>
</tr>
</tbody>
</table>

Replace root with the user under which the master runs, if different.

If your master does not have an `/etc/security/limits.d` directory, the lines can simply be appended to `/etc/security/limits.conf`.

As with any change to resource limits, it is best to stay logged into your current shell and open another shell to run `ulimit -n` again and verify that the changes were applied correctly. Additionally, if your master is running upstart, it may be necessary to specify the nofile limit in `/etc/default/salt-master` if upstart isn't respecting your resource limits:

```
limit nofile 4096 4096
```

Note: The above is simply an example of how to set these values, and you may wish to increase them even further if your Salt master is doing more than just running Salt.

**Salt Master Stops Responding**

There are known bugs with ZeroMQ versions less than 2.1.11 which can cause the Salt master to not respond properly. If you're running a ZeroMQ version greater than or equal to 2.1.9, you can work around the bug by setting the sysctls `net.core.rmem_max` and `net.core.wmem_max` to 16777216. Next, set the third field in `net.ipv4.tcp_rmem` and `net.ipv4.tcp_wmem` to at least 16777216.

You can do it manually with something like:

```
# echo 16777216 > /proc/sys/net/core/rmem_max
# echo 16777216 > /proc/sys/net/core/wmem_max
# echo "4096 87380 16777216" > /proc/sys/net/ipv4/tcp_rmem
# echo "4096 87380 16777216" > /proc/sys/net/ipv4/tcp_wmem
```

Or with the following Salt state:

```bash
1 net.core.rmem_max:
  2   sysctl:
  3     - present
  4     - value: 16777216
  5
1 net.core.wmem_max:
  2   sysctl:
```
Live Python Debug Output

If the master seems to be unresponsive, a SIGUSR1 can be passed to the salt-master threads to display what piece of code is executing. This debug information can be invaluable in tracking down bugs.

To pass a SIGUSR1 to the master, first make sure the minion is running in the foreground. Stop the service if it is running as a daemon, and start it in the foreground like so:

```
# salt-master -l debug
```

Then pass the signal to the master when it seems to be unresponsive:

```
# killall -SIGUSR1 salt-master
```

When filing an issue or sending questions to the mailing list for a problem with an unresponsive daemon, be sure to include this information if possible.

Live Salt-Master Profiling

When faced with performance problems one can turn on master process profiling by sending it SIGUSR2.

```
# killall -SIGUSR2 salt-master
```

This will activate yappi profiler inside salt-master code, then after some time one must send SIGUSR2 again to stop profiling and save results to file. If run in foreground salt-master will report filename for the results, which are usually located under /tmp on Unix-based OSes and c:\temp on windows.

Results can then be analyzed with kcachegrind or similar tool.

Commands Time Out or Do Not Return Output

Depending on your OS (this is most common on Ubuntu due to apt-get) you may sometimes encounter times where your highstate, or other long running commands do not return output.

Note: A number of timing issues were resolved in the 2014.1 release of Salt. Upgrading to at least this version is strongly recommended if timeouts persist.

By default the timeout is set to 5 seconds. The timeout value can easily be increased by modifying the timeout line within your /etc/salt/master configuration file.
Passing the -c Option to Salt Returns a Permissions Error

Using the -c option with the Salt command modifies the configuration directory. When the configuration file is read it will still base data off of the root_dir setting. This can result in unintended behavior if you are expecting files such as /etc/salt/pki to be pulled from the location specified with -c. Modify the root_dir setting to address this behavior.

Salt Master Doesn’t Return Anything While Running jobs

When a command being run via Salt takes a very long time to return (package installations, certain scripts, etc.) the master may drop you back to the shell. In most situations the job is still running but Salt has exceeded the set timeout before returning. Querying the job queue will provide the data of the job but is inconvenient. This can be resolved by either manually using the -t option to set a longer timeout when running commands (by default it is 5 seconds) or by modifying the master configuration file: /etc/salt/master and setting the timeout value to change the default timeout for all commands, and then restarting the salt-master service.

Salt Master Auth Flooding

In large installations, care must be taken not to overwhelm the master with authentication requests. Several options can be set on the master which mitigate the chances of an authentication flood from causing an interruption in service.

Note: recon_default:
The average number of seconds to wait between reconnection attempts.

recon_max: The maximum number of seconds to wait between reconnection attempts.

recon_randomize: A flag to indicate whether the recon_default value should be randomized.

acceptance_wait_time: The number of seconds to wait for a reply to each authentication request.

random_reauth_delay: The range of seconds across which the minions should attempt to randomize authentication attempts.

auth_timeout: The total time to wait for the authentication process to complete, regardless of the number of attempts.

33.1.2 Running state locally

To debug the states, you can use call locally.

\texttt{salt-call -l trace --local state.highstate}

The top.sls file is used to map what SLS modules get loaded onto what minions via the state system.

It is located in the file defined in the file_roots variable of the salt master configuration file which is defined by found in CONFIG_DIR/master, normally /etc/salt/master

The default configuration for the file_roots is:

\texttt{file_roots: base: - /srv/salt}

So the top file is defaulted to the location /srv/salt/top.sls
33.2 Troubleshooting the Salt Minion

In the event that your Salt minion is having issues, a variety of solutions and suggestions are available. Please refer to the following links for more information:

33.2.1 Troubleshooting the Salt Minion

Running in the Foreground

A great deal of information is available via the debug logging system, if you are having issues with minions connecting or not starting run the minion in the foreground:

```
# salt-minion -l debug
```

Anyone wanting to run Salt daemons via a process supervisor such as monit, runit, or supervisord, should omit the `-d` argument to the daemons and run them in the foreground.

What Ports does the Minion Need Open?

No ports need to be opened on the minion, as it makes outbound connections to the master. If you've put both your Salt master and minion in debug mode and don't see an acknowledgment that your minion has connected, it could very well be a firewall interfering with the connection. See our firewall configuration page for help opening the firewall on various platforms.

If you have netcat installed, you can check port connectivity from the minion with the `nc` command:

```
$ nc -v -z salt.master.ip.addr 4505
Connection to salt.master.ip.addr 4505 port [tcp/unknown] succeeded!
$ nc -v -z salt.master.ip.addr 4506
Connection to salt.master.ip.addr 4506 port [tcp/unknown] succeeded!
```

The Nmap utility can also be used to check if these ports are open:

```
# nmap -sS -q -p 4505-4506 salt.master.ip.addr
Starting Nmap 6.40 ( http://nmap.org ) at 2013-12-29 19:44 CST
Nmap scan report for salt.master.ip.addr (10.0.0.10)
Host is up (0.0026s latency).
PORT     STATE     SERVICE
4505/tcp open       unknown
4506/tcp open       unknown
MAC Address: 00:11:22:AA:BB:CC (Intel)
Nmap done: 1 IP address (1 host up) scanned in 1.64 seconds
```

If you've opened the correct TCP ports and still aren't seeing connections, check that no additional access control system such as SELinux or AppArmor is blocking Salt.

Using salt-call

The `salt-call` command was originally developed for aiding in the development of new Salt modules. Since then, many applications have been developed for running any Salt module locally on a minion. These range
from the original intent of salt-call, development assistance, to gathering more verbose output from calls like `state.highstate`

When initially creating your state tree, it is generally recommended to invoke `state.highstate` from the minion with `salt-call`. This displays far more information about the highstate execution than calling it remotely. For even more verbosity, increase the loglevel with the same argument as `salt-minion`:

```
# salt-call -l debug state.highstate
```

The main difference between using `salt` and using `salt-call` is that `salt-call` is run from the minion, and it only runs the selected function on that minion. By contrast, `salt` is run from the master, and requires you to specify the minions on which to run the command using salt's `targeting system`.

**Live Python Debug Output**

If the minion seems to be unresponsive, a SIGUSR1 can be passed to the process to display what piece of code is executing. This debug information can be invaluable in tracking down bugs.

To pass a SIGUSR1 to the minion, first make sure the minion is running in the foreground. Stop the service if it is running as a daemon, and start it in the foreground like so:

```
# salt-minion -l debug
```

Then pass the signal to the minion when it seems to be unresponsive:

```
# killall -SIGUSR1 salt-minion
```

When filing an issue or sending questions to the mailing list for a problem with an unresponsive daemon, be sure to include this information if possible.

**Multiprocessing in Execution Modules**

As is outlined in github issue #6300, Salt cannot use python's multiprocessing pipes and queues from execution modules. Multiprocessing from the execution modules is perfectly viable, it is just necessary to use Salt's event system to communicate back with the process.

The reason for this difficulty is that python attempts to pickle all objects in memory when communicating, and it cannot pickle function objects. Since the Salt loader system creates and manages function objects this causes the pickle operation to fail.

**Salt Minion Doesn’t Return Anything While Running Jobs Locally**

When a command being run via Salt takes a very long time to return (package installations, certain scripts, etc.) the minion may drop you back to the shell. In most situations the job is still running but Salt has exceeded the set timeout before returning. Querying the job queue will provide the data of the job but is inconvenient. This can be resolved by either manually using the `-t` option to set a longer timeout when running commands (by default it is 5 seconds) or by modifying the minion configuration file: `/etc/salt/minion` and setting the `timeout` value to change the default timeout for all commands, and then restarting the salt-minion service.

**Note:** Modifying the minion timeout value is not required when running commands from a Salt Master. It is only required when running commands locally on the minion.
33.3 Running in the Foreground

A great deal of information is available via the debug logging system, if you are having issues with minions connecting or not starting run the minion and/or master in the foreground:

```
salt-master -l debug
salt-minion -l debug
```

Anyone wanting to run Salt daemons via a process supervisor such as `monit`, `runit`, or `supervisord`, should omit the `-d` argument to the daemons and run them in the foreground.

33.4 What Ports do the Master and Minion Need Open?

No ports need to be opened up on each minion. For the master, TCP ports 4505 and 4506 need to be open. If you've put both your Salt master and minion in debug mode and don't see an acknowledgment that your minion has connected, it could very well be a firewall.

You can check port connectivity from the minion with the `nc` command:

```
nc -v -z salt.master.ip 4505
nc -v -z salt.master.ip 4506
```

There is also a firewall configuration document that might help as well.

If you've enabled the right TCP ports on your operating system or Linux distribution's firewall and still aren't seeing connections, check that no additional access control system such as SELinux or AppArmor is blocking Salt.

33.5 Using salt-call

The `salt-call` command was originally developed for aiding in the development of new Salt modules. Since then, many applications have been developed for running any Salt module locally on a minion. These range from the original intent of salt-call, development assistance, to gathering more verbose output from calls like `state.highstate`.

When creating your state tree, it is generally recommended to invoke `state.highstate` with `salt-call`. This displays far more information about the highstate execution than calling it remotely. For even more verbosity, increase the loglevel with the same argument as `salt-minion`:

```
salt-call -l debug state.highstate
```

The main difference between using `salt` and using `salt-call` is that `salt-call` is run from the minion, and it only runs the selected function on that minion. By contrast, `salt` is run from the master, and requires you to specify the minions on which to run the command using salt’s targeting system.

33.6 Too many open files

The salt-master needs at least 2 sockets per host that connects to it, one for the Publisher and one for response port. Thus, large installations may, upon scaling up the number of minions accessing a given master, encounter:
12:45:29,289 [salt.master][INFO] Starting Salt worker process 38
Too many open files
sock != -1 (tcp_listener.cpp:335)

The solution to this would be to check the number of files allowed to be opened by the user running salt-master (root by default):

[root@salt-master ~]# ulimit -n
1024

And modify that value to be at least equal to the number of minions x 2. This setting can be changed in limits.conf as the nofile value(s), and activated upon new a login of the specified user.

So, an environment with 1800 minions, would need 1800 x 2 = 3600 as a minimum.

### 33.7 Salt Master Stops Responding

There are known bugs with ZeroMQ versions less than 2.1.11 which can cause the Salt master to not respond properly. If you're running a ZeroMQ version greater than or equal to 2.1.9, you can work around the bug by setting the sysctls `net.core.rmem_max` and `net.core.wmem_max` to 16777216. Next, set the third field in `net.ipv4.tcp_rmem` and `net.ipv4.tcp_wmem` to at least 16777216.

You can do it manually with something like:

```bash
# echo 16777216 > /proc/sys/net/core/rmem_max
# echo 16777216 > /proc/sys/net/core/wmem_max
# echo "4096 87380 16777216" > /proc/sys/net/ipv4/tcp_rmem
# echo "4096 87380 16777216" > /proc/sys/net/ipv4/tcp_wmem
```

Or with the following Salt state:

```python
net.core.rmem_max:
  - sysctl:
    - present
    - value: 16777216

net.core.wmem_max:
  - sysctl:
    - present
    - value: 16777216

net.ipv4.tcp_rmem:
  - sysctl:
    - present
    - value: 4096 87380 16777216

net.ipv4.tcp_wmem:
  - sysctl:
    - present
    - value: 4096 87380 16777216
```
33.8 Salt and SELinux

Currently there are no SELinux policies for Salt. For the most part Salt runs without issue when SELinux is running in Enforcing mode. This is because when the minion executes as a daemon the type context is changed to initrc_t. The problem with SELinux arises when using salt-call or running the minion in the foreground, since the type context stays unconfined_t.

This problem is generally manifest in the rpm install scripts when using the pkg module. Until a full SELinux Policy is available for Salt the solution to this issue is to set the execution context of salt-call and salt-minion to rpm_exec_t:

```bash
# CentOS 5 and RHEL 5:
chcon -t system_u:system_r:rpm_exec_t:s0 /usr/bin/salt-minion
chcon -t system_u:system_r:rpm_exec_t:s0 /usr/bin/salt-call

# CentOS 6 and RHEL 6:
chcon system_u:object_r:rpm_exec_t:s0 /usr/bin/salt-minion
chcon system_u:object_r:rpm_exec_t:s0 /usr/bin/salt-call
```

This works well, because the rpm_exec_t context has very broad control over other types.

33.9 Red Hat Enterprise Linux 5

Salt requires Python 2.6 or 2.7. Red Hat Enterprise Linux 5 and its variants come with Python 2.4 installed by default. When installing on RHEL 5 from the EPEL repository this is handled for you. But, if you run Salt from git, be advised that its dependencies need to be installed from EPEL and that Salt needs to be run with the python26 executable.

33.10 Common YAML Gotchas

An extensive list of YAML idiosyncrasies has been compiled:

33.10.1 YAML Idiosyncrasies

One of Salt’s strengths, the use of existing serialization systems for representing SLS data, can also backfire. YAML is a general purpose system and there are a number of things that would seem to make sense in an sls file that cause YAML issues. It is wise to be aware of these issues. While reports or running into them are generally rare they can still crop up at unexpected times.

Spaces vs Tabs

YAML uses spaces, period. Do not use tabs in your SLS files! If strange errors are coming up in rendering SLS files, make sure to check that no tabs have crept in! In Vim, after enabling search highlighting with: `:set hlsearch`, you can check with the following key sequence in normal mode(you can hit ESC twice to be sure): `/`, `Ctrl-v`, `Tab`, then hit `Enter`. Also, you can convert tabs to 2 spaces by these commands in Vim: `:set tabstop=2` `expandtab` and then `:retab`. 
Indentation

The suggested syntax for YAML files is to use 2 spaces for indentation, but YAML will follow whatever indentation system that the individual file uses. Indentation of two spaces works very well for SLS files given the fact that the data is uniform and not deeply nested.

Nested Dictionaries

When `dicts` are nested within other data structures (particularly lists), the indentation logic sometimes changes. Examples of where this might happen include `context` and `defaults` options from the `file.managed` state:

```
/etc/http/conf/http.conf:
  file:
    - managed
    - source: salt://apache/http.conf
    - user: root
    - group: root
    - mode: 644
    - template: jinja
    - context:
      custom_var: "override"
    - defaults:
      custom_var: "default value"
      other_var: 123
```

Notice that while the indentation is two spaces per level, for the values under the `context` and `defaults` options there is a four-space indent. If only two spaces are used to indent, then those keys will be considered part of the same dictionary that contains the `context` key, and so the data will not be loaded correctly. If using a double indent is not desirable, then a deeply-nested dict can be declared with curly braces:

```
/etc/http/conf/http.conf:
  file:
    - managed
    - source: salt://apache/http.conf
    - user: root
    - group: root
    - mode: 644
    - template: jinja
    - context: {
      custom_var: "override"
    }
    - defaults: {
      custom_var: "default value",
      other_var: 123
    }
```

Here is a more concrete example of how YAML actually handles these indentations, using the Python interpreter on the command line:

```python
>>> import yaml
>>> yaml.safe_load('''mystate:
...    file.managed:
...      - context:
...        some: var''')
{'mystate': {'file.managed': [{'context': {'some': 'var'}}]}}
>>> yaml.safe_load('''mystate:
...    file.managed:
...      - context:
...        some: var'''}
```
... - context:
...  some: var''')
{'mystate': {'file.managed': [{'some': 'var', 'context': None}]}}

Note that in the second example, some is added as another key in the same dictionary, whereas in the first example, it's the start of a new dictionary. That's the distinction. context is a common example because it is a keyword arg for many functions, and should contain a dictionary.

**True/False, Yes/No, On/Off**

PyYAML will load these values as boolean True or False. Un-capitalized versions will also be loaded as booleans (true, false, yes, no, on, and off). This can be especially problematic when constructing Pillar data. Make sure that your Pillars which need to use the string versions of these values are enclosed in quotes.

**Integers are Parsed as Integers**

NOTE: This has been fixed in salt 0.10.0, as of this release passing an integer that is preceded by a 0 will be correctly parsed.

When passing integers into an SLS file, they are passed as integers. This means that if a state accepts a string value and an integer is passed, that an integer will be sent. The solution here is to send the integer as a string.

This is best explained when setting the mode for a file:

```yaml
/etc/vimrc:
  file:
    - managed
    - source: salt://edit/vimrc
    - user: root
    - group: root
    - mode: 644
```

Salt manages this well, since the mode is passed as 644, but if the mode is zero padded as 0644, then it is read by YAML as an integer and evaluated as an octal value, 0644 becomes 420. Therefore, if the file mode is preceded by a 0 then it needs to be passed as a string:

```yaml
/etc/vimrc:
  file:
    - managed
    - source: salt://edit/vimrc
    - user: root
    - group: root
    - mode: '0644'
```

**YAML does not like ``Double Short Decs''**

If I can find a way to make YAML accept ```Double Short Decs`` then I will, since I think that double short decs would be awesome. So what is a ```Double Short Dec```? It is when you declare a multiple short decs in one ID. Here is a standard short dec, it works great:

```yaml
vim:
  pkg.installed
```

33.10. Common YAML Gotchas
The short dec means that there are no arguments to pass, so it is not required to add any arguments, and it can save space.

YAML though, gets upset when declaring multiple short decs, for the record...

**THIS DOES NOT WORK:**

```yaml
vim:
  pkg.installed
  user.present
```

Similarly declaring a short dec in the same ID dec as a standard dec does not work either...

**ALSO DOES NOT WORK:**

```yaml
fred:
  user.present
  ssh_auth.present:
    - name: AAAAB3NzaC...
    - user: fred
    - enc: ssh-dss
    - require:
      - user: fred
```

The correct way is to define them like this:

```yaml
vim:
  pkg.installed: []
  user.present: []

fred:
  user.present: []
  ssh_auth.present:
    - name: AAAAB3NzaC...
    - user: fred
    - enc: ssh-dss
    - require:
      - user: fred
```

Alternatively, they can be defined the ```old way```; or with multiple ```full deces```:

```yaml
vim:
  pkg:
    - installed
  user:
    - present

fred:
  user:
    - present
  ssh_auth:
    - present
    - name: AAAAB3NzaC...
    - user: fred
    - enc: ssh-dss
    - require:
      - user: fred
```
YAML support only plain ASCII

According to YAML specification, only ASCII characters can be used. Within double-quotes, special characters may be represented with C-style escape sequences starting with a backslash (\). Examples:

- micro: "\u00b5"
- copyright: "\u00a9"
- A: "\x41"
- alpha: "\u0251"
- Alef: "\u05d0"

List of usable Unicode characters will help you to identify correct numbers. Python can also be used to discover the Unicode number for a character:

```
repr(u"Text with wrong characters i need to figure out")
```

This shell command can find wrong characters in your SLS files:

```
find . -name '*.sls' -exec grep --color='auto' -P -n '^[^\x00-\x7F]' {} \;
```

Alternatively you can toggle the yaml_utf8 setting in your master configuration file. This is still an experimental setting but it should manage the right encoding conversion in salt after yaml states compilations.

Underscores stripped in Integer Definitions

If a definition only includes numbers and underscores, it is parsed by YAML as an integer and all underscores are stripped. To ensure the object becomes a string, it should be surrounded by quotes. More information here.

Here's an example:

```
>>> import yaml
>>> yaml.safe_load('2013_05_10')
20130510
```

Automatic datetime conversion

If there is a value in a YAML file formatted 2014-01-20 14:23:23 or similar, YAML will automatically convert this to a Python datetime object. These objects are not msgpack serializable, and so may break core salt functionality. If values such as these are needed in a salt YAML file (specifically a configuration file), they should be formatted with surrounding strings to force YAML to serialize them as strings:

```
>>> import yaml
>>> yaml.safe_load('2014-01-20 14:23:23')
datetime.datetime(2014, 1, 20, 14, 23, 23)
```

33.10. Common YAML Gotchas
Additionally, numbers formatted like XXXX-XX-XX will also be converted (or YAML will attempt to convert them, and error out if it doesn’t think the date is a real one). Thus, for example, if a minion were to have an ID of 4017-16-20 the minion would not start because YAML would complain that the date was out of range. The workaround is the same, surround the offending string with quotes:

```python
>>> import yaml
>>> yaml.safe_load('4017-16-20')
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
  File "/usr/local/lib/python2.7/site-packages/yaml/__init__.py", line 93, in safe_load
    return load(stream, SafeLoader)
  File "/usr/local/lib/python2.7/site-packages/yaml/__init__.py", line 71, in load
    return loader.get_single_data()
  File "/usr/local/lib/python2.7/site-packages/yaml/constructor.py", line 39, in get_single_data
    return self.construct_document(node)
  File "/usr/local/lib/python2.7/site-packages/yaml/constructor.py", line 43, in construct_document
    data = self.construct_object(node)
  File "/usr/local/lib/python2.7/site-packages/yaml/constructor.py", line 88, in construct_object
    data = constructor(self, node)
  File "/usr/local/lib/python2.7/site-packages/yaml/constructor.py", line 312, in construct_yaml_timestamp
    return datetime.date(year, month, day)
ValueError: month must be in 1..12
>>> yaml.safe_load("4017-16-20")
'4017-16-20'
```

### 33.11 Live Python Debug Output

If the minion or master seems to be unresponsive, a SIGUSR1 can be passed to the processes to display where in the code they are running. If encountering a situation like this, this debug information can be invaluable. First make sure the master of minion are running in the foreground:

```bash
salt-master -l debug
salt-minion -l debug
```

Then pass the signal to the master or minion when it seems to be unresponsive:

```bash
killall -SIGUSR1 salt-master
killall -SIGUSR1 salt-minion
```

Also under BSD and Mac OS X in addition to SIGUSR1 signal, debug subroutine set up for SIGINFO which has an advantage of being sent by Ctrl+T shortcut.

When filing an issue or sending questions to the mailing list for a problem with an unresponsive daemon this information can be invaluable.

### 33.12 Salt 0.16.x minions cannot communicate with a 0.17.x master

As of release 0.17.1 you can no longer run different versions of Salt on your Master and Minion servers. This is due to a protocol change for security purposes. The Salt team will continue to attempt to ensure versions are as backwards compatible as possible.
33.13 Debugging the Master and Minion

A list of common master and minion troubleshooting steps provide a starting point for resolving issues you may encounter.
34.1 Overview

In its most typical use, Salt is a software application in which clients, called "minions" can be commanded and controlled from a central command server called a "master".

Commands are normally issued to the minions (via the master) by calling a client script simply called, 'salt'. Salt features a pluggable transport system to issue commands from a master to minions. The default transport is ZeroMQ.

34.2 Salt Client

34.2.1 Overview

The salt client is run on the same machine as the Salt Master and communicates with the salt-master to issue commands and to receive the results and display them to the user.

The primary abstraction for the salt client is called 'LocalClient'.

When LocalClient wants to publish a command to minions, it connects to the master by issuing a request to the master's ReqServer (TCP: 4506)

The LocalClient system listens to responses for its requests by listening to the master event bus publisher (master_event_pub.ipc).

34.3 Salt Master

34.3.1 Overview

The salt-master deamon runs on the designated Salt master and performs functions such as authenticating minions, sending, and receiving requests from connected minions and sending and receiving requests and replies to the `salt' CLI.
34.3.2 Moving Pieces

When a Salt master starts up, a number of processes are started, all of which are called `salt-master` in a process-list but have various role categories.

Among those categories are:

- Publisher
- EventPublisher
- MWorker

34.3.3 Publisher

The Publisher process is responsible for sending commands over the designated transport to connected minions. The Publisher is bound to the following:

- TCP: port 4505
- IPC: publish_pull.ipc

Each salt minion establishes a connection to the master Publisher.

34.3.4 EventPublisher

The EventPublisher publishes events onto the event bus. It is bound to the following:

- IPC: master_event_pull.ipc
- IPC: master_event_pub.ipc

34.3.5 MWorker

Worker processes manage the back-end operations for the Salt Master.

The number of workers is equivalent to the number of `worker_threads` specified in the master configuration and is always at least one.

Workers are bound to the following:

- IPC: workers.ipc

34.3.6 ReqServer

The Salt request server takes requests and distributes them to available MWorker processes for processing. It also receives replies back from minions.

The ReqServer is bound to the following:

- TCP: 4506
- IPC: workers.ipc

Each salt minion establishes a connection to the master ReqServer.
34.3.7 Job Flow

The Salt master works by always publishing commands to all connected minions and the minions decide if the command is meant for them by checking themselves against the command target.

The typical lifecycle of a salt job from the perspective of the master might be as follows:

1. A command is issued on the CLI. For example, `salt my_minion test.ping'.
2) The `salt' command uses LocalClient to generate a request to the salt master by connecting to the ReqServer on TCP:4506 and issuing the job.
3) The salt-master ReqServer sees the request and passes it to an available MWorker over workers.ipc.
4) A worker picks up the request and handles it. First, it checks to ensure that the requested user has permissions to issue the command. Then, it sends the publish command to all connected minions. For the curious, this happens in ClearFuncs.publish().
5) The worker announces on the master event bus that it is about to publish a job to connected minions. This happens by placing the event on the master event bus (master_event_pull.ipc) where the EventPublisher picks it up and distributes it to all connected event listeners on master_event_pub.ipc.
6) The message to the minions is encrypted and sent to the Publisher via IPC on publish_pull.ipc.
7) Connected minions have a TCP session established with the Publisher on TCP port 4505 where they await commands. When the Publisher receives the job over publish_pull, it sends the jobs across the wire to the minions for processing.
8) After the minions receive the request, they decrypt it and perform any requested work, if they determine that they are targeted to do so.
9) When the minion is ready to respond, it publishes the result of its job back to the master by sending the encrypted result back to the master on TCP 4506 where it is again picked up by the ReqServer and forwarded to an available MWorker for processing. (Again, this happens by passing this message across workers.ipc to an available worker.)
10) When the MWorker receives the job it decrypts it and fires an event onto the master event bus (master_event_pull.ipc). (Again for the curious, this happens in AESFuncs._return().
11) The EventPublisher sees this event and re-publishes it on the bus to all connected listeners of the master event bus (on master_event_pub.ipc). This is where the LocalClient has been waiting, listening to the event bus for minion replies. It gathers the job and stores the result.
12) When all targeted minions have replied or the timeout has been exceeded, the salt client displays the results of the job to the user on the CLI.

34.4 Salt Minion

34.4.1 Overview

The salt-minion is a single process that sits on machines to be managed by Salt. It can either operate as a stand-alone daemon which accepts commands locally via `salt-call' or it can connect back to a master and receive commands remotely.

When starting up, salt minions connect _back_ to a master defined in the minion config file. The connect to two ports on the master:

- TCP: 4505 This is the connection to the master Publisher. It is on this port that the minion receives jobs from the master.
- **TCP: 4506** This is the connection to the master ReqServer. It is on this port that the minion sends job results back to the master.

### 34.4.2 Event System

Similar to the master, a salt-minion has its own event system that operates over IPC by default. The minion event system operates on a push/pull system with IPC files at minion_event_<unique_id>_pub.ipc and minion_event_<unique_id>_pull.ipc.

The astute reader might ask why have an event bus at all with a single-process daemon. The answer is that the salt-minion may fork other processes as required to do the work without blocking the main salt-minion process and this necessitates a mechanism by which those processes can communicate with each other. Secondarily, this provides a bus by which any user with sufficient permissions can read or write to the bus as a common interface with the salt minion.

### 34.4.3 Job Flow

When a salt minion starts up, it attempts to connect to the Publisher and the ReqServer on the salt master. It then attempts to authenticate and once the minion has successfully authenticated, it simply listens for jobs.

Jobs normally come either come from the `salt-call` script run by a local user on the salt minion or they can come directly from a master.

### 34.4.4 Master Job Flow

1) A master publishes a job that is received by a minion as outlined by the master's job flow above.

2) The minion is polling its receive socket that's connected to the master Publisher (TCP 4505 on master). When it detects an incoming message, it picks it up from the socket and decrypts it.

3) A new minion process or thread is created and provided with the contents of the decrypted message. The _thread_return() method is provided with the contents of the received message.

4) The new minion thread is created. The _thread_return() function starts up and actually calls out to the requested function contained in the job.

5) The requested function runs and returns a result. [Still in thread.]

6) The result of the function that's run is encrypted and returned to the master's ReqServer (TCP 4506 on master). [Still in thread.]

7) Thread exits. Because the main thread was only blocked for the time that it took to initialize the worker thread, many other requests could have been received and processed during this time.

### 34.5 A Note on ClearFuncs vs. AESFuncs

A common source of confusion is determining when messages are passed in the clear and when they are passed using encryption. There are two rules governing this behaviour:

1) ClearFuncs is used for intra-master communication and during the initial authentication handshake between a minion and master during the key exchange.

2. AESFuncs is used everywhere else.
34.6 Contributing

There is a great need for contributions to Salt and patches are welcome! The goal here is to make contributions clear, make sure there is a trail for where the code has come from, and most importantly, to give credit where credit is due!

There are a number of ways to contribute to Salt development.

For details on how to contribute documentation improvements please review Writing Salt Documentation.

34.6.1 Sending a GitHub pull request

Sending pull requests on GitHub is the preferred method for receiving contributions. The workflow advice below mirrors GitHub's own guide and is well worth reading.

1. Fork saltstack/salt on GitHub.

2. Make a local clone of your fork.

   ```
   git clone git@github.com:my-account/salt.git
   cd salt
   ```

3. Add saltstack/salt as a git remote.

   ```
   git remote add upstream https://github.com/saltstack/salt.git
   ```

4. Create a new branch in your clone.

   ```
   git fetch upstream
   git checkout -b fix-broken-thing upstream/2015.5
   ```

   If you're working on a fix, create your branch from the oldest release branch having the bug. See Which Salt Branch?.

   ```
   git fetch upstream
   git checkout -b add-cool-feature upstream/develop
   ```

   If you're working on a feature, create your branch from the develop branch.

5. Edit and commit changes to your branch.

   ```
   vim path/to/file1 path/to/file2
   git diff
   git add path/to/file1 path/to/file2
   git commit
   ```

   Write a short, descriptive commit title and a longer commit message if necessary.

   ```
   Note: If your change fixes a bug or implements a feature already filed in the issue tracker, be sure to reference the issue number in the commit message body.
   ```
fix broken things in file1 and file2

Fixes #31337. The issue is now eradicated from file1 and file2.

# Please enter the commit message for your changes. Lines starting
# with '#' will be ignored, and an empty message aborts the commit.
# On branch fix-broken-thing
# Changes to be committed:
#   modified:  path/to/file1
#   modified:  path/to/file2

If you get stuck, there are many introductory Git resources on http://help.github.com.

6. Push your locally-committed changes to your GitHub fork,

**Note:** You may want to rebase before pushing to work out any potential conflicts.

```bash
git fetch upstream
git rebase upstream/2015.5 fix-broken-thing
git push --set-upstream origin fix-broken-thing
```

or,

```bash
git fetch upstream
git rebase upstream/develop add-cool-feature
git push --set-upstream origin add-cool-feature
```

7. Find the branch on your GitHub salt fork.

https://github.com/my-account/salt/branches/fix-broken-thing

8. Open a new pull request.

Click on Pull Request on the right near the top of the page,

https://github.com/my-account/salt/pull/new/fix-broken-thing

(a) If your branch is a fix for a release branch, choose that as the base branch (e.g. 2015.5),

https://github.com/my-account/salt/compare/saltstack:2015.5...fix-broken-thing

If your branch is a feature, choose develop as the base branch,

https://github.com/my-account/salt/compare/saltstack:develop...add-cool-feature

(b) Review that the proposed changes are what you expect.

(c) Write a descriptive comment. Include links to related issues (e.g. `Fixes #31337`) in the comment field.

(d) Click Create pull request.

9. Salt project members will review your pull request and automated tests will run on it.

If you recognize any test failures as being related to your proposed changes or if a reviewer asks for modifications:

(a) Make the new changes in your local clone on the same local branch.

(b) Push the branch to GitHub again using the same commands as before.

(c) New and updated commits will be added to the pull request automatically.
(d) Feel free to add a comment to the discussion.

Note: Jenkins

Pull request against saltstack/salt are automatically tested on a variety of operating systems and configurations. On average these tests take 30 minutes. Depending on your GitHub notification settings you may also receive an email message about the test results.

Test progress and results can be found at http://jenkins.saltstack.com/.

34.6.2 Which Salt branch?

GitHub will open pull requests against Salt's main branch, develop, by default. Ideally features should go into develop and bug fixes should go into the oldest supported release branch affected by the bug. See Sending a GitHub pull request.

If you have a bug fix and have already forked your working branch from develop and do not know how to rebase your commits against another branch, then submit it to develop anyway and we'll be sure to backport it to the correct place.

The current release branch

The current release branch is the most recent stable release. Pull requests containing bug fixes should be made against the release branch.

The branch name will be a date-based name such as 2015.5.

Bug fixes are made on this branch so that minor releases can be cut from this branch without introducing surprises and new features. This approach maximizes stability.

The Salt development team will "merge-forward" any fixes made on the release branch to the develop branch once the pull request has been accepted. This keeps the fix in isolation on the release branch and also keeps the develop branch up-to-date.

Note: Closing GitHub issues from commits

This "merge-forward" strategy requires that the magic keywords to close a GitHub issue appear in the commit message text directly. Only including the text in a pull request will not close the issue.

GitHub will close the referenced issue once the commit containing the magic text is merged into the default branch (develop). Any magic text input only into the pull request description will not be seen at the Git-level when those commits are merged-forward. In other words, only the commits are merged-forward and not the pull request.

The develop branch

The develop branch is unstable and bleeding-edge. Pull requests containing feature additions or non-bug-fix changes should be made against the develop branch.

The Salt development team will back-port bug fixes made to develop to the current release branch if the contributor cannot create the pull request against that branch.
34.6.3 Keeping Salt Forks in Sync

Salt is advancing quickly. It is therefore critical to pull upstream changes from upstream into your fork on a regular basis. Nothing is worse than putting hard work into a pull request only to see bunches of merge conflicts because it has diverged too far from upstream.

See also:
GitHub Fork a Repo Guide

The following assumes origin is the name of your fork and upstream is the name of the main saltstack/salt repository.

1. View existing remotes.
   
   ```
   git remote -v
   ```

2. Add the upstream remote.
   
   ```
   # For ssh github
   git remote add upstream git@github.com:saltstack/salt.git
   
   # For https github
   git remote add upstream https://github.com/saltstack/salt.git
   ```

3. Pull upstream changes into your clone.
   
   ```
   git fetch upstream
   ```

4. Update your copy of the develop branch.
   
   ```
   git checkout develop
   git merge --ff-only upstream/develop
   ```

   If Git complains that a fast-forward merge is not possible, you have local commits.
   - Run `git pull --rebase origin develop` to rebase your changes on top of the upstream changes.
   - Or, run `git branch <branch-name>` to create a new branch with your commits. You will then need to reset your develop branch before updating it with the changes from upstream.

   If Git complains that local files will be overwritten, you have changes to files in your working directory. Run `git status` to see the files in question.

5. Update your fork.
   
   ```
   git push origin develop
   ```

6. Repeat the previous two steps for any other branches you work with, such as the current release branch.

34.6.4 Posting patches to the mailing list

Patches will also be accepted by email. Format patches using `git format-patch` and send them to the salt-users mailing list. The contributor will then get credit for the patch, and the Salt community will have an archive of the patch and a place for discussion.
34.6.5 Backporting Pull Requests

If a bug is fixed on develop and the bug is also present on a currently-supported release branch it will need to be back-ported to all applicable branches.

Note: Most Salt contributors can skip these instructions. These instructions do not need to be read in order to contribute to the Salt project! The SaltStack team will back-port fixes on behalf of contributors in order to keep the contribution process easy. These instructions are intended for frequent Salt contributors, advanced Git users, SaltStack employees, or independent souls who wish to back-port changes themselves.

It is often easiest to fix a bug on the oldest supported release branch and then merge that branch forward into develop (as described earlier in this document). When that is not possible the fix must be back-ported, or copied, into any other affected branches.

These steps assume a pull request #1234 has been merged into develop. And upstream is the name of the remote pointing to the main Salt repo.

1. Identify the oldest supported release branch that is affected by the bug.

2. Create a new branch for the back-port by reusing the same branch from the original pull request.
   Name the branch bp-<NNNN> and use the number of the original pull request.
   ```
   git fetch upstream refs/pull/1234/head:bp-1234
   git checkout bp-1234
   ```

3. Find the parent commit of the original pull request.
   The parent commit of the original pull request must be known in order to rebase onto a release branch. The easiest way to find this is on GitHub.
   Open the original pull request on GitHub and find the first commit in the list of commits. Select and copy the SHA for that commit. The parent of that commit can be specified by appending ~1 to the end.

4. Rebase the new branch on top of the release branch.
   - `<release-branch>` is the branch identified in step #1.
   - `<orig-base>` is the SHA identified in step #3 -- don't forget to add ~1 to the end!
   ```
   git rebase --onto <release-branch> <orig-base> bp-1234
   ```
   Note, release branches prior to 2015.5 will not be able to make use of rebase and must use cherry-picking instead.

5. Push the back-port branch to GitHub and open a new pull request.
   Opening a pull request for the back-port allows for the test suite and normal code-review process.
   ```
   git push -u origin bp-1234
   ```

34.6.6 Issue and Pull Request Labeling System

SaltStack uses several labeling schemes to help facilitate code contributions and bug resolution. See the Labels and Milestones documentation for more information.
34.7 Deprecating Code

Salt should remain backwards compatible, though sometimes, this backwards compatibility needs to be broken because a specific feature and/or solution is no longer necessary or required. At first one might think, let me change this code, it seems that it’s not used anywhere else so it should be safe to remove. Then, once there’s a new release, users complain about functionality which was removed and they where using it, etc. This should, at all costs, be avoided, and, in these cases, that specific code should be deprecated.

In order to give users enough time to migrate from the old code behavior to the new behavior, the deprecation time frame should be carefully determined based on the significance and complexity of the changes required by the user.

A deprecation warning should be in place for at least two major releases before the deprecated code and its accompanying deprecation warning are removed. More time should be given for more complex changes. For example, if the current release under development is Sodium, the deprecated code and associated warnings should remain in place and warn for at least Aluminum.

To help in this deprecation task, salt provides salt.utils.warn_until. The idea behind this helper function is to show the deprecation warning to the user until salt reaches the provided version. Once that provided version is equal to salt.utils.warn_until, it will raise a RuntimeError making salt stop its execution. This stoppage is unpleasant and will remind the developer that the deprecation limit has been reached and that the code can then be safely removed.

Consider the following example:

```python
def some_function(bar=False, foo=None):
    if foo is not None:
        salt.utils.warn_until('Aluminum',
            'The `foo` argument has been deprecated and its ' +
            'functionality removed, as such, its usage is no longer ' +
            'required.'
        )
```

Development begins on the Aluminum release when the Magnesium branch is forked from the develop branch. Once this occurs, all uses of the warn_until function targeting Aluminum, along with the code they are warning about should be removed from the code.

34.8 Dunder Dictionaries

Salt provides several special `dunder` dictionaries as a convenience for Salt development. These include __opts__, __context__, __salt__, and others. This document will describe each dictionary and detail where they exist and what information and/or functionality they provide.

34.8.1 __opts__

Available in

- All loader modules

The __opts__ dictionary contains all of the options passed in the configuration file for the master or minion.

**Note:** In many places in salt, instead of pulling raw data from the __opts__ dict, configuration data should be pulled from the salt get functions such as config.get, aka - __salt__['config.get']('foo:bar') The get functions also allow for
dict traversal via the : delimiter. Consider using get functions whenever using __opts__ or __pillar__ and __grains__ (when using grains for configuration data)

The configuration file data made available in the __opts__ dictionary is the configuration data relative to the running daemon. If the modules are loaded and executed by the master, then the master configuration data is available, if the modules are executed by the minion, then the minion configuration is available. Any additional information passed into the respective configuration files is made available.

### 34.8.2 __salt__

Available in

- Execution Modules
- State Modules
- Returners

__salt__ contains the execution module functions. This allows for all functions to be called as they have been set up by the salt loader.

```python
__salt__['cmd.run']('fdisk -l')
__salt__['network.ip_addrs']()
```

### 34.8.3 __grains__

Available in

- Execution Modules
- State Modules
- Returners
- External Pillar

The __grains__ dictionary contains the grains data generated by the minion that is currently being worked with. In execution modules, state modules and returners this is the grains of the minion running the calls, when generating the external pillar the __grains__ is the grains data from the minion that the pillar is being generated for.

### 34.8.4 __pillar__

Available in

- Execution Modules
- State Modules
- Returners

The __pillar__ dictionary contains the pillar for the respective minion.
34.8.5 __context__

__context__ exists in state modules and execution modules.

During a state run the __context__ dictionary persists across all states that are run and then is destroyed when the state ends.

When running an execution module __context__ persists across all module executions until the modules are refreshed; such as when saltutils.sync_all or state.highstate are executed.

A great place to see how to use __context__ is in the cp.py module in salt/modules/cp.py. The fileclient authenticates with the master when it is instantiated and then is used to copy files to the minion. Rather than create a new fileclient for each file that is to be copied down, one instance of the fileclient is instantiated in the __context__ dictionary and is reused for each file. Here is an example from salt/modules/cp.py:

```python
if not 'cp.fileclient' in __context__:
    __context__['cp.fileclient'] = salt.fileclient.get_file_client(__opts__)
```

Note: Because __context__ may or may not have been destroyed, always be sure to check for the existence of the key in __context__ and generate the key before using it.

34.9 External Pillars

Salt provides a mechanism for generating pillar data by calling external pillar interfaces. This document will describe an outline of an ext_pillar module.

34.9.1 Location

Salt expects to find your ext_pillar module in the same location where it looks for other python modules. If the extension_modules option in your Salt master configuration is set, Salt will look for a pillar directory under there and load all the modules it finds. Otherwise, it will look in your Python site-packages salt/pillar directory.

34.9.2 Configuration

The external pillars that are called when a minion refreshes its pillars is controlled by the ext_pillar option in the Salt master configuration. You can pass a single argument, a list of arguments or a dictionary of arguments to your pillar:

```python
ext_pillar:
    - example_a: some argument
    - example_b:
        - argumentA
        - argumentB
    - example_c:
        keyA: valueA
        keyB: valueB
```
34.9.3 The Module

34.9.4 Imports and Logging

Import modules your external pillar module needs. You should first include generic modules that come with stock Python:

```python
import logging
```

And then start logging. This is an idiomatic way of setting up logging in Salt:

```python
log = logging.getLogger(__name__)
```

Finally, load modules that are specific to what you are doing. You should catch import errors and set a flag that the `__virtual__` function can use later.

```python
try:
    import weird_thing
    EXAMPLE_A_LOADED = True
except ImportError:
    EXAMPLE_A_LOADED = False
```

34.9.5 Options

If you define an `__opts__` dictionary, it will be merged into the `__opts__` dictionary handed to the `ext_pillar` function later. This is a good place to put default configuration items. The convention is to name things `module-name.option`.

```python
__opts__ = {'example_a.someconfig': 137}
```

34.9.6 Initialization

If you define an `__init__` function, it will be called with the following signature:

```python
def __init__(__opts__):
    # Do init work here
```

Note: The `__init__` function is ran every time a particular minion causes the external pillar to be called, so don't put heavy initialization code here. The `__init__` functionality is a side-effect of the Salt loader, so it may not be as useful in pillars as it is in other Salt items.

34.9.7 `__virtual__`

If you define a `__virtual__` function, you can control whether or not this module is visible. If it returns `False` then Salt ignores this module. If it returns a string, then that string will be how Salt identifies this external pillar in its `ext_pillar` configuration. If you're not renaming the module, simply return `True` in the `__virtual__` function, which is the same as if this function did not exist, then, the name Salt's `ext_pillar` will use to identify this module is its conventional name in Python.

This is useful to write modules that can be installed on all Salt masters, but will only be visible if a particular piece of software your module requires is installed.
This external pillar will be known as `example_a`

def __virtual__():
    if EXAMPLE_A_LOADED:
        return True
    return False

This external pillar will be known as `something_else`

__virtualname__ = 'something_else'

def __virtual__():
    if EXAMPLE_A_LOADED:
        return __virtualname__
    return False

### 34.9.8 ext_pillar

This is where the real work of an external pillar is done. If this module is active and has a function called `ext_pillar`, whenever a minion updates its pillar this function is called.

How it is called depends on how it is configured in the Salt master configuration. The first argument is always the current pillar dictionary, this contains pillar items that have already been added, starting with the data from `pillar_roots`, and then from any already-ran external pillars.

Using our example above:

```
ext_pillar( id, pillar, 'some argument' )  # example_a
ext_pillar( id, pillar, 'argumentA', 'argumentB' )  # example_b
ext_pillar( id, pillar, keyA='valueA', keyB='valueB' )  # example_c
```

In the example_a case, pillar will contain the items from the `pillar_roots`, in example_b pillar will contain that plus the items added by example_a, and in example_c pillar will contain that plus the items added by example_b. In all three cases, id will contain the ID of the minion making the pillar request.

This function should return a dictionary, the contents of which are merged in with all of the other pillars and returned to the minion. **Note**: this function is called once for each minion that fetches its pillar data.

```
def ext_pillar( minion_id, pillar, *args, **kwargs ):
    my_pillar = {}
    # Do stuff
    return my_pillar
```

You shouldn't just add items to `pillar` and return that, since that will cause Salt to merge data that already exists. Rather, just return the items you are adding or changing. You could, however, use `pillar` in your module to make some decision based on pillar data that already exists.

This function has access to some useful globals:

- `__opts__` A dictionary of mostly Salt configuration options. If you had an `__opts__` dictionary defined in your module, those values will be included.
- `__salt__` A dictionary of Salt module functions, useful so you don't have to duplicate functions that already exist. E.g. `__salt__['cmd.run']('ls -l')` **Note**, runs on the master
- `__grains__` A dictionary of the grains of the minion making this pillar call.
**34.9.9 Example configuration**

As an example, if you wanted to add external pillar via the `cmd_json` external pillar, add something like this to your master config:

```plaintext
ext_pillar:
- cmd_json: 'echo \"\"arg\\"\":\"value\\"\\"'
```

**34.9.10 Reminder**

Just as with traditional pillars, external pillars must be refreshed in order for minions to see any fresh data:

```plaintext
salt '*' saltutil.refresh_pillar
```

**34.10 Installing Salt for development**

Clone the repository using:

```plaintext
git clone https://github.com/saltstack/salt
```

**Note:** tags

Just cloning the repository is enough to work with Salt and make contributions. However, fetching additional tags from git is required to have Salt report the correct version for itself. To do this, first add the git repository as an upstream source:

```plaintext
git remote add upstream https://github.com/saltstack/salt
```

Fetching tags is done with the git `fetch` utility:

```plaintext
git fetch --tags upstream
```

Create a new virtualenv:

```plaintext
virtualenv /path/to/your/virtualenv
```

Avoid making your `virtualenv path too long`. On Arch Linux, where Python 3 is the default installation of Python, use the `virtualenv2` command instead of `virtualenv`.

**Note:** Using system Python modules in the virtualenv

To use already-installed python modules in virtualenv (instead of having pip download and compile new ones), run `virtualenv --system-site-packages` Using this method eliminates the requirement to install the salt dependencies again, although it does assume that the listed modules are all installed in the system PYTHONPATH at the time of virtualenv creation.

Activate the virtualenv:

```plaintext
source /path/to/your/virtualenv/bin/activate
```
Install Salt (and dependencies) into the virtualenv:

```
pip install M2Crypto       # Don't install on Debian/Ubuntu (see below)
pip install pyzmq PyYAML pycrypto msgpack-python jinja2 psutil
pip install -e ./salt      # the path to the salt git clone from above
```

**Note:** Installing M2Crypto

`swig` and `libssl-dev` are required to build M2Crypto. To fix the error command 'swig' failed with exit status 1 while installing M2Crypto, try installing it with the following command:

```
env SWIG_FEATURES="-cpperrswarn -includeall -D__`uname -m`__ -I/usr/include/openssl" pip install M2Crypto
```

Debian and Ubuntu systems have modified openssl libraries and mandate that a patched version of M2Crypto be installed. This means that M2Crypto needs to be installed via apt:

```
apt-get install python-m2crypto
```

This also means that pulling in the M2Crypto installed using apt requires using `--system-site-packages` when creating the virtualenv.

If you're using a platform other than Debian or Ubuntu, and you are installing M2Crypto via pip instead of a system package, then you will also need the `gcc` compiler.

**Note:** Installing psutil

Python header files are required to build this module, otherwise the pip install will fail. If your distribution separates binaries and headers into separate packages, make sure that you have the headers installed. In most Linux distributions which split the headers into their own package, this can be done by installing the `python-dev` or `python-devel` package. For other platforms, the package will likely be similarly named.

**Note:** Installing dependencies on OS X.

You can install needed dependencies on OS X using homebrew or macports. See [OS X Installation](#).

**Warning:** Installing on RedHat-based Distro

If installing from pip (or from source using `setup.py install`), be advised that the `yum-utils` package is needed for Salt to manage packages on RedHat-based systems.

### 34.10.1 Running a self-contained development version

During development it is easiest to be able to run the Salt master and minion that are installed in the virtualenv you created above, and also to have all the configuration, log, and cache files contained in the virtualenv as well.

Copy the master and minion config files into your virtualenv:

```
mkdir -p /path/to/your/virtualenv/etc/salt
cp ./salt/conf/master ./salt/conf/minion /path/to/your/virtualenv/etc/salt/
```

Edit the master config file:

1. Uncomment and change the `user: root` value to your own user.
2. Uncomment and change the `root_dir: /` value to point to `/path/to/your/virtualenv`.  

1944  Chapter 34. Developing Salt
3. If you are running version 0.11.1 or older, uncomment, and change the pidfile: `var/run/salt-master.pid` value to point to `/path/to/your/virtualenv/salt-master.pid`.

4. If you are also running a non-development version of Salt you will have to change the publish_port and ret_port values as well.

Edit the minion config file:

1. Repeat the edits you made in the master config for the user and root_dir values as well as any port changes.

2. If you are running version 0.11.1 or older, uncomment, and change the pidfile: `var/run/salt-minion.pid` value to point to `/path/to/your/virtualenv/salt-minion.pid`.

3. Uncomment and change the master: salt value to point at localhost.

4. Uncomment and change the id: value to something descriptive like `saltdev`. This isn't strictly necessary but it will serve as a reminder of which Salt installation you are working with.

5. If you changed the ret_port value in the master config because you are also running a non-development version of Salt, then you will have to change the master_port value in the minion config to match.

**Note:** Using salt-call with a Standalone Minion

If you plan to run salt-call with this self-contained development environment in a masterless setup, you should invoke salt-call with `-c /path/to/your/virtualenv/etc/salt` so that salt can find the minion config file. Without the -c option, Salt finds its config files in /etc/salt.

Start the master and minion, accept the minion's key, and verify your local Salt installation is working:

```
cd /path/to/your/virtualenv
salt-master -c ./etc/salt -d
salt-minion -c ./etc/salt -d
salt-key -c ./etc/salt -L
salt-key -c ./etc/salt -A
salt -c ./etc/salt '*' test.ping
```

Running the master and minion in debug mode can be helpful when developing. To do this, add `-l debug` to the calls to salt-master and salt-minion. If you would like to log to the console instead of to the log file, remove the `-d`.

**Note:** Too long socket path?

Once the minion starts, you may see an error like the following:

```
zmq.core.error.ZMQError: ipc path "/path/to/your/virtualenv/var/run/salt/minion/minion_event_7824dcbfcd7a8f6755939af78b96249f_pub.ipc" is longer than 107 characters (sizeof(sockaddr_un.sun_path)).
```

This means that the path to the socket the minion is using is too long. This is a system limitation, so the only workaround is to reduce the length of this path. This can be done in a couple different ways:

1. Create your virtualenv in a path that is short enough.

2. Edit the sock_dir minion config variable and reduce its length. Remember that this path is relative to the value you set in root_dir.

**NOTE:** The socket path is limited to 107 characters on Solaris and Linux, and 103 characters on BSD-based systems.

**Note:** File descriptor limits
Ensure that the system open file limit is raised to at least 2047:

```bash
# check your current limit
ulimit -n

# raise the limit. persists only until reboot
# use 'limit descriptors 2047' for c-shell
ulimit -n 2047
```

To set file descriptors on OSX, refer to the *OS X Installation* instructions.

### Changing Default Paths

Instead of updating your configuration files to point to the new root directory and having to pass the new configuration directory path to all of Salt’s CLI tools, you can explicitly tweak the default system paths that Salt expects:

```bash
GENERATE_SALT_SYSPATHS=1 pip --global-option='--salt-root-dir=/path/to/your/virtualenv/' \
    install -e ./salt  # the path to the salt git clone from above
```

You can now call all of Salt’s CLI tools without explicitly passing the configuration directory.

**Additional Options**

In case you want to distribute your virtualenv, you probably don’t want to include Salt’s clone .git/ directory, and, without it, Salt won’t report the accurate version. You can tell setup.py to generate the hardcoded version information which is distributable:

```bash
GENERATE_SALT_SYSPATHS=1 WRITE_SALT_VERSION=1 pip --global-option='--salt-root-dir=/path/to/your/virtualenv/' \
    install -e ./salt  # the path to the salt git clone from above
```

Instead of passing those two environmental variables, you can just pass a single one which will trigger the other two:

```bash
MIMIC_SALT_INSTALL=1 pip --global-option='--salt-root-dir=/path/to/your/virtualenv/' \
    install -e ./salt  # the path to the salt git clone from above
```

This last one will grant you an editable salt installation with hardcoded system paths and version information.

### 34.10.2 Installing Salt from the Python Package Index

If you are installing using easy_install, you will need to define a USE_SETUPTOOLS environment variable, otherwise dependencies will not be installed:

```bash
USE_SETUPTOOLS=1 easy_install salt
```
34.10.3 Editing and previewing the documentation

You need `sphinx-build` command to build the docs. In Debian/Ubuntu this is provided in the `python-sphinx` package. Sphinx can also be installed to a virtualenv using `pip`:

```
pip install sphinx==1.3b2
```

Change to salt documentation directory, then:

```
cd doc; make html
```

- This will build the HTML docs. Run `make` without any arguments to see the available make targets, which include `html`, `man`, and `text`.
- The docs then are built within the `docs/_build/` folder. To update the docs after making changes, run `make` again.
- The docs use `reStructuredText` for markup. See a live demo at http://rst.ninjs.org/.
- The help information on each module or state is culled from the python code that runs for that piece. Find them in `salt/modules/` or `salt/states/`.
- To build the docs on Arch Linux, the `python2-sphinx` package is required. Additionally, it is necessary to tell `make` where to find the proper `sphinx-build` binary, like so:

```
make SPHINXBUILD=sphinx-build2 html
```

- To build the docs on RHEL/CentOS 6, the `python-sphinx10` package must be installed from EPEL, and the following `make` command must be used:

```
make SPHINXBUILD=sphinx-1.0-build html
```

Once you've updated the documentation, you can run the following command to launch a simple Python HTTP server to see your changes:

```
cd _build/html; python -m SimpleHTTPServer
```

34.10.4 Running unit and integration tests

Run the test suite with following command:

```
./setup.py test
```

See here for more information regarding the test suite.

34.10.5 Issue and Pull Request Labeling System

SaltStack uses several labeling schemes to help facilitate code contributions and bug resolution. See the `Labels and Milestones` documentation for more information.
34.11 GitHub Labels and Milestones

SaltStack uses several label categories, as well as milestones, to triage incoming issues and pull requests in the GitHub issue tracker. Labels are used to sort issues by type, priority, severity, status, functional area, functional group, and targeted release and pull requests by status, functional area, functional group, type of change, and test status. Milestones are used to indicate whether an issue is fully triaged or is scheduled to be fixed by SaltStack in an upcoming sprint.

34.11.1 Milestones

All issues are assigned to a milestone, whereas pull requests are almost never assigned to a milestone as the mean lifetime of pull requests is short enough that there is no need to track them temporally.

SaltStack uses milestones to indicate which issues are blocked on submitter or upstream actions, are approved, or are scheduled to be fixed or implemented in an upcoming sprint. If an issue is not attached to a sprint milestone, you are welcome to work on it at your own desire and convenience. If it is attached to a sprint milestone and you have already begun working on it or have a solution in mind or have other ideas related to the issue, you are encouraged to coordinate with the assignee via the GitHub issue tracker to create the best possible solution or implementation.

**Approved** The issue has been validated and has all necessary information.

**Blocked** The issue is waiting on actions by parties outside of SaltStack, such as receiving more information from the submitter or resolution of an upstream issue. This milestone is usually applied in conjunction with the labels Info Needed, Question, Expected Behavior, Won't Fix For Now, or Upstream Bug.

**Under Review** The issue is having further validation done by a SaltStack engineer.

**<Sprint>** The issue is being actively worked on by a SaltStack engineer. Sprint milestones names are constructed from the chemical symbol of the next release's codename and the number of sprints until that release is made. For example, if the next release codename is Neon and there are five sprints until that release, the corresponding sprint milestone will be called Ne 5. See <topics/releases/version_numbers> for a discussion of Salt's release codenames.

34.11.2 Labels

Labels are used to sort and describe issues and pull requests. Some labels are usually reserved for one or the other, though most labels may be applied to both.

New issues will receive at least one label and a milestone, and new pull requests will receive at least one label. Except for the functional area and functional group label categories, issues will generally receive only up to one label per category.

**Type**

Issues are categorized into one of several types. Type labels are almost never used for pull requests. GitHub treats pull requests like issues in many ways, so a pull request could be considered an issue with an implicit Pull Request type label applied.

**Feature** The issue is a request for new functionality including changes, enhancements, refactors, etc.

**Bug** The issue documents broken, incorrect, or confusing behavior. This label is always accompanied by a severity label.

**Duplicate** The issue is a duplicate of another feature request or bug report.

**Upstream Bug** The issue is a result of an upstream issue.
**Question**  The issue is more of a question than a request for new features or a report of broken features, but can sometimes lead to further discussion or changes of confusing or incongruous behavior or documentation.

**Expected Behavior**  The issue is a bug report of intended functionality.

**Priority**

An issue's priority is relative to its *functional area*. If a bug report, for example, about `gitfs` indicates that all users of `gitfs` will encounter this bug, then a P1 label will be applied, even though users who are not using `gitfs` will not encounter the bug. If a feature is requested by many users, it may be given a high priority.

- **P1**  The issue will be seen by all users.
- **P2**  The issue will be seen by most users.
- **P3**  The issue will be seen by about half of users.
- **P4**  The issue will not be seen by most users. Usually the issue is a very specific use case or corner case.

**Severity**

Severity labels are almost always only applied to issues labeled Bug.

- **Blocker**  The issue is blocking an impending release.
- **Critical**  The issue causes data loss, crashes or hangs salt processes, makes the system unresponsive, etc.
- **High Severity**  The issue reports incorrect functionality, bad functionality, a confusing user experience, etc.
- **Medium Severity**  The issue reports cosmetic items, formatting, spelling, colors, etc.

**Functional Area**

Many major components of Salt have corresponding GitHub labels. These labels are applied to all issues and pull requests as is reasonably appropriate. They are useful in organizing issues and pull requests according to the source code relevant to issues or the source code changed by pull requests.

- Execution Module
- File Servers
- Grains
- Multi-Master
- Packaging Related to packaging of Salt, not Salt's support for package management.
- Pillar
- RAET
- Returners
- Runners
- SPM
- Salt-API
- Salt-Cloud
- Salt-SSH
Functional Group

These labels sort issues and pull requests according to the internal SaltStack engineering teams.

Core The issue or pull request relates to code that is central or existential to Salt itself.

Platform The issue or pull request relates to support and integration with various platforms like traditional operating systems as well as containers, platform-based utilities like filesystems, command schedulers, etc., and system-based applications like web servers, databases, etc.

RIoT The issue or pull request relates to support and integration with various abstract systems like cloud providers, hypervisors, API-based services, etc.

Console The issue or pull request relates to the SaltStack enterprise console.

Documentation The issue or pull request relates to documentation.

Status

Status labels are used to define and track the state of issues and pull requests. Not all potential statuses correspond to a label, but some statuses are common enough that labels have been created for them. If a status has not been moved beyond the Blocked milestone, it is very likely that it will only have a status label.

Bugfix - back-port The pull request needs to be back-ported to an older release branch. This is done by recreating the pull request against that branch. Once the back-port is completed, this label is replaced with a Bugfix - [Done] back-ported label. Normally, new features should go into the develop and bug fixes into the oldest supported release branch, see <which-salt-branch>.

Bugfix - [Done] back-ported The pull request has been back-ported to an older branch.

Cannot Reproduce The issue is a bug and has been reviewed by a SaltStack engineer, but it cannot be replicated with the provided information and context. Those involved with the bug will need to work through additional ideas until the bug can be isolated and verified.

Confirmed The issue is a bug and has been confirmed by a SaltStack engineer, who often documents a minimal working example that reproduces the bug.

Fixed Pending Verification The issue is a bug and has been fixed by one or more pull requests, which should link to the issue. Closure of the issue is contingent upon confirmation of resolution from the submitter. If the submitter reports a negative confirmation, this label is removed. If no response is given after a few weeks, then the issue will be assumed fixed and closed.

Info Needed The issue needs more information before it can be verified and resolved. For a feature request this may include a description of the use cases. Almost all bug reports need to include at least the versions of salt and its dependencies, the system type and version, commands used, debug logs, error messages, and relevant configs.

Pending Changes The pull request needs additional changes before it can be merged.
**Pending Discussion** The issue or pull request needs more discussion before it can be closed or merged. The status of the issue or pull request is not clear or apparent enough for definite action to be taken, or additional input from SaltStack, the submitter, or another party has been requested.

If the issue is not a pull request, once the discussion has arrived at a cogent conclusion, this label will be removed and the issue will be accepted. If it is a pull request, the results of the discussion may require additional changes and thus, a Pending Changes label.

**Won't Fix for Now** The issue is legitimate, but it is not something the SaltStack team is currently able or willing to fix or implement. Issues having this label may be revisited in the future.

**Type of Change**

Every pull request should receive a change label. These labels measure the quantity of change as well as the significance of the change. The amount of change and the importance of the code area changed are considered, but often the depth of secondary code review required and the potential repercussions of the change may also advise the label choice.

Core code areas include: state compiler, crypto engine, master and minion and syndic daemons, transport, pillar rendering, loader, transport layer, event system, salt.utils, client, cli, logging, netapi, runner engine, templating engine, top file compilation, file client, file server, mine, salt-ssh, test runner, etc.

Non-core code usually constitutes the specific set of plugins for each of the several plugin layers of Salt: execution modules, states, runners, returners, clouds, etc.

**Minor Change**
- Less than 64 lines changed, or
- Less than 8 core lines changed

**Medium Change**
- Less than 256 lines changed, or
- Less than 64 core lines changed

**Master Change**
- More than 256 lines changed, or
- More than 64 core lines changed

**Expert Change**
- Needs specialized, in-depth review

**Test Status**

These labels relate to the status of the automated tests that run on pull requests. If the tests on a pull request fail and are not overridden by one of these labels, the pull request submitter needs to update the code and/or tests so that the tests pass and the pull request can be merged.

**Lint** The pull request has passed all tests except for the code lint checker.

**Tests Passed** The pull request has passed all tests even though some test results are negative. Sometimes the automated testing infrastructure will encounter internal errors unrelated to the code change in the pull request that cause test runs to fail. These errors can be caused by cloud host and network issues and also Jenkins issues like erroneously accumulating workspace artifacts, resource exhaustion, and bugs that arise from long running Jenkins processes.
Other

These labels indicate miscellaneous issue types or statuses that are common or important enough to be tracked and sorted with labels.

**Awesome** The pull request implements an especially well crafted solution, or a very difficult but necessary change.

**Low Hanging Fruit** The issue is trivial or almost trivial to implement or fix. Issues having this label should be a good starting place for new contributors to Salt.

**Needs Testcase** The issue or pull request relates to a feature that needs test coverage. The pull request containing the tests should reference the issue or pull request having this label, whereupon the label should be removed.

**Regression** The issue is a bug that breaks functionality known to work in previous releases.

**Story** The issue is used by a SaltStack engineer to track progress on multiple related issues in a single place.

**ZD** The issue is related to a Zendesk customer support ticket.

<Release> The issue is scheduled to be implemented by <Release>. See [topics/releases/version_numbers](#) for a discussion of Salt's release codenames.

### 34.12 Logging Internals

**TODO**

### 34.13 Modular Systems

When first working with Salt, it is not always clear where all of the modular components are and what they do. Salt comes loaded with more modular systems than many users are aware of, making Salt very easy to extend in many places.

The most commonly used modular systems are execution modules and states. But the modular systems extend well beyond the more easily exposed components and are often added to Salt to make the complete system more flexible.

#### 34.13.1 Execution Modules

Execution modules make up the core of the functionality used by Salt to interact with client systems. The execution modules create the core system management library used by all Salt systems, including states, which interact with minion systems.

Execution modules are completely open ended in their execution. They can be used to do anything required on a minion, from installing packages to detecting information about the system. The only restraint in execution modules is that the defined functions always return a JSON serializable object.

For a list of all built in execution modules, click [here](#).

For information on writing execution modules, see [this page](#).

#### 34.13.2 Interactive Debugging

Sometimes debugging with `print()` and extra logs sprinkled everywhere is not the best strategy.
IPython is a helpful debug tool that has an interactive python environment which can be embedded in python programs.

First the system will require IPython to be installed.

```bash
# Debian
apt-get install ipython

# Arch Linux
pacman -Syu ipython2

# RHEL/CentOS (via EPEL)
yum install python-ipython
```

Now, in the troubling python module, add the following line at a location where the debugger should be started:

```python
test = 'test123'
import IPython; IPython.embed_kernel()
```

After running a Salt command that hits that line, the following will show up in the log file:

```
[CRITICAL] To connect another client to this kernel, use:
[IPKernelApp] --existing kernel-31271.json
```

Now on the system that invoked embed_kernel, run the following command from a shell:

```bash
# NOTE: use ipython2 instead of ipython for Arch Linux
ipython console --existing
```

This provides a console that has access to all the vars and functions, and even supports tab-completion.

```python
print(test)
test123
```

To exit IPython and continue running Salt, press Ctrl-d to logout.

### 34.13.3 State Modules

State modules are used to define the state interfaces used by Salt States. These modules are restrictive in that they must follow a number of rules to function properly.

**Note:** State modules define the available routines in sls files. If calling an execution module directly is desired, take a look at the `module` state.

### 34.13.4 Auth

The auth module system allows for external authentication routines to be easily added into Salt. The `auth` function needs to be implemented to satisfy the requirements of an auth module. Use the `pam` module as an example.

### 34.13.5 Fileserver

The fileserver module system is used to create fileserver backends used by the Salt Master. These modules need to implement the functions used in the fileserver subsystem. Use the `gitfs` module as an example.
34.13.6 Grains

Grain modules define extra routines to populate grains data. All defined public functions will be executed and MUST return a Python dict object. The dict keys will be added to the grains made available to the minion.

34.13.7 Output

The output modules supply the outputter system with routines to display data in the terminal. These modules are very simple and only require the output function to execute. The default system outputter is the nested module.

34.13.8 Pillar

Used to define optional external pillar systems. The pillar generated via the filesystem pillar is passed into external pillars. This is commonly used as a bridge to database data for pillar, but is also the backend to the libvirt state used to generate and sign libvirt certificates on the fly.

34.13.9 Renderers

Renderers are the system used to render sls files into salt highdata for the state compiler. They can be as simple as the py renderer and as complex as stateconf and pydsl.

34.13.10 Returners

Returners are used to send data from minions to external sources, commonly databases. A full returner will implement all routines to be supported as an external job cache. Use the redis returner as an example.

34.13.11 Runners

Runners are purely master-side execution sequences.

34.13.12 Tops

Tops modules are used to convert external data sources into top file data for the state system.

34.13.13 Wheel

The wheel system is used to manage master side management routines. These routines are primarily intended for the API to enable master configuration.

34.14 Package Providers

This page contains guidelines for writing package providers.
34.14.1 Package Functions

One of the most important features of Salt is package management. There is no shortage of package managers, so in the interest of providing a consistent experience in pkg states, there are certain functions that should be present in a package provider. Note that these are subject to change as new features are added or existing features are enhanced.

list_pkgs

This function should declare an empty dict, and then add packages to it by calling pkg_resource.add_pkg, like so:

```python
__salt__['pkg_resource.add_pkg'](ret, name, version)
```

The last thing that should be done before returning is to execute pkg_resource.sort_pkglist. This function does not presently do anything to the return dict, but will be used in future versions of Salt.

```python
__salt__['pkg_resource.sort_pkglist'](ret)
```

list_pkgs returns a dictionary of installed packages, with the keys being the package names and the values being the version installed. Example return data:

```python
{'foo': '1.2.3-4',
 'bar': '5.6.7-8'}
```

latest_version

Accepts an arbitrary number of arguments. Each argument is a package name. The return value for a package will be an empty string if the package is not found or if the package is up-to-date. The only case in which a non-empty string is returned is if the package is available for new installation (i.e. not already installed) or if there is an upgrade available.

If only one argument was passed, this function return a string, otherwise a dict of name/version pairs is returned.

This function must also accept **kwargs, in order to receive the fromrepo and repo keyword arguments from pkg states. Where supported, these arguments should be used to find the install/upgrade candidate in the specified repository. The fromrepo kwarg takes precedence over repo, so if both of those kwargs are present, the repository specified in fromrepo should be used. However, if repo is used instead of fromrepo, it should still work, to preserve backwards compatibility with older versions of Salt.

version

Like latest_version, accepts an arbitrary number of arguments and returns a string if a single package name was passed, or a dict of name/value pairs if more than one was passed. The only difference is that the return values are the currently-installed versions of whatever packages are passed. If the package is not installed, an empty string is returned for that package.

upgrade_available

Deprecated and destined to be removed. For now, should just do the following:

```python
return __salt__['pkg.latest_version']('name') != ''
```
install

The following arguments are required and should default to None:

1. name (for single-package pkg states)
2. pkgs (for multiple-package pkg states)
3. sources (for binary package file installation)

The first thing that this function should do is call `pkg_resource.parse_targets` (see below). This function will convert the SLS input into a more easily parsed data structure. `pkg_resource.parse_targets` may need to be modified to support your new package provider, as it does things like parsing package metadata which cannot be done for every package management system.

```python
pkg_params, pkg_type = __salt__['pkg_resource.parse_targets'](name, pkgs, sources)
```

Two values will be returned to the `install` function. The first of them will be a dictionary. The keys of this dictionary will be package names, though the values will differ depending on what kind of installation is being done:

- If `name` was provided (and `pkgs` was not), then there will be a single key in the dictionary, and its value will be `None`. Once the data has been returned, if the `version` keyword argument was provided, then it should replace the `None` value in the dictionary.

- If `pkgs` was provided, then `name` is ignored, and the dictionary will contain one entry for each package in the `pkgs` list. The values in the dictionary will be `None` if a version was not specified for the package, and the desired version if specified. See the Multiple Package Installation Options section of the `pkg.installed` state for more info.

- If `sources` was provided, then `name` is ignored, and the dictionary values will be the path/URI for the package.

The second return value will be a string with two possible values: `repository` or `file`. The `install` function can use this value (if necessary) to build the proper command to install the targeted package(s).

Both before and after the installing the target(s), you should run `list_pkgs` to obtain a list of the installed packages. You should then return the output of `salt.utils.compare_dicts()`

```python
return salt.utils.compare_dicts(old, new)
```

remove

Removes the passed package and return a list of the packages removed.

### 34.14.2 Package Repo Functions

There are some functions provided by `pkg` which are specific to package repositories, and not to packages themselves. When writing modules for new package managers, these functions should be made available as stated below, in order to provide compatibility with the `pkgrepo` state.

All repo functions should accept a `basedir` option, which defines which directory repository configuration should be found in. The default for this is dictated by the repo manager that is being used, and rarely needs to be changed.

```python
basedir = '/etc/yum.repos.d'
__salt__['pkg.list_repos'](basedir)
```
**list_repos**

Lists the repositories that are currently configured on this system.

```python
__salt__['pkg.list_repos']()
```

Returns a dictionary, in the following format:

```json
{ 'reponame': 'config_key_1': 'config value 1',
  'config_key_2': 'config value 2',
  'config_key_3': [ 'list item 1 (when appropriate)',
                  'list item 2 (when appropriate)']}
```

**get_repo**

Displays all local configuration for a specific repository.

```python
__salt__['pkg.get_repo'](repo='myrepo')
```

The information is formatted in much the same way as list_repos, but is specific to only one repo.

```json
{ 'config_key_1': 'config value 1',
  'config_key_2': 'config value 2',
  'config_key_3': [ 'list item 1 (when appropriate)',
                  'list item 2 (when appropriate)']}
```

**del_repo**

Removes the local configuration for a specific repository. Requires a repo argument, which must match the locally configured name. This function returns a string, which informs the user as to whether or not the operation was a success.

```python
__salt__['pkg.del_repo'](repo='myrepo')
```

**mod_repo**

Modify the local configuration for one or more option for a configured repo. This is also the way to create new repository configuration on the local system; if a repo is specified which does not yet exist, it will be created.

The options specified for this function are specific to the system; please refer to the documentation for your specific repo manager for specifics.

```python
__salt__['pkg.mod_repo'](repo='myrepo', url='http://myurl.com/repo')
```
34.14.3 Low-Package Functions

In general, the standard package functions as describes above will meet your needs. These functions use the system's native package manager (for instance, yum or the apt tools). In most cases, the package manager is actually separate from the repomanager. For instance, yum is usually a front-end for rpm, and apt is usually a front-end for dpkg. When possible, the package functions that use those package managers directly should do so through the low package functions.

It is normal and sane for \texttt{pkg} to make calls to \texttt{lowpkg}, but \texttt{lowpkg} must never make calls to \texttt{pkg}. This is affects functions which are required by both \texttt{pkg} and \texttt{lowpkg}, but the technique in \texttt{pkg} is more performant than what is available to \texttt{lowpkg}. When this is the case, the \texttt{lowpkg} function that requires that technique must still use the \texttt{lowpkg} version.

\textbf{list\_pkgs}

Returns a dict of packages installed, including the package name and version. Can accept a list of packages; if none are specified, then all installed packages will be listed.

\begin{verbatim}
installed = __salt__['lowpkg.list_pkgs']('foo', 'bar')
\end{verbatim}

Example output:

\begin{verbatim}
{'foo': '1.2.3-4',
 'bar': '5.6.7-8'}
\end{verbatim}

\textbf{verify}

Many (but not all) package management systems provide a way to verify that the files installed by the package manager have or have not changed. This function accepts a list of packages; if none are specified, all packages will be included.

\begin{verbatim}
installed = __salt__['lowpkg.verify']('httpd')
\end{verbatim}

Example output:

\begin{verbatim}
{/etc/httpd/conf/httpd.conf: {'mismatch': ['size', 'md5sum', 'mtime'],
 'type': 'config'}}
\end{verbatim}

\textbf{file\_list}

Lists all of the files installed by all packages specified. If not packages are specified, then all files for all known packages are returned.

\begin{verbatim}
installed = __salt__['lowpkg.file_list']('httpd', 'apache')
\end{verbatim}

This function does not return which files belong to which packages; all files are returned as one giant list (hence the \textit{file\_list} function name. However, This information is still returned inside of a dict, so that it can provide any errors to the user in a sane manner.
{'errors': ['package apache is not installed'],
'files': ['/etc/httpd',
'/etc/httpd/conf',
'/etc/httpd/conf.d',
'...SNIP...']}

file_dict

Lists all of the files installed by all packages specified. If not packages are specified, then all files for all known packages are returned.

installed = __salt__['lowpkg.file_dict']('httpd', 'apache', 'kernel')

Unlike file_list, this function will break down which files belong to which packages. It will also return errors in the same manner as file_list.

{ 'errors': ['package apache is not installed'],
'packages': { 'httpd': [ '/etc/httpd',
'/etc/httpd/conf',
'...SNIP...'],
'kernel': [ '/boot/.vmlinuz-2.6.32-279.el6.x86_64.hmac',
'/boot/System.map-2.6.32-279.el6.x86_64',
'...SNIP...']}

34.15 Reporting Bugs

Salt uses GitHub to track open issues and feature requests.

To file a bug, please navigate to the new issue page for the Salt project.

In an issue report, please include the following information:

- The output of salt --versions-report from the relevant machines. This can also be gathered remotely by using salt <my_tgt> test.versions_report.
- A description of the problem including steps taken to cause the issue to occur and the expected behaviour.
- Any steps taken to attempt to remediate the problem.
- Any configuration options set in a configuration file that may be relevant.
- A reproducible test case. This may be as simple as an SLS file that illustrates a problem or it may be a link to a repository that contains a number of SLS files that can be used together to re-produce a problem. If the problem is transitory, any information that can be used to try and reproduce the problem is helpful.
- [Optional] The output of each salt component (master/minion/CLI) running with the -ldebug flag set.

Note: Please be certain to scrub any logs or SLS files for sensitive data!
34.16 Community Projects That Use Salt

Below is a list of repositories that show real world Salt applications that you can use to get started. Please note that these projects do not adhere to any standards and express a wide variety of ideas and opinions on how an action can be completed with Salt.

https://github.com/terminalmage/djangocon2013-sls
https://github.com/jesusaurus/hpcs-salt-state
https://github.com/gravyboat/hungryadmin-sls
https://github.com/wunki/django-salted

34.17 Salt Topology

Salt is based on a powerful, asynchronous, network topology using ZeroMQ. Many ZeroMQ systems are in place to enable communication. The central idea is to have the fastest communication possible.

34.17.1 Servers

The Salt Master runs 2 network services. First is the ZeroMQ PUB system. This service by default runs on port 4505 and can be configured via the `publish_port` option in the master configuration.

Second is the ZeroMQ REP system. This is a separate interface used for all bi-directional communication with minions. By default this system binds to port 4506 and can be configured via the `ret_port` option in the master.

34.17.2 PUB/SUB

The commands sent out via the salt client are broadcast out to the minions via ZeroMQ PUB/SUB. This is done by allowing the minions to maintain a connection back to the Salt Master and then all connections are informed to download the command data at once. The command data is kept extremely small (usually less than 1K) so it is not a burden on the network.

34.17.3 Return

The PUB/SUB system is a one way communication, so once a publish is sent out the PUB interface on the master has no further communication with the minion. The minion, after running the command, then sends the command’s return data back to the master via the `ret_port`.

34.18 Translating Documentation

If you wish to help translate the Salt documentation to your language, please head over to the Transifex website and signup for an account.

Once registered, head over to the Salt Translation Project, and either click on Request Language if you can’t find yours, or, select the language for which you wish to contribute and click Join Team.

Transifex provides some useful reading resources on their support domain, namely, some useful articles directed to translators.
34.18.1 Building A Localized Version of the Documentation

While you're working on your translation on Transifex, you might want to have a look at how it's rendering.

Install The Transifex Client

To interact with the Transifex web service you will need to install the transifex-client:

```bash
pip install transifex-client
```

Configure The Transifex Client

Once installed, you will need to set it up on your computer. We created a script to help you with that:

```
scripts/setup-transifex-config
```

Download Remote Translations

There's a little script which simplifies the download process of the translations (which isn't that complicated in the first place). So, let's assume you're translating pt_PT, Portuguese(Portugal). To download the translations, execute from the `doc/` directory of your Salt checkout:

```bash
make download-translations SPHINXLANG=pt_PT
```

To download pt_PT, Portuguese(Portugal), and nl, Dutch, you can use the helper script directly:

```
scripts/download-translation-catalog pt_PT nl
```

Build Localized Documentation

After the download process finishes, which might take a while, the next step is to build a localized version of the documentation. Following the pt_PT example above:

```bash
make html SPHINXLANG=pt_PT
```

View Localized Documentation

Open your browser, point it to the local documentation path and check the localized output you've just build.

34.19 Running The Tests

There are requirements, in addition to Salt's requirements, which need to be installed in order to run the test suite. Install one of the lines below, depending on the relevant Python version:

```bash
pip install -r requirements/dev_python26.txt
pip install -r requirements/dev_python27.txt
```
Note: In Salt 0.17, testing libraries were migrated into their own repo. To install them:

```
pip install git+https://github.com/saltstack/salt-testing.git#egg=SaltTesting
```

Failure to install SaltTesting will result in import errors similar to the following:

```
ImportError: No module named salttesting
```

Once all requirements are set, use `tests/runtests.py` to run all of the tests included in Salt’s test suite. For more information, see `--help`.

An alternative way of invoking the test suite is available in `setup.py`:

```
./setup.py test
```

Instead of running the entire test suite, there are several ways to run only specific groups of tests or individual tests:

- Run unit tests only: `./tests/runtests.py --unit-tests`
- Run unit and integration tests for states: `./tests/runtests.py --state`
- Run integration tests for an individual module: `./tests/runtests.py -n integration.modules.virt`
- Run unit tests for an individual module: `./tests/runtests.py -n unit.modules.virt_test`
- Run an individual test by using the class and test name (this example is for the `test_default_kvm_profile` test in the `integration.module.virt`): `./tests/runtests.py -n integration.module.virt.VirtTest.test_default_kvm_profile`

### 34.19.1 Running Unit Tests Without Integration Test Daemons

Since the unit tests do not require a master or minion to execute, it is often useful to be able to run unit tests individually, or as a whole group, without having to start up the integration testing daemons. Starting up the master, minion, and syndic daemons takes a lot of time before the tests can even start running and is unnecessary to run unit tests. To run unit tests without invoking the integration test daemons, simple remove the `/tests` portion of the `runtests.py` command:

```
./runtests.py --unit
```

All of the other options to run individual tests, entire classes of tests, or entire test modules still apply.

### 34.19.2 Running Destructive Integration Tests

Salt is used to change the settings and behavior of systems. In order to effectively test Salt’s functionality, some integration tests are written to make actual changes to the underlying system. These tests are referred to as “destructive tests”. Some examples of destructive tests are changes may be testing the addition of a user or installing packages. By default, destructive tests are disabled and will be skipped.

Generally, destructive tests should clean up after themselves by attempting to restore the system to its original state. For instance, if a new user is created during a test, the user should be deleted after the related test(s) have completed. However, no guarantees are made that test clean-up will complete successfully. Therefore, running destructive tests should be done with caution.
Note: Running destructive tests will change the underlying system. Use caution when running destructive tests.

To run tests marked as destructive, set the `--run-destructive` flag:

```bash
./tests/runtests.py --run-destructive
```

### 34.19.3 Running Cloud Provider Tests

Salt’s testing suite also includes integration tests to assess the successful creation and deletion of cloud instances using `Salt-Cloud` for providers supported by Salt-Cloud.

The cloud provider tests are off by default and run on sample configuration files provided in `tests/integration/files/conf/cloud.providers.d/`. In order to run the cloud provider tests, valid credentials, which differ per provider, must be supplied. Each credential item that must be supplied is indicated by an empty string value and should be edited by the user before running the tests. For example, DigitalOcean requires a client key and an api key to operate. Therefore, the default cloud provider configuration file for DigitalOcean looks like this:

```yaml
digitalocean-config:
  driver: digital_ocean
  client_key: 
  api_key: 
  location: New York 1
```

As indicated by the empty string values, the `client_key` and the `api_key` must be provided:

```yaml
digitalocean-config:
  driver: digital_ocean
  client_key: wFGEwgregeqw3435gDger
  api_key: GDE43t43REGTrkilg43934t34qT43t4dgegerGEGg
  location: New York 1
```

Note: When providing credential information in cloud provider configuration files, do not include the single quotes.

Once all of the valid credentials for the cloud provider have been supplied, the cloud provider tests can be run by setting the `--cloud-provider-tests` flag:

```bash
./tests/runtests.py --cloud-provider-tests
```

### 34.19.4 Running The Tests In A Docker Container

The test suite can be executed under a Docker container using the `--docked` option flag. The Docker container must be properly configured on the system invoking the tests and the container must have access to the internet.

Here’s a simple usage example:

```bash
tests/runtests.py --docked=ubuntu-12.04 -v
```

The full Docker container repository can also be provided:
The SaltStack team is creating some containers which will have the necessary dependencies pre-installed. Running the test suite on a container allows destructive tests to run without making changes to the main system. It also enables the test suite to run under a different distribution than the one the main system is currently using.

The current list of test suite images is on Salt’s docker repository.

Custom docker containers can be provided by submitting a pull request against Salt’s docker Salt test containers repository.

## 34.20 Automated Test Runs

SaltStack maintains a Jenkins server to allow for the execution of tests across supported platforms. The tests executed from Salt’s Jenkins server create fresh virtual machines for each test run, then execute destructive tests on the new, clean virtual machine.

When a pull request is submitted to Salt’s repository on GitHub, Jenkins runs Salt’s test suite on a couple of virtual machines to gauge the pull request’s viability to merge into Salt’s develop branch. If these initial tests pass, the pull request can then merged into Salt’s develop branch by one of Salt’s core developers, pending their discretion. If the initial tests fail, core developers may request changes to the pull request. If the failure is unrelated to the changes in question, core developers may merge the pull request despite the initial failure.

Once the pull request is merged into Salt’s develop branch, a new set of Jenkins virtual machines will begin executing the test suite. The develop branch tests have many more virtual machines to provide more comprehensive results.

There are a few other groups of virtual machines that Jenkins tests against, including past and current release branches. For a full list of currently running test environments, go to http://jenkins.saltstack.com.

### 34.20.1 Using Salt-Cloud on Jenkins

For testing Salt on Jenkins, SaltStack uses `Salt-Cloud` to spin up virtual machines. The script using Salt-Cloud to accomplish this is open source and can be found here: https://github.com/saltstack/salt/blob/develop/tests/jenkins.py

## 34.21 Writing Tests

The salt testing infrastructure is divided into two classes of tests, integration tests and unit tests. These terms may be defined differently in other contexts, but for salt they are defined this way:

- **Unit Test**: Tests which validate isolated code blocks and do not require external interfaces such as `salt-call` or any of the salt daemons.
- **Integration Test**: Tests which validate externally accessible features.

Salt testing uses unittest2 from the python standard library and MagicMock.

### 34.21.1 Naming Conventions

Any function in either integration test files or unit test files that is doing the actual testing, such as functions containing assertions, must start with `test_`: 
def test_user_present(self):

When functions in test files are not prepended with `test_`, the function acts as a normal, helper function and is not run as a test by the test suite.

### 34.21.2 Integration Tests

The integration tests start up a number of salt daemons to test functionality in a live environment. These daemons include 2 salt masters, 1 syndic, and 2 minions. This allows the syndic interface to be tested and master/minion communication to be verified. All of the integration tests are executed as live salt commands sent through the started daemons.

Integration tests are particularly good at testing modules, states, and shell commands.

- Writing integration tests

### 34.21.3 Unit Tests

Unit tests are good for ensuring consistent results for functions that do not require more than a few mocks.

Mocking all external dependencies for unit tests is encouraged but not required as sometimes the isolation provided by completely mocking the external dependencies is not worth the effort of mocking those dependencies.

Overly detailed mocking can also result in decreased test readability and brittleness as the tests are more likely to fail when the code or its dependencies legitimately change. In these cases, it is better to add dependencies to the test runner dependency state, [https://github.com/saltstack/salt-jenkins/blob/master/git/salt.sls](https://github.com/saltstack/salt-jenkins/blob/master/git/salt.sls).

- Writing unit tests

### Integration Tests

The Salt integration tests come with a number of classes and methods which allow for components to be easily tested. These classes are generally inherited from and provide specific methods for hooking into the running integration test environment created by the integration tests.

It is noteworthy that since integration tests validate against a running environment that they are generally the preferred means to write tests.

The integration system is all located under `tests/integration` in the Salt source tree. Each directory within `tests/integration` corresponds to a directory in Salt's tree structure. For example, the integration tests for the `test.py` Salt module that is located in `salt/modules` should also be named `test.py` and reside in `tests/integration/modules`.

### Adding New Directories

If the corresponding Salt directory does not exist within `tests/integration`, the new directory must be created along with the appropriate test file to maintain Salt's testing directory structure.

In order for Salt's test suite to recognize tests within the newly created directory, options to run the new integration tests must be added to `tests/runtests.py`. Examples of the necessary options that must be added can be found here: [https://github.com/saltstack/salt/blob/develop/tests/runtests.py](https://github.com/saltstack/salt/blob/develop/tests/runtests.py). The functions that need to be edited are `setup_additional_options`, `validate_options`, and `run_integration_tests`.

---

34.21. Writing Tests 1965
Integration Classes

The integration classes are located in tests/integration/__init__.py and can be extended therein. There are three classes available to extend:

**ModuleCase**  Used to define executions run via the master to minions and to call single modules and states.

The available methods are as follows:

- **run_function:** Run a single salt function and condition the return down to match the behavior of the raw function call. This will run the command and only return the results from a single minion to verify.
- **state_result:** Return the result data from a single state return
- **run_state:** Run the state.single command and return the state return structure

**SyndicCase**  Used to execute remote commands via a syndic, only used to verify the capabilities of the Syndic.

The available methods are as follows:

- **run_function:** Run a single salt function and condition the return down to match the behavior of the raw function call. This will run the command and only return the results from a single minion to verify.

**ShellCase**  Shell out to the scripts which ship with Salt.

The available methods are as follows:

- **run_script:** Execute a salt script with the given argument string
- **run_salt:** Execute the salt command, pass in the argument string as it would be passed on the command line.
- **run_run:** Execute the salt-run command, pass in the argument string as it would be passed on the command line.
- **run_run_plus:** Execute Salt run and the salt run function and return the data from each in a dict
- **run_key:** Execute the salt-key command, pass in the argument string as it would be passed on the command line.
- **run_cp:** Execute salt-cp, pass in the argument string as it would be passed on the command line.
- **run_call:** Execute salt-call, pass in the argument string as it would be passed on the command line.

Examples

**Module Example via ModuleCase Class**  Import the integration module, this module is already added to the python path by the test execution. Inherit from the integration.ModuleCase class.

Now the workhorse method run_function can be used to test a module:

```python
import os
import integration

class TestModuleTest(integration.ModuleCase):
    '''
    Validate the test module
    '''
    def test_ping(self):
        '''
        test.ping
        '''
```

1966 Chapter 34. Developing Salt
```python
self.assertTrue(self.run_function('test.ping'))

def test_echo(self):
    test.echo
    self.assertIsInstance(self.run_function('test.echo', ['text']), 'text')
```

**Shell Example via ShellCase**  Validating the shell commands can be done via shell tests:

```python
import sys
import shutil
import tempfile
import integration

class KeyTest(integration.ShellCase):
    
    _call_binary_ = 'salt-key'

    def test_list(self):
        test salt-key -L
        data = self.run_key('-L')
        expect = [
            'Unaccepted Keys:',
            'Accepted Keys:',
            'minion',
            'sub_minion',
            'Rejected:', '']
        self.assertIsInstance(data, expect)

This example verifies that the `salt-key` command executes and returns as expected by making use of the `run_key` method.

**Integration Test Files**

Since using Salt largely involves configuring states, editing files, and changing system data, the integration test suite contains a directory named `files` to aid in testing functions that require files. Various Salt integration tests use these example files to test against instead of altering system files and data.

Each directory within `tests/integration/files` contain files that accomplish different tasks, based on the needs of the integration tests using those files. For example, `tests/integration/files/ssh` is used to bootstrap the test runner for salt-ssh testing, while `tests/integration/files/pillar` contains files storing data needed to test various pillar functions.

The `tests/integration/files` directory also includes an integration state tree. The integration state tree can be found at `tests/integration/files/file/base`.

The following example demonstrates how integration files can be used with ModuleCase to test states:
import os
import shutil
import integration

HFILE = os.path.join(integration.TMP, 'hosts')

class HostTest(integration.ModuleCase):
    '''Validate the host state'''
    def setUp(self):
        shutil.copyfile(os.path.join(integration.FILES, 'hosts'), HFILE)
        super(HostTest, self).setUp()
    
    def tearDown(self):
        if os.path.exists(HFILE):
            os.remove(HFILE)
        super(HostTest, self).tearDown()

    def test_present(self):
        '''host.present'''
        name = 'spam.bacon'
        ip = '10.10.10.10'
        ret = self.run_state('host.present', name=name, ip=ip)
        result = self.state_result(ret)
        self.assertTrue(result)

        with open(HFILE) as fp_:
            output = fp_.read()
        self.assertIn('{0}	{1}'.format(ip, name), output)

To access the integration files, a variable named integration.FILES points to the tests/integration/files directory. This is where the referenced host.present sls file resides.

In addition to the static files in the integration state tree, the location integration.TMP can also be used to store temporary files that the test system will clean up when the execution finishes.

**Destructive vs Non-Destructive Tests**

Since Salt is used to change the settings and behavior of systems, one testing approach is to run tests that make actual changes to the underlying system. This is where the concept of destructive integration tests comes into play. Tests can be written to alter the system they are running on. This capability is what fills in the gap needed to properly test aspects of system management like package installation.

Any test that changes the underlying system in any way, such as creating or deleting users, installing packages, or changing permissions should include the @destructive decorator to signal system changes and should be written with care. System changes executed within a destructive test should also be restored once the related tests have completed. For example, if a new user is created to test a module, the same user should be removed after the test is completed to maintain system integrity.

To write a destructive test, import, and use the destructiveTest decorator for the test method:

```python
import integration
from salttesting.helpers import destructiveTest
```
class DestructiveExampleModuleTest(integration.ModuleCase):
    '''
    Demonstrate a destructive test
    '''

    @destructiveTest
    @skipIf(os.geteuid() != 0, 'you must be root to run this test')
    def test_user_not_present(self):
        '''
        This is a DESTRUCTIVE TEST it creates a new user on the minion.
        And then destroys that user.
        '''
        ret = self.run_state('user.present', name='salt_test')
        self.assertSaltTrueReturn(ret)
        ret = self.run_state('user.absent', name='salt_test')
        self.assertSaltTrueReturn(ret)

Cloud Provider Tests

Cloud provider integration tests are used to assess Salt-Cloud’s ability to create and destroy cloud instances for various supported cloud providers. Cloud provider tests inherit from the ShellCase Integration Class.

Any new cloud provider test files should be added to the tests/integration/cloud/providers/ directory. Each cloud provider test file also requires a sample cloud profile and cloud provider configuration file in the integration test file directory located at tests/integration/files/conf/cloud.*.d/.

The following is an example of the default profile configuration file for Digital Ocean, located at: tests/integration/files/conf/cloud.profiles.d/digital_ocean.conf:

digitalocean-test:
    provider: digitalocean-config
    image: Ubuntu 14.04 x64
    size: 512MB

Each cloud provider requires different configuration credentials. Therefore, sensitive information such as API keys or passwords should be omitted from the cloud provider configuration file and replaced with an empty string. The necessary credentials can be provided by the user by editing the provider configuration file before running the tests.

The following is an example of the default provider configuration file for Digital Ocean, located at: tests/integration/files/conf/cloud.providers.d/digital_ocean.conf:

digitalocean-config:
    driver: digital_ocean
    client_key: ''
    api_key: ''
    location: New York 1

In addition to providing the necessary cloud profile and provider files in the integration test suite file structure, appropriate checks for if the configuration files exist and contain valid information are also required in the test class’s setUp function:

class LinodeTest(integration.ShellCase):
    '''
    Integration tests for the Linode cloud provider in Salt-Cloud
    '''

34.21. Writing Tests
def setUp(self):
    '''
    Sets up the test requirements
    '''
    super(LinodeTest, self).setUp()

    # check if appropriate cloud provider and profile files are present
    profile_str = 'linode-config:
    provider = 'linode'
    providers = self.run_cloud('--list-providers')
    if profile_str not in providers:
        self.skipTest(
            'Configuration file for {0} was not found. Check {0}.conf files '
            'in tests/integration/files/conf/cloud.*.d/ to run these tests.'
            .format(provider)
        )

    # check if apikey and password are present
    path = os.path.join(integration.FILES, 
                        'conf', 
                        'cloud.providers.d', 
                        provider + '.conf')
    config = cloud_providers_config(path)
    api = config['linode-config']['linode']['apikey']
    password = config['linode-config']['linode']['password']
    if api == '' or password == '':
        self.skipTest(
            'An api key and password must be provided to run these tests. Check '
            'tests/integration/files/conf/cloud.providers.d/{0}.conf'.format( 
                provider)
        )

Repeatedly creating and destroying instances on cloud providers can be costly. Therefore, cloud provider tests are off by default and do not run automatically. To run the cloud provider tests, the --cloud-provider-tests flag must be provided:

./tests/runtests.py --cloud-provider-tests

Since cloud provider tests do not run automatically, all provider tests must be preceded with the @expensiveTest decorator. The expensive test decorator is necessary because it signals to the test suite that the --cloud-provider-tests flag is required to run the cloud provider tests.

To write a cloud provider test, import, and use the expensiveTest decorator for the test function:

from salttesting.helpers import expensiveTest

@expensiveTest
def test_instance(self):
    '''
    Test creating an instance on Linode
    '''
    name = 'linode-testing'

    # create the instance
    instance = self.run_cloud('p linode-test {0}'.format(name))
    str = '{0}'.format(name)
# check if instance with salt installed returned as expected
try:
    self.assertIn(str, instance)
except AssertionError:
    self.run_cloud('-d {0} --assume-yes'.format(name))
    raise

# delete the instance
delete = self.run_cloud('-d {0} --assume-yes'.format(name))
str = 'True'
try:
    self.assertIn(str, delete)
except AssertionError:
    raise

---

Writing Unit Tests

Introduction

Like many software projects, Salt has two broad-based testing approaches -- integration testing and unit testing. While integration testing focuses on the interaction between components in a sandboxed environment, unit testing focuses on the singular implementation of individual functions.

Preparing to Write a Unit Test

This guide assumes you’ve followed the directions for setting up salt testing.

Unit tests should be written to the following specifications:

- Each raise and return statement needs to be independently tested.
- Unit tests for `salt/.../<module>.py` are contained in a file called `tests/unit/.../<module>_test.py`, e.g. the tests for `salt/modules/fib.py` are in `tests/unit/modules/fib_test.py`.
- Test functions are named `test_<fcn>_<test-name>` where `<fcn>` is the function being tested and `<test-name>` describes the raise or return being tested.
- A reasonable effort needs to be made to mock external resources used in the code being tested, such as APIs, function calls, external data either globally available or passed in through function arguments, file data, etc.
- Test functions should contain only one assertion and all necessary mock code and data for that assertion.

Most commonly, the following imports are necessary to create a unit test:

```python
# Import Salt Testing libs
from salttesting import skipIf, TestCase
from salttesting.helpers import ensure_in_syspath

If you need mock support to your tests, please also import:

from salttesting.mock import NO_MOCK, NO_MOCK_REASON, MagicMock, patch, call
```
A Simple Example

Let’s assume that we're testing a very basic function in an imaginary Salt execution module. Given a module called `fib.py` that has a function called `calculate(num_of_results)`, which given a `num_of_results`, produces a list of sequential Fibonacci numbers of that length.

A unit test to test this function might be commonly placed in a file called `tests/unit/modules/fib_test.py`. The convention is to place unit tests for Salt execution modules in `test/unit/modules/` and to name the tests module suffixed with `_test.py`.

Tests are grouped around test cases, which are logically grouped sets of tests against a piece of functionality in the tested software. Test cases are created as Python classes in the unit test module. To return to our example, here’s how we might write the skeleton for testing `fib.py`:

```python
# Import Salt Testing libs
from salttesting import TestCase

# Import Salt execution module to test
from salt.modules import fib

class FibTestCase(TestCase):
    '''
    This class contains a set of functions that test salt.modules.fib.
    '''
    def test_fib(self):
        '''
        To create a unit test, we should prefix the name with `test_` so
        that it's recognized by the test runner.
        '''
        fib_five = (0, 1, 1, 2, 3)
        self.assertEqual(fib.calculate(5), fib_five)
```

At this point, the test can now be run, either individually or as a part of a full run of the test runner. To ease development, a single test can be executed:

```bash
tests/runtests.py -v -n unit.modules.fib_test
```

This will report the status of the test: success, failure, or error. The `-v` flag increases output verbosity.

To review the results of a particular run, take a note of the log location given in the output for each test:

```bash
Logging tests on /var/folders/nl/d809xbq577l3qr6j3ymtpbq80000gn/T/salt-runtests.log
```

Evaluating Truth

A longer discussion on the types of assertions one can make can be found by reading Python's documentation on unit testing.
Tests Using Mock Objects

In many cases, the purpose of a Salt module is to interact with some external system, whether it be to control a database, manipulate files on a filesystem or something else. In these varied cases, it's necessary to design a unit test which can test the function whilst replacing functions which might actually call out to external systems. One might think of this as `blocking the exits` for code under tests and redirecting the calls to external systems with our own code which produces known results during the duration of the test.

To achieve this behavior, Salt makes heavy use of the `MagicMock` package.

To understand how one might integrate Mock into writing a unit test for Salt, let's imagine a scenario in which we're testing an execution module that's designed to operate on a database. Furthermore, let's imagine two separate methods, here presented in pseudo-code in an imaginary execution module called `db.py`.

```python
def create_user(username):
    qry = 'CREATE USER {0}'.format(username)
    execute_query(qry)

def execute_query(qry):
    # Connect to a database and actually do the query...
```

Here, let's imagine that we want to create a unit test for the `create_user` function. In doing so, we want to avoid any calls out to an external system and so while we are running our unit tests, we want to replace the actual interaction with a database with a function that can capture the parameters sent to it and return pre-defined values. Therefore, our task is clear -- to write a unit test which tests the functionality of `create_user` while also replacing `execute_query` with a mocked function.

To begin, we set up the skeleton of our class much like we did before, but with additional imports for `MagicMock`:

```python
# Import Salt Testing libs
from salttesting import TestCase

# Import Salt execution module to test
from salt.modules import db

# Import Mock libraries
from salttesting.mock import NO_MOCK, NO_MOCK_REASON, MagicMock, patch, call

# Create test case class and inherit from Salt's customized TestCase
# Skip this test case if we don't have access to mock!
@skipIf(NO_MOCK, NO_MOCK_REASON)
class DbTestCase(TestCase):
    def test_create_user(self):
        # First, we replace 'execute_query' with our own mock function
        db.execute_query = MagicMock()

        # Now that the exits are blocked, we can run the function under test.
        db.create_user('testuser')

        # We could now query our mock object to see which calls were made to it.
        # print db.execute_query.mock_calls

        # Construct a call object that simulates the way we expected
        # execute_query to have been called.
        expected_call = call('CREATE USER testuser')
```
# Compare the expected call with the list of actual calls. The test will succeed or fail depending on the output of this assertion.

db.execute_query.assert_has_calls(expected_call)

Modifying __salt__ In Place

At times, it becomes necessary to make modifications to a module's view of functions in its own __salt__ dictionary. Luckily, this process is quite easy.

Below is an example that uses MagicMock's patch functionality to insert a function into __salt__ that's actually a MagicMock instance.

```python
def show_patch(self):
    with patch.dict(my_module.__salt__,
                    {'function.to_replace': MagicMock()}):
        # From this scope, carry on with testing, with a modified __salt__!
```

A More Complete Example

Consider the following function from salt/modules/linux_sysctl.py.

```python
def get(name):
    '''
    Return a single sysctl parameter for this minion
    
    CLI Example:
    .. code-block:: bash
      
      salt '*' sysctl.get net.ipv4.ip_forward
    '''
    cmd = 'sysctl -n {0}'.format(name)
    out = __salt__['cmd.run'](cmd)
    return out
```

This function is very simple, comprising only four source lines of code and having only one return statement, so we know only one test is needed. There are also two inputs to the function, the name function argument and the call to __salt__['cmd.run'](), both of which need to be appropriately mocked.

Mocking a function parameter is straightforward, whereas mocking a function call will require, in this case, the use of MagicMock. For added isolation, we will also redefine the __salt__ dictionary such that it only contains 'cmd.run'.

```python
# Import Salt Libs
from salt.modules import linux_sysctl

# Import Salt Testing Libs
from salttesting import skipIf, TestCase
from salttesting.helpers import ensure_in_syspath
from salttesting.mock import (MagicMock, patch, NO_MOCK,
```
Since `get()` has only one raise or return statement and that statement is a success condition, the test function is simply named `test_get()`. As described, the single function call parameter, `name` is mocked with `net.ipv4.ip_forward` and `__salt__['cmd.run']` is replaced by a MagicMock function object. We are only interested in the return value of `__salt__['cmd.run']`, which MagicMock allows to be specified via `return_value=1`. Finally, the test itself tests for equality between the return value of `get()` and the expected return of 1. This assertion is expected to succeed because `get()` will determine its return value from `__salt__['cmd.run']`, which we have mocked to return 1.

A Complex Example

Now consider the `assign()` function from the same salt/modules/linux_sysctl.py source file.

```python
def assign(name, value):
    
    Assign a single sysctl parameter for this minion
    
    CLI Example:
    .. code-block:: bash
        
        salt '*' sysctl.assign net.ipv4.ip_forward 1
    
    value = str(value)
    sysctl_file = '/proc/sys/{0}.format(name.replace('.', '/'))
    if not os.path.exists(sysctl_file):
        raise CommandExecutionError('sysctl {0} does not exist'.format(name))
    ret = {}
```
This function contains two raise statements and one return statement, so we know that we will need (at least) three tests. It has two function arguments and many references to non-built-in functions. In the tests below you will see that MagicMock’s `patch()` method may be used as a context manager or as a decorator.

There are three test functions, one for each raise and return statement in the source function. Each function is self-contained and contains all and only the mocks and data needed to test the raise or return statement it is concerned with.

```python
from salt.modules import linux_sysctl
from salt.exceptions import CommandExecutionError

@skipIf(NO_MOCK, NO_MOCK_REASON)
class LinuxSysctlTestCase(TestCase):
    '''
    TestCase for salt.modules.linux_sysctl module
    '''
    @patch('os.path.exists', MagicMock(return_value=False))
def test_assign_proc_sys_failed(self):
        '''
        Test assign Proc Sys failed.
        '''
```

# Example:
# # sysctl -w net.ipv4.tcp_rmem="4096 87380 16777216"
# net.ipv4.tcp_rmem = 4096 87380 16777216
regex = re.compile(r'^{0}=\s+{1}$'.format(re.escape(name), re.escape(value)))
if not regex.match(out) or 'Invalid argument' in str(err):
    if data['retcode'] != 0 and err:
        error = err
    else:
        error = out
    raise CommandExecutionError('sysctl -w failed: {}'.format(error))
new_name, new_value = out.split('=', 1)
ret[new_name] = new_value
return ret
Tests if `/proc/sys/<kernel-subsystem>` exists or not

```python
cmd = { 'pid': 1337, 'retcode': 0, 'stderr': '', 'stdout': 'net.ipv4.ip_forward = 1'}
mock_cmd = MagicMock(return_value=cmd)
with patch.dict(linux_sysctl.__salt__, { 'cmd.run_all': mock_cmd }):
    self.assertRaises(CommandExecutionError,
        linux_sysctl.assign,
        'net.ipv4.ip_forward', 1)
```

```python
@patch('os.path.exists', MagicMock(return_value=True))
def test_assign_cmd_failed(self):
    Tests if the assignment was successful or not
    ```
    cmd = { 'pid': 1337, 'retcode': 0, 'stderr': '
        sysctl: setting key "net.ipv4.ip_forward": Invalid argument",
        'stdout': 'net.ipv4.ip_forward = backward'}
    mock_cmd = MagicMock(return_value=cmd)
    with patch.dict(linux_sysctl.__salt__, { 'cmd.run_all': mock_cmd }):
        self.assertRaises(CommandExecutionError,
            linux_sysctl.assign,
            'net.ipv4.ip_forward', 'backward')
```

```python
@patch('os.path.exists', MagicMock(return_value=True))
def test_assign_success(self):
    Tests the return of successful assign function
    ```
    cmd = { 'pid': 1337, 'retcode': 0, 'stderr': '',
        'stdout': 'net.ipv4.ip_forward = 1'}
    ret = { 'net.ipv4.ip_forward': '1'}
    mock_cmd = MagicMock(return_value=cmd)
    with patch.dict(linux_sysctl.__salt__, { 'cmd.run_all': mock_cmd }):
        self.assertEqual(linux_sysctl.assign(
            'net.ipv4.ip_forward', 1), ret)
```

```python
if __name__ == '__main__':
    from integration import run_tests
    run_tests(LinuxSysctlTestCase, needs_daemon=False)
```

34.22 raet

# RAET # Reliable Asynchronous Event Transport Protocol

See also:

RAET Overview

34.22.1 Protocol

Layering:
OSI Layers

Link is hidden from Raet Network is IP host address and Udp Port Transport is Raet transactions, service kind, tail error checking, Could include header signing as part of transport reliable delivery serialization of header Session is session id key exchange for signing. Grouping is Road (like 852 channel) Presentation is Encrypt Decrypt body Serialize Deserialize Body Application is body data dictionary

Header signing spans both the Transport and Session layers.

34.22.2 Header

JSON Header (Tradeoff some processing speed for extensibility, ease of use, readability)

Body initially JSON but support for `packed` binary body

34.22.3 Packet

Header ASCII Safe JSON Header termination: Empty line given by double pair of carriage return linefeed /r/n/r/n 10 13 10 13 ADAD 1010 1101 1010 1101

In json carriage return and newline characters cannot appear in a json encoded string unless they are escaped with backslash, so the 4 byte combination is illegal in valid json that does not have multi-byte unicode characters.

These means the header must be ascii safe so no multibyte utf-8 strings allowed in header.

Following Header Terminator is variable length signature block. This is binary and the length is provided in the header.

Following the signature block is the packet body or data. This may either be JSON or packed binary. The format is given in the json header

Finally is an optional tail block for error checking or encryption details

34.22.4 Header Fields

In UDP header

sh = source host sp = source port dh = destination host dp = destination port

In RAET Header

hk = header kind hl = header length

vn = version number

sd = Source Device ID dd = Destination Device ID cf = Corresponder Flag mf = Multicast Flag

si = Session ID ti = Transaction ID

sk = Service Kind pk = Packet Kind bf = Burst Flag (Send all Segments or Ordered packets without interleaved acks)

oi = Order Index dt = DateTime Stamp

sn = Segment Number sc = Segment Count
pf = Pending Segment Flag  af = All Flag (Resent all Segments not just one)
nk = Auth header kind nl = Auth header length
bk = body kind bl = body length
tk = tail kind tl = tail length

fg = flags packed (Flags) Default `00' hex string 2 byte Hex string with bits (0, 0, af, pf, 0, bf, mf, cf) Zeros are TBD flags

34.22.5 Session Bootstrap

Minion sends packet with SID of Zero with public key of minions Public Private Key pair Master acks packet with SID of Zero to let minion know it received the request

Some time later Master sends packet with SID of zero that accepts the Minion

Minion

34.22.6 Session

Session is important for security. Want one session opened and then multiple transactions within session.

Session ID SID sid

GUID hash to guarantee uniqueness since no guarantee of nonvolatile storage or require file storage to keep last session ID used.

34.22.7 Service Types or Modular Services

Four Service Types

1. One or more maybe (unacknowledged repeat) maybe means no guarantee

2. Exactly one at most (ack with retries) (duplicate detection idempotent) at most means fixed number of retries has finite probability of failing B1) finite retries B2) infinite retries with exponential back-off up to a maximum delay

3. Exactly one of sequence at most (sequence numbered) Receiver requests retry of missing packet with same B1 or B2 retry type

4. End to End (Application layer Request Response) This is two B sub transactions

Initially unicast messaging Eventually support for Multicast

The use case for C) is to fragment large packets as once a UDP packet exceeds the frame size its reliability goes way down So its more reliable to fragment large packets.

Better approach might be to have more modularity. Services Levels

1. Maybe one or more

   (a) Fire and forget no transaction either side

   (b) Repeat, no ack, no dupdet repeat counter send side, no transaction on receive side

   (c) Repeat, no Ack, dupdet repeat counter send side, dup detection transaction receive side

2. More or Less Once
(a) **retry finite, ack no dupdet** retry timer send side, finite number of retries ack receive side no dupdet

3. **At most Once**
   (a) **retry finite, ack, dupdet** retry timer send side, finite number of retries ack receive side dupdet

4. **Exactly once**
   (a) **ack retry** retry timer send side, ack and duplicate detection receive side Infinite retries with exponential backoff

5. **Sequential sequence number**
   (a) reorder escrow
   (b) Segmented packets

6. request response to application layer

Service Features
1. repeats
2. ack retry transaction id
3. sequence number duplicate detection out of order detection sequencing
4. rep-req

Always include transaction id since multiple transactions on same port So get duplicate detection for free if keep transaction alive but if use

A) Maybe one or more B1) At Least One B2) Exactly One C) One of sequence D) End to End

A) Sender creates transaction id for number of repeats but receiver does not keep transaction alive

B1) Sender creates transaction id keeps it for retries. Receiver keeps it to send ack then kills so retry could be duplicate not detected

B2) Sender creates transaction id keeps for retries Receiver keeps tid for acks on any retries so no duplicates.

C) Sender creates TID and Sequence Number. Receiver checks for out of order sequence and can request retry.

D) Application layer sends response. So question is do we keep transaction open or have response be new transaction. No because then we need a rep-req ID so might as well use the same transaction id. Just keep alive until get response.

Little advantage to B1 vs B2 not having duplicates.

So 4 service types
1. Maybe one or more (unacknowledged repeat)
2. Exactly One (At most one) (ack with retry) (duplicate detection idempotent)
3. One of Sequence (sequence numbered)
4. End to End

Also multicast or unicast

Modular Transaction Table

**Sender Side:** Transaction ID plus transaction source sender or receiver generated transaction id Repeat Counter Retry Timer Retry Counter (finite retries) Redo Timer (infinite redos with exponential backoff) Sequence number without acks (look for resend requests) Sequence with ack (wait for ack before sending next in sequence) Segmentation
**Receiver Side:** Nothing just accept packet Acknowledge (can delete transaction after acknowledge) No duplicate detection Transaction timeout (keep transaction until timeout) Duplicate detection save transaction id duplicate detection timeout Request resend of missing packet in sequence Sequence reordering with escrow timeout wait escrow before requesting resend Unsegmentation (request resends of missing segment)

### 34.23 SaltStack Git Policy

The SaltStack team follows a git policy to maintain stability and consistency with the repository.

The git policy has been developed to encourage contributions and make contributing to Salt as easy as possible. Code contributors to SaltStack projects **DO NOT NEED TO READ THIS DOCUMENT**, because all contributions come into SaltStack via a single gateway to make it as easy as possible for contributors to give us code.

The primary rule of git management in SaltStack is to make life easy on contributors and developers to send in code. Simplicity is always a goal!

#### 34.23.1 New Code Entry

All new SaltStack code is posted to the `develop` branch, which is the single point of entry. The only exception is when a bugfix to develop cannot be cleanly merged into a release branch and the bugfix needs to be rewritten for the release branch.

#### 34.23.2 Release Branching

SaltStack maintains two types of releases, **Feature Releases** and **Point Releases**. A feature release is managed by incrementing the first or second release point number, so 0.10.5 -> 0.11.0 signifies a feature release and 0.11.0 -> 0.11.1 signifies a point release, also a hypothetical 0.42.7 -> 1.0.0 would also signify a feature release.

**Feature Release Branching**

Each feature release is maintained in a dedicated git branch derived from the last applicable release commit on develop. All file changes relevant to the feature release will be completed in the develop branch prior to the creation of the feature release branch. The feature release branch will be named after the relevant numbers to the feature release, which constitute the first two numbers. This means that the release branch for the 0.11.0 series is named 0.11.

A feature release branch is created with the following command:

```
# git checkout -b 0.11 # From the develop branch
# git push origin 0.11
```

**Point Releases**

Each point release is derived from its parent release branch. Constructing point releases is a critical aspect of Salt development and is managed by members of the core development team. Point releases comprise bug and security fixes which are cherry picked from develop onto the aforementioned release branch. At the time when a core developer accepts a pull request a determination needs to be made if the commits in the pull request need to be backported to the release branch. Some simple criteria are used to make this determination:

- Is this commit fixing a bug? Backport
• Does this commit change or add new features in any way? Don’t backport
• Is this a PEP8 or code cleanup commit? Don’t backport
• Does this commit fix a security issue? Backport

Determining when a point release is going to be made is up to the project leader (Thomas Hatch). Generally point releases are made every 1-2 weeks or if there is a security fix they can be made sooner.

The point release is only designated by tagging the commit on the release branch with release number using the existing convention (version 0.11.1 is tagged with v0.11.1). From the tag point a new source tarball is generated and published to PyPI, and a release announcement is made.

34.24 Salt Conventions

34.24.1 Writing Salt Documentation

Salt’s documentation is built using the Sphinx documentation system. It can be build in a large variety of output formats including HTML, PDF, ePUB, and manpage.

All the documentation is contained in the main Salt repository. Speaking broadly, most of the narrative documentation is contained within the https://github.com/saltstack/salt/blob/develop/doc subdirectory and most of the reference and API documentation is written inline with Salt’s Python code and extracted using a Sphinx extension.

Style

The Salt project recommends the IEEE style guide as a general reference for writing guidelines. Those guidelines are not strictly enforced but rather serve as an excellent resource for technical writing questions. The NCBI style guide is another very approachable resource.

Point-of-view

Use third-person perspective and avoid ”’I”, ”’we”, ”’you” forms of address. Identify the addressee specifically e.g., ”’users should”, ”’the compiler does”, etc.

Active voice

Use active voice and present-tense. Avoid filler words.

Title capitalization

Document titles and section titles within a page should follow normal sentence capitalization rules. Words that are capitalized as part of a regular sentence should be capitalized in a title and otherwise left as lowercase. Punctuation can be omitted unless it aids the intent of the title (e.g., exclamation points or question marks).

For example:

This is a main heading
==================================

Paragraph.
This is an exciting sub-heading!
--------------------------------

Paragraph.

Serial Commas

According to Wikipedia: In English punctuation, a serial comma or series comma (also called Oxford comma and Harvard comma) is a comma placed immediately before the coordinating conjunction (usually and, or, or nor) in a series of three or more terms. For example, a list of three countries might be punctuated either as "France, Italy, and Spain" (with the serial comma), or as "France, Italy and Spain" (without the serial comma).

When writing a list that includes three or more items, the serial comma should always be used.

Documenting modules

Documentation for Salt's various module types is inline in the code. During the documentation build process it is extracted and formatted into the final HTML, PDF, etc format.

Inline documentation

Python has special multi-line strings called docstrings as the first element in a function or class. These strings allow documentation to live alongside the code and can contain special formatting. For example:

```python
def myfunction(value):
    """
    Upper-case the given value
    
    Usage:
    
    .. code-block:: python
    
        val = 'a string'
        new_val = myfunction(val)
        print(new_val) # 'A STRING'
    
    :param value: a string
    :return: a copy of `value` that has been upper-cased
    """
    return value.upper()
```

Specify a release for additions or changes

New functions or changes to existing functions should include a marker that denotes what Salt release will be affected. For example:

```python
def myfunction(value):
    """
    Upper-case the given value
    
    .. versionadded:: 2014.7.0
    """
```
```python
return value.upper()
```

For changes to a function:

```python
def myfunction(value, strip=False):
    
    Upper-case the given value
    ...
    .. versionchanged:: Boron
       Added a flag to also strip whitespace from the string.

    if strip:
        return value.upper().strip()
    return value.upper()
```

Adding module documentation to the index

Each module type has an index listing all modules of that type. For example: Full list of built-in execution modules, Full list of built-in state modules, Full list of built-in renderer modules. New modules must be added to the index manually.

1. Edit the file for the module type: execution modules, state modules, renderer modules, etc.
2. Add the new module to the alphabetized list.
3. Build the documentation which will generate an .rst file for the new module in the same directory as the index.rst.
4. Commit the changes to index.rst and the new .rst file and send a pull request.

Cross-references

The Sphinx documentation system contains a wide variety of cross-referencing capabilities.

Glossary entries

Link to glossary entries using the term role. A cross-reference should be added the first time a Salt-specific term is used in a document.

A common way to encapsulate master-side functionality is by writing a custom :term:`Runner Function`. Custom Runner Functions are easy to write.

Index entries

Sphinx automatically generates many kind of index entries but it is occasionally useful to manually add items to the index.

One method is to use the index directive above the document or section that should appear in the index.
Another method is to use the `index` role inline with the text that should appear in the index. The index entry is created and the target text is left otherwise intact.

**Information about the `Salt Reactor`**
-----------------------------

Paragraph.

Documents and sections

Each document should contain a unique top-level label of the form:

```yaml
.. _my-page:
```

**My page**

```

Paragraph.
```

Unique labels can be linked using the `ref` role. This allows cross-references to survive document renames or movement.

For more information see :ref:`my-page`.

Note, the `:doc:` role should not be used to link documents together.

Modules

Cross-references to Salt modules can be added using Sphinx's Python domain roles. For example, to create a link to the `test.ping` function:

```
A useful execution module to test active communication with a minion is the `test.ping <salt.modules.test.ping>` function.
```

Salt modules can be referenced as well:

```
The `test module <salt.modules.test>` contains many useful functions for inspecting an active Salt connection.
```

The same syntax works for all module types:

```
One of the workhorse state module functions in Salt is the `file.managed <salt.states.file.managed>` function.
```
**Settings**

Individual settings in the Salt Master or Salt Minion configuration files are cross-referenced using two custom roles, `conf_master` and `conf_minion`.

The `:conf_minion:` `minion ID <id>` setting is a unique identifier for a single minion.

**Building the documentation**

1. Install Sphinx using a system package manager or pip. The package name is often of the form `python-sphinx`. There are no other dependencies.

2. Build the documentation using the provided Makefile or `.bat` file on Windows.

   ```
   cd /path/to/salt/doc
   make html
   ```

3. The generated documentation will be written to the `doc/_build/<format>` directory.

4. A useful method of viewing the HTML documentation locally is the start Python's built-in HTTP server:

   ```
   cd /path/to/salt/doc/_build/html
   python -m SimpleHTTPServer
   ```

   Then pull up the documentation in a web browser at `http://localhost:8000/`.

**34.24.2 Salt Formulas**

Formulas are pre-written Salt States. They are as open-ended as Salt States themselves and can be used for tasks such as installing a package, configuring, and starting a service, setting up users or permissions, and many other common tasks.

All official Salt Formulas are found as separate Git repositories in the `saltstack-formulas` organization on GitHub: [https://github.com/saltstack-formulas](https://github.com/saltstack-formulas)

As a simple example, to install the popular Apache web server (using the normal defaults for the underlying distro) simply include the `apache-formula` from a top file:

```
base:
  'web*':
    - apache
```

**Installation**

Each Salt Formula is an individual Git repository designed as a drop-in addition to an existing Salt State tree. Formulas can be installed in the following ways.
Adding a Formula as a GitFS remote

One design goal of Salt's GitFS fileserver backend was to facilitate reusable States. GitFS is a quick and natural way to use Formulas.

1. **Install and configure GitFS.**

2. Add one or more Formula repository URLs as remotes in the `gitfs_remotes` list in the Salt Master configuration file:

   ```
   gitfs_remotes:
   - https://github.com/saltstack-formulas/apache-formula
   - https://github.com/saltstack-formulas/memcached-formula
   ```

   We strongly recommend forking a formula repository into your own GitHub account to avoid unexpected changes to your infrastructure.

   Many Salt Formulas are highly active repositories so pull new changes with care. Plus any additions you make to your fork can be easily sent back upstream with a quick pull request!

3. Restart the Salt master.

Adding a Formula directory manually

Formulas are simply directories that can be copied onto the local file system by using Git to clone the repository or by downloading and expanding a tarball or zip file of the repository. The directory structure is designed to work with `file_roots` in the Salt master configuration.

1. Clone or download the repository into a directory:

   ```bash
   mkdir -p /srv/formulas
cd /srv/formulas
git clone https://github.com/saltstack-formulas/apache-formula.git
   
   # or
   
mkdir -p /srv/formulas
cd /srv/formulas
wget https://github.com/saltstack-formulas/apache-formula/archive/master.tar.gz
tar xf apache-formula-master.tar.gz
   ```

2. Add the new directory to `file_roots`:

   ```
   file_roots:
   base:
   - /srv/salt
   - /srv/formulas/apache-formula
   ```

3. Restart the Salt Master.

Usage

Each Formula is intended to be immediately usable with sane defaults without any additional configuration. Many formulas are also configurable by including data in Pillar; see the `pillar.example` file in each Formula repository for available options.
Including a Formula in an existing State tree

Formula may be included in an existing sls file. This is often useful when a state you are writing needs to require or extend a state defined in the formula.

Here is an example of a state that uses the epel-formula in a require declaration which directs Salt to not install the python26 package until after the EPEL repository has also been installed:

```
include:
  - epel

python26:
  pkg.installed:
    - require:
      - pkg: epel
```

Including a Formula from a Top File

Some Formula perform completely standalone installations that are not referenced from other state files. It is usually cleanest to include these Formula directly from a Top File.

For example the easiest way to set up an OpenStack deployment on a single machine is to include the openstack-standalone-formula directly from a top.sls file:

```
base:
  'myopenstackmaster':
    - openstack
```

Quickly deploying OpenStack across several dedicated machines could also be done directly from a Top File and may look something like this:

```
base:
  'controller':
    - openstack.horizon
    - openstack.keystone
  'hyper-*':
    - openstack.nova
    - openstack.glance
  'storage-*':
    - openstack.swift
```

Configuring Formula using Pillar

Salt Formulas are designed to work out of the box with no additional configuration. However, many Formula support additional configuration and customization through Pillar. Examples of available options can be found in a file named pillar.example in the root directory of each Formula repository.

Using Formula with your own states

Remember that Formula are regular Salt States and can be used with all Salt's normal state mechanisms. Formula can be required from other States with require declarations, they can be modified using extend, they can made to watch other states with The in versions of requisites.
The following example uses the stock `apache-formula` alongside a custom state to create a vhost on a Debian/Ubuntu system and to reload the Apache service whenever the vhost is changed.

```
# Include the stock, upstream apache formula.
include:
  - apache

# Use the watch_in requisite to cause the apache service state to reload
# apache whenever the my-example-com-vhost state changes.
my-example-com-vhost:
  file:
    - managed
    - name: /etc/apache2/sites-available/my-example-com
    - watch_in:
      - service: apache
```

Don't be shy to read through the source for each Formula!

**Reporting problems & making additions**

Each Formula is a separate repository on GitHub. If you encounter a bug with a Formula please file an issue in the respective repository! Send fixes and additions as a pull request. Add tips and tricks to the repository wiki.

**Writing Formulas**

Each Formula is a separate repository in the saltstack-formulas organization on GitHub.

**Note:** Get involved creating new Formulas

The best way to create new Formula repositories for now is to create a repository in your own account on GitHub and notify a SaltStack employee when it is ready. We will add you to the contributors team on the saltstack-formulas organization and help you transfer the repository over. Ping a SaltStack employee on IRC (#salt on Freenode) or send an email to the salt-users mailing list.

There are a lot of repositories in that organization! Team members can manage which repositories they are subscribed to on GitHub's watching page: [https://github.com/watching](https://github.com/watching).

**Style**

Maintainability, readability, and reusability are all marks of a good Salt sls file. This section contains several suggestions and examples.

```
# Deploy the stable master branch unless version overridden by passing
# Pillar at the CLI or via the Reactor.

deploy_myapp:
  git.latest:
    - name: git@github.com/myco/myapp.git
    - version: {{ salt.pillar.get('myapp:version', 'master') }}
```
Use a descriptive State ID  The ID of a state is used as a unique identifier that may be referenced via other states in requisites. It must be unique across the whole state tree (it is a key in a dictionary, after all).

In addition a state ID should be descriptive and serve as a high-level hint of what it will do, or manage, or change. For example, deploy_webapp, or apache, or reload_firewall.

Use module.function notation  So-called `short-declaration` notation is preferred for referencing state modules and state functions. It provides a consistent pattern of module.function shared between Salt States, the Reactor, Salt Mine, the Scheduler, as well as with the CLI.

```
# Do
apache:
pkg.installed:
  - name: httpd

# Don't
apache:
pkg:
  - installed
  - name: httpd
```

Salt's state compiler will transform `short-decs` into the longer format when compiling the human-friendly highstate structure into the machine-friendly lowstate structure.

Specify the name parameter  Use a unique and permanent identifier for the state ID and reserve name for data with variability.

The name declaration is a required parameter for all state functions. The state ID will implicitly be used as name if it is not explicitly set in the state.

In many state functions the name parameter is used for data that varies such as OS-specific package names, OS-specific file system paths, repository addresses, etc. Any time the ID of a state changes all references to that ID must also be changed. Use a permanent ID when writing a state the first time to future-proof that state and allow for easier refactors down the road.

Comment state files  YAML allows comments at varying indentation levels. It is a good practice to comment state files. Use vertical whitespace to visually separate different concepts or actions.

```
# Start with a high-level description of the current sls file.
# Explain the scope of what it will do or manage.

# Comment individual states as necessary.
update_a_config_file:
  # Provide details on why an unusual choice was made. For example:
  #
  # This template is fetched from a third-party and does not fit our
  # company norm of using Jinja. This must be processed using Mako.
  file.managed:
    - name: /path/to/file.cfg
    - source: salt://path/to/file.cfg.template
    - template: mako

  # Provide a description or explanation that did not fit within the state
  # ID. For example:
  #
```
# Update the application's last-deployed timestamp.
# This is a workaround until Bob configures Jenkins to automate RPM builds of the app.
cmd.run:
    # FIXME: Joe needs this to run on Windows by next quarter. Switch these
    # from shell commands to Salt's file.managed and file.replace state
    # modules.
    - name: |
        touch /path/to/file_last_updated
        sed -e 's/foo/bar/g' /path/to/file_environment
    - onchanges:
        - file: a_config_file

BecarefultouseJinjacommentsforcommentingJinjacodeandYAMLcommentsforcommentingYAMLcode.

# BAD EXAMPLE
# The Jinja in this YAML comment is still executed!
# {% set apache_is_installed = 'apache' in salt.pkg.list_pkgs() %}

# GOOD EXAMPLE
# The Jinja in this Jinja comment will not be executed.
{{ # {% set apache_is_installed = 'apache' in salt.pkg.list_pkgs() %} #}

Easy on the Jinja!

Jinja templating provides vast flexibility and power when building Salt sls files. It can also create an unmaintainable tangle of logic and data. Speaking broadly, Jinja is best used when kept apart from the states (as much as is possible).

Below are guidelines and examples of how Jinja can be used effectively.

### Know the evaluation and execution order

High-level knowledge of how Salt states are compiled and run is useful when writing states.

The default renderer setting in Salt is Jinja piped to YAML. Each is a separate step. Each step is not aware of the previous or following step. Jinja is not YAML aware, YAML is not Jinja aware; they cannot share variables or interact.

- Whatever the Jinja step produces must be valid YAML.
- Whatever the YAML step produces must be a valid highstate data structure. (This is also true of the final step for any of the alternate renderers in Salt.)
- Highstate can be thought of as a human-friendly data structure; easy to write and easy to read.
- Salt's state compiler validates the highstate and compiles it to low state.
- Low state can be thought of as a machine-friendly data structure. It is a list of dictionaries that each map directly to a function call.
- Salt's state system finally starts and executes on each "chunk" in the low state. Remember that requisites are evaluated at runtime.
- The return for each function call is added to the "running" dictionary which is the final output at the end of the state run.

The full evaluation and execution order:
Jinja -> YAML -> Highstate -> low state -> execution

Avoid changing the underlying system with Jinja  Avoid calling commands from Jinja that change the underlying system. Commands run via Jinja do not respect Salt's dry-run mode (test=True)! This is usually in conflict with the idempotent nature of Salt states unless the command being run is also idempotent.

Inspect the local system  A common use for Jinja in Salt states is to gather information about the underlying system. The grains dictionary available in the Jinja context is a great example of common data points that Salt itself has already gathered. Less common values are often found by running commands. For example:

```python
{% set is_selinux_enabled = salt.cmd.run('sestatus') == '1' %}
```

This is usually best done with a variable assignment in order to separate the data from the state that will make use of the data.

Gather external data  One of the most common uses for Jinja is to pull external data into the state file. External data can come from anywhere like API calls or database queries, but it most commonly comes from flat files on the file system or Pillar data from the Salt Master. For example:

```python
{% set some_data = salt.pillar.get('some_data', { 'sane default': True }) %}
[# or #]
{% load_json 'path/to/file.json' as some_data %}
[# or #]
{% load_text 'path/to/ssh_key.pub' as ssh_pub_key %}
[# or #]
{% from 'path/to/other_file.jinja' import some_data with context %}
```

This is usually best done with a variable assignment in order to separate the data from the state that will make use of the data.

Light conditionals and looping  Jinja is extremely powerful for programatically generating Salt states. It is also easy to overuse. As a rule of thumb, if it is hard to read it will be hard to maintain!

Separate Jinja control-flow statements from the states as much as is possible to create readable states. Limit Jinja within states to simple variable lookups.

Below is a simple example of a readable loop:

```python
{% for user in salt.pillar.get('list_of_users', []) %}
[# Ensure unique state IDs when looping. #]
{{ user.name }}-{{ loop.index }}:
  user.present:
    - name: {{ user.name }}
    - shell: {{ user.shell }}
{% endfor %}
```
Avoid putting a Jinja conditionals within Salt states where possible. Readability suffers and the correct YAML indentation is difficult to see in the surrounding visual noise. Parameterization (discussed below) and variables are both useful techniques to avoid this. For example:

```yaml
# ---- Bad example ---- #

apache:
    pkg.installed:
        {% if grains.os_family == 'RedHat' %}
            - name: httpd
        {% elif grains.os_family == 'Debian' %}
            - name: apache2
        {% endif %}

# ---- Better example ---- #

{% if grains.os_family == 'RedHat' %}
    {% set name = 'httpd' %}
{% elif grains.os_family == 'Debian' %}
    {% set name = 'apache2' %}
{% endif %}

apache:
    pkg.installed:
        - name: {{ name }}

# ---- Good example ---- #

{% set name = {
    'RedHat': 'httpd',
    'Debian': 'apache2',
}.get(grains.os_family) %}

apache:
    pkg.installed:
        - name: {{ name }}
```

Dictionaries are useful to effectively "namespace" a collection of variables. This is useful with parameterization (discussed below). Dictionaries are also easily combined and merged. And they can be directly serialized into YAML which is often easier than trying to create valid YAML through templating. For example:

```yaml
# ---- Bad example ---- #

haproxy_conf:
    file.managed:
        - name: /etc/haproxy/haproxy.cfg
        - template: jinja
        {% if 'external_loadbalancer' in grains.roles %}
            - source: salt://haproxy/external_haproxy.cfg
        {% elif 'internal_loadbalancer' in grains.roles %}
            - source: salt://haproxy/internal_haproxy.cfg
        {% endif %}
        - context:
            {% if 'external_loadbalancer' in grains.roles %}
                ssl_termination: True
            {% elif 'internal_loadbalancer' in grains.roles %}
                ssl_termination: False
            {% endif %}
```

34.24. Salt Conventions
{% load_yaml as haproxy_defaults %}

common_settings:
    bind_port: 80

internal_loadbalancer:
    source: salt://haproxy/internal_haproxy.cfg
    settings:
        bind_port: 8080
        ssl_termination: False

external_loadbalancer:
    source: salt://haproxy/external_haproxy.cfg
    settings:
        ssl_termination: True

{% endload %}

{% if 'external_loadbalancer' in grains.roles %}
{% set haproxy = haproxy_defaults['external_loadbalancer'] %}
{% elif 'internal_loadbalancer' in grains.roles %}
{% set haproxy = haproxy_defaults['internal_loadbalancer'] %}
{% endif %}

{% do haproxy.settings.update(haproxy_defaults.common_settings) %}

haproxy_conf:
    file.managed:
        - name: /etc/haproxy/haproxy.cfg
        - template: jinja
        - source: {{ haproxy.source }}
        - context: {{ haproxy.settings | yaml() }}

There is still room for improvement in the above example. For example, extracting into an external file or replacing the if-elif conditional with a function call to filter the correct data more succinctly. However, the state itself is simple and legible, the data is separate and also simple and legible. And those suggested improvements can be made at some future date without altering the state at all!

Avoid heavy logic and programming  Jinja is not Python. It was made by Python programmers and shares many semantics and some syntax but it does not allow for arbitrary Python function calls or Python imports. Jinja is a fast and efficient templating language but the syntax can be verbose and visually noisy.

Once Jinja use within an sls file becomes slightly complicated -- long chains of if-elif-elif-else statements, nested conditionals, complicated dictionary merges, wanting to use sets -- instead consider using a different Salt renderer, such as the Python renderer. As a rule of thumb, if it is hard to read it will be hard to maintain -- switch to a format that is easier to read.

Using alternate renderers is very simple to do using Salt's `''she-bang''` syntax at the top of the file. The Python renderer must simply return the correct highstate data structure. The following example is a state tree of two sls files, one simple and one complicated.

/srv/salt/top.sls:

base:
    '*':
        - common_configuration
        - roles_configuration
Salt Documentation, Release 2015.8.0

/srv/salt/common_configuration.sls:

common_users:
    user.present:
        - names: [larry, curly, moe]

/srv/salt/roles_configuration:

```python
#!py
def run():
    list_of_roles = set()

    # This example has the minion id in the form 'web-03-dev'.
    # Easily access the grains dictionary:
    try:
        app, instance_number, environment = __grains__['id'].split('-')
        instance_number = int(instance_number)
    except ValueError:
        app, instance_number, environment = ['Unknown', 0, 'dev']

    list_of_roles.add(app)

    if app == 'web' and environment == 'dev':
        list_of_roles.add('primary')
        list_of_roles.add('secondary')
    elif app == 'web' and environment == 'staging':
        if instance_number == 0:
            list_of_roles.add('primary')
        else:
            list_of_roles.add('secondary')

    # Easily cross-call Salt execution modules:
    if __salt__['myutils.query_valid_ec2_instance']():
        list_of_roles.add('is_ec2_instance')

    return {
        'set_roles_grains': {
            'grains.present': [
                {'name': 'roles'},
                {'value': list(list_of_roles)},
            ],
        },
    }
```

Jinja Macros  In Salt sls files Jinja macros are useful for one thing and one thing only: creating mini templates that can be reused and rendered on demand. Do not fall into the trap of thinking of macros as functions; Jinja is not Python (see above).

Macros are useful for creating reusable, parameterized states. For example:

```jinja
{% macro user_state(state_id, user_name, shell='/bin/bash', groups=[]) %}
{{ state_id }}:
user.present:
    - name: {{ user_name }}
    - shell: {{ shell }}
{% endmacro %}
```
Macros are also useful for creating one-off `serializers` that can accept a data structure and write that out as a domain-specific configuration file. For example, the following macro could be used to write a php.ini config file:

```
/srv/salt/php.sls:

php_ini:
    file.managed:
    - name: /etc/php.ini
    - source: salt://php.ini.tmpl
    - template: jinja
    - context:
        php_ini_settings: {{ salt.pillar.get('php_ini', {}) | json() }}
```

```
/srv/pillar/php.sls:

php_ini:
    PHP:
        engine: 'On'
        short_open_tag: 'Off'
        error_reporting: 'E_ALL & ~E_DEPRECATED & ~E_STRICT'
```

```
/srv/salt/php.ini.tmpl:

{% macro php_ini_serializer(data) %}
{% for section_name, name_val_pairs in data.items() %}
  [{{ section_name }}]
  {% for name, val in name_val_pairs.items() -%}
  {{ name }} = "{{ val }}"
  {%- endfor %}
  {%- endfor %}
{%- endmacro %}

; File managed by Salt at <{{ source }}>.  
; Your changes will be overwritten.

{{ php_ini_serializer(php_ini_settings) }}
```

### Abstracting static defaults into a lookup table

Separate data that a state uses from the state itself to increases the flexibility and reusability of a state.

An obvious and common example of this is platform-specific package names and file system paths. Another example is sane defaults for an application, or common settings within a company or organization. Organizing such data as a dictionary (aka hash map, lookup table, associative array) often provides a lightweight namespace and allows for quick and easy lookups. In addition, using a dictionary allows for easily merging and overriding static values within a lookup table with dynamic values fetched from Pillar.

A strong convention in Salt Formulas is to place platform-specific data, such as package names and file system paths, into a file named `map.jinja` that is placed alongside the state files.
The following is an example from the MySQL Formula. The `grains.filter_by` function performs a lookup on that table using the `os_family` grain (by default).

The result is that the `mysql` variable is assigned to a subset of the lookup table for the current platform. This allows states to reference, for example, the name of a package without worrying about the underlying OS. The syntax for referencing a value is a normal dictionary lookup in Jinja, such as `{{ mysql['service'] }}` or the shorthand `{{ mysql.service }}`.

```jinja
map.jinja:
{% set mysql = salt['grains.filter_by']({
    'Debian': {
        'server': 'mysql-server',
        'client': 'mysql-client',
        'service': 'mysql',
        'config': '/etc/mysql/my.cnf',
        'python': 'python-mysqldb',
    },
    'RedHat': {
        'server': 'mysql-server',
        'client': 'mysql',
        'service': 'mysqld',
        'config': '/etc/my.cnf',
        'python': 'MySQL-python',
    },
    'Gentoo': {
        'server': 'dev-db/mysql',
        'client': 'dev-db/mysql',
        'service': 'mysql',
        'config': '/etc/mysql/my.cnf',
        'python': 'dev-python/mysql-python',
    },
}, merge=salt['pillar.get']['mysql:lookup']) %}
```

Values defined in the map file can be fetched for the current platform in any state file using the following syntax:

```jinja
{% from "mysql/map.jinja" import mysql with context %}

mysql-server:
  pkg.installed:
    - name: {{ mysql.server }}
  service.running:
    - name: {{ mysql.service }}
```

Collecting common values  Common values can be collected into a `base` dictionary. This minimizes repetition of identical values in each of the `Lookup_dict` sub-dictionaries. Now only the values that are different from the base must be specified of the alternates:

```jinja
map.jinja:
{% set mysql = salt['grains.filter_by']({
    'default': {
        'server': 'mysql-server',
        'client': 'mysql-client',
        'service': 'mysql',
        'config': '/etc/mysql/my.cnf',
        'python': 'python-mysqldb',
```
Overriding values in the lookup table  Allow static values within lookup tables to be overridden. This is a simple pattern which once again increases flexibility and reusability for state files.

The `merge` argument in `filter_by` specifies the location of a dictionary in Pillar that can be used to override values returned from the lookup table. If the value exists in Pillar it will take precedence.

This is useful when software or configuration files is installed to non-standard locations or on unsupported platforms. For example, the following Pillar would replace the `config` value from the call above.

```yaml
mysql:
  lookup:
    config: /usr/local/etc/mysql/my.cnf
```

Note: Protecting Expansion of Content with Special Characters

When templating keep in mind that YAML does have special characters for quoting, flows, and other special structure and content. When a Jinja substitution may have special characters that will be incorrectly parsed by YAML care must be taken. It is a good policy to use the `yaml_encode` or the `yaml_dquote` Jinja filters:

```jinja
{%- set foo = 7.7 %}
{%- set bar = "null" %}
{%- set baz = true %}
{%- set zap = 'The word of the day is "salty".' %}
{%- set zip = '"The quick brown fox . . ."' %}

foo: {{ foo|yaml_encode }}
bar: {{ bar|yamlEncode }}
baz: {{ baz|yaml_encode }}
zap: {{ zap|yaml_encode }}
zip: {{ zip|yaml_dquote }}
```

The above will be rendered as below:

```yaml
foo: 7.7
bar: null
baz: true
zap: "The word of the day is "salty"."
zip: ""The quick brown fox . . .""
```
The filter_by function performs a simple dictionary lookup but also allows for fetching data from Pillar and overriding data stored in the lookup table. That same workflow can be easily performed without using filter_by; other dictionaries besides data from Pillar can also be used.

```jinja
{% set lookup_table = {...} %}
{% do lookup_table.update(salt.pillar.get('my:custom:data')) %}
```

**When to use lookup tables**  The map.jinja file is only a convention within Salt Formulas. This greater pattern is useful for a wide variety of data in a wide variety of workflows. This pattern is not limited to pulling data from a single file or data source. This pattern is useful in States, Pillar and the Reactor, for example.

Working with a data structure instead of, say, a config file allows the data to be cobbled together from multiple sources (local files, remote Pillar, database queries, etc), combined, overridden, and searched.

Below are a few examples of what lookup tables may be useful for and how they may be used and represented.

**Platform-specific information**  An obvious pattern and one used heavily in Salt Formulas is extracting platform-specific information such as package names and file system paths in a file named map.jinja. The pattern is explained in detail above.

**Sane defaults**  Application settings can be a good fit for this pattern. Store default settings along with the states themselves and keep overrides and sensitive settings in Pillar. Combine both into a single dictionary and then write the application config or settings file.

The example below stores most of the Apache Tomcat server.xml file alongside the Tomcat states and then allows values to be updated or augmented via Pillar. (This example uses the BadgerFish format for transforming JSON to XML.)

```
/srv/salt/tomcat/defaults.yaml:

Server:
  '@port': '8005'
  '@shutdown': SHUTDOWN
GlobalNamingResources:
  Resource:
    '@auth': Container
    '@description': User database that can be updated and saved
    '@factory': org.apache.catalina.users.MemoryUserDatabaseFactory
    '@name': UserDatabase
    '@pathname': conf/tomcat-users.xml
    '@type': org.apache.catalina.UserDatabase
  # <...snip...>

/srv/pillar/tomcat.sls:

appX:
  server_xml_overrides:
    Server:
      Service:
        '@name': Catalina
      Connector:
        '@port': '8009'
        '@protocol': AJP/1.3
```
/srv/salt/tomcat/server_xml.sls:

{% import_yaml 'tomcat/defaults.yaml' as server_xml_defaults %}
{% set server_xml_final_values = salt.pillar.get('appX:server_xml_overrides',
    default=server_xml_defaults,
    merge=True) %}

appX_server_xml:
  file.serialize:
    - name: /etc/tomcat/server.xml
    - dataset: {{ server_xml_final_values | json() }}
    - formatter: xml_badgerfish

The `file.serialize` state can provide a shorthand for creating some files from data structures. There are also many examples within Salt Formulas of creating one-off `"serializers"` (often as Jinja macros) that reformat a data structure to a specific config file format. For example, `Nginx vhosts` or the `php.ini`:

```
https://github.com/saltstack-formulas/nginx-formula/blob/5cad4512/nginx/ng/vhosts_config.sls
```

```
https://github.com/saltstack-formulas/php-formula/blob/82e2cd3a/php/ng/files/php.ini
```

**Environment specific information** A single state can be reused when it is parameterized as described in the section below, by separating the data the state will use from the state that performs the work. This can be the difference between deploying Application X and Application Y, or the difference between production and development. For example:

/srv/salt/app/deploy.sls:

```
{% import_yaml 'app/defaults.yaml' as app_defaults %}

{% let app = app_defaults.get(salt.grains.get('role')) %}

deploy_application:
  git.latest:
    - name: {{ app.repo_url }}
    - version: {{ app.version }}
    - target: {{ app.deploy_dir }}

myco/myapp/deployed:
  event.send:
    - data:
      version: {{ app.version }}
    - onchanges:
      - git: deploy_application
```

/srv/salt/app/defaults.yaml:
Single-purpose SLS files

Each sls file in a Formula should strive to do a single thing. This increases the reusability of this file by keeping unrelated tasks from getting coupled together.

As an example, the base Apache formula should only install the Apache httpd server and start the httpd service. This is the basic, expected behavior when installing Apache. It should not perform additional changes such as set the Apache configuration file or create vhosts.

If a formula is single-purpose as in the example above, other formulas, and also other states can include and use that formula with Requisites and Other Global State Arguments without also including undesirable or unintended side-effects.

The following is a best-practice example for a reusable Apache formula. (This skips platform-specific options for brevity. See the full apache-formula for more.)

```
# apache/init.sls
apache:
  pkg.installed:
    [...]
  service.running:
    [...]

# apache/mod_wsgi.sls
include:
  - apache

mod_wsgi:
  pkg.installed:
    [...]
  require:
    - pkg: apache

# apache/conf.sls
include:
  - apache

apache_conf:
  file.managed:
    [...]
  watch_in:
    - service: apache
```

To illustrate a bad example, say the above Apache formula installed Apache and also created a default vhost. The mod_wsgi state would not be able to include the Apache formula to create that dependency tree without also installing the unneeded default vhost.

*Formulas should be reusable.* Avoid coupling unrelated actions together.
Parameterization

Parameterization is a key feature of Salt Formulas and also for Salt States. Parameterization allows a single Formula to be reused across many operating systems; to be reused across production, development, or staging environments; and to be reused by many people all with varying goals.

Writing states, specifying ordering and dependencies is the part that takes the longest to write and to test. Filling those states out with data such as users or package names or file locations is the easy part. How many users, what those users are named, or where the files live are all implementation details that should be parameterized. This separation between a state and the data that populates a state creates a reusable formula.

In the example below the data that populates the state can come from anywhere -- it can be hard-coded at the top of the state, it can come from an external file, it can come from Pillar, it can come from an execution function call, or it can come from a database query. The state itself doesn't change regardless of where the data comes from. Production data will vary from development data will vary from data from one company to another, however the state itself stays the same.

```
{% set user_list = [
    {'name': 'larry', 'shell': 'bash'},
    {'name': 'curly', 'shell': 'bash'},
    {'name': 'moe', 'shell': 'zsh'},
] %}

{% set user_list = salt['pillar.get']('user_list') %}

{% load_json "default_users.json" as user_list %}

{% set user_list = salt['acme_utils.get_user_list']() %}

{% for user in list_list %}
    {{ user.name }}:
    - name: {{ user.name }}
    - shell: {{ user.shell }}
{% endfor %}
```

Configuration

Formulas should strive to use the defaults of the underlying platform, followed by defaults from the upstream project, followed by sane defaults for the formula itself.

As an example, a formula to install Apache should not change the default Apache configuration file installed by the OS package. However, the Apache formula should include a state to change or override the default configuration file.

Pillar overrides

Pillar lookups must use the safe `get()` and must provide a default value. Create local variables using the Jinja set construct to increase readability and to avoid potentially hundreds or thousands of function calls across a large state.
tree.

```jinja
{% from "apache/map.jinja" import apache with context %}
{% set settings = salt['pillar.get']('apache', {}) %}

mod_status:
  file.managed:
    - name: {{ apache.conf_dir }}
    - source: {{ settings.get('mod_status_conf', 'salt://apache/mod_status.conf') }}
    - template: {{ settings.get('template_engine', 'jinja') }}
```

Any default values used in the Formula must also be documented in the `pillar.example` file in the root of the repository. Comments should be used liberally to explain the intent of each configuration value. In addition, users should be able copy-and-paste the contents of this file into their own Pillar to make any desired changes.

### Scripting

Remember that both State files and Pillar files can easily call out to Salt `execution modules` and have access to all the system grains as well.

```jinja
{% if '/storage' in salt['mount.active']() %}
/usr/local/etc/myfile.conf:
  file:
    - symlink
    - target: /storage/myfile.conf
{% endif %}
```

Jinja macros to encapsulate logic or conditionals are discouraged in favor of `writing custom execution modules` in Python.

### Repository structure

A basic Formula repository should have the following layout:

```
foo-formula
  |-- foo/
  |   |-- map.jinja
  |   |-- init.sls
  |   `-- bar.sls
  |-- CHANGELOG.rst
  |-- LICENSE
  `-- pillar.example
     |-- README.rst
        `-- VERSION
```

**See also:**

`template-formula`

The `template-formula` repository has a pre-built layout that serves as the basic structure for a new formula repository. Just copy the files from there and edit them.
README.rst

The README should detail each available .sls file by explaining what it does, whether it has any dependencies on other formulas, whether it has a target platform, and any other installation or usage instructions or tips.

A sample skeleton for the README.rst file:

```===
foo
===

Install and configure the FOO service.

.. note::
   See the full `Salt Formulas installation and usage instructions <http://docs.saltstack.com/en/latest/topics/development/conventions/formulas.html>`_.
```

Available states
================

.. contents::
   :local:

   `foo`
   -------
   Install the `foo` package and enable the service.

   `foo.bar`
   ---------
   Install the `bar` package.

CHANGELOG.rst

The CHANGELOG.rst file should detail the individual versions, their release date and a set of bullet points for each version highlighting the overall changes in a given version of the formula.

A sample skeleton for the CHANGELOG.rst file:

CHANGELOG.rst:

```
foo formula
============

0.0.2 (2013-01-01)
- Re-organized formula file layout
- Fixed filename used for upstart logger template
- Allow for pillar message to have default if none specified
```

Versioning

Formula are versioned according to Semantic Versioning, `http://semver.org/`.
Note: Given a version number MAJOR.MINOR.PATCH, increment the:

1. MAJOR version when you make incompatible API changes,
2. MINOR version when you add functionality in a backwards-compatible manner, and
3. PATCH version when you make backwards-compatible bug fixes.

Additional labels for pre-release and build metadata are available as extensions to the MAJOR.MINOR.PATCH format.

Formula versions are tracked using Git tags as well as the VERSION file in the formula repository. The VERSION file should contain the currently released version of the particular formula.

Testing Formulas

A smoke-test for invalid Jinja, invalid YAML, or an invalid Salt state structure can be performed by with the `state.show_sls` function:

```
salt '*' state.show_sls apache
```

Salt Formulas can then be tested by running each `.sls` file via `state.sls` and checking the output for the success or failure of each state in the Formula. This should be done for each supported platform.

34.24.3 SaltStack Packaging Guide

Since Salt provides a powerful toolkit for system management and automation, the package can be split into a number of sub-tools. While packaging Salt as a single package containing all components is perfectly acceptable, the split packages should follow this convention.

Patching Salt For Distributions

The occasion may arise where Salt source and default configurations may need to be patched. It is preferable if Salt is only patched to include platform specific additions or to fix release time bugs. It is preferable that configuration settings and operations remain in the default state, as changes here lowers the user experience for users moving across distributions.

In the event where a packager finds a need to change the default configuration it is advised to add the files to the master.d or minion.d directories.

Source Files

Release packages should always be built from the source tarball distributed via pypi. Release packages should NEVER use a git checkout as the source for distribution.

Single Package

Shipping Salt as a single package, where the minion, master, and all tools are together is perfectly acceptable and practiced by distributions such as FreeBSD.
Split Package

Salt should always be split in a standard way, with standard dependencies, this lowers cross distribution confusion about what components are going to be shipped with specific packages. These packages can be defined from the Salt Source as of Salt 2014.1.0:

Salt Common

The `salt-common` or `salt` package should contain the files provided by the salt python package, or all files distributed from the `salt/` directory in the source distribution packages. The documentation contained under the `doc/` directory can be a part of this package but splitting out a doc package is preferred. Since salt-call is the entry point to utilize the libs and is useful for all salt packages it is included in the `salt-common` package.

Name

- `salt` OR `salt-common`

Files

- `salt/*`
- `man/salt.7`
- `scripts/salt-call`
- `tests/*`
- `man/salt-call.1`

Depends

- `Python 2.6-2.7`
- `PyYAML`
- `jinja2`

Salt Master

The `salt-master` package contains the applicable scripts, related man pages and init information for the given platform.

Name

- `salt-master`

Files

- `scripts/salt-master`
- `scripts/salt`
- `scripts/salt-run`
- `scripts/salt-key`
- `scripts/salt-cp`
• pkg/<master init data>
• man/salt.1
• man/salt-master.1
• man/salt-run.1
• man/salt-key.1
• man/salt-cp.1
• conf/master

Depends

• Salt Common
• ZeroMQ >= 3.2
• PyZMQ >= 2.10
• PyCrypto
• M2Crypto
• Python MessagePack (Messagepack C lib, or msgpack-pure)

Salt Syndic

The Salt Syndic package can be rolled completely into the Salt Master package. Platforms which start services as part of the package deployment need to maintain a separate salt-syndic package (primarily Debian based platforms). The Syndic may optionally not depend on the anything more than the Salt Master since the master will bring in all needed dependencies, but fall back to the platform specific packaging guidelines.

Name

• salt-syndic

Files

• scripts/salt-syndic
• pkg/<syndic init data>
• man/salt-syndic.1

Depends

• Salt Common
• Salt Master
• ZeroMQ >= 3.2
• PyZMQ >= 2.10
• PyCrypto
• M2Crypto
• Python MessagePack (Messagepack C lib, or msgpack-pure)

Salt Minion

The Minion is a standalone package and should not be split beyond the salt-minion and salt-common packages.

Name

• salt-minion

Files

• scripts/salt-minion
• pkg/<minion init data>
• man/salt-minion.1
• conf/minion

Depends

• Salt Common
• ZeroMQ >= 3.2
• PyZMQ >= 2.10
• PyCrypto
• M2Crypto
• Python MessagePack (Messagepack C lib, or msgpack-pure)

Salt SSH

Since Salt SSH does not require the same dependencies as the minion and master, it should be split out.

Name

• salt-ssh

Files

• scripts/salt-ssh
• man/salt-ssh.1
• conf/cloud*

Depends

• Salt Common
• Python MessagePack (Messagepack C lib, or msgpack-pure)
Salt Cloud

As of Salt 2014.1.0 Salt Cloud is included in the same repo as Salt. This can be split out into a separate package or it can be included in the salt-master package.

Name

- `salt-cloud`

Files

- `scripts/salt-cloud`
- `man/salt-cloud.1`

Depends

- `Salt Common`
- `apache libcloud >= 0.14.0`

Salt Doc

The documentation package is very distribution optional. A completely split package will split out the documentation, but some platform conventions do not prefer this. If the documentation is not split out, it should be included with the `Salt Common` package.

Name

- `salt-doc`

Files

- `doc/*`

Optional Depends

- `Salt Common`
- `Python Sphinx`
- `Make`

34.24.4 Salt Release Process

The goal for Salt projects is to cut a new feature release every four to six weeks. This document outlines the process for these releases, and the subsequent bug fix releases which follow.
Feature Release Process

When a new release is ready to be cut, the person responsible for cutting the release will follow the following steps (written using the 0.16 release as an example):

1. All open issues on the release milestone should be moved to the next release milestone. (e.g. from the 0.16 milestone to the 0.17 milestone)
2. Release notes should be created documenting the major new features and bugfixes in the release.
3. Create an annotated tag with only the major and minor version numbers, preceded by the letter v. (e.g. v0.16) This tag will reside on the develop branch.
4. Create a branch for the new release, using only the major and minor version numbers. (e.g. 0.16)
5. On this new branch, create an annotated tag for the first revision release, which is generally a release candidate. It should be preceded by the letter v. (e.g. v0.16.0RC)
6. The release should be packaged from this annotated tag and uploaded to PyPI as well as the GitHub releases page for this tag.
7. The packagers should be notified on the salt-packagers mailing list so they can create packages for all the major operating systems. (note that release candidates should go in the testing repositories)
8. After the packagers have been given a few days to compile the packages, the release is announced on the salt-users mailing list.
9. Log into RTD and add the new release there. (Have to do it manually)

Maintenance and Bugfix Releases

Once a release has been cut, regular cherry-picking sessions should begin to cherry-pick any bugfixes from the develop branch to the release branch (e.g. 0.16). Once major bugs have been fixes and cherry-picked, a bugfix release can be cut:

1. On the release branch (i.e. 0.16), create an annotated tag for the revision release. It should be preceded by the letter v. (e.g. v0.16.2) Release candidates are unnecessary for bugfix releases.
2. The release should be packaged from this annotated tag and uploaded to PyPI.
3. The packagers should be notified on the salt-packagers mailing list so they can create packages for all the major operating systems.
4. After the packagers have been given a few days to compile the packages, the release is announced on the salt-users mailing list.

Cherry-Picking Process for Bugfixes

Bugfixes should be made on the develop branch. If the bug also applies to the current release branch, then on the pull request against develop, the user should mention @basep1 and ask for the pull request to be cherry-picked. If it is verified that the fix is a bugfix, then the Bugfix -- Cherry-Pick label will be applied to the pull request. When those commits are cherry-picked, the label will be switched to the Bugfix -- [Done] Cherry-Pick label. This allows easy recognition of which pull requests have been cherry-picked, and which are still pending to be cherry-picked. All cherry-picked commits will be present in the next release.

Features will not be cherry-picked, and will be present in the next feature release.
34.24.5 Salt Coding Style

Salt is developed with a certain coding style, while the style is dominantly PEP 8 it is not completely PEP 8. It is also noteworthy that a few development techniques are also employed which should be adhered to. In the end, the code is made to be “Salty”.

Most importantly though, we will accept code that violates the coding style and KINDLY ask the contributor to fix it, or go ahead and fix the code on behalf of the contributor. Coding style is NEVER grounds to reject code contributions, and is never grounds to talk down to another member of the community (There are no grounds to treat others without respect, especially people working to improve Salt)!!

Linting

Most Salt style conventions are codified in Salt's .pylintrc file. This file is found in the root of the Salt project and can be passed as an argument to the pylint program as follows:

```
pylint --rcfile=/path/to/salt/.pylintrc salt/dir/to/lint
```

Strings

Salt follows a few rules when formatting strings:

Single Quotes

In Salt, all strings use single quotes unless there is a good reason not to. This means that docstrings use single quotes, standard strings use single quotes etc.:

```python
def foo():
    '''
    A function that does things
    '''
    name = 'A name'
    return name
```

Formatting Strings

All strings which require formatting should use the `format` string method:

```python
data = 'some text'
more = '{0} and then some'.format(data)
```

Make sure to use indices or identifiers in the format brackets, since empty brackets are not supported by python 2.6. Please do NOT use printf formatting.

Docstring Conventions

Docstrings should always add a newline, docutils takes care of the new line and it makes the code cleaner and more vertical:

GOOD:
def bar():
    
    Here lies a docstring with a newline after the quotes and is the salty way to handle it! Vertical code is the way to go!
    
    return

BAD:

def baz():
    
    '''This is not ok!!'''
    
    return

When adding a new function or state, where possible try to use a `versionadded` directive to denote when the function or state was added.

def new_func(msg=' '):
    
    .. versionadded:: 0.16.0

    Prints what was passed to the function.

    msg : None
        The string to be printed.
    
    print msg

If you are uncertain what version should be used, either consult a core developer in IRC or bring this up when opening your pull request and a core developer will add the proper version once your pull request has been merged. Bugfixes will be available in a bugfix release (i.e. 0.17.1, the first bugfix release for 0.17.0), while new features are held for feature releases, and this will affect what version number should be used in the `versionadded` directive.

Similar to the above, when an existing function or state is modified (for example, when an argument is added), then under the explanation of that new argument a `versionadded` directive should be used to note the version in which the new argument was added. If an argument's function changes significantly, the `versionchanged` directive can be used to clarify this:

def new_func(msg=' ', signature=' '):
    
    .. versionadded:: 0.16.0

    Prints what was passed to the function.

    msg : None
        The string to be printed. Will be prepended with 'Greetings! '.
    
    .. versionchanged:: 0.17.1

    signature : None
        An optional signature.
    
    .. versionadded 0.17.0
    
    print 'Greetings! {0}\n\n{1}'.format(msg, signature)
Dictionaries

Dictionaries should be initialized using {} instead of dict().
See here for an in-depth discussion of this topic.

Imports

Salt code prefers importing modules and not explicit functions. This is both a style and functional preference. The functional preference originates around the fact that the module import system used by pluggable modules will include callable objects (functions) that exist in the direct module namespace. This is not only messy, but may unintentionally expose code python libs to the Salt interface and pose a security problem.

To say this more directly with an example, this is GOOD:

```python
import os
def minion_path():
    path = os.path.join(self.opts['cachedir'], 'minions')
    return path
```

This on the other hand is DISCOURAGED:

```python
from os.path import join
def minion_path():
    path = join(self.opts['cachedir'], 'minions')
    return path
```

The time when this is changed is for importing exceptions, generally directly importing exceptions is preferred:

This is a good way to import exceptions:

```python
from salt.exceptions import CommandExecutionError
```

Absolute Imports

Although absolute imports seems like an awesome idea, please do not use it. Extra care would be necessary all over salt's code in order for absolute imports to work as supposed. Believe it, it has been tried before and, as a tried example, by renaming salt.modules.sysmod to salt.modules.sys, all other salt modules which needed to import sys would have to also import absolute_import, which should be avoided.

Vertical is Better

When writing Salt code, vertical code is generally preferred. This is not a hard rule but more of a guideline. As PEP 8 specifies, Salt code should not exceed 79 characters on a line, but it is preferred to separate code out into more newlines in some cases for better readability:

```python
import os

os.chmod(
    os.path.join(self.opts['sock_dir'],
        'minion_event_pub.ipc'),
    34.24)
```
Where there are more line breaks, this is also apparent when constructing a function with many arguments, something very common in state functions for instance:

```python
def managed(name,
            source=None,
            source_hash='',
            user=None,
            group=None,
            mode=None,
            template=None,
            makedirs=False,
            context=None,
            replace=True,
            defaults=None,
            env=None,
            backup='',
            **kwargs):
```

**Note:** Making function and class definitions vertical is only required if the arguments are longer than 80 characters. Otherwise, the formatting is optional and both are acceptable.

---

**Line Length**

For function definitions and function calls, Salt adheres to the PEP-8 specification of at most 80 characters per line. Non function definitions or function calls, please adopt a soft limit of 120 characters per line. If breaking the line reduces the code readability, don’t break it. Still, try to avoid passing that 120 characters limit and remember, vertical is better... unless it isn’t

---

**Indenting**

Some confusion exists in the python world about indenting things like function calls, the above examples use 8 spaces when indenting comma-delimited constructs.

The confusion arises because the pep8 program INCORRECTLY flags this as wrong, where PEP 8, the document, cites only using 4 spaces here as wrong, as it doesn't differentiate from a new indent level.

Right:

```python
def managed(name,
            source=None,
            source_hash='',
            user=None)
```

WRONG:

```python
def managed(name,
            source=None,
            source_hash='',
            user=None)
```
Lining up the indent is also correct:

```python
def managed(name,
source=None,
source_hash=''
user=None)
```

This also applies to function calls and other hanging indents.

pep8 and Flake8 (and, by extension, the vim plugin Syntastic) will complain about the double indent for hanging indents. This is a known conflict between pep8 (the script) and the actual PEP 8 standard. It is recommended that this particular warning be ignored with the following lines in ~/.config/flake8:

```plaintext
[flake8]
ignore = E226,E241,E242,E126
```

Make sure your Flake8/pep8 are up to date. The first three errors are ignored by default and are present here to keep the behavior the same. This will also work for pep8 without the Flake8 wrapper -- just replace all instances of `flake8` with `pep8`, including the filename.

**Code Churn**

Many pull requests have been submitted that only churn code in the name of PEP 8. Code churn is a leading source of bugs and is strongly discouraged. While style fixes are encouraged they should be isolated to a single file per commit, and the changes should be legitimate, if there are any questions about whether a style change is legitimate please reference this document and the official PEP 8 (http://legacy.python.org/dev/peps/pep-0008/) document before changing code. Many claims that a change is PEP 8 have been invalid, please double check before committing fixes.
See the version numbers page for more information about the version numbering scheme.

### 35.1 Latest Stable Release

*Salt 2015.8.0 Release Notes - Codename Beryllium*

### 35.2 Previous Releases

#### 35.2.1 Salt 2015.8.0 Release Notes - Codename Beryllium

**2015.8.0 Detailed Change List**

Extended changelog courtesy of Todd Stansell ([https://github.com/tjstansell/salt-changelogs](https://github.com/tjstansell/salt-changelogs))

*Generated at: 2015-09-09T18:15:43Z*

This list includes all pull requests merged into the 2015.8 branch between the forking of the branch from develop and the release of 12015.8.0.

**Statistics:**

- Total Merges: 682
- Total Issue references: 342
- Total PR references: 866

**Pull Requests:**

- #26993: *(whiteinge)* Backport #26975
- #26970: *(cachedout)* Revert `"better path query parsing in fileserver"
- #26980: *(terminalmage)* Use human-readable cachedirs for gitfs-backed winrepo
- #26969: *(TheBigBear)* URL of salt windows downloads has changed
- #26968: *(TheBigBear)* URL of salt windows downloads has changed
- #26958: *(s0undt3ch)* Bradthuber bootstrap command line help doc update
- #26949: *(rallytime)* Back-port #25148 to 2015.8
- #26914: (cro) Add salt-proxy script and manpage to setup.py so they will get installed.
- #26909: (terminalmage) Don’t try to git clone from /tmp on Windows
- #26910: (s0undt3ch) Sometimes the event system is just too fast
- #26905: (s0undt3ch) Exit the loop if run_once is true
- #26897: (msteed) spm file hash part dekus
- #26900: (s0undt3ch) If no tag is passed, don’t actually subscribe to anything.
- #26880: (s0undt3ch) Restore backwards compatibility to salt.utils.event
- #26896: (msteed) spm remove: use pkgfiles to calculate file hashes
- #26891: (jtand) Fixed an unboundlocalerror
- #26892: (cachedout) Make the testing ioloop the current one
- #26886: (jtand) Gets the azure version correctly on python-azure 1.0.0
- #26870: (rallytime) Back-port #26834 to 2015.8
- #26865: (dmurphy18) Fix apt preferences for apts, repos for pbuilder building for Debian
- #26873: (terminalmage) Properly handle getting local config values in older git versions
- #26869: (rallytime) Fix provider --> driver change for salt-cloud lxc
- #26858: (terminalmage) Fix a couple version checks for git state and execution module
- #26853: (UtahDave) Fix salt-cloud on windows
- #26852: (basepi) [2015.8] Only reference msgpack if it imported successfully
- #26835: (terminalmage) Backport #26572 to 2015.8
- #26836: (jacobhammons) Added rst source for salt-proxy man page, added build and copy lines ...
- #26818: (terminalmage) Support empty repositories in git.latest
- #26819: (rallytime) Make sure we’re calling _validate_name in the correct place in 2015.8 Linode driver
- #26841: (l2ol33rt) Fix reference before assignment in sqs engine
- #26822: (terminalmage) Add some missing imports for masterless winrepo
- #26831: (basepi) [2015.8] Merge forward from 2015.5 to 2015.8
- #26826: (techhat) Pass a package name to unregister_file()
- #26757: (cachedout) Fix various filehandle leaks
- #26816: (gtmanfred) rev defaults to HEAD
- #26801: (jacobhammons) Added doc for dockerng minion configuration options
- #26808: (anlutro) Fix git init argument formatting
- #26807: (terminalmage) Move salt.utils.itersplit() to salt.utils.iterutils.split()
- #26796: (jacobhammons) Add doc for __states__
- #26764: (sjorge) salt.utils.is_proxy() is no longer always true on SunOS/Illumos/SmartOS
- #26772: (sjorge) pull in smartos `virt` module from develop
- #26726: (terminalmage) Redact HTTPS Basic Auth in states/funcs which deal with git remotes
- #26769: (terminalmage) Use --track to set tracking branch on older git versions
• #26765: (basepi) [2015.8] Merge forward from 2015.5 to 2015.8
• #26761: (sjorge) fix SPM paths on smartos/illumos esky
• #26751: (terminalmage) Fixes for masterless winrepo
• #26745: (rallytime) Make sure pyrax configs are in place before checking for deps
• #26746: (rallytime) Make sure nova configs are set before checking for dependencies
• #26750: (basepi) [2015.8] Add __utils__ to state modules
• #26752: (cro) Fix typo in some diagram labels
• #26747: (basepi) [2015.8] Add __states__ to state modules, for cross-calling states
• #26744: (basepi) [2015.8] Fix issue from #26717
• #26737: (dmurphy18) Fix to allow for package naming other than just salt
• #26742: (rallytime) Only warn about vsphere deprecation if vsphere is configured
• #26733: (sjorge) Refactor of smartos_vmadm module
• #26735: (s0und3ch) Add .hg and .cvs to spm_build_exclude
• #26720: (UtahDave) Updates for winrepo in 2015.8 to support jinja, while maintaining backwards compat
• #26719: (jodv) Backport 26532 to 2015.8
• #26721: (rallytime) Linode Driver Cleanup
• #26707: (techhat) Add top_level_dir to FORMULAs
• #26723: (s0und3ch) Handle SPM paths in the setup script
• #26717: (basepi) [2015.8] Revert loader changes from #26645
• #26712: (techhat) Move SPM paths around
• #26680: (TheBigBear) add more python libs info in `--versions-report`
• #26716: (terminalmage) Allow git identity to be a list
• #26691: (garethgreenaway) Fixes to ipset module for 2015.8
• #26701: (kev009) Ignore the first element of kern.disks split, which is the sysctl name (new disks grain)
• #26678: (terminalmage) Restructure git.latest rewrite to work better when following HEAD
• #26679: (rallytime) Back-port #26661 to 2015.8
• #26684: (techhat) Add reactor formulas to spm
• #26682: (basepi) [2015.8] Merge forward from 2015.5 to 2015.8
• #26671: (rallytime) Warn users if cloud driver dependencies are missing.
• #26674: (rallytime) Back-port #26583 to 2015.8
• #26670: (techhat) Set up SPM to install -conf packages
• #26657: (jfindlay) top file compilation fixes
• #26659: (TheBigBear) minor doc edits - spelling
• #26654: (jfindlay) merge `#26650`
• #26657: (jtand) Added git version check to git module
• #26649: (twangboy) Fixed Lint for real in win_repo.py

35.2. Previous Releases 2019
#26608: (jacobhammons) 2015.8.0 release notes and doc/conf.py updates

#26646: (basepi) [2015.8] Merge forward from 2015.5 to 2015.8

#26645: (rallytime) Back-port #26390 to 2015.8

#26642: (twangboy) Added function to render winrepo Jinja

#26625: (twangboy) Correctly detect packages with no version, docs

#26575: (msteed) Update spm for integration into raas

#26635: (cro) Don't report windows as a proxy.

#26622: (rallytime) [2015.8] Also add -Z to script args for cloud tests

#26619: (rallytime) Apply cloud test fixes from 2015.5 to 2015.8

#26603: (terminalmage) Fixes for git.latest, git module integration tests, etc.

#26577: (basepi) [2015.8] Merge forward from 2015.5 to 2015.8

#26534: (cachedout) Bump required Tornado version to 4.2.1

#26566: (cachedout) Don't stacktrace trying to publish without a master

#26541: (terminalmage) Make winrepo execution module use the same code as the runner

#26530: (basepi) [2015.8] Merge forward from 2015.5 to 2015.8

#26570: (cachedout) Fix haproxy docs to be valid

#26562: (cachedout) Fix suprious error message with systemd-detect

#26557: (jfindlay) add docs to #26550

#26544: (nmadhok) Do not raise KeyError when calling avail_images if VM/template is in disconnected state

#26501: (terminalmage) Update git_pillar docs, add git.list_worktrees function

#26521: (terminalmage) Work around upstream git bug when cloning repo as root

#26518: (krak3n) Fix for "#25492"_

#26514: (evverx) Unmask a runtime masked services too

#26529: (mnalt) bugfix: fix service.enable for missing rc.conf

#26516: (techhat) Move more path operations into SPM loader

#26533: (cachedout) Fix too aggressive even init check

#26522: (cro) Do not load package provider if its not a proxy

#26531: (cachedout) Fix failing event tests and modify event init

#26433: (cro) Add support for default proxy config options, change default location of proxy config and log to /etc/salt/proxy and /var/log/proxy

#26504: (nmadhok) [Backport] Adding ability to specify the virtual hardware version when creating VM

#26517: (cachedout) Better fix for opensuse tornado httpclient

#26479: (rallytime) Don't allow VMs with duplicate names to be created in EC2/AWS

#26488: (cachedout) Don't pass unsupported kwarg to tornado

#26451: (terminalmage) Use `rpm -qa` instead of repoquery to list installed packages

#26491: (jacobhammons) doc site css fix for tiny fonts that appeared in code or pre tags in ...
• #26442: (rallytime) Hide API Key from debug logs for Linode Driver
• #26441: (rallytime) Refactor a few linode functions to be useful with salt-cloud command
• #26485: (s0undt3ch) One more missed typo
• #26495: (basepi) [2015.8] Merge forward from 2015.5 to 2015.8
• #26492: (cachedout) Fix schedule test error on py26
• #26489: (cachedout) Fixing more tarfile tests on py2.6
• #26475: (cachedout) Better object checking on asyncreq cleanup
• #26477: (cachedout) Fix integration.modules.git.GitModuleTest.test_archive on py26
• #26469: (jtand) --annotate and --message aren't valid options in older versions of git.
• #26439: (basepi) [2015.8] Merge forward from 2015.5 to 2015.8
• #26464: (rallytime) Back-port #26456 to 2015.8
• #26463: (rallytime) Back-port #26455 to 2015.8
• #26449: (s0undt3ch) The CLI options are not meant to include underscores.
• #26270: (sjorge) salt.modules.network now supports SmartOS and SunOS < Solaris 11
• #26436: (TheBigBear) minor edits
• #26410: (basepi) [2015.8] Merge forward from 2015.5 to 2015.8
• #26427: (anlutro) git.latest with no rev: fix concatenation error (NoneType and str)
• #26307: (cachedout) Fix bug in top file ordering
• #26428: (cro) Update docs to reflect new pillar structure
• #26429: (cachedout) Add release note regarding tcp transport on freebsd
• #26418: (driskell) Fix forward-merged caching from 2015.5 into 2015.8 to be compatible with the new match_func
• #26252: (DmitryKuzmenko) Issues/24048 http client 2015.8
• #26413: (evverx) Fix service.[start,restart,reload,force-reload] for masked services
• #26393: (dmurphy18) Added option parameters to make_repo to allow for configuration settings
• #26422: (TheBigBear) no dots in SLS filename __AND__ any directories (incl git repos)
• #26323: (0xf10e) Fix Credentials used in glance Exec Module
• #26341: (terminalmage) Rewrite git state and execution modules
• #26419: (terminalmage) Only use pygit2.errors if it exists
• #26423: (ellasp) doc - Correct function name for peer configuration
• #26401: (cachedout) Adapt proxy minion to tornado (w/lint)
• #26400: (rallytime) Back-port #26318 to 2015.8
• #26397: (s0undt3ch) A single isinstance() check for all types is enough
• #26385: (gtmanfred) don't require volume endpoint in nova driver
• #26287: (techhat) Break out SPM components into loaders
• #26384: (TheBigBear) Fix shell quoting for cmd.run
• #26391: (rallytime) Back-port #26367 to 2015.8
• #26383: (rallytime) Allow the creation of a VM without a profile
• #26375: (s0undt3ch) [2015.8] Schema DictItem required attribute fixes
• #26363: (garethgreenaway) Fixes to mount state 2015.8
• #26347: (0xf10e) Load `pkgng` as `pkg` on FreeBSD 9 when providers:pkg == `pkgng`
• #26361: (TronPaul) sign security token
• #26346: (TronPaul) Fix s3 using IAM credentials
• #26331: (mnalt) fix bug in sysrc to allow for empty rc variables
• #26334: (rallytime) Call salt.utils.cloud.bootstrap in GCE Driver provisioning
• #26308: (dmurphy18) Support for environment overrides building packages
• #26279: (TheScriptSage) Merge changes for pull `#26083`_ and pull `#25632`_ into 2015.8
• #26224: (cachedout) Cleanup of a few cases to move to salt.utils.fopen
• #26260: (nmadhok) Correct spelling of integration in docs
• #26226: (rallytime) Fix `#25463`_
• #26248: (nmadhok) Initial commit of unit tests for vmware cloud driver
• #26228: (basepi) [2015.8] Merge forward from 2015.5 to 2015.8
• #26244: (nmadhok) Backport additions to VMware cloud driver from develop to 2015.8 branch
• #26235: (sjorge) salt.utils.is_smartos_zone, inverse of is_smartos_globalzone
• #26221: (sjorge) SmartOS grain fixes
• #26218: (terminalmage) Add warning about file.recurse unicode errors with vim swap files.
• #26214: (rallytime) Back-port #24878 to 2015.8
• #26211: (techhat) Move SPM to its own directory
• #26197: (TronPaul) Fix GitFS when whitelisting base
• #26200: (anlutro) Make it possible to run salt-cloud as current user
• #26201: (kev009) Avoid VBOX storage emulation bugs in FreeBSD disks grain
• #26188: (basepi) [2015.8] Merge forward from 2015.5 to 2015.8
• #26194: (basepi) Allow virtual grains to be generated even if virt-what is not available
• #26176: (rallytime) Back-port #26165 to 2015.8
• #26169: (terminalmage) Fix attribute error in gitsf's find_file functions
• #26170: (nmadhok) [Backport] Make sure variable is a dictionary before popping something from it.
• #26143: (nmadhok) VMware cloud driver fixes [forward port from 2015.5 into 2015.8]
• #26173: (jacobhammons) Updates to cloud docs for the provider > driver change
• #26125: (evverx) Use timedatectl set-timezone to tzsetting if available
• #26145: (sjorge) smartos_imgadm cleanup
• #26148: (terminalmage) Refactor winrepo support
• #26128: (sjorge) imgadm.avail should return multiple results
• #26109: (jfindlay) fix quote indent
• #26089: (anlutro) User state/module: fix coercion of None into string `"None" in GECOS
• #26081: (cachedout) Move invocation routine up
• #26086: (rallytime) Back-port #26019 to 2015.8
• #26087: (rallytime) Back-port #26059 to 2015.8
• #26052: (tjand) Rh_ip fix
• #26078: (cachedout) Fix missing key in error return
• #26074: (basepi) [2015.8] Re-apply #25358 in 2015.8
• #26069: (jfindlay) fix win_firewall.delete_rule
• #26066: (s0und3ch) [2015.8] Update to latest bootstrap stable release v2015.06.08
• #26049: (basepi) [2015.8] Merge forward from 2015.5 to 2015.8
• #26026: (anlutro) Fix htpasswd result false positive in test mode
• #26037: (rallytime) Back-port #25489 to 2015.8
• #26004: (techhat) Allow updating a single SPM repo at a time
• #26012: (cachedout) Merge kwargs into opts for tcp client
• #26007: (anlutro) file.managed: wrap os.remove in if isfile, don't remove on success
• #26009: (terminalmage) Add winrepo and dockerng information to 2015.8.0 release notes
• #26006: (basepi) Revert #25727 in favor of #25645
• #26001: (cachedout) Fix failing tests
• #25978: (anlutro) Correct service state changes in test mode
• #25982: (sjorge) salt.modules.smartos_* limit to global zone only
• #25989: (rallytime) Back-port #25832 to 2015.8
• #25988: (cachedout) Move #25642 to 2015.8
• #25999: (s0und3ch) Include subschema defaults
• #25997: (s0und3ch) Allow getting a defaults dictionary from schema defaults
• #25979: (basepi) [2015.8] Merge forward from 2015.5 to 2015.8
• #25902: (basepi) [2015.8] Merge forward from 2015.5 to 2015.8
• #25956: (anlutro) Fix user argument to cron functions
• #25946: (sjorge) Fix for salt.utils.decorators under esky
• #25957: (anlutro) Remove temporary file after file.managed with checkcmd
• #25874: (rallytime) Back-port #25668 to 2015.8
• #25929: (sjorge) salt.module.pkgin's __virtual__() should not return None if pkg_info is not present
• #25952: (garethgreenaway) Log when event.fire and event.fire_master fail 2015.8
• #25944: (sjorge) Smartos libcrypto nonesky fix
• #25906: (dmurphy18) Cherry-pick of pkgbuild changes from develop branch
• #25925: (sjorge) Create default log location in smartos esky buildscript
• #25928: (cachedout) Fix stacktrace for non-existant states
• #25922: (jackson) Correct max_wait -> max_auth_wait in MultiMinion
• #25907: (rallytime) Back-port #25892 to 2015.8
• #25910: (terminalmage) Pass osarch to check_32()
• #25849: (basepi) Repress template error for GPG renderer (can't seek an OrderedDict)
• #25868: (rallytime) Back-port #25404 to 2015.8
• #25896: (cachedout) Lint
• #25876: (jackson) Fixes for 2015.8
• #25867: (rallytime) Back-port #25370 to 2015.8
• #25845: (jacobhammons) updated versionadded
• #25836: (jackson) Keep track of SyncWrapper's IOLoop usage
• #25859: (0xf10e) warn_until(Carbon,...) instead of Boron
• #25505: (0xf10e) Glance state module for 2015.8 "Beryllium"
• #25843: (jtand) Fixed a lint error in parsers.py
• #25835: (techhat) spm update_repo doesn't always require arguments
• #25837: (jacobhammons) regenerated man pages
• #25830: (sjorge) Loading of libcrypto on smartos esky fixed
• #25808: (jfindlay) add highstate opts to config/__init__.py, update docs
• #25820: (sjorge) Prerequisite to fix the smartos libcrypto loading
• #25781: (anlutro) Fix iptables.build_rule
• #25764: (gtmanfred) allow use of cloudnetworks in ssh_interface
• #25736: (jfindlay) insert explicit formatter number
• #25742: (rallytime) Back-port #25731 to 2015.8
• #25741: (rallytime) Back-port #25727 to 2015.8
• #25712: (cachedout) Fix outputter for state.apply
• #25698: (rallytime) Back-port #25659 to 2015.8
• #25690: (anlutro) Fix highstate duration alignment (again)
• #25684: (davidjb) Fix doc around Include/Exclude for states
• #25549: (techhat) Switch Scaleway to salt.utils.cloud.bootstrap()
• #25667: (jfindlay) add 2015.8.0rc2 autogenerated changelog
• #25653: (anlutro) Properly align highstate duration sum
• #25663: (rallytime) Back-port #25638 to 2015.8
• #25639: (terminalmage) Don't do pre-flight check on git_pillar if it is not configured
• #25587: (cachedout) Fix prereq in salt.state
• #25628: (anlutro) Highstate output: show duration in seconds instead of milliseconds when appropriate
• #25631: (basepi) Remove trailing whitespace
- #25627: (basepi) [2015.8] Merge forward from 2015.5 to 2015.8
- #25626: (basepi) Fix the highstate outputer if `duration` is not present
- #25601: (terminalmage) Fix error message when local bin pkg path is not absolute
- #25595: (terminalmage) Bring git_pillar up to feature parity with gitfs
- #25619: (cachedout) Lint stateconf changes
- #25578: (davidjb) Allow parent relative includes in state files
- #25610: (s0undt3ch) [2015.8] Update the bootstrap script to latest release v2015.07.22
- #25599: (jfindlay) fix transport settings in #25596
- #25596: (jfindlay) Tcp test
- #25591: (garethgreenaway) Return data for scheduled jobs in 2015.8 default to True.
- #25588: (basepi) Fix some of the retcode work from #23105
- #25583: (jtand) Fixed lint error where pprint wasn't imported.
- #25572: (rallytime) Back-port #25570 to 2015.8
- #25575: (rallytime) Make Sure Scaleway driver works with deprecation paths
- #25564: (basepi) [2015.8] Merge forward from 2015.5 to 2015.8
- #25566: (techhat) Fix download process for SPM repo updates
- #25553: (techhat) Switch SoftLayer to salt.utils.cloud.bootstrap()
- #25552: (techhat) Update pricing for SoftlayerHW
- #25547: (techhat) Switch Parallels to salt.utils.cloud.bootstrap()
- #25548: (techhat) Switch Proxmox to salt.utils.cloud.bootstrap()
- #25543: (techhat) Switch GCE to salt.utils.cloud.bootstrap()
- #25546: (techhat) Switch CloudStack to salt.utils.cloud.bootstrap()
- #25558: (cachedout) Lint config_test
- #25515: (s0undt3ch) salt.utils.schema fixes
- #25514: (garethgreenaway) fixes to schedule.add documentation in 2015.8
- #25508: (s0undt3ch) [2015.8] Update bootstrap script to latest stable release, v2015.07.17
- #25501: (basepi) Add optional job end time to the local_cache returner
- #25491: (s0undt3ch) Let's call it for what it is!
- #25462: (rallytime) Wrap is_profile_configured calls in try/except block
- #25439: (rallytime) Reduce digital_ocean API call frequency
- #25451: (s0undt3ch) Salt-SSH Scan roster bugfixes (And Py3 support)
- #25449: (rizarowski) Exclude dotfiles and directories from minion key lists (Fixes `#25448`)
- #25421: (basepi) [2015.8] Merge forward from 2015.5 to 2015.8
- #25412: (basepi) [2015.8] Merge forward from 2015.5 to 2015.8
- #25415: (bechitold) [docs] declare YAML as code block
- #25407: (rallytime) Back-port #23236 to 2015.8
2026 Chapter 35. Release notes

- #25409: (rallytime) Back-port #24422 to 2015.8
- #25394: (rallytime) Back-port #25355 to 2015.8
- #25393: (rallytime) Back-port #25289 to 2015.8
- #25387: (cachedout) Lint #25319
- #25319: (ruzarowski) [cloud:EC2] Move SourceDest logic to _update_enis and add alias for delete_interface_on_terminate
- #25310: (anlutro) Add an ```is list``` test to the jinja environment
- #25264: (ruzarowski) Fix AttributeError in fileserver update_opts
- #25372: (rallytime) Don't stacktrace when provisioning instances with softlayer* drivers
- #25315: (ruzarowski) [cloud:EC2] Move handling of AssociatePublicIpAddress to associate_eip/allocate_new_eip logic depending on value type
- #25312: (ruzarowski) [cloud:EC2] Introduce eni Name property to set name tag value after its creation
- #25311: (ruzarowski) [cloud:EC2] Add ability to attach an existing eni
- #25280: (rallytime) Remove deprecation warnings for Beryllium
- #25329: (twangboy) Fixed some documentation errors
- #25300: (s0undt3ch) Fix ordering issue & Added requirements support
- #25283: (jfndlay) ensure ret is always defined
- #25252: (jfndlay) make args optional with default values in win_firewall.delete_rule
- #25257: (notpeter) Document SourceDestCheck added in #25242.
- #25298: (twangboy) Continue if profile not found
- #25296: (twangboy) Fixed file.comment for windows
- #25254: (rallytime) Change version added/changed references from Beryllium to 2015.8.0
- #25285: (thusoy) Remove error logging of missing victorops keys
- #25266: (ruzarowski) cloud: EC2 eni property SourceDestCheck is a AttributeBooleanValue
- #25216: (jfndlay) replace shell code with native python code
- #25278: (rallytime) Don't require size for all cloud drivers when checking profile configs
- #25271: (basepi) [2015.8] Merge forward from 2015.5 to 2015.8
- #25263: (techhat) Allow non-standard HTTP requests on tornado
- #25253: (s0undt3ch) Remove the deprecation warning. The driver has been renamed.
- #25248: (techhat) Do not resize while iterating
- #25244: (rallytime) Remove parted deprecations and fix failing tests
- #25242: (ruzarowski) Make SourceDestCheck flag available to network interface definition
- #25226: (nmadhok) Backporting fix for issue `#25223` on 2015.8 branch
- #25234: (krak3n) Fix: Bug in boto_asg state argument passing to boto_asg module
- #25222: (rallytime) Back-port #25219 to 2015.8
- #25188: (rallytime) Use linode status descriptions instead of ints when logging status to CLI
- #25203: (s0undt3ch) Added DictConfig with tests & More tests
The 2015.8.0 feature release of Salt contains several major new features. As usual the release notes are not exhaustive and primarily include the most notable additions and improvements. Hundreds of bugs have been fixed and many modules have been substantially updated and added.

New SaltStack Installation Repositories

SaltStack now provides installation repositories for several platforms, with more to come. See the following links for instructions:

- Red Hat / CentOS 5, 6, 7
- Debian 8
- Windows
- FreeBSD

Send Event on State Completion

A *fire_event* global state keyword argument was added that allows any state to send an event upon completion. Useful for custom progress bars and checking in on long state runs. See *fire_event*.

ZeroMQ socket monitoring

If *zmq_monitor* is enabled, log all ZMQ events for socket monitoring purposes. Verbose, but useful.

SPM (Salt Package Manager)

Allows Salt formulas to be packaged for ease of deployment. See *spm*.

Specify a Single Environment for Top Files

A new *default_top* option was added to load the state top file from a single, specific environment, rather than merging top data across all environments. Additionally, new *top_file_merge_strategy* and *env_order* options were added for more control over top file merging. See *The Top File*. 

---

35.2. Previous Releases

---

2027
Tornado TCP Transport

Implemented a pure-TCP transport, in addition to ZeroMQ and RAET. The new transport uses Tornado, which allows Salt to use a standardized set of libraries for asynchronous behavior, which should greatly improve reliability and performance.

Note: Tornado is considered experimental in this release. The following known issues were being investigated at the time of release:

- TCP tests show performance degradation over time (issue 26051)
- TCP transport stacktrace on windows minion: Future exception was never retrieved (issue 25718)
- [freebsd] TCP transport not working in 2015.8.0rc3 (issue 26364)

Proxy Minion Enhancements

Proxy Minions have undergone a significant overhaul in 2015.8, see Proxy Minion Enhancements.

Core Changes

- Add system version info to versions_report, which appears in both salt --versions-report and salt '*' test.versions_report. Also added is an alias test.versions to test.versions_report (issue 21906)
- Add colorized console logging support. This is activated by using ‘%(colorlevel)s, %(colormsg)s, %(colorprocess)s, %(colorname)s’ in log_fmt_console in the config file for any of salt-master, salt-minion, and salt-cloud.

Git Pillar

The git external pillar has been rewritten to bring it up to feature parity with gitfs. Support for pygit2 has been added, bringing with it the ability to access authenticated repositories.

Using the new features will require updates to the git ext_pillar configuration, further details can be found in the pillar.git_pillar docs.

Salt Cloud Improvements

- Pricing data from several cloud providers (GCE, DigitalOcean, SoftLayer_HW, EC2)
- All cloud providers now use standardized bootstrapping code.
- Modified the Linode Salt Cloud driver to use Linode's native API instead of depending on apache-libcloud or linode-python.

Salt Cloud Changes

- Changed the default behavior of rename_on_destroy to be set to True in the EC2 and AWS drivers.
- Changed the default behavior of the EC2 and AWS drivers to always check for duplicate names of VMs before trying to create a new VM. Will now throw an error similarly to other salt-cloud drivers when trying to create a VM of the same name, even if the VM is in the terminated state.
When querying for VMs in `digital_ocean.py`, the number of VMs to include in a page was changed from 20 (default) to 200 to reduce the number of API calls to Digital Ocean.Ocean.

### State and Execution Module Improvements

- New and improved Docker state and execution modules (`state` and `execution module`).

### Git State and Execution Modules Rewritten

The git state and execution modules have gone through an extensive overhaul.

#### Changes in the `git.latest` State

- The `branch` argument has been added, allowing for a custom branch name to be used in the local checkout maintained by the `git.latest` state. This can be helpful in avoiding ambiguous refs in the local checkout when a tag is used as the `rev` argument. If no `branch` is specified, then the state uses the value of `rev` as the branch name.
- The `always_fetch` argument no longer has any effect, and will be removed in a future release. The state now detects whether or not a fetch is needed based on comparisons made between the local and remote repositories.
- The `force_fetch` argument has been added to force a fetch if the fetch is not a fast-forward (for instance, if someone has done a reset and force-pushed to the remote repository).
- The `remote_name` argument has been deprecated and renamed to `remote`.
- The `force` argument has been deprecated and renamed to `force_clone` to reduce ambiguity with the other `force` arguments.
- Using SHA1 hashes (full or shortened) in the `rev` argument is now properly supported.
- Non-fast-forward merges are now detected before the repository is updated, and the state will not update the repository if the change is not a fast-forward. Non-fast-forward updates must be overridden with the `force_reset` argument. If `force_reset` is set to `True`, the state will only reset the repository if it cannot be fast-forwarded. This is in contrast to the earlier behavior, in which a hard-reset would be performed every time the state was run if `force_reset` was set to `True`.
- A `git pull` is no longer performed by this state, dropped in favor of a fetch-and-merge (or fetch-and-reset) workflow.

**`git.config_unset` state added**  This state allows for configuration values (or entire keys) to be unset. See [here](#) for more information and example SLS.

**`git.config` State Renamed to `git.config_set`** To reduce confusion after the addition of `git.config_unset`, the `git.config` state has been renamed to `git.config_set`. The old config.get name will still work for a couple releases, allowing time for SLS files to be updated.

In addition, this state now supports managing multivar git configuration values. See [here](#) for more information and example SLS.

**Initial Support for Git Worktrees in Execution Module**  Several functions have been added to the execution module to manage `worktrees` (a feature new to Git 2.5.0). State support does not exist yet, but will follow soon.
New Functions in Git Execution Module

- `git.config_get_regexp`
- `git.config_unset`
- `git.is_worktree`
- `git.list_branches`
- `git.list_tags`
- `git.list_worktrees`
- `git.merge_base`
- `git.merge_tree`
- `git.rev_parse`
- `git.version`
- `git.worktree_rm`
- `git.worktree_add`
- `git.worktree_prune`

Changes to Functions in Git Execution Module

**git.add**

- `--verbose` is now implied when running the `git add` command, to provide a list of the files added in the return data.

**git.archive**

- Now returns `True` when the `git archive` command was successful, and otherwise raises an error.
- The `overwrite` argument has been added to prevent an existing archive from being overwritten by this function.
- The `fmt` argument has been deprecated and renamed to `format`.
- Trailing slash no longer implied in `prefix` argument, must be included if this argument is passed.

**git.checkout**

- The `rev` argument is now optional when using `-b` or `-B` in `opts`, allowing for a branch to be created (or reset) using HEAD as the starting point.

**git.clone**

- The `name` argument has been added to specify the name of the directory in which to clone the repository. If this option is specified, then the clone will be made within the directory specified by the `cwd`, instead of at that location.
- The `repository` argument has been deprecated and renamed to `url`. 

git.config_get

- The setting_name argument has been deprecated and renamed to key.
- The global argument has been added, to query the global git configuration
- The all argument has been added to return a list of all values for the specified key, allowing for all values in a multivar to be returned.
- The cwd argument is now optional if global is set to True

git.config_set

- The value(s) of the key being set are now returned
- The setting_name argument has been deprecated and renamed to key.
- The setting_value argument has been deprecated and renamed to value.
- The is_global argument has been deprecated and renamed to global.
- The multivar argument has been added to specify a list of values to set for the specified key. The value argument is not compatible with multivar.
- The add argument has been added to add a value to a key (this essentially just adds an --add to the git config command that is run to set the value).

git.fetch

- The force argument has been added to force the fetch when it is not a fast-forward. This could have been achieved in previous Salt versions by including --force in the opts argument, this argument is just for convenience and to match the usage of other functions with force arguments.
- The refspecs argument has been added to allow for one or more refspecs to be provided which override the one(s) specified by the remote.remote_name.fetch git configuration option.

git.ls_remote

- The repository argument has been deprecated and renamed to remote.
- The branch argument has been deprecated and renamed to ref.
- The opts argument has been added to allow for additional CLI options to be passed to the git ls-remote command.

git.merge

- The branch argument has been deprecated and renamed to rev.

git.status

- Return data has been changed from a list of lists to a dictionary containing lists of files in the modified, added, deleted, and untracked states.
**git.submodule**

- Added the `command` argument to allow for operations other than `update` to be run on submodules, and deprecated the `init` argument. To do a submodule update with `init=True` moving forward, use `command=update opts='--init'`.

- OpenStack Glance API V2 execution module
- Amazon VPC state module
- RallyDev execution module
- BambooHR execution module
- Stormpath execution, state modules
- Remove unused argument `timeout` in `jboss7.status`.
- Deprecate `enabled` argument in `pkgrepo.managed` in favor of `disabled`.
- Archive module changes: In the `archive.tar` and `archive.cmd_unzip` module functions, remove the arbitrary prefixing of the options string with `-`. An options string beginning with a `--long-option`, would have uncharacteristically needed its first `-` removed under the former scheme. Also, tar will parse its options differently if short options are used with or without a preceding `-`, so it is better to not confuse the user into thinking they’re using the non- `-` format, when really they are using the with- `-` format.

- Added `__states__` to state modules, for cross-calling states. This enables using existing states when writing custom states. See [cross calling states](#).

**Windows Improvements**

- Enhanced the windows minion silent installation with command line parameters to configure the salt master and minion name. See [Silent Installer Options](#).
- Improved user management with additional capabilities in the user module for Windows.
- Improved patch management with a new module for managing windows updates (`win_wua`).
- Turned on multi-processing by default for windows in minion configuration.

**Windows Software Repo Changes**

Several config options have been renamed to make their naming more consistent. For a list of the winrepo config options, see [here](#) for master config options, and [here](#) for configuration options for masterless Windows minions.

On the master, the `winrepo.update_git_repos` runner has been updated to use either `pygit2` or `GitPython` to checkout the git repositories containing repo data. If `pygit2` or `GitPython` is installed, existing winrepo git checkouts should be removed after upgrading to 2015.8.0, to allow them to be checked out again by running `winrepo.update_git_repos`.

This enhancement also brings new functionality, see the [Windows Software Repository](#) documentation for more information.

If neither `GitPython` nor `pygit2` are installed, then Salt will fall back to the pre-existing behavior for `winrepo.update_git_repos`, and a warning will be logged in the master log.

**Note:** Standalone Windows minions do not support the new `GitPython/pygit2` functionality, and will instead use the `git.latest` state to keep repositories up-to-date. More information on how to use the Windows Software Repo on a standalone minion can be found [here](#).
Win System Module

The unit of the `timeout` parameter in the `system.halt`, `system.poweroff`, `system.reboot`, and `system.shutdown` functions has been changed from seconds to minutes in order to be consistent with the Linux timeout setting. ([issue 24411](https://github.com/saltstack/salt/issues/24411)) Optionally, the unit can be reverted to seconds by specifying `in_seconds=True`.

Other Improvements

- Sanitize sensitive fields in `http.query`
- Allow authorization to be read from Django and eauth
- Add templating to SMTP returner
- New REST module for SDB
- Added `rest_timeout` config option and timeout argument to jobs api call
- Provide config options for Raet lane and road buffer count. (Useful for BSD kernels)
- Implemented ZeroMQ socket monitor for master and minion
- Add end time to master job cache for jobs (optional, off by default)
- Tornado is now the default backend for `http.request`
- Support `pillerenv` selection as it's done for `saltenv`
- `salt` was updated to use python-crypto version 2.6.1, which removes the dependency on python-m2crypto.

Deprecations

- The `digital_ocean.py` Salt Cloud driver was removed in favor of the `digital_ocean_v2.py` driver as DigitalOcean has removed support for APIv1. The `digital_ocean_v2.py` was renamed to `digital_ocean.py` and supports DigitalOcean's APIv2.
- The `vsphere.py` Salt Cloud driver has been deprecated in favor of the `vmware.py` driver.
- The `openstack.py` Salt Cloud driver has been deprecated in favor of the `nova.py` driver.
- The use of `provider` in Salt Cloud provider files to define cloud drivers has been deprecated in favor of using `driver`. Both terms will work until the Nitrogen release of Salt. Example provider file:

```bash
my-ec2-cloud-config:
id: 'HJGRYCLJLJKJYG'
key: 'kdjgfsqmwoormgl/aserigjksjhasdfgjn'
private_key: /etc/salt/my_test_key.pem
keyname: my_test_key
securitygroup: default
driver: ec2
```

- The use of `lock` has been deprecated and from `salt.utils.fopen`, `salt.utils.files.fopen` should be used instead.
- The following args have been deprecated from the `rabbitmq_vhost.present` state: `user`, `owner`, `conf`, `write`, `read`, and `runas`.
- The use of `runas` has been deprecated from the `rabbitmq_vhost.absent` state.
- Support for output in `mine.get` was removed. `--out` should be used instead.
• The use of `delim` was removed from the following functions in the `match` execution module: `pillar_pcre`, `pillar`, `grain_pcre`,

**Major Bug Fixes**

• Fixed minion failover to next master on DNS errors ([issue 21082](#))
• Fixed memory consumption in SaltEvents ([issue 25557](#))
• Don't lookup outside system path in which() util ([issue 24085](#))
• Fixed broken jobs rest api call ([issue 23408](#))
• Fixed stale grains data using in modules ([issue 24073](#))
• Added ssh_identities_only config flag for ssh-agent configured environments ([issue 24096](#))
• Fixed ```object has no attribute`` errors for Raet transport ([issue 21640](#))
• Flush event returners before master exit ([issue 22814](#))
• Fix `CommandExecutionError` in grains generation with `lspci` missing ([issue 23342](#))
• Fix salt-ssh against CentOS 7 when python-zmq not installed ([issue 23503](#))
• Fix salt-ssh issues related to out-of-date six module ([issue 20949](#))
• Fix salt-ssh thin generation after previous run was interrupted ([issue 24376](#))
• Use proper line endings on Windows with ```file.managed`` w/contents ([issue 25675](#))
• Fixed broken comment/uncomment functions in `file.py` ([issue 24620](#))
• Fixed problem with unicode when changing computer description ([issue 12255](#))
• Fixed problem with chocolatey module not loading ([issue 25717](#))
• Fixed problem adding users to groups with spaces in the name ([issue 25144](#))
• Fixed problem adding full name to user account ([issue 25206](#))
• Fixed gem module stack trace ([issue 21041](#))
• Fixed problem with `file.managed` when `test=True` ([issue 20441](#))
• Fixed problem with powershell hanging while waiting for user input ([issue 13943](#))
• Fixed problem where the salt-minion service would not consistently start ([issue 25272](#))
• Fixed problem where `pkg.refresh_db` would return True even when `winrepo.p` was not found ([issue 18919](#))
• Could someone please provide end to end example for Proxy Minion with REST ([issue 25500](#))
• Proxy minions stopped working between 2014.7 and 2015.5 ([issue 25053](#))
• Proxy minion documentation includes outdated code sample ([issue 24018](#))
• Proxy Minion documentation missing grains example ([issue 18273](#))
• Improve process management in proxy minion ([issue 12024](#))
• Proxy minion never comes up with message ```I am XXX and I am not supposed to start any proxies.``` ([issue 25908](#))
• Fixed an issue that caused an exception when using Salt mine from pillar. ([issue 11509](#))
35.2.2 Salt 2015.5.0 Release Notes - Codename Lithium

The 2015.5.0 feature release of Salt is focused on hardening Salt and mostly on improving existing systems. A few major additions are present, primarily the new Beacon system. Most enhancements have been focused around improving existing features and interfaces.

As usual the release notes are not exhaustive and primarily include the most notable additions and improvements. Hundreds of bugs have been fixed and many modules have been substantially updated and added.

**Warning:** In order to fix potential shell injection vulnerabilities in salt modules, a change has been made to the various `cmd` module functions. These functions now default to `python_shell=False`, which means that the commands will not be sent to an actual shell.

The largest side effect of this change is that ‘shellisms’, such as pipes, will not work by default. The modules shipped with salt have been audited to fix any issues that might have arisen from this change. Additionally, the `cmd` state module has been unaffected, and use of `cmd.run` in jinja is also unaffected. `cmd.run` calls on the CLI will also allow shellisms.

However, custom execution modules which use shellisms in `cmd` calls will break, unless you pass `python_shell=True` to these calls.

As a temporary workaround, you can set `cmd_safe: False` in your minion and master configs. This will revert the default, but is also less secure, as it will allow shell injection vulnerabilities to be written in custom code. We recommend you only set this setting for as long as it takes to resolve these issues in your custom code, then remove the override.

**Note:** Starting in this version of salt, `pillar_opts` defaults to False instead of True. This means that master opts will not be present in minion pillar, and as a result, `config.get` calls will not include master opts.

We recommend pillar is used for configuration options which need to make it to the minion.

**Beacons**

The beacon system allows the minion to hook into system processes and continually translate external events into the salt event bus. The primary example of this is the `inotify` beacon. This beacon uses inotify to watch configured files or directories on the minion for changes, creation, deletion etc.

This allows for the changes to be sent up to the master where the reactor can respond to changes.

**Sudo Minion Settings**

It is now possible to run the minion as a non-root user and for the minion to execute commands via sudo. Simply add `sudo_user: root` to the minion config, run the minion as a non-root user and grant that user sudo rights to execute `salt-call`.

**Lazy Loader**

The Lazy Loader is a significant overhaul of Salt’s module loader system. The Lazy Loader will lazily load modules on access instead of all on start. In addition to a major performance improvement, this ‘sandbox’ modules so a bad/broken import of a single module will only affect jobs that require accessing the broken module. ([issue: 20274)]

**Enhanced Active Directory Support**

The eauth system for LDAP has been extended to support Microsoft Active Directory out of the box. This includes Active Directory and LDAP group support for eauth.
Salt Documentation, Release 2015.8.0

Salt LXC Enhancements

The LXC systems have been overhauled to be more consistent and to fix many bugs. This overhaul makes using LXC with Salt much easier and substantially improves the underlying capabilities of Salt’s LXC integration.

Salt SSH

- Additional configuration options and command line flags have been added to configure the scan roster on the fly
- Added support for `state.single` in `salt-ssh`
- Added support for `publish.publish`, `publish.full_data`, and `publish.runner` in `salt-ssh`
- Added support for `mine.get` in `salt-ssh`

New Windows Installer

The new Windows installer changes how Salt is installed on Windows. The old installer used bbfreeze to create an isolated python environment to execute in. This made adding modules and python libraries difficult. The new installer sets up a more flexible python environment making it easy to manage the python install and add python modules.

Instead of frozen packages, a full python implementation resides in the bin directory (C:\salt\bin). By executing pip or easy_install from within the Scripts directory (C:\salt\bin\Scripts) you can install any additional python modules you may need for your custom environment.

The .exe's that once resided at the root of the salt directory (C:\salt) have been replaced by .bat files and should function the same way as the .exe's in previous versions.

The new Windows Installer will not replace the minion config file and key if they already exist on the target system. Only the salt program files will be replaced. C:\salt\conf and C:\salt\var will remain unchanged.

Removed Requests Dependency

The hard dependency on the requests library has been removed. Requests is still required by a number of cloud modules but is no longer required for normal Salt operations.

This removal fixes issues that were introduced with requests and salt-ssh, as well as issues users experienced from the many different packaging methods used by requests package maintainers.

Python 3 Updates

While Salt does not YET run on Python 3 it has been updated to INSTALL on Python 3, taking us one step closer. What remains is getting the test suite to the point where it can run on Python 3 so that we can verify compatibility.

RAET Additions

The RAET support continues to improve. RAET now supports multi-master and many bugs and performance issues have been fixed. RAET is much closer to being a first class citizen.
Modified File Detection

A number of functions have been added to the RPM-based package managers to detect and diff files that are modified from the original package installs. This can be found in the new pkg.modified functions.

Reactor Update

Fix an infinite recursion problem for runner/wheel reactor jobs by passing a `'user` (Reactor) to all jobs that the reactor starts. The reactor skips all events created by that username -- thereby only reacting to events not caused by itself. Because of this, runner and wheel executions from the runner will have user `"Reactor"` in the job cache.

Misc Fixes/Additions

- SDB driver for etcd. ([issue: 22043])
- Add `only_upgrade` argument to apt-based `pkg.install` to only install a package version if the package is already installed. (Great for security updates!)
- Joyent now requires a `keyname` to be specified in the provider configuration. This change was necessitated upstream by the 7.0+ API.
- Add `args` argument to `cmd.script_retcode` to match `cmd.script` in the `cmd` module. ([issue: 21122])
- Fixed bug where TCP keepalive was not being sent on the defined interval on the return port (4506) from minion to master. ([issue: 21465])
- LocalClient may now optionally raise SaltClientError exceptions. If using this class directly, checking for and handling this exception is recommended. ([issue: 21501])
- The SAuth object is now a singleton, meaning authentication state is global (per master) on each minion. This reduces sign-ins of minions from 3->1 per startup.
- Nested outputter has been optimized, it is now much faster.
- Extensive fileserver backend updates.

Deprecations

- Removed parameter keyword argument from `eselect.exec_action` execution module.
- Removed `runas` parameter from the following pip` execution module functions: `install, uninstall, freeze, list_, list_upgrades, upgrade_available, upgrade`. Please migrate to user.
- Removed `runas` parameter from the following pip state module functions: `installed, removed, up-to-date`. Please migrate to user.
- Removed `quiet` option from all functions in `cmdmod` execution module. Please use `output_loglevel=quiet` instead.
- Removed parameter argument from `eselect.set_state`. Please migrate to `module_parameter` or `action_parameter`.
- The `salt_events` table schema has changed to include an additional field called `master_id` to distinguish between events flowing into a database from multiple masters. If `event_return` is enabled in the master config, the database schema must first be updated to add the `master_id` field. This alteration can be accomplished as follows:

  ```sql
  ALTER TABLE salt_events ADD master_id VARCHAR(255) NOT NULL;
  ```

35.2. Previous Releases
Known Issues

- In multi-master mode, a minion may become temporarily unresponsive if modules or pillars are refreshed at the same time that one or more masters are down. This can be worked around by setting `auth_timeout` and `auth_tries` down to shorter periods.

35.2.3 Salt 2015.5.1 Release Notes

release 2015-05-20

Version 2015.5.1 is a bugfix release for 2015.5.0.

Changes:

- `salt.runners.cloud.action()` has changed the `fun` keyword argument to `func`. Please update any calls to this function in the cloud runner.

Extended Changelog Courtesy of Todd Stansell (https://github.com/tjstansell/salt-changelogs):

PR #23989: *(rallytime)* Backport #23980 to 2015.5 @ 2015-05-20T19:33:41Z
  - PR #23980: (iggy) template: jinja2 -> jinja | refs: #23989
  - 117ecb1 Merge pull request #23989 from rallytime/bp-23980
  - 8f8557c template: jinja2 -> jinja

PR #23988: *(rallytime)* Backport #23977 to 2015.5 @ 2015-05-20T19:13:36Z
  - PR #23977: (ionutbalautoiu) Fixed glance image_create | refs: #23988
  - d4f1ba0 Merge pull request #23988 from rallytime/bp-23977
  - 46fc7c6 Fixed glance image_create

PR #23986: *(basepi)* [2015.5] Merge forward from 2014.7 to 2015.5 @ 2015-05-20T18:41:33Z
  - PR #23967d Merge pull request #23986 from basepi/merge-forward-2015.5
  - 0b78156 Merge remote-tracking branch `upstream/2014.7` into merge-forward-2015.5
  - 314e4db Merge pull request #23965 from hvnsweeting/20147-fix-gitfs-gitpython-exception
  - 2576301 handle all exception gitpython can raise

PR #23985: *(UtahDave)* Add 2014.7.5-2 and 2015.5.0-2 Windows installer download links @ 2015-05-20T18:32:44Z
  - 9d1130e Merge pull request #23985 from UtahDave/2015.5local
  - 10338d0 Add links to Windows 2015.5.0-2 install downloads
  - b84f975 updated Windows 2014.7.5-2 installer download link

PR #23983: *(rallytime)* Version added tags for https_user and https_pass args new in 2015.5.0 @ 2015-05-20T18:05:27Z
  - ca7729d Merge pull request #23983 from rallytime/versionadded_git_options
  - 14ae22 Version added tags for https_user and https_pass args new in 2015.5.0

PR #23970: *(jayeshka)* adding system unit test case @ 2015-05-20T17:12:57Z
  - b06df57 Merge pull request #23970 from jayeshka/system-unit-test
• 89eb008 adding system unit test case
PR #23967: (jayeshka) adding states/memcached unit test case @ 2015-05-20T17:12:26Z
  • 38d5f75 Merge pull request #23967 from jayeshka/memcached-states-unit-test
  • 8ef240 adding states/memcached unit test case
PR #23966: (jayeshka) adding states/modjk unit test case @ 2015-05-20T17:11:48Z
  • 868e807 Merge pull request #23966 from jayeshka/modjk-states-unit-test
  • 422a964 adding states/modjk unit test case
PR #23942: (jacobhammons) Updates to sphinx saltstack2 doc theme @ 2015-05-20T15:43:54Z
  • 6316490 Merge pull request #23942 from jacobhammons/2015.5
  • 3102c8 Updates to sphinx saltstack2 doc theme
PR #23874: (joejulian) Validate keyword arguments to be valid @ 2015-05-20T04:53:40Z
  • ISSUE #23872: (joejulian) create_ca_signed_cert can error if dereferenced dict is used for args | refs: #23874
  • 587957b Merge pull request #23874 from joejulian/2015.5_tls_validate_kwargs
  • 30102c8 Fix py3 and ordering inconsistency problems.
  • 493f7ad Validate keyword arguments to be valid
PR #23960: (rallytime) Backport #22114 to 2015.5 @ 2015-05-20T04:37:09Z
  • PR #22114: (dmyerscough) Fixing KeyError when there are no additional pages | refs: #23960
  • 00c5c22 Merge pull request #23960 from rallytime/bp-22114
  • f3e1d63 Catch KeyError
  • 306b1ea Fixing KeyError
  • 6b2c6a2 Fix PEP8 complaint
  • 239e50f Fixing KeyError when there are no additional pages
PR #23961: (rallytime) Backport #23944 to 2015.5 @ 2015-05-20T04:35:41Z
  • PR #23944: (ryan-lane) Add missing loginclass argument to _changes call | refs: #23961
  • 4648b46 Merge pull request #23961 from rallytime/bp-23944
  • 970d19a Add missing loginclass argument to _changes call
PR #23948: (jfindlay) augeas.change state now returns changes as a dict @ 2015-05-20T04:00:10Z
  • 8cb5cd3 Merge pull request #23948 from jfindlay/augeas_changes
  • f09b8a0 augeas.change state now returns changes as a dict
PR #23957: (rallytime) Backport #23951 to 2015.5 @ 2015-05-20T03:04:24Z
  • PR #23951: (ryan-lane) Do not check perms in file.copy if preserve | refs: #23957
  • 2d185f7 Merge pull request #23957 from rallytime/bp-23951
  • 996b431 Update file.py
  • 85d461f Do not check perms in file.copy if preserve
  • PR #23956: (rallytime) Backport #23906 to 2015.5 @ 2015-05-20T03:04:14Z
Salt Documentation, Release 2015.8.0

- ISSUE #23839: (gladiatr72) wonky loader syndrome | refs: #23906
- ISSUE #23373: (tnypex) reactor/orchestrate race condition on salt['pillar.get'] | refs: #23906
- PR #23906: (gladiatr72) Added exception handler to trap the `RuntimeError` raised when | refs: #23956
  - 9d87fd3 add proper marker for format argument
  - 197688e Added exception handler to trap the `RuntimeError` raised when `Depends.enforce_dependency()` class method fires unsuccessfully. There appears to be no synchronization within the `Depends` decorator class wrt the class global `dependency_dict` which results in incomplete population of any loader instantiation occurring at the time of one of these exceptions.

- **PR #23955: (rallytime) Backport #19305 to 2015.5 @ 2015-05-20T03:03:55Z**
  - ISSUE #19852: (TaiSHiNet) DigitalOcean APIv2 can't delete machines when there is only 1 page | refs: #19305
  - ISSUE #19304: (TaiSHiNet) DigitalOcean API v2 cannot delete VMs on 2nd page | refs: #19305
  - PR #19305: (TaiSHiNet) Fixes droplet listing past page 1 | refs: #19305
    - da3f919 Merge pull request #19305 from rallytime/bp-19305
    - bbf2429 Fixes droplet listing past page 1

- **PR #23940: (basepi) [2015.5] Merge forward from 2014.7 to 2015.5 @ 2015-05-19T22:37:58Z**
  - ISSUE #23820: (UtahDave) 2014.7.5 schedule error | refs: #23881
  - ISSUE #22131: (quixoten) `unexpected keyword argument 'merge''' on 2014.7.2 (salt-ssh) | refs: #23887
  - PR #23939: (basepi) Add extended changelog to 2014.7.6 release notes
  - PR #23887: (basepi) [2014.7] Bring salt-ssh pillar.get in line with mainline pillar.get
  - PR #23881: (garethgreenaway) Fixes to schedule module in 2014.7
    - 02a78fc Merge pull request #23881 from basepi/salt-ssh.pillar.get.22131
    - 36f0065 Merge remote-tracking branch 'upstream/2014.7' into merge-forward-2015.5
      - 9133912 Merge pull request #23939 from basepi/v2014.7.6release
        - 32b65dc Add extended changelog to 2014.7.6 release notes
      - 0031ca2 Merge pull request #23881 from garethgreenaway/23820_2014_7_schedule_list_issue
        - b207f2a Missing continue in the list function when deleting unused attributes.
      - 63bd21e Merge pull request #23887 from basepi/salt-ssh.pillar.get.22131
        - bc84502 Bring salt-ssh pillar.get in line with mainline pillar.get

- **PR #23932: (rallytime) Backport #23908 to 2015.5 @ 2015-05-19T21:41:28Z**
  - PR #23908: (nleib) fix connection function to mongo | refs: #23932
  - ee4c01b Merge pull request #23932 from rallytime/bp-23908
  - 5d520c9 fix connection function to mongo

- **PR #23931: (rallytime) Backport #23880 to 2015.5 @ 2015-05-19T21:41:18Z**
  - PR #23880: (bastiaanb) if setting client_config_dir to `~`, expand path | refs: #23931
  - 70bd407 Merge pull request #23931 from rallytime/bp-23880
- 8ce59a2 if setting client_config_dir to `~`, expand path
- PR #23898: (kiorky) Lxc profiles | refs: #23897 @ 2015-05-19T21:08:28Z
  - ISSUE #23847: (kiorky) lxc: systemd containers cant be seeded | refs: #23806 #23898 #23897 #23808
  - ISSUE #23833: (kiorky) lxc.set_dns fails intermittently | refs: #23898 #23807 #23897 #23808
  - ISSUE #23772: (cheuschober) lxc.init fails to bootstrap container | refs: #23806 #23898 #23807 #23897 #23808
  - ISSUE #23658: (arthurlogilab) [salt-cloud lxc] too verbose, shows host: True multiple times when starting
    | refs: #23898 #23897
  - ISSUE #23657: (arthurlogilab) [salt-cloud lxc] NameError: global name `__salt__` is not defined | refs: #23727 #23898 #23897
- PR #23897: (kiorky) Lxc seed and prof ports | refs: #23898
- PR #23808: (kiorky) Lxc seed and prof ports | refs: #23807 #23897
- PR #23807: (kiorky) Lxc profiles | refs: #23898
- PR #23806: (kiorky) Lxc seeding | refs: #23807
- 5bdbf0a Merge pull request #23898 from makinacorpus/lxc_profiles
- d9051a0 lxc: systemd support
- e8d674f lxc: chroot fallback toggle
- e2887a0 lxc: sync func name with develop
- e96e345 lxc more fixes (lxc.set_dns)
- fdb6424 lxc: Fix salt config (no more a kwarg)
- 63e63fa repair salt cloud lxc api on develop
- 80eabe2 lxc salt cloud doc
- 73f229d lxc: unificate saltconfig/master/master_port
- 0bc1f08 lxc: refactor a bit saltcloud/lxc interface
- 7a80370 lxc: get networkprofile from saltcloud
- 47acb2e lxc: default net profile has now correct options
- 7eadf48 lxc: select the appropriate default bridge
- PR #23922: (garethgreenaway) Fixes to debian_ip.py @ 2015-05-19T18:50:53Z
  - ISSUE #23900: (hashi825) salt ubuntu network building issue 2015.5.0 | refs: #23922
  - b818f72 Merge pull request #23922 from garethgreenaway/23900_2015_5_bonding_interface_fixes
  - 0bb5a36 Fixing issue reported when using bonded interfaces on Ubuntu. Attributes should be bond-, but
    the code was attempting to split just on bond_. Fix accounts for both, but the debian_ip.py module will
    write out bond attributes with bond-
- PR #23925: (jpic) Fixed wrong path in LXC cloud documentation @ 2015-05-19T18:23:56Z
  - PR #23924: (jpic) Fixed wrong path in LXC cloud documentation | refs: #23925
  - b1e98a3 Merge pull request #23925 from jpic/fix/wrong_lxc_path
  - a4bcd75 Fixed wrong path in LXC cloud documentation
- PR #23894: (whiteinge) Add __all__ attribute to Mock class for docs @ 2015-05-19T17:17:35Z
- 7f6a716 Merge pull request #23894 from whiteinge/doc-mock__all__
- 6eecea46 Add __all__ attribute to Mock class for docs

**PR #23884:** (jfindlay) Fix locale.set_locale on debian @ 2015-05-19T15:51:22Z
- ISSUE #23767: (chrini) Salt system.locale fails on non existent default locale | refs: #23884
- 8108a9b Merge pull request #23884 from jfindlay/fix_locale
- 91c2d51 use append_if_not_found in locale.set_locale
- e632603 (re)generate /etc/default/locale

**PR #23866:** (jfindlay) backport #23834, change portage.dep.strip_empty to list comprehension @ 2015-05-19T15:50:43Z
- PR #23834: (Arabus) Avoid deprecation warning from portage.dep.strip_empty() | refs: #23866
- 6bae12f Merge pull request #23866 from jfindlay/flag_strip
- aa032cc replace portage.dep.strip_empty() with list comprehension
- 7576872 Proper replacement for portage.dep.strip_empty() with list comprehension, pep8fix
- 2851a5c Switch portage.dep.strip_empty(...) to filter(None,...) to avoid deprecation warning and do essentially the same

**PR #23917:** (corywright) Split debian bonding options on dash instead of underscore @ 2015-05-19T15:44:35Z
- ISSUE #23904: (mbrgm) Network config bonding section cannot be parsed when attribute names use dashes | refs: #23917
- a67a008 Merge pull request #23917 from corywright/issue23904
- c06f8cf Split debian bonding options on dash instead of underscore

**PR #23909:** (jayeshka) `str` object has no attribute `capitalized` @ 2015-05-19T15:41:53Z
- e8fcd09 Merge pull request #23909 from jayeshka/file-exe-module
- e422d9d `str` object has no attribute `capitalized`

**PR #23903:** (garethgreenaway) Adding docs for missing schedule state module parameters. @ 2015-05-19T06:29:34Z
- c73bf38 Merge pull request #23903 from garethgreenaway/missing_docs_schedule_state
- acd8ab9 Adding docs for missing schedule state module parameters.

**f7eb70c** changed previous release to 2014.7.6

**608059f** Merge branch `2015.5` of https://github.com/jacobhammons/salt into 2015.5
- a56697b Merge branch `2015.5` of https://github.com/saltstack/salt into 2015.5
- 1c2af5c Merge branch `2015.5` of https://github.com/saltstack/salt into 2015.5
- ef58128 Merge branch `2015.5` of https://github.com/saltstack/salt into 2015.5
- 8664e8b Merge branch `2015.5` of https://github.com/saltstack/salt into 2015.5-2
- 46eb265 saltstack2 sphinx theme updates
- e7442d3 Merge branch `2015.5` of https://github.com/saltstack/salt into 2015.5
- ee3c1bd missed one
- 3872921 More updates to sphinx2 theme
- fcd4865 Merge branch `2015.5' of https://github.com/saltstack/salt into 2015.5
- 8c32152 removed TOC numbering, additional tweaks to layout.html
- 73daef Merge branch `2015.5' of https://github.com/saltstack/salt into 2015.5
- 16d8a75 saltstack2 sphinx theme and build settings

**PR #23806:** (kiorky) Lxc seeding | refs: #23807 @ 2015-05-18T23:18:33Z
- ISSUE #23847: (kiorky) lxc: systemd containers cant be seeded | refs: #23806 #23898 #23897 #23808
- ISSUE #23772: (cheuschober) lxc.init fails to bootstrap container | refs: #23806 #23898 #23807 #23897 #23808
- ff3cc7d Merge pull request #23806 from makinalcorpus/lxc_seeding
- 61b7aad runners/lxc: optim

**PR #23892:** (basepi) [2015.5] Merge forward from 2014.7 to 2015.5 @ 2015-05-18T23:07:57Z
- PR #23891: (basepi) Update the release notes index page
- PR #23888: (basepi) Update the 2014.7.6 release notes with CVE details
- PR #23871: (rallytime) Backport #23848 to 2014.7
- PR #23848: (dumol) Updated installation docs for SLES 12. | refs: #23871
- 5f1a93d Merge pull request #23892 from basepi/merge-forward-2015.5
- c2eed77 Merge remote-tracking branch `upstream/2014.7' into merge-forward-2015.5
- 17c5810 Merge pull request #23891 from basepi/releasenotes
  * dec153b Update the release notes index page
- a93e58f Merge pull request #23888 from basepi/v2014.7.6release
  * 49921b6 Update the 2014.7.6 release notes with CVE details
- 5073028 Merge pull request #23871 from rallytime/bp-23848
  * 379c09c Updated for SLES 12.

**PR #23875:** (rallytime) Backport #23838 to 2015.5 @ 2015-05-18T22:28:55Z
- PR #23838: (gtmanfred) add refresh_beacons and sync_beacons | refs: #23875
- 66d1335 Merge pull request #23875 from rallytime/bp-23838
- 3174227 Add versionadded directives to new beacon saltutil functions
- 4a94b2c add refresh_beacons and sync_beacons

**PR #23876:** (rallytime) Switch digital ocean tests to v2 driver @ 2015-05-18T22:17:13Z
- d294cf2 Merge pull request #23876 from rallytime/switch_digital_ocean_tests_v2
- dce9b54 Remove extra line
- 4acf58e Switch digital ocean tests to v2 driver

**PR #23882:** (garethgreenaway) Fixes to scheduler in 2015.5 @ 2015-05-18T22:09:24Z
- ISSUE #23792: (neogenix) Salt Scheduler Incorrect Response (True, should be False) | refs: #23882
- b97ad48c Merge pull request #23882 from garethgreenaway/23792_2015_5_wrong_return_code
- 37dbde6 Job already exists in schedule, should return False.
• PR #23868: (basepi) [2015.5] Merge forward from 2014.7 to 2015.5 @ 2015-05-18T18:35:54Z

  – 3c9bb813 Merge pull request #23859 from rahulhan/states_sysrc_unit_test
  – 6a903b0 Adding states/sysrc.py unit tests
• PR #23812: (rallytime) Backport #23790 to 2015.5 @ 2015-05-18T15:30:34Z
  – PR #23790: (aboe76) updated suse spec file to version 2015.5.0 | refs: #23812
  – 4cf30a7 Merge pull request #23812 from rallytime/bp-23790
- 3f65631 updated suse spec file to version 2015.5.0

- **PR #23811**: (rallytime) Backport #23786 to 2015.5 @ 2015-05-18T15:30:27Z
  - **PR #23786**: (kaithar) Log the error generated that causes returns.mysql.returner to except. | refs: #23811
  - c6f939a Merge pull request #23811 from rallytime/bp-23786
  - 346f30b Log the error generated that causes returns.mysql.returner to except.

- **PR #23850**: (jayeshka) adding sysbench unit test case @ 2015-05-18T15:28:04Z
  - ce60582 Merge pull request #23850 from jayeshka/sysbench-unit-test
  - 280abde adding sysbench unit test case

- **PR #23843**: (The-Loeki) Fix erroneous virtual:physical core grain detection @ 2015-05-18T15:24:22Z
  - 060902f Merge pull request #23843 from The-Loeki/patch-1
  - 9e2cf60 Fix erroneous virtual:physical core grain detection

- **PR #23816**: (Snergster) Doc for #23685 Added prereq, caution, and additional mask information @ 2015-05-18T15:18:03Z
  - Issue #23815: (Snergster) [beacons] inotify errors on subdir creation | refs: #23816
  - 3257a9b Merge pull request #23816 from Snergster/23685-doc-fix
  - 0fca49d Added prereq, caution, and additional mask information

- **PR #23832**: (ahus1) make saltify provider use standard boostrap procedure @ 2015-05-18T02:18:29Z
  - **PR #23829**: (ahus1) make saltify provider use standard boostrap procedure | refs: #23832
  - 3df3b85 Merge pull request #23832 from ahus1/ahus1_saltify_bootstrap_2015.5
  - f5b1734 fixing problem in unit test
  - cba47f6 make saltify to use standard bootstrap procedure, therefore providing all options like master_sign_pub_file

- **PR #23791**: (optix2000) Psutil compat @ 2015-05-16T04:05:54Z
  - 8ec4fb2 Merge pull request #23791 from optix2000/psutil_compat
  - 5470cf5 Fix pylint errors and sloppy inline comments
  - 64634b6 Update psutil.pid_list to use psutil.pids
  - 5dd6d69 Fix imports that aren't in __all__
  - 8a1da33 Fix test cases by mocking psutil_compat
  - 558798d Fix net_io_counters deprecation issue
  - 8140f92 Override unnecessary pylint errors
  - 7d02ad4 Fix some of the mock names for the new API
  - 9b3023e Fix overloaded getters/setters. Fix line lengths
  - 180eb87 Fix whitespace
  - f8edf72 Use new psutil API in ps module
  - e48982f Fix version checking in psutil_compat
  - 93ee411 Create compatibility psutil. psutil 3.0 drops 1.0 API, but we still support old psutil versions.
• **PR #23782**: (terminalmage) Replace `''command -v''` with `''which''` and get rid of spurious log messages @ 2015-05-16T04:30:30Z
  - 40517b Merge pull request #23782 from terminalmage/issue23772
  - 056419 More ignore_retcode to suppress spurious log msgs
  - b4c48e6 Ignore return code in lxc.attachable
  - 08658c0 Replace `''command -v''` with `''which''`

• **PR #23783**: (basepi) [2015.5] Merge forward from 2014.7 to 2015.5 @ 2015-05-15T21:38:51Z
  - ISSUE #22959: (highlyunavailable) Windows Salt hangs if file.directory is trying to write to a drive that doesn’t exist
  - ISSUE #22332: (rallytime) [salt-ssh] Add a check for host in /etc/salt/roster | refs: #23748
  - ISSUE #16424: (stanvit) salt-run cloud.create fails with saltify
  - PR #23748: (basepi) [2014.7] Log salt-ssh roster render errors more assertively and verbosely
  - PR #23731: (twangboy) Fixes #22959: Trying to add a directory to an unmapped drive in windows
  - PR #23730: (rallytime) Backport #23729 to 2014.7
  - PR #23729: (rallytime) Partially merge #23437 (grains fix) | refs: #23730
  - PR #23688: (twangboy) Added inet_pton to utils/validate/net.py for ip.set_static_ip in windows
  - PR #23488: (celscape) LXC cloud fixes
  - PR #23437: (cedwards) Grains item patch | refs: #23729
  - cb2eb40 Merge pull request #23783 from basepi/merge-forward-2015.5
  - 9df51ca __opts__get

  - 51d23ed Merge remote-tracking branch `upstream/2014.7` into merge-forward-2015.5
    - d9af0c3 Merge pull request #23488 from cellscape/lxc-cloud-fixes
      - 64250a6 Remove profile from opts after creating LXC container
      - c4047d2 Set destroy=True in opts when destroying cloud instance
      - 9e1311a Store instance names in opts when performing cloud action
      - 934bc57 Correctly pass custom env to lxc-attach
      - 7fb85f7 Preserve test=True option in cloud states
      - 9771b5a Fix detection of absent LXC container in cloud state
      - fb24f0c Report failure when failed to create/clone LXC container
      - 2d9aa2b Avoid shadowing variables in lxc module
      - 792e102 Allow to override profile options in lxc.cloud_init_interface
      - 42bd64b Return changes on successful lxc.create from salt-cloud
      - 4409eab Return correct result when creating cloud LXC container
      - 377015c Issue #16424: List all providers when creating salt-cloud instance without profile

  - 808bbe1 Merge pull request #23748 from basepi/salt-ssh.roster.host.check
    - bc53e04 Log entire exception for render errors in roster
    - 753de6a Log render errors in roster to error level
• e01a7a9 Always let the real YAML error through
  * 72e360 Merge pull request #23731 from twangboy/fix_22959
  * 88e5495 Fixes #22959: Trying to add a directory to an unmapped drive in windows
  * 2610195 Merge pull request #23730 from rallytime/bp-23729
  * 1877cae adding support for nested grains to grains.item
  * 3e9df88 Merge pull request #23688 from twangboy/fix_23415
    * 6a91169 Fixed unused-import pylint error
    * 5e25b3f fixed pylint errors
    * 1a96766 Added inet_pton to utils/validate/net.py for ip.set_static_ip in windows

• PR #23781: (jfindlay) fix unit test mock errors on arch @ 2015-05-15T19:40:07Z
  - 982f873 Merge pull request #23781 from jfindlay/fix_locale_tests
  - 14c711e fix unit test mock errors on arch

• PR #23740: (jfindlay) Binary write @ 2015-05-15T18:10:44Z
  - ISSUE #23566: (rks2286) Salt-cp corrupting the file after transfer to minion | refs: #23740
  - 916b1c4 Merge pull request #23740 from jfindlay/binary_write
  - 626930a update incorrect comment wording
  - a978f5c always use binary file write mode on windows

• PR #23736: (jfindlay) always load pip execution module @ 2015-05-15T18:10:16Z
  - ISSUE #23682: (chrish42) Pip module requires system pip, even when not used (with env_bin) | refs: #23736
  - 348645e Merge pull request #23736 from jfindlay/fix_pip
  - b8867a8 update pip tests
  - 040bbc4 only check pip version in one place
  - 6c453a5 check for executable status of bin_env
  - 3337257 always load the pip module as pip could be anywhere

• PR #23770: (cellscape) Fix cloud LXC container destruction @ 2015-05-15T17:38:59Z
  - 10cedfb Merge pull request #23770 from cellscape/fix-cloud-lxc-destruction
  - 4f6021c Fix cloud LXC container destruction

• PR #23759: (lisa2lisa) fixed the problem for not beable to revoke .., for more detail https... @ 2015-05-15T17:38:38Z
  - ddea822 Merge pull request #23759 from lisa2lisa/iss23664
  - a29f161 fixed the problem for not beable to revoke .., for more detail https://github.com/saltstack/salt/issues/23201, fixed mysql cannot create user with pure digit password, for more info https://github.com/saltstack/salt/issues/23664

• PR #23769: (cellscape) Fix file_roots CA lookup in salt.utils.http.get_ca_bundle @ 2015-05-15T16:21:49Z
  - 10615ff Merge pull request #23769 from cellscape/utils-http-ca-file-roots
  - 8e90f32 Fix file_roots CA lookup in salt.utils.http.get_ca_bundle

35.2. Previous Releases 2047
- **PR #23765**: (jayeshka) adding states/makeconf unit test case @ 2015-05-15T14:29:43Z
  - fd8a1b7 Merge pull request #23765 from jayeshka/makeconf_states-unit-test
  - 26e31af adding states/makeconf unit test case
- **PR #23760**: (ticsax) [doc] document refresh argument @ 2015-05-15T14:23:47Z
  - ee13b08 Merge pull request #23760 from ticosax/2015.5
  - e3ca859 document refresh argument
- **PR #23766**: (jayeshka) adding svn unit test case @ 2015-05-15T14:23:18Z
  - a017f72 Merge pull request #23766 from jayeshka/svn-unit-test
  - 19939cf adding svn unit test case
- **PR #23751**: (rallytime) Backport #23737 to 2015.5 @ 2015-05-15T03:58:37Z
  - ISSUE #23734: (bradthurb) 2015.5.0 modules/archive.py ZipFile instance has no attribute `_exit_` - only python 2.6? | refs: #23737
  - PR #23737: (bradthurb) fix for 2015.5.0 modules/archive.py ZipFile instance has no attribute... | refs: #23751
  - 0ed9d45 Merge pull request #23751 from rallytime/bp-23737
  - 8d1eb32 fix for 2015.5.0 modules/archive.py ZipFile instance has no attribute `_exit_` - only python 2.6? #23734
- **PR #23710**: (kiorky) Get more useful output from stateful commands @ 2015-05-14T21:58:10Z
  - ISSUE #23709: (kiorky) cmdmod: enhancement is really needed for stateful commands | refs: #23710
  - d73984e Merge pull request #23710 from makinacorpus/i23709
  - c706909 Get more useful output from stateful commands
- **PR #23724**: (rallytime) Backport #23609 to 2015.5 @ 2015-05-14T19:34:22Z
  - PR #23609: (kaidokert) file_map: chown created directories if not root #23608 | refs: #23724
  - cdf421b Merge pull request #23724 from rallytime/bp-23609
  - fe3a762 file_map: chmod created directories if not root
- **PR #23723**: (rallytime) Backport #23568 to 2015.5 @ 2015-05-14T19:34:11Z
  - PR #23568: (techhat) Allow Salt Cloud to use either SCP or SFTP, as configured | refs: #23723
  - 94f9099 Merge pull request #23723 from rallytime/bp-23568
  - bbc34a Allow Salt Cloud to use either SCP or SFTP, as configured
- **PR #23725**: (rallytime) Backport #23691 to 2015.5 @ 2015-05-14T19:32:30Z
  - PR #23691: (dennisjac) add initial configuration documentation for varstack pillar | refs: #23725
  - 137e5ee Merge pull request #23725 from rallytime/bp-23691
  - 28a846e add initial configuration documentation for varstack pillar
- **PR #23722**: (rallytime) Backport #23472 to 2015.5 @ 2015-05-14T19:31:52Z
  - PR #23472: (techhat) Allow neutron network list to be used as pillar data | refs: #23722
  - 0c00995 Merge pull request #23722 from rallytime/bp-23472
  - c3d0f39 Change version added tag for backport
- 023e88f Allow neutron network list to be used as pillar data

- **PR #23727:** (jfindlay) fix npm execution module stacktrace @ 2015-05-14T18:14:12Z
  - **ISSUE #23657:** (arthurlogilab) [salt-cloud lxc] NameError: global name `__salt__` is not defined | refs: #23727 #23898 #23897
  - cbf4ca8 Merge pull request #23727 from jfindlay/npm_salt
  - 05392f2 fix npm execution module stacktrace

- **PR #23718:** (rahulhan) Adding states/user.py unit tests @ 2015-05-14T17:15:38Z
  - ef536d5 Merge pull request #23718 from rahulhan/states_user_unit_tests
  - a0d27db Adding states/user.py unit tests

- **PR #23720:** (basepi) [2015.5] Merge forward from 2014.7 to 2015.5 @ 2015-05-14T17:13:02Z
  - ISSUE #23604: (Azidburn) service.dead on systemd Minion create an Error Message | refs: #23607
  - ISSUE #23548: (kkaig) grains.list_present produces incorrect (?) output | refs: #23674
  - ISSUE #23403: (iamfil) salt.runners.cloud.action fun parameter is replaced | refs: #23680
  - PR #23680: (cachedout) Rename kwarg in cloud runner
  - PR #23674: (cachedout) Handle lists correctly in grains.list_present
  - PR #23672: (twangboy) Fix user present
  - PR #23670: (rallytime) Backport #23607 to 2014.7
  - PR #23607: (Azidburn) Fix for #23604. No error reporting. Exitcode !=0 are ok | refs: #23670
  - a529d74 Merge pull request #23720 from basepi/merge-forward-2015.5
  - 06a3ebd Merge remote-tracking branch `upstream/2014.7` into merge-forward-2015.5
  - 1b86460 Merge pull request #23680 from cachedout/issue_23403
  - d5986c2 Rename kwarg in cloud runner
  - cd64af0 Merge pull request #23674 from cachedout/issue_23548
  - d322a19 Merge pull request #23672 from twangboy/fixed_present
  - 731e7af Merge branch `2014.7` of https://github.com/saltstack/salt into fixed_present
  - d6f70a4 Fixed user.present to create password in windows
  - 43f7025 Merge pull request #23670 from rallytime/bp-23607
  - ed30dc4 Fix for #23604. No error reporting. Exitcode !=0 are ok

- **PR #23704:** (jayeshka) adding states/lvs_server unit test case @ 2015-05-14T14:22:10Z
  - da323db Merge pull request #23704 from jayeshka/lvs_server_states-unit-test
  - da323db adding states/lvs_server unit test case

- **PR #23703:** (jayeshka) adding states/lvs_service unit test case @ 2015-05-14T14:21:23Z
  - f95ca31 Merge pull request #23703 from jayeshka/lvs_service_states-unit-test
  - 66717c8 adding states/lvs_service unit test case

- **PR #23702:** (jayeshka) Remove superfluous return statement. @ 2015-05-14T14:20:42Z
- 07e987e Merge pull request #23702 from jayeshka/fix_lvs_service
- ecf218 fix lvs_service

- **PR #23686**: (jfindlay) remove superflous return statement @ 2015-05-14T14:20:18Z
  - 39973d4 Merge pull request #23686 from jfindlay/fix_lvs_server
  - 5aae73 remove superflous return statement

- **PR #23690**: (rallytime) Backport #23424 to 2015.5 @ 2015-05-13T23:04:36Z
  - PR #23424: (jfindlay) Added python_shell=True for refresh_db in pacman.py | refs: #23690
  - be7c7ef Merge pull request #23690 from rallytime/bp-23424
  - 94574b7 Added python_shell=True for refresh_db in pacman.py

- **PR #23681**: (cachedout) Start on 2015.5.1 release notes @ 2015-05-13T19:44:22Z
  - 1a0db43 Merge pull request #23681 from cachedout/2015_5_1_release_notes
  - bdbba6 Start on 2015.5.1 release notes

- **PR #23679**: (jfindlay) Merge #23616 @ 2015-05-13T19:03:53Z
  - PR #23616: (Snergster) virtual returning none warning fixed in dev but missed in 2015.5 | refs: #23679
  - b54075a Merge pull request #23679 from jfindlay/merge_23616
  - 6e15e19 appease pylint's blank line strictures
  - 8750680 virtual returning none warning fixed in dev but missed in 2015.5

- **PR #23675**: (basepi) [2015.5] Merge forward from 2014.7 to 2015.5 @ 2015-05-13T18:35:54Z
  - ISSUE #23611: (hubez) master_type set to `failover` but `master` is not of type list but of type <type `str'> | refs: #23637
  - ISSUE #23479: (danielmorlock) Typo in pkg.removed for Gentoo? | refs: #23558
  - ISSUE #23452: (michaelforge) minion crashed with empty grain | refs: #23639
  - ISSUE #23411: (dr4Ke) grains.append should work at any level of a grain | refs: #23440
  - ISSUE #23355: (dr4Ke) salt-ssh: `sources: salt://' files from `pkg` state are not included in salt_state.tgz | refs: #23530
  - ISSUE #23110: (martinhoefling) Copying files from gitfs in file.recurse state fails
  - ISSUE #23004: (b18) 2014.7.5 - Windows - pkg.list_pkgs - `nxlog” never shows up in output. | refs: #23433
  - ISSUE #22908: (karanjad) Add failhard option to salt orchestration | refs: #23389
  - ISSUE #22141: (Deshke) grains.get_or_set_hash render error if hash begins with `\'%’” | refs: #23640
  - PR #23661: (rallytime) Merge #23640 with whitespace fix
  - PR #23640: (cachedout) Add warning to get_or_set_hash about reserved chars | refs: #23661
  - PR #23639: (cachedout) Handle exceptions raised by _virtual_
  - PR #23637: (cachedout) Convert str master to list
  - PR #23606: (twangboy) Fixed checkbox for starting service and actually starting it
  - PR #23595: (rallytime) Backport #23549 to 2014.7
  - PR #23594: (rallytime) Backport #23496 to 2014.7
- PR #23593: (rallytime) Backport #23442 to 2014.7
- PR #23592: (rallytime) Backport #23389 to 2014.7
- PR #23573: (techhat) Scan all available networks for public and private IPs | refs: #23802
- PR #23558: (jfindlay) reorder emerge command line
- PR #23554: (jleroy) Debian: Hostname always updated
- PR #23551: (dr4Ke) grains.append unit tests, related to #23474
- PR #23549: (vr-jack) Update __init__.py | refs: #23595
- PR #23537: (tdorantt) Update changelog
- PR #23530: (dr4Ke) salt-ssh state: fix including all salt:// references
- PR #23496: (martinhoefling) Fix for issue #23110 | refs: #23594
- PR #23474: (dr4Ke) Fix grains.append in nested dictionary grains #23411
- PR #23442: (clan) add directory itself to keep list | refs: #23593
- PR #23440: (dr4Ke) fix grains.append in nested dictionary grains #23411 | refs: #23474
- PR #23433: (twangboy) Obtain all software from the registry
- PR #23389: (cachedout) Correct fail_hard typo | refs: #23592
- e480f13 Merge pull request #23675 from basepi/merge-forward-2015.5
- bd63548 Merge remote-tracking branch `upstream/2014.7` into merge-forward-2015.5
  * 0f006ac Merge pull request #23661 from rallytime/merge-23640
  - 4427f42 Whitespace fix
  - dd91154 Add warning to get_or_set_hash about reserved chars
  * 84e2ef8 Merge pull request #23639 from cachedout/issue_23452
  - d418b49 Syntax error!
  - 45b4015 Handle exceptions raised by __virtual__
  * bd9b94b Merge pull request #23637 from cachedout/issue_23611
  - 56cb1f5 Fix typo
  - f6fcf19 Convert str master to list
  * f20c0e4 Merge pull request #23595 from rallytime/bp-23549
  - 6efca0 Update __init__.py
  * 1aca86 Merge pull request #23594 from rallytime/bp-23496
  - d5ae1d2 Fix for issue #23110 This resolves issues when the freshly created directory is removed by fileserver.update.
  * 2c221c7 Merge pull request #23593 from rallytime/bp-23442
  - 39869a1 check w/ low['name'] only
  - 304cc49 another fix for file defined w/ id, but require name
  - 8814d41 add directory itself to keep list
  * fadd1ef Merge pull request #23606 from twangboy/fix_installer
• 038331e Fixed checkbox for starting service and actually starting it
  – acdd3fc Fix lint
• 680e88f Merge remote-tracking branch `upstream/2014.7` into merge-forward-2015.5
  * 10b3f0f Merge pull request #23592 from rallytime/bp-23389
    – 734cc43 Correct fail_hard typo
  * cd34b9b Merge pull request #23573 from techhat/novaquery
    – f92db5e Linting
    – 26e00d3 Scan all available networks for public and private IPs

    – 4540fb reorder emerge command line
  * a66a3c Merge pull request #23530 from dr4Ke/fix_salt-ssh_to_include_pkg_sources
    – 5df6a80 fix pylint warning
    – d0549e5 salt-ssh state: fix including all salt:// references
  * 55c3869 Merge pull request #23433 from twangboy/list_pkgs_fix
    – 8ab5b1b Fix pylint error
    – 2d11d65 Obtain all software from the registry
  * 755bed0 Merge pull request #23554 from jleroy/debian-hostname-fix
    – 5ff749e Debian: Hostname always updated
  * 6ec87ce Merge pull request #23551 from dr4Ke/grains.append_unit_tests
    – ebf9df fix pylint errors
    – c495404 unit tests for grains.append module function
    – 0c9a323 use MagickMock
    – c838a22 unit tests for grains.append module function
  * e96c5c5 Merge pull request #23474 from dr4Ke/fix_grains.append_nested
    – 01a5bb grains.get, parameter delimititer, versionadded: 2014.7.6
    – b39f504 remove debugging output
    – b6e15e2 fix grains.append in nested dictionary grains #23411
  * ab7e1ae Merge pull request #23537 from t0rrant/patch-1
    – 8e03cc9 Update changelog

• PR #23669: (rallytime) Backport #23586 to 2015.5 @ 2015-05-13T18:27:11Z
  – PR #23586: (Lothiraldan) Fix salt.state.file._unify_sources_and_hashes when sources is used without sources_hashes | refs: #23669
  – 0dad6be Merge pull request #23669 from rallytime/bp-23586
  – ef4c6ad Remove another unused import
  – 73cfda7 Remove unused import
  – 52b68d6 Use the zip_longest from six module for python 3 compatibility
- 18d5ff9 Fix salt.state.file._unify_sources_and_hashes when sources is used without sources_hashes

- **PR #23662**: (rallytime) Merge #23642 with pylint fix @ 2015-05-13T15:46:51Z
  - **PR #23642**: (cachedout) Let saltmod handle lower-level exceptions gracefully | refs: #23662
  - fabef75 Merge pull request #23662 from rallytime/merge-23642
  - aa7bbd8 Remove unused import
  - 9e666d4c Let saltmod handle lower-level exceptions gracefully

- **PR #23622**: (jfindlay) merge #23508 @ 2015-05-13T15:36:49Z
  - **PR #23508**: (cro) Port mysql returner to postgres using jsonb datatype | refs: #23622
  - 072b927 Merge pull request #23622 from jfindlay/pgjsonb
  - 454322c appease pylint's proscription on blank line excess
  - 57c6171 Get time with timezone correct also in job return.
  - e109d0f Get time with timezone correct.
  - 21e06b9 Fix SQL, remove unneeded imports.
  - 653f360 Stop making changes in 2 places.
  - d6daa0 Typo.
  - 7d748b8f SSL is handled differently by Pg, so don't set it here.
  - cc7c377 Fill alter_time field in salt_events with current time with timezone.
  - 43defe9 Port mysql module to Postgres using jsonb datatypes

- **PR #23651**: (jayeshka) adding solr unit test case @ 2015-05-13T15:26:15Z
  - c1bdd4d Merge pull request #23651 from jayeshka/solr-unit-test
  - 6e05148 adding solr unit test case

- **PR #23649**: (jayeshka) adding states/libvirt unit test case @ 2015-05-13T15:24:48Z
  - ee43411 Merge pull request #23649 from jayeshka/libvirt_states-unit-test
  - 0fb923a adding states/libvirt unit test case

- **PR #23648**: (jayeshka) adding states/linux_acl unit test case @ 2015-05-13T15:24:11Z
  - c7fc466 Merge pull request #23648 from jayeshka/linux_acl_states-unit-test
  - 3f0ab29 removed error.
  - 11081c1 adding states/linux_acl unit test case

- **PR #23650**: (jayeshka) adding states/kmod unit test case @ 2015-05-13T15:09:18Z
  - 4c8a7ba Merge pull request #23650 from jayeshka/kmod_states-unit-test
  - 1987015 adding states/kmod unit test case

- **PR #23633**: (jayeshka) made changes to test_interfaces function. @ 2015-05-13T06:51:07Z
  - bc8faf1 Merge pull request #23633 from jayeshka/win_network-2015.5-unit-test
  - 093661d made changes to test_interfaces function.

- **PR #23619**: (jfindlay) fix kmod.present processing of module loading @ 2015-05-13T01:16:56Z
  - 7df3579 Merge pull request #23619 from jfindlay/fixed_kmod_state
• PR #23598: (rahulhan) Adding states/win_dns_client.py unit tests @ 2015-05-12T21:47:36Z
  - d4f3095 Merge pull request #23598 from rahulhan/states_win_dns_client_unit_test
  - d08d885 Adding states/win_dns_client.py unit tests
• PR #23597: (rahulhan) Adding states/vbox_guest.py unit tests @ 2015-05-12T21:46:30Z
  - 8116ea1 Merge pull request #23597 from rahulhan/states_vbox_guest_unit_test
  - 6a2909e Removed errors
  - 4cde78a Adding states/vbox_guest.py unit tests
• PR #23615: (rallytime) Backport #23577 to 2015.5 @ 2015-05-12T21:19:11Z
  - PR #23577: (msciciel) Fix find and remove functions to pass database param | refs: #23615
  - 029ff11 Merge pull request #23615 from rallytime/bp-23577
  - 6f74477 Fix find and remove functions to pass database param
• PR #23603: (rahulhan) Adding states/winrepo.py unit tests @ 2015-05-12T18:40:12Z
  - b858953 Merge pull request #23603 from rahulhan/states_winrepo_unit_test
  - a668e70 Adding states/winrepo.py unit tests
• PR #23602: (rahulhan) Adding states/win_path.py unit tests @ 2015-05-12T18:39:37Z
  - 3cbdb66 Merge pull request #23602 from rahulhan/states_win_path_unit_test
  - 122c29f Adding states/win_path.py unit tests
• PR #23600: (rahulhan) Adding states/win_network.py unit tests @ 2015-05-12T18:39:01Z
  - 39b0e88 Merge pull request #23600 from rahulhan/states_win_network_unit_test
  - b418404 removed lint error
  - 1be8023 Adding states/win_network.py unit tests
• PR #23599: (rahulhan) Adding win_firewall.py unit tests @ 2015-05-12T18:37:49Z
  - 10243a7 Merge pull request #23599 from rahulhan/states_win_firewall_unit_test
  - 6cda890 Adding win_firewall.py unit tests
• PR #23601: (basepi) Add versionadded for jboss module/state @ 2015-05-12T17:22:59Z
  - e73071d Merge pull request #23601 from basepi/jboss.version.added
  - 0174c8f Add versionadded for jboss module/state
• PR #23469: (sundayt3ch) Call the windows specific function not the general one @ 2015-05-12T16:47:22Z
  - 9beb7bc Merge pull request #23469 from sundayt3ch/hotfix/call-the-win-func
  - 83e88a3 Call the windows specific function not the general one
• PR #23583: (jayeshka) adding states/ipset unit test case @ 2015-05-12T16:31:55Z
  - d2f0975 Merge pull request #23583 from jayeshka/ipset_states-unit-test
  - 4330cf4 adding states/ipset unit test case
• PR #23582: (jayeshka) adding states/keyboard unit test case @ 2015-05-12T16:31:17Z
  - 82a47e8 Merge pull request #23582 from jayeshka/keyboard_states-unit-test
- fa94d7a adding states/keyboard unit test case

- **PR #23581**: (jayeshka) adding states/layman unit test case @ 2015-05-12T16:30:36Z
  - 77e5b28 Merge pull request #23581 from jayeshka/layman_states-unit-test
  - 297b055 adding states/layman unit test case

- **PR #23580**: (jayeshka) adding smf unit test case @ 2015-05-12T16:29:58Z
  - cbe3282 Merge pull request #23580 from jayeshka/smf-unit-test
  - 4f97191 adding smf unit test case

- **PR #23572**: (The-Loeki) Fix regression of #21355 introduced by #21603 @ 2015-05-12T16:28:05Z
  - ISSUE #21603: (ipmb) ssh_auth.present fails on key without comment | refs: #23572 #23572
  - PR #21355: (The-Loeki) Fix for comments containing whitespaces
  - 16a3338 Merge pull request #23572 from The-Loeki/ssh_auth_fix
  - d8248dd Fix regression of #21355 introduced by #21603

- **PR #23565**: (garethgreenaway) fix to aptpkg module @ 2015-05-12T16:25:46Z
  - ISSUE #23490: (lichtamberg) salt.modules.aptpkg.upgrade should have default `\$\$dist_upgrade=False` | refs: #23565
  - f843f89 Merge pull request #23565 from garethgreenaway/2015_2_aptpkg_upgrade_default_to_upgrade
  - 97ae514 aptpkg.upgrade should default to upgrade instead of dist_upgrade.

- **PR #23550**: (jfindlay) additional mock for rh_ip_test_test_build_bond @ 2015-05-12T15:17:16Z
  - ISSUE #23473: (terminalmage) unit.modules.rh_ip_test.RhipTestCase.test_build_bond is not properly mocked | refs: #23550
  - c1157cd Merge pull request #23550 from jfindlay-fix_rh_ip_test
  - e9b94d3 additional mock for rh_ip_test_test_build_bond

- **PR #23552**: (garethgreenaway) Fix for an issue caused by a previous pull request @ 2015-05-11T21:54:59Z
  - b59332b Merge pull request #23552 from garethgreenaway/2015_5_returner_fix_broken_previous_pr
  - 7d70e2b Passed argumentes in the call_fetch_profile_opts to were in the wrong order

- **PR #23547**: (slinu3d) Added AWS v4 signature support for 2015.5 @ 2015-05-11T21:52:24Z
  - d0f9682 Merge pull request #23547 from slinu3d/2015.5
  - f3fb5b5 Fixed urlparse and urlencode calls
  - 802dbdb Added AWS v4 signature support for 2015.5

- **PR #23544**: (basepi) [2015.5] Merge forward from 2014.7 to 2015.5 @ 2015-05-11T18:02:06Z
  - ISSUE #23159: (aneeshusa) Unused validator
  - ISSUE #20518: (ekle) module s3.get does not support eu-central-1 | refs: #23467
  - ISSUE #563: (chutz) pidfile support for minion and master daemons | refs: #23460 #23461
  - PR #23538: (cro) Update date in LICENSE file
  - PR #23505: (aneeshusa) Remove unused ssh config validator. Fixes #23159.
  - PR #23467: (slinu3d) Added AWS v4 signature support
  - PR #23460: (s0undt3ch) [2014.7] Update to latest stable bootstrap script v2015.05.07

35.2. Previous Releases

2055
Salt Documentation, Release 2015.8.0

- **PR #23444**: (techhat) Add create_attach_volume to nova driver
- **PR #23439**: (techhat) Add wait_for_passwd_maxtries variable
- 06c6a1f Merge pull request #23544 from basepi/merge-forward-2015.5
- f8a36bc Merge remote-tracking branch `upstream/2014.7` into merge-forward-2015.5
  * b79fed3 Merge pull request #23538 from cro/licupdate
    - 345efe2 Update date in LICENSE file
  * a123a36 Merge pull request #23505 from aneeshusa/remove-unused-ssh-config-validator
    - 90af167 Remove unused ssh config validator. Fixes #23159.
  * ca2c21a Merge pull request #23467 from slinu3d/2014.7
    - 0b4081d Fixed pylint error at line 363
    - 5be5eb5 Fixed pylink errors
    - e64f374 Fixed lint errors
    - b9d1ac4 Added AWS v4 signature support
  * e6f9eec Merge pull request #23444 from techhat/novacreateattach
    - ebdbea3 Add create_attach_volume to nova driver
  * e331463 Merge pull request #23460 from s0undt3ch/bootstrap-script-2014.7
    - edcd0c4 Update to latest stable bootstrap script v2015.05.07
  * 7a8ce1a Merge pull request #23439 from techhat/maxtries
    - 0ad3ff2 Add wait_for_passwd_maxtries variable
- **PR #23470**: (twangboy) Fixed service.restart for salt-minion @ 2015-05-11T17:54:47Z
  - ISSUE #23426: (twangboy) Can't restart salt-minion on 64 bit windows (2015.5.0) | refs: #23470
  - aa5b896 Merge pull request #23470 from twangboy/fix_svc_restart
  - b3f284c Fixed tests
  - ad44d79 Fixed service.restart for salt-minion
- **PR #23539**: (rahulhan) Adding states/virtualenv_mod.py unit tests @ 2015-05-11T17:02:31Z
  - 67988b2 Merge pull request #23539 from rahulhan/states_virtualenv_mod_unit_test
  - 750bb07 Adding states/virtualenv_mod.py unit tests
- 6f0cf2e Merge remote-tracking branch `upstream/2015.2` into 2015.5
  - ISSUE #23244: (freimer) Caller not available in reactors | refs: #23245
  - **PR #23509**: (keesbos) Catch the unset (empty/None) environment case
  - **PR #23423**: (cachedout) Remove jid_event from state.orch
  - **PR #23245**: (freimer) Add Caller functionality to reactors.
  - c966196 Merge pull request #23423 from cachedout/remove_jid_event_from_orch
    * f81aab7 Remove jid_event from state.orch
  - 2bb09b7 Merge pull request #23509 from keesbos/Catch_empty_environment
    * 6dedeac Catch the unset (empty/None) environment case
6d42f30 Merge pull request #23245 from freimer/issue_23244
   * 24cf6eb Add Caller functionality to reactors.

- PR #23513: (gladiatr72) short-circuit auto-failure of iptables.delete state @ 2015-05-11T15:18:33Z
  - c3f0d8 Merge pull request #23513 from gladiatr72/rfc_stop_iptables.check_from_short-circuiting_position-only_delete_rule
  - c71714c short-circuit auto-failure of iptables.delete state if position argument is set without the other accoutrements that check_rule requires.

- PR #23534: (jayeshka) adding states/ini_manage unit test case @ 2015-05-11T14:32:06Z
  - 4e77f6f Merge pull request #23534 from jayeshka/ini_manage_states-unit-test
  - 831223c adding states/ini_manage unit test case

- PR #23533: (jayeshka) adding states/hipchat unit test case @ 2015-05-11T14:30:22Z
  - 11ba9ed Merge pull request #23533 from jayeshka/hipchat-states-unit-test
  - 41d1b3 adding states/hipchat unit test case

- PR #23532: (jayeshka) adding states/ipmi unit test case @ 2015-05-11T14:28:15Z
  - e542113 Merge pull request #23532 from jayeshka/ipmi-states-unit-test
  - fc364a adding states/ipmi unit test case

- PR #23531: (jayeshka) adding service unit test case @ 2015-05-11T14:27:12Z
  - 9ba8f6f Merge pull request #23531 from jayeshka/service-unit-test
  - 3ad5314 adding service unit test case

- PR #23517: (garethgreenaway) fix to returners @ 2015-05-11T14:20:51Z
  - ISSUE #23512: (Code-Vortex) hipchat_returner / slack_returner not work correctly | refs: #23517
  - 32838cd Merge pull request #23517 from garethgreenaway/23512_2015_5_returners_with_profiles
  - 81e31e2 fix for returners that utilize profile attributes. code in the if else statement was backwards. #23512

- PR #23502: (rahulhan) Adding states/win_servermanager.py unit tests @ 2015-05-08T19:47:18Z
  - 6be7c8d Merge pull request #23502 from rahulhan/states_win_servermanager_unit_test
  - 2490074 Adding states/win_servermanager.py unit tests

- PR #23495: (jayeshka) adding seed unit test case @ 2015-05-08T17:30:38Z
  - 6048578 Merge pull request #23495 from jayeshka/seed-unit-test
  - 3f134bc adding seed unit test case

- PR #23494: (jayeshka) adding sensors unit test case @ 2015-05-08T17:30:18Z
  - 70bc3c1 Merge pull request #23494 from jayeshka/sensors-unit-test
  - 1fa48a3 adding sensors unit test case

- PR #23493: (jayeshka) adding states/incron unit test case @ 2015-05-08T17:29:59Z
  - b981b20 Merge pull request #23493 from jayeshka/incron-states-unit-test
  - cc7b617 adding states/incron unit test case

- PR #23492: (jayeshka) adding states/influxdb_database unit test case @ 2015-05-08T17:29:51Z
Chapter 35. Release notes

- 4019c49 Merge pull request #23492 from jayeshka/influxdb_database-states-unit-test
- e1fcac8 adding states/influxdb_database unit test case

- PR #23491: (jayeshka) adding states/influxdb_user unit test case @ 2015-05-08T16:24:07Z
  - d317a77 Merge pull request #23491 from jayeshka/influxdb_user-states-unit-test
  - 9d4043f adding states/influxdb_user unit test case

- PR #23477: (galet) LDAP auth: Escape filter value for group membership search @ 2015-05-07T22:04:48Z
  - e0b2a73 Merge pull request #23477 from galet/ldap-filter-escaping
  - 9d4043f adding states/influxdb_user unit test case

- PR #23476: (cachedout) Lint beacon @ 2015-05-07T19:55:36Z
  - PR #23431: (UtahDave) Beacon fixes | refs: #23476
    - e1719fe Merge pull request #23476 from cachedout/lint_23431
    - 8d1f20 Lint beacon

- PR #23431: (UtahDave) Beacon fixes | refs: #23476 @ 2015-05-07T19:53:47Z
  - 1e299ed Merge pull request #23431 from UtahDave/beacon_fixes
  - 152f223 remove unused import
  - 81198f9 fix interval logic and example
  - 5504778 update to proper examples
  - 6890439 fix list for mask
  - ee7b579 remove custom interval code.

- PR #23468: (rahulhan) Adding states/win_system.py unit tests @ 2015-05-07T19:20:50Z
  - ea55c44 Merge pull request #23468 from rahulhan/states_win_system_unit_test
  - 33f8c12 Adding states/win_system.py unit tests

- PR #23466: (UtahDave) minor spelling fix @ 2015-05-07T19:19:06Z
  - e6e1114 Merge pull request #23466 from UtahDave/2015.5local
  - b2c399a minor spelling fix

- PR #23461: (s0undt3ch) [2015.5] Update to latest stable bootstrap script v2015.05.07 @ 2015-05-07T19:16:18Z
  - ISSUE #563: (chutz) pidfile support for minion and master daemons | refs: #23460 #23461
  - 4eeb1e6 Merge pull request #23461 from s0undt3ch/hotfix/bootstrap-script
  - 638c63d Update to latest stable bootstrap script v2015.05.07

- PR #23450: (jayeshka) adding scsi unit test case @ 2015-05-07T19:00:28Z
  - 8651278 Merge pull request #23450 from jayeshka/scsi-unit-test
  - e7269ff adding scsi unit test case

- PR #23449: (jayeshka) adding s3 unit test case @ 2015-05-07T18:59:45Z
  - 8b374ae Merge pull request #23449 from jayeshka/s3-unit-test
  - 85786bf adding s3 unit test case

- PR #23448: (jayeshka) adding states/keystone unit test case @ 2015-05-07T18:58:59Z
PR #23447: (jayeshka) adding states/grafana unit test case @ 2015-05-07T18:58:20Z
- 23d7e7e Merge pull request #23447 from jayeshka/grafana-states-unit-test
- 7e90a4a adding states/grafana unit test case

PR #23438: (techhat) Gate requests import @ 2015-05-07T07:22:58Z
- 1fd0bc2 Merge pull request #23438 from techhat/gaterequests
- d5b15fc Gate requests import

PR #23429: (basepi) [2015.5] Merge forward from 2014.7 to 2015.5 @ 2015-05-07T05:35:13Z
- ISSUE #17245: (tomashavlas) localemod does not generate locale for Arch | refs: #23307 #23397
- PR #23425: (basepi) [2014.7] Fix typo in FunctionWrapper
- PR #23422: (cro) $HOME should not be used, some shells don’t set it.
- PR #23414: (jfindlay) 2015.2 -> 2015.5
- PR #23409: (terminalmage) Update Lithium docstrings in 2014.7 branch | refs: #23410
- PR #23404: (hvnsweeting) saltapi cherrypy: initialize var when POST body is empty
- PR #23397: (jfindlay) add more flexible whitespace to locale_gen search
- PR #23385: (rallytime) Backport #23346 to 2014.7
- PR #23346: (ericfode) Allow file_map in salt-cloud to handle folders. | refs: #23385
- 3c4f734 Merge pull request #23429 from basepi/merge-forward-2015.5
- 7729834 Merge remote-tracking branch `upstream/2014.7` into merge-forward-2015.5
- 644eb75 Merge pull request #23422 from cro/gce_sh_home
  * 4ef9e6b Don't use $HOME to find user's directory, some shells don't set it
- ef17ab4 Merge pull request #23425 from basepi/functionwrapper_typo
  * c390737 Fix typo in FunctionWrapper
- 1b13ec0 Merge pull request #23385 from rallytime/bp-23346
  * 9efe13c more linting fixes
  * cf131ec9 cleaned up some pylint errors
  * f981699 added logic to sftp_file and file_map to allow folder uploads using file_map
- f8c7a62 Merge pull request #23414 from jfindlay/update_branch
  * 8074d16 2015.2 -> 2015.5
- 54b3bd4 Merge pull request #23404 from hvnsweeting/cherrypy-post-emptybody-fix
  * f85f8f9 initialize var when POST body is empty
- 160f703 Merge pull request #23409 from terminalmage/update-lithium-docstrings-2014.7
  * be97d01 Fix sphinx typo
  * 20006b0 Update Lithium docstrings in 2014.7 branch
- aa5fba0 Merge pull request #23397 from jfindlay/fix_locale_gen
* 0941fef add more flexible whitespace to locale_gen search

  - ISSUE #23294: *(variia)* file.replace fails to append if repl string partially available | refs: #23350
  - ISSUE #23026: *(adelcast)* Incorrect salt-syndic logfile and pidfile locations | refs: #23341
  - ISSUE #22742: *(hvnsweeting)* salt-master says: ``This master address: `salt' was previously resolvable but now fails to resolve!`` | refs: #23344
  - ISSUE #19114: *(pykler)* salt-ssh and gpg pillar renderer | refs: #23272 #23347 #23188
  - ISSUE #17245: *(tomashavlas)* localemod does not generate locale for Arch | refs: #23307 #23397
  - ISSUE #580: *(thatch45)* recursive watch not being caught | refs: #23324
  - ISSUE #552: *(jhutchins)* Support require and watch under the same state dec | refs: #23324
  - PR #23368: *(kaithar)* Backport #23367 to 2014.7
  - PR #23367: *(kaithar)* Put the sed insert statement back in to the output. | refs: #23368
  - PR #23350: *(lorenegordon)* Append/prepend: search for full line
  - PR #23344: *(cachedout)* Explicitely set file_client on master
  - PR #23341: *(cachedout)* Fix syndic pid and logfile path
  - PR #23324: *(s0undt3ch)* [2014.7] Update to the latest stable release of the bootstrap script v2015.05.04
  - PR #23318: *(cellscape)* Honor seed argument in LXC container initialization
  - PR #23311: *(cellscape)* Fix new container initialization in LXC runner | refs: #23318
  - PR #23307: *(jfindlay)* check for /etc/locale.gen
  - PR #23272: *(basepi)* [2014.7] Allow salt-ssh minion config overrides via master config and roster | refs: #23347
  - PR #18368: *(basepi)* Merge forward from 2014.7 to develop | refs: #23367 #23368
  - PR #589: *(epoelke)* add --quiet and --outfile options to saltkey | refs: #23324
  - PR #567: *(bastichealaar)* Added upstart module | refs: #23324
  - PR #560: *(UtahDave)* The runs feature that was added in 93423aa2e5e4b7de6452090b0039560d2b13... | refs: #23324
  - PR #504: *(SEJeff)* File state goodies | refs: #23324
  - 1fb8445 Merge pull request #23396 from basepi/merge-forward-2015.2
  - 2766c8c Fix typo in FunctionWrapper
  - fd09ceda Merge remote-tracking branch `upstream/2014.7` into merge-forward-2015.2
    * 0c76dd4 Merge pull request #23368 from kaithar/bp-23367
      * 77f419 Pylint fix
    * 8d9ac6d1 Put the sed insert statement back in to the output.
  * 3493c1 Merge pull request #23350 from lorenegordon/file.replace_assume_line
    * b60e224 Append/prepend: search for full line
* 7be5c48 Merge pull request #23341 from cachedout/issue_23026
  - e98e65e Fix tests
  - 6011b43 Fix syndic pid and log file path
* ea61abf Merge pull request #23272 from basepi/salt-ssh.minion.config.19114
  - c223309 Add version added
  - be740ff Lint
  - c23375 Missing comma
  - 8e3e8e0 Pass the minion_opts through the FunctionWrapper
  - cb69cd0 Match the master config template in the master config reference
  - 87fc31e Add Salt-SSH section to master config template
  - 91dd9dc Add ssh_minion_opts to master config ref
  - c273ea1 Add minion config to salt-ssh doc
  - a6bb76 Add minion_opts to roster docs
  - 5212c35 Accept minion_opts from the target information
  - e2099b6 Process ssh_minion_opts from master config
  - 3b6421e Revert `Work around bug in salt-ssh in config.get for gpg renderer`
  - 494953a Remove the strip (embracing multi-line YAML dump)
  - fe87f0f Dump multi-line yaml into the SHIM
  - b751a72 Inject local minion config into shim if available
* 4f760dd Merge pull request #23347 from basepi/salt-ssh.functionwrapper.contains.19114
  - 3059e3 Backport FunctionWrapper.__contains__
* 02658b1 Merge pull request #23344 from cachedout/issue_22742
  - 5adc96c Explicitly set file_client on master
* ba7605d Merge pull request #23318 from cellscape/honor-seed-argument
  - 2281b1e Honor seed argument in LXC container initialization
* 4ac4509 Merge pull request #23307 from jfindlay/fix_locale_gen
  - 101199a check for /etc/locale.gen
* f790f42 Merge pull request #23324 from s0undt3ch/bootstrap-script-2014.7
* 6643e47 Update to the latest stable release of the bootstrap script v2015.05.04

  - 32923b5 Adding states/xmpp.py unit tests

- **PR #23335**: (steverweber) 2015.2: include doc in master config for module_dirs @ 2015-05-05T21:28:58Z
  - 8c057e6 Merge pull request #23335 from steverweber/2015.2
  - 5e3bae9 help installing python pysphere lib
  - 97513b0 include module_dirs
  - 36b1c87 include module_dirs
• **PR #23362:** (jayeshka) adding states/zk_concurrency unit test case @ 2015-05-05T15:50:06Z
  - 1648253 Merge pull request #23362 from jayeshka/zk_concurrency-states-unit-test
  - f60dda4 adding states/zk_concurrency unit test case

• **PR #23363:** (jayeshka) adding riak unit test case @ 2015-05-05T14:23:05Z
  - 1cdaeed Merge pull request #23363 from jayeshka/riak-unit-test
  - f9da6db adding riak unit test case

### 35.2.4 Salt 2015.5.2 Release Notes

**Release** 2015-06-10

Version 2015.5.2 is a bugfix release for 2015.5.0.

Extended Changelog Courtesy of Todd Stansell [https://github.com/tjstansell/salt-changelogs](https://github.com/tjstansell/salt-changelogs):

**PR #24346:** (rallytime) Backport #24271 to 2015.5 @ 2015-06-03T18:44:31Z

**PR #24271:** (randybias) Fixed the setup instructions

  refs: #24346
  - 76927c9 Merge pull request #24346 from rallytime/bp-24271
  - 04067b6 Fixed the setup instructions

**PR #24345:** (rallytime) Backport #24013 to 2015.5 @ 2015-06-03T18:39:41Z

**ISSUE #24012:** (jbq) Enabling a service does not create the appropriate rc.d symlinks on Ubuntu

  refs: #24013

**PR #24013:** (jbq) Fix enabling a service on Ubuntu #24012

  refs: #24345
  - 4afa03d Merge pull request #24345 from rallytime/bp-24013
  - 16e0732 Fix enabling a service on Ubuntu #24012

**PR #24365:** (jacobhammons) Fixes for PDF build errors @ 2015-06-03T17:50:02Z

  - c3392c2 Merge pull request #24365 from jacobhammons/DocFixes
  - 0fc1902 Fixes for PDF build errors

**PR #24313:** (nicholascapo) Fix #22991 Correctly set result when test=True @ 2015-06-03T14:49:18Z

  **ISSUE #22991:** (nicholascapo) npm.installed ignores test=True * ae681a4 Merge pull request #24313 from nicholascapo/fix-22991-npm.installed-test-true * ac9644c Fix #22991 npm.installed correctly set result on test=True

**PR #24312:** (nicholascapo) Fix #18966: file.serialize supports test=True @ 2015-06-03T14:49:06Z

  **ISSUE #18966:** (bechtoldt) file.serialize ignores test=True * d57a9a2 Merge pull request #24312 from nicholascapo/fix-18966-file.serialize-test-true * e7328e7 Fix #18966 file.serialize correctly set result on test=True

**PR #24302:** (jfindlay) fix pkg hold/unhold integration test @ 2015-06-03T03:27:43Z

  - 6b694e3 Merge pull request #24302 from jfindlay/pkg_tests
  - c2db0b1 fix pkg hold/unhold integration test

**PR #24349:** (rallytime) Remove references to mount_points in ec2 docs @ 2015-06-03T01:54:09Z
ISSUE #14021: (mathrawka) EC2 doc mentions mount_point, but unable to use properly
refs: #24349
  • aca8447 Merge pull request #24349 from rallytime/fix-14021
  • a235b11 Remove references to mount_points in ec2 docs

PR #24328: (dr4Ke) Fix state grains silently fails 2015.5 @ 2015-06-02T15:18:46Z
ISSUE #24319: (dr4Ke) grains state shouldn't fail silently * 88a997e Merge pull request #24328 from dr4Ke/fix_state_grains_silently_fails_2015.5 * 8a63d1e fix state grains silently fails #24319
  • ca1af20 grains state: add some tests

PR #24310: (techhat) Add warning about destroying maps @ 2015-06-02T03:01:28Z
ISSUE #24036: (arthurlogilab) [salt-cloud] Protect against passing command line arguments as names for the --destroy command
  refs: #24310

ISSUE #9772: (s0undt3ch) Delete VM’s in a map does not delete them all
refs: #24310
  • 7dc99bb Merge pull request #24310 from techhat/mapwarning
  • ca535a6 Add warning about destroying maps

PR #24281: (steverweber) ipmi docfix @ 2015-06-01T17:45:36Z
  • 02bfb25 Merge pull request #24281 from steverweber/ipmi_docfix
  • dd36f2c yaml formatting
  • f6def3 include api_kg kwarg in ipmi state
  • a7d4e97 doc cleanup
  • 0ded2fd save more cleanup to doc
  • 08872f2 fix name api_key to api_kg
  • 165a387 doc fix add api_kg kwargs
  • 1ec7888 cleanup docs

PR #24287: (jfindlay) fix pkg test on ubuntu 12.04 for realz @ 2015-06-01T14:16:37Z
  • 73cd2cb Merge pull request #24287 from jfindlay/pkg_test
  • 98944d8 fix pkg test on ubuntu 12.04 for realz

PR #24279: (rallytime) Backport #24263 to 2015.5 @ 2015-06-01T04:29:34Z
PR #24263: (cdarwin) Correct usage of import_yaml in formula documentation
  refs: #24279
  • 02017a0 Merge pull request #24279 from rallytime/bp-24263
  • beftc7c Correct usage of import_yaml in formula documentation

PR #24277: (rallytime) Put a space between after_jump commands @ 2015-06-01T04:28:26Z

ISSUE #24226: (c4urself) iptables state needs to keep ordering of flags
refs: #24277
  • 2ba696d Merge pull request #24277 from rallytime/fix_iptables_jump
- e2d1606 Move after_jump split out of loop
- d14f130 Remove extra loop
- 42ed532 Put a space between after_jump commands

**PR #24262: (basepi) More dictupdate after #24142 @ 2015-05-31T04:09:37Z**

**PR #24142: (basepi) Optimize dictupdate.update and add #24097 functionality**

ref: #24262

**PR #24097: (kiorky) Optimize dictupdate**

ref: #24142

- 113eba3 Merge pull request #24262 from basepi/dictupdatefix
- 0c4832c Raise a typeerror if non-dict types
- be21aaa Pylint
- bb8a6c6 More optimization
- c933249 py3 compat
- ff6b2a7 Further optimize dictupdate.update()
- c73f5ba Remove unused valtype

**PR #24269: (kiorky) zfs: Fix spurrious retcode hijacking in virtual @ 2015-05-30T17:47:49Z**

- 785d5a1 Merge pull request #24269 from makinacorpus/zfs
- 0bf23ce zfs: Fix spurrious retcode hijacking in virtual

**PR #24257: (jfindlay) fix pkg mod integration test on ubuntu 12.04 @ 2015-05-29T23:09:00Z**

- 3d885c0 Merge pull request #24257 from jfindlay/pkg_tests
- 9508924 fix pkg mod integration test on ubuntu 12.04

**PR #24260: (basepi) Fix some typos from #24080 @ 2015-05-29T22:54:58Z**

**ISSUE #23657: (arthurlogilab) [salt-cloud lxc] NameError: global name '__salt__' is not defined**

ref: #24080 #23982

**PR #24080: (kiorky) Lxc consistency2**

ref: #24260 #23982 #24066

**PR #24066: (kiorky) Merge forward 2015.5 -> develop**

ref: #23982

**PR #24065: (kiorky) continue to fix #23883**

ref: #24080 #24066

**PR #23982: (kiorky) lxc: path support**

ref: #24080

- 08a1075 Merge pull request #24260 from basepi/lxctypos24080
- 0fa1ad3 Fix another lxc typo
- 669938f s/you ll/you'll/

**PR #24080: (kiorky) Lxc consistency2**
refs: #24260 #23982 #24066
@ 2015-05-29T22:51:54Z

ISSUE #23657: (arthurlogilab) [salt-cloud lxc] NameError: global name '__salt__' is not defined
refs: #24080 #23982

PR #24066: (kiorky) Merge forward 2015.5 -> develop
refs: #23982

PR #24065: (kiorky) continue to fix #23883
refs: #24080 #24066

PR #23982: (kiorky) lxc: path support
refs: #24080
  • 75590cf Merge pull request #24080 from makinacorpus/lxc_consistency2
  • 81f8067 lxc: fix old lxc test
  • 458f506 seed: lint
  • 96b8d55 Fix seed.mkconfig yamldump
  • 76db68 lxc/aplynet: conservative
  • ce7096f variable collision
  • 8a8b28d lxc: lint
  • 458b18b more lxc docs
  • ef1f952 lxc docs: typos
  • d67a43d more lxc docs
  • 608da5e modules/lxc: merge resolution
  • 27c4689 modules/lxc: more consistent comparsion
  • 07c365a lxc: merge conflict spotted
  • 9993915 modules/lxc: rework settings for consistency
  • ce11d83 lxc: Global doc refresh
  • 61ed2f5 clouds/lxc: profile key is conflicting

PR #24247: (rallytime) Backport #24220 to 2015.5 @ 2015-05-29T21:40:01Z

ISSUE #24210: (damonnk) salt-cloud vsphere.py should allow key_filename param
refs: #24220

PR #24220: (djcrabhat) adding key_filename param to vsphere provider
refs: #24247
  • da14f3b Merge pull request #24247 from rallytime/bp-24220
  • 0b1041d adding key_filename param to vsphere provider

PR #24254: (rallytime) Add deprecation warning to Digital Ocean v1 Driver @ 2015-05-29T21:39:25Z

PR #22731: (dmyerscough) Decommission DigitalOcean APIv1 and have users use the new DigitalOcean APIv2
refs: #24254
- 21d6126 Merge pull request #24254 from rallytime/add_deprecation_warning_digitalocean
- cafe37b Add note to docs about deprecation
- ea0f1e0 Add deprecation warning to digital ocean driver to move to digital_ocean_v2

PR #24252: (aboe76) Updated suse spec to 2015.5.1 @ 2015-05-29T21:38:45Z
- dac055d Merge pull request #24252 from aboe76/opensuse_package
- 0ad617d Updated suse spec to 2015.5.1

PR #24251: (garethgreenaway) Returners broken in 2015.5 @ 2015-05-29T21:37:52Z
- 49e7fe8 Merge pull request #24251 from garethgreenaway/2015_5_returner_brokenness
- 5df6b52 The code calling cfg as a function vs treating it as a dictionary and using get is currently backwards causing returners to fail when used from the CLI and in scheduled jobs.

PR #24255: (rallytime) Clarify digital ocean documentation and mention v1 driver deprecation @ 2015-05-29T21:37:07Z
ISSUE #21498: (rallytime) Clarify Digital Ocean Documentation
refs: #24255
- bfb9461 Merge pull request #24255 from rallytime/clarify_digital_ocean_driver_docs
- 8d51f75 Clarify digital ocean documentation and mention v1 driver deprecation

PR #24232: (rallytime) Backport #23308 to 2015.5 @ 2015-05-29T21:36:46Z
PR #23308: (thusoy) Don't merge: Add missing jump arguments to iptables module
refs: #24232
- 41f5756 Merge pull request #24232 from rallytime/bp-23308
- 2733f66 Import string
- 9097cca Add missing jump arguments to iptables module

PR #24245: (Sacro) Unset PYTHONHOME when starting the service @ 2015-05-29T20:00:31Z
- a95982c Merge pull request #24245 from Sacro/patch-2
- 6632d06 Unset PYTHONHOME when starting the service

PR #24121: (hvnsweeting) deprecate setting user permission in rabbitmq_vhost.present @ 2015-05-29T15:55:40Z
- 1504c76 Merge pull request #24121 from hvnsweeting/rabbitmq-host-deprecate-set-permission
- 2223158 deprecate setting user permission in rabbitmq_host.present

PR #24179: (merll) Changing user and group only possible for existing ids. @ 2015-05-29T15:52:43Z
PR #24169: (merll) Changing user and group only possible for existing ids.
refs: #24179
- ba02f65 Merge pull request #24179 from Precis/fixed-file-uid-gid-2015.0
- ee4c9d5 Use ids if user or group is not present.

PR #24229: (msteed) Fix auth failure on syndic with external_auth @ 2015-05-29T15:04:06Z
ISSUE #24147: (paclat) Syndication issues when using authentication on master of masters.
Salt Documentation, Release 2015.8.0

refs: #24229

• 9fbf066 Merge pull request #24229 from msteeed/issue-24147
• 482d1cf Fix auth failure on syndic with external_auth

PR #24234: (jayeshka) adding states/quota unit test case. @ 2015-05-29T14:14:27Z

• 19fa43c Merge pull request #24234 from jayeshka/quota-states-unit-test
• c233565 adding states/quota unit test case.

PR #24217: (jfindlay) disable intermittently failing tests @ 2015-05-29T03:08:39Z

ISSUE #40: (thatch45) Clean up timeouts

refs: #22857

PR #23623: (jfindlay) Fix /jobs endpoint’s return

refs: #24217

PR #22857: (jacksontj) Fix /jobs endpoint’s return

refs: #23623

• e15142c Merge pull request #24217 from jfindlay/disable_bad_tests
• 6b62804 disable intermittently failing tests

PR #24199: (ryan-lane) Various fixes for boto_route53 and boto_elb @ 2015-05-29T03:02:41Z

• ce8e43b Merge pull request #24199 from lyft/route53-fix-elb
• d8dc9a7 Better unit tests for boto_elb state
• 62f214b Remove cnames_present test
• 7b9ae82 Lint fix
• b74b0d1 Various fixes for boto_route53 and boto_elb

PR #24142: (basepi) Optimize dictupdate.update and add #24097 functionality

refs: #24262

@ 2015-05-29T03:00:56Z

PR #24097: (kiorky) Optimize dictupdate

refs: #24142 #24142

PR #21968: (ryanwohara) Verifying the key has a value before using it. * a43465d Merge pull request #24142 from basepi/dictupdate24097 * 5c6e210 Deepcopy on merge_recurse

• a13c84a Fix None check from #21968
• 9ef2c64 Add docstring
• 8579429 Add in recursive_update from #24097
• 8599143 if key not in dest, don’t recurse
• d8a8b5 Rename klass to valtype

PR #24208: (jayeshka) adding states/ports unit test case. @ 2015-05-28T23:06:33Z

• 526698b Merge pull request #24208 from jayeshka/ports-states-unit-test
• 657b709 adding states/ports unit test case.
PR #24219: (jfindlay) find zfs without modinfo  @ 2015-05-28T21:07:26Z

ISSUE #20635: (dennisjac) 2015.2.0rc1: zfs errors in log after update
refs: #24219
- d00945f Merge pull request #24219 from jfindlay/zfs_check
- 15d4019 use the salt loader in the zfs mod
- 5599b67 try to search for zfs if modinfo is unavailable

PR #24190: (msteed) Fix issue 23815  @ 2015-05-28T20:10:34Z

ISSUE #23815: (Snrgster) [beacons] inotify errors on subdir creation * 3dc4b85 Merge pull request #24190 from msteed/issue-23815 * 086a1a9 lint
- 65de62f fix #23815
- d04e916 spelling
- db9f682 add inotify beacon unit tests

PR #24211: (rallytime) Backport #24205 to 2015.5  @ 2015-05-28T18:28:15Z

PR #24205: (hazelesque) Docstring fix in salt.modules.yumpkg.hold
refs: #24211
- 436634b Merge pull request #24211 from rallytime/bp-24205
- 23284b5 Docstring fix in salt.modules.yumpkg.hold

PR #24212: (terminalmage) Clarify error in rendering template for top file  @ 2015-05-28T18:26:20Z

- cc58624 Merge pull request #24212 from terminalmage/clarify-error-msg
- ca807fb Clarify error in rendering template for top file

PR #24213: (The-Loeki) ShouldFix _- troubles in debian_ip  @ 2015-05-28T18:24:39Z

ISSUE #23904: (mbrgm) Network config bonding section cannot be parsed when attribute names use dashes
refs: #23917

ISSUE #23900: (hashi825) salt ubuntu network building issue 2015.5.0
refs: #23922

PR #23922: (garethgreenaway) Fixes to debian_ip.py
refs: #24213

PR #23917: (corywright) Split debian bonding options on dash instead of underscore
refs: #24213
- 9825160 Merge pull request #24213 from The-Loeki/patch-3
- a68d515 ShouldFix _- troubles in debian_ip

PR #24214: (basepi) 2015.5.1release  @ 2015-05-28T16:23:57Z

- 071751d Merge pull request #24214 from basepi/2015.5.1release
- e5ba31b 2015.5.1 release date
- 768494c Update latest release in docs

PR #24202: (rallytime) Backport #24186 to 2015.5  @ 2015-05-28T05:16:48Z
PR #24186: (thcipriani) Update salt vagrant provisioner info
   refs: #24202
   • c2f1f6b Merge pull request #24202 from rallytime/bp-24186
   • db793dd Update salt vagrant provisioner info

PR #24192: (rallytime) Backport #20474 to 2015.5 @ 2015-05-28T05:16:18Z
   PR #20474: (djcrabhat) add sudo, sudo_password params to vsphere deploy to allow for non-root deploys
   refs: #24192
   • 8a085a2 Merge pull request #24192 from rallytime/bp-20474
   • fd3c783 add sudo, sudo_password params to deploy to allow for non-root deploys

PR #24184: (rallytime) Backport #24129 to 2015.5 @ 2015-05-28T05:15:08Z
   PR #24129: (pengyao) Wheel client doc
   refs: #24184
   • 7cc535b Merge pull request #24184 from rallytime/bp-24129
   • 722a662 fixed a typo
   • 565eb46 Add cmd doc for WheelClient

PR #24183: (rallytime) Backport #19320 to 2015.5 @ 2015-05-28T05:14:36Z
   PR #19320: (clan) add `state_output_profile` option for profile output
   refs: #24183
   • eb0af70 Merge pull request #24183 from rallytime/bp-19320
   • 55db1bf state_output_profile default to True
   • 9919227 fix type: statei -> state
   • 0549ca6 add `state_output_profile` option for profile output

PR #24201: (whiteinge) Add list of client libraries for the rest_cherrypy module to the top-level documentation @ 2015-05-28T02:12:09Z
   • 1b5bf23 Merge pull request #24201 from whiteinge/rest_cherrypy-client-libs
   • 5f71802 Add list of client libraries for the rest_cherrypy module
   • 28f77f7 Fix rest_cherrypy config example indentation

PR #24195: (rallytime) Merge #24185 with a couple of fixes @ 2015-05-27T22:18:37Z
   PR #24185: (jacobhammons) Fixes for doc build errors
   refs: #24195
   • 3307ec2 Merge pull request #24195 from rallytime/merge-24185
   • d8daa9d Merge #24185 with a couple of fixes
   • 634d56b Fixed pylon error
   • 0689815 Fixes for doc build errors

PR #24166: (jayeshka) adding states/pkgng unit test case. @ 2015-05-27T20:27:49Z
   • 7e400bc Merge pull request #24166 from jayeshka/pkgng-states-unit-test
- 2234bb0 adding states/pkgng unit test case.

**PR #24189** (basepi) [2015.5] Merge forward from 2014.7 to 2015.5 @ 2015-05-27T20:26:31Z

PR #24178: (rallytime) Backport #24118 to 2014.7, too. PR #24159: (rallytime) Fill out modules/keystone.py CLI Examples PR #24158: (rallytime) Fix test_valid_docs test for tls module PR #24118: (trevor-h) removed deprecated pymongo usage

refs: #24139 #24178

- 9fcda79 Merge pull request #24189 from basepi/merge-forward-2015.5
- 8839e9c Merge remote-tracking branch `upstream/2014.7` into merge-forward-2015.5
- 9d7331c Merge pull request #24178 from rallytime/bp-24118
  - e2217a0 removed deprecated pymongo usage as no longer functional with pymongo > 3.x
- 4e8c503 Merge pull request #24159 from rallytime/keystone_doc_examples
  - dadac8d Fill out modules/keystone.py CLI Examples
- fc10ee8 Merge pull request #24158 from rallytime/fixedoc_error
  - 49a517e Fix test_valid_docs test for tls module

**PR #24181** (jtand) Fixed error where file was evaluated as a symlink in test_absent @ 2015-05-27T18:26:28Z

- 2303dec Merge pull request #24181 from jtand/file_test
- 5f0e601 Fixed error where file was evaluated as a symlink in test_absent

**PR #24180** (terminalmage) Skip libvirt tests if not running as root @ 2015-05-27T18:18:47Z

- a16276a Merge pull request #24180 from terminalmage/fix-libvirt-test
- 72e7416 Skip libvirt tests if not running as root

**PR #24165** (jayeshka) adding states/portage_config unit test case. @ 2015-05-27T17:15:08Z

- 1fbc5b2 Merge pull request #24165 from jayeshka/portage_config-states-unit-test
- 8cf1505 adding states/portage_config unit test case.

**PR #24164** (jayeshka) adding states/pecl unit test case. @ 2015-05-27T17:14:26Z

- 4747856 Merge pull request #24164 from jayeshka/pecl-states-unit-test
- 5e6a5b3 adding states/pecl unit test case.

**PR #24160** (The-Loeki) small enhancement to data module; pop() @ 2015-05-27T17:03:10Z

- cd4a19 Merge pull request #24160 from The-Loeki/patch-1
- 2175ff3 doc & merge fix
- eba382c small enhancement to data module; pop() (The-Loeki)

**PR #24153** (techhat) Batch mode sometimes improperly builds lists of minions to process @ 2015-05-27T16:21:53Z

- 1af8c83 adding states/pagerduty unit test case.

- 1af8c83 adding states/pagerduty unit test case.
PR #24156: *(basepi) [2015.5]* Merge forward from 2014.7 to 2015.5  @ 2015-05-27T15:05:01Z

**ISSUE #23464**: *(tibold)* cmd_iter_no_block() blocks

refs: #24093

PR #24125: *(hvnsweeting)* Fix rabbitmq test mode  PR #24093: *(msteed)* Make LocalClient.cmd_iter_no_block() not block  PR #24008: *(davidjb)* Correct reST formatting for states.cmd documentation  PR #23933: *(jacobhammons)* sphinx saltstack2 doc theme * b9507d1 Merge pull request #24156 from basepi/merge-forward-2015.5 * e52b5ab Remove stray >>>>>>

- 7dfbd92 Merge remote-tracking branch `upstream/2014.7` into merge-forward-2015.5
  - c0d32e0 Merge pull request #24125 from hvnsweeting/fix-rabbitmq-test-mode
    * 71862c6 enhance log
    * 28e2594 change according to new output of rabbitmq module functions
    * cd0212e processes and returns better output for rabbitmq module
  - 39a8f30 Merge pull request #24093 from msteed/issue-23464
    * fd35903 Fix failing test
    * 41b344c Make LocalClient.cmd_iter_no_block() not block
  - 5bffd30 Merge pull request #24008 from davidjb/2014.7
    * 8b8d029 Correct reST formatting for documentation
  - 1aa0420 Merge pull request #23933 from jacobhammons/2014.7
  - a3613e6 removed numbering from doc TOC
  - 78b737c removed 2015.* release from release notes, updated index page to remove PDF/epub links
  - e867f7d Changed build settings to use saltstack2 theme and update release versions.
  - 81ed9c9 sphinx saltstack2 doc theme

PR #24145: *(jfindlay)* attempt to decode win update package  @ 2015-05-26T23:20:20Z

**ISSUE #24102**: *(bormotov)* win_update encondig problems

refs: #24145

- 05745fa Merge pull request #24145 from jfindlay/win_update_encoding
  - cc5e17e attempt to decode win update package

PR #24123: *(kiorky)* fix service enable/disable change  @ 2015-05-26T21:24:19Z

**ISSUE #24122**: *(kiorky)* service.dead is no more stateful: services does not handle correctly enable/disable change state

refs: #24123

- 7024789 Merge pull request #24123 from makinacorpus/ss
  - 2e2e1d2 fix service enable/disable change

PR #24146: *(rallytime)* Fixes the boto_vpc_test failure on CentOS 5 tests  @ 2015-05-26T20:15:19Z

- 51c3cec Merge pull request #24146 from rallytime/fix_centos_boto_failure
  - ac0f97d Fixes the boto_vpc_test failure on CentOS 5 tests

PR #24144: *(twangboy)* Compare Keys ignores all newlines and carriage returns  @ 2015-05-26T19:25:48Z
ISSUE #24052: (twangboy) v2015.5.1 Changes the way it interprets the minion_master.pub file
refs: #24089 #24144

ISSUE #23566: (rks2286) Salt-cp corrupting the file after transfer to minion

   - 26d6851 Merge pull request #24032 from kartiksubbarao/augeas_insert_16383
   - 368edcd Update augeas_cfg.py

PR #24025: (jayeshka) adding timezone unit test case @ 2015-05-21T16:50:53Z

   - 55c9245 Merge pull request #24025 from jayeshka/timezone-unit-test
   - 1ec33e2 removed assertion error
   - 16ecb28 adding timezone unit test case

PR #24023: (jayeshka) adding states/mongodb_database unit test case @ 2015-05-21T16:49:17Z

   - e243617 Merge pull request #24023 from jayeshka/mongodb_database-states-unit-test
   - 5e9ac7e adding states/mongodb_database unit test case

PR #24022: (jayeshka) adding states/modjk_worker unit test case @ 2015-05-21T16:48:29Z

   - b37bd9 Merge pull request #24022 from jayeshka/modjk_worker-states-unit-test
   - 05c0a98 adding states/modjk_worker unit test case

PR #24005: (msteed) issue #23776 @ 2015-05-21T01:55:34Z

   ISSUE #23776: (enblde) Presence change events constantly reporting all minions as new in 2015.5 * 701c51b
   Merge pull request #24005 from msteed/issue-23776 * 62e67d8 issue #23776

PR #23996: (neogenix) iptables state generates a 0 position which is invalid in iptables cli #23950 @ 2015-05-20T22:44:27Z

   ISSUE #23950: (neogenix) iptables state generates a 0 position which is invalid in iptables cli
   refs: #23996
   - 17bc0b Merge pull request #23996 from neogenix/2015.5-23950
   - ad417a5 fix for #23950

PR #23994: (rallytime) Skip the gpodder pkgrepo test for Ubuntu 15 - they don't have vivid ppa up yet @ 2015-05-20T21:18:21Z

   - 4cb8773 Merge pull request #23994 from rallytime/skip_test_ubuntu_15
   - 9e0ec07 Skip the gpodder pkgrepo test - they don't have vivid ppa up yet

35.2.5 Salt 2015.5.3 Release Notes

Extended Changelog Courtesy of Todd Stansell (https://github.com/tjstansell/salt-changelogs):

Generated at: 2015-07-01T19:40:52Z

Statistics:
  - Total Merges: 177
• Total Issue references: 81
• Total PR references: 231

Changes:

• PR #25096: (jfindlay) Postgres group test @ 2015-07-01T18:48:26Z
  – PR #24330: (jayeshka) adding states/postgres_group unit test case. | refs: #25096
  – 21709aa Merge pull request #25096 from jfindlay/postgres_group_test
  – 3c379dc declobber postgres group unit test mocking
  – a162ff8 adding states/postgres_group unit test case.

• PR #25085: (jfindlay) accept all sources in the file state @ 2015-07-01T18:23:45Z
  – ISSUE #25041: (wt) REGRESSION: pillar.get of integer fails to render in sls | refs: #25085
  – 0a84640 Merge pull request #25085 from jfindlay/fix_file
  – 937a252 remove unnecessary file state tests
  – 6f238e9 integration test file.managed sources
  – a5978d3 iterate an iterable source otherwise list+str it

• PR #25095: (jfindlay) Win groupadd unit tests @ 2015-07-01T18:18:53Z
  – PR #24207: (jayeshka) adding win_groupadd unit test case. | refs: #25095
  – a983942 Merge pull request #25095 from jfindlay/win_groupadd_test
  – 564dfbd depend on win libs rather than mocking them
  – 9b9aeb8 resolved all errors.
  – aaf8935 adding win_groupadd unit test case.

• PR #25089: (jfindlay) fix minion sudo @ 2015-07-01T15:53:16Z
  – ISSUE #21520: (jfindlay) sudo.salt_call is broken | refs: #25089
  – PR #20226: (thatch45) Allow sudo priv escalation | refs: #25089
  – 7c8d2a8 Merge pull request #25089 from jfindlay/fix_sudo
  – d8f91d4 add some apprehension to the sudo exec module
  – a9269c0 adding sudo exec module docs
  – e4a40b7 comment whitespace in minion config
  – 44cb167 adding sudo_user minion config docs
  – d461060 adding sudo_user minion config to default

• PR #25099: (driskell) Fix broken batch results @ 2015-07-01T15:51:29Z
  – ISSUE #24875: (ahammond) ValueError: list.remove(x): x not in list in File ```/usr/lib/python2.6/site-packages/salt/cli/batch.py```, line 179, in run active.remove(minion) | refs: #25099
  – 4d6078e Merge pull request #25099 from driskell/patch-1
  – 59b23e5 Fix broken batch results

• PR #25083: (steverweber) ipmi: get_sensor_data would always fail @ 2015-06-30T20:57:21Z
  – 4635079 Merge pull request #25083 from steverweber/fix_ipmi_stat
- 836f48c include _ in IpmiCommand
- 817e434 get_sensor_data would always fail

**PR #25067**: (The-Loeki) Fix for maxdepth=0 in find @ 2015-06-30T20:54:06Z
- 15f2a40 Merge pull request #25067 from The-Loeki/patch-1
- 61edad3 Fix for maxdepth=0 in find

**PR #25078**: (terminalmage) Use smaller number for upper limit of mac_user’s _first_avail_uid helper function @ 2015-06-30T20:53:24Z
- 58d933c Merge pull request #25078 from terminalmage/fix-mac-uid
- df2ab7e Use smaller number for upper limit of mac_user’s _first_avail_uid helper function

**PR #25045**: (garethgreenaway) Fixes to debian_ip.py in 2015.5 @ 2015-06-30T17:36:43Z
- ISSUE #24521: (multani) State network.managed fails on Debian (Jessie) | refs: #25045
- ebd6cde Merge pull request #25045 from garethgreenaway/24521_debian_networking
- 6f2a6e9 having proto default to static since it’s needed to build the template.

**PR #25065**: (lorenbgordon) Add download links for 2015.5.1-3 and 2015.5.2 Windows installers @ 2015-06-30T15:29:31Z
- ISSUE #25057: (TheBigBear) why is there still no newer salt-minion for windows than ver. 2015.5.0-2? no 2015.5.1 or 2015.5.2?
- ae31b27 Merge pull request #25065 from lorenbgordon/update-windows-installer-links
- 40a0c13 Add download links for 2015.5.1-3 and 2015.5.2, Fixes #25057

**PR #25052**: (basepi) [2015.5] Merge forward from 2014.7 to 2015.5 @ 2015-06-30T01:05:00Z
- ISSUE #15209: (hubez) file.manage: source_hash not working with s3:// (2014.7.0rc1) | refs: #25011
- PR #25011: (notpeter) Add s3 to protocols for remote source_hash (2014.7 backport)
- ddae60 Merge pull request #25052 from basepi/merge-forward-2015.5
- 2c5e664 Merge remote-tracking branch `upstream/2014.7` into merge-forward-2015.5
- a7154e7 Merge pull request #25011 from notpeter/s3_2014.7_backport
  * 8b8af64 Add s3 to protocols for remote source_hash

**PR #25038**: (jfindlay) versionadded @ 2015-06-29T19:49:27Z
- PR #24747: (msciciel) add get_route function to network module | refs: #25038
- c7003d4 Merge pull request #25038 from jfindlay/versionadded
- d6dc69 versionadded

**PR #24747**: (msciciel) add get_route function to network module | refs: #25038 @ 2015-06-29T16:51:43Z
- 28c87ca Merge pull request #24747 from msciciel/2015.5
- 79b4ec2 network module lint fix
- 0b6e78 network module: fix for ipv6
- f3d184c add get_route function to network module

**PR #24975**: (ryan-lane) Fix update of undefined env var in npm module @ 2015-06-29T16:45:05Z
- 46a9677 Merge pull request #24975 from lyft/npm-module-fix
- 6fde581 Try byte literals rather than unicode strings in the env
- c8514de Fix update of undefined env var in npm module

- **PR #24986**: (heewa) Don't modify empty change @ 2015-06-29T16:44:17Z
  - 9cf8550 Merge pull request #24986 from heewa/fixed-pkg-hold-when-errored
  - d47a448 Don't modify empty change

- **PR #24999**: (rallytime) Provide a less confusing error when cloud provider is misconfigured @ 2015-06-29T16:43:31Z
  - ISSUE #24969: (bradthuber) salt-cloud 2015.5.0: missing azure dependency results in misleading error | refs: #24999
  - ece897d Merge pull request #24999 from rallytime/cloud_error_help
  - 1e81a88 Clean up
  - be19a67 Provide a less confusing error when cloud provider is misconfigured

- **PR #24987**: (heewa) Don't try to cache a template when it's not a file @ 2015-06-29T14:02:59Z
  - 4af15cf Merge pull request #24987 from heewa/trying-to-cache-no-file
  - 9ae0c78 Don't try to cache a template when it's not a file

- **PR #25022**: (jfindlay) revise label and milestone documentation @ 2015-06-29T13:51:24Z
  - 8eeadb Merge pull request #25022 from jfindlay/label_docs
  - 8575192 revise label and milestone documentation

- **PR #25029**: (jayeshka) adding redismod unit test case. @ 2015-06-29T13:50:33Z
  - 89c2e01 Merge pull request #25029 from jayeshka/redismod-unit-test
  - e3045be adding redismod unit test case.

- **PR #24995**: (rallytime) Fix deprecated pymongo usage causing errors in latest pymongo @ 2015-06-27T22:28:56Z
  - **PR #24175**: (trevor-h) fix deprecated pymongo usage causing errors in latest pymongo | refs: #24995
  - 6425252 Merge pull request #24995 from rallytime/tops_mongo
  - a3c1063 fix deprecated pymongo usage causing errors in latest pymongo

- **PR #24994**: (garethgreenaway) Another Fix to gpg.py in 2015.5 @ 2015-06-27T22:28:15Z
  - ISSUE #24862: (dkatsanikakis) gpg.import_key returns error after succesfully completed | refs: #24966 #24994
  - e9aa11 Merge pull request #24994 from garethgreenaway/2015_5_24862_gpg_import_key
  - d2f0d8f variable was referenced before assignment. Just removing the variable and checking the return from distutils.version.LooseVersion directly.

- **PR #24988**: (jayeshka) adding states/supervisord unit test case. @ 2015-06-27T22:24:42Z
  - ebd666e Merge pull request #24988 from jayeshka/supervisord-states-unit-test
  - bb0a6d5 adding states/supervisord unit test case.

- **PR #25007**: (basepi) [2015.5] Merge forward from 2014.7 to 2015.5 @ 2015-06-26T21:28:57Z
  - ISSUE #24915: (jtand) Salt-cloud not working in 2014.7.6 | refs: #24944
  - **PR #24944**: (techhat) Double-check main_cloud_config

35.2. Previous Releases 2081
- PR #24936: (jtand) Fixed ps module to not use deprecated psutil commands
- 0487c3c Merge pull request #25007 from basepi/merge-forward-2015.5
- 4980fd5 Merge remote-tracking branch `upstream/2014.7` into merge-forward-2015.5
- a11e4c6 Merge pull request #24944 from techhat/issue24915
  * 59c3081 Double-check main_cloud_config
- d26a544 Merge pull request #24936 from jtand/psutil
  * bdb7a19 Fixed ps module to not use deprecated psutil commands

- PR #25003: (jacobhammons) Updated man pages @ 2015-06-26T19:13:41Z
  - 91a60e1 Merge pull request #25003 from jacobhammons/man-pages
  - cf97a4a Updated man pages

- PR #25002: (jacobhammons) sphinx html theme updates @ 2015-06-26T18:39:14Z
  - a60a2c4 Merge pull request #25002 from jacobhammons/doc-announcements
  - f88344 sphinx html theme updates

- PR #24977: (rallytime) Only warn about digital ocean deprecation if digital ocean is configured @ 2015-06-25T23:54:46Z
  - a791b23 Merge pull request #24977 from rallytime/do_move_warning
  - 6b54422 Only warn about digital ocean deprecation if digital ocean is configured

- PR #24966: (garethgreenaway) Fixes to gpg.py in 2015.5 @ 2015-06-25T19:58:49Z
  - ISSUE #24862: (dkatsanikakis) gpg.import_key returns error after succesfully completed | refs: #24966 #24994
  - a71c1b7 Merge pull request #24966 from garethgreenaway/2015_5_24862_gpg_import_key
  - 55eb73b fixing unit tests.
  - 80c24be Fixing an issue with the import_key method. Different results depending on which gnupg python module is installed.

- PR #24965: (jacksontj) Fix memory leak in saltnado @ 2015-06-25T18:48:03Z
  - ISSUE #24846: (mavenAtHouzz) Memory leak issue in rest_tornado EventListener | refs: #24965
  - 8622184 Merge pull request #24965 from jacksontj/2015.5
  - 48b5e16 pylint
  - 87ada4 Fix memory leak in saltnado

- PR #24948: (jfindlay) fix some malformed doc links and anchors @ 2015-06-25T15:51:38Z
  - 773c4cf Merge pull request #24948 from jfindlay/doc_links
  - 1529b92 fix some malformed doc links and anchors

- PR #24886: (anlutro) Be more careful about stripping away root_dir from directory options @ 2015-06-25T15:50:11Z
  - ISSUE #24885: (anlutro) Master config - Directories starting with a dot have the dot stripped when root_dir is . | refs: #24886
  - 4ebc01e Merge pull request #24886 from alprs/fix-root_dir_bug
  - 52caaf3d os.sep is the correct directory separator constant
0ecbf26 Be more careful about stripping away root_dir from directory options

- **PR #24930:** (jacksontj) Don't refetch file templates 100% of the time-- Performance optimization for templated files @ 2015-06-24T22:47Z
  - f52f7e1 Merge pull request #24930 from jacksontj/2015.5
  - 5fb7534 Only parse the source if we have one
  - e03a6fa Add support for sources of managed files to be local
  - 4cf78a0 pylint
  - d70914e Don't refetch the template 100% of the time-- Performance optimization for templated files

- **PR #24935:** (basepi) [2015.5] Merge forward from 2014.7 to 2015.5 @ 2015-06-24T18:17:54Z
  - **PR #24918:** (BretFisher) SmartOSSMF minion startup fix
  - **PR #473:** (whiteinge) Added a couple functions to work with the minion file cache | refs: #24918
  - 925a4d9 Merge pull request #24935 from basepi/merge-forward-2015.5
  - 8d8bf34 Merge remote-tracking branch `upstream/2014.7` into merge-forward-2015.5
  - eeb05a1 Merge pull request #24918 from BretFisher/minion-start-smartos-smf-fix
    * d7fb0c Smartos smf minion fix

- **PR #24873:** (jfindlay) convert osrelease grain to str before str op @ 2015-06-24T16:43:08Z
  - **ISSUE #24826:** (rakai93) rh_service.py: `int` object has no attribute `startswith` | refs: #24873
  - 4e8ed0d Merge pull request #24873 from jfindlay/rh_service
  - febe65f convert osrelease grain to str before str op

- **PR #24923:** (jayeshka) adding states/status unit test case. @ 2015-06-24T15:50:07Z
  - 90819f9 Merge pull request #24923 from jayeshka/status-states-unit-test
  - baec650 adding states/status unit test case.

- **PR #24902:** (cro) Fix minion failover, document same @ 2015-06-24T15:20:43Z
  - 2dd24ec Merge pull request #24902 from cro/fixfo2
  - 90c73ff References to documentation.
  - f0e9204 Add references to failover parameters in conf
  - 9da96a8 Docs
  - e2314f0 Move comment.
  - b9a756f Fix master failover and add documentation for same. Factor in syndics. Syndics will not failover (yet).

- **PR #24926:** (rallytime) Back-port #22263 to 2015.5 @ 2015-06-24T15:09:40Z
  - **PR #22263:** (cachedout) Prevent a load from being written if one already exists | refs: #24926
  - 087ee09 Merge pull request #24926 from rallytime/bp-22263
  - 8c9d29c Prevent a load from being written if one already exists

- **PR #24900:** (rallytime) Back-port #24848 to 2015.5 @ 2015-06-24T15:09:18Z
  - **PR #24848:** (nmadhok) Correcting bash code blocks | refs: #24900
  - b34a74f Merge pull request #24900 from rallytime/bp-24848
- d2b5456 Correcting bash code blocks

- **PR #24899**: (rallytime) Back-port #24847 to 2015.5 @ 2015-06-24T15:09:01Z
  - **PR #24847**: (borutmrak) unset size parameter for lxc.create when backing=zfs | refs: #24899
  - a54e8e8 Merge pull request #24899 from rallytime/bp-24847
  - 1e4ec7a unset size parameter for lxc.create when backing=zfs

- **PR #24898**: (rallytime) Back-port #24845 to 2015.5 @ 2015-06-24T15:06:09Z
  - **PR #24845**: (porterjames) fix bug in docker.loaded | refs: #24898
  - d4dd8d2 Merge pull request #24898 from rallytime/bp-24845
  - 6930855 Merge pull request #24897 from rallytime/bp-24839

- **PR #24897**: (rallytime) Back-port #24839 to 2015.5 @ 2015-06-24T15:05:35Z
  - **ISSUE #24799**: (infestdead) Forced remount because options changed when no options changed (glusterfs)
  - **PR #24839**: (infestdead) fix for issue #24799 | refs: #24897
  - a4f807c Merge pull request #24897 from rallytime/bp-24839

- **PR #24891**: (jayeshka) adding states/ssh_known_hostsunittestcase. @ 2015-06-23T16:46:58Z
  - 1650233 Merge pull request #24891 from jayeshka/ssh_known_hostsunittestcase.

- **PR #24874**: (dkiser) Fix for salt-cloud when ssh key used to auth and using sudo. @ 2015-06-22T23:46:08Z
  - **ISSUE #24870**: (dkiser) salt-cloud fails on sudo password prompt when using ssh key to auth | refs: #24874
  - c32aae9 Merge pull request #24874 from dkiser/salt-cloud-24870
  - 6c31143 Fix key error for the PR to fix #24870.
  - bdcf7d8 Fix pylint for #24874.

- **PR #24880**: (dkiser) Fix to allow password for salt-cloud to be set outside of a vm specif... @ 2015-06-22T23:44:59Z
  - **ISSUE #24871**: (dkiser) salt-cloud fails to honor `password` in cloud options before raising an exception | refs: #24880
  - ddaa21c Merge pull request #24880 from dkiser/salt-cloud-24871
  - 4f6c035 Fix to allow password for salt-cloud to be set outside of a vm specific context.

- **PR #24852**: (pruiz) Fix issue 24851: regular expression so it now matches packages with `.` or `~` at pkg name @ 2015-06-22T20:37:13Z
  - 3902b16 Merge pull request #24852 from pruiz/issue-24851
  - 73adb1d Fix regular expression so it now matches packages with `.` or `~` at pkg name.

- **PR #24861**: (jayeshka) adding states/ssh_auth unit test case. @ 2015-06-22T16:20:01Z
  - 6c5b788 Merge pull request #24861 from jayeshka/ssh_auth-states-unit-test
  - e5d7b0d adding states/ssh_auth unit test case.
- **PR #24824**: (kev009) Detect bhyve virtual type for FreeBSD guests @ 2015-06-22T15:24:35Z
  - ISSUE #23478: (calvinhp) grains.get virtual reports `physical` on bhyve FreeBSD VM | refs: #24824
  - 9e3321c Merge pull request #24824 from kev009/grains-bhyve-bsd
  - a226209 Detect bhyve virtual type for freebsd guests
- **PR #24795**: (anlutro) Fix state.apply for salt-ssh @ 2015-06-22T15:23:57Z
  - ISSUE #24746: (anlutro) state.apply doesn't seem to work | refs: #24795
  - 7b07ef9 Merge pull request #24795 from alprs/fix-salt_ssh_state_apply
  - 905840b Fix state.apply for salt-ssh
- **PR #24832**: (jacksontj) Don't incur a `__load_all` of the lazy_loader while looking for mod_init. @ 2015-06-22T15:17:10Z
  - PR #20540: (jacksontj) Loader no merge: Don't allow modules to `merge` | refs: #24832
  - PR #20481: (jacksontj) Add submodule support to LazyLoader | refs: #20540
  - PR #20473: (jacksontj) Add `disabled` support | refs: #20481
  - PR #20274: (jacksontj) Loader overhaul to LazyLoader | refs: #20473
  - PR #12327: (jacksontj) Add a LazyLoader class which will lazily load modules (with the given lo... | refs: #20274
  - 31d4c13 Merge pull request #24832 from jacksontj/2015.5
  - cfa7c0a pylint
  - be18439 Don't incur a `__load_all` of the lazy_loader while looking for mod_init.
- **PR #24834**: (rallytime) Back-port #24811 to 2015.5 @ 2015-06-19T18:43:49Z
  - ISSUE #14666: (luciddr34m3r) salt-cloud GoGrid exception when using map file | refs: #24811
  - PR #24811: (rallytime) Add notes to map and gogrind docs -- don't use -P with map files | refs: #24834
  - 2d8148f Merge pull request #24834 from rallytime/bp-24811
  - e2684ec Add notes to map and gogrind docs -- don't use -P with map files
- **PR #24790**: (rallytime) Back-port #24741 to 2015.5 @ 2015-06-19T17:25:58Z
  - PR #24741: (CameronNemo) Improve Upstart enable/disable handling | refs: #24790
  - d2ed63 Merge pull request #24790 from rallytime/bp-24741
  - a54245f Add missing import
  - 4ce6370 salt.modules.upstart: fix lint errors
  - aec53ec Improve Upstart enable/disable handling
- **PR #24789**: (rallytime) Back-port #24717 to 2015.5 @ 2015-06-19T17:00Z
  - PR #24717: (gthb) virtualenv.managed: document user and no_chown | refs: #24789
  - 645e62a Merge pull request #24789 from rallytime/bp-24717
  - 9ac4deb virtualenv.managed: document user and no_chown
- **PR #24823**: (jayeshka) adding states/splunk_search unit test case. @ 2015-06-19T17:14:12Z
  - 0a6c70f Merge pull request #24823 from jayeshka/splunk_search-states-unit-test
  - 98831a8 adding states/splunk_search unit test case.

35.2. Previous Releases 2085
• **PR #24809**: (jodv) Correctly create single item list for failover master type with string value for master opt @ 2015-06-19T15:22:20Z
  - 4c5a708 Merge pull request #24809 from jodv/single_item_master_list
  - 18ceebc single item list vs. list of characters

• **PR #24802**: (basepi) [2015.5] Merge forward from 2014.7 to 2015.5 @ 2015-06-18T20:11:58Z
  - **ISSUE #24776**: (nmadhok) --static option in salt raises ValueError and has been broken for a very long time | refs: #24777
  - **ISSUE #21318**: (thanatos) get_full_returns raises KeyError | refs: #24769
  - **ISSUE #18994**: (njhartwell) salt.client.get_cli_returns errors when called immediately after run_job | refs: #24769
  - **ISSUE #17041**: (xenophon) Confusing Salt error messages due to limited/incomplete PowerShell command error handling | refs: #24690
  - **ISSUE #19**: (thatch45) Sending a faulty command kills all the minions!
  - **PR #24780**: (nmadhok) Backporting PR #24777 to 2014.7 branch
  - **PR #24779**: (nmadhok) Backporting Changes to 2014.7 branch | refs: #24777
  - **PR #24778**: (nmadhok) Backporting PR #24777 to 2015.2 branch | refs: #24777
  - **PR #24777**: (nmadhok) Fixing issue where --static option fails with ValueError Fixes #24776 | refs: #24778
  - **PR #24769**: (msteed) Fix stacktrace in get_cli_returns()
  - **PR #24690**: (twangboy) Report powershell output instead of error
  - ae05e70 Merge pull request #24802 from basepi/merge-forward-2015.5
  - 5b7a65d Merge pull request #19 from twangboy/merge-forward-fixes
      * 98e7e90 Fixed test failures for Colton
  - b949856 Merge remote-tracking branch `upstream/2014.7` into merge-forward-2015.5
      * 4281dff Merge pull request #24780 from nmadhok/backport-2014.7-24777
          · c5b0d9 Backporting PR #24777 to 2014.7 branch
      * f3c5c62 Merge pull request #24769 from msteed/issue-21318
          · f40a9d5 Fix stacktrace in get_cli_returns()
      * 59db246 Merge pull request #24690 from twangboy/fix_17041
          · 7a01538 Added additional reporting
          · d84ad5d Fixed capitalization... Failed and Already
          · e955245 Merge branch `2014.7` of https://github.com/saltstack/salt into fix_17041
          · 144bff2 Report powershell output instead of error
  - **PR #24798**: (jtand) Revert `"adding states/postgres_database unit test case."` @ 2015-06-18T17:56:17Z
  - **PR #24329**: (jayeshka) adding states/postgres_database unit test case. | refs: #24798
  - daa76c3 Merge pull request #24329 from saltstack/revert-24329-postgres_database-states-unit-test
  - 179ce03 Revert `"adding states/postgres_database unit test case."
  - **PR #24791**: (rallytime) Back-port #24749 to 2015.5 @ 2015-06-18T17:43:15Z
- **PR #24749**: (obestwalter) add windows specific default for multiprocessing | refs: #24791
- 7073a9f Merge pull request #24791 from rallytime/bp-24749
- be43b2b add windows specific default for multiprocessing
- **PR #24792**: (rallytime) Back-port #24757 to 2015.5 @ 2015-06-18T15:58:35Z
  - **PR #24577**: (cachedout) Fix loader call in pyobjects | refs: #24792
  - **PR #24668**: (grischa) enable virtual package names in pyobjects render | refs: #24721 #24757
  - 1a158e8 Merge pull request #24792 from rallytime/bp-24757
  - 6c804f0 Fix loader call in pyobjects
- **PR #24768**: (jfindlay) fix yum versionlock on RHEL/CentOS 5, disable corresponding test @ 2015-06-18T15:13:12Z
  - 0f92982 Merge pull request #24768 from jfindlay/pkg_mod
  - 7a26c2b disable pkg.hold test for RHEL/CentOS 5
  - 4cadc93 use correct yum versionlock pkg name on centos 5
- **PR #24778**: (nmadhok) Backporting PR #24777 to 2015.2 branch | refs: #24777 @ 2015-06-18T14:53:04Z
  - ISSU #24776: (nmadhok) --static option in salt raises ValueError and has been broken for a very long time | refs: #24777
  - **PR #24777**: (nmadhok) Backporting Changes to 2014.7 branch | refs: #24777
  - **PR #24777**: (nmadhok) Fixing issue where --static option fails with ValueError | Fixes #24776 | refs: #24778
  - 39f088a Merge pull request #24778 from nmadhok/backport-2015.2-24777
  - ae3701f Backporting PR #24777 to 2015.2 branch
- **PR #24774**: (zefrog) Fix lxc lvname parameter command @ 2015-06-18T14:49:06Z
  - 2a4f65f Merge pull request #24774 from zefrog/fix-lxc-lvname-param
  - 21e0cd4 Fixed typo in lxc module: lvname parameter typo
  - 283d86e Fixed bug in lxc module: lvname using wrong parameter in cmd
- **PR #24782**: (jayeshka) adding states/slack unit test case. @ 2015-06-18T14:33:55Z
  - fd73390 Merge pull request #24782 from jayeshka/slack-states-unit-test
  - e2b6214 adding states/slack unit test case.
- **PR #24771**: (jacksontj) Always extend requisites, instead of replacing them @ 2015-06-18T14:29:09Z
  - ISSUE #24770: (jacksontj) Requisite and Requisite_in don’t play nice together | refs: #24771
  - c9e90af Merge pull request #24771 from jacksontj/2015.5
  - b1211c5 Re-enable tests for complex prereq and prereq_in
  - 378f6bf Only merge when the merge is of requisites
- **PR #24766**: (msteed) Remove doc references to obsolete minion opt @ 2015-06-17T21:36:55Z
  - 5fe4de8 Merge pull request #24766 from msteed/undoc-dns_check
  - f92a769 Remove doc references to obsolete minion opt
- **PR #24329**: (jayeshka) adding states/postgres_database unit test case. | refs: #24798 @ 2015-06-17T19:11:02Z
Chapter 35. Release notes

- a407ab7 Merge pull request #24329 from jayeshka/postgres_database-states-unit-test
- ee06f1a adding states/postgres_database unit test case.

- **PR #24632**: (jacobhammons) Doc bug fixes @ 2015-06-17T18:40:02Z
  - ISSUE #24560: (hydroside) Documentation missing on parameter | refs: #24632
  - ISSUE #24547: (dragonpaw) Artifactory docs say module is `jboss7`. | refs: #24632
  - ISSUE #24375: (companykitchen-dev) Custom grain won’t sync under any circumstances | refs: #24632
  - ISSUE #24275: (kartiksubbarao) augeas issue with apache and recognizing changes that have been already made | refs: #24632
  - ISSUE #24163: (tbaker57) enable_gpu_grains default value confusion | refs: #24632
  - 3ff6eff Merge pull request #24632 from jacobhammons/bug-fixes
  - 7c52012 Fixed typos
  - c7cdd41 Doc bug fixes Refs #24547 Refs #24275 Refs #24375 Refs #24163

- **PR #24607**: (garethgreenaway) fixes to minion.py @ 2015-06-17T18:16:42Z
  - ISSUE #24198: (ahammond) salt-call event.send doesn’t send events from minion | refs: #24607
  - 9995f64 Merge pull request #24607 from garethgreenaway/2015_5_sending_events_multi_master
  - 8abd3f0 A fix if you have multiple masters configured and try to fire events to the minion. Currently they fail silently. Might be the cause of #24198.

- **PR #24755**: (rallytime) Remove SALT_CLOUD_REQS from setup.py @ 2015-06-17T17:42:25Z
  - bf2dd94 Merge pull request #24755 from rallytime/fix_setup_15
  - 48769a5 Remove SALT_CLOUD_REQS from setup.py

- **PR #24740**: (rallytime) Backport #24720 to 2015.5 @ 2015-06-17T16:43:37Z
  - **PR #24720**: (TheScriptSage) Issue 24621 - AD/LDAP Group Auth Issue | refs: #24740
  - 3d53d79 Merge pull request #24740 from rallytime/bp-24720
  - a9bcdb5 Updating master.py to properly check against groups when user is only authed against group. Tested against unit.auth_test.

- **PR #24723**: (rallytime) Back-port #20124 to 2015.5 @ 2015-06-17T16:43:20Z
  - **PR #20124**: (cgtx) add init system to default grains | refs: #24723
  - ac2851b Merge pull request #24723 from rallytime/bp-20124
  - d4d061b fix infinite loop introduced by #20124 when the init system is not in the supported_inits list
  - 0c7fa0f Optimizations for #20124
  - f353454 add init system to default grains (resolve #20124)

- **PR #24754**: (anlutro) salt-cloud documentation - Add information about linode location @ 2015-06-17T16:04:48Z
  - 78cd09b Merge pull request #24754 from alprs/docs-add_linode_location_option
  - d88e071 add information about linode location

- **PR #24748**: (jayeshka) adding states/serverdensity_device unit test case. @ 2015-06-17T15:39:07Z
  - d5554f7 Merge pull request #24748 from jayeshka/serverdensity_device-states-unit-test
• PR #24739: (rallytime) Back-port #24735 to 2015.5 @ 2015-06-17T15:47Z
  - PR #24735: (notpeter) Add 2015.5 codename to version numbers docs | refs: #24739
  - 0b7e7ef Merge pull request #24739 from rallytime/bp-24735
  - 64c565d Add .0 to version number
  - 5ed801b Add codenames for 2015.5 and future versions. Trailing newline.

• PR #24732: (msteed) Fix stacktrace when --summary is used @ 2015-06-17T03:25Z
  - ISSUE #24111: (yermulnik) cli option `--summary' got broken after upgrade to 2015.5.1 | refs: #24732
  - c8713f2 Merge pull request #24732 from msteed/issue-24111
  - 54b33dd Fix stacktrace when --summary is used

• PR #24721: (rallytime) Back-port #24668 to 2015.5 @ 2015-06-17T03:47Z
  - PR #24668: (grischa) enable virtual package names in pyobjects renderer | refs: #24721 #24757
  - 70d3781 Merge pull request #24721 from rallytime/bp-24668
  - 68fb5af fixing other test
  - ba4f262 fixing text for virtual support in pyobjects
  - b349d91 enable virtual package names in pyobjects renderer

• PR #24718: (rallytime) Added some missing config documentation to the vsphere driver @ 2015-06-17T03:19:35Z
  - ISSUE #21923: (Fluro) Salt cloud not running provisioning script as root | refs: #24718
  - ISSUE #17241: (hasues) Salt-Cloud for vSphere needs additional documentation | refs: #24718
  - 1b9de89 Merge pull request #24718 from rallytime/update_vsphere_docs
  - bfdebb6 Added some missing config documentation to the vsphere driver

• PR #24714: (rallytime) Remove cloud-requirements.txt @ 2015-06-17T03:17:04Z
  - 64857c7 Merge pull request #24714 from rallytime/remove_cloud_reqs_15
  - 67b796d Remove cloud-requirements.txt

• PR #24733: (msteed) Include Tornado in versions report @ 2015-06-17T03:13:53Z
  - ISSUE #24439: (bechtoldt) Add tornado version to versions report | refs: #24733
  - f96b1d6 Merge pull request #24733 from msteed/issue-24439
  - 76cfef0 Include Tornado in versions report

• PR #24737: (jacksontj) Move AES command logging to trace @ 2015-06-17T01:48:11Z
  - a861fe0 Merge pull request #24737 from jacksontj/2015.5
  - a4ed41a Move AES command logging to trace

• PR #24724: (basepi) [2015.5] Merge forward from 2014.7 to 2015.5 @ 2015-06-16T22:46:27Z
  - ISSUE #24196: (johnccfm) Exception when using user.present with Windows | refs: #24646
  - PR #24646: (twangboy) Fixed user.present on existing user
  - 0d2dc46 Merge pull request #24724 from basepi/merge-forward-2015.5
– 4641028 Merge remote-tracking branch `upstream/2014.7` into merge-forward-2015.5
– a18dada Merge pull request #24646 from twangboy/fix_24196
  * a208e1d Fixed user.present on existing user
• **PR #24701**: (jayeshka) adding states/selinux unit test case. @ 2015-06-16T15:27:29Z
  – 3d33fe7 Merge pull request #24701 from jayeshka/selinux-states-unit-test
  – 0c136fd adding states/selinux unit test case.
• **PR #24687**: (cachedout) Note about minimum worker_threads @ 2015-06-15T20:46:23Z
  – 2e287a9 Merge pull request #24687 from cachedout/min_worker_threads
  – b7bb7ea Note about minimum worker_threads
• **PR #24688**: (cachedout) Update AUTHORS @ 2015-06-15T20:46:03Z
  – 432478c Merge pull request #24688 from cachedout/update_authors
  – 3f6880e Better email
  – 6c7b773 Update AUTHORS
• **PR #24649**: (cachedout) Improved error reporting for failed states @ 2015-06-15T16:04:20Z
  – ISSUE #22385: (cachedout) States which require unavailable modules should display the reason | refs: #24649
  – 9a2b50d Merge pull request #24649 from cachedout/issue_22385
  – b9fe792 States will now return the reason behind failure if a module could not be loaded
• **PR #24673**: (jayeshka) adding states/schedule unit test case. @ 2015-06-15T15:24:52Z
  – 66e9e16 Merge pull request #24673 from jayeshka/schedule-states-unit-test
  – 54aaa5 Adding states/schedule unit test case.
• **PR #24663**: (kartiksubbarao) Update augeas_cfg.py @ 2015-06-15T15:18:48Z
  – ISSUE #24661: (kartiksubbarao) augeas.change doesn’t support setting empty values | refs: #24663
  – 5eb19c4 Merge pull request #24663 from kartiksubbarao/patch-2
  – e18db50 Update augeas_cfg.py
• **PR #24667**: (dkiser) fix for #24583 clouds/openstack.py kerying first time succeeds @ 2015-06-14T21:58:58Z
  – ISSUE #24583: (dkiser) salt-cloud keyring password referenced before assignment | refs: #24667
  – 4450432 Merge pull request #24667 from dkiser/fixed-cloud-keyring
  – c92c05f fix for #24583 clouds/openstack.py kerying first time succeeds
• **PR #24659**: (kartiksubbarao) Update aliases.py @ 2015-06-13T17:31:42Z
  – ISSUE #24537: (kartiksubbarao) alias.present doesn’t update alias values that are substrings of the existing value | refs: #24659
  – 4c64ee9 Merge pull request #24659 from kartiksubbarao/patch-1
  – d683474 Update aliases.py
• **PR #24644**: (cro) Merge forward 2014.7->2015.5 @ 2015-06-12T21:31:41Z
  – PR #24643: (cro) Add reference to salt-announce mailing list
  – PR #24620: (twangboy) Fixed comment and uncomment functions in file.py
89eb616 Merge pull request #24644 from cro/2014.7-2015.5-20150612
- 4136dc3 Merge forward from 2014.7 to 2015.5
- b99484f Merge pull request #24643 from cro/saltannounce
  * ecb0623 Add salt-announce mailing list.
- 635121e Merge pull request #24620 from twangboy/fix_24215
  * d7a9999 Fixed comment and uncomment functions in file.py

• PR #24642: (basepi) Revert `fix target rule, remove unneeded quotation mark` @ 2015-06-12T20:14:26Z
  - PR #24595: (tankywoo) fix target rule, remove unneeded quotation mark | refs: #24642
  - b896a0d Merge pull request #24642 from saltstack/revert-24595-fix-iptables-target
  - 5f3224 Revert `fix target rule, remove unneeded quotation mark`

• PR #24628: (jayeshka) adding states/reg unit test case. @ 2015-06-12T17:29:11Z
  - 01092c2 Merge pull request #24628 from jayeshka/reg_states-unit-test
  - af1bd8f adding states/reg unit test case.

• PR #24631: (rallytime) Back-port #24591 to 2015.5 @ 2015-06-12T16:54:32Z
  - ISSUE #24494: (arnoutpierre) Computed comments in jinja states | refs: #24591
  - ISSUE #24073: (primechuck) State.highstate uses stale grain data. | refs: #24492
  - ISSUE #23359: (BalintSzigeti) init.sls parsing issue | refs: #24591
  - ISSUE #21217: (Colstuwix) Maybe a bug for jinja render? | refs: #24591
  - PR #24591: (tibaker57) Add some documentation surrounding Jinja vs yaml comments - | refs: #24631
  - PR #24492: (DmitryKuzmenko) Don’t remove grains from opts
  - 5f491f9 Merge pull request #24631 from rallytime/bp-24591
  - f13cd41 Add extra clarification why jinja comments are needed.
  - 2374971 Fix typo
  - 6a91747 Add some documentation surrounding Jinja comments - refs #24492, #21217, #23359

• PR #24616: (garethgreenaway) additional logging in state.py module @ 2015-06-12T16:25:39Z
  - f23f99e Merge pull request #24616 from garethgreenaway/2015.5_logging_disabled_states
  - 4db0feef Adding some logging statement to give feedback when states, including highstate, are disabled. Useful when running from scheduler.

• PR #24595: (tankywoo) fix target rule, remove unneeded quotation mark | refs: #24642 @ 2015-06-12T16:23:22Z
  - 6dccb0c Merge pull request #24595 from tankywoo/fix-iptables-target
  - 10a5160 fix target rule, remove unneeded quotation mark

• PR #24604: (jfindlay) fix pkg module integration tests @ 2015-06-12T16:04:26Z
  - 8ac3d94 Merge pull request #24604 from jfindlay/pkg_tests
  - d88b22 fix pkg module integration tests on CentOS 5
  - fb91b40 fix pkg module integration tests on ubuntu 12

• PR #24600: (basepi) [2015.5] Remove __kwarg__ from salt-ssh keyword args @ 2015-06-12T04:21:29Z

### 35.2. Previous Releases
• PR #24608: (basepi) [2015.5] Normalize salt-ssh flat roster minion IDs to strings @ 2015-06-11T21:35:07Z
  - ISSUE #22843: (Xiol) salt-ssh roster doesn't support integers as host keys | refs: #24608
  - 832916f Merge pull request #24608 from basepi/salt-ssh.flat.roster.integers.22843
  - 381820f Normalize salt-ssh flat roster minion IDs to strings

• PR #24605: (basepi) [2015.5] Merge forward from 2014.7 to 2015.5 @ 2015-06-11T19:15:21Z
  - PR #24589: (BretFisher) Fixed Mine example for jinja code block
  - 4eb5bb2 Merge pull request #24605 from basepi/merge-forward-2015.5
  - f96c502 Merge remote-tracking branch `upstream/2014.7` into merge-forward-2015.5
  - d83928a Merge pull request #24589 from BretFisher/patch-1
    * 65a1133 Fixed Mine example for jinja code block

• PR #24598: (jacobhammons) 2015.5.2 release changes @ 2015-06-11T21:35:07Z
  - ISSUE #24457: (ryan-lane) When selecting the version of docs on the docs site, it brings you to the homepage | refs: #24598
  - ISSUE #24250: (jfindlay) have version links on docs page link to that version of the current page | refs: #24598
  - e0bb177 Merge pull request #24598 from jacobhammons/doc-fixes
  - f3f34dd 2015.5.2 release changes Refs #24250 Refs #24457

• PR #24588: (basepi) Fixes for saltmod.function for salt-ssh @ 2015-06-11T16:15:21Z
  - ISSUE #20615: (aurynn) 2014.7.1: salt/states/saltmod using incorrect return dict for orchestrate | refs: #24588
  - 26930b4 Merge pull request #24588 from basepi/salt-ssh.orchestrate.20615
  - 826936c Movedocumentationintodocstringinsteadofcomments
  - de052e7 Assign `return` to `ret` if necessary in saltmod.function
  - 34ff989 Convert keyword args to key=value strings in salt-ssh

• PR #24593: (jayeshka) adding states/redismod unit test case. @ 2015-06-11T15:55:27Z
  - 5a21ad1 Merge pull request #24593 from jayeshka/redismod_states-unit-test
  - 3b95744 adding states/redismod unit test case.

• PR #24581: (rallytime) Disabled some flaky tests until we can figure out how to make them more reliable @ 2015-06-11T15:51:41Z
  - ISSUE #40: (thatch45) Clean up timeouts | refs: #22857
  - PR #24217: (jfindlay) disable intermittently failing tests | refs: #24581
  - PR #23623: (jfindlay) Fix /jobs endpoint's return | refs: #24217
  - PR #22857: (jacksontj) Fix /jobs endpoint's return | refs: #23623
  - 8ff886e Merge pull request #24581 from rallytime/disable_some_flaky_tests
  - c82f135 Disabled some flaky tests until we can figure out how to make them more reliable
• PR #24566: (jayeshka) adding states/rdp unit test case. @ 2015-06-11T02:14:39Z
  – a570d7f Merge pull request #24566 from jayeshka/rdp_states-unit-test
  – 273b994 adding states/rdp unit test case.

• PR #24551: (joejulian) 2015.5 dont pollute environment @ 2015-06-11T02:13:06Z
  – ISSUE #24480: (kiorky) [CRITICAL] [2015.5] tls breaks tzinfo | refs: #24551
  – 20ada1f Merge pull request #24551 from joejulian/2015.5_dont_pollute_environment
  – cfc3b43 Don't pollute the TZ environment variable
  – cba8d3f pep8
  – 9cb7015 Mark keyword version adds
  – 76e2583 Merge tls changes from develop

• PR #24574: (jacobhammons) Refs #19901 @ 2015-06-10T20:09:23Z
  – ISSUE #19901: (clinta) State cache is not documented | refs: #24468
  – bb2fd6a Merge pull request #24574 from jacobhammons/19901
  – e2a2946 Refs #19901

• PR #24577: (basepi) [2015.5] Merge forward from 2014.7 to 2015.5 @ 2015-06-10T19:46:22Z
  – ISSUE #24427: (fayetted) 2015.5.1-3 Windows 64Bit Minion fails to start after install | refs: #24530
  – PR #24530: (twangboy) Start Minion Service on Silent Install
  – b03166c Merge pull request #24577 from basepi/merge-forward-2015.5
  – e1d45cc Merge remote-tracking branch 'upstream/2014.7' into merge-forward-2015.5
  – d376390 Merge pull request #24530 from twangboy/fix_24427
    * 673e1d8 Added missing panel.bmp for installer
    * cc50218 Start Minion Service on Silent Install

• PR #24571: (jacobhammons) Refs #24235 @ 2015-06-10T17:02:18Z
  – ISSUE #24235: (tomasfejfar) Difference between running from minion and from master | refs: #24468
  – 3ec457b Merge pull request #24571 from jacobhammons/24235
  – 8df5d53 Refs #24235

• PR #24565: (pille) fix backtrace, when listing plugins @ 2015-06-10T16:33:11Z
  – fe07eb5 Merge pull request #24565 from pille/munin-ignore-broken-symlinks
  – 8511a6c fix backtrace, when listing plugins

• PR #24554: (ryan-lane) Fix yes usage for pecl defaults @ 2015-06-09T23:59:49Z
  – 251cbf9 Merge pull request #24554 from lyft/pecl-module-fix
  – 56a9cfc Fix yes usage for pecl defaults

• PR #24535: (rallytime) Back-port #24518 to 2015.5 @ 2015-06-09T20:06:18Z
  – PR #24518: (rallytime) Merge #24448 with Pylint Fixes | refs: #24535
  – PR #24448: (codertux) Update modules path for operating systems using systemd | refs: #24518
  – dbd49b4 Merge pull request #24535 from rallytime/bp-24518
- fc75197 Pylint fix
- 3e08840 Update modules path for operating systems using systemd

- **PR #24538**: (basepi) [2015.5] Merge forward from 2014.7 to 2015.5 @ 2015-06-09T17:27:20Z
  - PR #24513: (jquast) bugfix use of `iteritem` in 2014.7 branch
  - PR #24511: (jquast) bugfix: trailing "...done" in rabbitmq output | refs: #24513
  - 485ed3c Merge pull request #24538 from basepi/merge-forward-2015.5
  - 6a8039d Merge remote-tracking branch `upstream/2014.7` into merge-forward-2015.5
  - 6ebc476 Merge pull request #24513 from jquast/2014.7-bugfix-iteritem
    * 2be0180 bugfix use of `iteritem` in 2014.7 branch

- **PR #24495**: (jayeshka) adding states/rabbitmq_vhost unit test case. @ 2015-06-09T15:33:23Z
  - 73e6388 Merge pull request #24495 from jayeshka/rabbitmq_vhost_states-unit-test
  - 31889e3 cosmetic change.
  - cf501cf resolved error.
  - 4bb6087 Merge branch '2015.5' of https://github.com/saltstack/salt into rabbitmq_vhost_states-unit-test
  - 3ad7714 adding states/rabbitmq_vhost unit test case.

- **PR #24445**: (jayeshka) adding states/pyrax_queues unit test case. @ 2015-06-09T15:28:45Z
  - bf1abcc Merge pull request #24445 from jayeshka/pyrax_queues_states-unit-test
  - ea27cef adding states/pyrax_queues unit test case.

- **PR #24490**: (aneeshusa) Fix pacman.list_upgrades for new python_shell default. @ 2015-06-09T15:13:16Z
  - 0247e8d Merge pull request #24490 from aneeshusa/fixed-pacman-list-upgrades
  - 980e1cb lint fix.
  - dca33f1 Fix pacman.list_upgrades for new python_shell default.

- **PR #24517**: (steverweber) small fixes to the ipmi docs @ 2015-06-09T15:10:14Z
  - 6268dbd Merge pull request #24517 from steverweber/ipmi_doc
  - 6413712 lint
  - e78aae9 more small fixes to the ipmi docs

- **PR #24524**: (jayeshka) any() takes list oy tuple. @ 2015-06-09T13:49:42Z
  - 3728bf3 Merge pull request #24524 from jayeshka/rabbitmq_vhost states-module
  - 01c99ad any() takes list oy tuple.

- **PR #24482**: (eliasp) `docker.running` needs now the `image` param. @ 2015-06-09T04:43:04Z
  - dd23de8 Merge pull request #24482 from eliasp/2015.5-states.dockerio-docker.running-doc
  - 5de741d `docker.running` needs now the `image` param.

- **PR #24515**: (basepi) [2015.5] Add xml library to the salt-thin @ 2015-06-09T04:10:06Z
  - ISSUE #23503: (jfindlay) salt-ssh fails on CentOS 7 when python-zmq is not installed | refs: #24515
  - 2a727c3 Merge pull request #24515 from basepi/susexml23503
  - 078b33e Add xml library to the thin

2094  Chapter 35. Release notes
• PR #24497: (jayeshka) adding states/rbenv unit test case. @ 2015-06-09T03:56:10Z
  - fce99a Merge pull request #24497 from jayeshka/rbenv_states-unit-test
  - 79d343a adding states/rbenv unit test case.
• PR #24496: (jayeshka) adding states/rabbitmq_user unit test case. @ 2015-06-09T03:55:23Z
  - 2bcba4b1 Merge pull request #24496 from jayeshka/rabbitmq_user_states-unit-test
  - 7d96f27 adding states/rabbitmq_user unit test case.
• PR #24481: (eliasp) Fix typo (licnese → license). @ 2015-06-09T03:55:23Z
  - 02a507b Merge pull request #24481 from eliasp/2015.5-salt.states.powerpath-license_typo
  - 1280054 Fix typo (licnese → license).
• PR #24467: (thenewwazoo) Fix dockerio bound volumes @ 2015-06-09T03:55:23Z
  - 5ad3db5 Merge pull request #24467 from thenewwazoo/fix-dockerio-bound-volumes
  - db4e3dc Let's raise an exception if create fails
  - d1d85d5 Add logging
  - ddc63f0 Fix volumehandling when creating containers
• PR #24504: (rallytime) Move vspheredeprecation to 2015.5 @ 2015-06-08T22:43:05Z
  - PR #24487: (namdhok) Deprecating vsphere cloud driver in favor of vmware cloud driver | refs: #24504
  - d236fbd Merge pull request #24504 from rallytime/move_vsphere_deprecation_2015.5
  - d876535 Add Getting Started with VSphere doc to 2015.5
  - b685ebc Add vSphere deprecation warnings to 2015.5
• PR #24506: (rallytime) Backport #24450 to 2015.5 @ 2015-06-08T22:42:14Z
  - PR #24450: (ruzarowski) Fix salt cli runs with batch-size set | refs: #24506
  - cb55460 Merge pull request #24506 from rallytime/bp-24450
  - 1c0fca2 Backport #24450 to 2015.5
• PR #24498: (rallytime) Added ``CLI Example'' to make failing test happy on 2015.5 @ 2015-06-08T15:48:40Z
  - 3173fd1 Merge pull request #24498 from rallytime/fix_doc_failure_fifteen
  - d992ef4 Added ``CLI Example'' to make failing test happy on 2015.5
• PR #24471: (anlutro) Set up salt-ssh file logging @ 2015-06-08T15:26:49Z
  - 3639e41 Merge pull request #24471 from alprs/fixed-salt_ssh_logging
  - 6a11ec8 set up salt-ssh file logging
• PR #24469: (jfindlay) correctly handle user environment info for npm @ 2015-06-08T15:26:02Z
  - ISSUE #24231: (tarwich) npm.bootstrap | refs: #24469
  - 551e70f Merge pull request #24469 from jfindlay/npm_env
  - 8140c9e6 update npm's user info envs
  - cb572f8 add env parameter to npm.uninstall
• PR #24468: (jacobhammons) Bug fixes and build errors @ 2015-06-08T15:25:40Z
  - ISSUE #24268: (tkent-xetus) Ability to specify revision for win_gitrepos undocumented | refs: #24468
- ISSUE #24235: (tomasfejfar) Difference between running from minion and from master | refs: #24468
- ISSUE #24193: (abng88) Update ext_pillar docs to mention that this feature is supported masterless as well | refs: #24468
- ISSUE #24172: (zhujihe) Can lists be passed in the pillar on the command line on version 2015.5.0? | refs: #24468
- ISSUE #23211: (lloesche) Document that salt:// escapes special characters in filenames | refs: #24468
- ISSUE #19901: (clinta) State cache is not documented | refs: #24468
- ISSUE #19801: (ksalman) How are grains static? | refs: #24468
- 0d9e0c2 Merge pull request #24468 from jacobhammons/doc-fixes
- 1035959 Appended .0 to version added
- d45c4ed Bug fixes and build errors Refs #23211 Refs #24268 Refs #24235 Refs #24193 Refs #24172 Refs #19901 Refs #19801

- PR #24465: (jfindlay) catch exception from software repositories @ 2015-06-08T15:25:19Z
  - ISSUE #24318: (favadi) uncaught exception for pkgrepo.absent for invalid PPA | refs: #24465
  - be6905a Merge pull request #24465 from jfindlay/unknown_ppa
  - 19c9128 catch exception from software repositories

- PR #24464: (jfindlay) fix typo in modules/mount.py @ 2015-06-08T15:25:07Z
  - ISSUE #24296: (objectx) mount.mount calls file.mkdir with incorrect named argument | refs: #24464
  - 58d1ea8 Merge pull request #24464 from jfindlay/file.mkdir
  - 6e8c444 fix typo in modules/mount.py

- PR #24461: (dkiser) fix for #24434 @ 2015-06-08T15:24:53Z
  - ISSUE #24434: (dkiser) multimaster failover fails due to logic from issue #23611
  - 4f332a7 Merge pull request #24461 from dkiser/multimaster_minion_fix
  - 1944a74 fix for #24434

- PR #24479: (ahusl) change `\``path`` to `\``name`` for `\``file`` operations @ 2015-06-07T17:56:11Z
  - 8917416 Merge pull request #24479 from ahusl/patch-1
  - 7d6b60c change `\``path`` to `\``name`` for `\``file`` operations

- PR #24475: (rallytime) Back-port #24454 to 2015.5 @ 2015-06-07T01:29:32Z
  - PR #24454: (rhertzog) Strip extraneous newline character added in last environment variable | refs: #24475
  - 8618d5b Merge pull request #24475 from rallytime/bp-24454
  - a793c19 Avoid extraneous newline character added in last environment variable

- PR #24474: (rallytime) Back-port #24420 to 2015.5 @ 2015-06-07T01:29:11Z
  - ISSUE #24407: (aboeye) Please expand salt module random | refs: #24420
  - PR #24420: (aboeye) added random integer module to mod_random.py | refs: #24474
  - 61658ff Merge pull request #24474 from rallytime/bp-24420
  - 4219b40 Fix lint error and update version added to 2015.5.3
• PR #24472: (varia) ensure {} output is not treated as change in module.py state, fixes #...
  @ 2015-06-07T14:45:44Z
  - ISSUE #24233: (varia) yumpkg.group_install keeps returning state change
  - 508d7dd Merge pull request #24472 from varia/Fix-yumpkg_group_install-return-change-
  - 2e0609f Fix for # in inner strings in yaml arguments

• PR #24466: (basepi) [2015.5] Fix for # in inner strings in yaml arguments @ 2015-06-06T14:35:56Z
  - ISSUE #18045: (dstokes) Pillar kwargs parse error with # | refs: #24466
  - ISSUE #8585: (UtahDave) `#` in single quoted option on cli not making it into the execution module |
    | refs: #24466
  - 0292e67 Merge pull request #24466 from basepi/fixhashinargs 18045
  - 2e0609f Fix for # in inner strings in yaml arguments

• PR #24456: (rallytime) Back-port #24441 to 2015.5 @ 2015-06-05T22:32:25Z
  - PR #24441: (arthurlogilab) [doc] Alignment fix on external_auth documentation | refs: #24456
  - ced558a Merge pull request #24456 from rallytime/bp-24441
  - 7002855 yaml indentation should be 2 spaces
  - 2e0609f Fix for # in inner strings in yaml arguments

• PR #24398: (kiorky) VirtualName for states.apt | refs: #24399 @ 2015-06-05T17:40:04Z
  - ISSUE #24397: (kiorky) on debian: states.apt should use virtualname as it shadows system apt module |
    | refs: #24398 #24399 #24400
  - PR #24399: (kiorky) Versionvirtual | refs: #24398
  - c0ff411 Merge pull request #24398 from makinacorpus/aptv
  - 785d277 VirtualName for states.apt

• PR #24447: (jayeshka) adding states/rabbitmq_policy unit test case. @ 2015-06-05T15:26:11Z
  - 3626340 Merge pull request #24447 from jayeshka/rabbitmq_policy_states-unit-test
  - 9b038ab adding states/rabbitmq_policy unit test case.

• PR #24446: (jayeshka) adding states/rabbitmq_plugin unit test case. @ 2015-06-05T15:25:33Z
  - 8445a3f Merge pull request #24446 from jayeshka/rabbitmq_plugin_states-unit-test
  - cb9c9a adding states/rabbitmq_plugin unit test case.

• PR #24426: (basepi) [2015.5] Merge forward from 2014.7 to 2015.5 @ 2015-06-05T03:59:11Z
  - ISSUE #24276: (markuskramerlgitt) Live salt-master Profiling with SIGUSR2 fails
  - PR #24405: (jacksontj) Fix for #24276
  - PR #24395: (hvnswetting) handle exceptions when received data is not in good shape
  - PR #24305: (twangboy) Added documentation, fixed formatting
  - 9cc388 Merge pull request #24426 from basepi/merge-forward-2015.5
  - eafa20c Merge remote-tracking branch `upstream/2014.7` into merge-forward-2015.5
  * 83f853b Merge pull request #24405 from jacksontj/2014.7

35.2. Previous Releases
- 2c7afae Fix for #24276
  * cef919e Merge pull request #24395 from hvnsweeting/handle-exception-get-file
    - bb798a0 handle exceptions when received data is not in good shape
  * efb1a9 Merge pull request #24305 from twangboy/win_path_docs
  * 36804253 Fixed pylint error caused by `|P... added r
  * bc42a4b triple double quotes to triple single quotes
  * 77cd930 Added documentation, fixed formatting

- **PR #24429:** (jacobhammons) Salt cloud doc updates, build errors and bug fixes @ 2015-06-05T00:27:38Z
  - ISSUE #24309: (steverweber) missing docs | refs: #24429
  - 5d738b8 Merge pull request #24429 from jacobhammons/cloud-doc-updates
  - 1f7a13d Salt cloud doc updates, build errors and bug fixes Refs #24309

- **PR #24408:** (rallytime) Backport #24392 to 2015.5 @ 2015-06-04T22:09Z
  - PR #24392: (quixoten) Fix "No such file or directory" in grains/core.py | refs: #24408
  - cdff02 Merge pull request #24408 from rallytime/bp-24392
  - ff7461b Use path found by salt.utils.which

- **PR #24380:** (rallytime) Backport #24357 to 2015.5 @ 2015-06-04T20:13:51Z
  - PR #24357: (zhujinhe) fix invoke issues of Jinja Macros example | refs: #24380
  - a6a1f87 Merge pull request #24380 from rallytime/bp-24357
  - f08c875 fix invoke issues of Jinja Macros example

- **PR #24388:** (pengyao) fixes #24358 @ 2015-06-04T20:07:40Z
  - ISSUE #24358: (pengyao) Netapi SSH client don't support ssh_user and ssh_passwd arguments | refs: #24388
  - 86ce9deb Merge pull request #24388 from pengyao/sshclient-kwargs
  - 5c08ca4 fixes #24358

- **PR #24367:** (terminalmage) Improve error message when module does not exist @ 2015-06-04T20:07:12Z
  - ISSUE #22958: (highlyunavailable) Weird error when typoing a command | refs: #24367
  - 72d2ae7 Merge pull request #24367 from terminalmage/issue22958
  - d0d7a54 Improve error message when module does not exist

- **PR #24412:** (jfindlay) backport #23387 @ 2015-06-04T20:06:03Z
  - ISSUE #23101: (gravyboat) Create a docs page for labels | refs: #23387
  - PR #23387: (rallytime) Add some ```What are all these labels for?``` documentation | refs: #24412
  - a628778 Merge pull request #24412 from jfindlay/bp-23387
  - bff8577 Make sure the parameters are in the correct order
  - 9f53809 Add ```Change``` label parameters
  - b27a15e Remove ```workaround``` wording
  - 9ff35a Some small fixes
- 54a7089 Link the new labels doc in contributing and hacking docs
- 375695e Add pull request label definitions
- de94563 Add Feature Request label definition
- 684f291 Add issue definition and augment functional areas section
- 2da13dd Start a ```what are all of these labels for?``` doc

• **PR #24336:** (twangboy) Added line to give more descriptive error @ 2015-06-04T19:56:00Z
  - ISSUE #24154: (ssgward) Exception when running cp.get_url | refs: #24336
  - 485116c Merge pull request #24336 from twangboy/fix_cp_get_url
  - 37b11f9 Added line to give more descriptive error

• **PR #24413:** (techhat) Add more namespaced functions to GoGrid driver @ 2015-06-04T19:51:22Z
  - b3d39cc Merge pull request #24413 from techhat/gogridnamespace
  - 1b397cb Adding blank line
  - da08cc9 Add more namespaced functions to GoGrid driver

• **PR #24399:** (kiorky) Versionvirtual | refs: #24398 @ 2015-06-04T18:02:22Z
  - ISSUE #24397: (kiorky) on debian: states.apt should use virtualname as it shadows system apt module | refs: #24398 #24399 #24399 #24400
  - PR #24398: (kiorky) VirtualName for states.apt | refs: #24399
    - 27f109b Merge pull request #24399 from makinacorpus/versionvirtual
    - 235c78d Use apt_pkg.version_compare if available
    - 1c0cd45 reindent block to isolate conflict on merge forward
    - 699ceca use var to isolate conflict on merge forward

• **PR #24371:** (joejulian) 2015.5 tls module tests @ 2015-06-04T15:20:16Z
  - deaee68 Merge pull request #24371 from joejulian/2015.5_tls_module_tests
  - 4c5dee1 Add @destructiveTest decorator to destructive tests
  - 274bd4d Accept results from older pyOpenSSL
  - 161f913 All cert info should be in UTC always
  - 9affcca See the whole diff if dict compare fails
  - 94f6208 Ignore extensions for now. Resolve this as part of fixing issue 24338.
  - 84900d3 Mask lint warning for unused imported module
  - 5675b78 Do not test if PyOpenSSL is not installed
  - 563ce66 Add tls tests

35.2.6 Salt 2015.5.4 Release Notes

Version 2015.5.4 is a bugfix release for 2015.5.0.

Changes:

- The `cron.present` state now correctly defaults to state ID as identifier.
- When querying for VMs in `digital_ocean_v2.py`, the number of VMs to include in a page was changed from 20 (default) to 20 to reduce the number of API calls to Digital Ocean.
- The `vmware` Salt-Cloud driver was back-ported from the develop branch in order for installations of Salt that are older than 2015.8.0 to be able to use the `vmware` driver without stack-tracing on various deprecation paths that were implemented in the 2015.8.0 release.

Changes for v2015.5.3..v2015.5.4

35.2.7 Salt 2015.5.5 Release Notes

Version 2015.5.5 is a bugfix release for 2015.5.0.

Changes:

- The `cron.present` state now correctly defaults to state ID as identifier.
- When querying for VMs in `digital_ocean_v2.py`, the number of VMs to include in a page was changed from 20 (default) to 200 to reduce the number of API calls to Digital Ocean.
- The `vmware` Salt-Cloud driver was back-ported from the develop branch in order for installations of Salt that are older than 2015.8.0 to be able to use the `vmware` driver without stack-tracing on various deprecation paths that were implemented in the 2015.8.0 release.

Changes for v2015.5.3..v2015.5.5

  - ISSUE #16179: (UtahDave) Salt Cloud -l debug includes the entire bootstrap script twice in its output | refs: #26306

35.2.8 Salt 2014.7.0 Release Notes - Codename Helium

This release is the largest Salt release ever, with more features and commits then any previous release of Salt. Everything from the new RAET transport to major updates in Salt Cloud and the merging of Salt API into the main project.

**Important:** The Fedora/RHEL/CentOS salt-master package has been modified for this release. The following components of Salt have been broken out and placed into their own packages:

- salt-syndic
- salt-cloud
- salt-ssh

When the salt-master package is upgraded, these components will be removed, and they will need to be manually installed.

**Important:** Compound/pillar matching have been temporarily disabled for the mine and publish modules for this release due to the possibility of inferring pillar data using pillar glob matching. A proper fix is now in the 2014.7 branch and scheduled for the 2014.7.1 release, and compound matching and non-globbing pillar matching will be re-enabled at that point.

Compound and pillar matching for normal salt commands are unaffected.

**New Transport!**

**RAET Transport Option**

This has been a HUGE amount of work, but the beta release of Salt with RAET is ready to go. RAET is a reliable queuing transport system that has been developed in partnership with a number of large enterprises to give Salt an alternative to ZeroMQ and a way to get Salt to scale well beyond tens of thousands of servers. Unlike ZeroMQ, RAET is completely asynchronous in every aspect of its operation and has been developed using the flow programming paradigm. This allows for many new capabilities to be added to Salt in the upcoming releases.

Please keep in mind that this is a beta release of RAET and we hope for bugs to be worked out, performance to be better realized and more in the 2015.5.0 release.

Simply stated, users running Salt with RAET should expect some hiccups as we hammer out the update. This is a BETA release of Salt RAET.

For information about how to use Salt with RAET please see the [tutorial](#).

**Salt SSH Enhancements**

Salt SSH has just entered a new league, with substantial updates and improvements to make salt-ssh more reliable and easier then ever! From new features like the ansible roster and fileserver backends to the new pypi salt-ssh installer to lowered deps and a swath of bugfixes, salt-ssh is basically reborn!
Install salt-ssh Using pip

Salt-ssh is now pip-installable!
https://pypi.python.org/pypi/salt-ssh/

Pip will bring in all of the required deps, and while some deps are compiled, they all include pure python implementations, meaning that any compile errors which may be seen can be safely ignored.

```bash
pip install salt-ssh
```

Fileserver Backends

Salt-ssh can now use the salt fileserver backend system. This allows for the gitfs, hgfs, s3, and many more ways to centrally store states to be easily used with salt-ssh. This also allows for a distributed team to easily use a centralized source.

Saltfile Support

The new saltfile system makes it easy to have a user specific custom extended configuration.

Ext Pillar

Salt-ssh can now use the external pillar system. Making it easier then ever to use salt-ssh with teams.

No More sshpass

Thanks to the enhancements in the salt vt system, salt-ssh no longer requires sshpass to send passwords to ssh. This also makes the manipulation of ssh calls substantially more flexible, allowing for intercepting ssh calls in a much more fluid way.

Pure Python Shim

The salt-ssh call originally used a shell script to discover what version of python to execute with and determine the state of the ssh code deployment. This shell script has been replaced with a pure python version making it easy to increase the capability of the code deployment without causing platform inconsistency issues with different shell interpreters.

Custom Module Delivery

Custom modules are now seamlessly delivered. This makes the deployment of custom grains, states, execution modules and returners a seamless process.

CP Module Support

Salt-ssh now makes simple file transfers easier then ever! The cp module allows for files to be conveniently sent from the salt fileserver system down to systems.
More Thin Directory Options

Salt ssh functions by copying a subset of the salt code, or salt thin down to the target system. In the past this was always transferred to /tmp/salt and cached there for subsequent commands.

Now, salt thin can be sent to a random directory and removed when the call is complete with the -W option. The new -W option still uses a static location but will clean up that location when finished.

The default salt thin location is now user defined, allowing multiple users to cleanly access the same systems.

State System Enhancements

New Imperative State Keyword `Listen`

The new listen and listen_in keywords allow for completely imperative states by calling the mod_watch() routine after all states have run instead of re-ordering the states.

Mod Aggregate Runtime Manipulator

The new mod_aggregate system allows for the state system to rewrite the state data during execution. This allows for state definitions to be aggregated dynamically at runtime.

The best example is found in the pkg state. If mod_aggregate is turned on, then when the first pkg state is reached, the state system will scan all of the other running states for pkg states and take all other packages set for install and install them all at once in the first pkg state.

These runtime modifications make it easy to run groups of states together. In future versions, we hope to fill out the mod_aggregate system to build in more and more optimizations.

For more documentation on mod_aggregate, see the documentation.

New Requisites: onchanges and onfail

The new onchanges and onchanges_in requisites make a state apply only if there are changes in the required state. This is useful to execute post hooks after changes occur on a system.

The other new requisites, onfail, and onfail_in, allow for a state to run in reaction to the failure of another state.

For more information about these new requisites, see the requisites documentation.

Global onlyif and unless

The onlyif and unless options can now be used for any state declaration.

Use names to expand and override values

The names declaration in Salt's state system can now override or add values to the expanded data structure. For example:
my_users:
  user.present:
    - names:
      - larry
      - curly
      - moe:
        - shell: /bin/zsh
        - groups:
          - wheel
        - shell: /bin/bash

Major Features

Scheduler Additions

The Salt scheduler system has received MAJOR enhancements, allowing for cron-like scheduling and much more granular timing routines. See here for more info.

Red Hat 7 Family Support

All the needed additions have been made to run Salt on RHEL 7 and derived OSes like CentOS and Scientific.

Fileserver Backends in salt-call

Fileserver backends like gitfs can now be used without a salt master! Just add the fileserver backend configuration to the minion config and execute salt-call. This has been a much-requested feature and we are happy to finally bring it to our users.

Amazon Execution Modules

An entire family of execution modules further enhancing Salt’s Amazon Cloud support. They include the following:

- **Autoscale Groups** (includes state support) -- related: Launch Control states
- **Cloud Watch** (includes state support)
- **Elastic Cache** (includes state support)
- **Elastic Load Balancer** (includes state support)
- **IAM Identity and Access Management** (includes state support)
- **Route53 DNS** (includes state support)
- **Security Groups** (includes state support)
- **Simple Queue Service** (includes state support)

LXC Runner Enhancements

BETA The Salt LXC management system has received a number of enhancements which make running an LXC cloud entirely from Salt an easy proposition.
Next Gen Docker Management

The Docker support in Salt has been increased at least ten fold. The Docker API is now completely exposed and Salt ships with Docker data tracking systems which make automating Docker deployments very easy.

Peer System Performance Improvements

The peer system communication routines have been refined to make the peer system substantially faster.

SDB

Encryption at rest for configs

GPG Renderer

Encrypted pillar at rest

OpenStack Expansion

Lots of new OpenStack stuff

Queues System

Ran change external queue systems into Salt events

Multi Master Failover Additions

Connecting to multiple masters is more dynamic then ever

Chef Execution Module

Managing Chef with Salt just got even easier!

salt-api Project Merge

The salt-api project has been merged into Salt core and is now available as part of the regular salt-master package install. No API changes were made, the salt-api script and init scripts remain intact.

salt-api has always provided Yet Another Pluggable Interface to Salt (TM) in the form of `netapi` modules. These are modules that bind to a port and start a service. Like many of Salt's other module types, netapi modules often have library and configuration dependencies. See the documentation for each module for instructions.

See also:

The full list of netapi modules.
Synchronous and Asynchronous Execution of Runner and Wheel Modules

`salt.runner.RunnerClient` and `salt.wheel.WheelClient` have both gained complimentary `cmd_sync` and `cmd_async` methods allowing for synchronous and asynchronous execution of any Runner or Wheel module function, all protected using Salt’s `external authentication` system. `salt-api` benefits from this addition as well.

**rest_cherrypy** Additions

The `rest_cherrypy` netapi module provides the main REST API for Salt.

**Web Hooks**

This release of course includes the Web Hook additions from the most recent `salt-api` release, which allows external services to signal actions within a Salt infrastructure. External services such as Amazon SNS, Travis-CI, or GitHub, as well as internal services that cannot or should not run a Salt minion daemon can be used as first-class components in Salt’s rich orchestration capabilities.

The raw HTTP request body is now available in the event data. This is sometimes required information for checking an HMAC signature in order to verify a HTTP request. As an example, Amazon or GitHub requests are signed this way.

**Generating and Accepting Minion Keys**

The `/key` convenience URL generates a public and private key for a minion, automatically pre-accepts the public key on the Salt Master, and returns both keys as a tarball for download.

This allows for easily bootstrapping the key on a new minion with a single HTTP call, such as with a Kickstart script, all using regular shell tools.

```
curl -sS http://salt-api.example.com:8000/keys \
  -d mid=jerry \
  -d username=kickstart \
  -d password=kickstart \
  -d eauth=pam \
  -o jerry-salt-keys.tar
```

**Fileserver Backend Enhancements**

All of the fileserver backends have been overhauled to be faster, lighter, and more reliable. The VCS backends (`gitfs`, `hgfs`, and `svnfs`) have also received a lot of new features.

Additionally, most config parameters for the VCS backends can now be configured on a per-remote basis, allowing for global config parameters to be overridden for a specific `gitfs/hgfs/svnfs` remote.

**New `gitfs` Features**

**Pygit2 and Dulwich**

In addition to supporting GitPython, support for `pygit2` (0.20.3 and newer) and `dulwich` have been added. Provided a compatible version of `pygit2` is installed, it will now be the default provider. The config parameter `gitfs_provider` has been added to allow one to choose a specific provider for `gitfs`.

**Mountpoints**

Prior to this release, to serve a file from `gitfs` at a salt fileserver URL of `salt://foo/bar/baz.txt`, it was necessary to ensure that the parent directories existed in the repository. A new config parameter `gitfs_mountpoint` allows `gitfs` remotes to be exposed starting at a user-defined `salt://` URL.
Environment Whitelisting/Blacklisting  By default, gitfs will expose all branches and tags as Salt fileserver environments. Two new config parameters, `gitfs_env_whitelist` and `gitfs_env_blacklist`, allow more control over which branches and tags are exposed. More detailed information on how these two options work can be found in the *Gitfs Walkthrough*.

Expanded Authentication Support  As of pygit2 0.20.3, both http(s) and SSH key authentication are supported, and Salt now also supports both authentication methods when using pygit2. Keep in mind that pygit2 0.20.3 is not yet available on many platforms, so those who had been using authenticated git repositories with a passphraseless key should stick to GitPython if a new enough pygit2 is not yet available for the platform on which the master is running. A full explanation of how to use authentication can be found in the *Gitfs Walkthrough*.

New **hgfs** Features

**Mountpoints**  This feature works exactly like its *gitfs counterpart*. The new config parameter is called `hgfs_mountpoint`.

**Environment Whitelisting/Blacklisting**  This feature works exactly like its *gitfs counterpart*. The new config parameters are called `hgfs_env_whitelist` and `hgfs_env_blacklist`.

New **svnfs** Features

**Mountpoints**  This feature works exactly like its *gitfs counterpart*. The new config parameter is called `svnfs_mountpoint`.

**Environment Whitelisting/Blacklisting**  This feature works exactly like its *gitfs counterpart*. The new config parameters are called `svnfs_env_whitelist` and `svnfs_env_blacklist`.

**Configurable Trunk/Branches/Tags Paths**  Prior to this release, the paths where trunk, branches, and tags were located could only be in directories named ```trunk```, ```branches```, and ```tags``` directly under the root of the repository. Three new config parameters (`svnfs_trunk`, `svnfs_branches`, and `svnfs_tags`) allow SVN repositories which are laid out differently to be used with svnfs.

New **minionfs** Features

**Mountpoint**  This feature works exactly like its *gitfs counterpart*. The new config parameter is called `minionfs_mountpoint`. The one major difference is that, as minionfs doesn’t use multiple remotes (it just serves up files pushed to the master using `cp.push`) there is no such thing as a per-remote configuration for `minionfs_mountpoint`.

**Changing the Saltenv from Which Files are Served**  A new config parameter (`minionfs_env`) allows minionfs files to be served from a Salt fileserver environment other than `base`.

**Minion Whitelisting/Blacklisting**  By default, minionfs will expose the pushed files from all minions. Two new config parameters, `minionfs_whitelist`, and `minionfs_blacklist`, allow minionfs to be restricted to serve files from only the desired minions.
Pyobjects Renderer

Salt now ships with the Pyobjects Renderer that allows for construction of States using pure Python with an idiomatic object interface.

New Modules

In addition to the Amazon modules mentioned above, there are also several other new execution modules:

- Oracle
- Random
- Redis
- Amazon Simple Queue Service
- Block Device Management
- CoreOS etcd
- Genesis
- InfluxDB
- Server Density
- Twilio Notifications
- Varnish
- ZNC IRC Bouncer
- SMTP

New Runners

- Map/Reduce Style
- Queue

New External Pillars

- CoreOS etcd

New Salt-Cloud Providers

- Aliyun ECS Cloud
- LXC Containers
- Proxmox (OpenVZ containers & KVM)

Salt Call Change

When used with a returner, salt-call now contacts a master if --local is not specified.
Deprecations

salt.modules.virtualenv_mod

- Removed deprecated memoize function from salt/utils/__init__.py (deprecated)
- Removed deprecated no_site_packages argument from create function (deprecated)
- Removed deprecated check_dns argument from minion_config and apply_minion_config functions (deprecated)
- Removed deprecated OutputOptionsWithTextMixIn class from salt/utils/parsers.py (deprecated)
- Removed the following deprecated functions from salt/modules/ps.py: - physical_memory_usage (deprecated) - virtual_memory_usage (deprecated) - cached_physical_memory (deprecated) - physical_memory_buffers (deprecated)
- Removed deprecated cloud arguments from cloud_config function in salt/config.py: - vm_config (deprecated) - vm_config_path (deprecated)
- Removed deprecated libcloud_version function from salt/cloud/libcloudfuncs.py (deprecated)
- Removed deprecated CloudConfigMixIn class from salt/utils/parsers.py (deprecated)

35.2.9 Salt 2014.7.1 Release Notes

release 2015-01-12

Version 2014.7.1 is a bugfix release for 2014.7.0. The changes include:

- Fixed gifs serving symlinks in file.recurse states (issue 17700)
- Fixed holding of multiple packages (YUM) when combined with version pinning (issue 18468)
- Fixed use of Jinja templates in masterless mode with non-roots fileserver backend (issue 17963)
- Re-enabled pillar and compound matching for mine and publish calls. Note that pillar globbing is still disabled for those modes, for security reasons. (issue 17194)
- Fix for tty: True in salt-ssh (issue 16847)
- Fix for supervisor states when supervisor not installed to system python (issue 18044)
- Fix for logging when log_level='quiet' for cmd.run (issue 19479)

35.2.10 Salt 2014.7.2 Release Notes

release 2015-02-09

Version 2014.7.2 is a bugfix release for 2014.7.0. The changes include:

- Fix erroneous warnings for systemd service enabled check (issue 19606)
- Fix FreeBSD kernel module loading, listing, and persistence kmod (issue 197151, issue 19682)
- Allow case-sensitive npm package names in the npm state. This may break behavior for people expecting the state to lowercase their npm package names for them. The npm module was never affected by mandatory lowercasing. (issue 20329)
• Deprecate the activate parameter for pip.install for both the module and the state. If bin_env is given and points to a virtualenv, there is no need to activate that virtualenv in a shell for pip to install to the virtualenv.

• Fix a file-locking bug in gifs (issue 18839)

• Deprecated archive_user in favor of standardized user parameter in state and added group parameter.

35.2.11 Salt 2014.7.3 Release Notes

release  TBA
Version 2014.7.3 is a bugfix release for 2014.7.0.

Changes:
• Multi-master minions mode no longer route fileclient operations asymetrically. This fixes the source of many multi-master bugs where the minion would become unresponsive from one or more masters.

• Fix bug wherein network.iface could produce stack traces.

• net.arp will no longer be made available unless arp is installed on the system.

• Major performance improvements to SaltNado

• Allow KVM module to operate under KVM itself or VMWare Fusion

• Various fixes to the Windows installation scripts

• Fix issue where the syndic would not correctly propagate loads to the master job cache.

• Improve error handling on invalid /etc/network/interfaces file in salt networking modules

• Fix bug where a reponse status was not checked for in fileclient.get_url

• Enable eauth when running salt in batch mode

• Increase timeout in Boto Route53 module

• Fix bugs with Salt's `tar` module option parsing

• Fix parsing of NTP servers on Windows

• Fix issue with blockdev tuning not reporting changes correctly

• Update to the latest Salt bootstrap script

• Update Linode salt-cloud driver to use either linode-python or apache-libcloud

• Fix for s3.query function to return correct headers

• Fix for s3.head returning None for files that exist

• Fix the disable function in win_service module so that the service is disabled correctly

• Fix race condition between master and minion when making a directory when both daemons are on the same host

• Fix an issue where file.recurse would fail at the root of an svn repo when the repo has a mountpoint

• Fix an issue where file.recurse would fail at the root of an hgfs repo when the repo has a mountpoint

• Fix an issue where file.recurse would fail at the root of an gifs repo when the repo has a mountpoint

• Add status.master capability for Windows.

• Various fixes to ssh_known_hosts
- Various fixes to states.network bonding for Debian
- The debian_ip.get_interfaces module no longer removes nameservers.
- Better integration between grains.virtual and systemd-detect-virt and virt-what
- Fix traceback in sysctl.present state output
- Fix for issue where mount.mounted would fail when superopts were not a part of mount.active (extended=True). Also mount.mounted various fixes for Solaris and FreeBSD.
- Fix error where datetimes were not correctly safeguarded before being passed into msgpack.
- Fix file.replace regressions. If the pattern is not found, and if dry run is False, and if backup is False, and if a pre-existing file exists with extension .bak, then that backup file will be overwritten. This backup behavior is a result of how fileinput works. Fixing it requires either passing through the file twice (the first time only to search for content and set a flag), or rewriting file.replace so it doesn’t use fileinput
- VCS files server fixes/optimizations
- Catch fileserver configuration errors on master start
- Raise errors on invalid gitfs configurations
- set locale when locale file does not exist (Redhat family)
- Fix to correctly count active devices when created mdadm array with spares
- Fix to correctly target minions in batch mode
- Support ssh:// urls using the gitfs dul which backend
- New fileserver runner
- Fix various bugs with argument parsing to the publish module.
- Fix disk.usage for Synology OS
- Fix issue with tags occurring twice with docker.pulled
- Fix incorrect key error in SMTP returner
- Fix condition which would remount loopback filesystems on every state run
- Remove requisites from listen after they are called in the state system
- Make system implementation of service.running aware of legacy service calls
- Fix issue where publish.publish would not handle duplicate responses gracefully.
- Accept Kali Linux for aptpkg salt execution module
- Fix bug where cmd.which could not handle a dirname as an argument
- Fix issue in ps.pgrep where exceptions were thrown on Windows.

Known issues:

- In multimaster mode, a minion may become temporarily unresponsive if modules or pillars are refreshed at the same time that one or more masters are down. This can be worked around by setting ‘auth_timeout’ and ‘auth_tries’ down to shorter periods.

35.2.12 Salt 2014.7.4 Release Notes

release 2015-03-30
Version 2014.7.4 is a bugfix release for 2014.7.0.

This is a security release. The security issues fixed have only been present since 2014.7.0, and only users of the two listed modules are vulnerable. The following CVEs have been resolved:

- CVE-2015-1838 SaltStack: insecure /tmp file handling in salt/modules/serverdensity_device.py
- CVE-2015-1839 SaltStack: insecure /tmp file handling in salt/modules/chef.py

Changes:

- Multi-master minions mode no longer route file client operations asymmetrically. This fixes the source of many multi-master bugs where the minion would become unresponsive from one or more masters.
- Fix bug wherein network.iface could produce stack traces.
- net.arp will no longer be made available unless arp is installed on the system.
- Major performance improvements to SaltNado
- Allow KVM module to operate under KVM itself or VMWare Fusion
- Various fixes to the Windows installation scripts
- Fix issue where the syndic would not correctly propagate loads to the master job cache.
- Improve error handling on invalid /etc/network/interfaces file in salt networking modules
- Fix bug where a reponse status was not checked for in fileclient.get_url
- Enable eauth when running salt in batch mode
- Increase timeout in Boto Route53 module
- Fix bugs with Salt’s `tar` module option parsing
- Fix parsing of NTP servers on Windows
- Fix issue with blockdev tuning not reporting changes correctly
- Update to the latest Salt bootstrap script
- Update Linode salt-cloud driver to use either linode-python or apache-libcloud
- Fix for s3.query function to return correct headers
- Fix for s3.head returning None for files that exist
- Fix the disable function in win_service module so that the service is disabled correctly
- Fix race condition between master and minion when making a directory when both daemons are on the same host
- Fix an issue where file.recurse would fail at the root of an svn repo when the repo has a mountpoint
- Fix an issue where file.recurse would fail at the root of an hgfs repo when the repo has a mountpoint
- Fix an issue where file.recurse would fail at the root of an gitfs repo when the repo has a mountpoint
- Add status.master capability for Windows.
- Various fixes to ssh_known_hosts
- Various fixes to states.network bonding for Debian
- The debian_ip.get_interfaces module no longer removes nameservers.
- Better integration between grains.virtual and systemd-detect-virt and virt-what
- Fix traceback in sysctl.present state output
• Fix for issue where mount.mounted would fail when superopts were not a part of mount.active (extended=True). Also mount.mounted various fixes for Solaris and FreeBSD.

• Fix error where datetimes were not correctly safeguarded before being passed into msgpack.

• Fix file.replace regressions. If the pattern is not found, and if dry run is False, and if backup is False, and if a pre-existing file exists with extension .bak, then that backup file will be overwritten. This backup behavior is a result of how fileinput works. Fixing it requires either passing through the file twice (the first time only to search for content and set a flag), or rewriting file.replace so it doesn’t use fileinput

• VCS filereserver fixes/optimizations

• Catch fileserver configuration errors on master start

• Raise errors on invalid gitfs configurations

• set_locale when locale file does not exist (Redhat family)

• Fix to correctly count active devices when created mdadm array with spares

• Fix to correctly target minions in batch mode

• Support ssh:// urls using the gitfs dul which backend

• New fileserver runner

• Fix various bugs with argument parsing to the publish module.

• Fix disk.usage for Synology OS

• Fix issue with tags occurring twice with docker.pulled

• Fix incorrect key error in SMTP returner

• Fix condition which would remount loopback filesystems on every state run

• Remove requisites from listens after they are called in the state system

• Make system implementation of service.running aware of legacy service calls

• Fix issue where publish.publish would not handle duplicate responses gracefully.

• Accept Kali Linux for aptpkg salt execution module

• Fix bug where cmd.which could not handle a dirname as an argument

• Fix issue in ps.pgrep where exceptions were thrown on Windows.

Known issues:

• In multimaster mode, a minion may become temporarily unresponsive if modules or pillars are refreshed at the same time that one or more masters are down. This can be worked around by setting `auth_timeout' and `auth_tries' down to shorter periods.

• There are known issues with batch mode operating on the incorrect number of minions. This bug can be patched with the change in Pull Request #22464.

• The fun, state, and unless keywords are missing from the state internals, which can cause problems running some states. This bug can be patched with the change in Pull Request #22365.

35.2.13 Salt 2014.7.5 Release Notes

release 2015-04-16

Version 2014.7.5 is a bugfix release for 2014.7.0.

Changes:
• Fixed a key error bug in salt-cloud
• Updated man pages to better match documentation
• Fixed bug concerning high CPU usage with salt-ssh
• Fixed bugs with remounting cvfs and fuse filesystems
• Fixed bug with allowing requisite tracking of entire sls files
• Fixed bug with aptpkg.mod_repo returning OK even if apt-add-repository fails
• Increased frequency of ssh terminal output checking
• Fixed malformed locale string in localmod module
• Fixed checking of available version of package when accept_keywords were changed
• Fixed bug to make git.latest work with empty repositories
• Added **kwargs to service.mod_watch which removes warnings about enable and __reqs__ not being supported by the function
• Improved state comments to not grow so quickly on failed requisites
• Added force argument to service to trigger force_reload
• Fixed bug to andle pkgrepo keyids that have been converted to int
• Fixed module.portage_config bug with appending accept_keywords
• Fixed bug to correctly report disk usage on windows minion
• Added the ability to specify key prefix for S3 ext_pillar
• Fixed issues with batch mode operating on the incorrect number of minions
• Fixed a bug with the proxmox cloud provider stacktracing on disk definition
• Fixed a bug with the changes dictionary in the file state
• Fixed the TCP keep alive settings to work better with SREQ caching
• Fixed many bugs within the iptables state and module
• Fixed bug with states by adding fun, state, and unless to the state runtime internal keywords listing
• Added ability to eAuth against Active Directory
• Fixed some salt-ssh issues when running on Fedora 21
• Fixed grains.get_or_set_hash to work with multiple entries under same key
• Added better explanations and more examples of how the Reactor calls functions to docs
• Fixed bug to not pass ex_config_drive to libcloud unless it's explicitly enabled
• Fixed bug with pip.install on windows
• Fixed bug where puppet.run always returns a 0 retcode
• Fixed race condition bug with minion scheduling via pillar
• Made efficiency improvements and bug fixes to the windows installer
• Updated environment variables to fix bug with pygit2 when running salt as non-root user
• Fixed cas behavior on data module -- data.cas was not saving changes
• Fixed GPG rendering error
• Fixed strace error in virt.query
• Fixed stacktrace when running chef-solo command
• Fixed possible bug wherein uncaught exceptions seem to make zmq3 tip over when threading is involved
• Fixed argument passing to the reactor
• Fixed glibc caching to prevent bug where salt-minion getaddrinfo in dns_check() never got updated nameservers

Known issues:
• In multimaster mode, a minion may become temporarily unresponsive if modules or pillars are refreshed at the same time that one or more masters are down. This can be worked around by setting `auth_timeout' and `auth_tries' down to shorter periods.

35.2.14 Salt 2014.7.6 Release Notes

release 2015-05-18

Version 2014.7.6 is a bugfix release for 2014.7.0.

This release is a security release. A minor issue was found, as cited below:
• CVE-2015-4017 -- Certificates are not verified when connecting to server in the Aliyun and Proxmox modules

Only users of the Aliyun or Proxmox cloud modules are at risk. The vulnerability does not exist in the latest 2015.5.0 release of Salt.

Changes:
• salt.runners.cloud.action() has changed the fun keyword argument to func. Please update any calls to this function in the cloud runner.

Extended Changelog Courtesy of Todd Stansell (https://github.com/tjstansell/salt-changelogs):
• PR #23810: (rallytime) Backport #23757 to 2014.7 @ 2015-05-18T15:30:21Z
  -- PR #23757: (clan) use abspath, do not eliminating symlinks | refs: #23810

  – 54b3bd4 Merge pull request #23404 from hvnsweeting/cherrypy-post-emptybody-fix
  – f85f8f9 initialize var when POST body is empty

• PR #23409: (*terminalmage*) Update Lithium docstrings in 2014.7 branch @ 2015-05-06T16:20:46Z
- 160f703 Merge pull request #23409 from terminalmage/update-lithium-docstrings-2014.7
- bc97d01 Fix sphinx typo
- 20006b0 Update Lithium docstrings in 2014.7 branch

- **PR #23397:** (jfindlay) add more flexible whitespace to locale_gen search @ 2015-05-06T03:44:11Z
  - ISSUE #17245: (tomashavlas) localemod does not generate locale for Arch | refs: #23307 #23397
  - aa5fb0a Merge pull request #23397 from jfindlay/fix_locale_gen
  - 0941fe6 add more flexible whitespace to locale_gen search

- **PR #23368:** (kaithar) Backport #23367 to 2014.7 @ 2015-05-05T21:42:26Z
  - **PR #23367:** (kaithar) Put the sed insert statement back in to the output. | refs: #23368
  - **PR #18368:** (basepi) Merge forward from 2014.7 to develop | refs: #23367 #23368
  - 0c76dd4 Merge pull request #23368 from kaithar/bp-23367
  - 577f419 Pylint fix
  - 8d9acd1 Put the sed insert statement back in to the output.

- **PR #23350:** (lorenjordon) Append/prepend: search for full line @ 2015-05-05T21:42:11Z
  - ISSUE #23294: (variia) file.replace fails to append if repl string partially available | refs: #23350
  - 3493ec1 Merge pull request #23350 from lorenjordon/file.replace_assume_line
  - b60e224 Append/prepend: search for full line

- **PR #23341:** (cachedout) Fix syndic pid and logfile path @ 2015-05-05T21:29:10Z
  - ISSUE #23026: (adelcast) Incorrect salt-syndic logfile and pidfile locations | refs: #23341
  - 7be5c48 Merge pull request #23341 from cachedout/issue_23026
  - e98e65e Fix tests
  - 601b43 Fix syndic pid and logfile path

- **PR #23272:** (basepi) [2014.7] Allow salt-ssh minion config overrides via master config and roster | refs: #23347 @ **
  - ISSUE #19114: (pykler) salt-ssh and gpg pillar renderer | refs: #23188 #23272 #23347
  - **PR #23188:** (basepi) [2014.7] Work around bug in salt-ssh in config.get for gpg renderer | refs: #23272
  - ea61abf Merge pull request #23272 from basepi/salt-ssh.minion.config.19114
  - c223309 Add versionadded
  - be7407f Lint
  - c2c3375 Missing comma
  - 8e3e8e0 Pass the minion_opts through the FunctionWrapper
  - cb69cd0 Match the master config template in the master config reference
  - 87fc316 Add Salt-SSH section to master config template
  - 91dd9dc Add ssh_minion_opts to master config ref
  - c273ea1 Add minion config to salt-ssh doc
  - a0b6b76 Add minion_opts to roster docs
- 5212c35 Accept minion_opts from the target information
- e209b6 Process ssh_minion_opts from master config
- 3b64214 Revert "Work around bug in salt-ssh in config.get for gpg renderer"
- 494953a Remove the strip (embracing multi-line YAML dump)
- fe87f0f Dump multi-line yaml into the SHIM
- b751a72 Inject local minion config into shim if available

• PR #23347: (basepi) [2014.7] Salt-SSH Backport FunctionWrapper.__contains__ @ 2015-05-05T14:13:21Z

  - ISSUE #19114: (pykler) salt-ssh and gpg pillar renderer | refs: #23188 #23272 #23347
  - PR #23272: (basepi) [2014.7] Allow salt-ssh minion config overrides via master config and roster | refs: #23347
  - PR #23188: (basepi) [2014.7] Work around bug in salt-ssh in config.get for gpg renderer | refs: #23272
  - 4f760dd Merge pull request #23347 from basepi/salt-ssh.functionwrapper.contains.19114
  - 30595e3 Backport FunctionWrapper.__contains__

• PR #23344: (cachedout) Explicitly set file_client on master @ 2015-05-04T23:21:48Z

  - ISSUE #22742: (hvnsweeting) salt-master says: "This master address: `salt' was previously resolvable but now fails to resolve!" | refs: #23344
  - 02658b1 Merge pull request #23344 from cachedout/issue_22742
  - 5ad96c Explicitly set file_client on master

• PR #23318: (cellscape) Honor seed argument in LXC container initialization @ 2015-05-04T20:58:12Z

  - PR #23311: (cellscape) Fix new container initialization in LXC runner | refs: #23318
  - ba7605d Merge pull request #23318 from cellscape/honor-seed-argument
  - 228b1be Honor seed argument in LXC container initialization

• PR #23307: (jfindlay) check for /etc/locale.gen @ 2015-05-04T20:56:32Z

  - ISSUE #17245: (tomashavlas) localemod does not generate locale for Arch | refs: #23307 #23397
  - 4ac4509 Merge pull request #23307 from jfindlay/fix_locale_gen
  - 101199a check for /etc/locale.gen

• PR #23324: (s0undt3ch) [2014.7] Update to the latest stable release of the bootstrap script v2015.05.04 @ 2015-05-04T16:28:30Z

  - ISSUE #580: (thatch45) recursive watch not being caught | refs: #23324
  - ISSUE #552: (jhutchins) Support require and watch under the same state dec | refs: #23324
  - PR #589: (epoelke) add --quiet and --outfile options to saltkey | refs: #23324
  - PR #567: (bastichelaar) Added upstart module | refs: #23324
  - PR #560: (UtahDave) The runs feature that was added in 93423aa2e5e4b7de6452090b0039560d2b13... | refs: #23324
  - PR #504: (SEJeff) File state goodies | refs: #23324
  - f790f42 Merge pull request #23324 from s0undt3ch/hotfix/bootstrap-script-2014.7
  - 6643e47 Update to the latest stable release of the bootstrap script v2015.05.04

Chapter 35. Release notes
- **PR #23329**: (cro) Require requests to verify cert when talking to aliyun and proxmox cloud providers @ 2015-05-04T16:18:17Z
  - 5487367 Merge pull request #23329 from cro/cloud_verify_cert
  - 860d4b7 Turn on ssl verify for requests.
- **PR #23311**: (cellscape) Fix new container initialization in LXC runner | refs: #23318 @ 2015-05-04T09:55:29Z
  - ea20176 Merge pull request #23311 from cellscape/fix-salt-cloud-lxc-init
  - 76fb34 Fix new container initialization in LXC runner
- **PR #23298**: (chris-prince) Fixed issue #18880 in 2014.7 branch @ 2015-05-04T09:55:29Z
  - ISSUE #18880: (johtso) npm installed breaks when a module is missing
  - c399b8f Merge pull request #23298 from chris-prince/2014.7
  - 0fa25db Fixed issue #18880 in 2014.7 branch
- **PR #23292**: (rallytime) Merge #23151 with pylint fixes @ 2015-05-02T03:54:12Z
  - ISSUE #23148: (cr1stIp) virt - error handling bogus if machine image location is wrong
  - PR #23151: (cr1stIp) Fixes #23148 | refs: #23292
  - 16ecefd Merge pull request #23292 from rallytime/merge-23151
  - 8ff852a Merge #23151 with pylint fixes
  - 8fa12e Fixes #23148
- **PR #23274**: (basepi) [2014.7] Reduce salt-ssh debug log verbosity @ 2015-05-01T20:19:23Z
  - ce24315 Merge pull request #23274 from basepi/salt-ssh.debug.verbosity
  - ece6c6 Log stdout and stderr to trace
  - 08f54d7 Log stdout and stderr to trace as well
  - 9b9c30f Reduce salt-ssh debug log verbosity
- **PR #23261**: (rallytime) Fix tornado websocket event handler registration @ 2015-05-01T18:20:31Z
  - ISSUE #22605: (mavenAtHouzz) Tornado websockets event Handlers registration are incorrect | refs: #23261
  - 7b55e43 Merge pull request #23261 from rallytime/fix-22605
  - 4950bf8 Fix tornado websocket event handler registration
- **PR #23258**: (teizz) TCP keepalives on the ret side, Revisited. @ 2015-05-01T16:13:49Z
  - 83ef7cb Merge pull request #23258 from teizz/i>ret_keepalive_2014_7_5
  - 0bf9b6f The fixes by i>cachedout which were backported into 2015_2 were missing a single parameter thus not setting up the TCP keepalive for the ZeroMQ Channel by default.
- **PR #23241**: (techhat) Move iptables log options after the jump @ 2015-05-01T01:34:59Z
  - ISSUE #23224: (twellspring) iptables.append --log parameters must be after --jump LOG | refs: #23241
  - 8de3c83 Merge pull request #23241 from techhat/issue23224
  - 87f7948 Move iptables log options after the jump
- **PR #23228**: (rallytime) Backport #23171 to 2014.7 @ 2015-04-30T21:09:45Z
  - PR #23171: (skizunov) Bugfix: `clean_proc_dir` is broken | refs: #23228

35.2. Previous Releases
Chapter 35. Release notes

- f20210e Merge pull request #23228 from rallytime/bp-23171
- e670e99 Bugfix: `clean_proc_dir` is broken

- **PR #23227**: (rallytime) Backport #22808 to 2014.7 @ 2015-04-30T21:09:14Z
  - ISSUE #22703: (Xiol) salt-ssh does not work with list matcher | refs: #22808
  - **PR #22808**: (basepi) [2015.2] Add list targeting to salt-ssh flat roster | refs: #23227
  - 721cc28 Merge pull request #23227 from rallytime/bp-22808
  - d208a0 Dict, not list
  - a3f529e It's already been converted to a list
  - dd57f2d Add list targeting to salt-ssh flat roster

- **PR #22823**: (hvnsweeting) 22822 file directory clean @ 2015-04-30T15:25:51Z
  - 82c22af Merge pull request #22823 from hvnsweeting/22822-file-directory-clean
  - c74c27 fix lint - remove unnecessary parenthesis
  - cb3dee refactor
  - 8924b5a refactor: use relpath instead of do it manually
  - d306a5 refactor
  - 5759a0e bugfix: file.directory clean=True when it require parent dir

- **PR #22977**: (bersace) Fix fileserver backends __opts__ overwritten by _pillar @ 2015-04-30T15:24:56Z
  - ISSUE #22941: (bersace) _pillar func breaks fileserver globals | refs: #22977 #22942
  - **PR #22942**: (bersace) Fix fileserver backends global overwritten by _pillar | refs: #22977
  - f6c0728 Merge pull request #22977 from bersace/fix-fileserver-backends-pillar-side-effect
  - 5f451f6 Fix fileserver backends __opts__ overwritten by _pillar

- **PR #23180**: (jfindlay) fix typos from 36841bdd in masterapi.py @ 2015-04-30T15:22:41Z
  - ISSUE #23166: (claudiupopescu) ```Error in function _minion_event`` resulting in modules not loaded | refs: #23180
  - 34206f7 Merge pull request #23180 from jfindlay/remote_event
  - 7206e1 fix typos from 36841bdd in masterapi.py

- **PR #23176**: (jfindlay) copy standard cmd.run* kwargs into cmd.run_chroot @ 2015-04-30T15:22:12Z
  - ISSUE #23153: (cr1st1p) cmdmod : run_chroot - broken in 2014.7.5 - missing kwargs | refs: #23176
  - b6b8216 Merge pull request #23176 from jfindlay/run_chroot
  - cc3417 copy standard cmd.run* kwargs into cmd.run_chroot

- **PR #23193**: (joejulian) supervisord.mod_watch should accept sfun @ 2015-04-30T04:34:21Z
  - ISSUE #23192: (joejulian) supervisord mod_watch does not accept sfuns | refs: #23193
  - ef8f99c Merge pull request #23193 from joejulian/2014.7_supervisord_accept_sfun
  - ebf59f9 supervisord.mod_watch should accept sfuns

- **PR #23188**: (basepi) [2014.7] Work around bug in salt-ssh in config.get for gpg renderer | refs: #23272 @ 2015-04-30T04:34:10Z
  - ISSUE #19114: (pykler) salt-ssh and gpg pillar renderer | refs: #23188 #23272 #23347
- 72fe88e Merge pull request #23188 from basepi/salt-ssh.function.wrapper.gpg.19114
- d73979e Work around bug in salt-ssh in config.get for gpg render

- **PR #23154**: (cachedout) Re-establish channel on interruption in fileclient @ 2015-04-29T16:59Z
  - ISSUE #21480: (msciciel) TypeError: string indices must be integers, not str | refs: #23154
  - 168508e Merge pull request #23154 from cachedout/refresh_channel
  - 9f8dd80 Re-establish channel on interruption in fileclient

- **PR #23146**: (rallytime) Backport #20779 to 2014.7 @ 2015-04-28T20:45:06Z
  - ISSUE #20647: (ryan-lane) file.serialize fails to serialize due to ordered dicts | refs: #20779
  - PR #20779: (cachedout) Use declared yaml options | refs: #23146
  - 3b53e04 Merge pull request #23146 from rallytime/bp-20779
  - ffd1849 compare OrderedDicts in serializer unit test
  - a221706 Just change serialize
  - a111798 Use declared yaml options

- **PR #23145**: (rallytime) Backport #23089 to 2014.7 @ 2015-04-28T20:45:06Z
  - PR #23089: (cachedout) Stringify version number before lstrip | refs: #23145
  - 88b4664 Merge pull request #23145 from rallytime/bp-23089
  - 93c41af Stringify version number before lstrip

- **PR #23144**: (rallytime) Backport #23124 to 2014.7 @ 2015-04-28T20:44:46Z
  - ISSUE #16188: (drawks) salt.modules.parted has various functions with bogus input validation. | refs: #23124
  - PR #23124: (ether42) fix parsing the output of parted in parted.list_() | refs: #23144
  - c85d36f Merge pull request #23144 from rallytime/bp-23124-2014-7
  - 6b64da7 fix parsing the output of parted

- **PR #23120**: (terminalmage) Don’t run os.path.relpath() if repo doesn’t have a `“root”` param set @ 2015-04-28T15:46:54Z
  - a27b158 Merge pull request #23120 from terminalmage/fix-gitfs-relpath
  - 1860ff Don’t run os.path.relpath() if repo doesn’t have a `“root”` param set

- **PR #23132**: (clinta) Backport b27c176 @ 2015-04-28T15:00:30Z
  - fcba607 Merge pull request #23132 from clinta/patch-2
  - a824d72 Backport b27c176

- **PR #23114**: (rallytime) Adjust ZeroMQ 4 docs to reflect changes to Ubuntu 12 packages @ 2015-04-28T03:59:24Z
  - ISSUE #18476: (Auha) Upgrading salt on my master caused dependency issues | refs: #23114 #18610
  - PR #18610: (rallytime) Make ZMQ 4 installation docs for ubuntu more clear | refs: #23114
  - b66f8b8 Merge pull request #23114 from rallytime/remove_ubuntu_zmq4_docs
  - f6cc7c8 Adjust ZeroMQ 4 docs to reflect changes to Ubuntu 12 packages

- **PR #23108**: (rallytime) Backport #23097 to 2014.7 @ 2015-04-28T03:58:05Z
  - ISSUE #23085: (xenophonf) Use `“s3fs”` (not `“s3”`) in fileserver_roots | refs: #23097
- PR #23097: (rallytime) Change s3 to s3fs in fileserver_roots docs example | refs: #23108
- 399857f Merge pull request #23108 from rallytime/bp-23097
- fa88984 Change s3 to s3fs in fileserver_roots docs example

- PR #23112: (basepi) [2014.7] Backport #22199 to fix mysql returner save_load errors @ 2015-04-28T03:55:44Z
- ISSUE #22171: (basepi) We should only call returner.save_load once per jid | refs: #22199
- PR #22199: (basepi) [2015.2] Put a bandaid on the save_load duplicate issue (mysql returner) | refs: #23112
- 5541537 Merge pull request #23112 from basepi/mysql_returner_save_load
- 0127012 Put a bandaid on the save_load duplicate issue

- PR #23113: (rallytime) Revert `Backport #22895 to 2014.7` @ 2015-04-28T03:27:29Z
- PR #22925: (rallytime) Backport #22895 to 2014.7 | refs: #23113
- PR #22895: (aletourneau) pam_tally counter was not reset to 0 after a succesfull login | refs: #22925
- dfe2066 Merge pull request #23113 from saltstack/revert-22925-bp-22895
- b957ea8 Revert `Backport #22895 to 2014.7`

- PR #23094: (terminalmage) pygit2: disable cleaning of stale refs for authenticated remotes @ 2015-04-27T20:51:28Z
- ISSUE #23013: (markusr815) gitfs regression with authenticated repos | refs: #23094
- 2151f3 Merge pull request #23094 from terminalmage/issue23013
- aaf7b04 pygit2: disable cleaning of stale refs for authenticated remotes

- PR #23048: (jfindlay) py-2.6 compat for utils/boto.py ElementTree exception @ 2015-04-25T16:56:45Z
- d45aa21 Merge pull request #23048 from jfindlay/ET_error
- 64e42cc py-2.6 compat for utils/boto.py ElementTree exception

- PR #23025: (jfindlay) catch exceptions on bad system locales/encodings @ 2015-04-25T16:56:30Z
- ISSUE #22981: (syphernl) Locale state throwing traceback when generating not (yet) existing locale | refs: #23025
- d25a5c1 Merge pull request #23025 from jfindlay/fix_sys_locale
- 9c4d62b catch exceptions on bad system locales/encodings

- PR #22932: (hvnsweeting) bugfix: also manipulate dir_mode when source not defined @ 2015-04-25T16:54:58Z
- 5e44b59 Merge pull request #22932 from hvnsweeting/file-append-bugfix
- 3f368de do not use assert in execution module
- 9d4d4a bugfix: also manipulate dir_mode when source not defined

- PR #23055: (jfindlay) prevent ps module errors on accessing dead procs @ 2015-04-24T22:39:49Z
- ISSUE #23021: (ether42) ps.pgrep raises NoSuchProcess | refs: #23055
- c2416a4 Merge pull request #23055 from jfindlay/fix_ps
- c2dc7ad prevent ps module errors on accessing dead procs

- PR #23031: (jfindlay) convert exception e.message to just e @ 2015-04-24T18:38:13Z
- bfd9158 Merge pull request #23031 from jfindlay/exception
- 856bad1 convert exception e.message to just e
• PR #23015: (hvnsweeting) if status of service is stop, there is not an error with it @ 2015-04-24T14:35:10Z
  - 7747f33 Merge pull request #23015 from hvnsweeting/set-non-error-lvl-for-service-status-log
  - 92ea163 if status of service is stop, there is not an error with it

• PR #23000: (jfindlay) set systemd service killMode to process for minion @ 2015-04-24T03:42:39Z
  - ISSUE #22993: (jetpak) salt-minion restart causes all spawned daemons to die on centos7 (systemd) | refs: #23000
  - 2e09789 Merge pull request #23000 from jfindlay/systemd_kill
  - 3d575e2 set systemd service killMode to process for minion

• PR #22999: (jtand) Added retry_dns to minion doc. @ 2015-04-24T17:48:07Z
  - ISSUE #22707: (arthurlogilab) retry_dns of master configuration is missing from the documentation | refs: #22999
  - b5c059a Merge pull request #22999 from jtand/fix_22707
  - 8486e17 Added retry_dns to minion doc.

• PR #22990: (techhat) Use the proper cloud conf variable @ 2015-04-24T03:42:39Z
  - 27dc877 Merge pull request #22990 from techhat/2014.7
  - d3bcbad Use the proper cloud conf variable

• PR #22976: (multani) Improve state_output documentation @ 2015-04-23T12:24:22Z
  - 13df65 Merge pull request #22976 from multani/fix/state-output-doc
  - 19efd41 Improve state_output documentation

• PR #22955: (terminalmage) Fix regression introduced yesterday in dockerio module @ 2015-04-22T18:56:39Z
  - 89fa185 Merge pull request #22955 from terminalmage/dockerio-run-fix
  - b4472ad Fix regression introduced yesterday in dockerio module

• PR #22954: (rallytime) Backport #22909 to 2014.7 @ 2015-04-22T18:56:20Z
  - PR #22909: (mguegan) Fix compatibility with pkgin > 0.7 | refs: #22954
  - 46e227 Merge pull request #22954 from rallytime/bp-22909
  - 70c1dc3 Fix compatibility with pkgin > 0.7

• PR #22856: (jfindlay) increase timeout and decrease tries for route53 records @ 2015-04-22T16:47:01Z
  - ISSUE #18720: (Reiner030) timeouts when setting Route53 records | refs: #22856
  - c9ae59a Merge pull request #22856 from jfindlay/route53_timeout
  - ba4a786 add route53 record sync wait, default=False
  - ea2fd50 increase timeout and tries for route53 records

• PR #22946: (s0undt3ch) Test with a more recent pip version to avoid a traceback @ 2015-04-22T16:25:17Z
  - a178d44 Merge pull request #22946 from s0undt3ch/2014.7
  - bc87749 Test with a more recent pip version to avoid a traceback

• PR #22945: (garethgreenaway) Fixes to scheduler @ 2015-04-22T16:25:00Z
  - ISSUE #22571: (BoomerB) same error message as on issue #18504 | refs: #22945
  - de39bde Merge pull request #22945 from garethgreenaway/22571_2014_7_schedule_pillar_refresh_seconds_exceptions
- bfa6d25 Fixing a reported issue when using a scheduled job from pillar with splay. _seconds element that acted as a backup of the actual seconds was being removed when pillar was refreshed and causing exceptions. This fix moves some splay related code out of the if else condition so it's checked whether the job is in the job queue or not.

**PR #22887:** (hvnsweeting) fix #18843 @ 2015-04-22T15:47:05Z
- ISSUE #18843: (calvinhp) State user.present will fail to create home if user exists and homedir doesn't
- 12d2b91 Merge pull request #22887 from hvnsweeting/18843-fix-user-present-home
- 7fe7b08 run user.chhome once to avoid any side-effect when run it twice
- 19de995 clarify the usage of home arg
- d6dc09a enhance doc, as usermod on ubuntu 12.04 will not CREATE home
- 0ce4d7f refactor: force to use boolean
- 849d19e log debug the creating dir process
- c4e95b9 fix #18843: usermod won't create a dir if old home does not exist

**PR #22930:** (jfindlay) localemod.gen_locale now always returns a boolean @ 2015-04-22T15:37:39Z
- ISSUE #21140: (holms) locale.present state executed successfully, although originally fails | refs: #22930 #22829
- ISSUE #2417: (ff) Module standards | refs: #22829
- PR #22829: (f30) Always return a boolean in gen_locale() | refs: #22930
- b7de7bd Merge pull request #22930 from jfindlay/localegen_bool
- 399399f localemod.gen_locale now always returns a boolean

**PR #22933:** (hvnsweeting) add test for #18843 @ 2015-04-22T15:27:18Z
- ISSUE #18843: (calvinhp) State user.present will fail to create home if user exists and homedir doesn’t
- 11bcf14 Merge pull request #22933 from hvnsweeting/18843-test
- b13db32 add test for #18843

**PR #22925:** (rallytime) Backport #22895 to 2014.7 | refs: #23113 @ 2015-04-22T02:30:26Z
- PR #22895: (alex) pam_tally counter was not reset to 0 after a succesfull login | refs: #22925
- 6890752 Merge pull request #22925 from rallytime/bp-22895
- 3852d96 Pylint fix
- 90f7829 Fixed pylint issues
- 5eb1f59 Cleaned up pull request
- a08ac47 pam_tally counter was not reset to 0 after a succesfull login

**PR #22914:** (cachedout) Call proper returner function in jobs.list_jobs @ 2015-04-22T00:49:01Z
- ISSUE #22790: (whiteinge) jobs.list_jobs runner tracebacks on ‘missing’ argument | refs: #22914
- eca37eb Merge pull request #22914 from cachedout/issue_22790
- d828d6f Call proper returner function in jobs.list_jobs

**PR #22918:** (JaseFace) Add a note to the git_pillar docs stating that GitPython is the only currently supported provider @ 2015-04-22T00:48:26Z
- 44f3409 Merge pull request #22918 from JaseFace/git-pillar-provider-doc-note
- 0aee5c2 Add a note to the git_pillar docs stating that GitPython is the only currently supported provider

- **PR #22907**: (techhat) Properly merge cloud configs to create profiles @ 2015-04-21T22:02:44Z
  - 31c461f Merge pull request #22907 from techhat/cloudconfig
  - 3bf4e66 Properly merge cloud configs to create profiles

- **PR #22894**: (0xf10e) Fix issue #22782 @ 2015-04-21T18:55:18Z
  - f09397f Merge pull request #22894 from 0xf10e/2014.7
  - 58fa24c Clarify doc on kwarg `roles` for user_present().
  - f0ae2eb Improve readability by renaming tenant_role

- **PR #22902**: (rallytime) Change state example to use proper kwarg @ 2015-04-21T18:50:47Z
  - ISSUE #12003: (MarkusMuellerAU) [state.dockerio] docker.run TypeError: run() argument after ** must be a mapping, not str | refs: #22902
  - c802ba7 Merge pull request #22902 from rallytime/docker_doc_fix
  - 8f70346 Change state example to use proper kwarg

- **PR #22898**: (terminalmage) dockerio: better error message for native exec driver @ 2015-04-21T18:02:58Z
  - b1771a7 Merge pull request #22898 from terminalmage/issue12003
  - c375309 dockerio: better error message for native exec driver

- **PR #22897**: (rallytime) Add param documentation for file.replace state @ 2015-04-21T17:31:04Z
  - ISSUE #22825: (paolodina) Issue using file.replace in state file | refs: #22897
  - e2ec4ec Merge pull request #22897 from rallytime/fix-22825
  - 9c51630 Add param documentation for file.replace state

- **PR #22850**: (bersace) Fix pillar and salt files server mixed @ 2015-04-21T17:04:33Z
  - ISSUE #22844: (bersace) LocalClient file cache confuse pillar and state files | refs: #22850
  - df53889 Merge pull request #22850 from bersace/fix-pillar-salt-mixed
  - 31b98e7 Initialize state file client after pillar loading
  - f6bebb7 Use saltenv

- **PR #22818**: (twangboy) Added documentation regarding pip in windows @ 2015-04-21T03:58:59Z
  - 1380fec Merge pull request #22818 from twangboy/upd_pip_docs
  - cb999c7 Update pip.py
  - 3cc5e97 Added documentation regarding pip in windows

- **PR #22872**: (rallytime) Prevent stacktrace on os.path.exists in hosts module @ 2015-04-21T02:54:40Z
  - b2bf17f Merge pull request #22872 from rallytime/fix_hosts_stacktrace
  - c88a1ea Prevent stacktrace on os.path.exists in hosts module

- **PR #22853**: (s0undt3ch) Don’t assume package installation order. @ 2015-04-21T02:42:41Z
  - 03af523 Merge pull request #22853 from s0undt3ch/2014.7
  - b62df62 Don’t assume package installation order.

- **PR #22877**: (s0undt3ch) Don’t fail on make clean just because the directory does not exist @ 2015-04-21T02:40:47Z
- 9211e36 Merge pull request #22877 from s0undt3ch/hotfix/clean-docs-fix
- 95d6887 Don’t fail on make clean just because the directory does not exist

• PR #22873: (thatch45) Type check the version since it will often be numeric @ 2015-04-21T02:38:11Z
  - 5bd2d08 Merge pull request #22873 from thatch45/type_check
  - 53b8376 Type check the version since it will often be numeric

• PR #22870: (twangboy) Added ability to send a version with a space in it @ 2015-04-20T23:18:28Z
  - c965b0a Merge pull request #22870 from twangboy/fix_installer_again
  - 3f180cf Added ability to send a version with a space in it

• PR #22863: (rallytime) Backport #20974 to 2014.7 @ 2015-04-20T19:29:37Z
  - PR #20974: (JohannesEbke) Fix expr_match usage in salt.utils.check_whitelist_blacklist | refs: #22863
  - 2973eb1 Merge pull request #22863 from rallytime/bp-20974
  - 14913a4 Fix expr_match usage in salt.utils.check_whitelist_blacklist

• PR #22578: (hvnsweeting) gracefully handle when salt-minion cannot decrypt key @ 2015-04-20T15:24:45Z
  - c45b92b Merge pull request #22578 from hvnsweeting/2014-7-fix-compile-pillar
  - f75b24a gracefully handle when salt-minion cannot decrypt key

• PR #22800: (terminalmage) Improve error logging for pygit2 SSH-based remotes @ 2015-04-18T17:18:55Z
  - ISSUE #21979: (yrdevops) gitfs: error message not descriptive enough when libgit2 was compiled without libssh2 | refs: #22800
  - 900c7a5 Merge pull request #22800 from terminalmage/issue21979
  - 8f1c008 Clarify that for pygit2, receiving 0 objects means repo is up-to-date
  - 98885f7 Add information about libssh2 requirement for pygit2 ssh auth
  - 09468d2 Fix incorrect log message
  - 2093bf8 Adjust loglevels for gitfs errors
  - 9d394df Improve error logging for pygit2 SSH-based remotes

• PR #22813: (twangboy) Updated instructions for building salt @ 2015-04-18T04:10:07Z
  - e99f2fd Merge pull request #22813 from twangboy/win_doc_fix
  - 8d9f2e3 Fixed some formatting issues
  - 9890b3b Updated instructions for building salt

• PR #22810: (basepi) [2014.7] More msgpack gating for salt-ssh @ 2015-04-17T22:28:24Z
  - ISSUE #22708: (Bilge) salt-ssh file.accumulated error: NameError: global name `msgpack` is not defined | refs: #22810
  - fe1de89 Merge pull request #22810 from basepi/salt-ssh.more.msgpack.gating
  - d4da8e6 Gate msgpack in salt/modules/saltutil.py
  - 02303b2 Gate msgpack in salt/modules/data.py
  - d7e8741 Gate salt.states.file.py msgpack

• PR #22803: (rallytime) Allow map file to work with softlayer @ 2015-04-17T20:34:42Z
  - ISSUE #17144: (xpender) salt-cloud -m fails with softlayer | refs: #22803
- 11df71e Merge pull request #22803 from rallytime/fix-17144
- ce88b6a Allow map file to work with softlayer

- **PR #22807**: *(rallytime)* Add 2014.7.5 links to windows installation docs @ 2015-04-17T20:32:13Z
  - cd43a95 Merge pull request #22807 from rallytime/windows_docs_update
  - 5931a58 Replace all 4s with 5s
  - eadaed Add 2014.7.5 links to windows installation docs

- **PR #22795**: *(rallytime)* Added release note for 2014.7.5 release @ 2015-04-17T18:05:36Z
  - 0b295e2 Merge pull request #22795 from rallytime/release_notes
  - fde1fee Remove extra line
  - b19b95d Added release note for 2014.7.5 release

- **PR #22759**: *(twangboy)* Final edits to the batch files for running salt @ 2015-04-17T04:31:15Z
  - ISSUE #22740: *(lorengordon)* New Windows installer assumes salt is installed to the current directory |
    refs: #22759
  - **PR #22754**: *(twangboy)* Removed redundant \ and " | refs: #22759
  - 3c91459 Merge pull request #22759 from twangboy/fix_bat_one_last_time
  - 075f82e Final edits to the batch files for running salt

- **PR #22760**: *(thatch45)* Fix issues with the syndic @ 2015-04-17T04:30:48Z
  - 20d3f2b Merge pull request #22760 from thatch45/syndic_fix
  - e2db624 Fix issues with the syndic not resolving the master when the interface is set

- **PR #22762**: *(twangboy)* Fixed version not showing in Add/Remove Programs @ 2015-04-17T04:29:46Z
  - 54c4584 Merge pull request #22762 from twangboy/fix_installer
  - 4d25af8 Fixed version not showing in Add/Remove Programs

## 35.2.15 Salt 2014.1.0 Release Notes - Codename Hydrogen

**Note**: Due to a change in master to minion communication, 2014.1.0 minions are not compatible with older-version masters. Please upgrade masters first. More info on backwards-compatibility policy [here](#), under the "Upgrading Salt" subheading.

**Note**: A change in the grammar in the state compiler makes `module.run` in requisites illegal syntax. Its use is replaced simply with the word `module`. In other words you will need to change requisites like this:

```
require:
    module.run: some_module_name
```

to:

```
require:
    module: some_module_name
```

This is a breaking change. We apologize for the inconvenience, we needed to do this to remove some ambiguity in parsing requisites.
The 2014.1.0 release of Salt is a major release which not only increases stability but also brings new capabilities in virtualization, cloud integration, and more. This release brings a great focus on the expansion of testing making roughly double the coverage in the Salt tests, and comes with many new features.

2014.1.0 is the first release to follow the new date-based release naming system. See the version numbers page for more details.

**Major Features**

**Salt Cloud Merged into Salt**

Salt Cloud is a tool for provisioning salted minions across various cloud providers. Prior to this release, Salt Cloud was a separate project but this marks its full integration with the Salt distribution. A Getting Started guide and additional documentation for Salt Cloud can be found [here](#).

**Google Compute Engine**

Alongside Salt Cloud comes new support for the Google Compute Engine. Salt Stack can now deploy and control GCE virtual machines and the application stacks that they run.

For more information on Salt Stack and GCE, please see [this blog post](#).

Documentation for Salt and GCE can be found [here](#).

**Salt Virt**

Salt Virt is a cloud controller that supports virtual machine deployment, inspection, migration, and integration with many aspects of Salt.

Salt Virt has undergone a major overhaul with this release and now supports many more features and includes a number of critical improvements.

**Docker Integration**

Salt now ships with `states` and an `execution module` to manage Docker containers.

**Substantial Testing Expansion**

Salt continues to increase its unit/regression test coverage. This release includes over 300 new tests.

**BSD Package Management**

BSD package management has been entirely rewritten. FreeBSD 9 and older now default to using `pkg_add`, while FreeBSD 10 and newer will use `pkgng`. FreeBSD 9 can be forced to use `pkgng`, however, by specifying the following option in the minion config file:

```
providers:
  pkg: pkgng
```
In addition, support for installing software from the ports tree has been added. See the documentation for the ports state and execution module for more information.

Network Management for Debian/Ubuntu

Initial support for management of network interfaces on Debian-based distros has been added. See the documentation for the network state and the debian_ip for more information.

IPv6 Support for iptables State/Module

The iptables state and module now have IPv6 support. A new parameter family has been added to the states and execution functions, to distinguish between IPv4 and IPv6. The default value for this parameter is ipv4, specifying ipv6 will use ip6tables to manage firewall rules.

GitFS Improvements

Several performance improvements have been made to the Git fileserver backend. Additionally, file states can now use any any SHA1 commit hash as a fileserver environment:

```bash
/etc/httpd/httpd.conf:
file.managed:
  - source: salt://webserver/files/httpd.conf
  - saltenv: 45af879
```

This applies to the functions in the cp module as well:

```bash
salt '*' cp.get_file salt://readme.txt /tmp/readme.txt saltenv=45af879
```

MinionFS

This new fileserver backend allows files which have been pushed from the minion to the master (using cp.push) to be served up from the salt fileserver. The path for these files takes the following format:

```
salt://minion-id/path/to/file
```

minion-id is the id of the "source" minion, the one from which the files were pushed to the master. /path/to/file is the full path of the file.

The MinionFS Walkthrough contains a more thorough example of how to use this backend.

saltenv

To distinguish between fileserver environments and execution functions which deal with environment variables, fileserver environments are now specified using the saltenv parameter. env will continue to work, but is deprecated and will be removed in a future release.
Grains Caching

A caching layer has been added to the Grains system, which can help speed up minion startup. Disabled by default, it can be enabled by setting the minion config option `grains_cache`:

```
grains_cache: True
# Seconds before grains cache is considered to be stale.
grains_cache_expiration: 300
```

If set to `True`, the grains loader will read from/write to a msgpack-serialized file containing the grains data.

Additional command-line parameters have been added to salt-call, mainly for testing purposes:

- `--skip-grains` will completely bypass the grains loader when salt-call is invoked.
- `--refresh-grains-cache` will force the grains loader to bypass the grains cache and refresh the grains, writing a new grains cache file.

Improved Command Logging Control

When using the `cmd` module, either on the CLI or when developing Salt execution modules, a new keyword argument `output_loglevel` allows for greater control over how (or even if) the command and its output are logged. For example:

```
salt '*' cmd.run 'tail /var/log/messages' output_loglevel=debug
```

The package management modules (apt, yumpkg, etc.) have been updated to log the copious output generated from these commands at loglevel `debug`.

**Note:** To keep a command from being logged, `output_loglevel=quiet` can be used. Prior to this release, this could be done using `quiet=True`. This argument is still supported, but will be removed in a future Salt release.

PagerDuty Support

Initial support for firing events via PagerDuty has been added. See the documentation for the `pagerduty` module.

Virtual Terminal

Sometimes the subprocess module is not good enough, and, in fact, not even `askpass` is. This virtual terminal is still in its infant childhood, needs quite some love, and was originally created to replace `askpass`, but, while developing it, it immediately proved that it could do so much more. It’s currently used by salt-cloud when bootstrapping salt on clouds which require the use of a password.

Proxy Minions

Initial basic support for Proxy Minions is in this release. Documentation can be found here.
Proxy minions are a developing feature in Salt that enables control of devices that cannot run a minion. Examples include network gear like switches and routers that run a proprietary OS but offer an API, or "dumb" devices that just don't have the horsepower or ability to handle a Python VM.

Proxy minions can be difficult to write, so a simple REST-based example proxy is included. A Python bottle-based webserver can be found at https://github.com/cro/salt-proxy-rest as an endpoint for this proxy.

This is an ALPHA-quality feature. There are a number of issues with it currently, mostly centering around process control, logging, and inability to work in a masterless configuration.

Additional Bugfixes (Release Candidate Period)

Below are many of the fixes that were implemented in salt during the release candidate phase.

- Fix mount.mounted leaving conflicting entries in fstab (issue 7079)
- Fix mysql returner serialization to use json (issue 9590)
- Fix ZMQError: Operation cannot be accomplished in current state errors (issue 6306)
- Rbenv and ruby improvements
- Fix quoting issues with mysql port (issue 9568)
- Update mount module/state to support multiple swap partitions (issue 9520)
- Fix archive state to work with bsd.tar
- Clarify logs for minion ID caching
- Add numeric revision support to git state (issue 9718)
- Update master_uri with master_ip (issue 9694)
- Add comment to Debian mod_repo (issue 9923)
- Fix potential undefined loop variable in rabbitmq state (issue 8703)
- Fix for salt-virt runner to delete key on VM deletion
- Fix for salt-run -d to limit results to specific runner or function (issue 9975)
- Add tracebacks to jinja renderer when applicable (issue 10010)
- Fix parsing in monit module (issue 10041)
- Fix highstate output from syndic minions (issue 9732)
- Quiet logging when dealing with passwords/hashe (issue 10000)
- Fix for multiple remotes in git_pillar (issue 9932)
- Fix npm installed command (issue 10109)
- Add safeguards for utf8 errors in zcbuildout module
- Fix compound commands (issue 9746)
- Add systemd notification when master is started
- Many doc improvements
35.2.16 Salt 2014.1.1 Release Notes

release 2014-03-18

Version 2014.1.1 is a bugfix release for 2014.1.0. The changes include:

- Various doc fixes, including up-to-date Salt Cloud installation documentation.
- Renamed state.sls runner to state.orchestrate, to reduce confusion with the state.sls execution function
- Fix various bugs in the dig module (issue 10367)
- Add retry for query on certain EC2 status codes (issue 10154)
- Fix various bugs in mongodb_user state module (issue 10430)
- Fix permissions on ~/.salt_token (issue 10422)
- Add PyObjects support
- Fix launchctl module crash with missing files
- Fix saltutil.find_job for Windows (issue 10581)
- Fix OS detection for OpenSolaris (issue 10601)
- Fix broken salt-ssh key_deploy
- Add support for multiline cron comments (issue 10721)
- Fix timezone module for Arch (issue 10789)
- Fix symlink support for file.recurse (issue 10809)
- Fix multi-master bugs (issue 10732 and issue 10969)
- Fix file.patch to error when source file is unavailable (issue 10380)
- Fix pkg to handle packages set as purge in pkg.installed (issue 10719)
- Add zmqversion grain
- Fix highstate summary for masterless minions (issue 10945)
- Fix saltutil.find_job for 2014.1 masters talking to 0.17 minions (issue 11020)
- Fix file.recurse states with trailing slashes in source (issue 11002)
- Fix pkg states to allow pkgname.x86_64 (issue 7306)
- Make iptables states set a default table for flush (issue 11037)
- Added iptables --reject-with after final iptables call in iptables states (issue: 10757)
- Fix improper passing of “family” in iptables states (issue 10774)
- Fix traceback in iptables.insert states (issue 10988)
- Fix zombie processes (issue 10867 and others)
- Fix batch mode to obey --return settings (issue 9146)
- Fix localclient issue that was causing batch mode breakage (issue 11094, issue 10470, and others)
- Multiple salt-ssh fixes
- FreeBSD: look in /usr/local/etc/salt for configuration by default, if installed using pip --editable.
- Add a skip_suggestions parameter to pkg.installed states which allows pre-flight check to be skipped (issue 11106)
- Fixed tag-based gitfs fileserver environments regression ([issue 10956])
- Yum: fix cache of available pkgs not cleared when repos are changed ([issue 11001])
- Yum: fix for plugin-provided repositories (i.e. RHN/Spacewalk) ([issue 11145])
- Fix regression in `chocolatey.bootstrap` ([issue 10541])
- Fix fail on unknown target in `jobs runner` ([issue 11151])
- Don’t log errors for commands which are expected to sometimes exit with non-zero exit status ([issue 11154, issue 11090])
- Fix `test=True` CLI override of config option ([issue 10877])
- Log sysctl key listing at loglevel TRACE ([issue 10931])

### 35.2.17 Salt 2014.1.10 Release Notes

**release** 2014-08-01

**Note:** Version 2014.1.9 contained a regression which caused inaccurate Salt version detection, and thus was never packaged for general release. This version contains the version detection fix, but is otherwise identical to 2014.1.9.

Version 2014.1.10 is another bugfix release for 2014.1.0. Changes include:
- Ensure salt-ssh will not continue if permissions on a temporary directory are not correct.
- Use the bootstrap script distributed with Salt instead of relying on an external resource
- Remove unused testing code
- Ensure salt states are placed into the `.salt` directory in salt-ssh
- Use a randomized path for temporary files in a salt-cloud deployment
- Clean any stale directories to ensure a fresh copy of salt-ssh during a deployment

Salt 2014.1.10 fixes security issues documented by CVE-2014-3563: "Insecure tmp-file creation in seed.py, salt-ssh, and salt-cloud.” Upgrading is recommended.

### 35.2.18 Salt 2014.1.11 Release Notes

**release** 2014-08-29

Version 2014.1.11 is another bugfix release for 2014.1.0. Changes include:
- Fix for minion_id with byte-order mark (BOM) ([issue 12296])
- Fix `runas` deprecation in `at` module
- Fix trailing slash behavoir for `file.makedirs_` ([issue 14019])
- Fix chocolatey path ([issue 13870])
- Fix git_pillar infinite loop issues ([issue 14671])
- Fix json outputter `null` case
- Fix for minion error if one of multiple masters are down ([issue 14099])

---

**35.2. Previous Releases**
35.2.19 Salt 2014.1.12 Release Notes

release 2014-10-08

Version 2014.1.12 is another bugfix release for 2014.1.0. Changes include:

- Fix `scp_file` always failing (which broke salt-cloud) (issue 16437)
- Fix regression in pillar in masterless (issue 16210, issue 16416, issue 16428)

35.2.20 Salt 2014.1.13 Release Notes

release 2014-10-14

Version 2014.1.13 is another bugfix release for 2014.1.0. Changes include:

- Fix `sftp_file` by checking the exit status code of scp (which broke salt-cloud) (issue 16599)

35.2.21 Salt 2014.1.2 Release Notes

release 2014-04-15

Version 2014.1.2 is another bugfix release for 2014.1.0. The changes include:

- Fix username detection when su’ed to root on FreeBSD (issue 11628)
- Fix minionfs backend for file.recurse states
- Fix 32-bit packages of different arches than the CPU arch, on 32-bit RHEL/CentOS (issue 11822)
- Fix bug with specifying alternate home dir on user creation (FreeBSD) (issue 11790)
- Don’t reload site module on module refresh for MacOS
- Fix regression with running execution functions in Pillar SLS (issue 11453)
- Fix some modules missing from Windows installer
- Don’t log an error for yum commands that return nonzero exit status on non-failure (issue 11645)
- Fix bug in rabbitmq state (issue 8703)
- Fix missing ssh config options (issue 10604)
- Fix top.sls ordering (issue 10810 and issue 11691)
- Fix `salt-key --list all` (issue 10982)
- Fix `win_servermanager install/remove function` (issue 11038)
- Fix interaction with tokens when running commands as root (issue 11223)
- Fix overstate bug with `find_job` and `**kwargs` (issue 10503)
- Fix `saltenv` for `apt pkg.mod_repo` from `pkgrepo` state
- Fix environment issue causing file caching problems (issue 11189)
- Fix bug in `__parse_key` in registry state (issue 11408)
- Add minion auth retry on rejection (issue 10763)
- Fix `publish_session` updating the encryption key (issue 11493)
- Fix for bad `AssertionError` raised by GitPython (issue 11473)
• Fix debian_ip to allow disabling and enabling networking on Ubuntu (issue 11164)
• Fix potential memory leak caused by saved (and unused) events (issue 11582)
• Fix exception handling in the MySQL module (issue 11616)
• Fix environment-related error (issue 11534)
• Include psutil on Windows
• Add file.replace and file.search to Windows (issue 11471)
• Add additional file module helpers to Windows (issue 11235)
• Add pid to netstat output on Windows (issue 10782)
• Fix Windows not caching new versions of installers in winrepo (issue 10597)
• Fix hardcoded md5 hashing
• Fix kwargs in salt-ssh (issue 11609)
• Fix file backup timestamps (issue 11745)
• Fix stacktrace on sys.doc with invalid eauth (issue 11293)
• Fix git.latest with test=True (issue 11595)
• Fix file.check_perms hardcoded follow_symlinks (issue 11387)
• Fix certain pkg states for RHEL5/Cent5 machines (issue 11719)

35.2.22 Salt 2014.1.3 Release Notes

release 2014-04-15

Version 2014.1.3 is another bugfix release for 2014.1.0. It was created as a hotfix for a regression found in 2014.1.2, which was not distributed. The only change made was as follows:

• Fix regression that caused saltutil.find_job to fail, causing premature terminations of salt CLI commands.

Changes in the not-distributed 2014.1.2, also included in 2014.1.3:

• Fix username detection when su'ed to root on FreeBSD (issue 11628)
• Fix minionfs backend for file.recurse states
• Fix 32-bit packages of different arches than the CPU arch, on 32-bit RHEL/CentOS (issue 11822)
• Fix bug with specifying alternate home dir on user creation (FreeBSD) (issue 11790)
• Don’t reload site module on module refresh for MacOS
• Fix regression with running execution functions in Pillar SLS (issue 11453)
• Fix some modules missing from Windows installer
• Don’t log an error for yum commands that return nonzero exit status on non-failure (issue 11645)
• Fix bug in rabbitmq state (issue 8703)
• Fix missing ssh config options (issue 10604)
• Fix top.sls ordering (issue 10810 and issue 11691)
• Fix salt-key --list all (issue 10982)
• Fix win_servermanager install/remove function (issue 11038)
• Fix interaction with tokens when running commands as root (issue 11223)
• Fix overstate bug with **kwargs (issue 10503)
• Fix saltenv for aptpkg.mod_repo from pkgrepo state
• Fix environment issue causing file caching problems (issue 11189)
• Fix bug in __parse_key in registry state (issue 11408)
• Add minion auth retry on rejection (issue 10763)
• Fix publish_session updating the encryption key (issue 11493)
• Fix for bad AssertionError raised by GitPython (issue 11473)
• Fix debian_ip to allow disabling and enabling networking on Ubuntu (issue 11164)
• Fix potential memory leak caused by saved (and unused) events (issue 11582)
• Fix exception handling in the MySQL module (issue 11616)
• Fix environment-related error (issue 11534)
• Include psutil on Windows
• Add file.replace and file.search to Windows (issue 11471)
• Add additional file module helpers to Windows (issue 11235)
• Add pid to netstat output on Windows (issue 10782)
• Fix Windows not caching new versions of installers in winrepo (issue 10597)
• Fix hardcoded md5 hashing
• Fix kwargs in salt-ssh (issue 11609)
• Fix file backup timestamps (issue 11745)
• Fix stacktrace on sys.doc with invalid eauth (issue 11293)
• Fix git.latest with test=True (issue 11595)
• Fix file.check_perms hardcoded follow_symlinks (issue 11387)
• Fix certain pkg states for RHEL5/Cent5 machines (issue 11719)

35.2.23 Salt 2014.1.4 Release Notes

release 2014-05-05

Version 2014.1.4 is another bugfix release for 2014.1.0. Changes include:
• Fix setup.py dependency issue (issue 12031)
• Fix handling for IOErrors under certain circumstances (issue 11783 and issue 11853)
• Fix fatal exception when /proc/1/cgroup is not readable (issue 11619)
• Fix os grains for OpenSolaris (issue 11907)
• Fix lvs.zero module argument pass-through (issue 9001)
• Fix bug in debian_ip interaction with network.system state (issue 11164)
• Remove bad binary package verification code (issue 12177)
• Fix traceback in solaris package installation (issue 12237)
- Fix `file.directory` state symlink handling (issue 12209)
- Remove `external_ip` grain
- Fix `file.managed` makedirs issues (issue 10446)
- Fix hang on non-existent Windows drive letter for `file` module (issue 9880)
- Fix salt minion caching all users on the server (issue 9743)
- Add strftime formatting for `ps.boot_time` (issue 12428)

### 35.2.24 Salt 2014.1.5 Release Notes

**release** 2014-06-11

Version 2014.1.5 is another bugfix release for 2014.1.0. Changes include:

- Add function for finding cached job on the minion
- Fix iptables save file location for Debian (issue 11730)
- Fix for minion caching jobs when master is down
- Bump default `syndic_wait` to 5 to fix syndic-related problems (issue 12262)
- Add OpenBSD, FreeBSD, and NetBSD support for `network.netstat` (issue 12121)
- Fix false positive error in logs for `makeconf` state (issue 9762)
- Fix for `yum fromrepo` package installs when repo is disabled by default (issue 12466)
- Fix for extra blank lines in `file.blockreplace` (issue 12422)
- Fix grain detection for OpenVZ guests (issue 11877)
- Fix `get_dns_servers` function for Windows `win_dns_client`
- Use system locale for ports package installations
- Use correct stop/restart procedure for Debian networking in `debian_ip` (issue 12614)
- Fix for `cmd_iter/cmd_iter_no_block` blocking issues (issue 12617)
- Fix traceback when syncing custom types (issue 12883)
- Fix cleaning directory symlinks in `file.directory`
- Add performance optimizations for `saltutil.sync_all` and `state.highstate`
- Fix possible error in `saltutil.running`
- Fix for kmod modules with dashes (issue 13239)
- Fix possible race condition for Windows minions in state module reloading (issue 12370)
- Fix bug with roster for `passwd` option that is loaded as a non-string object (issue 13249)
- Keep duplicate version numbers from showing up in `pkg.list_pkgs` output
- Fixes for Jinja renderer, timezone `module/state` (issue 12724)
- Fix `timedatectl` parsing for systemd>=210 (issue 12728)
- Fix `saltenv` being written to YUM repo config files (issue 12887)
- Removed the deprecated external nodes classifier (originally accessible by setting a value for `external_nodes` in the master configuration file). Note that this functionality has been marked deprecated for some time and was replaced by the more general `master tops` system.
• More robust escaping of ldap filter strings.
• Fix trailing slash in gitfs_root causing files not to be available (issue 13185)

35.2.25 Salt 2014.1.6 Release Notes

release 2014-07-08

Version 2014.1.6 is another bugfix release for 2014.1.0. Changes include:

• Fix extra iptables --help output (Sorry!) (issue 13648, issue 13507, issue 13527, issue 13607)
• Fix mount.active for Solaris
• Fix support for allow-hotplug statement in debian_ip network module
• Add sqlite3 to esky builds
• Fix jobs.active output (issue 9526)
• Fix the virtual grain for Xen (issue 13534)
• Fix eauth for batch mode (issue 9605)
• Fix force-related issues with tomcat support (issue 12889)
• Fix KeyError when cloud mapping
• Fix salt-minion restart loop in Windows (issue 12086)
• Fix detection of service virtual module on Fedora minions
• Fix traceback with missing ipv4 grain (issue 13838)
• Fix issue in roots backend with invalid data in mtime_map (issue 13836)
• Fix traceback in jobs.active (issue 11151)
• Fix master_tops and _ext_nodes issue (issue 13535, issue 13673)

35.2.26 Salt 2014.1.7 Release Notes

release 2014-07-09

Version 2014.1.7 is another bugfix release for 2014.1.0. Changes include:

• Fix batch mode regression (issue 14046)

This release was a hotfix release for the regression listed above which was present in the 2014.1.6 release. The changes included in 2014.1.6 are listed below:

• Fix extra iptables --help output (Sorry!) (issue 13648, issue 13507, issue 13527, issue 13607)
• Fix mount.active for Solaris
• Fix support for allow-hotplug statement in debian_ip network module
• Add sqlite3 to esky builds
• Fix jobs.active output (issue 9526)
• Fix the virtual grain for Xen (issue 13534)
• Fix eauth for batch mode (issue 9605)
• Fix force-related issues with tomcat support (issue 12889)
• Fix KeyError when cloud mapping
• Fix salt-minion restart loop in Windows (issue 12086)
• Fix detection of service virtual module on Fedora minions
• Fix traceback with missing ipv4 grain (issue 13838)
• Fix issue in roots backend with invalid data in mtime_map (issue 13836)
• Fix traceback in jobs.active (issue 11151)
• Fix master_tops and _ext_nodes issue (issue 13535, issue 13673)

35.2.27 Salt 2014.1.8 Release Notes

release  2014-07-30

Note:  This release contained a regression which caused inaccurate Salt version detection, and thus was never packaged for general release. Please use version 2014.1.10 instead.

Version 2014.1.8 is another bugfix release for 2014.1. Changes include:
• Ensure salt-ssh will not continue if permissions on a temporary directory are not correct.
• Use the bootstrap script distributed with Salt instead of relying on an external resource
• Remove unused testing code
• Ensure salt states are placed into the .salt directory in salt-ssh
• Use a randomized path for temporary files in a salt-cloud deployment
• Clean any stale directories to ensure a fresh copy of salt-sshd during a deployment

35.2.28 Salt 2014.1.9 Release Notes

release  2014-07-31

Note:  This release contained a regression which caused inaccurate Salt version detection, and thus was never packaged for general release. Please use version 2014.1.10 instead.

Note:  Version 2014.1.8 contained a regression which caused inaccurate Salt version detection, and thus was never packaged for general release. This version contains the version detection fix, but is otherwise identical to 2014.1.8.

Version 2014.1.9 is another bugfix release for 2014.1. Changes include:
• Ensure salt-ssh will not continue if permissions on a temporary directory are not correct.
• Use the bootstrap script distributed with Salt instead of relying on an external resource
• Remove unused testing code
• Ensure salt states are placed into the .salt directory in salt-ssh
• Use a randomized path for temporary files in a salt-cloud deployment
• Clean any stale directories to ensure a fresh copy of salt-sshd during a deployment

35.2. Previous Releases  2175
35.2.29 Salt 0.10.0 Release Notes

release 2012-06-16

0.10.0 has arrived! This release comes with MANY bug fixes, and new capabilities which greatly enhance performance and reliability. This release is primarily a bug fix release with many new tests and many repaired bugs. This release also introduces a few new key features which were brought in primarily to repair bugs and some limitations found in some of the components of the original architecture.

Major Features

Event System

The Salt Master now comes equipped with a new event system. This event system has replaced some of the back end of the Salt client and offers the beginning of a system which will make plugging external applications into Salt. The event system relies on a local ZeroMQ publish socket and other processes can connect to this socket and listen for events. The new events can be easily managed via Salt’s event library.

Unprivileged User Updates

Some enhancements have been added to Salt for running as a user other than root. These new additions should make switching the user that the Salt Master is running as very painless, simply change the user option in the master configuration and restart the master, Salt will take care of all of the particulars for you.

Peer Runner Execution

Salt has long had the peer communication system used to allow minions to send commands via the salt master. 0.10.0 adds a new capability here, now the master can be configured to allow for minions to execute Salt runners via the peer_run option in the salt master configuration.

YAML Parsing Updates

In the past the YAML parser for sls files would return the incorrect numbers when the file mode was set with a preceding 0. The YAML parser used in Salt has been modified to no longer convert these number into octal but to keep them as the correct value so that sls files can be a little cleaner to write.

State Call Data Files

It was requested that the minion keep a local cache of the most recent executed state run. This has been added and now with state runs the data is stored in a msgpack file in the minion’s cachedir.

Turning Off the Job Cache

A new option has been added to the master configuration file. In previous releases the Salt client would look over the Salt job cache to read in the minion return data. With the addition of the event system the Salt client can now watch for events directly from the master worker processes.

This means that the job cache is no longer a hard requirement. Keep in mind though, that turning off the job cache means that historic job execution data cannot be retrieved.
Test Updates

Minion Swarms Are Faster

To continue our efforts with testing Salt’s ability to scale the minionswarm script has been updated. The minion-swarm can now start up minions much faster than it could before and comes with a new feature allowing modules to be disabled, thus lowering the minion’s footprint when making a swarm. These new updates have allows us to test

```bash
# python minionswarm.py -m 20 --master salt-master
```

Many Fixes

To get a good idea for the number of bugfixes this release offers take a look at the closed tickets for 0.10.0, this is a very substantial update:

https://github.com/saltstack/salt/issues?milestone=12&state=closed

Master and Minion Stability Fixes

As Salt deployments grow new ways to break Salt are discovered. 0.10.0 comes with a number of fixes for the minions and master greatly improving Salt stability.

35.2.30 Salt 0.10.1 Release Notes

release 2012-06-19

35.2.31 Salt 0.10.2 Release Notes

release 2012-07-30

0.10.2 is out! This release comes with enhancements to the pillar interface, cleaner ways to access the salt-call capabilities in the API, minion data caching and the event system has been added to salt minions.

There have also been updates to the ZeroMQ functions, many more tests (thanks to sponsors, the code sprint and many contributors) and a swath of bug fixes.

Major Features

Ext Pillar Modules

The ranks of available Salt modules directories sees a new member in 0.10.2. With the popularity of pillar a higher demand has arisen for ext_pillar interfaces to be more like regular Salt module additions. Now ext_pillar interfaces can be added in the same way as other modules, just drop it into the pillar directory in the salt source.
Minion Events

In 0.10.0 an event system was added to the Salt master. 0.10.2 adds the event system to the minions as well. Now event can be published on a local minion as well.

The minions can also send events back up to the master. This means that Salt is able to communicate individual events from the minions back up to the Master which are not associated with command.

Minion Data Caching

When pillar was introduced the landscape for available data was greatly enhanced. The minion's began sending grain data back to the master on a regular basis.

The new config option on the master called minion_data_cache instructs the Salt master to maintain a cache of the minion's grains and pillar data in the cachedir. This option is turned off by default to avoid hitting the disk more, but when enabled the cache is used to make grain matching from the salt command more powerful, since the minions that will match can be predetermined.

Backup Files

By default all files replaced by the file.managed and file.recurse states we simply deleted. 0.10.2 adds a new option. By setting the backup option to minion the files are backed up before they are replaced.

The backed up files are located in the cachedir under the file_backup directory. On a default system this will be at: /var/cache/salt/file_backup

Configuration files

salt-master and salt-minion automatically load additional configuration files from master.d/*.conf respective minion.d/*.conf where master.d/minion.d is a directory in the same directory as the main configuration file.

Salt Key Verification

A number of users complained that they had inadvertently deleted the wrong salt authentication keys. 0.10.2 now displays what keys are going to be deleted and verifies that they are the keys that are intended for deletion.

Key auto-signing

If autosign_file is specified in the configuration file incoming keys will be compared to the list of keynames in autosign_file. Regular expressions as well as globbing is supported.

The file must only be writable by the user otherwise the file will be ignored. To relax the permission and allow group write access set the permissive_pki_access option.

Module changes

Improved OpenBSD support    New modules for managing services and packages were provided by Joshua Elsasser to further improve the support for OpenBSD.

Existing modules like the disk module were also improved to support OpenBSD.
SQL Modules  The MySQL and PostgreSQL modules have both received a number of additions thanks to the work of Avi Marcus and Roman Imankulov.

ZFS Support on FreeBSD  A new ZFS module has been added by Kurtis Velarde for FreeBSD supporting various ZFS operations like creating, extending or removing zpools.

Augeas  A new Augeas module by Ulrich Dangel for editing and verifying config files.

Native Debian Service module  The support for the Debian was further improved with an new service module for Debian by Ahmad Khayyat supporting disable and enable.

Cassandra  Cassandra support has been added by Adam Garside. Currently only status and diagnostic information are supported.

Networking  The networking support for RHEL has been improved and supports bonding support as well as zero-conf configuration.

Monit  Basic monit support by Kurtis Velarde to control services via monit.

nzbget  Basic support for controlling nzbget by Joseph Hall

Bluetooth  Basic bluez support for managing and controlling Bluetooth devices. Supports scanning as well as pairing/unpairing by Joseph Hall.

Test Updates

Consistency Testing

Another testing script has been added. A bug was found in pillar when many minions generated pillar data at the same time. The new consist.py script is the tests directory was created to reproduce bugs where data should always be consistent.

Many Fixes

To get a good idea for the number of bugfixes this release offers take a look at the closed tickets for 0.10.2, this is a very substantial update:
https://github.com/saltstack/salt/issues?milestone=24&page=1&state=closed

Master and Minion Stability Fixes

As Salt deployments grow new ways to break Salt are discovered. 0.10.2 comes with a number of fixes for the minions and master greatly improving Salt stability.
35.2.32 Salt 0.10.3 Release Notes

release 2012-09-30

The latest taste of Salt has come, this release has many fixes and feature additions. Modifications have been made to make ZeroMQ connections more reliable, the beginning of the ACL system is in place, a new command line parsing system has been added, dynamic module distribution has become more environment aware, the new master_finger option and many more!

Major Features

ACL System

The new ACL system has been introduced. The ACL system allows for system users other than root to execute salt commands. Users can be allowed to execute specific commands in the same way that minions are opened up to the peer system.

The configuration value to open up the ACL system is called client_acl and is configured like so:

```yaml
client_acl:
    fred:
    - test..*
    - pkg.list_pkgs
```

Where fred is allowed access to functions in the test module and to the pkg.list_pkgs function.

Master Finger Option

The master_finger option has been added to improve the security of minion provisioning. The master_finger option allows for the fingerprint of the master public key to be set in the configuration file to double verify that the master is valid. This option was added in response to a motivation to pre-authenticate the master when provisioning new minions to help prevent man in the middle attacks in some situations.

Salt Key Fingerprint Generation

The ability to generate fingerprints of keys used by Salt has been added to salt-key. The new option finger accepts the name of the key to generate and display a fingerprint for.

```
salt-key -F master
```

Will display the fingerprints for the master public and private keys.

Parsing System

Pedro Algavio, aka s0undt3ch, has added a substantial update to the command line parsing system that makes the help message output much cleaner and easier to search through. Salt parsers now have --versions-report besides usual --version info which you can provide when reporting any issues found.
Key Generation

We have reduced the requirements needed for `salt-key` to generate minion keys. You’re no longer required to have salt configured and it’s common directories created just to generate keys. This might prove useful if you’re batch creating keys to pre-load on minions.

Startup States

A few configuration options have been added which allow for states to be run when the minion daemon starts. This can be a great advantage when deploying with Salt because the minion can apply states right when it first runs. To use startup states set the `startup_states` configuration option on the minion to `highstate`.

New Exclude Declaration

Some users have asked about adding the ability to ensure that other sls files or ids are excluded from a state run. The exclude statement will delete all of the data loaded from the specified sls file or will delete the specified id:

```yaml
exclude:
  - sls: http
  - id: /etc/vimrc
```

Max Open Files

While we’re currently unable to properly handle ZeroMQ’s abort signals when the max open files is reached, due to the way that’s handled on ZeroMQ’s, we have minimized the chances of this happening without at least warning the user.

More State Output Options

Some major changes have been made to the state output system. In the past state return data was printed in a very verbose fashion and only states that failed or made changes were printed by default. Now two options can be passed to the master and minion configuration files to change the behavior of the state output. State output can be set to verbose (default) or non-verbose with the `state_verbose` option:

```yaml
state_verbose: False
```

It is noteworthy that the state_verbose option used to be set to `False` by default but has been changed to `True` by default in 0.10.3 due to many requests for the change.

The next option to be aware of new and called `state_output`. This option allows for the state output to be set to `full` (default) or `terse`.

The `full` output is the standard state output, but the new `terse` output will print only one line per state making the output much easier to follow when executing a large state system.

```yaml
state_output: terse
```
**state.file.append Improvements**

The salt state `file.append()` tries not to append existing text. Previously the matching check was being made line by line. While this kind of check might be enough for most cases, if the text being appended was multi-line, the check would not work properly. This issue is now properly handled, the match is done as a whole ignoring any white space addition or removal except inside commas. For those thinking that, in order to properly match over multiple lines, salt will load the whole file into memory, that's not true. For most cases this is not important but an erroneous order to read a 4GB file, if not properly handled, like salt does, could make salt chew that amount of memory. Salt has a buffered file reader which will keep in memory a maximum of 256KB and iterates over the file in chunks of 32KB to test for the match, more than enough, if not, explain your usage on a ticket. With this change, also `salt.modules.file.contains()`, `salt.modules.file.contains_regex()`, `salt.modules.file.contains_glob()` and `salt.utils.find` now do the searching and/or matching using the buffered chunks approach explained above.

Two new keyword arguments were also added, `makedirs` and `source`. The first, `makedirs` will create the necessary directories in order to append to the specified file, of course, it only applies if we’re trying to append to a non-existing file on a non-existing directory:

```
/tmp/salttest/file-append-makedirs:
    file.append:
        text: foo
        makedirs: True
```

The second, `source`, allows one to append the contents of a file instead of specifying the text.

```
/tmp/salttest/file-append-source:
    file.append:
        - source: salt://testfile
```

**Security Fix**

A timing vulnerability was uncovered in the code which decrypts the AES messages sent over the network. This has been fixed and upgrading is strongly recommended.

### 35.2.33 Salt 0.10.4 Release Notes

**release** 2012-10-23

Salt 0.10.4 is a monumental release for the Salt team, with two new module systems, many additions to allow granular access to Salt, improved platform support and much more.

This release is also exciting because we have been able to shorten the release cycle back to under a month. We are working hard to keep up the aggressive pace and look forward to having releases happen more frequently!

This release also includes a serious security fix and all users are very strongly recommended to upgrade. As usual, upgrade the master first, and then the minion to ensure that the process is smooth.

**Major Features**

**External Authentication System**

The new external authentication system allows for Salt to pass through authentication to any authentication system to determine if a user has permission to execute a Salt command. The Unix PAM system is the first supported system
The external authentication system allows for specific users to be granted access to execute specific functions on specific minions. Access is configured in the master configuration file, and uses the new access control system:

```yaml
external_auth:
pam:
  thatch:
    - 'web*':
    - test.*
    - network.*
```

The configuration above allows the user `thatch` to execute functions in the test and network modules on minions that match the `web*` target.

**Access Control System**

All Salt systems can now be configured to grant access to non-administrative users in a granular way. The old configuration continues to work. Specific functions can be opened up to specific minions from specific users in the case of external auth and client ACLs, and for specific minions in the case of the peer system.

Access controls are configured like this:

```yaml
client_acl:
  fred:
    - web\*:
      - pkg.list_pkgs
      - test.*
      - apache.*
```

**Target by Network**

A new matcher has been added to the system which allows for minions to be targeted by network. This new matcher can be called with the `-S` flag on the command line and is available in all places that the matcher system is available. Using it is simple:

```bash
$ salt -S '192.168.1.0/24' test.ping
$ salt -S '192.168.1.100' test.ping
```

**Nodegroup Nesting**

Previously a nodegroup was limited by not being able to include another nodegroup, this restraint has been lifted and now nodegroups will be expanded within other nodegroups with the `N@` classifier.

**Salt Key Delete by Glob**

The ability to delete minion keys by glob has been added to `salt-key`. To delete all minion keys whose minion name starts with `web`:

```bash
$ salt-key -d 'web*'`
Master Tops System

The `external_nodes` system has been upgraded to allow for modular subsystems to be used to generate the top file data for a highstate run.

The `external_nodes` option still works but will be deprecated in the future in favor of the new `master_tops` option.

Example of using `master_tops`:

```yaml
master_tops:
  ext_nodes: cobbler-external-nodes
```

Next Level Solaris Support

A lot of work has been put into improved Solaris support by Romeo Theriault. Packaging modules (pkgadd/pkgrm and pkgutil) and states, cron support and user and group management have all been added and improved upon. These additions along with SMF (Service Management Facility) service support and improved Solaris grain detection in 0.10.3 add up to Salt becoming a great tool to manage Solaris servers with.

Security

A vulnerability in the security handshake was found and has been repaired, old minions should be able to connect to a new master, so as usual, the master should be updated first and then the minions.

Pillar Updates

The pillar communication has been updated to add some extra levels of verification so that the intended minion is the only one allowed to gather the data. Once all minions and the master are updated to salt 0.10.4 please activate pillar 2 by changing the `pillar_version` in the master config to 2. This will be set to 2 by default in a future release.

35.2.34 Salt 0.10.5 Release Notes

Salt 0.10.5 is ready, and comes with some great new features. A few more interfaces have been modularized, like the outputter system. The job cache system has been made more powerful and can now store and retrieve jobs archived in external databases. The returner system has been extended to allow minions to easily retrieve data from a returner interface.

As usual, this is an exciting release, with many noteworthy additions!

Major Features

External Job Cache

The external job cache is a system which allows for a returner interface to also act as a job cache. This system is intended to allow users to store job information in a central location for longer periods of time and to make the act of looking up information from jobs executed on other minions easier.

Currently the external job cache is supported via the mongo and redis returners:
ext_job_cache: redis
redis.host: salt

Once the external job cache is turned on the new ret module can be used on the minions to retrieve return information from the job cache. This can be a great way for minions to respond and react to other minions.

OpenStack Additions

OpenStack integration with Salt has been moving forward at a blistering pace. The new nova, glance, and keystone modules represent the beginning of ongoing OpenStack integration.

The Salt team has had many conversations with core OpenStack developers and is working on linking to OpenStack in powerful new ways.

Wheel System

A new API was added to the Salt Master which allows the master to be managed via an external API. This new system allows Salt API to easily hook into the Salt Master and manage configs, modify the state tree, manage the pillar and more. The main motivation for the wheel system is to enable features needed in the upcoming web UI so users can manage the master just as easily as they manage minions.

The wheel system has also been hooked into the external auth system. This allows specific users to have granular access to manage components of the Salt Master.

Render Pipes

Jack Kuan has added a substantial new feature. The render pipes system allows Salt to treat the render system like unix pipes. This new system enables sls files to be passed through specific render engines. While the default renderer is still recommended, different engines can now be more easily merged. So to pipe the output of Mako used in YAML use this shebang line:

#!/mako|yaml

Salt Key Overhaul

The Salt Key system was originally developed as only a CLI interface, but as time went on it was pressed into becoming a clumsy API. This release marks a complete overhaul of Salt Key. Salt Key has been rewritten to function purely from an API and to use the outputter system. The benefit here is that the outputter system works much more cleanly with Salt Key now, and the internals of Salt Key can be used much more cleanly.

Modular Outputters

The outputter system is now loaded in a modular way. This means that output systems can be more easily added by dropping a python file down on the master that contains the function output.

Gzip from Fileserver

Gzip compression has been added as an option to the cp.get_file and cp.get_dir commands. This will make file transfers more efficient and faster, especially over slower network links.
Unified Module Configuration

In past releases of Salt, the minions needed to be configured for certain modules to function. This was difficult because it required pre-configuring the minions. 0.10.5 changes this by making all module configs on minions search the master config file for values.

Now if a single database server is needed, then it can be defined in the master config and all minions will become aware of the configuration value.

Salt Call Enhancements

The `salt-call` command has been updated in a few ways. Now, `salt-call` can take the `--return` option to send the data to a returner. Also, `salt-call` now reports executions in the minion proc system, this allows the master to be aware of the operation salt-call is running.

Death to `pub_refresh` and `sub_timeout`

The old configuration values `pub_refresh` and `sub_timeout` have been removed. These options were in place to alleviate problems found in earlier versions of ZeroMQ which have since been fixed. The continued use of these options has proven to cause problems with message passing and have been completely removed.

Git Revision Versions

When running Salt directly from git (for testing or development, of course) it has been difficult to know exactly what code is being executed. The new versioning system will detect the git revision when building and how many commits have been made since the last release. A release from git will look like this:

0.10.4-736-gec74d69

Svn Module Addition

Anthony Cornehl (twinshadow) contributed a module that adds Subversion support to Salt. This great addition helps round out Salt’s VCS support.

Noteworthy Changes

Arch Linux Defaults to Systemd

Arch Linux recently changed to use systemd by default and discontinued support for init scripts. Salt has followed suit and defaults to systemd now for managing services in Arch.

Salt, Salt Cloud and Openstack

With the releases of Salt 0.10.5 and Salt Cloud 0.8.2, OpenStack becomes the first (non-OS) piece of software to include support both on the user level (with Salt Cloud) and the admin level (with Salt). We are excited to continue to extend support of other platforms at this level.
35.2.35 Salt 0.11.0 Release Notes

```
release  2012-12-14
```

Salt 0.11.0 is here, with some highly sought after and exciting features. These features include the new overstate system, the reactor system, a new state run scope component called __context__, the beginning of the search system (still needs a great deal of work), multiple package states, the MySQL returner and a better system to arbitrarily reference outputters.

It is also noteworthy that we are changing how we mark release numbers. For the life of the project we have been pushing every release with features and fixes as point releases. We will now be releasing point releases for only bug fixes on a more regular basis and major feature releases on a slightly less regular basis. This means that the next release will be a bugfix only release with a version number of 0.11.1. The next feature release will be named 0.12.0 and will mark the end of life for the 0.11 series.

**Major Features**

**OverState**

The overstate system is a simple way to manage rolling state executions across many minions. The overstate allows for a state to depend on the successful completion of another state.

**Reactor System**

The new reactor system allows for a reactive logic engine to be created which can respond to events within a salted environment. The reactor system uses sls files to match events fired on the master with actions, enabling Salt to react to problems in an infrastructure.

Your load-balanced group of webservers is under extra load? Spin up a new VM and add it to the group. Your fileserver is filling up? Send a notification to your sysadmin on call. The possibilities are endless!

**Module Context**

A new component has been added to the module loader system. The module context is a data structure that can hold objects for a given scope within the module.

This allows for components that are initialized to be stored in a persistent context which can greatly speed up ongoing connections. Right now the best example can be found in the cp execution module.

**Multiple Package Management**

A long desired feature has been added to package management. By definition Salt States have always installed packages one at a time. On most platforms this is not the fastest way to install packages. Erik Johnson, aka terminalmage, has modified the package modules for many providers and added new capabilities to install groups of packages. These package groups can be defined as a list of packages available in repository servers:

```
python_pkgs:
  pkg.installed:
    - pkgs:
      - python-mako
      - whoosh
      - python-git
```
or specify based on the location of specific packages:

```
python_pkgs:
  pkg.installed:
  - sources:
    - python-mako: http://some-rpms.org/python-mako.rpm
    - whoosh: salt://whoosh/whoosh.rpm
    - python-git: ftp://companyserver.net/python-git.rpm
```

**Search System**

The bones to the search system have been added. This is a very basic interface that allows for search backends to be added as search modules. The first supported search module is the whoosh search backend. Right now only the basic paths for the search system are in place, making this very experimental. Further development will involve improving the search routines and index routines for whoosh and other search backends.

The search system has been made to allow for searching through all of the state and pillar files, configuration files and all return data from minion executions.

**Notable Changes**

All previous versions of Salt have shared many directories between the master and minion. The default locations for keys, cached data and sockets has been shared by master and minion. This has created serious problems with running a master and a minion on the same systems. 0.11.0 changes the defaults to be separate directories. Salt will also attempt to migrate all of the old key data into the correct new directories, but if it is not successful it may need to be done manually. If your keys exhibit issues after updating make sure that they have been moved from `/etc/salt/pki` to `/etc/salt/pki/{master, minion}`.

The old setup will look like this:

```
/etc/salt/pki
|-- master.pem
|-- master.pub
|-- minions
   |-- ragnarok.saltstack.net
   |-- minions_pre
   |-- minion.pem
   |-- minion.pub
   `-- minion_master.pub
      `-- minions_pre
         `-- minions_rejected
```

With the accepted minion keys in `/etc/salt/pki/minions`, the new setup places the accepted minion keys in `/etc/salt/pki/master/minions`.

```
/etc/salt/pki
|-- master
   |-- master.pem
   |-- master.pub
   |-- minions
      |-- ragnarok.saltstack.net
```

2188 Chapter 35. Release notes
35.2.36 Salt 0.11.1 Release Notes

release 2012-12-19

35.2.37 Salt 0.12.0 Release Notes

release 2013-01-15

Another feature release of Salt is here! Some exciting additions are included with more ways to make salt modular and even easier management of the salt file server.

Major Features

Modular Fileserver Backend

The new modular fileserver backend allows for any external system to be used as a salt file server. The main benefit here is that it is now possible to tell the master to directly use a git remote location, or many git remote locations, automatically mapping git branches and tags to salt environments.

Windows is First Class!

A new Salt Windows installer is now available! Much work has been put in to improve Windows support. With this much easier method of getting Salt on your Windows machines, we hope even more development and progress will occur. Please file bug reports on the Salt GitHub repo issue tracker so we can continue improving.

One thing that is missing on Windows that Salt uses extensively is a software package manager and a software package repository. The Salt pkg state allows sys admins to install software across their infrastructure and across operating systems. Software on Windows can now be managed in the same way. The SaltStack team built a package manager that interfaces with the standard Salt pkg module to allow for installing and removing software on Windows. In addition, a software package repository has been built on top of the Salt fileserver. A small YAML file provides the information necessary for the package manager to install and remove software.

An interesting feature of the new Salt Windows software package repository is that one or more remote git repositories can supplement the master’s local repository. The repository can point to software on the master’s fileserver or on an HTTP, HTTPS, or ftp server.

New Default Outputer

Salt displays data to the terminal via the outputer system. For a long time the default outputer for Salt has been the python pretty print library. While this has been a generally reasonable outputer, it did have many failings. The new default outputer is called `nested`, it recursively scans return data structures and prints them out cleanly.
If the result of the new nested outputter is not desired any other outputter can be used via the --out option, or the output option can be set in the master and minion configs to change the default outputter.

**Internal Scheduler**

The internal Salt scheduler is a new capability which allows for functions to be executed at given intervals on the minion, and for runners to be executed at given intervals on the master. The scheduler allows for sequences such as executing state runs (locally on the minion or remotely via an overstate) or continually gathering system data to be run at given intervals.

The configuration is simple, add the schedule option to the master or minion config and specify jobs to run, this in the master config will execute the state.over runner every 60 minutes:

```
schedule:
  overstate:
    function: state.over
    minutes: 60
```

This example for the minion configuration will execute a highstate every 30 minutes:

```
schedule:
  highstate:
    function: state.highstate
    minutes: 30
```

**Optional DSL for SLS Formulas**

Jack Kuan, our renderer expert, has created something that is astonishing. Salt, now comes with an optional Python based DSL, this is a very powerful interface that makes writing SLS files in pure python easier than it was with the raw py renderer. As usual this can be used with the renderer shebang line, so a single sls can be written with the DSL if pure python power is needed while keeping other sls files simple with YAML.

**Set Grains Remotely**

A new execution function and state module have been added that allows for grains to be set on the minion. Now grains can be set via a remote execution or via states. Use the `grains.present` state or the `grains.setval` execution functions.

**Gentoo Additions**

Major additions to Gentoo specific components have been made. The encompasses executions modules and states ranging from supporting the make.conf file to tools like layman.

**35.2.38 Salt 0.12.1 Release Notes**

```
release 2013-01-21
```
Salt Documentation, Release 2015.8.0

35.2.39 Salt 0.13.0 Release Notes
release 2013-02-12
The lucky number 13 has turned the corner! From CLI notifications when quitting a salt command, to substantial
improvements on Windows, Salt 0.13.0 has arrived!
Major Features
Improved file.recurse Performance

The file.recurse system has been deployed and used in a vast array of situations. Fixes to the file state and module
have led towards opening up new ways of running file.recurse to make it faster. Now the file.recurse state will
download fewer files and will run substantially faster.
Windows Improvements

Minion stability on Windows has improved. Many file operations, including file.recurse, have been fixed and improved. The network module works better, to include network.interfaces. Both 32bit and 64bit installers are now
available.
Nodegroup Targeting in Peer System

In the past, nodegroups were not available for targeting via the peer system. This has been fixed, allowing the new
nodegroup expr_form argument for the publish.publish function:
salt-call publish.publish group1 test.ping expr_form=nodegroup
Blacklist Additions

Additions allowing more granular blacklisting are available in 0.13.0. The ability to blacklist users and functions in
client_acl have been added, as well as the ability to exclude state formulas from the command line.
Command Line Pillar Embedding

Pillar data can now be embedded on the command line when calling state.sls and state.highstate. This
allows for on the fly changes or settings to pillar and makes parameterizing state formulas even easier. This is done
via the keyword argument:
salt '*' state.highstate pillar='{"cheese": "spam"}'

The above example will extend the existing pillar to hold the cheese key with a value of spam. If the cheese key
is already specified in the minion's pillar then it will be overwritten.
CLI Notifications

In the past hitting ctrl-C and quitting from the salt command would just drop to a shell prompt, this caused
confusion with users who expected the remote executions to also quit. Now a message is displayed showing what
command can be used to track the execution and what the job id is for the execution.

35.2. Previous Releases

2191


Version Specification in Multiple-Package States

Versions can now be specified within multiple-package `pkg.installed` states. An example can be found below:

```
mypkgs:
    pkg.installed:
        - pkgs:
            - foo
            - bar: 1.2.3-4
            - baz
```

Noteworthy Changes

The configuration subsystem in Salt has been overhauled to make the `opts` dict used by Salt applications more portable, the problem is that this is an incompatible change with salt-cloud, and salt-cloud will need to be updated to the latest git to work with Salt 0.13.0. Salt Cloud 0.8.5 will also require Salt 0.13.0 or later to function.

The SaltStack team is sorry for the inconvenience here, we work hard to make sure these sorts of things do not happen, but sometimes hard changes get in.

35.2.40 Salt 0.13.1 Release Notes

    release 2013-02-15

35.2.41 Salt 0.13.2 Release Notes

    release 2013-03-13

35.2.42 Salt 0.13.3 Release Notes

    release 2013-03-18

35.2.43 Salt 0.14.0 Release Notes

    release 2013-03-23

Salt 0.14.0 is here! This release was held up primarily by PyCon, Scale, and illness, but has arrived! 0.14.0 comes with many new features and is breaking ground for Salt in the area of cloud management with the introduction of Salt providing basic cloud controller functionality.

Major Features

Salt - As a Cloud Controller

This is the first primitive inroad to using Salt as a cloud controller is available in 0.14.0. Be advised that this is alpha, only tested in a few very small environments.

The cloud controller is built using kvm and libvirt for the hypervisors. Hypervisors are autodetected as minions and only need to have libvirt running and kvm installed to function. The features of the Salt cloud controller are as follows:
• Basic vm discovery and reporting
• Creation of new virtual machines
• Seeding virtual machines with Salt via qemu-nbd or libguestfs
• Live migration (shared and non shared storage)
• Delete existing VMs

It is noteworthy that this feature is still Alpha, meaning that all rights are reserved to change the interface if needs be in future releases!

Libvirt State

One of the problems with libvirt is management of certificates needed for live migration and cross communication between hypervisors. The new libvirt state makes the Salt Master hold a CA and manage the signing and distribution of keys onto hypervisors, just add a call to the libvirt state in the sls formulas used to set up a hypervisor:

```
libvirt_keys:
  libvirt.keys
```

New get Functions

An easier way to manage data has been introduced. The pillar, grains, and config execution modules have been extended with the new get function. This function works much in the same way as the get method in a python dict, but with an enhancement, nested dict components can be extracted using a : delimiter.

If a structure like this is in pillar:

```
foo:
  bar:
    baz: quo
```

Extracting it from the raw pillar in an sls formula or file template is done this way:

```
{{ pillar['foo']['bar']['baz'] }}
```

Now with the new get function the data can be safely gathered and a default can be set allowing the template to fall back if the value is not available:

```
{{ salt['pillar.get']('foo:bar:baz', 'qux') }}
```

This makes handling nested structures much easier, and defaults can be cleanly set. This new function is being used extensively in the new formulae repository of salt sls formulas.

35.2.44 Salt 0.14.1 Release Notes

release  2013-04-13
The many new features of Salt 0.15.0 have arrived! Salt 0.15.0 comes with many smaller features and a few larger ones.

These features range from better debugging tools to the new Salt Mine system.

**Major Features**

**The Salt Mine**

First there was the peer system, allowing for commands to be executed from a minion to other minions to gather data live. Then there was the external job cache for storing and accessing long term data. Now the middle ground is being filled in with the Salt Mine. The Salt Mine is a system used to execute functions on a regular basis on minions and then store only the most recent data from the functions on the master, then the data is looked up via targets.

The mine caches data that is public to all minions, so when a minion posts data to the mine all other minions can see it.

**IPV6 Support**

0.13.0 saw the addition of initial IPV6 support but errors were encountered and it needed to be stripped out. This time the code covers more cases and must be explicitly enabled. But the support is much more extensive than before.

**Copy Files From Minions to the Master**

Minions have long been able to copy files down from the master file server, but until now files could not be easily copied from the minion up to the master.

A new function called `cp.push` can push files from the minions up to the master server. The uploaded files are then cached on the master in the master cachedir for each minion.

**Better Template Debugging**

Template errors have long been a burden when writing states and pillar. 0.15.0 will now send the compiled template data to the debug log, this makes tracking down the intermittent stage templates much easier. So running `state.sls` or `state.highstate` with `-l debug` will now print out the rendered templates in the debug information.

**State Event Firing**

The state system is now more closely tied to the master's event bus. Now when a state fails the failure will be fired on the master event bus so that the reactor can respond to it.

**Major Syndic Updates**

The Syndic system has been basically re-written. Now it runs in a completely asynchronous way and functions primarily as an event broker. This means that the events fired on the syndic are now pushed up to the higher level master instead of the old method used which waited for the client libraries to return.
This makes the syndic much more accurate and powerful, it also means that all events fired on the syndic master make it up the pipe as well making a reactor on the higher level master able to react to minions further downstream.

Peer System Updates

The Peer System has been updated to run using the client libraries instead of firing directly over the publish bus. This makes the peer system much more consistent and reliable.

Minion Key Revocation

In the past when a minion was decommissioned the key needed to be manually deleted on the master, but now a function on the minion can be used to revoke the calling minion's key:

```
$ salt-call saltutil.revoke_auth
```

Function Return Codes

Functions can now be assigned numeric return codes to determine if the function executed successfully. While not all functions have been given return codes, many have and it is an ongoing effort to fill out all functions that might return a non-zero return code.

Functions in Overstate

The overstate system was originally created to just manage the execution of states, but with the addition of return codes to functions, requisite logic can now be used with respect to the overstate. This means that an overstate stage can now run single functions instead of just state executions.

Pillar Error Reporting

Previously if errors surfaced in pillar, then the pillar would consist of only an empty dict. Now all data that was successfully rendered stays in pillar and the render error is also made available. If errors are found in the pillar, states will refuse to run.

Using Cached State Data

Sometimes states are executed purely to maintain a specific state rather than to update states with new configs. This is grounds for the new cached state system. By adding `cache=True` to a state call the state will not be generated fresh from the master but the last state data to be generated will be used. If no previous state data is available then fresh data will be generated.

Monitoring States

The new monitoring states system has been started. This is very young but allows for states to be used to configure monitoring routines. So far only one monitoring state is available, the `disk.status` state. As more capabilities are added to Salt UI the monitoring capabilities of Salt will continue to be expanded.
35.2.46 Salt 0.15.1 Release Notes

release 2013-05-08

The 0.15.1 release has been posted, this release includes fixes to a number of bugs in 0.15.1 and a three security patches.

Security Updates

A number of security issues have been resolved via the 0.15.1 release.

Path Injection in Minion IDs

Salt masters did not properly validate the id of a connecting minion. This can lead to an attacker uploading files to the master in arbitrary locations. In particular this can be used to bypass the manual validation of new unknown minions.Exploiting this vulnerability does not require authentication.

This issue affects all known versions of Salt.

This issue was reported by Ronald Volgers.

Patch The issue is fixed in Salt 0.15.1. Updated packages are available in the usual locations.

Specific commits:
https://github.com/saltstack/salt/commit/5427b9438e452a5a8910d9128c6aafb45d8fd5d3
https://github.com/saltstack/salt/commit/7560908ee62351769c3cd43b03d74c1ca772cc52
https://github.com/saltstack/salt/commit/e200b8a7ff53780124e08d2bdefde7587e52bfca

RSA Key Generation Fault

RSA key generation was done incorrectly, leading to very insecure keys. It is recommended to regenerate all RSA keys.

This issue can be used to impersonate Salt masters or minions, or decrypt any transferred data.

This issue can only be exploited by attackers who are able to observe or modify traffic between Salt minions and the legitimate Salt master.

A tool was included in 0.15.1 to assist in mass key regeneration, the manage.regen_keys runner.

This issue affects all known versions of Salt.

This issue was reported by Ronald Volgers.

Patch The issue is fixed in Salt 0.15.1. Updated packages are available in the usual locations.

Specific commits:
https://github.com/saltstack/salt/commit/5dd304276ba5745ec21fc1e6686a0b28da29e6fc
Command Injection Via ext_pillar

Arbitrary shell commands could be executed on the master by an authenticated minion through options passed when requesting a pillar.

Ext pillar options have been restricted to only allow safe external pillars to be called when prompted by the minion.

This issue affects Salt versions from 0.14.0 to 0.15.0.

This issue was reported by Ronald Volgers.

Patch   The issue is fixed in Salt 0.15.1. Updated packages are available in the usual locations.

Specific commits:
https://github.com/saltstack/salt/commit/43d8c16bd26159d827d1a945c83ac28159ec5865

35.2.47 Salt 0.15.2 Release Notes

release 2013-05-29

35.2.48 Salt 0.15.3 Release Notes

release 2013-06-01

35.2.49 Salt 0.16.0 Release Notes

release 2013-07-01

The 0.16.0 release is an exciting one, with new features in master redundancy, and a new, powerful requisite.

Major Features

Multi-Master

This new capability allows for a minion to be actively connected to multiple salt masters at the same time. This allows for multiple masters to send out commands to minions and for minions to automatically reconnect to masters that have gone down. A tutorial is available to help get started here:

Multi Master Tutorial

Prereq, the New Requisite

The new prereq requisite is very powerful! It allows for states to execute based on a state that is expected to make changes in the future. This allows for a change on the system to be preempted by another execution. A good example is needing to shut down a service before modifying files associated with it, allowing, for instance, a webserver to be shut down allowing a load balancer to stop sending requests while server side code is updated. In this case, the prereq will only run if changes are expected to happen in the prerequired state, and the prerequired state will always run after the prereq state and only if the prereq state succeeds.
Peer System Improvements

The peer system has been revamped to make it more reliable, faster, and like the rest of Salt, async. The peer calls when an updated minion and master are used together will be much faster!

Relative Includes

The ability to include an sls relative to the defined sls has been added, the new syntax id documented here:

Includes

More State Output Options

The state_output option in the past only supported full and terse, 0.16.0 add the mixed and changes modes further refining how states are sent to users’ eyes.

Improved Windows Support

Support for Salt on Windows continues to improve. Software management on Windows has become more seamless with Linux/UNIX/BSD software management. Installed software is now recognized by the short names defined in the repository SLS. This makes it possible to run salt '*' pkg.version firefox and get back results from Windows and non-Windows minions alike.

When templating files on Windows, Salt will now correctly use Windows appropriate line endings. This makes it much easier to edit and consume files on Windows.

When using the cmd state the shell option now allows for specifying Windows Powershell as an alternate shell to execute cmd.run and cmd.script. This opens up Salt to all the power of Windows Powershell and its advanced Windows management capabilities.

Several fixes and optimizations were added for the Windows networking modules, especially when working with IPv6.

A system module was added that makes it easy to restart and shutdown Windows minions.

The Salt Minion will now look for its config file in c:\salt\conf by default. This means that it’s no longer necessary to specify the -c option to specify the location of the config file when starting the Salt Minion on Windows in a terminal.

Multiple Targets for pkg.removed, pkg.purged States

Both pkg.removed and pkg.purged now support the pkgs argument, which allow for multiple packages to be targeted in a single state. This, as in pkg.installed, helps speed up these states by reducing the number of times that the package management tools (apt, yum, etc.) need to be run.

Random Times in Cron States

The temporal parameters in cron.present states (minute, hour, etc.) can now be randomized by using random instead of a specific value. For example, by using the random keyword in the minute parameter of a cron state, the same cron job can be pushed to hundreds or thousands of hosts, and they would each use a randomly-generated minute. This can be helpful when the cron job accesses a network resource, and it is not desirable for all hosts to run the job concurrently.
/path/to/cron/script:
cron.present:
  - user: root
  - minute: random
  - hour: 2

Since Salt assumes a value of * for unspecified temporal parameters, adding a parameter to the state and setting it to random will change that value from * to a randomized numeric value. However, if that field in the cron entry on the minion already contains a numeric value, then using the random keyword will not modify it.

Confirmation Prompt on Key Acceptance

When accepting new keys with salt-key -a minion-id or salt-key -A, there is now a prompt that will show the affected keys and ask for confirmation before proceeding. This prompt can be bypassed using the -y or --yes command line argument, as with other salt-key commands.

Support for Setting Password Hashes on BSD Minions

FreeBSD, NetBSD, and OpenBSD all now support setting passwords in user.present states.

35.2.50 Salt 0.16.1 Release Notes

release 2013-07-29

35.2.51 Salt 0.16.2 Release Notes

release 2013-08-01

Version 0.16.2 is a bugfix release for 0.16.0, and contains a number of fixes.

Windows

- Only allow Administrator’s group and SYSTEM user access to C:salt. This eliminates a race condition where a non-admin user could modify a template or managed file before it is executed by the minion (which is running as an elevated user), thus avoiding a potential escalation of privileges. (issue 6361)

Grains

- Fixed detection of virtual grain on OpenVZ hardware nodes
- Gracefully handle lsb_release data when it is enclosed in quotes
- LSB grains are now prefixed with lsb_distrib_ instead of simply lsb_. The old naming is not preserved, so SLS may be affected.
- Improved grains detection on MacOS
Pillar

- Don’t try to load `git_pillar` if not enabled in master config (issue 6052)
- Functions `pillar.item` and `pillar.items` added for parity with `grains.item/grains.items`. The old function `pillar.data` is preserved for backwards compatibility.
- Fixed minion traceback when Pillar SLS is malformed (issue 5910)

Peer Publishing

- More gracefully handle improperly quoted publish commands (issue 5958)
- Fixed traceback when timeout specified via the CLI for `publish.publish, publish.full_data` (issue 5959)
- Fixed unintended change in output of `publish.publish` (issue 5928)

Minion

- Fixed salt-key usage in minionswarm script
- Quieted warning about `SALT_MINION_CONFIG` environment variable on minion startup and for CLI commands run via `salt-call` (issue 5956)
- Added minion config parameter `random_reauth_delay` to stagger re-auth attempts when the minion is waiting for the master to approve its public key. This helps prevent SYN flooding in larger environments.

User/Group Management

- Implement previously-ignored `unique` option for `user.present` states in FreeBSD
- Report in state output when a `group.present` state attempts to use a gid in use by another group
- Fixed regression that prevents a `user.present` state to set the password hash to the system default (i.e. an unset password)
- Fixed multiple `group.present` states with the same group (issue 6439)

File Management

- Fixed file.mkdir setting incorrect permissions (issue 6033)
- Fixed cleanup of source files for templates when `/tmp` is in file_roots (issue 6118)
- Fixed caching of zero-byte files when a non-empty file was previously cached at the same path
- Added HTTP authentication support to the `cp` module (issue 5641)
- Diffs are now suppressed when binary files are changed

Package/Repository Management

- Fixed traceback when there is only one target for `pkg.latest` states
- Fixed regression in detection of virtual packages (apt)
- Limit number of pkg database refreshes to once per `state.sls/state.highstate`
• YUM: Allow 32-bit packages with arches other than x86 to be managed on 64-bit systems (issue 6299)
• Fixed incorrect reporting in pkgrepo.managed states (issue 5517)
• Fixed 32-bit binary package installs on 64-bit RHEL-based distros, and added proper support for 32-bit packages on 64-bit Debian-based distros (issue 6303)
• Fixed issue where requisites were inadvertently being put into YUM repo files (issue 6471)

Service Management

• Fixed inaccurate reporting of results in service.running states when the service fails to start (issue 5894)
• Fixed handling of custom initscripts in RHEL-based distros so that they are immediately available, negating the need for a second state run to manage the service that the initscript controls

Networking

• Function network.hwaddr renamed to network.hw_addr to match network.ip_addrs and network.ip_addrs6. All three functions also now work without the underscore in the name, as well.
• Fixed traceback in bridge.show when interface is not present (issue 6326)

SSH

• Fixed incorrect result reporting for some ssh_known_hosts.present states
• Fixed inaccurate reporting when ssh_auth.present states are run with test=True, when rsa/dss is used for the enc param instead of ssh-rsa/ssh-dss (issue 5374)

pip

• Properly handle -f lines in pip freeze output
• Fixed regression in pip.installed states with specifying a requirements file (issue 6003)
• Fixed use of editable argument in pip.installed states (issue 6025)
• Deprecated runas parameter in execution function calls, in favor of user

MySQL

• Allow specification of MySQL connection arguments via the CLI, overriding/bypassing minion config params
• Allow mysql_user.present states to set a passwordless login (issue 5550)
• Fixed endless loop when mysql.processlist is run (issue 6297)

PostgreSQL

• Fixed traceback in postgres.user_list (issue 6352)
Miscellaneous

- Don't allow `npm states` to be used if `npm module` is not available
- Fixed `alternatives.install` states for which the target is a symlink (issue 6162)
- Fixed traceback in `sysbench module` (issue 6175)
- Fixed traceback in job cache
- Fixed tempfile cleanup for windows
- Fixed issue where SLS files using the `pydsl renderer` were not being run
- Fixed issue where returners were being passed incorrect information (issue 5518)
- Fixed traceback when numeric args are passed to `cmd.script` states
- Fixed bug causing `cp.get_dir` to return more directories than expected (issue 6048)
- Fixed traceback when `supervisord.running` states are run with `test=True` (issue 6053)
- Fixed tracebacks when Salt encounters problems running rbenv (issue 5888)
- Only make the `monit module` available if monit binary is present (issue 5871)
- Fixed incorrect behavior of `img.mount_image`
- Fixed traceback in `tomcat.deploy_war` in Windows
- Don't re-write `/etc/fstab` if mount fails
- Fixed tracebacks when Salt encounters problems running gem (issue 5886)
- Fixed incorrect behavior of `selinux.boolean` states (issue 5912)
- *RabbitMQ*: Quote passwords to avoid symbols being interpolated by the shell (issue 6338)
- Fixed tracebacks in `extfs.mkfs` and `extfs.tune` (issue 6462)
- Fixed a regression with the `module.run` state where the `m_name` and `m_fun` arguments were being ignored (issue 6464)

35.2.52 Salt 0.16.3 Release Notes

release 2013-08-09

Version 0.16.3 is another bugfix release for 0.16.0. The changes include:

- Various documentation fixes
- Fix proc directory regression (issue 6502)
- Properly detect Linaro Linux (issue 6496)
- Fix regressions in `mount.mounted` (issue 6522, issue 6545)
- Skip malformed state requisites (issue 6521)
- Fix regression in gitsfs from bad import
- Fix for watching prereq states (including recursive requisite error) (issue 6057)
- Fix `mod_watch` not overriding prereq (issue 6520)
- Don't allow functions which compile states to be called within states (issue 5623)
- Return error for malformed `top.sls` (issue 6544)
• Fix traceback in `mysql.query`
• Fix regression in binary package installation for 64-bit packages on Debian-based Linux distros (issue 6563)
• Fix traceback caused by running `cp.push` without having set `file_recv` in the master config file
• Fix scheduler configuration in pillar (issue 6201)

35.2.53 Salt 0.16.4 Release Notes

release 2013-09-07

Version 0.16.4 is another bugfix release for 0.16.0, likely to be the last before 0.17.0 is released. The changes include:

• Multiple documentation improvements/additions
• Added the osfinger and osarch grains
• Properly handle 32-bit packages for debian32 on x86_64 (issue 6607)
• Fix regression in yum package installation in CentOS 5 (issue 6677)
• Fix bug in `hg.latest` state that would erroneously delete directories (issue 6661)
• Fix bug related to pid not existing for `ps.top` (issue 6679)
• Fix regression in MySQL returner (issue 6695)
• Fix IP addresses grains (ipv4 and ipv6) to include all addresses (issue 6656)
• Fix regression preventing authenticated FTP (issue 6733)
• Fix setting password for windows users (issue 6824)
• Fix `file.contains` on values YAML parses as non-string (issue 6817)
• Fix `file.get_gid`, `file.get_uid`, and `file.chown` for broken symlinks (issue 6826)
• Fix comment for service reloads in service state (issue 6851)

35.2.54 Salt 0.17.0 Release Notes

release 2013-09-26

The 0.17.0 release is a very exciting release of Salt, this brings to Salt some very powerful new features and advances. The advances range from the state system to the test suite, covering new transport capabilities and making states easier and more powerful, to extending Salt Virt and much more!

The 0.17.0 release will also be the last release of Salt to follow the old 0.XX.X numbering system, the next release of Salt will change the numbering to be date based following this format:

<Year>-<Month>-<Minor>

So if the release happens in November of 2013 the number will be 13.11.0, the first bugfix release will be 13.11.1 and so forth.
Major Features

Halite

The new Halite web GUI is now available on PyPI. A great deal of work has been put into Halite to make it fully event driven and amazingly fast. The Halite UI can be started from within the Salt Master (after being installed from PyPI), or standalone, and does not require an external database to run. It is very lightweight!

This initial release of Halite is primarily the framework for the UI and the communication systems, making it easy to extend and build the UI up. It presently supports watching the event bus and firing commands over Salt.

At this time, Halite is not available as a package, but installation documentation is available at: http://docs.saltstack.com/topics/tutorials/halite.html

Halite is, like the rest of Salt, Open Source!

Much more will be coming in the future of Halite!

Salt SSH

The new salt-ssh command has been added to Salt. This system allows for remote execution and states to be run over ssh. The benefit here being, that salt can run relying only on the ssh agent, rather than requiring a minion to be deployed.

The salt-ssh system runs states in a compatible way as Salt and states created and run with salt-ssh can be moved over to a standard salt deployment without modification.

Since this is the initial release of salt-ssh, there is plenty of room for improvement, but it is fully operational, not just a bootstrap tool.

Rosters

Salt is designed to have the minions be aware of the master and the master does not need to be aware of the location of the minions. The new salt roster system was created and designed to facilitate listing the targets for salt-ssh.

The roster system, like most of Salt, is a plugin system, allowing for the list of systems to target to be derived from any pluggable backend. The rosters shipping with 0.17.0 are flat and scan. Flat is a file which is read in via the salt render system and the scan roster does simple network scanning to discover ssh servers.

State Auto Order

This is a major change in how states are evaluated in Salt. State Auto Order is a new feature that makes states get evaluated and executed in the order in which they are defined in the sls file. This feature makes it very easy to see the finite order in which things will be executed, making Salt now, fully imperative AND fully declarative.

The requisite system still takes precedence over the order in which states are defined, so no existing states should break with this change. But this new feature can be turned off by setting state_auto_order: False in the master config, thus reverting to the old lexicographical order.

state.sls Runner

The state.sls runner has been created to allow for a more powerful system for orchestrating state runs and function calls across the salt minions. This new system uses the state system for organizing executions.
This allows for states to be defined that are executed on the master to call states on minions via `salt-run state.sls`.

**Salt Thin**

Salt Thin is an exciting new component of Salt, this is the ability to execute Salt routines without any transport mechanisms installed, it is a pure python subset of Salt.

Salt Thin does not have any networking capability, but can be dropped into any system with Python installed and then `salt-call` can be called directly. The Salt Thin system, is used by the `salt-ssh` command, but can still be used to just drop salt somewhere for easy use.

**Event Namespacing**

Events have been updated to be much more flexible. The tags in events have all been namespaced allowing easier tracking of event names.

**Mercurial Fileserver Backend**

The popular git fileserver backend has been joined by the mercurial fileserver backend, allowing the state tree to be managed entirely via mercurial.

**External Logging Handlers**

The external logging handler system allows for Salt to directly hook into any external logging system. Currently supported are sentry and logstash.

**Jenkins Testing**

The testing systems in Salt have been greatly enhanced, tests for salt are now executed, via jenkins.saltstack.com, across many supported platforms. Jenkins calls out to salt-cloud to create virtual machines on Rackspace, then the minion on the virtual machine checks into the master running on Jenkins where a state run is executed that sets up the minion to run tests and executes the test suite.

This now automates the sequence of running platform tests and allows for continuous destructive tests to be run.

**Salt Testing Project**

The testing libraries for salt have been moved out of the main salt code base and into a standalone codebase. This has been done to ease the use of the testing systems being used in salt based projects other than Salt itself.

**StormPath External Authentication**

The external auth system now supports the fantastic Stormpath cloud based authentication system.
LXC Support

Extensive additions have been added to Salt for LXC support. This included the backend libs for managing LXC containers. Addition into the salt-virt system is still in the works.

Mac OS X User/Group Support

Salt is now able to manage users and groups on Minions running Mac OS X. However, at this time user passwords cannot be managed.

Django ORM External Pillar

Pillar data can now be derived from Django managed databases.

Fixes from RC to release

- Multiple documentation fixes
- Add multiple source files + templating for file.append (issue 6905)
- Support sysctl configuration files in systemd>=207 (issue 7351)
- Add file.search and file.replace
- Fix cross-calling execution functions in provider overrides
- Fix locale override for postgres (issue 4543)
- Fix Raspbian identification for service/pkg support (issue 7371)
- Fix cp.push file corruption (issue 6495)
- Fix ALT Linux password hash specification (issue 3474)
- Multiple salt-ssh-related fixes and improvements

35.2.55 Salt 0.17.1 Release Notes

release 2013-10-17

Note: THIS RELEASE IS NOT COMPATIBLE WITH PREVIOUS VERSIONS. If you update your master to 0.17.1, you must update your minions as well. Sorry for the inconvenience -- this is a result of one of the security fixes listed below.

The 0.17.1 release comes with a number of improvements to salt-ssh, many bugfixes, and a number of security updates.

Salt SSH has been improved to be faster, more featureful and more secure. Since the original release of Salt SSH was primarily a proof of concept, it has been very exciting to see its rapid adoption. We appreciate the willingness of security experts to review Salt SSH and help discover oversights and ensure that security issues only exist for such a tiny window of time.
SSH Enhancements

Shell Improvements

Improvements to Salt SSH’s communication have been added that improve routine execution regardless of the target system’s login shell.

Performance

Deployment of routines is now faster and takes fewer commands to execute.

Security Updates

Be advised that these security issues all apply to a small subset of Salt users and mostly apply to Salt SSH.

Insufficient Argument Validation

This issue allowed for a user with limited privileges to embed executions inside of routines to execute routines that should be restricted. This applies to users using external auth or client ACL and opening up specific routines.

Be advised that these patches address the direct issue. Additional commits have been applied to help mitigate this issue from resurfacing.

CVE  CVE-2013-4435

Affected Versions

0.15.0 - 0.17.0

Patches  https://github.com/saltstack/salt/commit/6d8ef68b605fd63e36bb8ed96122a75ad2e80269

MITM SSH attack in salt-ssh

SSH host keys were being accepted by default and not enforced on future SSH connections. These patches set SSH host key checking by default and can be overridden by passing the -i flag to salt-ssh.

CVE  CVE-2013-4436
Affected Versions 0.17.0

Found By Michael Scherer, Red Hat

Insecure Usage of /tmp in salt-ssh

The initial release of salt-ssh used the /tmp directory in an insecure way. These patches not only secure usage of files under /tmp in salt-ssh, but also add checksum validation for all packages sent into the now secure locations on target systems.

CVE CVE-2013-4438

Affected Versions 0.17.0

Found By Michael Scherer, Red Hat

YAML Calling Unsafe Loading Routine

It has been argued that this is not a valid security issue, as the YAML loading that was happening was only being called after an initial gateway filter in Salt has already safely loaded the YAML and would fail if non-safe routines were embedded. Nonetheless, the CVE was filed and patches applied.

CVE CVE-2013-4438

Patches

https://github.com/saltstack/salt/commit/339b0a51befae6b6b218ebcb55daa9cd3329a1c5

Found By Michael Scherer, Red Hat

Failure to Drop Supplementary Group on Salt Master

If a salt master was started as a non-root user by the root user, root's groups would still be applied to the running process. This fix changes the process to have only the groups of the running user.

CVE CVE not considered necessary by submitter.
Affected Versions  0.11.0 - 0.17.0

Patches  https://github.com/saltstack/salt/commit/b89fa9135822d029795ab1eecd68cce2d1ced715

Found By  Michael Scherer, Red Hat

Failure to Validate Minions Posting Data

This issue allowed a minion to pose as another authorized minion when posting data such as the mine data. All minions now pass through the id challenge before posting such data.

CVE  CVE-2013-4439

Affected Versions  0.15.0 - 0.17.0

Found By  David Anderson

Fix Reference

Version 0.17.1 is the first bugfix release for 0.17.0. The changes include:

- Fix symbolic links in thin.tgz (issue 7482)
- Pass env through to file.patch state (issue 7452)
- Service provider fixes and reporting improvements (issue 7361)
- Add --priv option for specifying salt-ssh private key
- Fix salt-thin’s salt-call on setuptools installations (issue 7516)
- Fix salt-ssh to support passwords with spaces (issue 7480)
- Fix regression in wildcard includes (issue 7455)
- Fix salt-call outputter regression (issue 7456)
- Fix custom returner support for startup states (issue 7540)
- Fix value handling in augeas (issue 7605)
- Fix regression in apt (issue 7624)
- Fix minions ID guessing to use socket.getfqdn() first (issue 7558)
- Add minion ID caching (issue 7558)
- Fix salt-key race condition (issue 7304)
- Add --include-all flag to salt-key (issue 7399)

35.2. Previous Releases
- Fix custom grains in pillar (part of issue 5716, issue 6083)
- Fix race condition in salt-key (issue 7304)
- Fix regression in minion ID guessing, prioritize socket.getfqdn() (issue 7558)
- Cache minion ID on first guess (issue 7558)
- Allow trailing slash in file.directory state
- Fix reporting of file.roots in pillar return (issue 5449 and issue 5951)
- Remove pillar matching for mine.get (issue 7197)
- Sanitize args for multiple execution modules
- Fix yumpkg mod_repo functions to filter hidden args (issue 7656)
- Fix conflicting IDs in state includes (issue 7526)
- Fix mysql_grants.absent string formatting issue (issue 7827)
- Fix postgres.version so it won't return None (issue 7695)
- Fix for trailing slashes in mount.mounted state
- Fix rogue AttributeError in the outputter system (issue 7845)
- Fix for incorrect ssh key encodings resulting in incorrect key added (issue 7718)
- Fix for pillar/grains naming regression in python renderer (issue 7693)
- Fix args/kwargshandling in the scheduler (issue 7422)
- Fix logfile handling for file://, tcp://, and udp:// (issue 7754)
- Fix error handling in config file parsing (issue 6714)
- Fix RVM using sudo when running as non-root user (issue 2193)
- Fix client ACL and underlying logging bugs (issue 7706)
- Fix scheduler bug with returner (issue 7367)
- Fix user management bug related to default groups (issue 7690)
- Fix various salt-ssh bugs (issue 7528)
- Many various documentation fixes

**35.2.56 Salt 0.17.2 Release Notes**

release 2013-11-14

Version 0.17.2 is another bugfix release for 0.17.0. The changes include:

- Add ability to delete key with grains.delval (issue 7872)
- Fix possible state compiler stack trace (issue 5767)
- Fix architecture regression in yumpkg (issue 7813)
- Use correct ps on Debian to prevent truncating (issue 5646)
- Fix grains targeting for new grains (issue 5737)
- Fix bug with merging in git_pillar (issue 6992)
- Fix print_jobs duplicate results
• Fix apt version specification for pkg.install
• Fix possible KeyError from ext_job_cache missing option
• Fix auto_order for - names states (issue 7649)
• Fix regression in new gitfs installs (directory not found error)
• Fix escape pipe issue on Windows for file.recurse (issue 7967)
• Fix fileclient in case of master restart (issue 7987)
• Try to output warning if CLI command malformed (issue 6538)
• Fix --out=quiet to actually be quiet (issue 8000)
• Fix for state.sls in salt-ssh (issue 7991)
• Fix for MySQL grants ordering issue (issue 5817)
• Fix traceback for certain missing CLI args (issue 8016)
• Add ability to disable lspci queries on master (issue 4906)
• Fail if sls defined in topline does not exist (issue 5998)
• Add ability to downgrade MySQL grants (issue 6606)
• Fix ssh_auth.absent traceback (issue 8043)
• Add upstart detection for Debian/Raspbian (issue 8039)
• Fix ID-related issues (issue 8052, issue 8050, and others)
• Fix for jinja rendering issues (issue 8066 and issue 8079)
• Fix argument parsing in salt-ssh (issue 7928)
• Fix some GPU detection instances (issue 6945)
• Fix bug preventing includes from other environments in SLS files
• Fix for kwargs with dashes (issue 8102)
• Fix salt.utils.which for windows `.exe` (issue 7904)
• Fix apache.adduser without apachectl (issue 8123)
• Fix issue with evaluating test kwarg in states (issue 7788)
• Fix regression in salt.client.Caller() (issue 8078)
• Fix apt-key silent failure
• Fix bug where cmd.script would try to run even if caching failed (issue 7601)
• Fix apt pkg.latest regression (issue 8067)
• Fix for mine data not being updated (issue 8144)
• Fix for noarch packages in yum
• Fix a Xen detection edge case (issue 7839)
• Fix windows __opts__ dictionary persistence (issue 7714)
• Fix version generation for when it’s part of another git repo (issue 8090)
• Fix _handle_iorder stacktrace so that the real syntax error is shown (issue 8114 and issue 7905)
• Fix git.latest state when a commit SHA is used (issue 8163)
• Fix various small bugs in yumpkg.py (issue 8201)
• Fix for specifying identify file in git.latest (issue 8094)
• Fix for --output-file CLI arg (issue 8205)
• Add ability to specify shutdown time for system.shutdown (issue 7833)
• Fix for salt version using non-salt git repo info (issue 8266)
• Add additional hints at impact of pkgrepo states when test=True (issue 8247)
• Fix for salt-ssh files not being owned by root (issue 8216)
• Fix retry logic and error handling in fileserver (related to issue 7755)
• Fix file.replace with test=True (issue 8279)
• Add flag for limiting file traversal in fileserver (issue 6928)
• Fix for extra mine processes (issue 5729)
• Fix for unloading custom modules (issue 7691)
• Fix for salt-ssh opts (issue 8005 and issue 8271)
• Fix compound matcher for grains (issue 7944)
• Improve error reporting in ebuild module (related to issue 5393)
• Add dir_mode to file.managed (issue 7860)
• Improve traceroute support for FreeBSD and OS X (issue 4927)
• Fix for matching minions under syndics (issue 7671)
• Improve exception handling for missing ID (issue 8259)
• Fix grain mismatch for ScientificLinux (issue 8338)
• Add configuration option for minion_id_caching
• Fix open mode auth errors (issue 8402)

### 35.2.57 Salt 0.17.3 Release Notes

release 2013-12-08

Note: 0.17.3 had some regressions which were promptly fixed in the 0.17.4 release. Please use 0.17.4 instead.

Version 0.17.3 is another bugfix release for 0.17.0. The changes include:

• Fix some jinja render errors (issue 8418)
• Fix file.replace state changing file ownership (issue 8399)
• Fix state ordering with the PyDSL renderer (issue 8446)
• Fix for new npm version (issue 8517)
• Fix for pip state requiring name even with requirements file (issue 8519)
• Fix yum logging to open terminals (issue 3855)
• Add sane maxrunning defaults for scheduler (issue 8563)
• Fix states duplicate key detection (issue 8053)
• Fix SUSE patch level reporting (issue 8428)
• Fix managed file creation umask (issue 8590)
• Fix logstash exception (issue 8635)
• Improve argument exception handling for salt command (issue 8016)
• Fix pecl success reporting (issue 8750)
• Fix launchctl module exceptions (issue 8759)
• Fix argument order in pw_user module
• Add warnings for failing grains (issue 8690)
• Fix hgfs problems caused by connections left open (issue 8811 and issue 8810)
• Add Debian iptables default for iptables-persistent package (issue 8889)
• Fix installation of packages with dots in pkg name (issue 8614)
• Fix noarch package installation on CentOS 6 (issue 8945)
• Fix portage_config.enforce_nice_config (issue 8252)
• Fix salt.util.copyfile umask usage (issue 8590)
• Fix rescheduling of failed jobs (issue 8941)
• Fix pkg on Amazon Linux (uses yumpkg5 now) (issue 8226)
• Fix conflicting options in postgres module (issue 8717)
• Fix ps modules for psutil >= 0.3.0 (issue 7432)
• Fix postgres module to return False on failure (issue 8778)
• Fix argument passing for args with pound signs (issue 8585)
• Fix pid of salt CLI command showing in status.pid output (issue 8720)
• Fix rvm to run gem as the correct user (issue 8951)
• Fix namespace issue in win_file module (issue 9060)
• Fix masterless state paths on windows (issue 9021)
• Fix timeout option in master config (issue 9040)

35.2.58 Salt 0.17.4 Release Notes

release 2013-12-10

Version 0.17.4 is another bugfix release for 0.17.0. The changes include:
• Fix file.replace bug when replacement str is numeric (issue 9101)
• Fix regression in file.managed (issue 9131)
• Prevent traceback when job is None. (issue 9145)
35.2.59 Salt 0.17.5 Release Notes

release 2014-01-27

Version 0.17.5 is another bugfix release for 0.17.0. The changes include:

- Fix user.present states with non-string fullname (issue 9085)
- Fix virt.init return value on failure (issue 6870)
- Fix reporting of file.blockreplace state when test=True
- Fix network.interfaces when used in cron (issue 7990)
- Fix bug in pkgrepo when switching to/from mirrorlist-based repo def (issue 9121)
- Fix infinite recursion when cache file is corrupted
- Add checking for rev and mirror/bare args in git.latest (issue 9107)
- Add cmd.watch alias (points to cmd.wait) (issue 8612)
- Fix stacktrace when prereq is not formed as a list (issue 8235)
- Fix stdin issue with lvdisplay command (issue 9128)
- Add pre-check function for range matcher (issue 9236)
- Add exception handling for psutil for processes that go missing (issue 9274)
- Allow _in requisites to match both on ID and name (issue 9061)
- Fix multiple client timeout issues (issue 7157 and issue 9302, probably others)
- Fix ZMQError: Operation cannot be accomplished in current state errors (issue 6306)
- Multiple optimization in minion auth routines
- Clarify logs for minion ID caching

35.2.60 Salt 0.6.0 release notes

The Salt remote execution manager has reached initial functionality! Salt is a management application which can be used to execute commands on remote sets of servers.

The whole idea behind Salt is to create a system where a group of servers can be remotely controlled from a single master, not only can commands be executed on remote systems, but salt can also be used to gather information about your server environment.

Unlike similar systems, like Func and MCollective, Salt is extremely simple to setup and use, the entire application is contained in a single package, and the master and minion daemons require no running dependencies in the way that Func requires Certmaster and MCollective requires activeMQ.

Salt also manages authentication and encryption. Rather than using SSL for encryption, salt manages encryption on a payload level, so the data sent across the network is encrypted with fast AES encryption, and authentication uses RSA keys. This means that Salt is fast, secure, and very efficient.

Messaging in Salt is executed with ZeroMQ, so the message passing interface is built into salt and does not require an external ZeroMQ server. This also adds speed to Salt since there is no additional bloat on the networking layer, and ZeroMQ has already proven itself as a very fast networking system.

The remote execution in Salt is `Lazy Execution`; in that once the command is sent the requesting network connection is closed. This makes it easier to detach the execution from the calling process on the master, it also means that replies are cached, so that information gathered from historic commands can be queried in the future.
Salt also allows users to make execution modules in Python. Writers of these modules should also be pleased to know that they have access to the impressive information gathered from PuppetLabs’ Facter application, making Salt module more flexible. In the future I hope to also allow Salt to group servers based on Facter information as well.

All in all Salt is fast, efficient, and clean, can be used from a simple command line client or through an API, uses message queue technology to make network execution extremely fast, and encryption is handled in a very fast and efficient manner. Salt is also VERY easy to use and VERY easy to extend.

You can find the source code for Salt on my GitHub page, I have also set up a few wiki pages explaining how to use and set up Salt. If you are using Arch Linux there is a package available in the Arch Linux AUR.

Salt 0.6.0 Source: https://cloud.github.com/downloads/saltstack/salt/salt-0.6.0.tar.gz
GitHub page: https://github.com/saltstack/salt
Wiki: https://github.com/saltstack/salt/wiki
Arch Linux Package: https://aur.archlinux.org/packages/salt-git/

I am very open to contributions, for instance I need packages for more Linux distributions as well as BSD packages and testers.

Give Salt a try, this is the initial release and is not a 1.0 quality release, but it has been working well for me! I am eager to get your feedback!

35.2.61 Salt 0.7.0 release notes

I am pleased to announce the release of Salt 0.7.0!

This release marks what is the first stable release of salt, 0.7.0 should be suitable for general use.

0.7.0 brings the following new features to Salt:

- Integration with Facter data from puppet labs
- Allow for matching minions from the salt client via Facter information
- Minion job threading, many jobs can be executed from the master at once
- Preview of master clustering support - Still experimental
- Introduce new minion modules for stats, virtualization, service management and more
- Add extensive logging to the master and minion daemons
- Add sys.reload_functions for dynamic function reloading
- Greatly improve authentication
- Introduce the saltkey command for managing public keys
- Begin backend development preparatory to introducing butter
- Addition of man pages for the core commands
- Extended and cleaned configuration

0.7.0 fixes the following major bugs:

- Fix crash in minions when matching failed
- Fix configuration file lookups for the local client
- Repair communication bugs in encryption
- Numerous fixes in the minion modules

35.2. Previous Releases
The next release of Salt should see the following features:

- Stabilize the cluster support
- Introduce a remote client for salt command tiers
- salt-ftp system for distributed file copies
- Initial support for `butter`

Coming up next is a higher level management framework for salt called Butter. I want salt to stay as a simple and effective communication framework, and allow for more complicated executions to be managed via Butter.

Right now Butter is being developed to act as a cloud controller using salt as the communication layer, but features like system monitoring and advanced configuration control (a puppet manager) are also in the pipe.

Special thanks to Joseph Hall for the status and network modules, and thanks to Matthias Teege for tracking down some configuration bugs!

Salt can be downloaded from the following locations:

Source Tarball:
https://cloud.github.com/downloads/saltstack/salt/salt-0.7.0.tar.gz

Arch Linux Package:
https://aur.archlinux.org/packages/salt-git/

Please enjoy the latest Salt release!

### 35.2.62 Salt 0.8.0 release notes

Salt 0.8.0 is ready for general consumption! The source tarball is available on GitHub for download:
https://cloud.github.com/downloads/saltstack/salt/salt-0.8.0.tar.gz

A lot of work has gone into salt since the last release just 2 weeks ago, and salt has improved a great deal. A swath of new features are here along with performance and threading improvements!

The main new features of salt 0.8.0 are:

- **Salt-cp**
- Cython minion modules
- Dynamic returners
- Faster return handling
- Lowered required Python version to 2.6
- Advanced minion threading
- Configurable minion modules

**Salt-cp**

The salt-cp command introduces the ability to copy simple files via salt to targeted servers. Using salt-cp is very simple, just call salt-cp with a target specification, the source file(s) and where to copy the file(s) on the minions. For instance:

```
# salt-cp "/" /etc/hosts /etc/hosts
```

Will copy the local /etc/hosts file to all of the minions.
Salt-cp is very young, in the future more advanced features will be added, and the functionality will much more closely resemble the cp command.

Cython minion modules

Cython is an amazing tool used to compile Python modules down to c. This is arguably the fastest way to run Python code, and since pyzmq requires cython, adding support to salt for cython adds no new dependencies.

Cython minion modules allow minion modules to be written in cython and therefore executed in compiled c. Simply write the salt module in cython and use the file extension “.pyx” and the minion module will be compiled when the minion is started. An example cython module is included in the main distribution called cytest.pyx:
https://github.com/saltstack/salt/blob/develop/salt/modules/cytest.pyx

Dynamic Returners

By default salt returns command data back to the salt master, but now salt can return command data to any system. This is enabled via the new returners modules feature for salt. The returners modules take the return data and sends it to a specific module. The returner modules work like minion modules, so any returner can be added to the minions.

This means that a custom data returner can be added to communicate the return data so anything from MySQL, Redis, MongoDB, and more!

There are 2 simple stock returners in the returners directory:
https://github.com/saltstack/salt/blob/develop/salt/returners

The documentation on writing returners will be added to the wiki shortly, and returners can be written in pure Python, or in cython.

Configurable Minion Modules

Minion modules may need to be configured, now the options passed to the minion configuration file can be accessed inside of the minion modules via the __opt__ dict.

Information on how to use this simple addition has been added to the wiki: Writing modules

The test module has an example of using the __opts__ dict, and how to set default options:
https://github.com/saltstack/salt/blob/develop/salt/modules/test.py

Advanced Minion Threading

In 0.7.0 the minion would block after receiving a command from the master, now the minion will spawn a thread or multiprocess. By default Python threads are used because for general use they have proved to be faster, but the minion can now be configured to use the Python multiprocessing module instead. Using multiprocessing will cause executions that are CPU bound or would otherwise exploit the negative aspects of the Python GIL to run faster and more reliably, but simple calls will still be faster with Python threading. The configuration option can be found in the minion configuration file:
https://github.com/saltstack/salt/blob/develop/conf/minion
Lowered Supported Python to 2.6

The requirement for Python 2.7 has been removed to support Python 2.6. I have received requests to take the minimum Python version back to 2.4, but unfortunately this will not be possible, since the ZeroMQ Python bindings do not support Python 2.4.

Salt 0.8.0 is a very major update, it also changes the network protocol slightly which makes communication with older salt daemons impossible, your master and minions need to be upgraded together!

I could use some help bringing salt to the people! Right now I only have packages for Arch Linux, Fedora 14 and Gentoo. We need packages for Debian and people willing to help test on more platforms. We also need help writing more minion modules and returner modules. If you want to contribute to salt please hop on the mailing list and send in patches, make a fork on GitHub and send in pull requests! If you want to help but are not sure where you can, please email me directly or post to the mailing list!

I hope you enjoy salt, while it is not yet 1.0 salt is completely viable and usable!

-Thomas S. Hatch

35.2.63 Salt 0.8.7 release notes

It has been a month since salt 0.8.0, and it has been a long month! But Salt is still coming along strong. 0.8.7 has a lot of changes and a lot of updates. This update makes Salt’s ZeroMQ back end better, strips Facter from the dependencies, and introduces interfaces to handle more capabilities.

Many of the major updates are in the background, but the changes should shine through to the surface. A number of the new features are still a little thin, but the back end to support expansion is in place.

I also recently gave a presentation to the Utah Python users group in Salt Lake City, the slides from this presentation are available here: https://cloud.github.com/downloads/saltstack/salt/Salt.pdf

The video from this presentation will be available shortly.

The major new features and changes in Salt 0.8.7 are:

- Revamp ZeroMQ topology on the master for better scalability
- State enforcement
- Dynamic state enforcement managers
- Extract the module loader into salt.loader
- Make Job ids more granular
- Replace Facter functionality with the new salt grains interface
- Support for “virtual” salt modules
- Introduce the salt-call command
- Better debugging for minion modules

The new ZeroMQ topology allows for better scalability, this will be required by the need to execute massive file transfers to multiple machines in parallel and state management. The new ZeroMQ topology is available in the aforementioned presentation.

0.8.7 introduces the capability to declare states, this is similar to the capabilities of Puppet. States in salt are declared via state data structures. This system is very young, but the core feature set is available. Salt states work around rendering files which represent Salt high data. More on the Salt state system will be documented in the near future.

The system for loading salt modules has been pulled out of the minion class to be a standalone module, this has enabled more dynamic loading of Salt modules and enables many of the updates in 0.8.7 –
Salt Job ids are now microsecond precise, this was needed to repair a race condition unveiled by the speed improvements in the new ZeroMQ topology.

The new grains interface replaces the functionality of Facter, the idea behind grains differs from Facter in that the grains are only used for static system data, dynamic data needs to be derived from a call to a salt module. This makes grains much faster to use, since the grains data is generated when the minion starts.

Virtual salt modules allows for a salt module to be presented as something other than its module name. The idea here is that based on information from the minion decisions about which module should be presented can be made. The best example is the pacman module. The pacman module will only load on Arch Linux minions, and will be called pkg. Similarly the yum module will be presented as pkg when the minion starts on a Fedora/RedHat system.

The new salt-call command allows for minion modules to be executed from the minion. This means that on the minion a salt module can be executed, this is a great tool for testing Salt modules. The salt-call command can also be used to view the grains data.

In previous releases when a minion module threw an exception very little data was returned to the master. Now the stack trace from the failure is returned making debugging of minion modules MUCH easier.

Salt is nearing the goal of 1.0, where the core feature set and capability is complete!

Salt 0.8.7 can be downloaded from GitHub here: https://cloud.github.com/downloads/saltstack/salt/salt-0.8.7.tar.gz

-Thomas S Hatch

35.2.64 Salt 0.8.8 release notes

Salt 0.8.8 is here! This release adds a great deal of code and some serious new features. The latest release can be downloaded here: https://cloud.github.com/downloads/saltstack/salt/salt-0.8.8.tar.gz

Improved Documentation has been set up for salt using sphinx thanks to the efforts of Seth House. This new documentation system will act as the back end to the salt website which is still under heavy development. The new sphinx documentation system has also been used to greatly clean up the salt manpages. The salt 7 manpage in particular now contains extensive information which was previously only in the wiki. The new documentation can be found at: http://docs.saltstack.com/ We still have a lot to add, and when the domain is set up I will post another announcement.

More additions have been made to the ZeroMQ setup, particularly in the realm of file transfers. Salt 0.8.8 introduces a built in, stateless, encrypted file server which allows salt minions to download files from the salt master using the same encryption system used for all other salt communications. The main motivation for the salt file server has been to facilitate the new salt state system.

Much of the salt code has been cleaned up and a new cleaner logging system has been introduced thanks to the efforts of Pedro Algarvio. These additions will allow for much more flexible logging to be executed by salt, and fixed a great deal of my poor spelling in the salt docstrings! Pedro Algarvio has also cleaned up the API, making it easier to embed salt into another application.

The biggest addition to salt found in 0.8.8 is the new state system. The salt module system has received a new front end which allows salt to be used as a configuration management system. The configuration management system allows for system configuration to be defined in data structures. The configuration management system, or as it is called in salt, the "salt state system" supports many of the features found in other configuration managers, but allows for system states to be written in a far simpler format, executes at blazing speeds, and operates via the salt minion matching system. The state system also operates within the normal scope of salt, and requires no additional configuration to use.

The state system can enforce the following states with many more to come: Packages Files Services Executing commands Hosts
The system used to define the salt states is based on a data structure, the data structure used to define the salt states has been made to be as easy to use as possible. The data structure is defined by default using a YAML file rendered via a Jinja template. This means that the state definition language supports all of the data structures that YAML supports, and all of the programming constructs and logic that Jinja supports. If the user does not like YAML or Jinja the states can be defined in yaml-mako, json-jinja, or json-mako. The system used to render the states is completely dynamic, and any rendering system can be added to the capabilities of Salt, this means that a rendering system that renders XML data in a cheetah template, or whatever you can imagine, can be easily added to the capabilities of salt.

The salt state system also supports isolated environments, as well as matching code from several environments to a single salt minion.

The feature base for Salt has grown quite a bit since my last serious documentation push. As we approach 0.9.0 the goals are becoming very clear, and the documentation needs a lot of work. The main goals for 0.9.0 are to further refine the state system, fix any bugs we find, get Salt running on as many platforms as we can, and get the documentation filled out. There is a lot more to come as Salt moves forward to encapsulate a much larger scope, while maintaining supreme usability and simplicity.

If you would like a more complete overview of Salt please watch the Salt presentation: Slides: https://cloud.github.com/downloads/saltstack/salt/Salt.pdf

-Thomas S Hatch

35.2.65 Salt 0.8.9 Release Notes

Salt 0.8.9 has finally arrived! Unfortunately this is much later than I had hoped to release 0.8.9, life has been very crazy over the last month. But despite challenges, Salt has moved forward!

This release, as expected, adds few new features and many refinements. One of the most exciting aspect of this release is that the development community for salt has grown a great deal and much of the code is from contributors.

Also, I have filled out the documentation a great deal. So information on States is properly documented, and much of the documentation that was out of date has been filled in.

Download!

The Salt source can be downloaded from the salt GitHub site:

https://cloud.github.com/downloads/saltstack/salt/salt-0.8.9.tar.gz

Or from PyPI:

https://pypi.python.org/packages/source/s/salt/salt-0.8.9.tar.gz

Here s the md5sum:

7d5aca4633bc22f59045f9e82f43b56

For instructions on how to set up Salt please see the Installation instructions.

New Features

Salt Run

A big feature is the addition of Salt run, the salt-run command allows for master side execution modules to be made that gather specific information or execute custom routines from the master.

Documentation for salt-run can be found here
Refined Outputters

One problem often complained about in salt was the fact that the output was so messy. Thanks to help from Jeff Schroeder a cleaner interface for the command output for the Salt CLI has been made. This new interface makes adding new printout formats easy and additions to the capabilities of minion modules makes it possible to set the printout mode or `outputter` for functions in minion modules.

Cross Calling Salt Modules

Salt modules can now call each other, the `__salt__` dict has been added to the predefined references in minion modules. This new feature is documented in the *modules documentation*.

Watch Option Added to Salt State System

Now in Salt states you can set the watch option, this will allow watch enabled states to change based on a change in the other defined states. This is similar to subscribe and notify statements in puppet.

Root Dir Option

Travis Cline has added the ability to define the option `root_dir` which allows the salt minion to operate in a subdir. This is a strong move in supporting the minion running as an unprivileged user.

Config Files Defined in Variables

Thanks again to Travis Cline, the master and minion configuration file locations can be defined in environment variables now.

New Modules

Quite a few new modules, states, returners, and runners have been made.

New Minion Modules

- **apt** Support for apt-get has been added, this adds greatly improved Debian and Ubuntu support to Salt!
- **useradd** and **groupadd** Support for manipulating users and groups on Unix-like systems.
- **moosefs** Initial support for reporting on aspects of the distributed file system, MooseFS. For more information on MooseFS please see: [http://www.moosefs.org](http://www.moosefs.org)
  Thanks to Joseph Hall for his work on MooseFS support.
- **mount** Manage mounts and the fstab.
- **puppet** Execute puppet on remote systems.
shadow    Manipulate and manage the user password file.

ssh        Interact with ssh keys.

New States

user and group    Support for managing users and groups in Salt States.

mount        Enforce mounts and the fstab.

New Returners

mongo_return    Send the return information to a MongoDB server.

New Runners

manage        Display minions that are up or down.

35.2.66 Salt 0.9.0 Release Notes

release 2011-08-27
Salt 0.9.0 is here. This is an exciting release, 0.9.0 includes the new network topology features allowing peer salt commands and masters of masters via the syndic interface.
0.9.0 also introduces many more modules, improvements to the API and improvements to the ZeroMQ systems.

Download!

The Salt source can be downloaded from the salt GitHub site:
https://cloud.github.com/downloads/saltstack/salt/salt-0.9.0.tar.gz
Or from PyPI:
https://pypi.python.org/packages/source/s/salt/salt-0.9.0.tar.gz
Here is the md5sum:
9a925da04981e65a0f237f2e77ddab37
For instructions on how to set up Salt please see the Installation instructions.

New Features

Salt Syndic

The new Syndic interface allows a master to be commanded via another higher level salt master. This is a powerful solution allowing a master control structure to exist, allowing salt to scale to much larger levels then before.
Peer Communication

0.9.0 introduces the capability for a minion to call a publication on the master and receive the return from another set of minions. This allows salt to act as a communication channel between minions and as a general infrastructure message bus.

Peer communication is turned off by default but can be enabled via the peer option in the master configuration file. Documentation on the new Peer interface.

Easily Extensible API

The minion and master classes have been redesigned to allow for specialized minion and master servers to be easily created. An example on how this is done for the master can be found in the master.py salt module:
https://github.com/saltstack/salt/blob/develop/salt/master.py

The Master class extends the SMaster class and set up the main master server.

The minion functions can now also be easily added to another application via the SMinion class, this class can be found in the minion.py module:
https://github.com/saltstack/salt/blob/develop/salt/minion.py

Cleaner Key Management

This release changes some of the key naming to allow for multiple master keys to be held based on the type of minion gathering the master key.

The -d option has also been added to the salt-key command allowing for easy removal of accepted public keys.

The --gen-keys option is now available as well for salt-key, this allows for a salt specific RSA key pair to be easily generated from the command line.

Improved 0MQ Master Workers

The 0MQ worker system has been further refined to be faster and more robust. This new system has been able to handle a much larger load than the previous setup. The new system uses the IPC protocol in 0MQ instead of TCP.

New Modules

Quite a few new modules have been made.

New Minion Modules

apache Work directly with apache servers, great for managing balanced web servers

cron Read out the contents of a systems crontabs

mdadm Module to manage raid devices in Linux, appears as the raid module

mysql Gather simple data from MySQL databases
ps  Extensive utilities for managing processes

publish  Used by the peer interface to allow minions to make publications

35.2.67  Salt 0.9.1 Release Notes

release  2011-08-29

35.2.68  Salt 0.9.2 Release Notes

release  2011-09-17

Salt 0.9.2 has arrived! 0.9.2 is primarily a bugfix release, the exciting component in 0.9.2 is greatly improved support for salt states. All of the salt states interfaces have been more thoroughly tested and the new salt-states git repo is growing with example of how to use states.

This release introduces salt states for early developers and testers to start helping us clean up the states interface and make it ready for the world!

0.9.2 also fixes a number of bugs found on Python 2.6.

Download!

The Salt source can be downloaded from the salt GitHub site:
https://cloud.github.com/downloads/saltstack/salt/salt-0.9.2.tar.gz

Or from PyPI:
https://pypi.python.org/packages/source/s/salt/salt-0.9.2.tar.gz

For instructions on how to set up Salt please see the Installation instructions.

New Features

Salt-Call Additions

The salt-call command has received an overhaul, it now hooks into the outputter system so command output looks clean, and the logging system has been hooked into salt-call, so the -l option allows the logging output from salt minion functions to be displayed.

The end result is that the salt-call command can execute the state system and return clean output:

# salt-call state.highstate

State System Fixes

The state system has been tested and better refined. As of this release the state system is ready for early testers to start playing with. If you are interested in working with the state system please check out the (still very small) salt-states GitHub repo:
https://github.com/saltstack/salt-states
This git repo is the active development branch for determining how a clean salt-state database should look and act. Since the salt state system is still very young a lot of help is still needed here. Please fork the salt-states repo and help us develop a truly large and scalable system for configuration management!

**Notable Bug Fixes**

**Python 2.6 String Formatting**

Python 2.6 does not support format strings without an index identifier, all of them have been repaired.

**Cython Loading Disabled by Default**

Cython loading requires a development tool chain to be installed on the minion, requiring this by default can cause problems for most Salt deployments. If Cython auto loading is desired it will need to be turned on in the minion config.

### 35.2.69 Salt 0.9.3 Release Notes

**release** 2011-11-05

Salt 0.9.3 is finally arrived. This is another big step forward for Salt, new features range from proper FreeBSD support to fixing issues seen when attaching a minion to a master over the Internet.

The biggest improvements in 0.9.3 though can be found in the state system, it has progressed from something ready for early testers to a system ready to compete with platforms such as Puppet and Chef. The backbone of the state system has been greatly refined and many new features are available.

**Download!**

The Salt source can be downloaded from the salt GitHub site:

https://cloud.github.com/downloads/saltstack/salt/salt-0.9.3.tar.gz

Or from PyPI:

https://pypi.python.org/packages/source/s/salt/salt-0.9.3.tar.gz

For instructions on how to set up Salt please see the *Installation* instructions.

**New Features**

**WAN Support**

Recently more people have been testing Salt minions connecting to Salt Masters over the Internet. It was found that Minions would commonly lose their connection to the master when working over the internet. The minions can now detect if the connection has been lost and reconnect to the master, making WAN connections much more reliable.
State System Fixes

Substantial testing has gone into the state system and it is ready for real world usage. A great deal has been added to the documentation for states and the modules and functions available to states have been cleanly documented.

A number of State System bugs have also been found and repaired, the output from the state system has also been refined to be extremely clear and concise.

Error reporting has also been introduced, issues found in sls files will now be clearly reported when executing Salt States.

Extend Declaration

The Salt States have also gained the `extend` declaration. This declaration allows for states to be cleanly modified in a post environment. Simply said, if there is an apache.sls file that declares the apache service, then another sls can include apache and then extend it:

```yaml
include:
  - apache

extend:
  apache:
    service:
      - require:
        - pkg: mod_python

mod_python:
  pkg:
    - installed
```

The notable behavior with the extend functionality is that it literally extends or overwrites a declaration set up in another sls module. This means that Salt will behave as though the modifications were made directly to the apache sls. This ensures that the apache service in this example is directly tied to all requirements.

Highstate Structure Specification

This release comes with a clear specification of the Highstate data structure that is used to declare Salt States. This specification explains everything that can be declared in the Salt SLS modules.

The specification is extremely simple, and illustrates how Salt has been able to fulfill the requirements of a central configuration manager within a simple and easy to understand format and specification.

SheBang Renderer Switch

It came to our attention that having many renderers means that there may be a situation where more than one State Renderer should be available within a single State Tree.

The method chosen to accomplish this was something already familiar to developers and systems administrators, a SheBang. The Python State Renderer displays this new capability.
Python State Renderer

Until now Salt States could only be declared in yaml or json using Jinja or Mako. A new, very powerful, renderer has been added, making it possible to write Salt States in pure Python:

```python
#!py

def run():
    '''
    Install the python-mako package
    '''
    return {
        'include': ['python'],
        'python-mako': {'pkg': ['installed']}}
```

This renderer is used by making a run function that returns the Highstate data structure. Any capabilities of Python can be used in pure Python sls modules.

This example of a pure Python sls module is the same as this example in yaml:

```yaml
include:
    - python

python-mako:
    pkg:
        - installed
```

FreeBSD Support

Additional support has been added for FreeBSD, this is Salt’s first branch out of the Linux world and proves the viability of Salt on non-Linux platforms.

Salt remote execution already worked on FreeBSD, and should work without issue on any Unix-like platform. But this support comes in the form of package management and user support, so Salt States also work on FreeBSD now.

The new freebsdpkg module provides package management support for FreeBSD and the new pw_user and pw_group provide user and group management.

Module and State Additions

Cron Support

Support for managing the system crontab has been added, declaring a cron state can be done easily:

```bash
date > /tmp/datemstamp:
    cron:
        - present
        - user: fred
        - minute: 5
        - hour: 3
```
File State Additions

The file state has been given a number of new features, primarily the directory, recurse, symlink, and absent functions.

file.directory Make sure that a directory exists and has the right permissions.

```
/srv/foo:
  file:
    - directory
    - user: root
    - group: root
    - mode: 1755
```

file.symlink Make a symlink.

```
/var/lib/www:
  file:
    - symlink
    - target: /srv/www
    - force: True
```

file.recurse The recurse state function will recursively download a directory on the master file server and place it on the minion. Any change in the files on the master will be pushed to the minion. The recurse function is very powerful and has been tested by pushing out the full Linux kernel source.

```
/opt/code:
  file:
    - recurse
    - source: salt://linux
```

file.absent Make sure that the file is not on the system, recursively deletes directories, files, and symlinks.

```
/etc/httpd/conf.d/somebogusfile.conf:
  file:
    - absent
```

Sysctl Module and State

The sysctl module and state allows for sysctl components in the kernel to be managed easily. The sysctl module contains the following functions:

- **sysctl.show** Return a list of sysctl parameters for this minion
- **sysctl.get** Return a single sysctl parameter for this minion
- **sysctl.assign** Assign a single sysctl parameter for this minion
- **sysctl.persist** Assign and persist a simple sysctl parameter for this minion

The sysctl state allows for sysctl parameters to be assigned:

```
vm.swappiness:
  sysctl:
    - present
    - value: 20
```
Kernel Module Management

A module for managing Linux kernel modules has been added. The new functions are as follows:

- **kmod.available** Return a list of all available kernel modules
- **kmod.check_available** Check to see if the specified kernel module is available
- **kmod.lsmod** Return a dict containing information about currently loaded modules
- **kmod.load** Load the specified kernel module
- **kmod.remove** Unload the specified kernel module

The kmod state can enforce modules be either present or absent:

```yaml
kvm_intel:
  kmod:
    - present
```

Ssh Authorized Keys

The ssh_auth state can distribute ssh authorized keys out to minions. Ssh authorized keys can be present or absent.

```plaintext
AAAAAB3NzaC1kc3MAACBAL0sQ9fJ5bYTEyYvlRBsJdD0o49CNfhlWhWXQRqul6rwL4KIUprhY7hBw0tv7Unc7J9iZRN04iGod9C+0
ssh_auth:
  - present
  - user: frank
  - enc: dsa
  - comment: 'Frank's key'
```

35.2.70 Salt 0.9.4 Release Notes

**release** 2011-11-27

Salt 0.9.4 has arrived. This is a critical update that repairs a number of key bugs found in 0.9.3. But this update is not without feature additions as well! 0.9.4 adds support for Gentoo portage to the pkg module and state system. Also there are 2 major new state additions, the failhard option and the ability to set up finite state ordering with the **order** option.

This release also sees our largest increase in community contributions. These contributors have and continue to be the life blood of the Salt project, and the team continues to grow. I want to put out a big thanks to our new and existing contributors.

Download!

The Salt source can be downloaded from the salt GitHub site:

https://cloud.github.com/downloads/saltstack/salt/salt-0.9.4.tar.gz

Or from PyPI:

https://pypi.python.org/packages/source/s/salt/salt-0.9.4.tar.gz

For instructions on how to set up Salt please see the Installation instructions.
New Features

Failhard State Option

Normally, when a state fails Salt continues to execute the remainder of the defined states and will only refuse to execute states that require the failed state.

But the situation may exist, where you would want all state execution to stop if a single state execution fails. The capability to do this is called failing hard.

State Level Failhard  A single state can have a failhard set, this means that if this individual state fails that all state execution will immediately stop. This is a great thing to do if there is a state that sets up a critical config file and setting a require for each state that reads the config would be cumbersome. A good example of this would be setting up a package manager early on:

```
/etc/yum.repos.d/company.repo:
    file:
        - managed
        - source: salt://company/yumrepo.conf
        - user: root
        - group: root
        - mode: 644
        - order: 1
        - failhard: True
```

In this situation, the yum repo is going to be configured before other states, and if it fails to lay down the config file, than no other states will be executed.

Global Failhard  It may be desired to have failhard be applied to every state that is executed, if this is the case, then failhard can be set in the master configuration file. Setting failhard in the master configuration file will result in failing hard when any minion gathering states from the master have a state fail.

This is NOT the default behavior, normally Salt will only fail states that require a failed state.

Using the global failhard is generally not recommended, since it can result in states not being executed or even checked. It can also be confusing to see states failhard if an admin is not actively aware that the failhard has been set.

To use the global failhard set failhard: True in the master configuration

Finite Ordering of State Execution

When creating salt sls files, it is often important to ensure that they run in a specific order. While states will always execute in the same order, that order is not necessarily defined the way you want it.

A few tools exist in Salt to set up the correct state ordering, these tools consist of requisite declarations and order options.

The Order Option  Before using the order option, remember that the majority of state ordering should be done with requisite statements, and that a requisite statement will override an order option.

The order option is used by adding an order number to a state declaration with the option order:
vim:
pkg:
  - installed
  - order: 1

By adding the order option to 1 this ensures that the vim package will be installed in tandem with any other state declaration set to the order 1.

Any state declared without an order option will be executed after all states with order options are executed.

But this construct can only handle ordering states from the beginning. Sometimes you may want to send a state to the end of the line, to do this set the order to last:

vim:
pkg:
  - installed
  - order: last

Substantial testing has gone into the state system and it is ready for real world usage. A great deal has been added to the documentation for states and the modules and functions available to states have been cleanly documented.

A number of State System bugs have also been founds and repaired, the output from the state system has also been refined to be extremely clear and concise.

Error reporting has also been introduced, issues found in sls files will now be clearly reported when executing Salt States.

**Gentoo Support**

Additional experimental support has been added for Gentoo. This is found in the contribution from Doug Renn, aka nestegg.

### 35.2.71 Salt 0.9.5 Release Notes

**release** 2012-01-15

Salt 0.9.5 is one of the largest steps forward in the development of Salt.

0.9.5 comes with many milestones, this release has seen the community of developers grow out to an international team of 46 code contributors and has many feature additions, feature enhancements, bug fixes and speed improvements.

**Warning:** Be sure to read the upgrade instructions about the switch to msgpack before upgrading!

**Community**

Nothing has proven to have more value to the development of Salt that the outstanding community that has been growing at such a great pace around Salt. This has proven not only that Salt has great value, but also the expandability of Salt is as exponential as I originally intended.

0.9.5 has received over 600 additional commits since 0.9.4 with a swath of new committers. The following individuals have contributed to the development of 0.9.5:

- Aaron Bull Schaefer
- Antti Kaihola
This makes 21 new developers since 0.9.4 was released!

To keep up with the growing community follow Salt on Ohloh (http://www.ohloh.net/p/salt), to join the Salt development community, fork Salt on GitHub, and get coding (https://github.com/saltstack/salt)!

**Major Features**

**SPEED! Pickle to msgpack**

For a few months now we have been talking about moving away from Python pickles for network serialization, but a preferred serialization format had not yet been found. After an extensive performance testing period involving everything from JSON to protocol buffers, a clear winner emerged. Message Pack (http://msgpack.org/) proved to
not only be the fastest and most compact, but also the most "salt like". Message Pack is simple, and the code involved is very small. The msgpack library for Python has been added directly to Salt.

This move introduces a few changes to Salt. First off, Salt is no longer a "noarch" package, since the msgpack lib is written in C. Salt 0.9.5 will also have compatibility issues with 0.9.4 with the default configuration.

We have gone through great lengths to avoid backwards compatibility issues with Salt, but changing the serialization medium was going to create issues regardless. Salt 0.9.5 is somewhat backwards compatible with earlier minions. A 0.9.5 master can command older minions, but only if the `serial` config value in the master is set to `pickle`. This will tell the master to publish messages in pickle format and will allow the master to receive messages in both msgpack and pickle formats.

Therefore the **suggested methods for upgrading** are either to just upgrade everything at once, or:

1. Upgrade the master to 0.9.5
2. Set `serial` to `pickle` in the master config
3. Upgrade the minions
4. Remove the `serial` option from the master config

Since pickles can be used as a security exploit the ability for a master to accept pickles from minions at all will be removed in a future release.

**C Bindings for YAML**

All of the YAML rendering is now done with the YAML C bindings. This speeds up all of the sls files when running states.

**Experimental Windows Support**

David Boucha has worked tirelessly to bring initial support to Salt for Microsoft Windows operating systems. Right now the Salt Minion can run as a native Windows service and accept commands.

In the weeks and months to come Windows will receive the full treatment and will have support for Salt States and more robust support for managing Windows systems. This is a big step forward for Salt to move entirely outside of the Unix world, and proves Salt is a viable cross platform solution. Big Thanks to Dave for his contribution here!

**Dynamic Module Distribution**

Many Salt users have expressed the desire to have Salt distribute in-house modules, states, renderers, returners, and grains. This support has been added in a number of ways:

**Modules via States**  Now when salt modules are deployed to a minion via the state system as a file, then the modules will be automatically loaded into the active running minion - no restart required - and into the active running state. So custom state modules can be deployed and used in the same state run.

**Modules via Module Environment Directories**  Under the file_roots each environment can now have directories that are used to deploy large groups of modules. These directories sync modules at the beginning of a state run on the minion, or can be manually synced via the Salt module `salt.modules.saltutil.sync_all`.

The directories are named:

- _modules
Module Reloading

Modules can now be reloaded without restarting the minion, this is done by calling the `salt.modules.sys.reload_modules` function.

But wait, there's more! Now when a salt module of any type is added via states the modules will be automatically reloaded, allowing for modules to be laid down with states and then immediately used.

Finally, all modules are reloaded when modules are dynamically distributed from the salt master.

Enable / Disable Added to Service

A great deal of demand has existed for adding the capability to set services to be started at boot in the service module. This feature also comes with an overhaul of the service modules and initial systemd support.

This means that the `service state` can now accept `- enable: True` to make sure a service is enabled at boot, and `- enable: False` to make sure it is disabled.

Compound Target

A new target type has been added to the lineup, the compound target. In previous versions the desired minions could only be targeted via a single specific target type, but now many target specifications can be declared.

These targets can also be separated by and/or operators, so certain properties can be used to omit a node:

```
salt -C 'webserv* and G@os:Debian or E@db.*' test.ping
```

will match all minions with ids starting with webserv via a glob and minions matching the `os:Debian` grain. Or minions that match the `db.*` regular expression.

Node Groups

Often the convenience of having a predefined group of minions to execute targets on is desired. This can be accomplished with the new nodegroups feature. Nodegroups allow for predefined compound targets to be declared in the master configuration file:

```
nodegroups:
  group1: 'L@foo.domain.com,bar.domain.com,baz.domain.com and bl*.domain.com'
  group2: 'G@os:Debian and foo.domain.com'
```

And then used via the `-N` option:

```
salt -N group1 test.ping
```
Minion Side Data Store

The data module introduces the initial approach into storing persistent data on the minions, specific to the minions. This allows for data to be stored on minions that can be accessed from the master or from the minion.

The Minion datastore is young, and will eventually provide an interface similar to a more mature key/value pair server.

Major Grains Improvement

The Salt grains have been overhauled to include a massive amount of extra data. This includes hardware data, os data and salt specific data.

Salt -Q is Useful Now

In the past the salt query system, which would display the data from recent executions would be displayed in pure Python, and it was unreadable.

0.9.5 has added the outputter system to the –Q option, thus enabling the salt query system to return readable output.

Packaging Updates

Huge strides have been made in packaging Salt for distributions. These additions are thanks to our wonderful community where the work to set up packages has proceeded tirelessly.

FreeBSD

Salt on FreeBSD? There a port for that:
http://svnweb.freebsd.org/ports/head/sysutils/py-salt/

This port was developed and added by Christer Edwards. This also marks the first time Salt has been included in an upstream packaging system!

Fedora and Red Hat Enterprise

Salt packages have been prepared for inclusion in the Fedora Project and in EPEL for Red Hat Enterprise 5 and 6. These packages are the result of the efforts made by Clint Savage (herlo).

Debian/Ubuntu

A team of many contributors have assisted in developing packages for Debian and Ubuntu. Salt is still actively seeking inclusion in upstream Debian and Ubuntu and the package data that has been prepared is being pushed through the needed channels for inclusion.

These packages have been prepared with the help of:

- Corey
- Aaron Toponce
- and another person.
More to Come

We are actively seeking inclusion in more distributions. Primarily getting Salt into Gentoo, SUSE, OpenBSD, and preparing Solaris support are all turning into higher priorities.

Refinement

Salt continues to be refined into a faster, more stable and more usable application. 0.9.5 comes with more debug logging, more bug fixes and more complete support.

More Testing, More BugFixes

0.9.5 comes with more bug fixes due to more testing than any previous release. The growing community and the introduction a dedicated QA environment have unearthed many issues that were hiding under the covers. This has further refined and cleaned the state interface, taking care of things from minor visual issues to repairing misleading data.

Custom Exceptions

A custom exception module has been added to throw salt specific exceptions. This allows Salt to give much more granular error information.

New Modules

data The new data module manages a persistent datastore on the minion. Big thanks to bastichelaar for his help refining this module.

freebsdkmod FreeBSD kernel modules can now be managed in the same way Salt handles Linux kernel modules. This module was contributed thanks to the efforts of Christer Edwards.

gentoo_service Support has been added for managing services in Gentoo. Now Gentoo services can be started, stopped, restarted, enabled, disabled, and viewed.

pip The pip module introduces management for pip installed applications. Thanks goes to whitinge for the addition of the pip module.

rh_service The rh_service module enables Red Hat and Fedora specific service management. Now Red Hat like systems come with extensive management of the classic init system used by Red Hat.

saltutil The saltutil module has been added as a place to hold functions used in the maintenance and management of salt itself. Saltutil is used to salt the salt minion. The saltutil module is presently used only to sync extension modules from the master server.

systemd Systemd support has been added to Salt, now systems using this next generation init system are supported on systems running systemd.
**virtualenv**  The virtualenv module has been added to allow Salt to create virtual Python environments. Thanks goes to Whitinge for the addition of the virtualenv module.

**win_disk**  Support for gathering disk information on Microsoft Windows minions The windows modules come courtesy of Utah_Dave

**win_service**  The win_service module adds service support to Salt for Microsoft Windows services

**win_useradd**  Salt can now manage local users on Microsoft Windows Systems

**yumpkg5**  The yumpkg module introduces in 0.9.4 uses the yum API to interact with the yum package manager. Unfortunately, on Red Hat 5 systems salt does not have access to the yum API because the yum API is running under Python 2.4 and Salt needs to run under Python 2.6.

The yumpkg5 module bypasses this issue by shelling out to yum on systems where the yum API is not available.

**New States**

**mysql_database**  The new mysql_database state adds the ability to systems running a mysql server to manage the existence of mysql databases.

The mysql states are thanks to syphernl

**mysql_user**  The mysql_user state enables mysql user management.

**virtualenv**  The virtualenv state can manage the state of Python virtual environments. Thanks to Whitinge for the virtualenv state

**New Returners**

**cassandra_returner**  A returner allowing Salt to send data to a cassandra server. Thanks to Byron Clark for contributing this returner

### 35.2.72 Salt 0.9.6 Release Notes

**release**  2012-01-21

Salt 0.9.6 is a release targeting a few bugs and changes. This is primarily targeting an issue found in the names declaration in the state system. But a few other bugs were also repaired, like missing support for grains in extmods.

Due to a conflict in distribution packaging msgpack will no longer be bundled with Salt, and is required as a dependency.

**New Features**

**HTTP and ftp support in files.managed**

Now under the source option in the file.managed state a HTTP or ftp address can be used instead of a file located on the salt master.
Allow Multiple Returners

Now the returner interface can define multiple returners, and will also return data back to the master, making the process less ambiguous.

Minion Memory Improvements

A number of modules have been taken out of the minion if the underlying systems required by said modules are not present on the minion system. A number of other modules need to be stripped out in this same way which should continue to make the minion more efficient.

Minions Can Locally Cache Return Data

A new option, cache_jobs, has been added to the minion to allow for all of the historically run jobs to cache on the minion, allowing for looking up historic returns. By default cache_jobs is set to False.

Pure Python Template Support For file.managed

Templates in the file.managed state can now be defined in a Python script. This script needs to have a run function that returns the string that needs to be in the named file.

35.2.73 Salt 0.9.7 Release Notes

release  2012-02-15

Salt 0.9.7 is here! The latest iteration of Salt brings more features and many fixes. This release is a great refinement over 0.9.6, adding many conveniences under the hood, as well as some features that make working with Salt much better.

A few highlights include the new Job system, refinements to the requisite system in states, the mod_inits interface for states, external node classification, search path to managed files in the file state, and refinements and additions to dynamic module loading.

0.9.7 also introduces the long developed (and oft changed) unit test framework and the initial unit tests.

Major Features

Salt Jobs Interface

The new jobs interface makes the management of running executions much cleaner and more transparent. Building on the existing execution framework the jobs system allows clear introspection into the active running state of the running Salt interface.

The Jobs interface is centered in the new minion side proc system. The minions now store msgpack serialized files under /var/cache/salt/proc. These files keep track of the active state of processes on the minion.
Functions in the saltutil Module  A number of functions have been added to the saltutil module to manage and view the jobs:

**running** - Returns the data of all running jobs that are found in the proc directory.

**find_job** - Returns specific data about a certain job based on job id.

**signal_job** - Allows for a given jid to be sent a signal.

**term_job** - Sends a termination signal (**SIGTERM**, **15**) to the process controlling the specified job.

**kill_job** Sends a kill signal (**SIGKILL**, **9**) to the process controlling the specified job.

The jobs Runner

A convenience runner front end and reporting system has been added as well. The jobs runner contains functions to make viewing data easier and cleaner.

The jobs runner contains a number of functions...

**active**  The active function runs **saltutil.running** on all minions and formats the return data about all running jobs in a much more usable and compact format. The active function will also compare jobs that have returned and jobs that are still running, making it easier to see what systems have completed a job and what systems are still being waited on.

**lookup_jid**  When jobs are executed the return data is sent back to the master and cached. By default is is cached for 24 hours, but this can be configured via the **keep_jobs** option in the master configuration.

Using the **lookup_jid** runner will display the same return data that the initial job invocation with the salt command would display.

**list_jobs**  Before finding a historic job, it may be required to find the job id. **list_jobs** will parse the cached execution data and display all of the job data for jobs that have already, or partially returned.

External Node Classification

Salt can now use external node classifiers like Cobbler's **cobbler-ext-nodes**.

Salt uses specific data from the external node classifier. In particular the classes value denotes which sls modules to run, and the environment value sets to another environment.

An external node classification can be set in the master configuration file via the **external_nodes** option:

http://salt.readthedocs.org/en/latest/ref/configuration/master.html#external-nodes

External nodes are loaded in addition to the top files. If it is intended to only use external nodes, do not deploy any top files.

State Mod Init System

An issue arose with the pkg state. Every time a package was run Salt would need to refresh the package database. This made systems with slower package metadata refresh speeds much slower to work with. To alleviate this issue the **mod_init** interface has been added to salt states.
The **mod_init** interface is a function that can be added to a state file. This function is called with the first state called. In the case of the pkg state, the **mod_init** function sets up a tag which makes the package database only refresh on the first attempt to install a package.

In a nutshell, the **mod_init** interface allows a state to run any command that only needs to be run once, or can be used to set up an environment for working with the state.

**Source File Search Path**

The file state continues to be refined, adding speed and capabilities. This release adds the ability to pass a list to the source option. This list is then iterated over until the source file is found, and the first found file is used.

The new syntax looks like this:

```
/etc/httpd/conf/httpd.conf:
    file:
    - managed
    - source:
      - salt://httpd/httpd.conf
      - http://myserver/httpd.conf: md5=8c1fe119e6f1fd96bc06614473509bf1
```

The source option can take sources in the list from the salt file server as well as an arbitrary web source. If using an arbitrary web source the checksum needs to be passed as well for file verification.

**Refinements to the Requisite System**

A few discrepancies were still lingering in the requisite system, in particular, it was not possible to have a `require` and a `watch` requisite declared in the same state declaration.

This issue has been alleviated, as well as making the requisite system run more quickly.

**Initial Unit Testing Framework**

Because of the module system, and the need to test real scenarios, the development of a viable unit testing system has been difficult, but unit testing has finally arrived. Only a small amount of unit testing coverage has been developed, much more coverage will be in place soon.

A huge thanks goes out to those who have helped with unit testing, and the contributions that have been made to get us where we are. Without these contributions unit tests would still be in the dark.

**Compound Targets Expanded**

Originally only support for `and` and `or` were available in the compound target. 0.9.7 adds the capability to negate compound targets with `not`.

**Nodegroups in the Top File**

Previously the nodegroups defined in the master configuration file could not be used to match nodes for states. The nodegroups support has been expanded and the nodegroups defined in the master configuration can now be used to match minions in the top file.
35.2.74 Salt 0.9.8 Release Notes

**release** 2012-03-21

Salt 0.9.8 is a big step forward, with many additions and enhancements, as well as a number of precursors to advanced future developments.

This version of Salt adds much more power to the command line, making the old hard timeout issues a thing of the past and adds keyword argument support. These additions are also available in the salt client API, making the available API tools much more powerful.

The new pillar system allows for data to be stored on the master and assigned to minions in a granular way similar to the state system. It also allows flexibility for users who want to keep data out of their state tree similar to 'external lookup' functionality in other tools.

A new way to extend requisites was added, the `requisite in` statement. This makes adding requires or watch statements to external state decs much easier.

Additions to requisites making them much more powerful have been added as well as improved error checking for sls files in the state system. A new provider system has been added to allow for redirecting what modules run in the background for individual states.

Support for OpenSUSE has been added and support for Solaris has begun serious development. Windows support has been significantly enhanced as well.

The matcher and target systems have received a great deal of attention. The default behavior of grain matching has changed slightly to reflect the rest of salt and the compound matcher system has been refined.

A number of impressive features with keyword arguments have been added to both the CLI and to the state system. This makes states much more powerful and flexible while maintaining the simple configuration everyone loves.

The new batch size capability allows for executions to be rolled through a group of targeted minions a percentage or specific number at a time. This was added to prevent the `thundering herd` problem when targeting large numbers of minions for things like service restarts or file downloads.

**Upgrade Considerations**

**Upgrade Issues**

There was a previously missed oversight which could cause a newer minion to crash an older master. That oversight has been resolved so the version incompatibility issue will no longer occur. When upgrading to 0.9.8 make sure to upgrade the master first, followed by the minions.

**Debian/Ubuntu Packages**

The original Debian/Ubuntu packages were called salt and included all salt applications. New packages in the ppa are split by function. If an old salt package is installed then it should be manually removed and the new split packages need to be freshly installed.

On the master:

```
# apt-get purge salt
# apt-get install salt-{master,minion}
```

On the minions:

---

35.2. Previous Releases
# apt-get purge salt
# apt-get install salt-minion

And on any Syndics:

# apt-get install salt-syndic

The official Salt PPA for Ubuntu is located at: https://launchpad.net/~saltstack/+archive/salt

## Major Features

### Pillar

*Pillar* offers an interface to declare variable data on the master that is then assigned to the minions. The pillar data is made available to all modules, states, sls files etc. It is compiled on the master and is declared using the existing renderer system. This means that learning pillar should be fairly trivial to those already familiar with salt states.

### CLI Additions

The `salt` command has received a serious overhaul and is more powerful than ever. Data is returned to the terminal as it is received, and the salt command will now wait for all running minions to return data before stopping. This makes adding very large `--timeout` arguments completely unnecessary and gets rid of long running operations returning empty `{}` when the timeout is exceeded.

When calling salt via sudo, the user originally running salt is saved to the log for auditing purposes. This makes it easy to see who ran what by just looking through the minion logs.

The `salt-key` command gained the `-D` and `--delete-all` arguments for removing all keys. Be careful with this one!

### Running States Without a Master

The addition of running states without a salt-master has been added to 0.9.8. This feature allows for the unmodified salt state tree to be read locally from a minion. The result is that the UNMODIFIED state tree has just become portable, allowing minions to have a local copy of states or to manage states without a master entirely.

This is accomplished via the new file client interface in Salt that allows for the salt:// URI to be redirected to custom interfaces. This means that there are now two interfaces for the salt file server, calling the master or looking in a local, minion defined file_roots.

This new feature can be used by modifying the minion config to point to a local file_roots and setting the file_client option to local.

### Keyword Arguments and States

State modules now accept the `**kwargs` argument. This results in all data in a sls file assigned to a state being made available to the state function.

This passes data in a transparent way back to the modules executing the logic. In particular, this allows adding arguments to the pkg.install module that enable more advanced and granular controls with respect to what the state is capable of.

An example of this along with the new debconf module for installing ldap client packages on Debian:
ldap-client-packages:
  pkg:
    - debconf: salt://debconf/ldap-client.ans
    - installed
    - names:
      - nslcd
      - libpam-ldapd
      - libnss-ldapd

Keyword Arguments and the CLI

In the past it was required that all arguments be passed in the proper order to the `salt` and `salt-call` commands. As of 0.9.8, keyword arguments can be passed in the form of `kwaeg=argument`.

```
# salt -G 'type:dev' git.clone \\n    repository=https://github.com/saltstack/salt.git cwd=/tmp/salt user=jeff
```

Matcher Refinements and Changes

A number of fixes and changes have been applied to the Matcher system. The most noteworthy is the change in the grain matcher. The grain matcher used to use a regular expression to match the passed data to a grain, but now defaults to a shell glob like the majority of match interfaces in Salt. A new option is available that still uses the old style regex matching to grain data called `grain-pcre`. To use regex matching in compound matches use the letter `P`.

For example, this would match any ArchLinux or Fedora minions:

```
# salt --grain-pcre 'os:(Arch:Fed).*' test.ping
```

And the associated compound matcher suitable for `top.sls` is `P`:

```
P@os:(Arch|Fed).*
```

**NOTE:** Changing the grains matcher from pcre to glob is backwards incompatible.

Support has been added for matching minions with Yahoo's range library. This is handled by passing range syntax with `-R` or `--range` arguments to `salt`.

More information at: https://github.com/ytoolshed/range/wiki/%22yamlfile%22-module-file-spec

Requisite ``in``

A new means to updating requisite statements has been added to make adding watchers and requires to external states easier. Before 0.9.8 the only way to extend the states that were watched by a state outside of the sls was to use an extend statement:

```
include:
  - http
extend:
  apache:
    service:
      watch:
```

35.2. Previous Releases
- pkg: tomcat

tomcat:
  pkg:
    - installed

But the new Requisite in statement allows for easier extends for requisites:

include:
  - http
tomcat:
  pkg:
    - installed
    - watch_in:
      - service: apache

Requisite in is part of the extend system, so still remember to always include the sls that is being extended!

Providers

Salt predetermines what modules should be mapped to what uses based on the properties of a system. These determinations are generally made for modules that provide things like package and service management. The apt module maps to pkg on Debian and the yum module maps to pkg on Fedora for instance.

Sometimes in states, it may be necessary for a non-default module to be used for the desired functionality. For instance, an Arch Linux system may have been set up with systemd support. Instead of using the default service module detected for Arch Linux, the systemd module can be used:

http:
  service:
    - running
    - enable: True
    - provider: systemd

Default providers can also be defined in the minion config file:

providers:
  service: systemd

When default providers are passed in the minion config, then those providers will be applied to all functionality in Salt, this means that the functions called by the minion will use these modules, as well as states.

Requisite Glob Matching

Requisites can now be defined with glob expansion. This means that if there are many requisites, they can be defined on a single line.

To watch all files in a directory:

http:
  service:
    - running
    - enable: True
This example will watch all defined files that match the glob `/etc/http/conf.d/*`

**Batch Size**

The new batch size option allows commands to be executed while maintaining that only so many hosts are executing the command at one time. This option can take a percentage or a finite number:

```
salt '*' -b 10 test.ping
salt -G 'os:RedHat' --batch-size 25% apache.signal restart
```

This will only run test.ping on 10 of the targeted minions at a time and then restart apache on 25% of the minions matching `os:RedHat` at a time and work through them all until the task is complete. This makes jobs like rolling web server restarts behind a load balancer or doing maintenance on BSD firewalls using carp much easier with salt.

**Module Updates**

This is a list of notable, but non-exhaustive updates with new and existing modules.

Windows support has seen a flurry of support this release cycle. We've gained all new `file`, `network`, and `shadow` modules. Please note that these are still a work in progress.

For our ruby users, new `rvm` and `gem` modules have been added along with the `associated states`.

The `virt` module gained basic Xen support.

The `yum` module gained Scientific Linux support.

The `pkg` module on Debian, Ubuntu, and derivatives force apt to run in a non-interactive mode. This prevents issues when package installation waits for confirmation.

A `pkg` module for OpenSUSE's zypper was added.

The `service` module on Ubuntu natively supports `upstart`.

A new `debconf` module was contributed by our community for more advanced control over deb package deployments on Debian based distributions.

The `mysql.user` state and `mysql` module gained a `password_hash` argument.

The `cmd` module and state gained a `shell` keyword argument for specifying a shell other than `/bin/sh` on Linux / Unix systems.

New `git` and `mercurial` modules have been added for fans of distributed version control.

**In Progress Development**

**Master Side State Compiling**

While we feel strongly that the advantages gained with minion side state compiling are very critical, it does prevent certain features that may be desired. 0.9.8 has support for initial master side state compiling, but many more components still need to be developed, it is hoped that these can be finished for 0.9.9.
The goal is that states can be compiled on both the master and the minions allowing for compilation to be split between master and minion. Why will this be great? It will allow storing sensitive data on the master and sending it to some minions without all minions having access to it. This will be good for handling ssl certificates on front-end web servers for instance.

**Solaris Support**

Salt 0.9.8 sees the introduction of basic Solaris support. The daemon runs well, but grains and more of the modules need updating and testing.

**Windows Support**

Salt states on windows are now much more viable thanks to contributions from our community! States for file, service, local user, and local group management are more fully fleshed out along with network and disk modules. Windows users can also now manage registry entries using the new `reg` module.

### 35.2.75 Salt 0.9.9 Release Notes

**Release** 2012-04-27

0.9.9 is out and comes with some serious bug fixes and even more serious features. This release is the last major feature release before 1.0.0 and could be considered the 1.0.0 release candidate.

A few updates include more advanced kwarg support, the ability for salt states to more safely configure a running salt minion, better job directory management and the new state test interface.

Many new tests have been added as well, including the new minion swarm test that allows for easier testing of Salt working with large groups of minions. This means that if you have experienced stability issues with Salt before, particularly in larger deployments, that these bugs have been tested for, found, and killed.

**Major Features**

**State Test Interface**

Until 0.9.9 the only option when running states to see what was going to be changed was to print out the highstate with `state.show_highstate` and manually look it over. But now states can be run to discover what is going to be changed.

Passing the option `test=True` to many of the state functions will now cause the salt state system to only check for what is going to be changed and report on those changes.

```bash
salt '*' state.highstate test=True
```

Now states that would have made changes report them back in yellow.

**State Syntax Update**

A shorthand syntax has been added to sls files, and it will be the default syntax in documentation going forward. The old syntax is still fully supported and will not be deprecated, but it is recommended to move to the new syntax in the future. This change moves the state function up into the state name using a dot notation. This is in-line with how state functions are generally referred to as well:
The new way:

```
/etc/sudoers:
   file.present:
       - source: salt://sudo/sudoers
       - user: root
       - mode: 400
```

**Use and Use_in Requisites**

Two new requisite statements are available in 0.9.9. The use and use_in requisite and requisite-in allow for the transparent duplication of data between states. When a state `"uses"` another state it copies the other state's arguments as defaults. This was created in direct response to the new network state, and allows for many network interfaces to be configured in the same way easily. A simple example:

```
root_file:
   file.absent:
       - name: /tmp/nothing
       - user: root
       - mode: 644
       - group: root
       - use_in:
           - file: /etc/vimrc

fred_file:
   file.absent:
       - name: /tmp/nothing
       - user: fred
       - group: marketing
       - mode: 660

/files/marketing/district7.rst:
   file.present:
       - source: salt://marketing/district7.rst
       - template: jinja
       - use:
           - file: fred_file

/etc/vimrc:
   file.present:
       - source: salt://edit/vimrc
```

This makes the 2 lower state decs inherit the options from their respectively `"used"` state decs.

**Network State**

The new network state allows for the configuration of network devices via salt states and the ip salt module. This addition has been given to the project by Jeff Hutchins and Bret Palsson from Jive Communications. Currently the only network configuration backend available is for Red Hat based systems, like Red Hat Enterprise, CentOS, and Fedora.
Exponential Jobs

Originally the jobs executed were stored on the master in the format: `<cachedir>/jobs/jid/{minion ids}` But this format restricted the number of jobs in the cache to the number of subdirectories allowed on the filesystem. Ext3 for instance limits subdirectories to 32000. To combat this the new format for 0.9.9 is: `<cachedir>/jobs/jid_hash[:2]/jid_hash[2:]/{minion ids}` So that now the number of maximum jobs that can be run before the cleanup cycle hits the job directory is substantially higher.

ssh_auth Additions

The original ssh_auth state was limited to accepting only arguments to apply to a public key, and the key itself. This was restrictive due to the way the we learned that many people were using the state, so the key section has been expanded to accept options and arguments to the key that over ride arguments passed in the state. This gives substantial power to using ssh_auth with names:

```
sshkeys:
  ssh_auth:
    - present
    - user: backup
    - enc: ssh-dss
    - options:
      - option1="value1"
      - option2="value2 flag2"
    - comment: backup
    - names:
      - AAAAB3NzaC1yc2EAAABIwAAAAQAEAlEyE26SMFFVY5YJvnL7AF5CRTPtAigSW1U887ASfBt6FDa7Qr1Yd0SochiLoz8aSiM62
      - AAAAB3NzaC1yc2EAAABIwAAAAQAEAlEyE26SMFFVY5YJvnL7AF5CRTPtAigSW1U887ASfBt6FDa7Qr1Yd0SochiLoz8aSiM62
      - ssh-rsa AAAAB3NzaC1yc2EAAABIwAAAAQAEAlEyE26SMFFVY5YJvnL7AF5CRTPtAigSW1U887ASfBt6FDa7Qr1Yd0SochiLoz8aSiM62
      - ssh-rsa AAAAB3NzaC1yc2EAAABIwAAAAQAEAlEyE26SMFFVY5YJvnL7AF5CRTPtAigSW1U887ASfBt6FDa7Qr1Yd0SochiLoz8aSiM62
      - option3="value3",option4="value4 flag4" ssh-rsa AAAAB3NzaC1yc2EAAABIwAAAAQAEAlEyE26SMFFVY5YJvnL7AF5CRTPtAigSW1U887ASfBt6FDa7Qr1Yd0SochiLoz8aSiM62
      - option3="value3" ssh-rsa AAAAB3NzaC1yc2EAAABIwAAAAQAEAlEyE26SMFFVY5YJvnL7AF5CRTPtAigSW1U887ASfBt6FDa7Qr1Yd0SochiLoz8aSiM62
```

LocalClient Additions

To follow up the recent additions in 0.9.8 of additional kwargs support, 0.9.9 also adds the capability to send kwargs into commands via a dict. This addition to the LocalClient api can be used like so:

```
import salt.client

client = salt.client.LocalClient('/etc/salt/master')
ret = client.cmd('*', 'cmd.run', ['ls -l'], kwarg={'cwd': '/etc'})
```

This update has been added to all cmd methods in the LocalClient class.

Better Self Salting

One problem faced with running Salt states, is that it has been difficult to manage the Salt minion via states, this is due to the fact that if the minion is called to restart while a state run is happening then the state run would be killed. 0.9.9 slightly changes the process scope of the state runs, so now when salt is executing states it can safely restart the salt-minion daemon.
In addition to daemonizing the state run, the apt module also daemonizes. This update makes it possible to cleanly update the salt-minion package on Debian/Ubuntu systems without leaving apt in an inconsistent state or killing the active minion process mid-execution.

**Wildcards for SLS Modules**

Now, when including sls modules in include statements or in the top file, shell globs can be used. This can greatly simplify listing matched sls modules in the top file and include statements:

```python
base:
  '*':
    - files*
    - core*

include:
  - users.dev.*
  - apache.ser*
```

**External Pillar**

Since the pillar data is just, data, it does not need to come expressly from the pillar interface. The external pillar system allows for hooks to be added making it possible to extract pillar data from any arbitrary external interface. The external pillar interface is configured via the `ext_pillar` option. Currently interfaces exist to gather external pillar data via hiera or via a shell command that sends yaml data to the terminal:

```python
ext_pillar:
  - cmd_yaml: cat /etc/salt/ext.yaml
  - hiera: /etc/hirea.yaml
```

The initial external pillar interfaces and extra interfaces can be added to the file salt/pillar.py, it is planned to add more external pillar interfaces. If the need arises a new module loader interface will be created in the future to manage external pillar interfaces.

**Single State Executions**

The new `state.single` function allows for single states to be cleanly executed. This is a great tool for setting up a small group of states on a system or for testing out the behavior of single states:

```bash
salt '*' state.single user.present name=wade uid=2000
```

The test interface functions here as well, so changes can also be tested against as:

```bash
salt '*' state.single user.present name=wade uid=2000 test=True
```

**New Tests**

A few exciting new test interfaces have been added, the minion swarm allows not only testing of larger loads, but also allows users to see how Salt behaves with large groups of minions without having to create a large deployment.
Minion Swarm

The minion swarm test system allows for large groups of minions to be tested against easily without requiring large numbers of servers or virtual machines. The minion swarm creates as many minions as a system can handle and roots them in the /tmp directory and connects them to a master.

The benefit here is that we were able to replicate issues that happen only when there are large numbers of minions. A number of elusive bugs which were causing stability issues in masters and minions have since been hunted down. Bugs that used to take careful watch by users over several days can now be reliably replicated in minutes, and fixed in minutes.

Using the swarm is easy, make sure a master is up for the swarm to connect to, and then use the minionswarm.py script in the tests directory to spin up as many minions as you want. Remember, this is a fork bomb, don't spin up more than your hardware can handle!

```bash
python minionswarm.py -m 20 --master salt-master
```

Shell Tests

The new Shell testing system allows us to test the behavior of commands executed from a high level. This allows for the high level testing of salt runners and commands like salt-key.

Client Tests

Tests have been added to test the aspects of the client APIs and ensure that the client calls work, and that they manage passed data, in a desirable way.

A number of unofficial open source projects, based on Salt, or written to enhance Salt have been created.

### 36.1 Salt Sandbox

Created by Aaron Bull Schaefer, aka `elasticdog`.

[https://github.com/elasticdog/salt-sandbox](https://github.com/elasticdog/salt-sandbox)

Salt Sandbox is a multi-VM Vagrant-based Salt development environment used for creating and testing new Salt state modules outside of your production environment. It’s also a great way to learn firsthand about Salt and its remote execution capabilities.

Salt Sandbox will set up three separate virtual machines:

- `salt.example.com` - the Salt master server
- `minion1.example.com` - the first Salt minion machine
- `minion2.example.com` - the second Salt minion machine

These VMs can be used in conjunction to segregate and test your modules based on node groups, top file environments, grain values, etc. You can even test modules on different Linux distributions or release versions to better match your production infrastructure.

The SaltStack Security Team is available at security@saltstack.com for security-related bug reports or questions.

We request the disclosure of any security-related bugs or issues be reported non-publicly until such time as the issue can be resolved and a security-fix release can be prepared. At that time we will release the fix and make a public announcement with upgrade instructions and download locations.

### 37.1 Security response procedure

SaltStack takes security and the trust of our customers and users very seriously. Our disclosure policy is intended to resolve security issues as quickly and safely as is possible.

1. A security report sent to security@saltstack.com is assigned to a team member. This person is the primary contact for questions and will coordinate the fix, release, and announcement.
2. The reported issue is reproduced and confirmed. A list of affected projects and releases is made.
3. Fixes are implemented for all affected projects and releases that are actively supported. Back-ports of the fix are made to any old releases that are actively supported.
4. Packagers are notified via the salt-packagers mailing list that an issue was reported and resolved, and that an announcement is incoming.
5. A new release is created and pushed to all affected repositories. The release documentation provides a full description of the issue, plus any upgrade instructions or other relevant details.
6. An announcement is made to the salt-users and salt-announce mailing lists. The announcement contains a description of the issue and a link to the full release documentation and download locations.

### 37.2 Receiving security announcements

The fastest place to receive security announcements is via the salt-announce mailing list. This list is low-traffic.
Frequently Asked Questions

FAQ

- Is Salt open-core?
- I think I found a bug! What should I do?
- What ports should I open on my firewall?
- I’m seeing weird behavior (including but not limited to packages not installing their users properly)
- My script runs every time I run a `state.highstate`. Why?
- When I run `test.ping`, why don’t the Minions that aren’t responding return anything? Returning `False` would be helpful.
- How does Salt determine the Minion’s id?
- I’m trying to manage packages/services but I get an error saying that the state is not available. Why?
- I’m using gitfs and my custom modules/states/etc are not syncing. Why?
- Why aren’t my custom modules/states/etc. available on my Minions?
- Module X isn’t available, even though the shell command it uses is installed. Why?
- Can I run different versions of Salt on my Master and Minion?
- Does Salt support backing up managed files?
- What is the best way to restart a Salt daemon using Salt?
  - * Linux/Unix
  - * Windows
- Salting the Salt Master

38.1 Is Salt open-core?

No. Salt is 100% committed to being open-source, including all of our APIs. It is developed under the Apache 2.0 license, allowing it to be used in both open and proprietary projects.

38.2 I think I found a bug! What should I do?

The salt-users mailing list as well as the salt IRC channel can both be helpful resources to confirm if others are seeing the issue and to assist with immediate debugging.

To report a bug to the Salt project, please follow the instructions in reporting a bug.
38.3 What ports should I open on my firewall?

Minions need to be able to connect to the Master on TCP ports 4505 and 4506. Minions do not need any inbound ports open. More detailed information on firewall settings can be found here.

38.4 I'm seeing weird behavior (including but not limited to packages not installing their users properly)

This is often caused by SELinux. Try disabling SELinux or putting it in permissive mode and see if the weird behavior goes away.

38.5 My script runs every time I run a state.highstate. Why?

You are probably using cmd.run rather than cmd.wait. A cmd.wait state will only run when there has been a change in a state that it is watching.

A cmd.run state will run the corresponding command every time (unless it is prevented from running by the unless or onlyif arguments).

More details can be found in the documentation for the cmd states.

38.6 When I run test.ping, why don't the Minions that aren't responding return anything? Returning False would be helpful.

When you run test.ping the Master tells Minions to run commands/functions, and listens for the return data, printing it to the screen when it is received. If it doesn't receive anything back, it doesn't have anything to display for that Minion.

There are a couple options for getting information on Minions that are not responding. One is to use the verbose (-v) option when you run salt commands, as it will display ``Minion did not return” for any Minions which time out.

    salt -v '*/' pkg.install zsh

Another option is to use the manage.down runner:

    salt-run manage.down

Also, if the Master is under heavy load, it is possible that the CLI will exit without displaying return data for all targeted Minions. However, this doesn't mean that the Minions did not return; this only means that the Salt CLI timed out waiting for a response. Minions will still send their return data back to the Master once the job completes. If any expected Minions are missing from the CLI output, the jobs.list_jobs runner can be used to show the job IDs of the jobs that have been run, and the jobs.lookup_jid runner can be used to get the return data for that job.

    salt-run jobs.list_jobs
    salt-run jobs.lookup_jid 20130916125524463507
If you find that you are often missing Minion return data on the CLI, only to find it with the jobs runners, then this may be a sign that the `worker_threads` value may need to be increased in the master config file. Additionally, running your Salt CLI commands with the `-t` option will make Salt wait longer for the return data before the CLI command exits. For instance, the below command will wait up to 60 seconds for the Minions to return:

```
salt -t 60 '*' test.ping
```

### 38.7 How does Salt determine the Minion's id?

If the Minion id is not configured explicitly (using the `id` parameter), Salt will determine the id based on the hostname. Exactly how this is determined varies a little between operating systems and is described in detail [here](#).

### 38.8 I'm trying to manage packages/services but I get an error saying that the state is not available. Why?

Salt detects the Minion’s operating system and assigns the correct package or service management module based on what is detected. However, for certain custom spins and OS derivatives this detection fails. In cases like this, an issue should be opened on our [tracker](#), with the following information:

1. The output of the following command:
   
   ```
salt <minion_id> grains.items | grep os
   ```

2. The contents of `/etc/lsb-release`, if present on the Minion.

### 38.9 I'm using gitfs and my custom modules/states/etc are not syncing. Why?

In versions of Salt 0.16.3 or older, there is a bug in [gitfs](#) which can affect the syncing of custom types. Upgrading to 0.16.4 or newer will fix this.

### 38.10 Why aren't my custom modules/states/etc. available on my Minions?

Custom modules are only synced to Minions when `state.highstate`, `saltutil.sync_modules`, or `saltutil.sync_all` is run. Similarly, custom states are only synced to Minions when `state.highstate`, `saltutil.sync_states`, or `saltutil.sync_all` is run.

Other custom types (renderers, outputters, etc.) have similar behavior, see the documentation for the `saltutil` module for more information.
38.11 Module X isn't available, even though the shell command it uses is installed. Why?

This is most likely a PATH issue. Did you custom-compile the software which the module requires? RHEL/CentOS/etc. in particular override the root user's path in /etc/init.d/functions, setting it to /sbin:/usr/sbin:/bin:/usr/bin, making software installed into /usr/local/bin unavailable to Salt when the Minion is started using the init script. In version 2014.1.0, Salt will have a better solution for these sort of PATH-related issues, but recompiling the software to install it into a location within the PATH should resolve the issue in the meantime. Alternatively, you can create a symbolic link within the PATH using a file.symlink state.

```
/usr/bin/foo:
  file.symlink:
    - target: /usr/local/bin/foo
```

38.12 Can I run different versions of Salt on my Master and Minion?

This depends on the versions. In general, it is recommended that Master and Minion versions match.

When upgrading Salt, the master(s) should always be upgraded first. Backwards compatibility for minions running newer versions of salt than their masters is not guaranteed.

Whenever possible, backwards compatibility between new masters and old minions will be preserved. Generally, the only exception to this policy is in case of a security vulnerability.

Recent examples of backwards compatibility breakage include the 0.17.1 release (where all backwards compatibility was broken due to a security fix), and the 2014.1.0 release (which retained compatibility between 2014.1.0 masters and 0.17 minions, but broke compatibility for 2014.1.0 minions and older masters).

38.13 Does Salt support backing up managed files?

Yes. Salt provides an easy to use addition to your file.managed states that allow you to back up files via backup_mode, backup_mode can be configured on a per state basis, or in the minion config (note that if set in the minion config this would simply be the default method to use, you still need to specify that the file should be backed up!).

38.14 What is the best way to restart a Salt daemon using Salt?

Updating the salt-minion package requires a restart of the salt-minion service. But restarting the service while in the middle of a state run interrupts the process of the minion running states and sending results back to the master. It's a tricky problem to solve, and we're working on it, but in the meantime one way of handling this (on Linux and UNIX-based operating systems) is to use at (a job scheduler which predates cron) to schedule a restart of the service. at is not installed by default on most distros, and requires a service to be running (usually called atd) in order to schedule jobs. Here's an example of how to upgrade the salt-minion package at the end of a Salt run, and schedule a service restart for one minute after the package update completes.
### 38.14.1 Linux/Unix

```yaml
salt-minion:
  pkg.installed:
    - name: salt-minion
    - version: 2014.1.7-3.el6
    - order: last
  service.running:
    - name: salt-minion
    - require:
      - pkg: salt-minion
  cmd.wait:
    - name: echo service salt-minion restart | at now + 1 minute
    - watch:
      - pkg: salt-minion
```

To ensure that `at` is installed and `atd` is running, the following states can be used (be sure to double-check the package name and service name for the distro the minion is running, in case they differ from the example below.

```yaml
at:
  pkg.installed:
    - name: at
  service.running:
    - name: atd
      - enable: True
```

An alternative to using the `atd` daemon is to fork and disown the process.

```yaml
restart_minion:
  cmd.run:
    - name: |
      exec 0<&- # close stdin
      exec 1<&- # close stdout
      exec 2<&- # close stderr
      nohup /bin/sh -c 'sleep 10 && salt-call --local service.restart salt-minion' &
    - python_shell: True
    - order: last
```

### 38.14.2 Windows

For Windows machines, restarting the minion at can be accomplished by adding the following state:

```yaml
schedule-start:
  cmd.run:
    - name: 'start powershell "Restart-Service -Name salt-minion"'
    - order: last
```

or running immediately from the command line:

```bash
salt -G kernel:Windows cmd.run 'start powershell "Restart-Service -Name salt-minion"'
```
38.15 Salting the Salt Master

In order to configure a master server via states, the Salt master can also be ``salted'' in order to enforce state on the Salt master as well as the Salt minions. Salting the Salt master requires a Salt minion to be installed on the same machine as the Salt master. Once the Salt minion is installed, the minion configuration file must be pointed to the local Salt master:

```
master: 127.0.0.1
```

Once the Salt master has been ``salted'' with a Salt minion, it can be targeted just like any other minion. If the minion on the salted master is running, the minion can be targeted via any usual `salt` command. Additionally, the `salt-call` command can execute operations to enforce state on the salted master without requiring the minion to be running.

More information about salting the Salt master can be found in the salt-formula for salt itself:

https://github.com/saltstack-formulas/salt-formula
Auto-Order  The evaluation of states in the order that they are defined in a SLS file. See also: ordering.

Bootstrap  A stand-alone Salt project which can download and install a Salt master and/or a Salt minion onto a host. See also: salt-bootstrap.

Compound Matcher  A combination of many target definitions that can be combined with boolean operators. See also: targeting.

EAuth  Shorthand for `external authentication'. A system for calling to a system outside of Salt in order to authenticate users and determine if they are allowed to issue particular commands to Salt. See also: external auth.

Environment  A directory tree containing state files which can be applied to minions. See also: top file.

Execution Function  A Python function inside an Execution Module that may take arguments and performs specific system-management tasks. See also: the list of execution modules.

External Job Cache  An external data-store that can archive information about jobs that have been run. A default returner. See also: ext_job_cache, the list of returners.

Execution Module  A Python module that contains execution functions which directly perform various system-management tasks on a server. Salt ships with a number of execution modules but users can also write their own execution modules to perform specialized tasks. See also: the list of execution modules.

External Pillar  A module that accepts arbitrary arguments and returns a dictionary. The dictionary is automatically added to a pillar for a minion.

Event  A notice emitted onto an event bus. Events are often driven by requests for actions to occur on a minion or master and the results of those actions. See also: Salt Reactor.

File Server  A local or remote location for storing both Salt-specific files such as top files or SLS files as well as files that can be distributed to minions, such as system configuration files. See also: Salt's file server.

Grain  A key-value pair which contains a fact about a system, such as its hostname, network addresses. See also: targeting with grains.

Highdata  The data structure in a SLS file the represents a set of state declarations. See also: state layers.

Highstate  The collection of states to be applied to a system. See also: state layers.

Jinja  A templating language which allows variables and simple logic to be dynamically inserted into static text files when they are rendered. See also: Salt's Jinja documentation.

Job  The complete set of tasks to be performed by the execution of a Salt command are a single job. See also: jobs runner.

Job ID  A unique identifier to represent a given job.
Low State  The collection of processed states after requisites and order are evaluated. See also: state layers.

Master  A central Salt daemon which from which commands can be issued to listening minions.

Masterless  A minion which does not require a Salt master to operate. All configuration is local. See also: file_client.

Master Tops  A system for the master that allows hooks into external systems to generate top file data.

Mine  A facility to collect arbitrary data from minions and store that data on the master. This data is then available to all other minions. [Sometimes referred to as Salt Mine.] See also: Salt Mine.

Minion  A server running a Salt minion daemon which can listen to commands from a master and perform the requested tasks. Generally, minions are servers which are to be controlled using Salt.

Minion ID  A globally unique identifier for a minion. See also: id.

Multi-Master  The ability for a minion to be actively connected to multiple Salt masters at the same time in high-availability environments.

Node Group  A pre-defined group of minions declared in the master configuration file. See also: targeting.

OUTPUTTER  A formatter for defining the characteristics of output data from a Salt command. See also: list of outputters.

Peer Communication  The ability for minions to communicate directly with other minions instead of brokering commands through the Salt master. See also: peer communication.

Pillar  A simple key-value store for user-defined data to be made available to a minion. Often used to store and distribute sensitive data to minions. See also: Pillar, list of Pillar modules.

Proxy Minion  A minion which can control devices that are unable to run a Salt minion locally, such as routers and switches.

PyDSL  A Pythonic domain-specific-language used as a Salt renderer. PyDSL can be used in cases where adding pure Python into SLS files is beneficial. See also: PyDSL.

Reactor  An interface for listening to events and defining actions that Salt should taken upon receipt of given events. See also: Reactor.

Render Pipe  Allows SLS files to be rendered by multiple renderers, with each renderer receiving the output of the previous. See also: composing renderers.

Renderer  Responsible for translating a given data serialization format such as YAML or JSON into a Python data structure that can be consumed by Salt. See also: list of renderers.

Returner  Allows for the results of a Salt command to be sent to a given data-store such as a database or log file for archival. See also: list of returners.

Roster  A flat-file list of target hosts. (Currently only used by salt-ssh.)

Runner Module  A module containing a set of runner functions. See also: list of runner modules.

Runner Function  A function which is is called by the salt-run command and executes on the master instead of on a minion. See also: Runner Module.

Salt Cloud  A suite of tools used to create and deploy systems on many hosted cloud providers. See also: salt-cloud.

Salt SSH  A configuration management and remote orchestration system that does not require that any software besides SSH be installed on systems to be controlled.

Salt Thin  A subset of the normal Salt distribution that does not include any transport routines. A Salt Thin bundle can be dropped onto a host and used directly without any requirement that the host be connected to a network. Used by Salt SSH. See also: thin runner.

Salt Virt  Used to manage the creation and deployment of virtual machines onto a set of host machines. Often used to create and deploy private clouds. See also: virt runner.
SLS Module  Contains a set of state declarations.

State Compiler  Translates highdata into lowdata.

State Declaration  A data structure which contains a unique ID and describes one or more states of a system such as ensuring that a package is installed or a user is defined. See also: highstate structure.

State Function  A function contained inside a state module which can manages the application of a particular state to a system. State functions frequently call out to one or more execution modules to perform a given task.

State Module  A module which contains a set of state functions. See also: list of state modules.

State Run  The application of a set of states on a set of systems.

Syndic  A forwarder which can relay messages between tiered masters. See also: Syndic.

Target  Minion(s) to which a given salt command will apply. See also: targeting.

Top File  Determines which SLS files should be applied to various systems and organizes those groups of systems into environments. See also: top file, list of master top modules.

__virtual__  A function in a module that is called on module load to determine whether or not the module should be available to a minion. This function commonly contains logic to determine if all requirements for a module are available, such as external libraries.

Worker  A master process which can send notices and receive replies from minions. See also: worker_threads.
