We're not just talking about NaCl.

1.1 The 30 second summary

Salt is:

- a configuration management system, capable of maintaining remote nodes in defined states (for example, ensuring that specific packages are installed and specific services are running)
- a distributed remote execution system used to execute commands and query data on remote nodes, either individually or by arbitrary selection criteria

It was developed in order to bring the best solutions found in the world of remote execution together and make them better, faster, and more malleable. Salt accomplishes this through its ability to handle large loads of information, and not just dozens but hundreds and even thousands of individual servers quickly through a simple and manageable interface.

1.2 Simplicity

Providing versatility between massive scale deployments and smaller systems may seem daunting, but Salt is very simple to set up and maintain, regardless of the size of the project. The architecture of Salt is designed to work with any number of servers, from a handful of local network systems to international deployments across different data centers. The topology is a simple server/client model with the needed functionality built into a single set of daemons. While the default configuration will work with little to no modification, Salt can be fine tuned to meet specific needs.

1.3 Parallel execution

The core functions of Salt:

- enable commands to remote systems to be called in parallel rather than serially
- use a secure and encrypted protocol
- use the smallest and fastest network payloads possible
- provide a simple programming interface

Salt also introduces more granular controls to the realm of remote execution, allowing systems to be targeted not just by hostname, but also by system properties.
1.4 Building on proven technology

Salt takes advantage of a number of technologies and techniques. The networking layer is built with the excellent ZeroMQ networking library, so the Salt daemon includes a viable and transparent AMQ broker. Salt uses public keys for authentication with the master daemon, then uses faster AES encryption for payload communication; authentication and encryption are integral to Salt. Salt takes advantage of communication via msgpack, enabling fast and light network traffic.

1.5 Python client interface

In order to allow for simple expansion, Salt execution routines can be written as plain Python modules. The data collected from Salt executions can be sent back to the master server, or to any arbitrary program. Salt can be called from a simple Python API, or from the command line, so that Salt can be used to execute one-off commands as well as operate as an integral part of a larger application.

1.6 Fast, flexible, scalable

The result is a system that can execute commands at high speed on target server groups ranging from one to very many servers. Salt is very fast, easy to set up, amazingly malleable and provides a single remote execution architecture that can manage the diverse requirements of any number of servers. The Salt infrastructure brings together the best of the remote execution world, amplifies its capabilities and expands its range, resulting in a system that is as versatile as it is practical, suitable for any network.

1.7 Open

Salt is developed under the Apache 2.0 license, and can be used for open and proprietary projects. Please submit your expansions back to the Salt project so that we can all benefit together as Salt grows. Please feel free to sprinkle Salt around your systems and let the deliciousness come forth.

1.8 Salt Community

Join the Salt!

There are many ways to participate in and communicate with the Salt community.

Salt has an active IRC channel and a mailing list.

1.9 Mailing List

Join the salt-users mailing list. It is the best place to ask questions about Salt and see what’s going on with Salt development! The Salt mailing list is hosted by Google Groups. It is open to new members.

https://groups.google.com/forum/#!forum/salt-users

There is also a low-traffic list used to announce new releases called salt-announce

https://groups.google.com/forum/#!forum/salt-announce
1.10 IRC

The #salt IRC channel is hosted on the popular Freenode network. You can use the Freenode webchat client right from your browser.

Logs of the IRC channel activity are being collected courtesy of Moritz Lenz.

If you wish to discuss the development of Salt itself join us in #salt-devel.

1.11 Follow on GitHub

The Salt code is developed via GitHub. Follow Salt for constant updates on what is happening in Salt development:
https://github.com/saltstack/salt

1.12 Blogs

SaltStack Inc. keeps a blog with recent news and advancements:
http://www.saltstack.com/blog/

Thomas Hatch also shares news and thoughts on Salt and related projects in his personal blog The Red45:
http://red45.wordpress.com/

1.13 Example Salt States

The official salt-states repository is: https://github.com/saltstack/salt-states

A few examples of salt states from the community:

1.16 Hack the Source

If you want to get involved with the development of source code or the documentation efforts, please review the 
*hacking section*!
Installation

See also:

*Installing Salt for development* and contributing to the project.

## 2.1 Quick Install

On most distributions, you can set up a Salt Minion with the Salt Bootstrap.

## 2.2 Platform-specific Installation Instructions

These guides go into detail how to install Salt on a given platform.

### 2.2.1 Arch Linux

**Installation**

Salt (stable) is currently available via the Arch Linux Official repositories. There are currently -git packages available in the Arch User repositories (AUR) as well.

**Stable Release**

Install Salt stable releases from the Arch Linux Official repositories as follows:

```
pacman -S salt-zmq
```

To install Salt stable releases using the RAET protocol, use the following:

```
pacman -S salt-raet
```

**Note:** transports

Unlike other Linux distributions, please be aware that Arch Linux’s package manager pacman defaults to RAET as the Salt transport. If you want to use ZeroMQ instead, make sure to enter the associated number for the salt-zmq repository when prompted.
Tracking development

To install the bleeding edge version of Salt (may include bugs!), use the -git package. Installing the -git package as follows:

```
wget https://aur.archlinux.org/packages/sa/salt-git/salt-git.tar.gz
tar xf salt-git.tar.gz
cd salt-git/
makepkg -is
```

Note: `yaourt`

If a tool such as `Yaourt` is used, the dependencies will be gathered and built automatically.

The command to install salt using the `yaourt` tool is:

```
yaourt salt-git
```

Post-installation tasks

```
systemctl
```

Activate the Salt Master and/or Minion via `systemctl` as follows:

```
systemctl enable salt-master.service
systemctl enable salt-minion.service
```

Start the Master

Once you’ve completed all of these steps you’re ready to start your Salt Master. You should be able to start your Salt Master now using the command seen here:

```
systemctl start salt-master
```

Now go to the `Configuring Salt` page.

### 2.2.2 Debian Installation

#### Installation from the SaltStack Repository

Debian 8 packages are available in the SaltStack Debian repository.

To install using the SaltStack Debian repository:

1. Run the following command to import the SaltStack repository key:

   ```
   wget -O - https://repo.saltstack.com/apt/debian/SALTSTACK-GPG-KEY.pub | sudo apt-key add -
   ```

2. Add the following line to `/etc/apt/sources.list`:

   ```
   deb http://repo.saltstack.com/apt/debian jessie contrib
   ```

3. Run `sudo apt-get update`

4. Install the salt-minion, salt-master, or other Salt components:

   ```
   • apt-get install salt-master
   ```
- `apt-get install salt-minion`
- `apt-get install salt-ssh`
- `apt-get install salt-syndic`
- `apt-get install salt-cloud`

**Configure Apt**

Currently the latest packages for Debian Old Stable, Stable, and Unstable (Squeeze, Wheezy, and Sid) are published in our (saltstack.com) Debian repository.

**Squeeze (Old Old Stable)**

For squeeze, you will need to enable the Debian backports repository as well as the debian.saltstack.com repository. To do so, add the following to `/etc/apt/sources.list` or a file in `/etc/apt/sources.list.d`:

```
deb http://debian.saltstack.com/debian squeeze-saltstack main
deb http://backports.debian.org/debian-backports squeeze-backports main
```

**Wheezy (Old Stable)**

For wheezy, the following line is needed in either `/etc/apt/sources.list` or a file in `/etc/apt/sources.list.d`:

```
deb http://debian.saltstack.com/debian wheezy-saltstack main
```

**Jessie (Stable)**

For jessie, the following line is needed in either `/etc/apt/sources.list` or a file in `/etc/apt/sources.list.d`:

```
deb http://debian.saltstack.com/debian jessie-saltstack main
```

**Sid (Unstable)**

For sid, the following line is needed in either `/etc/apt/sources.list` or a file in `/etc/apt/sources.list.d`:

```
deb http://debian.saltstack.com/debian unstable main
```

**Import the repository key.**

You will need to import the key used for signing.

```
wget -q -O- "http://debian.saltstack.com/debian-salt-team-joehealy.gpg.key" | apt-key add -
```

**Note:** You can optionally verify the key integrity with `sha512sum` using the public key signature shown here. E.g:
echo "b782969447140d5553e31e9701be13ca11cc0a7ed5fe2b30ac8b491567560ee62f834772b5b90d735e1f7ecc2384a5c1a20045f52861c417f50b68dd5ff4660e6 debian-salt-team-joehealy.gpg.key"

Update the package database

apt-get update

Install packages

Install the Salt master, minion, or syndic from the repository with the apt-get command. These examples each install one daemon, but more than one package name may be given at a time:

apt-get install salt-master

apt-get install salt-minion

apt-get install salt-syndic

Post-installation tasks

Now, go to the Configuring Salt page.

2.2.3 Fedora

Beginning with version 0.9.4, Salt has been available in the primary Fedora repositories and EPEL. It is installable using yum. Fedora will have more up to date versions of Salt than other members of the Red Hat family, which makes it a great place to help improve Salt!

WARNING: Fedora 19 comes with systemd 204. Systemd has known bugs fixed in later revisions that prevent the salt-master from starting reliably or opening the network connections that it needs to. It’s not likely that a salt-master will start or run reliably on any distribution that uses systemd version 204 or earlier. Running salt-minions should be OK.

Installation

Salt can be installed using yum and is available in the standard Fedora repositories.

Stable Release

Salt is packaged separately for the minion and the master. It is necessary only to install the appropriate package for the role the machine will play. Typically, there will be one master and multiple minions.

yum install salt-master
yum install salt-minion
Installing from `updates-testing`

When a new Salt release is packaged, it is first admitted into the `updates-testing` repository, before being moved to the stable repo.

To install from `updates-testing`, use the `enablerepo` argument for `yum`:

```
yum --enablerepo=updates-testing install salt-master
yum --enablerepo=updates-testing install salt-minion
```

Installation Using `pip`

Since Salt is on PyPI, it can be installed using pip, though most users prefer to install using a package manager.

Installing from pip has a few additional requirements:

- Install the group `Development Tools`, `dnf groupinstall 'Development Tools'
- Install the `zeromq-devel` package if it fails on linking against that afterwards as well.

A pip install does not make the init scripts or the `/etc/salt` directory, and you will need to provide your own systemd service unit.

Installation from pip:

```
pip install salt
```

**Warning:** If installing from pip (or from source using `setup.py install`), be advised that the `yum-utils` package is needed for Salt to manage packages. Also, if the Python dependencies are not already installed, then you will need additional libraries/tools installed to build some of them. More information on this can be found [here](#).

Post-installation tasks

**Master**

To have the Master start automatically at boot time:

```
systemctl enable salt-master.service
```

To start the Master:

```
systemctl start salt-master.service
```

**Minion**

To have the Minion start automatically at boot time:

```
systemctl enable salt-minion.service
```

To start the Minion:

```
systemctl start salt-minion.service
```

Now go to the *Configuring Salt* page.
2.2.4 FreeBSD

Salt was added to the FreeBSD ports tree Dec 26th, 2011 by Christer Edwards <christer.edwards@gmail.com>. It has been tested on FreeBSD 7.4, 8.2, 9.0, 9.1, 10.0 and later releases.

Installation

Salt is available in binary package form from both the FreeBSD pkgng repository or directly from SaltStack. The instructions below outline installation via both methods:

FreeBSD repo

The FreeBSD pkgng repository is preconfigured on systems 10.x and above. No configuration is needed to pull from these repositories.

```
pkg install py27-salt
```

These packages are usually available within a few days of upstream release.

SaltStack repo

SaltStack also hosts internal binary builds of the Salt package, available from http://repo.saltstack.org/freebsd/. To make use of this repository, add the following file to your system:

```
/usr/local/etc/pkg/repos/saltstack.conf:

saltstack: {
    url: "http://repo.saltstack.com/freebsd/${ABI}/",
    mirror_type: "http",
    enabled: yes
    priority: 10
}
```

You should now be able to install Salt from this new repository:

```
pkg install py27-salt
```

These packages are usually available earlier than upstream FreeBSD. Also available are release candidates and development releases. Use these pre-release packages with caution.

Post-installation tasks

Master

Copy the sample configuration file:

```
cp /usr/local/etc/salt/master.sample /usr/local/etc/salt/master
```

rc.conf

Activate the Salt Master in /etc/rc.conf:

```
sysrc salt_master_enable="YES"
```
Start the Master

Start the Salt Master as follows:

```
service salt_master start
```

Minion

Copy the sample configuration file:

```
cp /usr/local/etc/salt/minion.sample /usr/local/etc/salt/minion
```

Activate the Salt Minion in `/etc/rc.conf`:

```
sysrc salt_minion_enable="YES"
```

Start the Minion

Start the Salt Minion as follows:

```
service salt_minion start
```

Now go to the Configuring Salt page.

### 2.2.5 Gentoo

Salt can be easily installed on Gentoo via Portage:

```
emerge app-admin/salt
```

Post-installation tasks

Now go to the Configuring Salt page.

### 2.2.6 OpenBSD

Salt was added to the OpenBSD ports tree on Aug 10th 2013. It has been tested on OpenBSD 5.5 onwards.

Salt is dependent on the following additional ports. These will be installed as dependencies of the `sysutils/salt` port:

```
/net/py-msgpack
/net/py-zmq
/security/py-M2Crypto
/security/py-crypto
/textproc/py-MarkupSafe
/textproc/py-yaml
/www/py-jinja2
/www/py-requests
```

Installation

To install Salt from the OpenBSD pkg repo, use the command:
pkg_add salt

Post-installation tasks

Master
To have the Master start automatically at boot time:

```bash
rcctl enable salt_master
```

To start the Master:

```bash
rcctl start salt_master
```

Minion
To have the Minion start automatically at boot time:

```bash
rcctl enable salt_minion
```

To start the Minion:

```bash
rcctl start salt_minion
```

Now go to the Configuring Salt page.

2.2.7 OS X

Dependency Installation

It should be noted that Homebrew explicitly discourages the use of sudo:

Homebrew is designed to work without using sudo. You can decide to use it but we strongly recommend not to do so. If you have used sudo and run into a bug then it is likely to be the cause. Please don’t file a bug report unless you can reproduce it after reinstalling Homebrew from scratch without using sudo

So when using Homebrew, if you want support from the Homebrew community, install this way:

```bash
brew install saltstack
```

When using MacPorts, install this way:

```bash
sudo port install salt
```

When only using the OS X system’s pip, install this way:

```bash
sudo pip install salt
```

Salt-Master Customizations

To run salt-master on OS X, the root user maxfiles limit must be increased:

Note: On OS X 10.10 (Yosemite) and higher, maxfiles should not be adjusted. The default limits are sufficient in all but the most extreme scenarios. Overriding these values with the setting below will cause system instability!
sudo launchctl limit maxfiles 4096 8192

And sudo add this configuration option to the /etc/salt/master file:

```
max_open_files: 8192
```

Now the salt-master should run without errors:

`sudo salt-master --log-level=all`

Post-installation tasks

Now go to the Configuring Salt page.

## 2.2.8 RHEL / CentOS / Scientific Linux / Amazon Linux / Oracle Linux

### Installation from the SaltStack Repository

To install using the SaltStack yum repository:

1. Run one of the following commands based on your version to import the SaltStack repository key:

   **Version 7:**
   
   ```bash
   wget https://repo.saltstack.com/yum/rhel7/SALTSTACK-GPG-KEY.pub
   rpm --import SALTSTACK-GPG-KEY.pub
   rm -f SALTSTACK-GPG-KEY.pub
   ```

   **Version 6:**
   
   ```bash
   wget https://repo.saltstack.com/yum/rhel6/SALTSTACK-GPG-KEY.pub
   rpm --import SALTSTACK-GPG-KEY.pub
   rm -f SALTSTACK-GPG-KEY.pub
   ```

   **Version 5:**
   
   ```bash
   wget https://repo.saltstack.com/yum/rhel5/SALTSTACK-EL5-GPG-KEY.pub
   rpm --import SALTSTACK-EL5-GPG-KEY.pub
   rm -f SALTSTACK-EL5-GPG-KEY.pub
   ```

2. Save the following file to `/etc/yum.repos.d/saltstack.repo`:

   **Versions 6 / 7:**
   
   ```
   ####################
   # Enable SaltStack's package repository
   [saltstack-repo]
   name=SaltStack repo for RHEL/CentOS $releasever
   baseurl=https://repo.saltstack.com/yum/rhel$releasever
   enabled=1
   gpgcheck=1
   gpgkey=https://repo.saltstack.com/yum/rhel$releasever/SALTSTACK-GPG-KEY.pub
   ```

   **Version 5:**
   
   ```
   ```
### Enable SaltStack's package repository

```
[saltstack-repo]
name=SaltStack repo for RHEL/CentOS $releasever
baseurl=https://repo.saltstack.com/yum/rhel$releasever
enabled=1
gpgcheck=1
gpgkey=https://repo.saltstack.com/yum/rhel$releasever/SALTSTACK-EL5-GPG-KEY.pub
```

3. Run `sudo yum clean expire-cache`
4. Run `sudo yum update`
5. Install the salt-minion, salt-master, or other Salt components:
   • `yum install salt-master`
   • `yum install salt-minion`
   • `yum install salt-ssh`
   • `yum install salt-syndic`
   • `yum install salt-cloud`

**Note:** EPEL support is not required when installing using the SaltStack repository on Red Hat 6 and 7. EPEL must be enabled when installing on Red Hat 5.

### Installation from Repository

**RHEL/CentOS 6 and 7, Scientific Linux, etc.**

**Warning:** Salt 2015.8 requires `python-crypto` 2.6.1 or higher, and `python-tornado` version 4.2.1 or higher. These packages are not currently available in EPEL for Red Hat 5 and 6. You must install these dependencies from another location or use the SaltStack repository documented above.

Beginning with version 0.9.4, Salt has been available in EPEL. It is installable using yum. Salt should work properly with all mainstream derivatives of RHEL, including CentOS, Scientific Linux, Oracle Linux and Amazon Linux. Report any bugs or issues on the [issue tracker](https://github.com/saltstack/salt/issues).

On RHEL6, the proper Jinja package `python-jinja2` was moved from EPEL to the `RHEL Server Optional Channel`. Verify this repository is enabled before installing salt on RHEL6.

**RHEL/CentOS 5**

Due to the removal of some of Salt's dependencies from EPEL5, we recommend using the SaltStack Repository or the repository on Fedora COPR.

**Enabling EPEL** If the EPEL repository is not installed on your system, you can download the RPM from [here](https://fedorahosted.org/releases/epel/) for RHEL/CentOS 6 (or [here](https://fedorahosted.org/releases/epel/) for RHEL/CentOS 7) and install it using the following command:

```
rpm -Uvh epel-release-X-Y.rpm
```

Replace `epel-release-X-Y.rpm` with the appropriate filename.
Installing Stable Release  Salt is packaged separately for the minion and the master. It is necessary only to install the appropriate package for the role the machine will play. Typically, there will be one master and multiple minions.

On the salt-master, run this:

```
yum install salt-master
```

On each salt-minion, run this:

```
yum install salt-minion
```

Installing from `epel-testing`  When a new Salt release is packaged, it is first admitted into the `epel-testing` repository, before being moved to the stable repo.

To install from `epel-testing`, use the `enablerepo` argument for `yum`:

```
yum --enablerepo=epel-testing install salt-minion
```

Installation Using `pip`  Since Salt is on PyPI, it can be installed using pip, though most users prefer to install using RPMs (which can be installed from EPEL).

Installing from pip has a few additional requirements:

- Install the group `Development Tools`, `yum groupinstall 'Development Tools'`
- Install the `zeromq-devel` package if it fails on linking against that afterwards as well.

A pip install does not make the init scripts or the `/etc/salt` directory, and you will need to provide your own systemd service unit.

Installation from pip:

```
pip install salt
```

**Warning:** If installing from pip (or from source using `setup.py install`), be advised that the `yum-utils` package is needed for Salt to manage packages. Also, if the Python dependencies are not already installed, then you will need additional libraries/tools installed to build some of them. More information on this can be found [here](#).

**ZeroMQ 4**

We recommend using ZeroMQ 4 where available. SaltStack provides ZeroMQ 4.0.4 and pyzmq 14.3.1 in the SaltStack Repository as well as a COPR repository.

If this repo is added before Salt is installed, then installing either `salt-master` or `salt-minion` will automatically pull in ZeroMQ 4.0.4, and additional states to upgrade ZeroMQ and pyzmq are unnecessary.

**Warning:** RHEL/CentOS 5 Users Using COPR repos on RHEL/CentOS 5 requires that the `python-hashlib` package be installed. Not having it present will result in checksum errors because YUM will not be able to process the SHA256 checksums used by COPR.

**Note:** For RHEL/CentOS 5 installations, if using the new repository to install Salt (as detailed above), then it is not necessary to enable the zeromq4 COPR, as the new EL5 repository includes ZeroMQ 4.
Package Management

Salt’s interface to yum makes heavy use of the repoquery utility, from the yum-utils package. This package will be installed as a dependency if salt is installed via EPEL. However, if salt has been installed using pip, or a host is being managed using salt-ssh, then as of version 2014.7.0 yum-utils will be installed automatically to satisfy this dependency.

Post-installation tasks

Master

To have the Master start automatically at boot time:

chkconfig salt-master on

To start the Master:

service salt-master start

Minion

To have the Minion start automatically at boot time:

chkconfig salt-minion on

To start the Minion:

service salt-minion start

Now go to the Configuring Salt page.

2.2.9 Solaris

Salt was added to the OpenCSW package repository in September of 2012 by Romeo Theriault <romeot@hawaii.edu> at version 0.10.2 of Salt. It has mainly been tested on Solaris 10 (sparc), though it is built for and has been tested minimally on Solaris 10 (x86), Solaris 9 (sparc/x86) and 11 (sparc/x86). (Please let me know if you’re using it on these platforms!) Most of the testing has also just focused on the minion, though it has verified that the master starts up successfully on Solaris 10.

Comments and patches for better support on these platforms is very welcome.

As of version 0.10.4, Solaris is well supported under salt, with all of the following working well:

1. remote execution
2. grain detection
3. service control with SMF
4. `pkg` states with `pkgadd` and `pkgutil` modules
5. cron modules/states
6. user and group modules/states
7. shadow password management modules/states

Salt is dependent on the following additional packages. These will automatically be installed as dependencies of the py_salt package:

- py_yam1
• py_pyzmq
• py_jinja2
• py_msgpack_python
• py_m2crypto
• py_crypto
• python

**Installation**

To install Salt from the OpenCSW package repository you first need to install `pkgutil` assuming you don't already have it installed:

On Solaris 10:
```
pkgadd -d http://get.opencsw.org/now
```

On Solaris 9:
```
wget http://mirror.opencsw.org/opencsw/pkgutil.pkg
pkgadd -d pkgutil.pkg all
```

Once `pkgutil` is installed you'll need to edit it's config file `/etc/opt/csw/pkgutil.conf` to point it at the unstable catalog:

```
- #mirror=http://mirror.opencsw.org/opencsw/testing
+ mirror=http://mirror.opencsw.org/opencsw/unstable
```

OK, time to install salt.

```
# Update the catalog
root> /opt/csw/bin/pkgutil -U
# Install salt
root> /opt/csw/bin/pkgutil -i -y py_salt
```

**Minion Configuration**

Now that salt is installed you can find it's configuration files in `/etc/opt/csw/salt/`.

You'll want to edit the minion config file to set the name of your salt master server:

```
- #master: salt
+ master: your-salt-server
```

If you would like to use `pkgutil` as the default package provider for your Solaris minions, you can do so using the `providers` option in the minion config file.

You can now start the salt minion like so:

On Solaris 10:
```
svcadm enable salt-minion
```

On Solaris 9:
/etc/init.d/salt-minion start

You should now be able to log onto the salt master and check to see if the salt-minion key is awaiting acceptance:
salt-key -l un

Accept the key:
salt-key -a <your-salt-minion>

Run a simple test against the minion:
salt '<<your-salt-minion>>' test.ping

Troubleshooting

Logs are in /var/log/salt

2.2.10 Ubuntu Installation

Add repository

The latest packages for Ubuntu are published in the saltstack PPA. If you have the add-apt-repository utility, you can add the repository and import the key in one step:
sudo add-apt-repository ppa:saltstack/salt

In addition to the main repository, there are secondary repositories for each individual major release. These repositories receive security and point releases but will not upgrade to any subsequent major release. There are currently four available repos: salt16, salt17, salt2014-1, salt2014-7. For example to follow 2014.7.x releases:
sudo add-apt-repository ppa:saltstack/salt2014-7

add-apt-repository: command not found?
The add-apt-repository command is not always present on Ubuntu systems. This can be fixed by installing python-software-properties:
sudo apt-get install python-software-properties

The following may be required as well:
sudo apt-get install software-properties-common

Note that since Ubuntu 12.10 (Raring Ringtail), add-apt-repository is found in the software-properties-common package, and is part of the base install. Thus, add-apt-repository should be able to be used out-of-the-box to add the PPA.

Alternately, manually add the repository and import the PPA key with these commands:
echo deb http://ppa.launchpad.net/saltstack/salt/ubuntu `lsb_release -sc` main | sudo tee /etc/apt/sources.list.d/saltstack.list
wget -q -O- "http://keyserver.ubuntu.com:11371/pks/lookup?op=get&search=0x4759FA960E27C0A6" | sudo apt-key add -

After adding the repository, update the package management database:
Install packages

Install the Salt master, minion, or syndic from the repository with the apt-get command. These examples each install one daemon, but more than one package name may be given at a time:

```
sudo apt-get install salt-master
```

```
sudo apt-get install salt-minion
```

```
sudo apt-get install salt-syndic
```

Some core components are packaged separately in the Ubuntu repositories. These should be installed as well: salt-cloud, salt-ssh, salt-api

```
sudo apt-get install salt-cloud
```

```
sudo apt-get install salt-ssh
```

```
sudo apt-get install salt-api
```

ZeroMQ 4

ZeroMQ 4 is available by default for Ubuntu 14.04 and newer. However, for Ubuntu 12.04 LTS, starting with Salt version 2014.7.5, ZeroMQ 4 is included with the Salt installation package and nothing additional needs to be done.

Post-installation tasks

Now go to the Configuring Salt page.

2.2.11 Windows

Salt has full support for running the Salt Minion on Windows.

There are no plans for the foreseeable future to develop a Salt Master on Windows. For now you must run your Salt Master on a supported operating system to control your Salt Minions on Windows.

Many of the standard Salt modules have been ported to work on Windows and many of the Salt States currently work on Windows, as well.

Windows Installer

Salt Minion Windows installers can be found here. The output of `md5sum <salt minion exe>` should match the contents of the corresponding md5 file.

Latest stable build from the selected branch:

Earlier builds from supported branches

Archived builds from unsupported branches
Note: The installation executable installs dependencies that the Salt minion requires.

The 64bit installer has been tested on Windows 7 64bit and Windows Server 2008R2 64bit. The 32bit installer has been tested on Windows 2003 Server 32bit. Please file a bug report on our GitHub repo if issues for other platforms are found.

The installer asks for 2 bits of information; the master hostname and the minion name. The installer will update the minion config with these options and then start the minion.

The `salt-minion` service will appear in the Windows Service Manager and can be started and stopped there or with the command line program `sc` like any other Windows service.

If the minion won't start, try installing the Microsoft Visual C++ 2008 x64 SP1 redistributable. Allow all Windows updates to run salt-minion smoothly.

Silent Installer Options

The installer can be run silently by providing the `/S` option at the command line. The options `/master` and `/minion-name` allow for configuring the master hostname and minion name, respectively. Here's an example of using the silent installer:

```
Salt-Minion-0.17.8-Setup-amd64.exe /S /master=yoursaltmaster /minion-name=yourminionname
```

Setting up a Windows build environment

This document will explain how to set up a development environment for salt on Windows. The development environment allows you to work with the source code to customize or fix bugs. It will also allow you to build your own installation.

The Easy Way

Prerequisite Software To do this the easy way you only need to install Git for Windows.

Create the Build Environment

1. Clone the Salt-Windows-Dev repo from github.
   
   Open a command line and type:
   ```
   git clone https://github.com/saltstack/salt-windows-dev
   ```

2. Build the Python Environment
   
   Go into the salt-windows-dev directory. Right-click the file named `dev_env.ps1` and select Run with Powershell
   
   If you get an error, you may need to change the execution policy.
   
   Open a powershell window and type the following:
   ```
   Set-ExecutionPolicy RemoteSigned
   ```

   This will download and install Python with all the dependencies needed to develop and build salt.
3. Build the Salt Environment

Right-click on the file named `dev_env_salt.ps1` and select **Run with Powershell**

This will clone salt into `C:\Salt-Dev\salt` and set it to the 2015.5 branch. You could optionally run the command from a powershell window with a `-Version` switch to pull a different version. For example:

```
dev_env_salt.ps1 -Version '2014.7'
```

To view a list of available branches and tags, open a command prompt in your `C:Salt-Dev\salt` directory and type:

```
git branch -a  
git tag -n
```

**The Hard Way**

**Prerequisite Software**  Install the following software:

1. Git for Windows
2. Nullsoft Installer

Download the Prerequisite zip file for your CPU architecture from the SaltStack download site:

- Salt32.zip
- Salt64.zip

These files contain all software required to build and develop salt. Unzip the contents of the file to `C:\Salt-Dev\temp`.

**Create the Build Environment**

1. Build the Python Environment
   - Install Python:
     
     Browse to the `C:\Salt-Dev\temp` directory and find the Python installation file for your CPU Architecture under the corresponding subfolder. Double-click the file to install python.
     
     Make sure the following are in your `PATH` environment variable:

     ```
     C:\Python27
     C:\Python27\Scripts
     ```

   - Install Pip
     
     Open a command prompt and navigate to `C:\Salt-Dev\temp` Run the following command:

     ```
     python get-pip.py
     ```

   - Easy Install compiled binaries.
     
     M2Crypto, PyCrypto, and PyWin32 need to be installed using Easy Install. Open a command prompt and navigate to `C:\Salt-Dev\temp\<cpuarch>`. Run the following commands:

     ```
     easy_install -Z <M2Crypto file name>
     easy_install -Z <PyCrypto file name>
     easy_install -Z <PyWin32 file name>
     ```

2.2. Platform-specific Installation Instructions
Note: You can type the first part of the file name and then press the tab key to auto-complete the name of the file.

- Pip Install Additional Prerequisites

All remaining prerequisites need to be pip installed. These prerequisites are as follow:

- MarkupSafe
- Jinja
- MsgPack
- PSUtil
- PyYAML
- PyZMQ
- WMI
- Requests
- Certifi

Open a command prompt and navigate to `C:\Salt-Dev\temp`. Run the following commands:

```
pip install <cpuarch>\<MarkupSafe file name>
pip install <Jinja file name>
pip install <cpuarch>\<MsgPack file name>
pip install <cpuarch>\<psutil file name>
pip install <cpuarch>\<PyYAML file name>
pip install <cpuarch>\<pyzmq file name>
pip install <WMI file name>
pip install <requests file name>
pip install <certifi file name>
```

2. Build the Salt Environment

- Clone Salt

Open a command prompt and navigate to `C:\Salt-Dev`. Run the following command to clone salt:

```
git clone https://github.com/saltstack/salt
```

- Checkout Branch

Checkout the branch or tag of salt you want to work on or build. Open a command prompt and navigate to `C:\Salt-Dev\salt`. Get a list of available tags and branches by running the following commands:

```
git fetch --all
```

To view a list of available branches:
```
git branch -a
```

To view a list of available tags:
```
git tag -n
```

Checkout the branch or tag by typing the following command:

```
git checkout <branch/tag name>
```
• Clean the Environment

When switching between branches residual files can be left behind that will interfere with the functionality of salt. Therefore, after you check out the branch you want to work on, type the following commands to clean the salt environment:

Developing with Salt

There are two ways to develop with salt. You can run salt’s setup.py each time you make a change to source code or you can use the setup tools develop mode.

Configure the Minion

Both methods require that the minion configuration be in the C:\salt directory. Copy the conf and var directories from C:\Salt-Dev\salt\pkg\windows\buildenv to C:\salt. Now go into the C:\salt\conf directory and edit the file name minion (no extension). You need to configure the master and id parameters in this file. Edit the following lines:

master: <ip or name of your master>
id: <name of your minion>

Setup.py Method

Go into the C:\Salt-Dev\salt directory from a cmd prompt and type:

```bash
python setup.py install --force
```

This will install python into your python installation at C:\Python27. Everytime you make an edit to your source code, you’ll have to stop the minion, run the setup, and start the minion.

To start the salt-minion go into C:\Python27\Scripts from a cmd prompt and type:

```bash
salt-minion
```

For debug mode type:

```bash
salt-minion -l debug
```

To stop the minion press Ctrl+C.

Setup Tools Develop Mode (Preferred Method)

To use the Setup Tools Develop Mode go into C:\Salt-Dev\salt from a cmd prompt and type:

```bash
pip install -e .
```

This will install pointers to your source code that resides at C:\Salt-Dev\salt. When you edit your source code you only have to restart the minion.

Build the windows installer

This is the method of building the installer as of version 2014.7.4.
Clean the Environment

Make sure you don’t have any leftover salt files from previous versions of salt in your Python directory.
1. Remove all files that start with salt in the C:\Python27\Scripts directory
2. Remove all files and directorys that start with salt in the C:\Python27\Lib\site-packages directory

Install Salt

Install salt using salt’s setup.py. From the C:\Salt-Dev\salt directory type the following command:

```bash
python setup.py install --force
```

Build the Installer

From cmd prompt go into the C:\Salt-Dev\salt\pkg\windows directory. Type the following command for the branch or tag of salt you’re building:

```
BuildSalt.bat <branch or tag>
```

This will copy python with salt installed to the buildenv\bin directory, make it portable, and then create the windows installer. The .exe for the windows installer will be placed in the installer directory.

Testing the Salt minion

1. Create the directory C:salt (if it doesn’t exist already)
2. Copy the example conf and var directories from pkg/windows/buildenv/ into C:salt
3. Edit C:salt\conf\minion

```
master: ipaddress or hostname of your salt-master
```

4. Start the salt-minion

```
cd C:\Python27\Scripts
python salt-minion
```

5. On the salt-master accept the new minion’s key

```
sudo salt-key -A
```

This accepts all unaccepted keys. If you’re concerned about security just accept the key for this specific minion.

6. Test that your minion is responding

On the salt-master run:

```
sudo salt '*' test.ping
```

You should get the following response: {"your minion hostname": True}
Single command bootstrap script

On a 64 bit Windows host the following script makes an unattended install of salt, including all dependencies:

```powershell
# (All in one line.)
```

You can execute the above command remotely from a Linux host using winexe:

```powershell
winexe -U "administrator" //fqdn "PowerShell (New-Object ......);"
```

For more info check http://csa-net.dk/salt

Packages management under Windows 2003

On windows Server 2003, you need to install optional component `"wmi windows installer provider"` to have full list of installed packages. If you don't have this, salt-minion can't report some installed softwares.

2.2.12 SUSE Installation

With openSUSE 13.2, Salt 2014.1.11 is available in the primary repositories. The devel:language:python repo will have more up to date versions of salt, all package development will be done there.

Installation

Salt can be installed using `zypper` and is available in the standard openSUSE repositories.

Stable Release

Salt is packaged separately for the minion and the master. It is necessary only to install the appropriate package for the role the machine will play. Typically, there will be one master and multiple minions.

```bash
zypper install salt-master
zypper install salt-minion
```

Post-installation tasks openSUSE

Master

To have the Master start automatically at boot time:

```bash
systemctl enable salt-master.service
```

To start the Master:

```bash
systemctl start salt-master.service
```
Minion

To have the Minion start automatically at boot time:

```bash
systemctl enable salt-minion.service
```

To start the Minion:

```bash
systemctl start salt-minion.service
```

Post-installation tasks SLES

Master

To have the Master start automatically at boot time:

```bash
chkconfig salt-master on
```

To start the Master:

```bash
rcsalt-master start
```

Minion

To have the Minion start automatically at boot time:

```bash
chkconfig salt-minion on
```

To start the Minion:

```bash
rcsalt-minion start
```

Unstable Release

openSUSE

For openSUSE Factory run the following as root:

```bash
zypper refresh
zypper install salt salt-minion salt-master
```

For openSUSE 13.2 run the following as root:

```bash
zypper refresh
zypper install salt salt-minion salt-master
```

For openSUSE 13.1 run the following as root:

```bash
zypper refresh
zypper install salt salt-minion salt-master
```

For bleeding edge python Factory run the following as root:

```bash
zypper refresh
zypper install salt salt-minion salt-master
```
Suse Linux Enterprise

For SLE 12 run the following as root:

```
zypper refresh
zypper install salt salt-minion salt-master
```

For SLE 11 SP3 run the following as root:

```
zypper refresh
zypper install salt salt-minion salt-master
```

For SLE 11 SP2 run the following as root:

```
zypper refresh
zypper install salt salt-minion salt-master
```

Now go to the Configuring Salt page.

### 2.3 Dependencies

Salt should run on any Unix-like platform so long as the dependencies are met.

- **Python 2.6 >= 2.6 <3.0**
- **msgpack-python** - High-performance message interchange format
- **YAML** - Python YAML bindings
- **Jinja2** - parsing Salt States (configurable in the master settings)
- **MarkupSafe** - Implements a XML/HTML/XHTML Markup safe string for Python
- **apache-libcloud** - Python lib for interacting with many of the popular cloud service providers using a unified API
- **Requests** - HTTP library

Depending on the chosen Salt transport, **ZeroMQ** or **RAET**, dependencies vary:

- **ZeroMQ**:
  - **ZeroMQ >= 3.2.0**
  - **pyzmq >= 2.2.0** - ZeroMQ Python bindings
  - **PyCrypto** - The Python cryptography toolkit
  - **M2Crypto** - "Me Too Crypto" - Python OpenSSL wrapper

- **RAET**:
  - **libnacl** - Python bindings to **libsodium**
  - **ioflo** - The flo programming interface raet and salt-raet is built on
  - **RAET** - The worlds most awesome UDP protocol

Salt defaults to the **ZeroMQ** transport, and the choice can be made at install time, for example:
python setup.py --salt-transport=raet install

This way, only the required dependencies are pulled by the setup script if need be.

If installing using pip, the --salt-transport install option can be provided like:

deploy

```
pip install --install-option="--salt-transport=raet" salt
```

2.4 Optional Dependencies

- **mako** - an optional parser for Salt States (configurable in the master settings)
- **gcc** - dynamic **Cython** module compiling

2.5 Upgrading Salt

When upgrading Salt, the master(s) should always be upgraded first. Backward compatibility for minions running newer versions of salt than their masters is not guaranteed.

Whenever possible, backward compatibility between new masters and old minions will be preserved. Generally, the only exception to this policy is in case of a security vulnerability.
3.1 Introduction

3.1.1 Salt Masterless Quickstart

Running a masterless salt-minion lets you use Salt’s configuration management for a single machine without calling out to a Salt master on another machine.

Since the Salt minion contains such extensive functionality it can be useful to run it standalone. A standalone minion can be used to do a number of things:

- Stand up a master server via States (Salting a Salt Master)
- Use salt-call commands on a system without connectivity to a master
- Masterless States, run states entirely from files local to the minion

It is also useful for testing out state trees before deploying to a production setup.

Bootstrap Salt Minion

The salt-bootstrap script makes bootstrapping a server with Salt simple for any OS with a Bourne shell:

```
curl -L https://bootstrap.saltstack.com -o install_salt.sh
sudo sh install_salt.sh
```

See the salt-bootstrap documentation for other one liners. When using Vagrant to test out salt, the Vagrant salt provisioner will provision the VM for you.

Telling Salt to Run Masterless

To instruct the minion to not look for a master, the file_client configuration option needs to be set in the minion configuration file. By default the file_client is set to remote so that the minion gathers file server and pillar data from the salt master. When setting the file_client option to local the minion is configured to not gather this data from the master.

```
file_client: local
```

Now the salt minion will not look for a master and will assume that the local system has all of the file and pillar resources.
Note: When running Salt in masterless mode, do not run the salt-minion daemon. Otherwise, it will attempt to connect to a master and fail. The salt-call command stands on its own and does not need the salt-minion daemon.

Create State Tree

Following the successful installation of a salt-minion, the next step is to create a state tree, which is where the SLS files that comprise the possible states of the minion are stored.

The following example walks through the steps necessary to create a state tree that ensures that the server has the Apache webserver installed.

Note: For a complete explanation on Salt States, see the tutorial.

1. Create the top.sls file:

```
/srv/salt/top.sls:
base:    
  '*':  
    - webserver
```

2. Create the webserver state tree:

```
/srv/salt/webserver.sls:
apache: # ID declaration
  pkg:   # state declaration
    - installed # function declaration
```

Note: The apache package has different names on different platforms, for instance on Debian/Ubuntu it is apache2, on Fedora/RHEL it is httpd and on Arch it is apache

The only thing left is to provision our minion using salt-call and the highstate command.

Salt-call

The salt-call command is used to run module functions locally on a minion instead of executing them from the master. Normally the salt-call command checks into the master to retrieve file server and pillar data, but when running standalone salt-call needs to be instructed to not check the master for this data:

```
salt-call --local state.highstate
```

The --local flag tells the salt-minion to look for the state tree in the local file system and not to contact a Salt Master for instructions.

To provide verbose output, use -l debug:

```
salt-call --local state.highstate -l debug
```

The minion first examines the top.sls file and determines that it is a part of the group matched by * glob and that the webserver SLS should be applied.

It then examines the webserver.sls file and finds the apache state, which installs the Apache package.

The minion should now have Apache installed, and the next step is to begin learning how to write more complex states.
3.2 Basics

3.2.1 Standalone Minion

Since the Salt minion contains such extensive functionality it can be useful to run it standalone. A standalone minion can be used to do a number of things:

- Use salt-call commands on a system without connectivity to a master
- Masterless States, run states entirely from files local to the minion

Note: When running Salt in masterless mode, do not run the salt-minion daemon. Otherwise, it will attempt to connect to a master and fail. The salt-call command stands on its own and does not need the salt-minion daemon.

Telling Salt Call to Run Masterless

The salt-call command is used to run module functions locally on a minion instead of executing them from the master. Normally the salt-call command checks into the master to retrieve file server and pillar data, but when running standalone salt-call needs to be instructed to not check the master for this data. To instruct the minion to not look for a master when running salt-call the `file_client` configuration option needs to be set. By default the `file_client` is set to `remote` so that the minion knows that file server and pillar data are to be gathered from the master. When setting the `file_client` option to `local` the minion is configured to not gather this data from the master.

```
file_client: local
```

Now the salt-call command will not look for a master and will assume that the local system has all of the file and pillar resources.

Running States Masterless

The state system can be easily run without a Salt master, with all needed files local to the minion. To do this the minion configuration file needs to be set up to know how to return file_roots information like the master. The `file_roots` setting defaults to `/srv/salt` for the base environment just like on the master:

```
file_roots:
  base:
    - /srv/salt
```

Now set up the Salt State Tree, top file, and SLS modules in the same way that they would be set up on a master. Now, with the `file_client` option set to `local` and an available state tree then calls to functions in the state module will use the information in the file_roots on the minion instead of checking in with the master.

Remember that when creating a state tree on a minion there are no syntax or path changes needed, SLS modules written to be used from a master do not need to be modified in any way to work with a minion.

This makes it easy to "script" deployments with Salt states without having to set up a master, and allows for these SLS modules to be easily moved into a Salt master as the deployment grows.

The declared state can now be executed with:

```
salt-call state.highstate
```

Or the salt-call command can be executed with the `--local` flag, this makes it unnecessary to change the configuration file:
salt-call state.highstate --local

External Pillars

*External pillars* are supported when running in masterless mode.

### 3.2.2 Opening the Firewall up for Salt

The Salt master communicates with the minions using an AES-encrypted ZeroMQ connection. These communications are done over TCP ports `4505` and `4506`, which need to be accessible on the master only. This document outlines suggested firewall rules for allowing these incoming connections to the master.

**Note:** No firewall configuration needs to be done on Salt minions. These changes refer to the master only.

#### Fedora 18 and beyond / RHEL 7 / CentOS 7

Starting with Fedora 18 **FirewallD** is the tool that is used to dynamically manage the firewall rules on a host. It has support for IPv4/6 settings and the separation of runtime and permanent configurations. To interact with FirewallD use the command line client `firewall-cmd`.

**firewall-cmd example:**

```
firewall-cmd --permanent --zone=<zone> --add-port=4505-4506/tcp
```

Please choose the desired zone according to your setup. Don't forget to reload after you made your changes.

```
firewall-cmd --reload
```

#### RHEL 6 / CentOS 6

The **lokkit** command packaged with some Linux distributions makes opening iptables firewall ports very simple via the command line. Just be careful to not lock out access to the server by neglecting to open the ssh port.

**lokkit example:**

```
```

The **system-config-firewall-tui** command provides a text-based interface to modifying the firewall.

**system-config-firewall-tui:**

```
system-config-firewall-tui
```

#### openSUSE

Salt installs firewall rules in `/etc/sysconfig/SuSEfirewall2.d/services/salt`. Enable with:

```
SuSEfirewall2 open
SuSEfirewall2 start
```
If you have an older package of Salt where the above configuration file is not included, the `SuSEfirewall2` command makes opening iptables firewall ports very simple via the command line.

**SuSEfirewall example:**

```bash
SuSEfirewall2 open EXT TCP 4505
SuSEfirewall2 open EXT TCP 4506
```

The firewall module in YaST2 provides a text-based interface to modifying the firewall.

**YaST2:**

```
yast2 firewall
```

**iptables**

Different Linux distributions store their `iptables` (also known as `netfilter`) rules in different places, which makes it difficult to standardize firewall documentation. Included are some of the more common locations, but your mileage may vary.

**Fedora / RHEL / CentOS:**

```
/etc/sysconfig/iptables
```

**Arch Linux:**

```
/etc/iptables/iptables.rules
```

**Debian**

Follow these instructions: [https://wiki.debian.org/iptables](https://wiki.debian.org/iptables)

Once you’ve found your firewall rules, you’ll need to add the two lines below to allow traffic on `tcp/4505` and `tcp/4506`:

```bash
-A INPUT -m state --state new -m tcp -p tcp --dport 4505 -j ACCEPT
-A INPUT -m state --state new -m tcp -p tcp --dport 4506 -j ACCEPT
```

**Ubuntu**

Salt installs firewall rules in `/etc/ufw/applications.d/salt.ufw`. Enable with:

```
ufw allow salt
```

**pf.conf**

The BSD-family of operating systems uses `packet filter (pf)`. The following example describes the additions to `pf.conf` needed to access the Salt master.

```bash
pass in on $int_if proto tcp from any to $int_if port 4505
pass in on $int_if proto tcp from any to $int_if port 4506
```

Once these additions have been made to the `pf.conf` the rules will need to be reloaded. This can be done using the `pfctl` command.

```
pfctl -vf /etc/pf.conf
```
3.2.3 Whitelist communication to Master

There are situations where you want to selectively allow Minion traffic from specific hosts or networks into your Salt Master. The first scenario which comes to mind is to prevent unwanted traffic to your Master out of security concerns, but another scenario is to handle Minion upgrades when there are backwards incompatible changes between the installed Salt versions in your environment.

Here is an example *Linux iptables* ruleset to be set on the Master:

```bash
# Allow Minions from these networks
-I INPUT -s 10.1.2.0/24 -p tcp -m multiport --dports 4505,4506 -j ACCEPT
-I INPUT -s 10.1.3.0/24 -p tcp -m multiport --dports 4505,4506 -j ACCEPT
# Allow Salt to communicate with Master on the loopback interface
-A INPUT -i lo -p tcp -m multiport --dports 4505,4506 -j ACCEPT
# Reject everything else
-A INPUT -p tcp -m multiport --dports 4505,4506 -j REJECT
```

Note: The important thing to note here is that the salt command needs to communicate with the listening network socket of salt-master on the loopback interface. Without this you will see no outgoing Salt traffic from the master, even for a simple `salt '*' test.ping`, because the salt client never reached the salt-master to tell it to carry out the execution.

3.2.4 Using cron with Salt

The Salt Minion can initiate its own highstate using the `salt-call` command.

```bash
$ salt-call state.highstate
```

This will cause the minion to check in with the master and ensure it is in the correct 'state'.

Use cron to initiate a highstate

If you would like the Salt Minion to regularly check in with the master you can use the venerable cron to run the `salt-call` command.

```bash
# PATH=/bin:/sbin:/usr/bin:/usr/sbin
00 00 * * * salt-call state.highstate
```

The above cron entry will run a highstate every day at midnight.

Note: Be aware that you may need to ensure the PATH for cron includes any scripts or commands that need to be executed.

3.2.5 Remote execution tutorial

Before continuing make sure you have a working Salt installation by following the installation and the configuration instructions.

Stuck?

There are many ways to get help from the Salt community including our mailing list and our IRC channel #salt.
Order your minions around

Now that you have a master and at least one minion communicating with each other you can perform commands on the minion via the salt command. Salt calls are comprised of three main components:

```
salt '<target>' <function> [arguments]
```

See also:

salt manpage

target

The target component allows you to filter which minions should run the following function. The default filter is a glob on the minion id. For example:

```
salt '*' test.ping
salt '*.example.org' test.ping
```

Targets can be based on minion system information using the Grains system:

```
salt -G 'os:Ubuntu' test.ping
```

See also:

Grains system

Targets can be filtered by regular expression:

```
salt -E 'virtmach[0-9]' test.ping
```

Targets can be explicitly specified in a list:

```
salt -L 'foo,bar,baz,quo' test.ping
```

Or Multiple target types can be combined in one command:

```
salt -C 'G@os:Ubuntu and webser* or E@database.*' test.ping
```

function

A function is some functionality provided by a module. Salt ships with a large collection of available functions. List all available functions on your minions:

```
salt '*' sys.doc
```

Here are some examples:

Show all currently available minions:

```
salt '*' test.ping
```

Run an arbitrary shell command:

```
salt '*' cmd.run 'uname -a'
```

See also:

the full list of modules
arguments

Space-delimited arguments to the function:

```cmd.exec_code python 'import sys; print sys.version'
```

Optional, keyword arguments are also supported:

```pip.install salt timeout=5 upgrade=True```

They are always in the form of `kwarg=argument`.

### 3.2.6 Pillar Walkthrough

**Note:** This walkthrough assumes that the reader has already completed the initial Salt walkthrough.

Pillars are tree-like structures of data defined on the Salt Master and passed through to minions. They allow confidential, targeted data to be securely sent only to the relevant minion.

**Note:** Grains and Pillar are sometimes confused, just remember that Grains are data about a minion which is stored or generated from the minion. This is why information like the OS and CPU type are found in Grains. Pillar is information about a minion or many minions stored or generated on the Salt Master.

Pillar data is useful for:

- **Highly Sensitive Data:** Information transferred via pillar is guaranteed to only be presented to the minions that are targeted, making Pillar suitable for managing security information, such as cryptographic keys and passwords.

- **Minion Configuration:** Minion modules such as the execution modules, states, and returners can often be configured via data stored in pillar.

- **Variables:** Variables which need to be assigned to specific minions or groups of minions can be defined in pillar and then accessed inside sls formulas and template files.

- **Arbitrary Data:** Pillar can contain any basic data structure in dictionary format, so a key/value store can be defined making it easy to iterate over a group of values in sls formulas.

Pillar is therefore one of the most important systems when using Salt. This walkthrough is designed to get a simple Pillar up and running in a few minutes and then to dive into the capabilities of Pillar and where the data is available.

### Setting Up Pillar

The pillar is already running in Salt by default. To see the minion’s pillar data:

```pillar.items```

**Note:** Prior to version 0.16.2, this function is named `pillar.data`. This function name is still supported for backwards compatibility.

By default the contents of the master configuration file are loaded into pillar for all minions. This enables the master configuration file to be used for global configuration of minions.

Similar to the state tree, the pillar is comprised of sls files and has a top file. The default location for the pillar is in `/srv/pillar`. 

Note: The pillar location can be configured via the pillar_roots option inside the master configuration file. It must not be in a subdirectory of the state tree.

To start setting up the pillar, the /srv/pillar directory needs to be present:

```bash
mkdir /srv/pillar
```

Now create a simple top file, following the same format as the top file used for states:

```
/srv/pillar/top.sls:
base:
  '*':
    - data
```

This top file associates the data.sls file to all minions. Now the /srv/pillar/data.sls file needs to be populated:

```
/srv/pillar/data.sls:
info: some data
```

To ensure that the minions have the new pillar data, issue a command to them asking that they fetch their pillars from the master:

```
salt '*' saltutil.refresh_pillar
```

Now that the minions have the new pillar, it can be retrieved:

```
salt '*' pillar.items
```

The key info should now appear in the returned pillar data.

**More Complex Data**

Unlike states, pillar files do not need to define formulas. This example sets up user data with a UID:

```
/srv/pillar/users/init.sls:
users:
  thatch: 1000
  shouse: 1001
  utahdave: 1002
  redbeard: 1003
```

Note: The same directory lookups that exist in states exist in pillar, so the file users/init.sls can be referenced with users in the top file.

The top file will need to be updated to include this sls file:

```
/srv/pillar/top.sls:
base:
  '*':
    - data
    - users
```

Now the data will be available to the minions. To use the pillar data in a state, you can use Jinja:

```
/srv/salt/users/init.sls
```

---

3.2. Basics 37
{% for user, uid in pillar.get('users', {}).items() %}
  {user}:
    - uid: {{uid}}
{% endfor %}

This approach allows for users to be safely defined in a pillar and then the user data is applied in an sls file.

**Parameterizing States With Pillar**

Pillar data can be accessed in state files to customise behavior for each minion. All pillar (and grain) data applicable to each minion is substituted into the state files through templating before being run. Typical uses include setting directories appropriate for the minion and skipping states that don’t apply.

A simple example is to set up a mapping of package names in pillar for separate Linux distributions:

/srv/pillar/pkg/init.sls:

```
pkgs:
  {% if grains['os_family'] == 'RedHat' %}
    apache: httpd
    vim: vim-enhanced
  {% elif grains['os_family'] == 'Debian' %}
    apache: apache2
    vim: vim
  {% elif grains['os'] == 'Arch' %}
    apache: apache
    vim: vim
  {% endif %}
```

The new pkg sls needs to be added to the top file:

/srv/pillar/top.sls:

```
base:
  '*':
    - data
    - users
    - pkg
```

Now the minions will auto map values based on respective operating systems inside of the pillar, so sls files can be safely parameterized:

/srv/salt/apache/init.sls:

```
apache:
  pkg.installed:
    - name: {{ pillar['pkgs']['apache'] }}
```

Or, if no pillar is available a default can be set as well:

**Note:** The function pillar.get used in this example was added to Salt in version 0.14.0

/srv/salt/apache/init.sls:

```
apache:
  pkg.installed:
    - name: {{ salt['pillar.get']['pkgs:apache', 'httpd'] }}
```
In the above example, if the pillar value `pillar['pkgs']['apache']` is not set in the minion's pillar, then the default of `httpd` will be used.

**Note:** Under the hood, pillar is just a Python dict, so Python dict methods such as `get` and `items` can be used.

---

**Pillar Makes Simple States Grow Easily**

One of the design goals of pillar is to make simple sls formulas easily grow into more flexible formulas without refactoring or complicating the states.

A simple formula:

```
/srv/salt/edit/vim.sls:
```

```yaml
vim:
  pkg.installed: []

/etc/vimrc:
  file.managed:
    - source: salt://edit/vimrc
    - mode: 644
    - user: root
    - group: root
    - require:
      - pkg: vim
```

Can be easily transformed into a powerful, parameterized formula:

```
/srv/salt/edit/vim.sls:
```

```yaml
vim:
  pkg.installed:
    - name: {{ pillar['pkgs']['vim'] }}

/etc/vimrc:
  file.managed:
    - source: {{ pillar['vimrc'] }}
    - mode: 644
    - user: root
    - group: root
    - require:
      - pkg: vim
```

Where the vimrc source location can now be changed via pillar:

```
/srv/pillar/edit/vim.sls:
```

```yaml
{% if grains['id'].startswith('dev') %}
vimrc: salt://edit/dev_vimrc
{% elseif grains['id'].startswith('qa') %}
vimrc: salt://edit/qa_vimrc
{% else %}
vimrc: salt://edit/vimrc
{% endif %}
```

Ensuring that the right vimrc is sent out to the correct minions.
Setting Pillar Data on the Command Line

Pillar data can be set on the command line like so:

```shell
call ' '*' state.highstate pillar='"foo": "bar"'}
```

The `state.sls` command can also be used to set pillar values via the command line:

```shell
call ' '*' state.sls my_sls_file pillar='"hello": "world"'}
```

**Note:** If a key is passed on the command line that already exists on the minion, the key that is passed in will overwrite the entire value of that key, rather than merging only the specified value set via the command line.

More On Pillar

Pillar data is generated on the Salt master and securely distributed to minions. Salt is not restricted to the pillar sls files when defining the pillar but can retrieve data from external sources. This can be useful when information about an infrastructure is stored in a separate location.

Reference information on pillar and the external pillar interface can be found in the Salt documentation:

*Pillar*

Minion Config in Pillar

Minion configuration options can be set on pillars. Any option that you want to modify, should be in the first level of the pillars, in the same way you set the options in the config file. For example, to configure the MySQL root password to be used by MySQL Salt execution module:

```shell
mysql.pass: hardtoguesspassword
```

This is very convenient when you need some dynamic configuration change that you want to be applied on the fly. For example, there is a chicken and the egg problem if you do this:

```shell
mysql-admin-passwd:
  mysql_user.present:
    - name: root
    - password: somepasswd
mydb:
  mysql_db.present
```

The second state will fail, because you changed the root password and the minion didn't notice it. Setting `mysql.pass` in the pillar, will help to sort out the issue. But always change the root admin password in the first place.

This is very helpful for any module that needs credentials to apply state changes: mysql, keystone, etc.

### 3.3 States

#### 3.3.1 How Do I Use Salt States?

Simplicity, Simplicity, Simplicity
Many of the most powerful and useful engineering solutions are founded on simple principles. Salt States strive to do just that: K.I.S.S. (Keep It Stupidly Simple)

The core of the Salt State system is the SLS, or Salt State file. The SLS is a representation of the state in which a system should be in, and is set up to contain this data in a simple format. This is often called configuration management.

Note: This is just the beginning of using states, make sure to read up on pillar Pillar next.

It is All Just Data

Before delving into the particulars, it will help to understand that the SLS file is just a data structure under the hood. While understanding that the SLS is just a data structure isn’t critical for understanding and making use of Salt States, it should help bolster knowledge of where the real power is.

SLS files are therefore, in reality, just dictionaries, lists, strings, and numbers. By using this approach Salt can be much more flexible. As one writes more state files, it becomes clearer exactly what is being written. The result is a system that is easy to understand, yet grows with the needs of the admin or developer.

The Top File

The example SLS files in the below sections can be assigned to hosts using a file called top.sls. This file is described in-depth here.

Default Data - YAML

By default Salt represents the SLS data in what is one of the simplest serialization formats available - YAML.

A typical SLS file will often look like this in YAML:

```
apache:
  pkg.installed: []
  service.running:
    - require:
      - pkg: apache
```

This SLS data will ensure that the package named apache is installed, and that the apache service is running. The components can be explained in a simple way.

The first line is the ID for a set of data, and it is called the ID Declaration. This ID sets the name of the thing that needs to be manipulated.

The second and third lines contain the state module function to be run, in the format `<state_module>..<function>`. The pkg.installed state module function ensures that a software package is installed via the system’s native package manager. The service.running state module function ensures that a given system daemon is running.

Finally, on line five, is the word require. This is called a Requisite Statement, and it makes sure that the Apache service is only started after a successful installation of the apache package.
Adding Configs and Users

When setting up a service like an Apache web server, many more components may need to be added. The Apache configuration file will most likely be managed, and a user and group may need to be set up.

```yaml
apache:
  pkg.installed: []
  service.running:
    - watch:
      - pkg: apache
      - file: /etc/httpd/conf/httpd.conf
      - user: apache
  user.present:
    - uid: 87
    - gid: 87
    - home: /var/www/html
    - shell: /bin/nologin
    - require:
      - group: apache
  group.present:
    - gid: 87
    - require:
      - pkg: apache

/etc/httpd/conf/httpd.conf:
  file.managed:
    - source: salt://apache/httpd.conf
    - user: root
    - group: root
    - mode: 644
```

This SLS data greatly extends the first example, and includes a config file, a user, a group and new requisite statement: `watch`.

Adding more states is easy, since the new user and group states are under the Apache ID, the user and group will be the Apache user and group. The `require` statements will make sure that the user will only be made after the group, and that the group will be made only after the Apache package is installed.

Next, the `require` statement under service was changed to watch, and is now watching 3 states instead of just one. The watch statement does the same thing as require, making sure that the other states run before running the state with a watch, but it adds an extra component. The `watch` statement will run the state's watcher function for any changes to the watched states. So if the package was updated, the config file changed, or the user uid modified, then the service state's watcher will be run. The service state's watcher just restarts the service, so in this case, a change in the config file will also trigger a restart of the respective service.

Moving Beyond a Single SLS

When setting up Salt States in a scalable manner, more than one SLS will need to be used. The above examples were in a single SLS file, but two or more SLS files can be combined to build out a State Tree. The above example also references a file with a strange source - `salt://apache/httpd.conf`. That file will need to be available as well.

The SLS files are laid out in a directory structure on the Salt master; an SLS is just a file and files to download are just files.

The Apache example would be laid out in the root of the Salt file server like this:
apache/init.sls
apache/httpd.conf

So the httpd.conf is just a file in the apache directory, and is referenced directly.

**Do not use dots in SLS file names or their directories**

The initial implementation of `top.sls` and *Include declaration* followed the python import model where a slash is represented as a period. This means that a SLS file with a period in the name (besides the suffix period) cannot be referenced. For example, webserver_1.0.sls is not referenceable because webserver_1.0 would refer to the directory/file webserver_1/0.sls

The same applies for any subdirectories, this is especially 'tricky' when git repos are created. Another command that typically can’t render it’s output is `state.show_sls` of a file in a path that contains a dot.

But when using more than one single SLS file, more components can be added to the toolkit. Consider this SSH example:

```
ssh/init.sls:

.openssh-client:
  pkg.installed

/etc/ssh/ssh_config:
  file.managed:
    - user: root
    - group: root
    - mode: 644
    - source: salt://ssh/ssh_config
    - require:
      - pkg: openssh-client

ssh/server.sls:

include:
  - ssh

.openssh-server:
  pkg.installed

/sshd:
  service.running:
    - require:
      - pkg: openssh-client
      - pkg: openssh-server
      - file: /etc/ssh/banner
      - file: /etc/ssh/sshd_config

/etc/ssh/sshd_config:
  file.managed:
    - user: root
    - group: root
    - mode: 644
    - source: salt://ssh/sshd_config
    - require:
      - pkg: openssh-server

/etc/ssh/banner:
  file:
```

3.3. States
- managed
- user: root
- group: root
- mode: 644
- source: salt://ssh/banner
- require:
  - pkg: openssh-server

Note: Notice that we use two similar ways of denoting that a file is managed by Salt. In the /etc/ssh/sshd_config state section above, we use the file.managed state declaration whereas with the /etc/ssh/banner state section, we use the file state declaration and add a managed attribute to that state declaration. Both ways produce an identical result; the first way -- using file.managed -- is merely a shortcut.

Now our State Tree looks like this:

apache/init.sls
apache/httpd.conf
ssh/init.sls
ssh/server.sls
ssh/banner
ssh/ssh_config
ssh/sshd_config

This example now introduces the include statement. The include statement includes another SLS file so that components found in it can be required, watched or as will soon be demonstrated - extended.

The include statement allows for states to be cross linked. When an SLS has an include statement it is literally extended to include the contents of the included SLS files.

Note that some of the SLS files are called init.sls, while others are not. More info on what this means can be found in the States Tutorial.

Extending Included SLS Data

Sometimes SLS data needs to be extended. Perhaps the apache service needs to watch additional resources, or under certain circumstances a different file needs to be placed.

In these examples, the first will add a custom banner to ssh and the second will add more watchers to apache to include mod_python.

ssh/custom-server.sls:

include:
  - ssh.server

extend:
  /etc/ssh/banner:
    file:
      - source: salt://ssh/custom-banner

python/mod_python.sls:

include:
  - apache

extend:
  apache:
The `custom-server.sls` file uses the `extend` statement to overwrite where the banner is being downloaded from, and therefore changing what file is being used to configure the banner.

In the new `mod_python` SLS the `mod_python` package is added, but more importantly the `apache` service was extended to also watch the `mod_python` package.

### Using `extend` with `require` or `watch`

The `extend` statement works differently for `require` or `watch`. It appends to, rather than replacing the requisite component.

### Understanding the Render System

Since SLS data is simply that (data), it does not need to be represented with YAML. Salt defaults to YAML because it is very straightforward and easy to learn and use. But the SLS files can be rendered from almost any imaginable medium, so long as a renderer module is provided.

The default rendering system is the `yaml_jinja` renderer. The `yaml_jinja` renderer will first pass the template through the Jinja2 templating system, and then through the YAML parser. The benefit here is that full programming constructs are available when creating SLS files.

Other renderers available are `yaml_mako` and `yaml_wempy` which each use the Mako or Wempy templating system respectively rather than the Jinja templating system, and more notably, the pure Python or `pydsl` & `pyobjects` renderers. The `py` renderer allows for SLS files to be written in pure Python, allowing for the utmost level of flexibility and power when preparing SLS data; while the `pydsl` renderer provides a flexible, domain-specific language for authoring SLS data in Python; and the `pyobjects` renderer gives you a “Pythonic” interface to building state data.

### Note

The templating engines described above aren’t just available in SLS files. They can also be used in `file.managed` states, making file management much more dynamic and flexible. Some examples for using templates in managed files can be found in the documentation for the `file states`, as well as the `MooseFS example` below.

### Getting to Know the Default - `yaml_jinja`

The default renderer - `yaml_jinja`, allows for use of the Jinja templating system. A guide to the Jinja templating system can be found here: [http://jinja.pocoo.org/docs](http://jinja.pocoo.org/docs)

When working with renderers a few very useful bits of data are passed in. In the case of templating engine based renderers, three critical components are available, `salt`, `grains`, and `pillar`. The `salt` object allows for any Salt function to be called from within the template, and `grains` allows for the Grains to be accessed from within the template. A few examples:

```python
apache/init.sls:

apache:
    pkg.installed:
        {% if grains['os'] == 'RedHat' %}
            - name: httpd
        {% endif %}
```

3.3. **States**
{% endif %}

service.running:
  {% if grains['os'] == 'RedHat' %}
    - name: httpd
  {% endif %}
  - watch:
    - pkg: apache
    - file: /etc/httpd/conf/httpd.conf
    - user: apache

user.present:
  - uid: 87
  - gid: 87
  - home: /var/www/html
  - shell: /bin/nologin
  - require:
    - group: apache

group.present:
  - gid: 87
  - require:
    - pkg: apache

/etc/httpd/conf/httpd.conf:
  file.managed:
    - source: salt://apache/httpd.conf
    - user: root
    - group: root
    - mode: 644

This example is simple. If the os grain states that the operating system is Red Hat, then the name of the Apache package and service needs to be httpd. A more aggressive way to use Jinja can be found here, in a module to set up a MooseFS distributed filesystem chunkserver:

moosefs/chunk.sls:

include:
  - moosefs

{% for mnt in salt['cmd.run']('ls /dev/data/moose*').split() %}
/mnt/moose{{ mnt[-1] }}:
  mount.mounted:
    - device: {{ mnt }}
    - fstype: xfs
    - mkmnt: True

file.directory:
  - user: mfs
  - group: mfs
  - require:
    - user: mfs
    - group: mfs
{% endfor %}

/etc/mfshdd.cfg:
  file.managed:
    - source: salt://moosefs/mfshdd.cfg
    - user: root
    - group: root
    - mode: 644
    - template: jinja
    - require:
- pkg: mfs-chunkserver

/etc/mfschunckserver.cfg:
  file.managed:
    - source: salt://moosefs/mfschunckserver.cfg
    - user: root
    - group: root
    - mode: 644
    - template: jinja
    - require:
      - pkg: mfs-chunkserver

mfs-chunkserver:
  pkg.installed: []
mfschunkserver:
  service.running:
    - require:
      {% for mnt in salt['cmd.run']('ls /dev/data/moose*') %}
        - mount: /mnt/moose{{ mnt[-1] }}
        - file: /mnt/moose{{ mnt[-1] }}
      {% endfor %}
    - file: /etc/mfschunkserver.cfg
    - file: /etc/mfshdd.cfg
    - file: /var/lib/mfs

This example shows much more of the available power of Jinja. Multiple for loops are used to dynamically detect available hard drives and set them up to be mounted, and the salt object is used multiple times to call shell commands to gather data.

**Introducing the Python, PyDSL, and the Pyobjects Renderers**

Sometimes the chosen default renderer might not have enough logical power to accomplish the needed task. When this happens, the Python renderer can be used. Normally a YAML renderer should be used for the majority of SLS files, but an SLS file set to use another renderer can be easily added to the tree.

This example shows a very basic Python SLS file:

```python
# !py
def run():
    '''
    Install the django package
    '''
    return {'include': ['python'],
            'django': {'pkg': ['installed']}}
```

This is a very simple example; the first line has an SLS shebang that tells Salt to not use the default renderer, but to use the py renderer. Then the run function is defined, the return value from the run function must be a Salt friendly data structure, or better known as a Salt HighState data structure.

Alternatively, using the pydsl renderer, the above example can be written more succinctly as:

```python
#!/pydsl
include('python', delayed=True)
state('django').pkg.installed()
```

3.3. States
The `pyobjects` renderer provides an "Pythonic" object based approach for building the state data. The above example could be written as:

```python
#!pyobjects
include('python')
Pkg.installed("django")
```

These Python examples would look like this if they were written in YAML:

```yaml
include:
  - python

django:
  pkg.installed
```

This example clearly illustrates that; one, using the YAML renderer by default is a wise decision and two, unbridled power can be obtained where needed by using a pure Python SLS.

Running and debugging salt states.

Once the rules in an SLS are ready, they should be tested to ensure they work properly. To invoke these rules, simply execute `salt '*' state.highstate` on the command line. If you get back only hostnames with a `:` after, but no return, chances are there is a problem with one or more of the sls files. On the minion, use the `salt-call` command: `salt-call state.highstate -l debug` to examine the output for errors. This should help troubleshoot the issue. The minions can also be started in the foreground in debug mode: `salt-minion -l debug`.

Next Reading

With an understanding of states, the next recommendation is to become familiar with Salt's pillar interface:

*Pillar Walkthrough*

3.3.2 States tutorial, part 1 - Basic Usage

The purpose of this tutorial is to demonstrate how quickly you can configure a system to be managed by Salt States. For detailed information about the state system please refer to the full states reference.

This tutorial will walk you through using Salt to configure a minion to run the Apache HTTP server and to ensure the server is running.

**Before continuing** make sure you have a working Salt installation by following the installation and the configuration instructions.

Stuck?

There are many ways to get help from the Salt community including our mailing list and our IRC channel #salt.

Setting up the Salt State Tree

States are stored in text files on the master and transferred to the minions on demand via the master's File Server. The collection of state files make up the State Tree.
To start using a central state system in Salt, the Salt File Server must first be set up. Edit the master config file (file_roots) and uncomment the following lines:

```yaml
file_roots:
    base:
        - /srv/salt
```

**Note:** If you are deploying on FreeBSD via ports, the file_roots path defaults to /usr/local/etc/salt/states.

Restart the Salt master in order to pick up this change:

```bash
pkill salt-master
salt-master -d
```

### Preparing the Top File

On the master, in the directory uncommented in the previous step, (/srv/salt by default), create a new file called top.sls and add the following:

```yaml
base:
    '*':
        - webserver
```

The top file is separated into environments (discussed later). The default environment is base. Under the base environment a collection of minion matches is defined; for now simply specify all hosts (*).

#### Targeting minions

The expressions can use any of the targeting mechanisms used by Salt — minions can be matched by glob, PCRE regular expression, or by grains. For example:

```yaml
base:
    'os:Fedora':
        - match: grain
        - webserver
```

### Create an sls file

In the same directory as the top file, create a file named webserver.sls, containing the following:

```yaml
apache: # ID declaration
    pkg: # state declaration
        - installed # function declaration
```

The first line, called the **ID declaration**, is an arbitrary identifier. In this case it defines the name of the package to be installed.

**Note:** The package name for the Apache httpd web server may differ depending on OS or distro — for example, on Fedora it is httpd but on Debian/Ubuntu it is apache2.

The second line, called the **State declaration**, defines which of the Salt States we are using. In this example, we are using the pkg state to ensure that a given package is installed.

The third line, called the **Function declaration**, defines which function in the pkg state module to call.

### 3.3. States

49
Renderers
States SLS files can be written in many formats. Salt requires only a simple data structure and is not concerned with how that data structure is built. Templating languages and DSLs are a dime-a-dozen and everyone has a favorite. Building the expected data structure is the job of Salt renderers and they are dead-simple to write.

In this tutorial we will be using YAML in Jinja2 templates, which is the default format. The default can be changed by editing renderer in the master configuration file.

Install the package

Next, let's run the state we created. Open a terminal on the master and run:

```
% salt '*' state.highstate
```

Our master is instructing all targeted minions to run state.highstate. When a minion executes a highstate call it will download the top file and attempt to match the expressions. When it does match an expression the modules listed for it will be downloaded, compiled, and executed.

Once completed, the minion will report back with a summary of all actions taken and all changes made.

**Warning:** If you have created custom grain modules, they will not be available in the top file until after the first highstate. To make custom grains available on a minion's first highstate, it is recommended to use this example to ensure that the custom grains are synced when the minion starts.

SLS File Namespace

Note that in the example above, the SLS file webserver.sls was referred to simply as webserver. The namespace for SLS files when referenced in top.sls or an Include declaration follows a few simple rules:

1. The .sls is discarded (i.e. webserver.sls becomes webserver).
2. Subdirectories can be used for better organization.
   a. Each subdirectory can be represented with a dot (following the python import model) or a slash.
      webserver/dev.sls can also be referred to as webserver.dev
   b. Because slashes can be represented as dots, SLS files can not contain dots in the name besides the dot for the SLS suffix. The SLS file webserver_1.0.sls can not be matched, and webserver_1.0 would match the directory/file webserver/1/0.sls
3. A file called init.sls in a subdirectory is referred to by the path of the directory. So, webserver/init.sls is referred to as webserver.
4. If both webserver.sls and webserver/init.sls happen to exist, webserver/init.sls will be ignored and webserver.sls will be the file referred to as webserver.

Troubleshooting Salt

If the expected output isn't seen, the following tips can help to narrow down the problem.

**Turn up logging** Salt can be quite chatty when you change the logging setting to debug:

```
salt-minion -l debug
```

**Run the minion in the foreground** By not starting the minion in daemon mode (-d) one can view any output from the minion as it works:
Increase the default timeout value when running salt. For example, to change the default timeout to 60 seconds:

```
salt -t 60
```

For best results, combine all three:

```
salt-minion -l debug &    # On the minion
salt '*' state.highstate -t 60 # On the master
```

Next steps

This tutorial focused on getting a simple Salt States configuration working. Part 2 will build on this example to cover more advanced sls syntax and will explore more of the states that ship with Salt.

### 3.3.3 States tutorial, part 2 - More Complex States, Requisites

Note: This tutorial builds on topics covered in part 1. It is recommended that you begin there.

In the last part of the Salt States tutorial we covered the basics of installing a package. We will now modify our `webserver.sls` file to have requirements, and use even more Salt States.

#### Call multiple States

You can specify multiple State declaration under an ID declaration. For example, a quick modification to our `webserver.sls` to also start Apache if it is not running:

```
apache:
  pkg.installed: []
  service.running:
    - require:
      - pkg: apache
```

Try stopping Apache before running state.highstate once again and observe the output.

#### Require other states

We now have a working installation of Apache so let’s add an HTML file to customize our website. It isn’t exactly useful to have a website without a webserver so we don’t want Salt to install our HTML file until Apache is installed and running. Include the following at the bottom of your `webserver/init.sls` file:

```
apache:
  pkg.installed: []
  service.running:
    - require:
      - pkg: apache

/var/www/index.html:
  file:
    - managed
    - source: salt://webserver/index.html
```

3.3. States
line 7 is the **ID declaration**. In this example it is the location we want to install our custom HTML file. *(Note: the default location that Apache serves may differ from the above on your OS or distro. `/srv/www` could also be a likely place to look.)*

**Line 8** the **State declaration**. This example uses the Salt **file state**.

**Line 9** is the **Function declaration**. The managed function will download a file from the master and install it in the location specified.

**Line 10** is a **Function arg declaration** which, in this example, passes the `source` argument to the managed function.

**Line 11** is a **Requisite declaration**.

**Line 12** is a **Requisite reference** which refers to a state and an ID. In this example, it is referring to the ID declaration from our example in part 1. This declaration tells Salt not to install the HTML file until Apache is installed.

Next, create the `index.html` file and save it in the `webserver` directory:

```html
<!DOCTYPE html>
<html>
  <head>
    <title>Salt rocks</title>
  </head>
  <body>
    <h1>This file brought to you by Salt</h1>
  </body>
</html>
```

Last, call `state.highstate` again and the minion will fetch and execute the highstate as well as our HTML file from the master using Salt’s File Server:

```bash
salt '*' state.highstate
```

Verify that Apache is now serving your custom HTML.

**require vs. watch**

There are two **Requisite declaration**, “require”, and “watch”. Not every state supports “watch”. The **service state** does support “watch” and will restart a service based on the watch condition.

For example, if you use Salt to install an Apache virtual host configuration file and want to restart Apache whenever that file is changed you could modify our Apache example from earlier as follows:

```bash
/etc/httpd/extra/httpd-vhosts.conf:
  file.managed:
    - source: salt://webserver/httpd-vhosts.conf

apache:
  pkg.installed: []
  service.running:
    - watch:
      - file: /etc/httpd/extra/httpd-vhosts.conf
    - require:
      - pkg: apache
```

If the `pkg` and service names differ on your OS or distro of choice you can specify each one separately using a **Name declaration** which explained in **Part 3**.
Next steps

In part 3 we will discuss how to use includes, extends, and templating to make a more complete State Tree configuration.

3.3.4 States tutorial, part 3 - Templating, Includes, Extends

Note: This tutorial builds on topics covered in part 1 and part 2. It is recommended that you begin there.

This part of the tutorial will cover more advanced templating and configuration techniques for SLS files.

Templating SLS modules

SLS modules may require programming logic or inline execution. This is accomplished with module templating. The default module templating system used is Jinja2 and may be configured by changing the renderer value in the master config.

All states are passed through a templating system when they are initially read. To make use of the templating system, simply add some templating markup. An example of an SLS module with templating markup may look like this:

```jinja
{% for usr in ['moe', 'larry', 'curly'] %}
  {{ usr }}:
    user.present
{% endfor %}
```

This templated SLS file once generated will look like this:

```
moe: user.present
larry: user.present
curly: user.present
```

Here’s a more complex example:

```jinja
# Comments in yaml start with a hash symbol.
# Since jinja rendering occurs before yaml parsing, if you want to include jinja # in the comments you may need to escape them using 'jinja' comments to prevent # jinja from trying to render something which is not well-defined jinja. # e.g.
# {% for usrs in ['moe', 'larry', 'curly'] %}
{% for usrs in ['moe', 'larry', 'curly'] %}
  {% if usrs == 'moe' %}
    group:
      - present
  {% endif %}
  user:
    - present
    - gid_from_name: True
    - require:
      - group: {{ usrs }}
  {% endfor %}
{% endfor %}
```

3.3. States
Using Grains in SLS modules

Often times a state will need to behave differently on different systems. *Salt grains* objects are made available in the template context. The *grains* can be used from within sls modules:

```yaml
apache:
  pkg.installed:
    {% if grains['os'] == 'RedHat' %}
      - name: httpd
    {% elif grains['os'] == 'Ubuntu' %}
      - name: apache2
    {% endif %}
```

Calling Salt modules from templates

All of the Salt modules loaded by the minion are available within the templating system. This allows data to be gathered in real time on the target system. It also allows for shell commands to be run easily from within the sls modules.

The Salt module functions are also made available in the template context as *salt*:

```yaml
moe:
  user.present:
    - gid: {{ salt['file.group_to_gid']('some_group_that_exists') }}
```

Note that for the above example to work, *some_group_that_exists* must exist before the state file is processed by the templating engine.

Below is an example that uses the *network.hw_addr* function to retrieve the MAC address for eth0:

```yaml
salt['network.hw_addr']('eth0')
```

Advanced SLS module syntax

Lastly, we will cover some incredibly useful techniques for more complex State trees.

Include declaration

A previous example showed how to spread a Salt tree across several files. Similarly, *requisites* span multiple files by using an *Include declaration*. For example:

```yaml
python/python-libs.sls:
  python-dateutil:
    pkg.installed

python/django.sls:
  include:
    - python.python-libs

django:
  pkg.installed:
    - require:
      - pkg: python-dateutil
```
Extend declaration

You can modify previous declarations by using an *Extend declaration*. For example the following modifies the Apache tree to also restart Apache when the vhosts file is changed:

```bash
apache/apache.sls:
apache:
    pkg.installed

apache/mywebsite.sls:
include:
    - apache.apache
extend:
    apache:
        service:
            - running
            - watch:
                - file: /etc/httpd/extra/httpd-vhosts.conf

/etc/httpd/extra/httpd-vhosts.conf:
    file.managed:
        - name: /etc/httpd/extra/httpd-vhosts.conf
          source: salt://apache/httpd-vhosts.conf

Using extend with require or watch

The *extend* statement works differently for *require* or *watch*. It appends to, rather than replacing the requisite component.

Name declaration

You can override the *ID declaration* by using a *Name declaration*. For example, the previous example is a bit more maintainable if rewritten as follows:

```bash
apache/mywebsite.sls:
include:
    - apache.apache
extend:
    apache:
        service:
            - running
            - watch:
                - file: mywebsite

mywebsite:
    file.managed:
        - name: /etc/httpd/extra/httpd-vhosts.conf
          source: salt://apache/httpd-vhosts.conf
```
Names declaration

Even more powerful is using a *Names declaration* to override the *ID declaration* for multiple states at once. This often can remove the need for looping in a template. For example, the first example in this tutorial can be rewritten without the loop:

```bash
stooges:
    user.present:
        - names:
            - moe
            - larry
            - curly
```

Next steps

In *part 4* we will discuss how to use salt’s *file_roots* to set up a workflow in which states can be "promoted" from dev, to QA, to production.

### 3.3.5 States tutorial, part 4

*Note:* This tutorial builds on topics covered in *part 1*, *part 2* and *part 3*. It is recommended that you begin there.

This part of the tutorial will show how to use salt’s *file_roots* to set up a workflow in which states can be "promoted" from dev, to QA, to production.

Salt fileserver path inheritance

Salt’s fileserver allows for more than one root directory per environment, like in the below example, which uses both a local directory and a secondary location shared to the salt master via NFS:

```bash
# In the master config file (/etc/salt/master)
file_roots:
    base:
        - /srv/salt
        - /mnt/salt-nfs/base
```

Salt’s fileserver collapses the list of root directories into a single virtual environment containing all files from each root. If the same file exists at the same relative path in more than one root, then the top-most match "wins". For example, if `/srv/salt/foo.txt` and `/mnt/salt-nfs/base/foo.txt` both exist, then `salt://foo.txt` will point to `/srv/salt/foo.txt`.

*Note:* When using multiple fileserver backends, the order in which they are listed in the *fileserver_backend* parameter also matters. If both *roots* and *git* backends contain a file with the same relative path, and *roots* appears before *git* in the *fileserver_backend* list, then the file in *roots* will "win", and the file in *git*s will be ignored.

A more thorough explanation of how Salt’s modular fileserver works can be found *here*. We recommend reading this.
Environment configuration

Configure a multiple-environment setup like so:

```yaml
file_roots:
  base:
    - /srv/salt/prod
  qa:
    - /srv/salt/qa
    - /srv/salt/prod
  dev:
    - /srv/salt/dev
    - /srv/salt/qa
    - /srv/salt/prod
```

Given the path inheritance described above, files within `/srv/salt/prod` would be available in all environments. Files within `/srv/salt/qa` would be available in both qa, and dev. Finally, the files within `/srv/salt/dev` would only be available within the dev environment.

Based on the order in which the roots are defined, new files/states can be placed within `/srv/salt/dev`, and pushed out to the dev hosts for testing.

Those files/states can then be moved to the same relative path within `/srv/salt/qa`, and they are now available only in the dev and qa environments, allowing them to be pushed to QA hosts and tested.

Finally, if moved to the same relative path within `/srv/salt/prod`, the files are now available in all three environments.

Practical Example

As an example, consider a simple website, installed to `/var/www/foobarcom`. Below is a top.sls that can be used to deploy the website:

```
/srv/salt/prod/top.sls:

base:
  'web*prod*':
    - webserver.foobarcom
qa:
  'web*qa*':
    - webserver.foobarcom
dev:
  'web*dev*':
    - webserver.foobarcom
```

Using pillar, roles can be assigned to the hosts:

```
/srv/pillar/top.sls:

base:
  'web*prod*':
    - webserver.prod
  'web*qa*':
    - webserver.qa
  'web*dev*':
    - webserver.dev
```

```
/srv/pillar/webserver/prod.sls:
```
webserver_role: prod

/srv/pillar/webserver/qa.sls:
webserver_role: qa

/srv/pillar/webserver/dev.sls:
webserver_role: dev

And finally, the SLS to deploy the website:

/srv/salt/prod/webserver/foobarcom.sls:

{% if pillar.get('webserver_role', '') %}
/var/www/foobarcom:
  file.recurse:
    - source: salt://webserver/src/foobarcom
    - env: {{ pillar['webserver_role'] }}
    - user: www
    - group: www
    - dir_mode: 755
    - file_mode: 644
{% endif %}

Given the above SLS, the source for the website should initially be placed in /srv/salt/dev/webserver/src/foobarcom.

First, let's deploy to dev. Given the configuration in the top file, this can be done using state.highstate:

```bash
salt --pillar 'webserver_role:dev' state.highstate
```

However, in the event that it is not desirable to apply all states configured in the top file (which could be likely in more complex setups), it is possible to apply just the states for the foobarcom website, using state.sls:

```bash
salt --pillar 'webserver_role:dev' state.sls webserver.foobarcom
```

Once the site has been tested in dev, then the files can be moved from /srv/salt/dev/webserver/src/foobarcom to /srv/salt/qa/webserver/src/foobarcom, and deployed using the following:

```bash
salt --pillar 'webserver_role:qa' state.sls webserver.foobarcom
```

Finally, once the site has been tested in qa, then the files can be moved from /srv/salt/qa/webserver/src/foobarcom to /srv/salt/prod/webserver/src/foobarcom, and deployed using the following:

```bash
salt --pillar 'webserver_role:prod' state.sls webserver.foobarcom
```

Thanks to Salt's fileserver inheritance, even though the files have been moved to within /srv/salt/prod, they are still available from the same salt:// URI in both the qa and dev environments.

**Continue Learning**

The best way to continue learning about Salt States is to read through the reference documentation and to look through examples of existing state trees. Many pre-configured state trees can be found on GitHub in the saltstack-formulas collection of repositories.
If you have any questions, suggestions, or just want to chat with other people who are using Salt, we have a very active community and we’d love to hear from you.

In addition, by continuing to part 5, you can learn about the powerful orchestration of which Salt is capable.

### 3.3.6 States Tutorial, Part 5 - Orchestration with Salt

**Note:** This tutorial builds on some of the topics covered in the earlier States Walkthrough pages. It is recommended to start with Part 1 if you are not familiar with how to use states.

Orchestration is accomplished in salt primarily through the Orchestrate Runner. Added in version 0.17.0, this Salt Runner can use the full suite of requisites available in states, and can also execute states/functions using salt-ssh.

**The Orchestrate Runner**

New in version 0.17.0.

**Note:** Orchestrate Deprecates OverState

The Orchestrate Runner (originally called the state.sls runner) offers all the functionality of the OverState, but with some advantages:

- All requisites available in states can be used.
- The states/functions will also work on salt-ssh minions.

The Orchestrate Runner was added with the intent to eventually deprecate the OverState system, however the Over-State will still be maintained until Salt Boron.

The orchestrate runner generalizes the Salt state system to a Salt master context. Whereas the state.sls, state.highstate, et al functions are concurrently and independently executed on each Salt minion, the state.orchestrate runner is executed on the master, giving it a master-level view and control over requisites, such as state ordering and conditionals. This allows for inter minion requisites, like ordering the application of states on different minions that must not happen simultaneously, or for halting the state run on all minions if a minion fails one of its states.

If you want to setup a load balancer in front of a cluster of web servers, for example, you can ensure the load balancer is setup before the web servers or stop the state run altogether if one of the minions does not set up correctly.

The state.sls, state.highstate, et al functions allow you to statefully manage each minion and the state.orchestrate runner allows you to statefully manage your entire infrastructure.

**Executing the Orchestrate Runner**

The Orchestrate Runner command format is the same as for the state.sls function, except that since it is a runner, it is executed with salt-run rather than salt. Assuming you have a state.sls file called /srv/salt/orch/webserver.sls the following command run on the master will apply the states defined in that file.

```
salt-run state.orchestrate orch.webserver
```

**Note:** state.orch is a synonym for state.orchestrate
Changed in version 2014.1.1: The runner function was renamed to `state.orchestrate` to avoid confusion with the `state.sls` execution function. In versions 0.17.0 through 2014.1.0, `state.sls` must be used.

**Examples**

**Function** To execute a function, use `salt.function`:

```bash
# /srv/salt/orch/cleanfoo.sls
cmd.run:
    salt.function:
      - tgt: '*'
      - arg:
        - rm -rf /tmp/foo

salt-run state.orchestrate orch.cleanfoo
```

**State** To execute a state, use `salt.state`.

```bash
# /srv/salt/orch/webserver.sls
install_nginx:
  salt.state:
    - tgt: 'web*'
    - sls:
      - nginx

salt-run state.orchestrate orch.webserver
```

**Highstate** To run a highstate, set `highstate: True` in your state config:

```bash
# /srv/salt/orch/web_setup.sls
webserver_setup:
  salt.state:
    - tgt: 'web*'
    - highstate: True

salt-run state.orchestrate orch.web_setup
```

**More Complex Orchestration**

Many states/functions can be configured in a single file, which when combined with the full suite of `requisites`, can be used to easily configure complex orchestration tasks. Additionally, the states/functions will be executed in the order in which they are defined, unless prevented from doing so by any `requisites`, as is the default in SLS files since 0.17.0.

```bash
cmd.run:
    salt.function:
      - tgt: 10.0.0.0/24
      - tgt_type: ipcidr
      - arg:
        - bootstrap

storage_setup:
    salt.state:
```

60 Chapter 3. Tutorials
- tgt: 'role:storage'
- tgt_type: grain
- sls: ceph
- require:
  - salt: webserver_setup

webserver_setup:
  salt.state:
    - tgt: 'web*'
    - highstate: True

Given the above setup, the orchestration will be carried out as follows:

1. The shell command `bootstrap` will be executed on all minions in the 10.0.0.0/24 subnet.
2. A Highstate will be run on all minions whose ID starts with "web", since the `storage_setup` state requires it.
3. Finally, the `ceph` SLS target will be executed on all minions which have a grain called `role` with a value of `storage`.

Note: Remember, salt-run is always executed on the master.

### 3.3.7 Syslog-ng usage

**Overview**

Syslog_ng state module is for generating syslog-ng configurations. You can do the following things:

- generate syslog-ng configuration from YAML,
- use non-YAML configuration,
- start, stop or reload syslog-ng.

There is also an execution module, which can check the syntax of the configuration, get the version and other information about syslog-ng.

**Configuration**

Users can create syslog-ng configuration statements with the `syslog_ng.config` function. It requires a `name` and a `config` parameter. The `name` parameter determines the name of the generated statement and the `config` parameter holds a parsed YAML structure.

A statement can be declared in the following forms (both are equivalent):

```
source.s_localhost:
  syslog_ng.config:
    - config:
      - tcp:
        - ip: "127.0.0.1"
        - port: 1233

s_localhost:
  syslog_ng.config:
    - config:
      source:
```
The first one is called short form, because it needs less typing. Users can use lists and dictionaries to specify their configuration. The format is quite self describing and there are more examples [at the end](#examples) of this document.

Quotation

The quotation can be tricky sometimes but here are some rules to follow:

- when a string meant to be "string" in the generated configuration, it should be like "'string'" in the YAML document
- similarly, users should write "'string'" to get 'string' in the generated configuration

Full example

The following configuration is an example, how a complete syslog-ng configuration looks like:

```yaml
# Set the location of the configuration file
set_location:
  module.run:
    - name: syslog_ng.set_config_file
      m_name: "'/home/tibi/install/syslog-ng/etc/syslog-ng.conf"

# The syslog-ng and syslog-ng-ctl binaries are here. You needn't use
# this method if these binaries can be found in a directory in your PATH.
set_bin_path:
  module.run:
    - name: syslog_ng.set_binary_path
      m_name: "'/home/tibi/install/syslog-ng/sbin"

# Writes the first lines into the config file, also erases its previous
# content
write_version:
  module.run:
    - name: syslog_ng.write_version
      m_name: "'3.6"

# There is a shorter form to set the above variables
set_variables:
  module.run:
    - name: syslog_ng.set_parameters
      version: "3.6"
      binary_path: "'/home/tibi/install/syslog-ng/sbin"
      config_file: "'/home/tibi/install/syslog-ng/etc/syslog-ng.conf"

# Some global options
options.global_options:
  syslog_ng.config:
    config:
      - time_reap: 30
      - mark_freq: 10
      - keep_hostname: "yes"
```
source.s_localhost:
  syslog_ng.config:
    - config:
      - tcp:
        - ip: "127.0.0.1"
        - port: 1233

destination.d_log_server:
  syslog_ng.config:
    - config:
      - tcp:
        - "127.0.0.1"
        - port: 1234

log.l_log_to_central_server:
  syslog_ng.config:
    - config:
      - source: s_localhost
      - destination: d_log_server

some_comment:
module.run:
  - name: syslog_ng.write_config
  - config: |
    # Multi line
    # comment

# An other mode to use comments or existing configuration snippets
config.other_comment_form:
  syslog_ng.config:
    - config: |
      # Multi line
      # comment

The `syslog_ng.reloaded` function can generate syslog-ng configuration from YAML. If the statement (source, destination, parser, etc.) has a name, this function uses the id as the name, otherwise (log statement) it's purpose is like a mandatory comment.

After execution this example the syslog_ng state will generate this file:

```yaml
# Generated by Salt on 2014-08-18 00:11:11
@version: 3.6

options {
  time_reap(30);
  mark_freq(10);
  keep_hostname(yes);
};

source_s_localhost {
  tcp(
```
Users can include arbitrary texts in the generated configuration with using the `config` statement (see the example above).

**Syslog_ng module functions**

You can use `syslog_ng.set_binary_path` to set the directory which contains the syslog-ng and syslog-ng-ctl binaries. If this directory is in your PATH, you don’t need to use this function. There is also a `syslog_ng.set_config_file` function to set the location of the configuration file.

**Examples**

**Simple source**

```bash
source s_tail {
    file("/var/log/apache/access.log",
         follow_freq(1),
         flags(no-parse, validate-utf8)
```

```bash
};

destination d_log_server {
    tcp(127.0.0.1,
        port(1234)
    );
};;

log {
    source(s_localhost);
    destination(d_log_server);
};;
```

# Multi line
# comment

# Multi line
# comment

```
```
Salt will call the source function of syslog_ng module

```python
s_tail:
    # Salt will call the source function of syslog_ng module
    syslog_ng.config:
        - config:
            source:
                - file:
                    - file: './var/log/apache/access.log'
                    - follow_freq : 1
                    - flags:
                        - no-parse
                        - validate-utf8
```

OR

```python
s_tail:
    syslog_ng.config:
        - config:
            source:
                - file:
                    - file: './var/log/apache/access.log'
                    - follow_freq : 1
                    - flags:
                        - no-parse
                        - validate-utf8
```

OR

```python
source.s_tail:
    syslog_ng.config:
        - config:
            - file:
                - file: './var/log/apache/access.log'
                - follow_freq : 1
                - flags:
                    - no-parse
                    - validate-utf8
```

Complex source

```python
source s_gsoc2014 {
    tcp(
        ip("0.0.0.0"),
        port(1234),
        flags(no-parse)
    );
}
```

```python
s_gsoc2014:
    syslog_ng.config:
        - config:
            source:
                - tcp:
                    - ip: 0.0.0.0
```

3.3. States
- port: 1234
  - flags: no-parse

Filter

filter f_json {
  match( 
    "@json:"
  );
};

f_json:
  syslog_ng.config:
    - config:
      - filter:
        - match:
          - ""@json:""

Template

template t_demo_filetemplate {
  template( 
    "$ISODATE $HOST $MSG 
  );
  template_escape( 
    no
  );
};

t_demo_filetemplate:
  syslog_ng.config:
    - config:
      - template:
        - template:
          - "$ISODATE $HOST $MSG\n"
        - template_escape:
          - "no"

Rewrite

rewrite r_set_message_to_MESSAGE {
  set( 
    "${.json.message}"
    value("$MESSAGE"
  );
};

r_set_message_to_MESSAGE:
  syslog_ng.config:
    - config:
      - rewrite:
        - set:
- '${.json.message}'
- value : '"$MESSAGE"'

Global options

options {
    time_reap(30);
    mark_freq(10);
    keep_hostname(yes);
};

global_options:
    syslog_ng.config:
        - config:
            options:
                - time_reap: 30
                - mark_freq: 10
                - keep_hostname: "yes"

Log

log {
    source(s_gsoc2014);
    junction {
        channel {
            filter(f_json);
            parser(p_json);
            rewrite(r_set_json_tag);
            rewrite(r_set_message_to_MESSAGE);
            destination {
                file("/tmp/json-input.log",
                template(t_gsoc2014)
            )
            }
            flags(final);
        }
        channel {
            filter(f_not_json);
            parser {
                syslog-parser(
                )
            }
            rewrite(r_set_syslog_tag);
            flags(final);
        }
        destination {
            file("/tmp/all.log",
            template(t_gsoc2014)
        );
    }
}
3.4 Advanced Topics

3.4.1 SaltStack Walk-through

Note: Welcome to SaltStack! I am excited that you are interested in Salt and starting down the path to better infrastructure management. I developed (and am continuing to develop) Salt with the goal of making the best software available to manage computers of almost any kind. I hope you enjoy working with Salt and that the software can solve your real world needs!

- Thomas S Hatch
  - Salt creator and Chief Developer
  - CTO of SaltStack, Inc.

Getting Started

What is Salt?

Salt is a different approach to infrastructure management, founded on the idea that high-speed communication with large numbers of systems can open up new capabilities. This approach makes Salt a powerful multitasking system that can solve many specific problems in an infrastructure.
The backbone of Salt is the remote execution engine, which creates a high-speed, secure and bi-directional communication net for groups of systems. On top of this communication system, Salt provides an extremely fast, flexible, and easy-to-use configuration management system called Salt States.

**Installing Salt**

SaltStack has been made to be very easy to install and get started. The *installation documents* contain instructions for all supported platforms.

**Starting Salt**

Salt functions on a master/minion topology. A master server acts as a central control bus for the clients, which are called minions. The minions connect back to the master.

**Setting Up the Salt Master**  Turning on the Salt Master is easy -- just turn it on! The default configuration is suitable for the vast majority of installations. The Salt Master can be controlled by the local Linux/Unix service manager:

- **On Systemd based platforms (OpenSuse, Fedora):**
  ```
  systemctl start salt-master
  ```

- **On Upstart based systems (Ubuntu, older Fedora/RHEL):**
  ```
  service salt-master start
  ```

- **On SysV Init systems (Debian, Gentoo etc.):**
  ```
  /etc/init.d/salt-master start
  ```

Alternatively, the Master can be started directly on the command-line:

```
salt-master -d
```

The Salt Master can also be started in the foreground in debug mode, thus greatly increasing the command output:

```
salt-master -l debug
```

The Salt Master needs to bind to two TCP network ports on the system. These ports are 4505 and 4506. For more in depth information on firewalling these ports, the firewall tutorial is available [here](#).

**Setting up a Salt Minion**  **Note:** The Salt Minion can operate with or without a Salt Master. This walk-through assumes that the minion will be connected to the master, for information on how to run a master-less minion please see the master-less quick-start guide:

**Masterless Minion Quickstart**

The Salt Minion only needs to be aware of one piece of information to run, the network location of the master.

By default the minion will look for the DNS name `salt` for the master, making the easiest approach to set internal DNS to resolve the name `salt` back to the Salt Master IP.

Otherwise, the minion configuration file will need to be edited so that the configuration option `master` points to the DNS name or the IP of the Salt Master:

**Note:** The default location of the configuration files is `/etc/salt`. Most platforms adhere to this convention, but
platforms such as FreeBSD and Microsoft Windows place this file in different locations.

/etc/salt/minion:

| master: saltmaster.example.com |

Now that the master can be found, start the minion in the same way as the master; with the platform init system or via the command line directly:

As a daemon:

| salt-minion -d |

In the foreground in debug mode:

| salt-minion -l debug |

When the minion is started, it will generate an id value, unless it has been generated on a previous run and cached in the configuration directory, which is /etc/salt by default. This is the name by which the minion will attempt to authenticate to the master. The following steps are attempted, in order to try to find a value that is not localhost:

1. The Python function socket.getfqdn() is run
2. /etc/hostname is checked (non-Windows only)
3. /etc/hosts (%WINDIR%\system32\drivers\etc\hosts on Windows hosts) is checked for hostnames that map to anything within 127.0.0.0/8.

If none of the above are able to produce an id which is not localhost, then a sorted list of IP addresses on the minion (excluding any within 127.0.0.0/8) is inspected. The first publicly-routable IP address is used, if there is one. Otherwise, the first privately-routable IP address is used.

If all else fails, then localhost is used as a fallback.

**Note:** Overriding the id

The minion id can be manually specified using the id parameter in the minion config file. If this configuration value is specified, it will override all other sources for the id.

Now that the minion is started, it will generate cryptographic keys and attempt to connect to the master. The next step is to venture back to the master server and accept the new minion’s public key.

**Using salt-key** Salt authenticates minions using public-key encryption and authentication. For a minion to start accepting commands from the master, the minion keys need to be accepted by the master.

The salt-key command is used to manage all of the keys on the master. To list the keys that are on the master:

| salt-key -L |

The keys that have been rejected, accepted, and pending acceptance are listed. The easiest way to accept the minion key is to accept all pending keys:

| salt-key -A |

**Note:** Keys should be verified! Print the master key fingerprint by running salt-key -F master on the Salt master. Copy the master.pub fingerprint from the Local Keys section, and then set this value as the master_finger in the minion configuration file. Restart the Salt minion.
On the master, run `salt-key -f minion-id` to print the fingerprint of the minion's public key that was received by the master. On the minion, run `salt-call key.finger --local` to print the fingerprint of the minion key.

On the master:

```bash
# salt-key -f foo.domain.com
Unaccepted Keys:
```

On the minion:

```bash
# salt-call key.finger --local
local:
```

If they match, approve the key with `salt-key -a foo.domain.com`.

---

**Sending the First Commands**  
Now that the minion is connected to the master and authenticated, the master can start to command the minion.

Salt commands allow for a vast set of functions to be executed and for specific minions and groups of minions to be targeted for execution.

The `salt` command is comprised of command options, target specification, the function to execute, and arguments to the function.

A simple command to start with looks like this:

```bash
salt '*' test.ping
```

The `*` is the target, which specifies all minions.

`test.ping` tells the minion to run the `test.ping` function.

In the case of `test.ping`, `test` refers to a **execution module**, `ping` refers to the `ping` function contained in the aforementioned `test` module.

**Note:** Execution modules are the workhorses of Salt. They do the work on the system to perform various tasks, such as manipulating files and restarting services.

The result of running this command will be the master instructing all of the minions to execute `test.ping` in parallel and return the result.

This is not an actual ICMP ping, but rather a simple function which returns `True`. Using `test.ping` is a good way of confirming that a minion is connected.

**Note:** Each minion registers itself with a unique minion ID. This ID defaults to the minion's hostname, but can be explicitly defined in the minion config as well by using the `id` parameter.

Of course, there are hundreds of other modules that can be called just as `test.ping` can. For example, the following would return disk usage on all targeted minions:

```bash
salt '*' disk.usage
```

**Getting to Know the Functions**  
Salt comes with a vast library of functions available for execution, and Salt functions are self-documenting. To see what functions are available on the minions execute the `sys.doc` function:

---

3.4. Advanced Topics
This will display a very large list of available functions and documentation on them.

**Note:** Module documentation is also available on the web.

These functions cover everything from shelling out to package management to manipulating database servers. They comprise a powerful system management API which is the backbone to Salt configuration management and many other aspects of Salt.

**Note:** Salt comes with many plugin systems. The functions that are available via the `salt` command are called *Execution Modules*.

### Helpful Functions to Know

The `cmd` module contains functions to shell out on minions, such as `cmd.run` and `cmd.run_all`:

```
salt '*' cmd.run 'ls -l /etc'
```

The `pkg` functions automatically map local system package managers to the same salt functions. This means that `pkg.install` will install packages via `yum` on Red Hat based systems, `apt` on Debian systems, etc.:

```
salt '*' pkg.install vim
```

**Note:** Some custom Linux spins and derivatives of other distributions are not properly detected by Salt. If the above command returns an error message saying that `pkg.install` is not available, then you may need to override the `pkg` provider. This process is explained [here](#).

The `network.interfaces` function will list all interfaces on a minion, along with their IP addresses, netmasks, MAC addresses, etc:

```
salt '*' network.interfaces
```

### Changing the Output Format

The default output format used for most Salt commands is called the *nested* outputter, but there are several other outputters that can be used to change the way the output is displayed. For instance, the `pprint` outputter can be used to display the return data using Python's `pprint` module:

```
root@saltmaster:~# salt myminion grains.item pythonpath --out=pprint
{
    'myminion': {
        'pythonpath': [
            '/usr/lib64/python2.7',
            '/usr/lib/python2.7/plat-linux2',
            '/usr/lib64/python2.7/lib-tk',
            '/usr/lib/python2.7/lib-tk',
            '/usr/lib/python2.7/site-packages',
            '/usr/lib/python2.7/site-packages/gst-0.10',
            '/usr/lib/python2.7/site-packages/gtk-2.0']}
}
```

The full list of Salt outputters, as well as example output, can be found [here](#).

### `salt-call`

The examples so far have described running commands from the Master using the `salt` command, but when troubleshooting it can be more beneficial to login to the minion directly and use `salt-call`.

Doing so allows you to see the minion log messages specific to the command you are running (which are *not* part of the return data you see when running the command from the Master using `salt`), making it unnecessary to tail the minion log. More information on `salt-call` and how to use it can be found [here](#).
Grains  Salt uses a system called Grains to build up static data about minions. This data includes information about the operating system that is running, CPU architecture and much more. The grains system is used throughout Salt to deliver platform data to many components and to users.

Grains can also be statically set, this makes it easy to assign values to minions for grouping and managing.

A common practice is to assign grains to minions to specify what the role or roles a minion might be. These static grains can be set in the minion configuration file or via the grains.setval function.

Targeting  Salt allows for minions to be targeted based on a wide range of criteria. The default targeting system uses globular expressions to match minions, hence if there are minions named larry1, larry2, curly1, and curly2, a glob of larry* will match larry1 and larry2, and a glob of *1 will match larry1 and curly1.

Many other targeting systems can be used other than globs, these systems include:

Regular Expressions  Target using PCRE-compliant regular expressions

Grains  Target based on grains data: Targeting with Grains

Pillar  Target based on pillar data: Targeting with Pillar

IP  Target based on IP address/subnet/range

Compound  Create logic to target based on multiple targets: Targeting with Compound

Nodegroup  Target with nodegroups: Targeting with Nodegroup

The concepts of targets are used on the command line with Salt, but also function in many other areas as well, including the state system and the systems used for ACLs and user permissions.

Passing in Arguments  Many of the functions available accept arguments which can be passed in on the command line:

```bash
salt '*' pkg.install vim
```

This example passes the argument vim to the pkg.install function. Since many functions can accept more complex input than just a string, the arguments are parsed through YAML, allowing for more complex data to be sent on the command line:

```bash
salt '*' test.echo 'foo: bar'
```

In this case Salt translates the string 'foo: bar' into the dictionary `{foo: 'bar'}`

Note: Any line that contains a newline will not be parsed by YAML.

Salt States

Now that the basics are covered the time has come to evaluate States. Salt States, or the State System is the component of Salt made for configuration management.

The state system is already available with a basic Salt setup, no additional configuration is required. States can be set up immediately.

Note: Before diving into the state system, a brief overview of how states are constructed will make many of the concepts clearer. Salt states are based on data modeling and build on a low level data structure that is used to execute each state function. Then more logical layers are built on top of each other.

The high layers of the state system which this tutorial will cover consists of everything that needs to be known to use states, the two high layers covered here are the sls layer and the highest layer highstate.
Understanding the layers of data management in the State System will help with understanding states, but they never
need to be used. Just as understanding how a compiler functions assists when learning a programming language,
understanding what is going on under the hood of a configuration management system will also prove to be a
valuable asset.

The First SLS Formula

The state system is built on SLS formulas. These formulas are built out in files on Salt’s file server. To make a very
basic SLS formula open up a file under /srv/salt named vim.sls. The following state ensures that vim is installed on
a system to which that state has been applied.

```
/srv/salt/vim.sls:

vim:
  pkg.installed
```

Now install vim on the minions by calling the SLS directly:

```
salt '*' state.sls vim
```

This command will invoke the state system and run the vim SLS.

Now, to beef up the vim SLS formula, a vimrc can be added:

```
/srv/salt/vim.sls:

vim:
  pkg.installed: []

/etc/vimrc:
  file.managed:
    - source: salt://vimrc
    - mode: 644
    - user: root
    - group: root
```

Now the desired vimrc needs to be copied into the Salt file server to /srv/salt/vimrc. In Salt, everything is a
file, so no path redirection needs to be accounted for. The vimrc file is placed right next to the vim.sls file. The
same command as above can be executed to all the vim SLS formulas and now include managing the file.

**Note:** Salt does not need to be restarted/reloaded or have the master manipulated in any way when changing SLS
formulas. They are instantly available.

Adding Some Depth

Obviously maintaining SLS formulas right in a single directory at the root of the file server will not scale out to
reasonably sized deployments. This is why more depth is required. Start by making an nginx formula a better way,
make an nginx subdirectory and add an init.sls file:

```
/srv/salt/nginx/init.sls:

nginx:
  pkg.installed: []
  service.running:
    - require:
      - pkg: nginx
```

74 Chapter 3. Tutorials
A few concepts are introduced in this SLS formula. First is the service statement which ensures that the nginx service is running. Of course, the nginx service can’t be started unless the package is installed -- hence the require statement which sets up a dependency between the two. The require statement makes sure that the required component is executed before and that it results in success.

Note: The require option belongs to a family of options called requisites. Requisites are a powerful component of Salt States, for more information on how requisites work and what is available see: Requisites

Also evaluation ordering is available in Salt as well: Ordering States

This new sls formula has a special name -- init.sls. When an SLS formula is named init.sls it inherits the name of the directory path that contains it. This formula can be referenced via the following command:

```
salt '*' state.sls nginx
```

Note: Reminder! Just as one could call the test.ping or disk.usage execution modules, state.sls is simply another execution module. It simply takes the name of an SLS file as an argument.

Now that subdirectories can be used, the vim.sls formula can be cleaned up. To make things more flexible, move the vim.sls and vimrc into a new subdirectory called edit and change the vim.sls file to reflect the change:

```
/srv/salt/edit/vim.sls:

vim:
    pkg.installed

/etc/vimrc:
    file.managed:
        - source: salt://edit/vimrc
        - mode: 644
        - user: root
        - group: root
```

Only the source path to the vimrc file has changed. Now the formula is referenced as edit.vim because it resides in the edit subdirectory. Now the edit subdirectory can contain formulas for emacs, nano, joe or any other editor that may need to be deployed.

Next Reading

Two walk-throughs are specifically recommended at this point. First, a deeper run through States, followed by an explanation of Pillar.

1. Starting States
2. Pillar Walkthrough

An understanding of Pillar is extremely helpful in using States.

Getting Deeper Into States

Two more in-depth States tutorials exist, which delve much more deeply into States functionality.
1. *How Do I Use Salt States?*, covers much more to get off the ground with States.

2. The *States Tutorial* also provides a fantastic introduction.

These tutorials include much more in-depth information including templating SLS formulas etc.

**So Much More!**

This concludes the initial Salt walk-through, but there are many more things still to learn! These documents will cover important core aspects of Salt:

- Pillar
- Job Management

A few more tutorials are also available:

- Remote Execution Tutorial
- Standalone Minion

This still is only scratching the surface, many components such as the reactor and event systems, extending Salt, modular components and more are not covered here. For an overview of all Salt features and documentation, look at the *Table of Contents*.

### 3.4.2 running salt as normal user tutorial

**Before continuing** make sure you have a working Salt installation by following the *installation* and the *configuration* instructions.

**Stuck?**

There are many ways to *get help from the Salt community* including our *mailing list* and our *IRC channel #salt*.

**Running Salt functions as non root user**

If you don’t want to run salt cloud as root or even install it you can configure it to have a virtual root in your working directory.

The salt system uses the *salt.syspath* module to find the variables

If you run the salt-build, it will generated in:

```
./build/lib.linux-x86_64-2.7/salt/_syspaths.py
```

To generate it, run the command:

```
python setup.py build
```

Copy the generated module into your salt directory

```
cp ./build/lib.linux-x86_64-2.7/salt/_syspaths.py salt/_syspaths.py
```

Edit it to include needed variables and your new paths
# you need to edit this
ROOT_DIR = *your current dir* + '/salt/root'

# you need to edit this
INSTALL_DIR = *location of source code*

CONFIG_DIR = ROOT_DIR + '/etc/salt'
CACHE_DIR = ROOT_DIR + '/var/cache/salt'
SOCK_DIR = ROOT_DIR + '/var/run/salt'
SRV_ROOT_DIR = ROOT_DIR + '/srv'
BASE_FILE_ROOTS_DIR = ROOT_DIR + '/srv/salt'
BASE_PILLAR_ROOTS_DIR = ROOT_DIR + '/srv/pillar'
BASE_MASTER_ROOTS_DIR = ROOT_DIR + '/srv/salt-master'
LOGS_DIR = ROOT_DIR + '/var/log/salt'
PIDFILE_DIR = ROOT_DIR + '/var/run'
CLOUD_DIR = INSTALL_DIR + '/cloud'
BOOTSTRAP = CLOUD_DIR + '/deploy/bootstrap-salt.sh'

Create the directory structure

```bash
```

Populate the configuration files:

```bash
cp -r conf/* root/etc/salt/
```

Edit your `root/etc/salt/master` configuration that is used by salt-cloud:

```bash
user: *your user name*
```

Run like this:

```bash
PYTHONPATH=`pwd` scripts/salt-cloud
```

## 3.4.3 MinionFS Backend Walkthrough

New in version 2014.1.0.

Sometimes, you might need to propagate files that are generated on a minion. Salt already has a feature to send files from a minion to the master:

```bash
salt 'minion-id' cp.push /path/to/the/file
```

This command will store the file, including its full path, under `cachedir/master/minions/minion-id/files`. With the default `cachedir` the example file above would be stored as `/var/cache/salt/master/minions/minion-id/files/path/to/the/file`.

**Note:** This walkthrough assumes basic knowledge of Salt and `cp.push`. To get up to speed, check out the walkthrough.

Since it is not a good idea to expose the whole `cachedir`, MinionFS should be used to send these files to other minions.
Simple Configuration

To use the minionfs backend only two configuration changes are required on the master. The `file-server_backend` option needs to contain a value of `minion` and `file_recv` needs to be set to true:

```yaml
fileserver_backend:
  - roots
  - minion
file_recv: True
```

These changes require a restart of the master, then new requests for the `salt://minion-id/` protocol will send files that are pushed by `cp.push` from `minion-id` to the master.

**Note:** All of the files that are pushed to the master are going to be available to all of the minions. If this is not what you want, please remove `minion` from `fileserver_backend` in the master config file.

**Note:** Having directories with the same name as your minions in the root that can be accessed like `salt://minion-id/` might cause confusion.

Commandline Example

Let's assume that we are going to generate SSH keys on a minion called `minion-source` and put the public part in `~/.ssh/authorized_keys` of root user of a minion called `minion-destination`.

First, let's make sure that `/root/.ssh` exists and has the right permissions:

```bash
[root@salt-master file]# salt '*' file.mkdir dir_path=/root/.ssh user=root group=root mode=700
```

```
minion-source:
None
```

```
minion-destination:
None
```

We create an RSA key pair without a passphrase:

```bash
[root@salt-master file]# salt 'minion-source' cmd.run 'ssh-keygen -N "" -f /root/.ssh/id_rsa'
```

```
minion-source:
Generating public/private rsa key pair.
Your identification has been saved in /root/.ssh/id_rsa.
Your public key has been saved in /root/.ssh/id_rsa.pub.
The key fingerprint is:
The key's randomart image is:

```
1 Yes, that was the actual key on my server, but the server is already destroyed.
```
and we send the public part to the master to be available to all minions:

```bash
[root@salt-master file]# salt 'minion-source' cp.push /root/.ssh/id_rsa.pub
minion-source:
    True
```

now it can be seen by everyone:

```bash
[root@salt-master file]# salt 'minion-destination' cp.list_master_dirs
minion-destination:
    - .
    - etc
    - minion-source/root
    - minion-source/root/.ssh
```

Lets copy that as the only authorized key to minion-destination:

```bash
[root@salt-master file]# salt 'minion-destination' cp.get_file salt://minion-source/root/.ssh/id_rsa.pub /root/.ssh/authorized_keys
minion-destination:
    /root/.ssh/authorized_keys
```

Or we can use a more elegant and salty way to add an SSH key:

```bash
[root@salt-master file]# salt 'minion-destination' ssh.set_auth_key_from_file user=root source=salt://minion-source/root/.ssh/id_rsa.pub
minion-destination:
    new
```

### 3.4.4 Automatic Updates / Frozen Deployments

New in version 0.10.3.

Salt has support for the Esky application freezing and update tool. This tool allows one to build a complete zipfile out of the salt scripts and all their dependencies - including shared objects / DLLs.

**Getting Started**

To build frozen applications, suitable build environment will be needed for each platform. You should probably set up a virtualenv in order to limit the scope of Q/A.

This process does work on Windows. Directions are available at [https://github.com/saltstack/salt-windows-install](https://github.com/saltstack/salt-windows-install) for details on installing Salt in Windows. Only the 32-bit Python and dependencies have been tested, but they have been tested on 64-bit Windows.

Install bbfreeze, and then esky from PyPI in order to enable the bdist_esky command in setup.py. Salt itself must also be installed, in addition to its dependencies.

**Building and Freezing**

Once you have your tools installed and the environment configured, use `setup.py` to prepare the distribution files.

```bash
python setup.py sdist
python setup.py bdist
```

Once the distribution files are in place, Esky can be used to traverse the module tree and pack all the scripts up into a redistributable.
python setup.py bdist_esky

There will be an appropriately versioned salt-VERSION.zip in dist/ if everything went smoothly.

**Windows**

C:\Python27\lib\site-packages\zmq will need to be added to the PATH variable. This helps bbfreeze find the zmq DLL so it can pack it up.

**Using the Frozen Build**

Unpack the zip file in the desired install location. Scripts like salt-minion and salt-call will be in the root of the zip file. The associated libraries and bootstrapping will be in the directories at the same level. (Check the Esky documentation for more information)

To support updating your minions in the wild, put the builds on a web server that the minions can reach. salt.modules.saltutil.update() will trigger an update and (optionally) a restart of the minion service under the new version.

**Troubleshooting**

**A Windows minion isn't responding**

The process dispatch on Windows is slower than it is on *nix. It may be necessary to add `-t 15` to salt commands to give minions plenty of time to return.

**Windows and the Visual Studio Redist**

The Visual C++ 2008 32-bit redistributable will need to be installed on all Windows minions. Esky has an option to pack the library into the zipfile, but OpenSSL does not seem to acknowledge the new location. If a no OPENSSL_Applink error appears on the console when trying to start a frozen minion, the redistributable is not installed.

**Mixed Linux environments and Yum**

The Yum Python module doesn't appear to be available on any of the standard Python package mirrors. If RHEL/CentOS systems need to be supported, the frozen build should created on that platform to support all the Linux nodes. Remember to build the virtualenv with `--system-site-packages` so that the yum module is included.

**Automatic (Python) module discovery**

Automatic (Python) module discovery does not work with the late-loaded scheme that Salt uses for (Salt) modules. Any misbehaving modules will need to be explicitly added to the freezer_includes in Salt's setup.py. Always check the zipped application to make sure that the necessary modules were included.
3.4.5 Multi Master Tutorial

As of Salt 0.16.0, the ability to connect minions to multiple masters has been made available. The multi-master system allows for redundancy of Salt masters and facilitates multiple points of communication out to minions. When using a multi-master setup, all masters are running hot, and any active master can be used to send commands out to the minions.

Note: If you need failover capabilities with multiple masters, there is also a MultiMaster-PKI setup available, that uses a different topology MultiMaster-PKI with Failover Tutorial

In 0.16.0, the masters do not share any information, keys need to be accepted on both masters, and shared files need to be shared manually or use tools like the git files server backend to ensure that the file_roots are kept consistent.

Summary of Steps

1. Create a redundant master server
2. Copy primary master key to redundant master
3. Start redundant master
4. Configure minions to connect to redundant master
5. Restart minions
6. Accept keys on redundant master

Prepping a Redundant Master

The first task is to prepare the redundant master. If the redundant master is already running, stop it. There is only one requirement when preparing a redundant master, which is that masters share the same private key. When the first master was created, the master's identifying key pair was generated and placed in the master's pki_dir. The default location of the master's key pair is /etc/salt/pki/master/. Take the private key, master.pem, and copy it to the same location on the redundant master. Do the same for the master's public key, master.pub. Assuming that no minions have yet been connected to the new redundant master, it is safe to delete any existing key in this location and replace it.

Note: There is no logical limit to the number of redundant masters that can be used.

Once the new key is in place, the redundant master can be safely started.

Configure Minions

Since minions need to be master-aware, the new master needs to be added to the minion configurations. Simply update the minion configurations to list all connected masters:

```
master:
  - saltmaster1.example.com
  - saltmaster2.example.com
```

Now the minion can be safely restarted.

Now the minions will check into the original master and also check into the new redundant master. Both masters are first-class and have rights to the minions.
Note: Minions can automatically detect failed masters and attempt to reconnect to reconnect to them quickly. To enable this functionality, set `master_alive_interval` in the minion config and specify a number of seconds to poll the masters for connection status.

If this option is not set, minions will still reconnect to failed masters but the first command sent after a master comes back up may be lost while the minion authenticates.

Sharing Files Between Masters

Salt does not automatically share files between multiple masters. A number of files should be shared or sharing of these files should be strongly considered.

Minion Keys

Minion keys can be accepted the normal way using `salt-key` on both masters. Keys accepted, deleted, or rejected on one master will NOT be automatically managed on redundant masters; this needs to be taken care of by running salt-key on both masters or sharing the `/etc/salt/pki/master/{minions,minions_pre,minions_rejected}` directories between masters.

Note: While sharing the `/etc/salt/pki/master` directory will work, it is strongly discouraged, since allowing access to the `master.pem` key outside of Salt creates a SERIOUS security risk.

File_Roots

The `file_roots` contents should be kept consistent between masters. Otherwise state runs will not always be consistent on minions since instructions managed by one master will not agree with other masters.

The recommended way to sync these is to use a fileserver backend like gitfs or to keep these files on shared storage.

Pillar_Roots

Pillar roots should be given the same considerations as `file_roots`.

Master Configurations

While reasons may exist to maintain separate master configurations, it is wise to remember that each master maintains independent control over minions. Therefore, access controls should be in sync between masters unless a valid reason otherwise exists to keep them inconsistent.

These access control options include but are not limited to:

- `external_auth`
- `client_acl`
- `peer`
- `peer_run`
3.4.6 Multi-Master-PKI Tutorial With Failover

This tutorial will explain, how to run a salt-environment where a single minion can have multiple masters and fail-over between them if its current master fails.

The individual steps are

- setup the master(s) to sign its auth-replies
- setup minion(s) to verify master-public-keys
- enable multiple masters on minion(s)
- enable master-check on minion(s)

Please note, that it is advised to have good knowledge of the salt-authentication and communication-process to understand this tutorial. All of the settings described here, go on top of the default authentication/communication process.

Motivation

The default behaviour of a salt-minion is to connect to a master and accept the masters public key. With each publication, the master sends his public-key for the minion to check and if this public-key ever changes, the minion complains and exits. Practically this means, that there can only be a single master at any given time.

Would it not be much nicer, if the minion could have any number of masters (1:n) and jump to the next master if its current master died because of a network or hardware failure?

Note: There is also a MultiMaster-Tutorial with a different approach and topology than this one, that might also suite your needs or might even be better suited Multi-Master Tutorial

It is also desirable, to add some sort of authenticity-check to the very first public key a minion receives from a master. Currently a minions takes the first masters public key for granted.

The Goal

Setup the master to sign the public key it sends to the minions and enable the minions to verify this signature for authenticity.

Prepping the master to sign its public key

For signing to work, both master and minion must have the signing and/or verification settings enabled. If the master signs the public key but the minion does not verify it, the minion will complain and exit. The same happens, when the master does not sign but the minion tries to verify.

The easiest way to have the master sign its public key is to set

```
master_sign_pubkey: True
```

After restarting the salt-master service, the master will automatically generate a new key-pair

```
master_sign.pem
master_sign.pub
```

A custom name can be set for the signing key-pair by setting
master_sign_key_name: <name_without_suffix>

The master will then generate that key-pair upon restart and use it for creating the public keys signature attached to the auth-reply.

The computation is done for every auth-request of a minion. If many minions auth very often, it is advised to use conf_master:master_pubkey_signature and conf_master:master_use_pubkey_signature settings described below.

If multiple masters are in use and should sign their auth-replies, the signing key-pair master_sign.* has to be copied to each master. Otherwise a minion will fail to verify the masters public when connecting to a different master than it did initially. That is because the public keys signature was created with a different signing key-pair.

Prepping the minion to verify received public keys

The minion must have the public key (and only that one!) available to be able to verify a signature it receives. That public key (default to master_sign.pub) must be copied from the master to the minions pki-directory.

/etc/salt/pki/minion/master_sign.pub

DO NOT COPY THE master_sign.pem FILE. IT MUST STAY ON THE MASTER AND ONLY THERE!

When that is done, enable the signature checking in the minions configuration

verify_master_pubkey_sign: True

and restart the minion. For the first try, the minion should be run in manual debug mode.

$ salt-minion -l debug

Upon connecting to the master, the following lines should appear on the output:

[DEBUG ] Attempting to authenticate with the Salt Master at 172.16.0.10
[DEBUG ] Loaded minion key: /etc/salt/pki/minion/minion.pem
[DEBUG ] salt.crypt.verify_signature: Loading public key
[DEBUG ] salt.crypt.verify_signature: Verifying signature
[DEBUG ] Successfully verified signature of master public key with verification public key master_sign.pub
[INFO ] Received signed and verified master pubkey from master 172.16.0.10
[DEBUG ] Decrypting the current master AES key

If the signature verification fails, something went wrong and it will look like this

[DEBUG ] Attempting to authenticate with the Salt Master at 172.16.0.10
[DEBUG ] Loaded minion key: /etc/salt/pki/minion/minion.pem
[DEBUG ] salt.crypt.verify_signature: Loading public key
[DEBUG ] salt.crypt.verify_signature: Verifying signature
[DEBUG ] Failed to verify signature of public key
[CRITICAL] The Salt Master server's public key did not authenticate!

In a case like this, it should be checked, that the verification pubkey (master_sign.pub) on the minion is the same as the one on the master.

Once the verification is successful, the minion can be started in daemon mode again.

For the paranoid among us, its also possible to verify the public whenever it is received from the master. That is, for every single auth-attempt which can be quite frequent. For example just the start of the minion will force the signature to be checked 6 times for various things like auth, mine, highstate, etc.

If that is desired, enable the setting
always_verify_signature: True

**Multiple Masters For A Minion**

Configuring multiple masters on a minion is done by specifying two settings:

- a list of masters addresses
- what type of master is defined

```yaml
master:
  - 172.16.0.10
  - 172.16.0.11
  - 172.16.0.12

master_type: failover
```

This tells the minion that all the master above are available for it to connect to. When started with this configuration, it will try the master in the order they are defined. To randomize that order, set

```yaml
master_shuffle: True
```

The master-list will then be shuffled before the first connection attempt.

The first master that accepts the minion, is used by the minion. If the master does not yet know the minion, that counts as accepted and the minion stays on that master.

For the minion to be able to detect if its still connected to its current master enable the check for it

```yaml
master_alive_interval: <seconds>
```

If the loss of the connection is detected, the minion will temporarily remove the failed master from the list and try one of the other masters defined (again shuffled if that is enabled).

**Testing the setup**

At least two running masters are needed to test the failover setup.

Both masters should be running and the minion should be running on the command line in debug mode

```bash
$ salt-minion -l debug
```

The minion will connect to the first master from its master list

```
[DEBU 2] Attempting to authenticate with the Salt Master at 172.16.0.10
[DEBU 2] Loaded minion key: /etc/salt/pki/minion/minion.pem
[DEBU 2] salt.crypt.verify_signature: Loading public key
[DEBU 2] salt.crypt.verify_signature: Verifying signature
[DEBU 2] Successfully verified signature of master public key with verification public key master_sign.pub
[INFO 3] Received signed and verified master pubkey from master 172.16.0.10
[DEBU 2] Decrypting the current master AES key
```

A test.ping on the master the minion is currently connected to should be run to test connectivity.

If successful, that master should be turned off. A firewall-rule denying the minions packets will also do the trick.

Depending on the configured `conf_minion:master_alive_interval`, the minion will notice the loss of the connection and log it to its logfile.

---

3.4. Advanced Topics
Connection to master 172.16.0.10 lost
Trying to tune in to next master from master-list

The minion will then remove the current master from the list and try connecting to the next master.

Removing possibly failed master 172.16.0.10 from list of masters
Master ip address changed from 172.16.0.10 to 172.16.0.11
Attempting to authenticate with the Salt Master at 172.16.0.11

If everything is configured correctly, the new master's public key will be verified successfully.

Received signed and verified master pub key from master 172.16.0.11
Authentication with master successful!

Performance Tuning

With the setup described above, the master computes a signature for every auth-request of a minion. With many minions and many auth-requests, that can chew up quite a bit of CPU-Power.

To avoid that, the master can use a pre-created signature of its public-key. The signature is saved as a base64 encoded string which the master reads once when starting and attaches only that string to auth-replies.

Enabling this also gives paranoid users the possibility, to have the signing key-pair on a different system than the actual salt-master and create the public keys signature there. Probably on a system with more restrictive firewall rules, without internet access, less users, etc.

That signature can be created with

$ salt-key --gen-signature

This will create a default signature file in the master pki-directory

/etc/salt/pki/master/master_pubkey_signature

It is a simple text-file with the binary-signature converted to base64.

If no signing-pair is present yet, this will auto-create the signing pair and the signature file in one call

$ salt-key --gen-signature --auto-create

Telling the master to use the pre-created signature is done with

master_use_pubkey_signature: True

That requires the file `master_pubkey_signature` to be present in the masters pki-directory with the correct signature.

If the signature file is named differently, its name can be set with
With many masters and many public-keys (default and signing), it is advised to use the salt-masters hostname for the signature-files name. Signatures can be easily confused because they do not provide any information about the key the signature was created from.

Verifying that everything works is done the same way as above.

**How the signing and verification works**

The default key-pair of the salt-master is

```
/etc/salt/pki/master/master.pem
/etc/salt/pki/master/master.pub
```

To be able to create a signature of a message (in this case a public-key), another key-pair has to be added to the setup. Its default name is:

```
master_sign.pem
master_sign.pub
```

The combination of the master* and master_sign* key-pairs give the possibility of generating signatures. The signature of a given message is unique and can be verified, if the public-key of the signing-key-pair is available to the recipient (the minion).

The signature of the masters public-key in master.pub is computed with

```
M2Crypto.EVP.sign_update()
```

This results in a binary signature which is converted to base64 and attached to the auth-reply send to the minion.

With the signing-pairs public-key available to the minion, the attached signature can be verified with

```
M2Crypto.EVP.verify_update().
```

When running multiple masters, either the signing key-pair has to be present on all of them, or the master_pubkey_signature has to be pre-computed for each master individually (because they all have different public-keys).

**DO NOT PUT THE SAME master.pub ON ALL MASTERS FOR EASE OF USE.**

### 3.4.7 Preseed Minion with Accepted Key

In some situations, it is not convenient to wait for a minion to start before accepting its key on the master. For instance, you may want the minion to bootstrap itself as soon as it comes online. You may also want to to let your developers provision new development machines on the fly.

**See also:**

Many ways to preseed minion keys

Salt has other ways to generate and pre-accept minion keys in addition to the manual steps outlined below. salt-cloud performs these same steps automatically when new cloud VMs are created (unless instructed not to).
Salt exposes an HTTP call to Salt's REST API to generate and download the new minion keys as a tarball.

There is a general four step process to do this:

1. Generate the keys on the master:
   ```
   root@saltmaster# salt-key --gen-keys=[key_name]
   ```
   Pick a name for the key, such as the minion's id.

2. Add the public key to the accepted minion folder:
   ```
   root@saltmaster# cp key_name.pub /etc/salt/pki/master/minions/[minion_id]
   ```
   It is necessary that the public key file has the same name as your minion id. This is how Salt matches minions with their keys. Also note that the pki folder could be in a different location, depending on your OS or if specified in the master config file.

3. Distribute the minion keys.
   There is no single method to get the keypair to your minion. The difficulty is finding a distribution method which is secure. For Amazon EC2 only, an AWS best practice is to use IAM Roles to pass credentials. (See blog post, http://blogs.aws.amazon.com/security/post/Tx610S2MLVZWEA/Using-IAM-roles-to-distribute-non-AWS-credentials-to-your-EC2-instances)

   **Security Warning**
   Since the minion key is already accepted on the master, distributing the private key poses a potential security risk. A malicious party will have access to your entire state tree and other sensitive data if they gain access to a preseeded minion key.

4. Preseed the Minion with the keys
   You will want to place the minion keys before starting the salt-minion daemon:
   ```
   /etc/salt/pki/minion/minion.pem
   /etc/salt/pki/minion/minion.pub
   ```
   Once in place, you should be able to start salt-minion and run `salt-call state.highstate` or any other salt commands that require master authentication.

### 3.4.8 Salt Bootstrap

The Salt Bootstrap script allows for a user to install the Salt Minion or Master on a variety of system distributions and versions. This shell script known as `bootstrap-salt.sh` runs through a series of checks to determine the operating system type and version. It then installs the Salt binaries using the appropriate methods. The Salt Bootstrap script installs the minimum number of packages required to run Salt. This means that in the event you run the bootstrap to install via package, Git will not be installed. Installing the minimum number of packages helps ensure the script stays as lightweight as possible, assuming the user will install any other required packages after the Salt binaries are present on the system. The script source is available on GitHub: https://github.com/saltstack/salt-bootstrap

**Supported Operating Systems**

- Amazon Linux 2012.09
- Arch
• CentOS 5/6
• Debian 6.x/7.x/8 (git installations only)
• Fedora 17/18
• FreeBSD 9.1/9.2/10
• Gentoo
• Linaro
• Linux Mint 13/14
• OpenSUSE 12.x
• Oracle Linux 5/5
• Red Hat 5/6
• Red Hat Enterprise 5/6
• Scientific Linux 5/6
• SmartOS
• SuSE 11 SP1/11 SP2
• Ubuntu 10.x/11.x/12.x/13.04/13.10
• Elementary OS 0.2

Note: In the event you do not see your distribution or version available please review the develop branch on GitHub as it main contain updates that are not present in the stable release: https://github.com/saltstack/salt-bootstrap/tree/develop

Example Usage

If you're looking for the one-liner to install salt, please scroll to the bottom and use the instructions for Installing via an Insecure One-Liner

Note: In every two-step example, you would be well-served to examine the downloaded file and examine it to ensure that it does what you expect.

Using curl to install latest git:

```
curl -L https://bootstrap.saltstack.com -o install_salt.sh
sudo sh install_salt.sh git develop
```

Using wget to install your distribution's stable packages:

```
wget -O install_salt.sh https://bootstrap.saltstack.com
sudo sh install_salt.sh
```

Install a specific version from git using wget:

```
wget -O install_salt.sh https://bootstrap.saltstack.com
sudo sh install_salt.sh -P git v0.16.4
```

If you already have python installed, python 2.6, then it's as easy as:
python -m urllib "https://bootstrap.saltstack.com" > install_salt.sh
sudo sh install_salt.sh git develop

All python versions should support the following one liner:

python -c "import urllib; print urllib.urlopen("https://bootstrap.saltstack.com").read()" > install_salt.sh
sudo sh install_salt.sh git develop

On a FreeBSD base system you usually don’t have either of the above binaries available. You do have fetch available though:

fetch -o install_salt.sh https://bootstrap.saltstack.com
sudo sh install_salt.sh

If all you want is to install a salt-master using latest git:

curl -o install_salt.sh -L https://bootstrap.saltstack.com
sudo sh install_salt.sh -M -N git develop

If you want to install a specific release version (based on the git tags):

curl -o install_salt.sh -L https://bootstrap.saltstack.com
sudo sh install_salt.sh git v0.16.4

To install a specific branch from a git fork:

curl -o install_salt.sh -L https://bootstrap.saltstack.com
sudo sh install_salt.sh -g https://github.com/myuser/salt.git git mybranch

**Installing via an Insecure One-Liner**

The following examples illustrate how to install Salt via a one-liner.

**Note:** Warning! These methods do not involve a verification step and assume that the delivered file is trustworthy.

**Examples**

Installing the latest develop branch of Salt:

curl -L https://bootstrap.saltstack.com | sudo sh -s -- git develop

Any of the example above which use two-lines can be made to run in a single-line configuration with minor modifications.

**Example Usage**

The Salt Bootstrap script has a wide variety of options that can be passed as well as several ways of obtaining the bootstrap script itself.

For example, using curl to install your distribution’s stable packages:

curl -L https://bootstrap.saltstack.com | sudo sh

Using wget to install your distribution's stable packages:
wget -O - https://bootstrap.saltstack.com | sudo sh

Installing the latest version available from git with curl:

curl -L https://bootstrap.saltstack.com | sudo sh -s -- git develop

Install a specific version from git using wget:

wget -O - https://bootstrap.saltstack.com | sh -s -- -P git v0.16.4

If you already have python installed, python 2.6, then it’s as easy as:

python -m urllib "https://bootstrap.saltstack.com" | sudo sh -s -- git develop

All python versions should support the following one liner:

python -c 'import urllib; print urllib.urlopen("https://bootstrap.saltstack.com").read()' | \  
sudo sh -s -- git develop

On a FreeBSD base system you usually don’t have either of the above binaries available. You do have fetch available though:

fetch -O - https://bootstrap.saltstack.com | sudo sh

If all you want is to install a salt-master using latest git:

curl -L https://bootstrap.saltstack.com | sudo sh -s -- -M -N git develop

If you want to install a specific release version (based on the git tags):

curl -L https://bootstrap.saltstack.com | sudo sh -s -- git v0.16.4

Downloading the develop branch (from here standard command line options may be passed):

wget https://bootstrap.saltstack.com/develop

**Command Line Options**

Here’s a summary of the command line options:

```
$ sh bootstrap-salt.sh -h

Usage : bootstrap-salt.sh [options] <install-type> <install-type-args>

Installation types:
- stable (default)
- stable [version] (ubuntu specific)
- daily (ubuntu specific)
- testing (redhat specific)
- git

Examples:
- bootstrap-salt.sh
- bootstrap-salt.sh stable
- bootstrap-salt.sh stable 2014.7
- bootstrap-salt.sh daily
- bootstrap-salt.sh testing
- bootstrap-salt.sh git
```
Salt Documentation, Release 2015.8.0

- bootstrap-salt.sh git develop
- bootstrap-salt.sh git v0.17.0
- bootstrap-salt.sh git 8c3fadf15ec183e5ce8c63739850d543617e4357

Options:
- h Display this message
- v Display script version
- n No colours.
- D Show debug output.
- c Temporary configuration directory
- g Salt repository URL. (default: git://github.com/saltstack/salt.git)
- G Instead of cloning from git://github.com/saltstack/salt.git, clone from https://github.com/saltstack/salt.git (Usually necessary on systems which have the regular git protocol port blocked, where https usually is not)
- k Temporary directory holding the minion keys which will pre-seed the master.
- s Sleep time used when waiting for daemons to start, restart and when checking for the services running. Default: 3
- M Also install salt-master
- S Also install salt-syndic
- N Do not install salt-minion
- X Do not start daemons after installation
- C Only run the configuration function. This option automatically bypasses any installation.
- P Allow pip based installations. On some distributions the required salt packages or its dependencies are not available as a package for that distribution. Using this flag allows the script to use pip as a last resort method. NOTE: This only works for functions which actually implement pip based installations.
- F Allow copied files to overwrite existing(config, init.d, etc)
- U If set, fully upgrade the system prior to bootstrapping salt
- K If set, keep the temporary files in the temporary directories specified with -c and -k.
- I If set, allow insecure connections while downloading any files. For example, pass '--no-check-certificate' to 'wget' or '--insecure' to 'curl'
- A Pass the salt-master DNS name or IP. This will be stored under ${_SALT_ETC_DIR}/minion.d/99-master-address.conf
- i Pass the salt-minion id. This will be stored under ${_SALT_ETC_DIR}/minion_id
- L Install the Apache Libcloud package if possible(required for salt-cloud)
- p Extra-package to install while installing salt dependencies. One package per -p flag. You're responsible for providing the proper package name.
- d Disable check_service functions. Setting this flag disables the 'install_<distro>_check_services' checks. You can also do this by touching /tmp/disable_salt_checks on the target host. Defaults ${BS_FALSE}
- H Use the specified http proxy for the installation
- Z Enable external software source for newer ZeroMQ(Only available for RHEL/CentOS/Fedora/Ubuntu based distros)

3.4.9 Git Fileserver Backend Walkthrough

Note: This walkthrough assumes basic knowledge of Salt. To get up to speed, check out the Salt Walkthrough.

The gitfs backend allows Salt to serve files from git repositories. It can be enabled by adding git to the file-server_backend list, and configuring one or more repositories in gitfs_remotes.

Branches and tags become Salt fileserver environments.
Installing Dependencies

Beginning with version 2014.7.0, both pygit2 and Dulwich are supported as alternatives to GitPython. The desired provider can be configured using the gitfs_provider parameter in the master config file.

If gitfs_provider is not configured, then Salt will prefer pygit2 if a suitable version is available, followed by GitPython and Dulwich.

pygit2

The minimum supported version of pygit2 is 0.20.3. Availability for this version of pygit2 is still limited, though the SaltStack team is working to get compatible versions available for as many platforms as possible.

For the Fedora/EPEL versions which have a new enough version packaged, the following command would be used to install pygit2:

```
# yum install python-pygit2
```

Provided a valid version is packaged for Debian/Ubuntu (which is not currently the case), the package name would be the same, and the following command would be used to install it:

```
# apt-get install python-pygit2
```

If pygit2 is not packaged for the platform on which the Master is running, the pygit2 website has installation instructions here. Keep in mind however that following these instructions will install libgit2 and pygit2 without system packages. Additionally, keep in mind that SSH authentication in pygit2 requires libssh2 (not libssh) development libraries to be present before libgit2 is built. On some distros (debian based) pkg-config is also required to link libgit2 with libssh2.

GitPython

GitPython 0.3.0 or newer is required to use GitPython for gitfs. For RHEL-based Linux distros, a compatible version is available in EPEL, and can be easily installed on the master using yum:

```
# yum install GitPython
```

Ubuntu 14.04 LTS and Debian Wheezy (7.x) also have a compatible version packaged:

```
# apt-get install python-git
```

If your master is running an older version (such as Ubuntu 12.04 LTS or Debian Squeeze), then you will need to install GitPython using either pip or easy_install (it is recommended to use pip). Version 0.3.2.RC1 is now marked as the stable release in PyPI, so it should be a simple matter of running pip install GitPython (or easy_install GitPython) as root.

**Warning:** Keep in mind that if GitPython has been previously installed on the master using pip (even if it was subsequently uninstalled), then it may still exist in the build cache (typically /tmp/pip-build-root/GitPython) if the cache is not cleared after installation. The package in the build cache will override any requirement specifiers, so if you try upgrading to version 0.3.2.RC1 by running pip install 'GitPython==0.3.2.RC1' then it will ignore this and simply install the version from the cache directory. Therefore, it may be necessary to delete the GitPython directory from the build cache in order to ensure that the specified version is installed.
Salt Documentation, Release 2015.8.0

Dulwich

Dulwich 0.9.4 or newer is required to use Dulwich as backend for gitfs.

Dulwich is available in EPEL, and can be easily installed on the master using yum:

```bash
# yum install python-dulwich
```

For APT-based distros such as Ubuntu and Debian:

```bash
# apt-get install python-dulwich
```

**Important:** If switching to Dulwich from GitPython/pygit2, or switching from GitPython/pygit2 to Dulwich, it is necessary to clear the gitfs cache to avoid unpredictable behavior. This is probably a good idea whenever switching to a new `gitfs_provider`, but it is less important when switching between GitPython and pygit2.

Beginning in version 2015.5.0, the gitfs cache can be easily cleared using the `fileservers.clear_cache` runner.

```bash
salt-run fileservers.clear_cache backend=git
```

If the Master is running an earlier version, then the cache can be cleared by removing the `gitfs` and `file_lists/gitfs` directories (both paths relative to the master cache directory, usually `/var/cache/salt/master`).

```bash
rm -rf /var/cache/salt/master{,,file_lists}/gitfs
```

**Simple Configuration**

To use the gitfs backend, only two configuration changes are required on the master:

1. Include `git` in the `fileservers.backend` list in the master config file:

   ```yaml
   fileservers_backend:
   - git
   ```

2. Specify one or more `git://`, `https://`, or `file://` URLs in `gitfs_remotes` to configure which repositories to cache and search for requested files:

   ```yaml
gitfs_remotes:
   - https://github.com/saltstack-formulas/salt-formula.git
   ```

   SSH remotes can also be configured using scp-like syntax:

   ```yaml
gitfs_remotes:
   - git@github.com:user/repo.git
   - ssh://user@domain.tld/path/to/repo.git
   ```

   Information on how to authenticate to SSH remotes can be found [here](#).

   **Note:** Dulwich does not recognize `ssh://` URLs, `git+ssh://` must be used instead. Salt version 2015.5.0 and later will automatically add the `git+` to the beginning of these URLs before fetching, but earlier Salt versions will fail to fetch unless the URL is specified using `git+ssh://`.

3. Restart the master to load the new configuration.

**Note:** In a master/minion setup, files from a gitfs remote are cached once by the master, so minions do not need direct access to the git repository.
Multiple Remotes

The `gitfs_remotes` option accepts an ordered list of git remotes to cache and search, in listed order, for requested files.

A simple scenario illustrates this cascading lookup behavior:

If the `gitfs_remotes` option specifies three remotes:

```yaml
gitfs_remotes:
  - git://github.com/example/first.git
  - https://github.com/example/second.git
  - file:///root/third
```

And each repository contains some files:

```plaintext
first.git:
  top.sls
  edit/vim.sls
  edit/vimrc
  nginx/init.sls

second.git:
  edit/dev_vimrc
  haproxy/init.sls

third:
  haproxy/haproxy.conf
  edit/dev_vimrc
```

Salt will attempt to lookup the requested file from each `gitfs` remote repository in the order in which they are defined in the configuration. The `git://github.com/example/first.git` remote will be searched first. If the requested file is found, then it is served and no further searching is executed. For example:

- A request for the file `salt://haproxy/init.sls` will be served from the `https://github.com/example/second.git` git repo.
- A request for the file `salt://haproxy/haproxy.conf` will be served from the `file:///root/third` repo.

**Note:** This example is purposefully contrived to illustrate the behavior of the `gitfs` backend. This example should not be read as a recommended way to lay out files and git repos.

The `file://` prefix denotes a git repository in a local directory. However, it will still use the given `file://` URL as a remote, rather than copying the git repo to the salt cache. This means that any refs you want accessible must exist as `local` refs in the specified repo.

**Warning:** Salt versions prior to 2014.1.0 are not tolerant of changing the order of remotes or modifying the URI of existing remotes. In those versions, when modifying remotes it is a good idea to remove the `gitfs` cache directory (`/var/cache/salt/master/gitfs`) before restarting the salt-master service.

Per-remote Configuration Parameters

New in version 2014.7.0.

The following master config parameters are global (that is, they apply to all configured `gitfs` remotes):
Salt Documentation, Release 2015.8.0

- `gitfs_base`
- `gitfs_root`
- `gitfs_mountpoint` (new in 2014.7.0)
- `gitfs_user` (pygit2 only, new in 2014.7.0)
- `gitfs_password` (pygit2 only, new in 2014.7.0)
- `gitfs_insecure_auth` (pygit2 only, new in 2014.7.0)
- `gitfs_pubkey` (pygit2 only, new in 2014.7.0)
- `gitfs_privkey` (pygit2 only, new in 2014.7.0)
- `gitfs_passphrase` (pygit2 only, new in 2014.7.0)

These parameters can now be overridden on a per-remote basis. This allows for a tremendous amount of customization. Here's some example usage:

```
gitfs_provider: pygit2
gitfs_base: develop

gitfs_remotes:  
- https://foo.com/foo.git  
- https://foo.com/bar.git:  
  - root: salt  
  - mountpoint: salt://foo/bar/baz  
  - base: salt-base  
- http://foo.com/baz.git:  
  - root: salt/states  
  - user: joe  
  - password: mysupersecretpassword  
  - insecure_auth: True
```

**Important:** There are two important distinctions which should be noted for per-remote configuration:

1. The URL of a remote which has per-remote configuration must be suffixed with a colon.
2. Per-remote configuration parameters are named like the global versions, with the `gitfs_` removed from the beginning.

In the example configuration above, the following is true:

1. The first and third `gitfs` remotes will use the `develop` branch/tag as the `base` environment, while the second one will use the `salt-base` branch/tag as the `base` environment.
2. The first remote will serve all files in the repository. The second remote will only serve files from the `salt` directory (and its subdirectories), while the third remote will only serve files from the `salt/states` directory (and its subdirectories).
3. The files from the second remote will be located under `salt://foo/bar/baz`, while the files from the first and third remotes will be located under the root of the Salt fileserver namespace (`salt://`).
4. The third remote overrides the default behavior of not authenticating to insecure (non-HTTPS) remotes.

**Serving from a Subdirectory**

The `gitfs_root` parameter allows files to be served from a subdirectory within the repository. This allows for only part of a repository to be exposed to the Salt fileserver.
Assume the below layout:

```
.gitignore
README.txt
foo/
  foo/bar/
  foo/bar/one.txt
  foo/bar/two.txt
  foo/bar/three.txt
  foo/baz/
  foo/baz/top.sls
  foo/baz/edit/vim.sls
  foo/baz/edit/vimrc
  foo/baz/nginx/init.sls
```

The below configuration would serve only the files under `foo/baz`, ignoring the other files in the repository:

```
gitfs_remotes:
  - git://mydomain.com/stuff.git

gitfs_root: foo/baz
```

The root can also be configured on a *per-remote basis*.

**Mountpoints**

New in version 2014.7.0.

The `gitfs_mountpoint` parameter will prepend the specified path to the files served from gitfs. This allows an existing repository to be used, rather than needing to reorganize a repository or design it around the layout of the Salt fileserver.

Before the addition of this feature, if a file being served up via gitfs was deeply nested within the root directory (for example, `salt://webapps/foo/files/foo.conf`), it would be necessary to ensure that the file was properly located in the remote repository, and that all of the parent directories were present (for example, the directories `webapps/foo/files/` would need to exist at the root of the repository).

The below example would allow for a file `foo.conf` at the root of the repository to be served up from the Salt fileserver path `salt://webapps/foo/files/foo.conf`.

```
gitfs_remotes:
  - https://mydomain.com/stuff.git

gitfs_mountpoint: salt://webapps/foo/files
```

Mountpoints can also be configured on a *per-remote basis*.

**Using gitfs Alongside Other Backends**

Sometimes it may make sense to use multiple backends; for instance, if SLS files are stored in git but larger files are stored directly on the master.

The cascading lookup logic used for multiple remotes is also used with multiple backends. If the `fileserver_backend` option contains multiple backends:

```
fileserver_backend:
  - roots
  - git
```

3.4. Advanced Topics
Then the roots backend (the default backend of files in /srv/salt) will be searched first for the requested file; then, if it is not found on the master, each configured git remote will be searched.

**Branches, Environments, and Top Files**

When using the gitfs backend, branches, and tags will be mapped to environments using the branch/tag name as an identifier.

There is one exception to this rule: the master branch is implicitly mapped to the base environment.

So, for a typical base, qa, dev setup, the following branches could be used:

```
master
qa
dev
```

top.sls files from different branches will be merged into one at runtime. Since this can lead to overly complex configurations, the recommended setup is to have a separate repository, containing only the top.sls file with just one single master branch.

To map a branch other than master as the base environment, use the gitfs_base parameter.

```
gitfs_base: salt-base
```

The base can also be configured on a *per-remote basis*.

**Environment Whitelist/Blacklist**

New in version 2014.7.0.

The gitfs_env_whitelist and gitfs_env_blacklist parameters allow for greater control over which branches/tags are exposed as fileserver environments. Exact matches, globs, and regular expressions are supported, and are evaluated in that order. If using a regular expression, ^ and $ must be omitted, and the expression must match the entire branch/tag.

```
gitfs_env_whitelist:
- base
- v1.*
- 'mybranch\d+'
```

**Note:** v1.*, in this example, will match as both a glob and a regular expression (though it will have been matched as a glob, since globs are evaluated before regular expressions).

The behavior of the blacklist/whitelist will differ depending on which combination of the two options is used:

- If only gitfs_env_whitelist is used, then only branches/tags which match the whitelist will be available as environments
- If only gitfs_env_blacklist is used, then the branches/tags which match the blacklist will not be available as environments
- If both are used, then the branches/tags which match the whitelist, but do not match the blacklist, will be available as environments.
Authentication

pygit2

New in version 2014.7.0.

Both HTTPS and SSH authentication are supported as of version 0.20.3, which is the earliest version of pygit2 supported by Salt for gitfs.

Note: The examples below make use of per-remote configuration parameters, a feature new to Salt 2014.7.0. More information on these can be found here.

HTTPS For HTTPS repositories which require authentication, the username and password can be provided like so:

```yaml
gitfs_remotes:
- https://domain.tld/myrepo.git:
  - user: git
  - password: mypassword
```

If the repository is served over HTTP instead of HTTPS, then Salt will by default refuse to authenticate to it. This behavior can be overridden by adding an insecure_auth parameter:

```yaml
 gitfs_remotes:
- http://domain.tld/insecure_repo.git:
  - user: git
  - password: mypassword
  - insecure_auth: True
```

SSH SSH repositories can be configured using the ssh:// protocol designation, or using scp-like syntax. So, the following two configurations are equivalent:

- ssh://git@github.com/user/repo.git
- git@github.com:user/repo.git

Both gitfs_pubkey and gitfs_privkey (or their per-remote counterparts) must be configured in order to authenticate to SSH-based repos. If the private key is protected with a passphrase, it can be configured using gitfs_passphrase (or simply passphrase if being configured per-remote). For example:

```yaml
 gitfs_remotes:
- git@github.com:user/repo.git:
  - pubkey: /root/.ssh/id_rsa.pub
  - privkey: /root/.ssh/id_rsa
  - passphrase: myawesomepassphrase
```

Finally, the SSH host key must be added to the known_hosts file.

GitPython

With GitPython, only passphrase-less SSH public key authentication is supported. The auth parameters (pubkey, privkey, etc.) shown in the pygit2 authentication examples above do not work with GitPython.

```yaml
 gitfs_remotes:
- ssh://git@github.com/example/salt-states.git
```

3.4. Advanced Topics
Since **GitPython** wraps the git CLI, the private key must be located in `~/.ssh/id_rsa` for the user under which the Master is running, and should have permissions of `0600`. Also, in the absence of a user in the repo URL, **GitPython** will (just as SSH does) attempt to login as the current user (in other words, the user under which the Master is running, usually `root`).

If a key needs to be used, then `~/.ssh/config` can be configured to use the desired key. Information on how to do this can be found by viewing the manpage for `ssh_config`. Here's an example entry which can be added to the `~/.ssh/config` to use an alternate key for gitfs:

```
Host github.com
  IdentityFile /root/.ssh/id_rsa_gitfs
```

The `Host` parameter should be a hostname (or hostname glob) that matches the domain name of the git repository.

It is also necessary to **add the SSH host key to the known_hosts file**. The exception to this would be if strict host key checking is disabled, which can be done by adding `StrictHostKeyChecking no` to the entry in `~/.ssh/config`:

```
Host github.com
  IdentityFile /root/.ssh/id_rsa_gitfs
  StrictHostKeyChecking no
```

However, this is generally regarded as insecure, and is not recommended.

### Adding the SSH Host Key to the known_hosts File

To use SSH authentication, it is necessary to have the remote repository's SSH host key in the `~/.ssh/known_hosts` file. If the master is also a minion, this can be done using the `ssh.set_known_host` function:

```
# salt mymaster ssh.set_known_host user=root hostname=github.com
mymaster:  
   ----------
   new:  
      ------
      enc:  
         ssh-rsa  
         fingerprint:  
         hostname:  
            1|0iefWwqOD4kw03BhoIGa8loRSAA=|BIXVtmcTbPER+68HvXmceodDcfI=  
         key:  
            AAAAB3NzaC1yc2EAAAABlwAAAQEAq2A7hRGmdnm9tUDb0IDSwBK6TbQa+PXYPbPy6rbTrTtw7PZhccKrpp0yVhp5
      old:  
      status:
         updated
```

If not, then the easiest way to add the key is to su to the user (usually `root`) under which the salt-master runs and attempt to login to the server via SSH:

```
$ su
Password:  
# ssh github.com
The authenticity of host 'github.com (192.30.252.128)' can't be established.  
Are you sure you want to continue connecting (yes/no)? yes
```
Warning: Permanently added 'github.com,192.30.252.128' (RSA) to the list of known hosts. Permission denied (publickey).

It doesn’t matter if the login was successful, as answering yes will write the fingerprint to the known_hosts file.

Verifying the Fingerprint  To verify that the correct fingerprint was added, it is a good idea to look it up. One way to do this is to use nmap:

```
$ nmap github.com --script ssh-hostkey
```

Nmap scan report for github.com (192.30.252.129)
Host is up (0.17s latency).
Not shown: 996 filtered ports

```
PORT     STATE SERVICE  
22/tcp   open     ssh
80/tcp   open     http
443/tcp  open     https
9418/tcp open     git
```

Nmap done: 1 IP address (1 host up) scanned in 28.78 seconds

Another way is to check one’s own known_hosts file, using this one-liner:

```
$ ssh-keygen -l -f /dev/stdin <<<`ssh-keyscan -t rsa github.com 2>/dev/null` | awk '{print $2}'
```

```
```

Refreshing gitfs Upon Push

By default, Salt updates the remote fileserver backends every 60 seconds. However, if it is desirable to refresh quicker than that, the Reactor System can be used to signal the master to update the fileserver on each push, provided that the git server is also a Salt minion. There are three steps to this process:

1. On the master, create a file /srv/reactor/update_fileserver.sls, with the following contents:

   ```
   update_fileserver:
   runner.fileserver.update
   ```

2. Add the following reactor configuration to the master config file:

   ```
   reactor:
   - 'salt/fileserver/gitfs/update':
     - /srv/reactor/update_fileserver.sls
   ```

3. On the git server, add a post-receive hook with the following contents:

   ```
   #!/usr/bin/env sh
   salt-call event.fire_master update salt/fileserver/gitfs/update
   ```

The update argument right after event.fire_master in this example can really be anything, as it represents the data being passed in the event, and the passed data is ignored by this reactor.

Similarly, the tag name salt/fileserver/gitfs/update can be replaced by anything, so long as the usage is consistent.
Using Git as an External Pillar Source

The git external pillar (a.k.a. git_pillar) has been rewritten for the 2015.8.0 release. This rewrite brings with it pygit2 support (allowing for access to authenticated repositories), as well as more granular support for per-remote configuration.

To make use of the new features, changes to the git ext_pillar configuration must be made. The new configuration schema is detailed here.

For Salt releases before 2015.8.0, click here for documentation.

Why aren't my custom modules/states/etc. syncing to my Minions?

In versions 0.16.3 and older, when using the git fileserver backend, certain versions of GitPython may generate errors when fetching, which Salt fails to catch. While not fatal to the fetch process, these interrupt the fileserver update that takes place before custom types are synced, and thus interrupt the sync itself. Try disabling the git fileserver backend in the master config, restarting the master, and attempting the sync again.

This issue is worked around in Salt 0.16.4 and newer.

3.4.10 The MacOS X (Maverick) Developer Step By Step Guide To Salt Installation

This document provides a step-by-step guide to installing a Salt cluster consisting of one master, and one minion running on a local VM hosted on Mac OS X.

Note: This guide is aimed at developers who wish to run Salt in a virtual machine. The official (Linux) walkthrough can be found here.

The 5 Cent Salt Intro

Since you’re here you’ve probably already heard about Salt, so you already know Salt lets you configure and run commands on hordes of servers easily. Here’s a brief overview of a Salt cluster:

- Salt works by having a `master` server sending commands to one or multiple `minion` servers. The master server is the `command center`. It is going to be the place where you store your configuration files, aka: `which server is the db, which is the web server, and what libraries and software they should have installed`.
  The minions receive orders from the master. Minions are the servers actually performing work for your business.

- Salt has two types of configuration files:

  1. the `salt communication channels` or `meta` or `config` configuration files (not official names): one for the master (usually is `/etc/salt/master`, on the master server), and one for minions (default is `/etc/salt/minion` or `/etc/salt/minion.conf, on the minion servers`). Those files are used to determine things like the Salt Master IP, port, Salt folder locations, etc.. If these are configured incorrectly, your minions will probably be unable to receive orders from the master, or the master will not know which software a given minion should install.

        2. the `business` or `service` configuration files (once again, not an official name): these are configuration files, ending with `.sls` extension, that describe which software should run on which server, along with particular configuration properties for the software that is being installed. These files should be created in the `/srv/salt` folder by default, but their location can be changed using ... /etc/salt/master configuration file!

2 Salt also works with `masterless` configuration where a minion is autonomous (in which case salt can be seen as a local configuration tool), or in `multiple master` configuration. See the documentation for more on that.
Note: This tutorial contains a third important configuration file, not to be confused with the previous two: the virtual machine provisioning configuration file. This in itself is not specifically tied to Salt, but it also contains some Salt configuration. More on that in step 3. Also note that all configuration files are YAML files. So indentation matters.

Before Digging In, The Architecture Of The Salt Cluster

Salt Master

The `Salt master` server is going to be the Mac OS machine, directly. Commands will be run from a terminal app, so Salt will need to be installed on the Mac. This is going to be more convenient for toying around with configuration files.

Salt Minion

We’ll only have one `Salt minion` server. It is going to be running on a Virtual Machine running on the Mac, using VirtualBox. It will run an Ubuntu distribution.

3.4.11 Step 1 - Configuring The Salt Master On Your Mac

Because Salt has a lot of dependencies that are not built in Mac OS X, we will use Homebrew to install Salt. Homebrew is a package manager for Mac, it’s great, use it (for this tutorial at least!). Some people spend a lot of time installing libs by hand to better understand dependencies, and then realize how useful a package manager is once they’re configuring a brand new machine and have to do it all over again. It also lets you `uninstall` things easily.

Note: Brew is a Ruby program (Ruby is installed by default with your Mac). Brew downloads, compiles, and links software. The linking phase is when compiled software is deployed on your machine. It may conflict with manually installed software, especially in the `/usr/local` directory. It’s ok, remove the manually installed version then refresh the link by typing `brew link 'packageName'`. Brew has a `brew doctor` command that can help you troubleshoot. It’s a great command, use it often. Brew requires xcode command line tools. When you run brew the first time it asks you to install them if they’re not already on your system. Brew installs software in `/usr/local/bin` (system bins are in `/usr/bin`). In order to use those bins you need your `$PATH` to search there first. Brew tells you if your `$PATH` needs to be fixed.

Tip: Use the keyboard shortcut `cmd + shift + period` in the `open` Mac OS X dialog box to display hidden files and folders, such as `.profile`.

Install Homebrew

Install Homebrew here [http://brew.sh/](http://brew.sh/) Or just type

```
ruby -e "$(curl -fsSL https://raw.githubusercontent.com/Homebrew/homebrew/go/install)"
```

Now type the following commands in your terminal (you may want to type `brew doctor` after each to make sure everything’s fine):
brew install python  
brew install swig  
brew install zmq

**Note:** zmq is ZeroMQ. It's a fantastic library used for server to server network communication and is at the core of Salt efficiency.

### Install Salt

You should now have everything ready to launch this command:

```
pip install salt
```

**Note:** There should be no need for `sudo pip install salt`. Brew installed Python for your user, so you should have all the access. In case you would like to check, type `which python` to ensure that it's `/usr/local/bin/python`, and `which pip` which should be `/usr/local/bin/pip`.

Now type `python` in a terminal then, `import salt`. There should be no errors. Now exit the Python terminal using `exit()`.

### Create The Master Configuration

If the default `/etc/salt/master` configuration file was not created, copy-paste it from here: `http://docs.saltstack.com/ref/configuration/examples.html#configuration-examples-master`

**Note:** `/etc/salt/master` is a file, not a folder.

Salt Master configuration changes. The Salt master needs a few customization to be able to run on Mac OS X:

```
sudo launchctl limit maxfiles 4096 8192
```

In the `/etc/salt/master` file, change `max_open_files` to 8192 (or just add the line: `max_open_files: 8192` (no quote) if it doesn't already exists).

You should now be able to launch the Salt master:

```
sudo salt-master --log-level=all
```

There should be no errors when running the above command.

**Note:** This command is supposed to be a daemon, but for toying around, we'll keep it running on a terminal to monitor the activity.

Now that the master is set, let's configure a minion on a VM.

### 3.4.12 Step 2 - Configuring The Minion VM

The Salt minion is going to run on a Virtual Machine. There are a lot of software options that let you run virtual machines on a mac, But for this tutorial we're going to use VirtualBox. In addition to virtualBox, we will use Vagrant, which allows you to create the base VM configuration.
Vagrant lets you build ready to use VM images, starting from an OS image and customizing it using "provisioners". In our case, we'll use it to:

- Download the base Ubuntu image
- Install salt on that Ubuntu image (Salt is going to be the "provisioner" for the VM).
- Launch the VM
- SSH into the VM to debug
- Stop the VM once you're done.

**Install VirtualBox**

Go get it here: [https://www.virtualBox.org/wiki/Downloads](https://www.virtualBox.org/wiki/Downloads) (click on VirtualBox for OS X hosts => x86/amd64)

**Install Vagrant**

Go get it here: [http://downloads.vagrantup.com/](http://downloads.vagrantup.com/) and choose the latest version (1.3.5 at time of writing), then the .dmg file. Double-click to install it. Make sure the `vagrant` command is found when run in the terminal. Type `vagrant`. It should display a list of commands.

**Create The Minion VM Folder**

Create a folder in which you will store your minion's VM. In this tutorial, it's going to be a minion folder in the `$home` directory.

```
cd $home
mkdir minion
```

**Initialize Vagrant**

From the minion folder, type

```
vagrant init
```

This command creates a default Vagrantfile configuration file. This configuration file will be used to pass configuration parameters to the Salt provisioner in Step 3.

**Import Precise64 Ubuntu Box**

```
vagrant box add precise64 http://files.vagrantup.com/precise64.box
```

**Note:** This box is added at the global Vagrant level. You only need to do it once as each VM will use this same file.

**Modify the Vagrantfile**

Modify `.minion/Vagrantfile` to use the `precise64` box. Change the `config.vm.box` line to:

```
config.vm.box = "precise64"
```
Uncomment the line creating a host-only IP. This is the ip of your minion (you can change it to something else if that IP is already in use):

```text
config.vm.network :private_network, ip: "192.168.33.10"
```

At this point you should have a VM that can run, although there won't be much in it. Let's check that.

**Checking The VM**

From the $home/minion folder type:

```
vagrant up
```

A log showing the VM booting should be present. Once it's done you'll be back to the terminal:

```
ping 192.168.33.10
```

The VM should respond to your ping request.

Now log into the VM in ssh using Vagrant again:

```
vagrant ssh
```

You should see the shell prompt change to something similar to `vagrant@precise64:` meaning you're inside the VM. From there, enter the following:

```
ping 10.0.2.2
```

**Note:** That ip is the ip of your VM host (the Mac OS X OS). The number is a VirtualBox default and is displayed in the log after the Vagrant ssh command. We'll use that IP to tell the minion where the Salt master is. Once you're done, end the ssh session by typing `exit`.

It's now time to connect the VM to the salt master

### 3.4.13 Step 3 - Connecting Master and Minion

**Creating The Minion Configuration File**

Create the `/etc/salt/minion` file. In that file, put the following lines, giving the ID for this minion, and the IP of the master:

```text
master: 10.0.2.2
id: 'minion1'
file_client: remote
```

Minions authenticate with the master using keys. Keys are generated automatically if you don't provide one and can accept them later on. However, this requires accepting the minion key every time the minion is destroyed or created (which could be quite often). A better way is to create those keys in advance, feed them to the minion, and authorize them once.

**Preseed minion keys**

From the minion folder on your Mac run:
 sudo salt-key --gen-keys=minion1

This should create two files: minion1.pem, and minion1.pub. Since those files have been created using sudo, but will be used by vagrant, you need to change ownership:

 sudo chown youruser:yourgroup minion1.pem
 sudo chown youruser:yourgroup minion1.pub

Then copy the .pub file into the list of accepted minions:

 sudo cp minion1.pub /etc/salt/pki/master/minions/minion1

Modify Vagrantfile to Use Salt Provisioner

Let's now modify the Vagrantfile used to provision the Salt VM. Add the following section in the Vagrantfile (note: it should be at the same indentation level as the other properties):

```
# salt-vagrant config
config.vm.provision :salt do |salt|
    salt.run_highstate = true
    salt.minion_config = "'/etc/salt/minion"
    salt.minion_key = "./minion1.pem"
    salt.minion_pub = "./minion1.pub"
end
```

Now destroy the vm and recreate it from the /minion folder:

 vagrant destroy
 vagrant up

If everything is fine you should see the following message:

"Bootstrapping Salt... (this may take a while)
Salt successfully configured and installed!"

Checking Master-Minion Communication

To make sure the master and minion are talking to each other, enter the following:

 sudo salt '*' test.ping

You should see your minion answering the ping. It's now time to do some configuration.

3.4.14 Step 4 - Configure Services to Install On the Minion

In this step we'll use the Salt master to instruct our minion to install Nginx.

Checking the system's original state

First, make sure that an HTTP server is not installed on our minion. When opening a browser directed at http://192.168.33.10/ You should get an error saying the site cannot be reached.
**Initialize the top.sls file**

System configuration is done in the /srv/salt/top.sls file (and subfiles/folders), and then applied by running the state.highstate command to have the Salt master give orders so minions will update their instructions and run the associated commands.

First Create an empty file on your Salt master (Mac OS X machine):

```bash
touch /srv/salt/top.sls
```

When the file is empty, or if no configuration is found for our minion an error is reported:

```bash
sudo salt 'minion1' state.highstate
```

Should return an error stating: ``No Top file or external nodes data matches found''.

**Create The Nginx Configuration**

Now is finally the time to enter the real meat of our server’s configuration. For this tutorial our minion will be treated as a web server that needs to have Nginx installed.

Insert the following lines into the /srv/salt/top.sls file (which should current be empty).

```yaml
base:
  'minion1':
    - bin.nginx
```

Now create a /srv/salt/bin/nginx.sls file containing the following:

```yaml
nginx:
  pkg.installed:
    - name: nginx
  service.running:
    - enable: True
    - reload: True
```

**Check Minion State**

Finally run the state.highstate command again:

```bash
sudo salt 'minion1' state.highstate
```

You should see a log showing that the Nginx package has been installed and the service configured. To prove it, open your browser and navigate to http://192.168.33.10/, you should see the standard Nginx welcome page.

Congratulations!

**Where To Go From Here**

A full description of configuration management within Salt (sls files among other things) is available here: http://docs.saltstack.com/en/latest/index.html#configuration-management
3.4.15 Writing Salt Tests

Note: THIS TUTORIAL IS A WORK IN PROGRESS

Salt comes with a powerful integration and unit test suite. The test suite allows for the fully automated run of integration and/or unit tests from a single interface. The integration tests are surprisingly easy to write and can be written to be either destructive or non-destructive.

Getting Set Up For Tests

To walk through adding an integration test, start by getting the latest development code and the test system from GitHub:

```plaintext
Note: The develop branch often has failing tests and should always be considered a staging area. For a checkout that tests should be running perfectly on, please check out a specific release tag (such as v2014.1.4).

git clone git@github.com:saltstack/salt.git
pip install git+https://github.com/saltstack/salt-testing.git#egg=SaltTesting
```

Now that a fresh checkout is available run the test suite

Destructive vs Non-destructive

Since Salt is used to change the settings and behavior of systems, often, the best approach to run tests is to make actual changes to an underlying system. This is where the concept of destructive integration tests comes into play. Tests can be written to alter the system they are running on. This capability is what fills in the gap needed to properly test aspects of system management like package installation.

To write a destructive test import and use the `destructiveTest` decorator for the test method:

```python
import integration
from salttesting.helpers import destructiveTest

class PkgTest(integration.ModuleCase):
    @destructiveTest
    def test_pkg_install(self):
        ret = self.run_function('pkg.install', name='finch')
        self.assertSaltTrueReturn(ret)
        ret = self.run_function('pkg.purge', name='finch')
        self.assertSaltTrueReturn(ret)
```

Automated Test Runs

SaltStack maintains a Jenkins server which can be viewed at http://jenkins.saltstack.com. The tests executed from this Jenkins server create fresh virtual machines for each test run, then execute the destructive tests on the new clean virtual machine. This allows for the execution of tests across supported platforms.

3.4.16 HTTP Modules

This tutorial demonstrates using the various HTTP modules available in Salt. These modules wrap the Python tornado, urllib2, and requests libraries, extending them in a manner that is more consistent with Salt workflows.
The `salt.utils.http` Library

This library forms the core of the HTTP modules. Since it is designed to be used from the minion as an execution module, in addition to the master as a runner, it was abstracted into this multi-use library. This library can also be imported by 3rd-party programs wishing to take advantage of its extended functionality.

Core functionality of the execution, state, and runner modules is derived from this library, so common usages between them are described here. Documentation specific to each module is described below.

This library can be imported with:

```python
import salt.utils.http
```

Configuring Libraries

This library can make use of either `tornado`, which is required by Salt, `urllib2`, which ships with Python, or `requests`, which can be installed separately. By default, `tornado` will be used. In order to switch to `urllib2`, set the following variable:

```python
backend: urllib2
```

In order to switch to `requests`, set the following variable:

```python
backend: requests
```

This can be set in the master or minion configuration file, or passed as an option directly to any `http.query()` functions.

`salt.utils.http.query()`

This function forms a basic query, but with some add-ons not present in the `tornado`, `urllib2`, and `requests` libraries. Not all functionality currently available in these libraries has been added, but can be in future iterations.

A basic query can be performed by calling this function with no more than a single URL:

```python
salt.utils.http.query('http://example.com')
```

By default the query will be performed with a `GET` method. The method can be overridden with the `method` argument:

```python
salt.utils.http.query('http://example.com/delete/url', 'DELETE')
```

When using the `POST` method (and others, such as `PUT`), extra data is usually sent as well. This data can be sent directly, in whatever format is required by the remote server (XML, JSON, plain text, etc).

```python
salt.utils.http.query(
    'http://example.com/delete/url',
    method='POST',
    data=json.loads(mydict)
)
```

Bear in mind that this data must be sent pre-formatted; this function will not format it for you. However, a templated file stored on the local system may be passed through, along with variables to populate it with. To pass through only the file (untemplated):
To pass through a file that contains jinja + yaml templating (the default):

```python
salt.utils.http.query(
    'http://example.com/post/url',
    method='POST',
    data_file='/srv/salt/somefile.jinja',
    data_render=True,
    template_data={'key1': 'value1', 'key2': 'value2'}
)
```

To pass through a file that contains mako templating:

```python
salt.utils.http.query(
    'http://example.com/post/url',
    method='POST',
    data_file='/srv/salt/somefile.mako',
    data_render=True,
    data_renderer='mako',
    template_data={'key1': 'value1', 'key2': 'value2'}
)
```

Because this function uses Salt's own rendering system, any Salt renderer can be used. Because Salt's renderer requires __opts__ to be set, an opts dictionary should be passed in. If it is not, then the default __opts__ values for the node type (master or minion) will be used. Because this library is intended primarily for use by minions, the default node type is minion. However, this can be changed to master if necessary.

```python
salt.utils.http.query(
    'http://example.com/post/url',
    method='POST',
    data_file='/srv/salt/somefile.jinja',
    data_render=True,
    template_data={'key1': 'value1', 'key2': 'value2'},
    opts=__opts__
)
```

```python
salt.utils.http.query(
    'http://example.com/delete/url',
    method='POST',
    header_file='/srv/salt/headers.jinja',
    header_render=True,
    node='master'
)
```

Headers may also be passed through, either as a header_list, a header_dict, or as a header_file. As with the data_file, the header_file may also be templated. Take note that because HTTP headers are normally syntactically-correct YAML, they will automatically be imported as an a Python dict.
header_renderer='jinja',
    template_data={"key1": 'value1', 'key2': 'value2'}
)

Because much of the data that would be templated between headers and data may be the same, the template_data is the same for both. Correcting possible variable name collisions is up to the user.

The query() function supports basic HTTP authentication. A username and password may be passed in as username and password, respectively.

salt.utils.http.query(
    'http://example.com',
    username='larry',
    password='5700g3543v4r',
)

Cookies are also supported, using Python's built-in cookielib. However, they are turned off by default. To turn cookies on, set cookies to True.

salt.utils.http.query(
    'http://example.com',
    cookies=True
)

By default cookies are stored in Salt's cache directory, normally /var/cache/salt, as a file called cookies.txt. However, this location may be changed with the cookie_jar argument:

salt.utils.http.query(
    'http://example.com',
    cookies=True,
    cookie_jar='/path/to/cookie_jar.txt'
)

By default, the format of the cookie jar is LWP (aka, lib-www-perl). This default was chosen because it is a human-readable text file. If desired, the format of the cookie jar can be set to Mozilla:

salt.utils.http.query(
    'http://example.com',
    cookies=True,
    cookie_jar='/path/to/cookie_jar.txt',
    cookie_format='mozilla'
)

Because Salt commands are normally one-off commands that are piped together, this library cannot normally behave as a normal browser, with session cookies that persist across multiple HTTP requests. However, the session can be persisted in a separate cookie jar. The default filename for this file, inside Salt's cache directory, is cookies.session.p. This can also be changed.

salt.utils.http.query(
    'http://example.com',
    persist_session=True,
    session_cookie_jar='/path/to/jar.p'
)

The format of this file is msgpack, which is consistent with much of the rest of Salt's internal structure. Historically, the extension for this file is .p. There are no current plans to make this configurable.
Return Data

By default, `query()` will attempt to decode the return data. Because it was designed to be used with REST interfaces, it will attempt to decode the data received from the remote server. First it will check the Content-type header to try and find references to XML. If it does not find any, it will look for references to JSON. If it does not find any, it will fall back to plain text, which will not be decoded.

JSON data is translated into a dict using Python's built-in `json` library. XML is translated using `salt.utils.xml_util`, which will use Python's built-in XML libraries to attempt to convert the XML into a dict. In order to force either JSON or XML decoding, the `decode_type` may be set:

```python
salt.utils.http.query(
    'http://example.com',
    decode_type='xml'
)
```

Once translated, the return dict from `query()` will include a dict called `dict`.

If the data is not to be translated using one of these methods, decoding may be turned off.

```python
salt.utils.http.query(
    'http://example.com',
    decode=False
)
```

If decoding is turned on, and references to JSON or XML cannot be found, then this module will default to plain text, and return the undecoded data as `text` (even if `text` is set to `False`; see below).

The `query()` function can return the HTTP status code, headers, and/or text as required. However, each must individually be turned on.

```python
salt.utils.http.query(
    'http://example.com',
    status=True,
    headers=True,
    text=True
)
```

The return from these will be found in the return dict as `status`, `headers` and `text`, respectively.

Writing Return Data to Files

It is possible to write either the return data or headers to files, as soon as the response is received from the server, but specifying file locations via the `text_out` or `headers_out` arguments. `text` and `headers` do not need to be returned to the user in order to do this.

```python
salt.utils.http.query(
    'http://example.com',
    text=False,
    headers=False,
    text_out='/path/to/url_download.txt',
    headers_out='/path/to/headers_download.txt',
)
```
SSL Verification

By default, this function will verify SSL certificates. However, for testing or debugging purposes, SSL verification can be turned off.

```python
salt.utils.http.query(  
    'https://example.com',  
    ssl_verify=False,  
)
```

CA Bundles

The requests library has its own method of detecting which CA (certificate authority) bundle file to use. Usually this is implemented by the packager for the specific operating system distribution that you are using. However, urllib2 requires a little more work under the hood. By default, Salt will try to auto-detect the location of this file. However, if it is not in an expected location, or a different path needs to be specified, it may be done so using the ca_bundle variable.

```python
salt.utils.http.query(  
    'https://example.com',  
    ca_bundle='/path/to/ca_bundle.pem',  
)
```

Updating CA Bundles  The update_ca_bundle() function can be used to update the bundle file at a specified location. If the target location is not specified, then it will attempt to auto-detect the location of the bundle file. If the URL to download the bundle from does not exist, a bundle will be downloaded from the cURL website.

CAUTION: The target and the source should always be specified! Failure to specify the target may result in the file being written to the wrong location on the local system. Failure to specify the source may cause the upstream URL to receive excess unnecessary traffic, and may cause a file to be download which is hazardous or does not meet the needs of the user.

```python
salt.utils.http.update_ca_bundle(  
    target='/path/to/ca-bundle.crt',  
    source='https://example.com/path/to/ca-bundle.crt',  
    opts=__opts__,  
)
```

The opts parameter should also always be specified. If it is, then the target and the source may be specified in the relevant configuration file (master or minion) as ca_bundle and ca_bundle_url, respectively.

```ini
ca_bundle: /path/to/ca-bundle.crt  
ca_bundle_url: https://example.com/path/to/ca-bundle.crt
```

If Salt is unable to auto-detect the location of the CA bundle, it will raise an error.

The update_ca_bundle() function can also be passed a string or a list of strings which represent files on the local system, which should be appended (in the specified order) to the end of the CA bundle file. This is useful in environments where private certs need to be made available, and are not otherwise reasonable to add to the bundle file.

```python
salt.utils.http.update_ca_bundle(  
    opts=__opts__,  
    merge_files=['/etc/ssl/private_cert_1.pem',
                  '/etc/ssl/private_cert_2.pem'],  
)
```
Test Mode

This function may be run in test mode. This mode will perform all work up until the actual HTTP request. By default, instead of performing the request, an empty dict will be returned. Using this function with TRACE logging turned on will reveal the contents of the headers and POST data to be sent.

Rather than returning an empty dict, an alternate test_url may be passed in. If this is detected, then test mode will replace the url with the test_url, set test to True in the return data, and perform the rest of the requested operations as usual. This allows a custom, non-destructive URL to be used for testing when necessary.

Execution Module

The http execution module is a very thin wrapper around the salt.utils.http library. The opts can be passed through as well, but if they are not specified, the minion defaults will be used as necessary.

Because passing complete data structures from the command line can be tricky at best and dangerous (in terms of execution injection attacks) at worse, the data_file, and header_file are likely to see more use here.

All methods for the library are available in the execution module, as kwargs.

```bash
salt myminion http.query http://example.com/restapi method=POST \
    username='larry' password='5700g3543v4r' headers=True text=True \
    status=True decode_type=xml data_render=True \ 
    header_file=/tmp/headers.txt data_file=/tmp/data.txt \ 
    header_render=True cookies=True persist_session=True
```

Runner Module

Like the execution module, the http runner module is a very thin wrapper around the salt.utils.http library. The only significant difference is that because runners execute on the master instead of a minion, a target is not required, and default opts will be derived from the master config, rather than the minion config.

All methods for the library are available in the runner module, as kwargs.

```bash
salt-run http.query http://example.com/restapi method=POST \
    username='larry' password='5700g3543v4r' headers=True text=True \
    status=True decode_type=xml data_render=True \ 
    header_file=/tmp/headers.txt data_file=/tmp/data.txt \ 
    header_render=True cookies=True persist_session=True
```

State Module

The state module is a wrapper around the runner module, which applies stateful logic to a query. All kwargs as listed above are specified as usual in state files, but two more kwargs are available to apply stateful logic. A required parameter is match, which specifies a pattern to look for in the return text. By default, this will perform a string comparison of looking for the value of match in the return text. In Python terms this looks like:
If more complex pattern matching is required, a regular expression can be used by specifying a \texttt{match\_type}. By default this is set to \texttt{string}, but it can be manually set to \texttt{pcre} instead. Please note that despite the name, this will use Python's \texttt{re.search()} rather than \texttt{re.match()}.

Therefore, the following states are valid:

\begin{verbatim}
http://example.com/restapi:
  http.query:
    - match: 'SUCCESS'
    - username: 'larry'
    - password: '5700g3543v4r'
    - data_render: True
    - header_file: /tmp/headers.txt
    - data_file: /tmp/data.txt
    - header_render: True
    - cookies: True
    - persist_session: True

http://example.com/restapi:
  http.query:
    - match\_type: pcre
    - match: '(?!succe[ss|ed]'
    - username: 'larry'
    - password: '5700g3543v4r'
    - data_render: True
    - header_file: /tmp/headers.txt
    - data_file: /tmp/data.txt
    - header_render: True
    - cookies: True
    - persist_session: True
\end{verbatim}

In addition to, or instead of a match pattern, the status code for a URL can be checked. This is done using the \texttt{status} argument:

\begin{verbatim}
http://example.com/:
  http.query:
    - status: '200'
\end{verbatim}

If both are specified, both will be checked, but if only one is \texttt{True} and the other is \texttt{False}, then \texttt{False} will be returned. In this case, the comments in the return data will contain information for troubleshooting.

Because this is a monitoring state, it will return extra data to code that expects it. This data will always include \texttt{text} and \texttt{status}. Optionally, \texttt{headers} and \texttt{dict} may also be requested by setting the \texttt{headers} and \texttt{decode} arguments to \texttt{True}, respectively.

### 3.4.17 LXC Management with Salt

\textbf{Note:} This walkthrough assumes basic knowledge of Salt. To get up to speed, check out the \textit{Salt Walkthrough}.

\section*{Dependencies}

Manipulation of LXC containers in Salt requires the minion to have an LXC version of at least 1.0 (an alpha or beta release of LXC 1.0 is acceptable). The following distributions are known to have new enough versions of LXC

packaged:

- RHEL/CentOS 6 and later (via EPEL)
- Fedora (All non-EOL releases)
- Debian 8.0 (Jessie)
- Ubuntu 14.04 LTS and later (LXC templates are packaged separately as lxc-templates, it is recommended to also install this package)
- openSUSE 13.2 and later

Profiles

Profiles allow for a sort of shorthand for commonly-used configurations to be defined in the minion config file, grains, pillar, or the master config file. The profile is retrieved by Salt using the config.get function, which looks in those locations, in that order. This allows for profiles to be defined centrally in the master config file, with several options for overriding them (if necessary) on groups of minions or individual minions.

There are two types of profiles:

- One for defining the parameters used in container creation/clone.
- One for defining the container's network interface(s) settings.

Container Profiles

LXC container profiles are defined defined underneath the lxc.container_profile config option:

```yaml
lxc.container_profile:
  centos:
    template: centos
    backing: lvm
    vname: vg1
    lvname: lxclv
    size: 10G
  centos_big:
    template: centos
    backing: lvm
    vname: vg1
    lvname: lxclv
    size: 20G
```

Profiles are retrieved using the config.get function, with the recurse merge strategy. This means that a profile can be defined at a lower level (for example, the master config file) and then parts of it can be overridden at a higher level (for example, in pillar data). Consider the following container profile data:

In the Master config file:

```yaml
lxc.container_profile:
  centos:
    template: centos
    backing: lvm
    vname: vg1
    lvname: lxclv
    size: 10G
```

In the Pillar data

```yaml

```
lxc.container_profile:
    centos:
        size: 20G

Any minion with the above Pillar data would have the size parameter in the centos profile overridden to 20G, while those minions without the above Pillar data would have the 10G size value. This is another way of achieving the same result as the centos_big profile above, without having to define another whole profile that differs in just one value.

Note: In the 2014.7.x release cycle and earlier, container profiles are defined under lxc.profile. This parameter will still work in version 2015.5.0, but is deprecated and will be removed in a future release. Please note however that the profile merging feature described above will only work with profiles defined under lxc.container_profile, and only in versions 2015.5.0 and later.

Additionally, in version 2015.5.0 container profiles have been expanded to support passing template-specific CLI options to lxc.create. Below is a table describing the parameters which can be configured in container profiles:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>2015.5.0 and Newer</th>
<th>2014.7.x and Earlier</th>
</tr>
</thead>
<tbody>
<tr>
<td>template\a</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>options\a</td>
<td>Yes</td>
<td>No</td>
</tr>
<tr>
<td>image\a</td>
<td>Yes</td>
<td></td>
</tr>
<tr>
<td>backing</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>snapshot\b</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>lvname\a</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>fstype\a</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>size</td>
<td>Yes</td>
<td>Yes</td>
</tr>
</tbody>
</table>

1. Parameter is only supported for container creation, and will be ignored if the profile is used when cloning a container.

2. Parameter is only supported for container cloning, and will be ignored if the profile is used when not cloning a container.

Network Profiles

LXC network profiles are defined defined underneath the lxc.network_profile config option. By default, the module uses a DHCP based configuration and try to guess a bridge to get connectivity.

Warning: on pre 2015.5.2, you need to specify explicitly the network bridge

lxc.network_profile:
    centos:
        eth0:
            link: br0
            type: veth
            flags: up
    ubuntu:
        eth0:
            link: lxcbr0
            type: veth
            flags: up

As with container profiles, network profiles are retrieved using the config.get function, with the recurse merge strategy. Consider the following network profile data:
In the Master config file:

```yaml
lxc.network_profile:
  centos:
    eth0:
      link: br0
      type: veth
      flags: up
```

In the Pillar data

```yaml
lxc.network_profile:
  centos:
    eth0:
      link: lxcbr0
```

Any minion with the above Pillar data would use the `lxcbr0` interface as the bridge interface for any container configured using the `centos` network profile, while those minions without the above Pillar data would use the `br0` interface for the same.

**Note:** In the 2014.7.x release cycle and earlier, network profiles are defined under `lxc.nic`. This parameter will still work in version 2015.5.0, but is deprecated and will be removed in a future release. Please note however that the profile merging feature described above will only work with profiles defined under `lxc.network_profile`, and only in versions 2015.5.0 and later.

The following are parameters which can be configured in network profiles. These will directly correspond to a parameter in an LXC configuration file (see `man 5 lxc.container.conf`).

- **type** - Corresponds to `lxc.network.type`
- **link** - Corresponds to `lxc.network.link`
- **flags** - Corresponds to `lxc.network.flags`

Interface-specific options (MAC address, IPv4/IPv6, etc.) must be passed on a container-by-container basis, for instance using the `nic_opts` argument to `lxc.create`:

```
salt myminion lxc.create container1 profile=centos network_profile=centos nic_opts='{eth0: {ipv4: 10.0.0.20/24, gateway: 10.0.0.1}}'
```

**Warning:** The `ipv4`, `ipv6`, `gateway`, and `link` (bridge) settings in network profiles / `nic_opts` will only work if the container does not redefine the network configuration (for example in `/etc/sysconfig/network-scripts/ifcfg-<interface_name>` on RHEL/CentOS, or `/etc/network/interfaces` on Debian/Ubuntu/etc.). Use these with caution. The container images installed using the download template, for instance, typically are configured for eth0 to use DHCP, which will conflict with static IP addresses set at the container level.

**Note:** For LXC < 1.0.7 and DHCP support, set `ipv4.gateway`: 'auto' is your network profile, ie:

```yaml
lxc.network_profile.nic:
  debian:
    eth0:
      link: lxcbr0
      ipv4.gateway: 'auto'
```

---

3.4. Advanced Topics 119
Old lxc support (<1.0.7)

With saltstack 2015.5.2 and above, normally the setting is autoselected, but before, you'll need to teach your network profile to set `lxc.network.ipv4.gateway` to `auto` when using a classic ipv4 configuration.

Thus you'll need

```yaml
lxc.network_profile.foo:
  eth0:
    link: lxcbr0
    ipv4.gateway: auto
```

Tricky network setups Examples

This example covers how to make a container with both an internal ip and a public routable ip, wired on two veth pairs.

The another interface which receives directly a public routable ip can't be on the first interface that we reserve for private inter LXC networking.

```yaml
lxc.network_profile.foo:
  eth0: {gateway: null, bridge: lxcbr0}
  eth1:
    # replace that by your main interface
    'link': 'br0'
    'mac': '00:16:5b:01:24:e1'
    'gateway': '2.20.9.14'
    'ipv4': '2.20.9.1'
```

Creating a Container on the CLI

From a Template

LXC is commonly distributed with several template scripts in `/usr/share/lxc/templates`. Some distros may package these separately in an `lxc-templates` package, so make sure to check if this is the case.

There are LXC template scripts for several different operating systems, but some of them are designed to use tools specific to a given distribution. For instance, the `ubuntu` template uses `deb_bootstrap`, the `centos` template uses `yum`, etc., making these templates impractical when a container from a different OS is desired.

The `lxc.create` function is used to create containers using a template script. To create a CentOS container named `container1` on a CentOS minion named `mycentosminion`, using the `centos` LXC template, one can simply run the following command:

```bash
salt mycentosminion lxc.create container1 template=centos
```

For these instances, there is a `download` template which retrieves minimal container images for several different operating systems. To use this template, it is necessary to provide an `options` parameter when creating the container, with three values:

1. `dist` - the Linux distribution (i.e. `ubuntu` or `centos`)
2. `release` - the release name/version (i.e. `trusty` or `6`)
3. `arch` - CPU architecture (i.e. `amd64` or `i386`)
The `lxc.images` function (new in version 2015.5.0) can be used to list the available images. Alternatively, the releases can be viewed on [http://images.linuxcontainers.org/images/](http://images.linuxcontainers.org/images/). The images are organized in such a way that the `dist`, `release`, and `arch` can be determined using the following URL format: [http://images.linuxcontainers.org/images/dist/release/arch](http://images.linuxcontainers.org/images/dist/release/arch). For example, [http://images.linuxcontainers.org/images/centos/6/amd64](http://images.linuxcontainers.org/images/centos/6/amd64) would correspond to a `dist` of `centos`, a `release` of `6`, and an `arch` of `amd64`.

Therefore, to use the `download` template to create a new 64-bit CentOS 6 container, the following command can be used:

```
salt myminion lxc.create container1 template=download options='{dist: centos, release: 6, arch: amd64}'
```

Note: These command-line options can be placed into a container profile, like so:

```
lxc.container_profile.cent6:
  template: download
  options:
    dist: centos
    release: 6
    arch: amd64
```

The `options` parameter is not supported in profiles for the 2014.7.x release cycle and earlier, so it would still need to be provided on the command-line.

### Cloning an Existing Container

To clone a container, use the `lxc.clone` function:

```
salt myminion lxc.clone container2 orig=container1
```

### Using a Container Image

While cloning is a good way to create new containers from a common base container, the source container that is being cloned needs to already exist on the minion. This makes deploying a common container across minions difficult. For this reason, Salt's `lxc.create` is capable of installing a container from a tar archive of another container's rootfs. To create an image of a container named `cent6`, run the following command as root:

```
tar czf cent6.tar.gz -C /var/lib/lxc/cent6 rootfs
```

Note: Before doing this, it is recommended that the container is stopped.

The resulting tarball can then be placed alongside the files in the salt fileserver and referenced using a `salt:// URL. To create a container using an image, use the `image` parameter with `lxc.create`:

```
salt myminion lxc.create new-cent6 image=salt://path/to/cent6.tar.gz
```

Note: Making images of containers with LVM backing

For containers with LVM backing, the rootfs is not mounted, so it is necessary to mount it first before creating the tar archive. When a container is created using LVM backing, an empty `rootfs` dir is handily created within `/var/lib/lxc/container_name`, so this can be used as the mountpoint. The location of the logical volume for the container will be `/dev/vgname/lvname`, where `vgname` is the name of the volume group, and `lvname` is the name of the logical volume. Therefore, assuming a volume group of `vg1`, a logical volume of `lxc-cent6`, and a container name of `cent6`, the following commands can be used to create a tar archive of the rootfs:
mount /dev/vg1/lxc-cent6 /var/lib/lxc/cent6/rootfs

tar czf cent6.tar.gz -C /var/lib/lxc/cent6 rootfs

umount /var/lib/lxc/cent6/rootfs

**Warning:** One caveat of using this method of container creation is that `/etc/hosts` is left unmodified. This could cause confusion for some distros if salt-minion is later installed on the container, as the functions that determine the hostname take `/etc/hosts` into account. Additionally, when creating an rootfs image, be sure to remove `/etc/salt/minion_id` and make sure that `id` is not defined in `/etc/salt/minion`, as this will cause similar issues.

### Initializing a New Container as a Salt Minion

The above examples illustrate a few ways to create containers on the CLI, but often it is desirable to also have the new container run as a Minion. To do this, the `lxc.init` function can be used. This function will do the following:

1. Create a new container
2. Optionally set password and/or DNS
3. Bootstrap the minion (using either `salt-bootstrap` or a custom command)

By default, the new container will be pointed at the same Salt Master as the host machine on which the container was created. It will then request to authenticate with the Master like any other bootstrapped Minion, at which point it can be accepted.

```bash
salt myminion lxc.init test1 profile=centos
salt-key -a test1
```

For even greater convenience, the `LXC runner` contains a runner function of the same name (`lxc.init`), which creates a keypair, seeds the new minion with it, and pre-accepts the key, allowing for the new Minion to be created and authorized in a single step:

```bash
salt-run lxc.init test1 host=myminion profile=centos
```

### Running Commands Within a Container

For containers which are not running their own Minion, commands can be run within the container in a manner similar to using `(cmd.run <salt.modules.cmdmod.run)`. The means of doing this have been changed significantly in version 2015.5.0 (though the deprecated behavior will still be supported for a few releases). Both the old and new usage are documented below.

#### 2015.5.0 and Newer

New functions have been added to mimic the behavior of the functions in the `cmd` module. Below is a table with the `cmd` functions and their `lxc` module equivalents:

<table>
<thead>
<tr>
<th>Description</th>
<th><code>cmd</code> Module</th>
<th><code>lxc</code> Module</th>
</tr>
</thead>
<tbody>
<tr>
<td>Run a command and get all output</td>
<td><code>cmd.run</code></td>
<td><code>lxc.run</code></td>
</tr>
<tr>
<td>Run a command and get just stdout</td>
<td><code>cmd.run_stdout</code></td>
<td><code>lxc.run_stdout</code></td>
</tr>
<tr>
<td>Run a command and get just stderr</td>
<td><code>cmd.run_stderr</code></td>
<td><code>lxc.run_stderr</code></td>
</tr>
<tr>
<td>Run a command and get just the retcode</td>
<td><code>cmd.retcode</code></td>
<td><code>lxc.retcode</code></td>
</tr>
<tr>
<td>Run a command and get all information</td>
<td><code>cmd.run_all</code></td>
<td><code>lxc.run_all</code></td>
</tr>
</tbody>
</table>
2014.7.x and Earlier

Earlier Salt releases use a single function (`lxc.run_cmd`) to run commands within containers. Whether stdout, stderr, etc. are returned depends on how the function is invoked.

To run a command and return the stdout:

```bash
salt myminion lxc.run_cmd web1 'tail /var/log/messages'
```

To run a command and return the stderr:

```bash
salt myminion lxc.run_cmd web1 'tail /var/log/messages' stdout=False stderr=True
```

To run a command and return the retcode:

```bash
salt myminion lxc.run_cmd web1 'tail /var/log/messages' stdout=False stderr=False
```

To run a command and return all information:

```bash
salt myminion lxc.run_cmd web1 'tail /var/log/messages' stdout=True stderr=True
```

Container Management Using salt-cloud

Salt cloud uses under the hood the salt runner and module to manage containers, Please look at this chapter

Container Management Using States

Several states are being renamed or otherwise modified in version 2015.5.0. The information in this tutorial refers to the new states. For 2014.7.x and earlier, please refer to the documentation for the LXC states.

Ensuring a Container Is Present

To ensure the existence of a named container, use the `lxc.present` state. Here are some examples:

```yaml
# Using a template
web1:
  lxc.present:
    - template: download
    - options:
      dist: centos
      release: 6
      arch: amd64

# Cloning
web2:
  lxc.present:
    - clone_from: web-base

# Using a rootfs image
web3:
  lxc.present:
    - image: salt://path/to/cent6.tar.gz

# Using profiles
web4:
```

3.4. Advanced Topics
The `lxc.present` state also includes an optional `running` parameter which can be used to ensure that a container is running/stopped. Note that there are standalone `lxc.running` and `lxc.stopped` states which can be used for this purpose.

### Ensuring a Container Does Not Exist

To ensure that a named container is not present, use the `lxc.absent` state. For example:

```yaml
web1:
  lxc.absent
```

### Ensuring a Container is Running/Stopped/Frozen

Containers can be in one of three states:

- **running** - Container is running and active
- **frozen** - Container is running, but all process are blocked and the container is essentially non-active until the container is ```unfrozen```
- **stopped** - Container is not running

Salt has three states (`lxc.running`, `lxc.frozen`, and `lxc.stopped`) which can be used to ensure a container is in one of these states:

```yaml
web1:
  lxc.running

# Restart the container if it was already running
web2:
  lxc.running:
    - restart: True

web3:
  lxc.stopped

# Explicitly kill all tasks in container instead of gracefully stopping
web4:
  lxc.stopped:
    - kill: True

web5:
  lxc.frozen

# If container is stopped, do not start it (in which case the state will fail)
web6:
  lxc.frozen:
    - start: False
```
3.4.18 Using Salt with Stormpath

Stormpath is a user management and authentication service. This tutorial covers using SaltStack to manage and take advantage of Stormpath’s features.

External Authentication

Stormpath can be used for Salt’s external authentication system. In order to do this, the master should be configured with an apiid, apikey, and the ID of the application that is associated with the users to be authenticated:

```
stormpath:
  apiid: 367DFSF4FRJ8767FSF4G34FGH
  apikey: FEFREF43t3FEFRe/f323fwer4FWF3445gferWRWeer1
  application: 786786FREFrefreg435fr1
```

Note: These values can be found in the Stormpath dashboard <https://api.stormpath.com/ui2/index.html#/>.

Users that are to be authenticated should be set up under the stormpath dict under external_auth:

```
external_auth:
  stormpath:
    larry:
      - *
      - '@runner'
      - '@wheel'
```

Keep in mind that while Stormpath defaults the username associated with the account to the email address, it is better to use a username without an @ sign in it.

Configuring Stormpath Modules

Stormpath accounts can be managed via either an execution or state module. In order to use either, a minion must be configured with an API ID and key.

```
stormpath:
  apiid: 367DFSF4FRJ8767FSF4G34FGH
  apikey: FEFREF43t3FEFRe/f323fwer4FWF3445gferWRWeer1
  directory: efreg435fr1786786FREFr
  application: 786786FREFrefreg435fr1
```

Some functions in the stormpath modules can make use of other options. The following options are also available.

directory

The ID of the directory that is to be used with this minion. Many functions require an ID to be specified to do their work. However, if the ID of a directory is specified, then Salt can often look up the resource in question.

application

The ID of the application that is to be used with this minion. Many functions require an ID to be specified to do their work. However, if the ID of a application is specified, then Salt can often look up the resource in question.
Managing Stormpath Accounts

With the `stormpath` configuration in place, Salt can be used to configure accounts (which may be thought of as users) on the Stormpath service. The following functions are available.

`stormpath.create_account`

Create an account on the Stormpath service. This requires a `directory_id` as the first argument; it will not be retrieved from the minion configuration. An `email` address, `password`, first name (givenName) and last name (surname) are also required. For the full list of other parameters that may be specified, see:

http://docs.stormpath.com/rest/product-guide/#account-resource

When executed with no errors, this function will return the information about the account, from Stormpath.

```bash
salt myminion stormpath.create_account <directory_id> shemp@example.com letmein Shemp Howard
```

`stormpath.list_accounts`

Show all accounts on the Stormpath service. This will return all accounts, regardless of directory, application, or group.

```bash
salt myminion stormpath.list_accounts
```

`stormpath.show_account`

Show the details for a specific Stormpath account. An `account_id` is normally required. However, if an email is provided instead, along with either a `directory_id`, `application_id`, or `group_id`, then Salt will search the specified resource to try and locate the `account_id`.

```bash
salt myminion stormpath.show_account <account_id>
salt myminion stormpath.show_account email=<email> directory_id=<directory_id>
```

`stormpath.update_account`

Update one or more items for this account. Specifying an empty value will clear it for that account. This function may be used in one of two ways. In order to update only one key/value pair, specify them in order:

```bash
salt myminion stormpath.update_account <account_id> givenName shemp
salt myminion stormpath.update_account <account_id> middleName ""
```

In order to specify multiple items, they need to be passed in as a dict. From the command line, it is best to do this as a JSON string:

```bash
salt myminion stormpath.update_account <account_id> items='{"givenName": "Shemp"}"
salt myminion stormpath.update_account <account_id> items='{"middleName": ""}"
```

When executed with no errors, this function will return the information about the account, from Stormpath.
stormpath.delete_account

Delete an account from Stormpath.

```
salt myminion stormpath.delete_account <account_id>
```

stormpath.list_directories

Show all directories associated with this tenant.

```
salt myminion stormpath.list_directories
```

Using Stormpath States

Stormpath resources may be managed using the state system. The following states are available.

stormpath_account.present

Ensure that an account exists on the Stormpath service. All options that are available with the `stormpath.create_account` function are available here. If an account needs to be created, then this function will require the same fields that `stormpath.create_account` requires, including the password. However, if a password changes for an existing account, it will NOT be updated by this state.

```
curly@example.com:
    stormpath_account.present:
        - directory_id: efgreg435fr1786786FREFr
        - password: badpass
        - firstName: Curly
        - surname: Howard
        - nickname: curly
```

It is advisable to always set a nickname that is not also an email address, so that it can be used by Salt's external authentication module.

stormpath_account.absent

Ensure that an account does not exist on Stormpath. As with `stormpath_account.present`, the name supplied to this state is the email address associated with this account. Salt will use this, with or without the directory ID that is configured for the minion. However, lookups will be much faster with a directory ID specified.

3.5 Salt Virt

3.5.1 Salt as a Cloud Controller

In Salt 0.14.0, an advanced cloud control system were introduced, allow private cloud vms to be managed directly with Salt. This system is generally referred to as Salt Virt.

The Salt Virt system already exists and is installed within Salt itself, this means that beside setting up Salt, no additional salt code needs to be deployed.
The main goal of Salt Virt is to facilitate a very fast and simple cloud. The cloud that can scale and fully featured. Salt Virt comes with the ability to set up and manage complex virtual machine networking, powerful image, and disk management, as well as virtual machine migration with and without shared storage.

This means that Salt Virt can be used to create a cloud from a blade center and a SAN, but can also create a cloud out of a swarm of Linux Desktops without a single shared storage system. Salt Virt can make clouds from truly commodity hardware, but can also stand up the power of specialized hardware as well.

Setting up Hypervisors

The first step to set up the hypervisors involves getting the correct software installed and setting up the hypervisor network interfaces.

Installing Hypervisor Software

Salt Virt is made to be hypervisor agnostic but currently the only fully implemented hypervisor is KVM via libvirt. The required software for a hypervisor is libvirt and kvm. For advanced features install libguestfs or qemu-nbd.

Note: Libguestfs and qemu-nbd allow for virtual machine images to be mounted before startup and get pre-seeded with configurations and a salt minion

This sls will set up the needed software for a hypervisor, and run the routines to set up the libvirt pki keys.

Note: Package names and setup used is Red Hat specific, different package names will be required for different platforms

```python
libvirt:
    pkg.installed: []
    file.managed:
        - name: /etc/sysconfig/libvirtd
        - contents: \"LIBVIRTD_ARGS="--listen"\" 
        - require:
            - pkg: libvirt
    libvirt.keys:
        - require:
            - pkg: libvirt
    service.running:
        - name: libvirtd
        - require:
            - pkg: libvirt
            - network: br0
            - libvirt: libvirt
        - watch:
            - file: libvirt

libvirt-python:
    pkg.installed: []

libguestfs:
    pkg.installed:
        - pkgs:
            - libguestfs
            - libguestfs-tools
```
Hypervisor Network Setup

The hypervisors will need to be running a network bridge to serve up network devices for virtual machines, this formula will set up a standard bridge on a hypervisor connecting the bridge to eth0:

```
eth0:
    network.managed:
        - enabled: True
        - type: eth
        - bridge: br0

br0:
    network.managed:
        - enabled: True
        - type: bridge
        - proto: dhcp
        - require:
          - network: eth0
```

Virtual Machine Network Setup

Salt Virt comes with a system to model the network interfaces used by the deployed virtual machines; by default a single interface is created for the deployed virtual machine and is bridged to $br0$. To get going with the default networking setup, ensure that the bridge interface named $br0$ exists on the hypervisor and is bridged to an active network device.

**Note:** To use more advanced networking in Salt Virt, read the *Salt Virt Networking* document:

*Salt Virt Networking*

Libvirt State

One of the challenges of deploying a libvirt based cloud is the distribution of libvirt certificates. These certificates allow for virtual machine migration. Salt comes with a system used to auto deploy these certificates. Salt manages the signing authority key and generates keys for libvirt clients on the master, signs them with the certificate authority and uses pillar to distribute them. This is managed via the *libvirt* state. Simply execute this formula on the minion to ensure that the certificate is in place and up to date:

**Note:** The above formula includes the calls needed to set up libvirt keys.

```
libvirt_keys:
    libvirt.keys
```

Getting Virtual Machine Images Ready

Salt Virt, requires that virtual machine images be provided as these are not generated on the fly. Generating these virtual machine images differs greatly based on the underlying platform.

Virtual machine images can be manually created using KVM and running through the installer, but this process is not recommended since it is very manual and prone to errors.

Virtual Machine generation applications are available for many platforms:
Once virtual machine images are available, the easiest way to make them available to Salt Virt is to place them in the Salt file server. Just copy an image into /srv/salt and it can now be used by Salt Virt.

For purposes of this demo, the file name centos.img will be used.

Existing Virtual Machine Images

Many existing Linux distributions distribute virtual machine images which can be used with Salt Virt. Please be advised that NONE OF THESE IMAGES ARE SUPPORTED BY SALTSTACK.

CentOS  These images have been prepared for OpenNebula but should work without issue with Salt Virt, only the raw qcow image file is needed: http://wiki.centos.org/Cloud/OpenNebula

Fedora Linux  Images for Fedora Linux can be found here: http://fedoraproject.org/en/get-fedora#clouds

Ubuntu Linux  Images for Ubuntu Linux can be found here: http://cloud-images.ubuntu.com/

Using Salt Virt

With hypervisors set up and virtual machine images ready, Salt can start issuing cloud commands.

Start by running a Salt Virt hypervisor info command:

```
salt-run virt.hyper_info
```

This will query what the running hypervisor stats are and display information for all configured hypervisors. This command will also validate that the hypervisors are properly configured.

Now that hypervisors are available a virtual machine can be provisioned. The `virt.init` routine will create a new virtual machine:

```
salt-run virt.init centos1 2 512 salt://centos.img
```

This command assumes that the CentOS virtual machine image is sitting in the root of the Salt fileserver. Salt Virt will now select a hypervisor to deploy the new virtual machine on and copy the virtual machine image down to the hypervisor.

Once the VM image has been copied down the new virtual machine will be seeded. Seeding the VMs involves setting pre-authenticated Salt keys on the new VM and if needed, will install the Salt Minion on the new VM before it is started.

**Note:** The biggest bottleneck in starting VMs is when the Salt Minion needs to be installed. Making sure that the source VM images already have Salt installed will GREATLY speed up virtual machine deployment.

Now that the new VM has been prepared, it can be seen via the `virt.query` command:

```
salt-run virt.query
```
This command will return data about all of the hypervisors and respective virtual machines.

Now that the new VM is booted it should have contacted the Salt Master, a `test.ping` will reveal if the new VM is running.

**Migrating Virtual Machines**

Salt Virt comes with full support for virtual machine migration, and using the libvirt state in the above formula makes migration possible.

A few things need to be available to support migration. Many operating systems turn on firewalls when originally set up, the firewall needs to be opened up to allow for libvirt and kvm to cross communicate and execution migration routines. On Red Hat based hypervisors in particular port 16514 needs to be opened on hypervisors:

```
iptables -A INPUT -m state --state NEW -m tcp -p tcp --dport 16514 -j ACCEPT
```

**Note:** More in-depth information regarding distribution specific firewall settings can read in:

*Opening the Firewall up for Salt*

Salt also needs an additional flag to be turned on as well. The `virt.tunnel` option needs to be turned on. This flag tells Salt to run migrations securely via the libvirt TLS tunnel and to use port 16514. Without `virt.tunnel` libvirt tries to bind to random ports when running migrations. To turn on `virt.tunnel` simple apply it to the master config file:

```
virt.tunnel: True
```

Once the master config has been updated, restart the master and send out a call to the minions to refresh the pillar to pick up on the change:

```
salt * saltutil.refresh_modules
```

Now, migration routines can be run! To migrate a VM, simply run the Salt Virt migrate routine:

```
salt-run virt.migrate centos <new hypervisor>
```

**VNC Consoles**

Salt Virt also sets up VNC consoles by default, allowing for remote visual consoles to be oped up. The information from a `virt.query` routine will display the vnc console port for the specific vms:

```
centos
    CPU: 2
    Memory: 524288
    State: running
    Graphics: vnc - hyper6:5900
    Disk - vda:
        Size: 2.0G
        File: /srv/salt-images/ubuntu2/system.qcow2
        File Format: qcow2
    Nic - ac:de:48:98:08:77:
        Source: br0
        Type: bridge
```

The line `Graphics: vnc - hyper6:5900` holds the key. First the port named, in this case 5900, will need to be available in the hypervisor's firewall. Once the port is open, then the console can be easily opened via vncviewer:
vncviewer hyper6:5900

By default there is no VNC security set up on these ports, which suggests that keeping them firewalled and mandating that SSH tunnels be used to access these VNC interfaces. Keep in mind that activity on a VNC interface that is accessed can be viewed by any other user that accesses that same VNC interface, and any other user logging in can also operate with the logged in user on the virtual machine.

Conclusion

Now with Salt Virt running, new hypervisors can be seamlessly added just by running the above states on new bare metal machines, and these machines will be instantly available to Salt Virt.

3.6 LXC

3.6.1 LXC Management with Salt

Note: This walkthrough assumes basic knowledge of Salt. To get up to speed, check out the Salt Walkthrough.

Dependencies

Manipulation of LXC containers in Salt requires the minion to have an LXC version of at least 1.0 (an alpha or beta release of LXC 1.0 is acceptable). The following distributions are known to have new enough versions of LXC packaged:

- RHEL/CentOS 6 and later (via EPEL)
- Fedora (All non-EOL releases)
- Debian 8.0 (Jessie)
- Ubuntu 14.04 LTS and later (LXC templates are packaged separately as lxc-templates, it is recommended to also install this package)
- openSUSE 13.2 and later

Profiles

Profiles allow for a sort of shorthand for commonly-used configurations to be defined in the minion config file, grains, pillar, or the master config file. The profile is retrieved by Salt using the config.get function, which looks in those locations, in that order. This allows for profiles to be defined centrally in the master config file, with several options for overriding them (if necessary) on groups of minions or individual minions.

There are two types of profiles:

- One for defining the parameters used in container creation/clone.
- One for defining the container’s network interface(s) settings.
Container Profiles

LXC container profiles are defined underneath the `lxc.container_profile` config option:

```yaml
lxc.container_profile:
    centos:
        template: centos
        backing: lvm
        vgname: vg1
        lvname: lxclv
        size: 10G
    centos_big:
        template: centos
        backing: lvm
        vgname: vg1
        lvname: lxclv
        size: 20G
```

Profiles are retrieved using the `config.get` function, with the `recurse` merge strategy. This means that a profile can be defined at a lower level (for example, the master config file) and then parts of it can be overridden at a higher level (for example, in pillar data). Consider the following container profile data:

**In the Master config file:**

```yaml
lxc.container_profile:
    centos:
        template: centos
        backing: lvm
        vgname: vg1
        lvname: lxclv
        size: 10G
```

**In the Pillar data**

```yaml
lxc.container_profile:
    centos:
        size: 20G
```

Any minion with the above Pillar data would have the `size` parameter in the `centos` profile overridden to 20G, while those minions without the above Pillar data would have the 10G `size` value. This is another way of achieving the same result as the `centos_big` profile above, without having to define another whole profile that differs in just one value.

**Note:** In the 2014.7.x release cycle and earlier, container profiles are defined under `lxc.profile`. This parameter will still work in version 2015.5.0, but is deprecated and will be removed in a future release. Please note however that the profile merging feature described above will only work with profiles defined under `lxc.container_profile`, and only in versions 2015.5.0 and later.

Additionally, in version 2015.5.0 container profiles have been expanded to support passing template-specific CLI options to `lxc.create`. Below is a table describing the parameters which can be configured in container profiles:
<table>
<thead>
<tr>
<th>Parameter</th>
<th>2015.5.0 and Newer</th>
<th>2014.7.x and Earlier</th>
</tr>
</thead>
<tbody>
<tr>
<td>template</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>options</td>
<td>Yes</td>
<td>No</td>
</tr>
<tr>
<td>image</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>backing</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>snapshot</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>lvname</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>fstype</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>size</td>
<td>Yes</td>
<td>Yes</td>
</tr>
</tbody>
</table>

1. Parameter is only supported for container creation, and will be ignored if the profile is used when cloning a container.

2. Parameter is only supported for container cloning, and will be ignored if the profile is used when not cloning a container.

Network Profiles

LXC network profiles are defined under the `lxc.network_profile` config option. By default, the module uses a DHCP based configuration and try to guess a bridge to get connectivity.

**Warning:** on pre 2015.5.2, you need to specify explicitly the network bridge

```yaml
lxc.network_profile:
  centos:
    eth0:
      link: br0
      type: veth
      flags: up
  ubuntu:
    eth0:
      link: lxcbr0
      type: veth
      flags: up
```

As with container profiles, network profiles are retrieved using the `config.get` function, with the `recurse` merge strategy. Consider the following network profile data:

**In the Master config file:**

```yaml
lxc.network_profile:
  centos:
    eth0:
      link: br0
      type: veth
      flags: up
```

**In the Pillar data**

```yaml
lxc.network_profile:
  centos:
    eth0:
      link: lxcbr0
```

Any minion with the above Pillar data would use the `lxcbr0` interface as the bridge interface for any container configured using the `centos` network profile, while those minions without the above Pillar data would use the `br0` interface for the same.
Note: In the 2014.7.x release cycle and earlier, network profiles are defined under lxc.nic. This parameter will
still work in version 2015.5.0, but is deprecated and will be removed in a future release. Please note however that
the profile merging feature described above will only work with profiles defined under lxc.network_profile,
and only in versions 2015.5.0 and later.

The following are parameters which can be configured in network profiles. These will directly correspond to a
parameter in an LXC configuration file (see man 5 lxc.container.conf).

- **type** - Corresponds to lxc.network.type
- **link** - Corresponds to lxc.network.link
- **flags** - Corresponds to lxc.network.flags

Interface-specific options (MAC address, IPv4/IPv6, etc.) must be passed on a container-by-container basis, for in-
stance using the nic_opts argument to lxc.create:

```bash
salt myminion lxc.create container1 profile=centos network_profile=centos nic_opts='{eth0: {ipv4: 10.0.0.20/24, gateway: 10.0.0.1}}'
```

**Warning:** The ipv4, ipv6, gateway, and link (bridge) settings in network profiles/nic_opts will only work
if the container doesnt redefine the network configuration (for example in /etc/sysconfig/network-
scripts/ifcfg-<interface_name> on RHEL/CentOS, or /etc/network/interfaces on De-
bian/Ubuntu/etc.). Use these with caution. The container images installed using the download template, for in-
stance, typically are configured for eth0 to use DHCP, which will conflict with static IP addresses set at the
container level.

Note: For LXC < 1.0.7 and DHCP support, set ipv4.gateway: 'auto' is your network profile, ie:

```bash
lxc.network_profile.nic:
  debian:
    eth0:
      link: lxcbr0
      ipv4.gateway: 'auto'
```

**Old lxc support (<1.0.7)**

With saltstack 2015.5.2 and above, normally the setting is autoslected, but before, you'll need to teach your network
profile to set lxc.network.ipv4.gateway to auto when using a classic ipv4 configuration.

Thus you'll need

```bash
lxc.network_profile.foo:
  etho:
    link: lxcbr0
    ipv4.gateway: auto
```

**Tricky network setups Examples**

This example covers how to make a container with both an internal ip and a public routable ip, wired on two veth
pairs.

The another interface which receives directly a public routable ip can't be on the first interface that we reserve for
private inter LXC networking.
lxc.network_profile.foo:
  eth0: {gateway: null, bridge: lxcbr0}
  eth1:
    # replace that by your main interface
    'link': 'br0'
    'mac': '00:16:5b:01:24:e1'
    'gateway': '2.20.9.14'
    'ipv4': '2.20.9.1'

Creating a Container on the CLI

From a Template

LXC is commonly distributed with several template scripts in /usr/share/lxc/templates. Some distros may package these separately in an lxc-templates package, so make sure to check if this is the case.

There are LXC template scripts for several different operating systems, but some of them are designed to use tools specific to a given distribution. For instance, the ubuntu template uses deb_bootstrap, the centos template uses yum, etc., making these templates impractical when a container from a different OS is desired.

The lxc.create function is used to create containers using a template script. To create a CentOS container named container1 on a CentOS minion named mycentosminion, using the centos LXC template, one can simply run the following command:

```
salt mycentosminion lxc.create container1 template=centos
```

For these instances, there is a download template which retrieves minimal container images for several different operating systems. To use this template, it is necessary to provide an options parameter when creating the container, with three values:

1. dist - the Linux distribution (i.e. ubuntu or centos)
2. release - the release name/version (i.e. trusty or 6)
3. arch - CPU architecture (i.e. amd64 or i386)

The lxc.images function (new in version 2015.5.0) can be used to list the available images. Alternatively, the releases can be viewed on http://images.linuxcontainers.org/images/. The images are organized in such a way that the dist, release, and arch can be determined using the following URL format: http://images.linuxcontainers.org/images/dist/release/arch. For example, http://images.linuxcontainers.org/images/centos/6/amd64 would correspond to a dist of centos, a release of 6, and an arch of amd64.

Therefore, to use the download template to create a new 64-bit CentOS 6 container, the following command can be used:

```
salt myminion lxc.create container1 template=download options='{dist: centos, release: 6, arch: amd64}'
```

Note: These command-line options can be placed into a container profile, like so:

```
lxc.container_profile.cent6:
  template: download
  options:
    dist: centos
    release: 6
    arch: amd64
```
The `options` parameter is not supported in profiles for the 2014.7.x release cycle and earlier, so it would still need to be provided on the command-line.

## Cloning an Existing Container

To clone a container, use the `lxc.clone` function:

```
salt myminion lxc.clone container2 orig=container1
```

## Using a Container Image

While cloning is a good way to create new containers from a common base container, the source container that is being cloned needs to already exist on the minion. This makes deploying a common container across minions difficult. For this reason, Salt’s `lxc.create` is capable of installing a container from a tar archive of another container’s rootfs. To create an image of a container named `cent6`, run the following command as root:

```
tar czf cent6.tar.gz -C /var/lib/lxc/cent6 rootfs
```

**Note:** Before doing this, it is recommended that the container is stopped.

The resulting tarball can then be placed alongside the files in the salt fileserver and referenced using a `salt://` URL. To create a container using an image, use the `image` parameter with `lxc.create`:

```
salt myminion lxc.create new-cent6 image=salt://path/to/cent6.tar.gz
```

**Note:** Making images of containers with LVM backing

For containers with LVM backing, the rootfs is not mounted, so it is necessary to mount it first before creating the tar archive. When a container is created using LVM backing, an empty `rootfs` dir is handily created within `/var/lib/lxc/container_name`, so this can be used as the mountpoint. The location of the logical volume for the container will be `/dev/vgname/lvname`, where `vgname` is the name of the volume group, and `lvname` is the name of the logical volume. Therefore, assuming a volume group of `vg1`, a logical volume of `lxc-cent6`, and a container name of `cent6`, the following commands can be used to create a tar archive of the rootfs:

```
mount /dev/vg1/lxc-cent6 /var/lib/lxc/cent6/rootfs
tar czf cent6.tar.gz -C /var/lib/lxc/cent6/rootfs
umount /var/lib/lxc/cent6/rootfs
```

**Warning:** One caveat of using this method of container creation is that `/etc/hosts` is left unmodified. This could cause confusion for some distros if salt-minion is later installed on the container, as the functions that determine the hostname take `/etc/hosts` into account. Additionally, when creating a rootfs image, be sure to remove `/etc/salt/minion_id` and make sure that `id` is not defined in `/etc/salt/minion`, as this will cause similar issues.

## Initializing a New Container as a Salt Minion

The above examples illustrate a few ways to create containers on the CLI, but often it is desirable to also have the new container run as a Minion. To do this, the `lxc.init` function can be used. This function will do the following:

1. Create a new container
2. Optionally set password and/or DNS

3. Bootstrap the minion (using either salt-bootstrap or a custom command)

By default, the new container will be pointed at the same Salt Master as the host machine on which the container was created. It will then request to authenticate with the Master like any other bootstrapped Minion, at which point it can be accepted.

```
salt myminion lxc.init test1 profile=centos
salt-key -a test1
```

For even greater convenience, the LXC runner contains a runner function of the same name (`lxc.init`), which creates a keypair, seeds the new minion with it, and pre-accepts the key, allowing for the new Minion to be created and authorized in a single step:

```
salt-run lxc.init test1 host=myminion profile=centos
```

### Running Commands Within a Container

For containers which are not running their own Minion, commands can be run within the container in a manner similar to using (`cmd.run <salt.modules.cmdmod.run`). The means of doing this have been changed significantly in version 2015.5.0 (though the deprecated behavior will still be supported for a few releases). Both the old and new usage are documented below.

#### 2015.5.0 and Newer

New functions have been added to mimic the behavior of the functions in the `cmd` module. Below is a table with the `cmd` functions and their `lxc` module equivalents:

<table>
<thead>
<tr>
<th>Description</th>
<th><code>cmd</code> module</th>
<th><code>lxc</code> module</th>
</tr>
</thead>
<tbody>
<tr>
<td>Run a command and get all output</td>
<td><code>cmd.run</code></td>
<td><code>lxc.run</code></td>
</tr>
<tr>
<td>Run a command and get just stdout</td>
<td><code>cmd.run_stdout</code></td>
<td><code>lxc.run_stdout</code></td>
</tr>
<tr>
<td>Run a command and get just stderr</td>
<td><code>cmd.run_stderr</code></td>
<td><code>lxc.run_stderr</code></td>
</tr>
<tr>
<td>Run a command and get just the retcode</td>
<td><code>cmd.retcode</code></td>

</tbody>
</table>

#### 2014.7.x and Earlier

Earlier Salt releases use a single function (`lxc.run_cmd`) to run commands within containers. Whether stdout, stderr, etc. are returned depends on how the function is invoked.

To run a command and return the stdout:

```
salt myminion lxc.run_cmd web1 'tail /var/log/messages'
```

To run a command and return the stderr:

```
salt myminion lxc.run_cmd web1 'tail /var/log/messages' stdout=False stderr=True
```

To run a command and return the retcode:

```
salt myminion lxc.run_cmd web1 'tail /var/log/messages' stdout=False stderr=False
```

To run a command and return all information:
Salt Documentation, Release 2015.8.0

```bash
salt myminion lxc.run_cmd web1 'tail /var/log/messages' stdout=True stderr=True
```

**Container Management Using salt-cloud**

Salt cloud uses under the hood the salt runner and module to manage containers. Please look at this chapter

**Container Management Using States**

Several states are being renamed or otherwise modified in version 2015.5.0. The information in this tutorial refers to the new states. For 2014.7.x and earlier, please refer to the documentation for the LXC states.

**Ensuring a Container Is Present**

To ensure the existence of a named container, use the `lxc.present` state. Here are some examples:

```yaml
web1:
  lxc.present:
    - template: download
      options:
        dist: centos
        release: 6
        arch: amd64

web2:
  lxc.present:
    - clone_from: web-base

web3:
  lxc.present:
    - image: salt://path/to/cent6.tar.gz

web4:
  lxc.present:
    - profile: centos_web
      network_profile: centos
```

**Warning:** The `lxc.present` state will not modify an existing container (in other words, it will not re-create the container). If an `lxc.present` state is run on an existing container, there will be no change and the state will return a `True` result.

The `lxc.present` state also includes an optional `running` parameter which can be used to ensure that a container is running/stopped. Note that there are standalone `lxc.running` and `lxc.stopped` states which can be used for this purpose.

**Ensuring a Container Does Not Exist**

To ensure that a named container is not present, use the `lxc.absent` state. For example:
Ensuring a Container is Running/Stopped/Frozen

Containers can be in one of three states:

- **running** - Container is running and active
- **frozen** - Container is running, but all process are blocked and the container is essentially non-active until the container is ``unfrozen``
- **stopped** - Container is not running

Salt has three states (lxc.running, lxc.frozen, and lxc.stopped) which can be used to ensure a container is in one of these states:

```python
web1:
  lxc.absent

# Restart the container if it was already running
web2:
  lxc.running:
    - restart: True

# Explicitly kill all tasks in container instead of gracefully stopping
web4:
  lxc.stopped:
    - kill: True

# If container is stopped, do not start it (in which case the state will fail)
web6:
  lxc.frozen:
    - start: False
```

3.7 Using Salt at scale

3.7.1 Using Salt at scale

The focus of this tutorial will be building a Salt infrastructure for handling large numbers of minions. This will include tuning, topology, and best practices.

For how to install the Salt Master please go here: Installing saltstack

**Note:** This tutorial is intended for large installations, although these same settings won't hurt, it may not be worth the complexity to smaller installations.

When used with minions, the term `many' refers to at least a thousand and `a few' always means 500.

For simplicity reasons, this tutorial will default to the standard ports used by Salt.
The Master

The most common problems on the Salt Master are:

1. too many minions authing at once
2. too many minions re-authing at once
3. too many minions re-connecting at once
4. too many minions returning at once
5. too few resources (CPU/HDD)

The first three are all "thundering herd" problems. To mitigate these issues we must configure the minions to back-off appropriately when the Master is under heavy load.

The fourth is caused by masters with little hardware resources in combination with a possible bug in ZeroMQ. At least that's what it looks like till today ([Issue 118651](https://github.com/saltstack/salt/issues/118651), [Issue 5948](https://github.com/saltstack/salt/issues/5948), [Mail thread](https://github.com/saltstack/salt/issues/5948)).

To fully understand each problem, it is important to understand, how Salt works.

Very briefly, the Salt Master offers two services to the minions.

- a job publisher on port 4505
- an open port 4506 to receive the minions returns

All minions are always connected to the publisher on port 4505 and only connect to the open return port 4506 if necessary. On an idle Master, there will only be connections on port 4505.

Too many minions authing

When the Minion service is first started up, it will connect to its Master’s publisher on port 4505. If too many minions are started at once, this can cause a "thundering herd". This can be avoided by not starting too many minions at once.

The connection itself usually isn’t the culprit, the more likely cause of master-side issues is the authentication that the Minion must do with the Master. If the Master is too heavily loaded to handle the auth request it will time it out. The Minion will then wait `acceptance_wait_time` to retry. If `acceptance_wait_time_max` is set then the Minion will increase its wait time by the `acceptance_wait_time` each subsequent retry until reaching `acceptance_wait_time_max`.

Too many minions re-authing

This is most likely to happen in the testing phase of a Salt deployment, when all Minion keys have already been accepted, but the framework is being tested and parameters are frequently changed in the Salt Master’s configuration file(s).

The Salt Master generates a new AES key to encrypt its publications at certain events such as a Master restart or the removal of a Minion key. If you are encountering this problem of too many minions re-authing against the Master, you will need to recalibrate your setup to reduce the rate of events like a Master restart or Minion key removal (`salt-key -d`).

When the Master generates a new AES key, the minions aren’t notified of this but will discover it on the next pub job they receive. When the Minion receives such a job it will then re-auth with the Master. Since Salt does minion-side filtering this means that all the minions will re-auth on the next command published on the master-- causing another "thundering herd". This can be avoided by setting the
random_reauth_delay: 60

in the minions configuration file to a higher value and stagger the amount of re-auth attempts. Increasing this value will of course increase the time it takes until all minions are reachable via Salt commands.

Too many minions re-connecting

By default the zmq socket will re-connect every 100ms which for some larger installations may be too quick. This will control how quickly the TCP session is re-established, but has no bearing on the auth load.

To tune the minions sockets reconnect attempts, there are a few values in the sample configuration file (default values)

```
recon_default: 100ms
recon_max: 5000
recon_randomize: True
```

- `recon_default`: the default value the socket should use, i.e. 100ms
- `recon_max`: the max value that the socket should use as a delay before trying to reconnect
- `recon_randomize`: enables randomization between `recon_default` and `recon_max`

To tune this values to an existing environment, a few decision have to be made.

1. How long can one wait, before the minions should be online and reachable via Salt?
2. How many reconnects can the Master handle without a syn flood?

These questions can not be answered generally. Their answers depend on the hardware and the administrators requirements.

Here is an example scenario with the goal, to have all minions reconnect within a 60 second time-frame on a Salt Master service restart.

```
recon_default: 1000
recon_max: 59000
recon_randomize: True
```

Each Minion will have a randomized reconnect value between `recon_default` and `recon_default + recon_max`, which in this example means between 1000ms and 60000ms (or between 1 and 60 seconds). The generated random value will be doubled after each attempt to reconnect (ZeroMQ default behavior).

Lets say the generated random value is 11 seconds (or 11000ms).

```
reconnect 1: wait 11 seconds
reconnect 2: wait 22 seconds
reconnect 3: wait 33 seconds
reconnect 4: wait 44 seconds
reconnect 5: wait 55 seconds
reconnect 6: wait time is bigger than 60 seconds (recon_default + recon_max)
reconnect 7: wait 11 seconds
reconnect 8: wait 22 seconds
reconnect 9: wait 33 seconds
reconnect x: etc.
```

With a thousand minions this will mean

```
1000/60 = ~16
```
round about 16 connection attempts a second. These values should be altered to values that match your environment. Keep in mind though, that it may grow over time and that more minions might raise the problem again.

**Too many minions returning at once**

This can also happen during the testing phase, if all minions are addressed at once with

```
$ salt * test.ping
```

it may cause thousands of minions trying to return their data to the Salt Master open port 4506. Also causing a flood of syn-flood if the Master can't handle that many returns at once.

This can be easily avoided with Salt's batch mode:

```
$ salt * test.ping -b 50
```

This will only address 50 minions at once while looping through all addressed minions.

**Too few resources**

The masters resources always have to match the environment. There is no way to give good advise without knowing the environment the Master is supposed to run in. But here are some general tuning tips for different situations:

**The Master is CPU bound**

Salt uses RSA-Key-Pairs on the masters and minions end. Both generate 4096 bit key-pairs on first start. While the key-size for the Master is currently not configurable, the minions keysize can be configured with different key-sizes. For example with a 2048 bit key:

```
keysize: 2048
```

With thousands of decryptions, the amount of time that can be saved on the masters end should not be neglected. See here for reference: Pull Request 9235 how much influence the key-size can have.

Downsizing the Salt Master's key is not that important, because the minions do not encrypt as many messages as the Master does.

**The Master is disk IO bound**

By default, the Master saves every Minion's return for every job in its job-cache. The cache can then be used later, to lookup results for previous jobs. The default directory for this is:

```
cachedir: /var/cache/salt
```

and then in the `/proc` directory.

Each job return for every Minion is saved in a single file. Over time this directory can grow quite large, depending on the number of published jobs. The amount of files and directories will scale with the number of jobs published and the retention time defined by

```
keep_jobs: 24
```

```
 250 jobs/day * 2000 minions returns = 500.000 files a day
```
If no job history is needed, the job cache can be disabled:

```yaml
job_cache: False
```

If the job cache is necessary there are (currently) 2 options:

- `ext_job_cache`: this will have the minions store their return data directly into a returner (not sent through the Master)

- `master_job_cache` (New in 2014.7.0): this will make the Master store the job data using a returner (instead of the local job cache on disk).
Targeting Minions

Targeting minions is specifying which minions should run a command or execute a state by matching against hostnames, or system information, or defined groups, or even combinations thereof.

For example the command `salt web1 apache.signal restart` to restart the Apache httpd server specifies the machine `web1` as the target and the command will only be run on that one minion.

Similarly when using States, the following `top file` specifies that only the `web1` minion should execute the contents of `webserver.sls`:

```yaml
base:
  'web1':
    - webserver
```

There are many ways to target individual minions or groups of minions in Salt:

### 4.1 Matching the minion id

Each minion needs a unique identifier. By default when a minion starts for the first time it chooses its FQDN (fully qualified domain name) as that identifier. The minion id can be overridden via the minion's `id` configuration setting.

**Tip:** minion id and minion keys

The `minion id` is used to generate the minion's public/private keys and if it ever changes the master must then accept the new key as though the minion was a new host.

#### 4.1.1 Globbing

The default matching that Salt utilizes is *shell-style globbing* around the `minion id`. This also works for states in the `top file`.

**Note:** You must wrap `salt` calls that use globbing in single-quotes to prevent the shell from expanding the globs before Salt is invoked.

- Match all minions:

  ```bash
  salt '1' test.ping
  ```

- Match all minions in the example.net domain or any of the example domains:
Match all the webN minions in the example.net domain (web1.example.net, web2.example.net ... webN.example.net):

```bash
salt 'web?.example.net' test.ping
```

Match the web1 through web5 minions:

```bash
salt 'web[1-5]' test.ping
```

Match the web1 and web3 minions:

```bash
salt 'web[1,3]' test.ping
```

Match the web-x, web-y, and web-z minions:

```bash
salt 'web-[x-z]' test.ping
```

Note: For additional targeting methods please review the compound matchers documentation.

### 4.1.2 Regular Expressions

Minions can be matched using Perl-compatible regular expressions (which is globbing on steroids and a ton of caffeine).

Match both web1-prod and web1-devel minions:

```bash
salt -E 'web1-(prod|devel)' test.ping
```

When using regular expressions in a State's top file, you must specify the matcher as the first option. The following example executes the contents of webserver.sls on the above-mentioned minions.

```bash
base:
  'web1-(prod|devel)'}:
  - match: pcre
  - webserver
```

### 4.1.3 Lists

At the most basic level, you can specify a flat list of minion IDs:

```bash
salt -L 'web1,web2,web3' test.ping
```

### 4.2 Grains

Salt comes with an interface to derive information about the underlying system. This is called the grains interface, because it presents salt with grains of information. Grains are collected for the operating system, domain name, IP address, kernel, OS type, memory, and many other system properties.

The grains interface is made available to Salt modules and components so that the right salt minion commands are automatically available on the right systems.
Grain data is relatively static, though if system information changes (for example, if network settings are changed), or if a new value is assigned to a custom grain, grain data is refreshed.

**Note:** Grain data resolves to lowercase letters. For example, `FOO` and `foo` target the same grain.

Match all CentOS minions:

```
salt -G 'os:CentOS' test.ping
```

Match all minions with 64-bit CPUs, and return number of CPU cores for each matching minion:

```
salt -G 'cpuarch:x86_64' grains.item num_cpus
```

Additionally, globs can be used in grain matches, and grains that are nested in a `dictionary` can be matched by adding a colon for each level that is traversed. For example, the following will match hosts that have a grain called `ec2_tags`, which itself is a `dict` with a key named `environment`, which has a value that contains the word `production`:

```
salt -G 'ec2_tags:environment:*production*'
```

### 4.2.1 Listing Grains

Available grains can be listed by using the `grains.ls` module:

```
salt '*' grains.ls
```

Grains data can be listed by using the `grains.items` module:

```
salt '*' grains.items
```

### 4.2.2 Grains in the Minion Config

Grains can also be statically assigned within the minion configuration file. Just add the option `grains` and pass options to it:

```
grains:
  roles:
    - webserver
    - memcache
  deployment: datacenter4
  cabinet: 13
  cab_u: 14-15
```

Then status data specific to your servers can be retrieved via Salt, or used inside of the State system for matching. It also makes targeting, in the case of the example above, simply based on specific data about your deployment.

### 4.2.3 Grains in /etc/salt/grains

If you do not want to place your custom static grains in the minion config file, you can also put them in `/etc/salt/grains` on the minion. They are configured in the same way as in the above example, only without a top-level `grains:` key:
4.2.4 Matching Grains in the Top File

With correctly configured grains on the Minion, the top file used in Pillar or during Highstate can be made very efficient. For example, consider the following configuration:

```yaml
'node_type:web':
    - match: grain
    - webserver

'node_type:postgres':
    - match: grain
    - database

'node_type:redis':
    - match: grain
    - redis

'node_type:lb':
    - match: grain
    - lb
```

For this example to work, you would need to have defined the grain node_type for the minions you wish to match. This simple example is nice, but too much of the code is similar. To go one step further, Jinja templating can be used to simplify the top file.

```yaml
{% set the_node_type = salt['grains.get']('node_type', '') %}

{% if the_node_type %}
    'node_type:{{ the_node_type }}':
        - match: grain
        - {{ the_node_type }}
{% endif %}
```

Using Jinja templating, only one match entry needs to be defined.

Note: The example above uses the grains.get function to account for minions which do not have the node_type grain set.

4.2.5 Writing Grains

The grains interface is derived by executing all of the `public` functions found in the modules located in the grains package or the custom grains directory. The functions in the modules of the grains must return a Python `dict`, where the keys in the `dict` are the names of the grains and the values are the values.

Custom grains should be placed in a _grains directory located under the file_roots specified by the master config file. The default path would be /srv/salt/_grains. Custom grains will be distributed to the minions when state.highstate is run, or by executing the saltutil.sync_grains or saltutil.sync_all functions.
Grains are easy to write, and only need to return a dictionary. A common approach would be code something similar to the following:

```python
#!/usr/bin/env python
def yourfunction():
    # initialize a grains dictionary
    grains = {}
    # Some code for logic that sets grains like
    grains['yourcustomgrain'] = True
    grains['anothergrain'] = 'somevalue'
    return grains
```

Before adding a grain to Salt, consider what the grain is and remember that grains need to be static data. If the data is something that is likely to change, consider using Pillar instead.

**Warning:** Custom grains will not be available in the top file until after the first highstate. To make custom grains available on a minion's first highstate, it is recommended to use this example to ensure that the custom grains are synced when the minion starts.

### 4.2.6 Precedence

Core grains can be overridden by custom grains. As there are several ways of defining custom grains, there is an order of precedence which should be kept in mind when defining them. The order of evaluation is as follows:

1. Core grains.
2. Custom grain modules in `_grains` directory, synced to minions.
3. Custom grains in `/etc/salt/grains`.
4. Custom grains in `/etc/salt/minion`.

Each successive evaluation overrides the previous ones, so any grains defined by custom grains modules synced to minions that have the same name as a core grain will override that core grain. Similarly, grains from `/etc/salt/grains` override both core grains and custom grain modules, and grains in `/etc/salt/minion` will override any grains of the same name.

### 4.2.7 Examples of Grains

The core module in the grains package is where the main grains are loaded by the Salt minion and provides the principal example of how to write grains:

https://github.com/saltstack/salt/blob/develop/salt/grains/core.py

### 4.2.8 Syncing Grains

Syncing grains can be done a number of ways, they are automatically synced when `state.highstate` is called, or (as noted above) the grains can be manually synced and reloaded by calling the `saltutil.sync_grains` or `saltutil.sync_all` functions.

### 4.3 Subnet/IP Address Matching

Minions can easily be matched based on IP address, or by subnet (using CIDR notation).
salt -S 192.168.40.20 test.ping
salt -S 10.0.0.0/24 test.ping

Ipcidr matching can also be used in compound matches

salt -C 'S@10.0.0.0/24 and G@os:Debian' test.ping

It is also possible to use in both pillar and state-matching

'172.16.0.0/12':
- match: ipcidr
- internal

Note: Only IPv4 matching is supported at this time.

4.4 Compound matchers

Compound matchers allow very granular minion targeting using any of Salt's matchers. The default matcher is a glob match, just as with CLI and top file matching. To match using anything other than a glob, prefix the match string with the appropriate letter from the table below, followed by an @ sign.

<table>
<thead>
<tr>
<th>Letter</th>
<th>Delimiter</th>
<th>Match Type</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>G</td>
<td>x</td>
<td>Grains glob</td>
<td>G@os:Ubuntu</td>
</tr>
<tr>
<td>E</td>
<td></td>
<td>PCRE Minion ID</td>
<td>E@web\d+.(dev</td>
</tr>
<tr>
<td>P</td>
<td>x</td>
<td>Grains PCRE</td>
<td>P@os:(RedHat</td>
</tr>
<tr>
<td>L</td>
<td></td>
<td>List of minions</td>
<td><a href="mailto:L@minion1.example.com">L@minion1.example.com</a>,minion3.domain.com or bl*.domain.com</td>
</tr>
<tr>
<td>I</td>
<td>x</td>
<td>Pillar glob</td>
<td>I@pdata:foobar</td>
</tr>
<tr>
<td>J</td>
<td>x</td>
<td>Pillar PCRE</td>
<td>J@pdata:^(foo</td>
</tr>
<tr>
<td>S</td>
<td></td>
<td>Subnet/IP address</td>
<td>S@192.168.1.0/24 or S@192.168.1.100</td>
</tr>
<tr>
<td>R</td>
<td></td>
<td>Range cluster</td>
<td>R@%foo.bar</td>
</tr>
</tbody>
</table>

Matchers can be joined using boolean and, or, and not operators.

For example, the following string matches all Debian minions with a hostname that begins with webserv, as well as any minions that have a hostname which matches the regular expression web-dc1-srv.**:

salt -C 'webserv* and G@os:Debian or E@web-dc1-srv.*' test.ping

That same example expressed in a top file looks like the following:

base:
  'webserv* and G@os:Debian or E@web-dc1-srv.*':
    - match: compound
    - webserver

New in version 2015.8.0.

Excluding a minion based on its ID is also possible:

salt -C 'not web-dc1-srv' test.ping
Versions prior to 2015.8.0 a leading not was not supported in compound matches. Instead, something like the following was required:

```bash
salt -C '* and not G@kernel:Darwin' test.ping
```

Excluding a minion based on its ID was also possible:

```bash
salt -C '* and not web-dc1-srv' test.ping
```

### 4.4.1 Precedence Matching

Matches can be grouped together with parentheses to explicitly declare precedence amongst groups.

```bash
salt -C '( ms-1 or G@id:ms-3 ) and G@id:ms-3' test.ping
```

**Note:** Be certain to note that spaces are required between the parentheses and targets. Failing to obey this rule may result in incorrect targeting!

### 4.4.2 Alternate Delimiters

New in version 2015.8.0.

Some matchers allow an optional delimiter character specified between the leading matcher character and the @ pattern separator character. This can be essential when the globbing or PCRE pattern may use the default delimiter character :. This avoids incorrect interpretation of the pattern as part of the grain or pillar data structure traversal.

```bash
salt -C 'J[@foo|bar|^foo:bar$ or J[@gitrepo!https://github.com:example/project.git' test.ping
```

### 4.5 Node groups

Nodegroups are declared using a compound target specification. The compound target documentation can be found [here](#).

The `nodegroups` master config file parameter is used to define nodegroups. Here's an example nodegroup configuration within `/etc/salt/master`:

```yaml
nodegroups:
    group1: 'L@foo.domain.com,bar.domain.com,baz.domain.com or bl*.domain.com'
    group2: 'G@os:Debian and foo.domain.com'
    group3: 'G@os:Debian and N@group1'
    group4:
        - 'G@foo:bar'
        - 'or'
        - 'G@foo:baz'

**Note:** The L within group1 is matching a list of minions, while the G in group2 is matching specific grains. See the `compound matchers` documentation for more details.

New in version 2015.8.0.

**Note:** Nodegroups can reference other nodegroups as seen in `group3`. Ensure that you do not have circular references. Circular references will be detected and cause partial expansion with a logged error message.
New in version 2015.8.0.

Compound nodegroups can be either string values or lists of string values. When the nodegroup is a string value, it will be tokenized by splitting on whitespace. This may be a problem if whitespace is necessary as part of a pattern. When a nodegroup is a list of strings, tokenization will happen for each list element as a whole.

To match a nodegroup on the CLI, use the -N command-line option:

```
salt -N group1 test.ping
```

To match a nodegroup in your top file, make sure to put `- match: nodegroup` on the line directly following the nodegroup name.

```
base:
  group1:
    - match: nodegroup
    - webserver
```

**Note:** When adding or modifying nodegroups to a master configuration file, the master must be restarted for those changes to be fully recognized.

A limited amount of functionality, such as targeting with -N from the command-line may be available without a restart.

### 4.6 Batch Size

The -b (or --batch-size) option allows commands to be executed on only a specified number of minions at a time. Both percentages and finite numbers are supported.

```
salt '*' -b 10 test.ping
salt -G 'os:RedHat' --batch-size 25% apache.signal restart
```

This will only run test.ping on 10 of the targeted minions at a time and then restart apache on 25% of the minions matching os:RedHat at a time and work through them all until the task is complete. This makes jobs like rolling web server restarts behind a load balancer or doing maintenance on BSD firewalls using carp much easier with salt.

The batch system maintains a window of running minions, so, if there are a total of 150 minions targeted and the batch size is 10, then the command is sent to 10 minions, when one minion returns then the command is sent to one additional minion, so that the job is constantly running on 10 minions.

### 4.7 SECO Range

SECO range is a cluster-based metadata store developed and maintained by Yahoo!

The Range project is hosted here:

https://github.com/ytoolshed/range

Learn more about range here:

https://github.com/ytoolshed/range/wiki/
4.7.1 Prerequisites

To utilize range support in Salt, a range server is required. Setting up a range server is outside the scope of this document. Apache modules are included in the range distribution.

With a working range server, cluster files must be defined. These files are written in YAML and define hosts contained inside a cluster. Full documentation on writing YAML range files is here:

https://github.com/ytoolshed/range/wiki/%22yamlfile%22-module-file-spec

Additionally, the Python seco range libraries must be installed on the salt master. One can verify that they have been installed correctly via the following command:

```python
python -c 'import seco.range'
```

If no errors are returned, range is installed successfully on the salt master.

4.7.2 Preparing Salt

Range support must be enabled on the salt master by setting the hostname and port of the range server inside the master configuration file:

```
range_server: my.range.server.com:80
```

Following this, the master must be restarted for the change to have an effect.

4.7.3 Targeting with Range

Once a cluster has been defined, it can be targeted with a salt command by using the -R or --range flags.

For example, given the following range YAML file being served from a range server:

```
$ cat /etc/range/test.yaml
CLUSTER: host1..100.test.com
APPS:
  - frontend
  - backend
  - mysql
```

One might target host1 through host100 in the test.com domain with Salt as follows:

```
salt --range %test:CLUSTER test.ping
```

The following salt command would target three hosts: frontend, backend, and mysql:

```
salt --range %test:APPS test.ping
```
Pillar is an interface for Salt designed to offer global values that can be distributed to all minions. Pillar data is managed in a similar way as the Salt State Tree.

Pillar was added to Salt in version 0.9.8

**Note:** Storing sensitive data

Unlike state tree, pillar data is only available for the targeted minion specified by the matcher type. This makes it useful for storing sensitive data specific to a particular minion.

### 5.1 Declaring the Master Pillar

The Salt Master server maintains a pillar_roots setup that matches the structure of the file_roots used in the Salt file server. Like the Salt file server the pillar_roots option in the master config is based on environments mapping to directories. The pillar data is then mapped to minions based on matchers in a top file which is laid out in the same way as the state top file. Salt pillars can use the same matcher types as the standard top file.

The configuration for the pillar_roots in the master config file is identical in behavior and function as file_roots:

```yaml
pillar_roots:
  base:
    - /srv/pillar
```

This example configuration declares that the base environment will be located in the /srv/pillar directory. It must not be in a subdirectory of the state tree.

The top file used matches the name of the top file used for States, and has the same structure:

```yaml
/srv/pillar/top.sls
```

```yaml
base:
  '*':
    - packages
```

In the above top file, it is declared that in the base environment, the glob matching all minions will have the pillar data found in the packages pillar available to it. Assuming the pillar_roots value of /srv/pillar taken from above, the packages pillar would be located at /srv/pillar/packages.sls.

Another example shows how to use other standard top matching types to deliver specific salt pillar data to minions with different properties.
Here is an example using the grains matcher to target pillars to minions by their os grain:

```yaml
dev:
  'os:Debian':
    - match: grain
    - servers
```

/srv/pillar/packages.sls

```yaml
{% if grains['os'] == 'RedHat' %}
apache: httpd
```

```yaml
{% elif grains['os'] == 'Debian' %}
apache: apache2
```

```yaml
git: git
{% endif %}
```

compny: Foo Industries

The above pillar sets two key/value pairs. If a minion is running RedHat, then the apache key is set to httpd and the git key is set to the value of git. If the minion is running Debian, those values are changed to apache2 and git-core respectively. All minions that have this pillar targeting to them via a top file will have the key of company with a value of Foo Industries.

Consequently this data can be used from within modules, renderers, State SLS files, and more via the shared pillar dict:

```yaml
apache:
  pkg.installed:
    - name: {{ pillar['apache'] }}
```

```yaml
git:
  pkg.installed:
    - name: {{ pillar['git'] }}
```

Finally, the above states can utilize the values provided to them via Pillar. All pillar values targeted to a minion are available via the `pillar` dictionary. As seen in the above example, Jinja substitution can then be utilized to access the keys and values in the Pillar dictionary.

Note that you cannot just list key/value-information in top.sls. Instead, target a minion to a pillar file and then list the keys and values in the pillar. Here is an example top file that illustrates this point:

```yaml
base:
  '*':
    - common_pillar
```

And the actual pillar file at `/srv/pillar/common_pillar.sls`:

```yaml
foo: bar
boo: baz
```

### 5.2 Pillar namespace flattened

The separate pillar files all share the same namespace. Given a top.sls of:

```yaml
base:
  '*':
```

```yaml
{# Billing and usage are server-side and not exposed to httpd #}
```

```yaml
pillar defaults
```
packages

- packages
- services

a packages.sls file of:

```
bind: bind9
```

and a services.sls file of:

```
bind: named
```

Then a request for the bind pillar will only return named; the bind9 value is not available. It is better to structure your pillar files with more hierarchy. For example your package.sls file could look like:

```
packages:
    bind: bind9
```

### 5.3 Pillar Namespace Merges

With some care, the pillar namespace can merge content from multiple pillar files under a single key, so long as conflicts are avoided as described above.

For example, if the above example were modified as follows, the values are merged below a single key:

```
base:
    '*':
        - packages
        - services
```

And a packages.sls file like:

```
bind:
    package-name: bind9
    version: 9.9.5
```

And a services.sls file like:

```
bind:
    port: 53
    listen-on: any
```

The resulting pillar will be as follows:

```
$ salt-call pillar.get bind
local:
    listen-on: any
    package-name: bind9
    port: 53
    version: 9.9.5
```

Note: Remember: conflicting keys will be overwritten in a non-deterministic manner!
5.4 Including Other Pillars

New in version 0.16.0.

Pillar SLS files may include other pillar files, similar to State files. Two syntaxes are available for this purpose. The simple form simply includes the additional pillar as if it were part of the same file:

```yaml
include:
  - users
```

The full include form allows two additional options -- passing default values to the templating engine for the included pillar file as well as an optional key under which to nest the results of the included pillar:

```yaml
include:
  - users:
      defaults:
        sudo: ['bob', 'paul']
      key: users
```

With this form, the included file (users.sls) will be nested within the `users` key of the compiled pillar. Additionally, the `sudo` value will be available as a template variable to users.sls.

5.5 Viewing Minion Pillar

Once the pillar is set up the data can be viewed on the minion via the `pillar` module, the pillar module comes with functions, `pillar.items` and `pillar.raw`. `pillar.items` will return a freshly reloaded pillar and `pillar.raw` will return the current pillar without a refresh:

```
salt '*' pillar.items
```

Note: Prior to version 0.16.2, this function is named `pillar.data`. This function name is still supported for backwards compatibility.

5.6 Pillar `get" Function

New in version 0.14.0.

The `pillar.get` function works much in the same way as the `get` method in a python dict, but with an enhancement: nested dict components can be extracted using a `:` delimiter.

If a structure like this is in pillar:

```
foo:
  bar:
    baz: qux
```

Extracting it from the raw pillar in an sls formula or file template is done this way:

```
{{ pillar['foo']['bar']['baz'] }}
```

Now, with the new `pillar.get` function the data can be safely gathered and a default can be set, allowing the template to fall back if the value is not available:
{{ salt['pillar.get'](‘foo:bar:baz', ‘qux’) }}

This makes handling nested structures much easier.

---

**Note:** pillar.get() vs salt['pillar.get']()

It should be noted that within templating, the pillar variable is just a dictionary. This means that calling pillar.get() inside of a template will just use the default dictionary .get() function which does not include the extra : delimiter functionality. It must be called using the above syntax (salt['pillar.get']('foo:bar:baz', 'qux')) to get the salt function, instead of the default dictionary behavior.

---

### 5.7 Refreshing Pillar Data

When pillar data is changed on the master the minions need to refresh the data locally. This is done with the saltutil.refresh_pillar function.

```
salt '*' saltutil.refresh_pillar
```

This function triggers the minion to asynchronously refresh the pillar and will always return None.

### 5.8 Targeting with Pillar

Pillar data can be used when targeting minions. This allows for ultimate control and flexibility when targeting minions.

```
salt -I 'somekey:specialvalue' test.ping
```

Like with *Grains*, it is possible to use globbing as well as match nested values in Pillar, by adding colons for each level that is being traversed. The below example would match minions with a pillar named `foo`, which is a dict containing a key `bar`, with a value beginning with `baz`:

```
salt -I 'foo:bar:baz*' test.ping
```

### 5.9 Set Pillar Data at the Command Line

Pillar data can be set at the command line like the following example:

```
salt '*' state.highstate pillar='{"cheese": "spam"}'
```

This will create a dict with a key of `cheese` and a value of `spam`. A list can be created like this:

```
salt '*' state.highstate pillar='["cheese", "milk", "bread"]'
```

### 5.10 Master Config In Pillar

For convenience the data stored in the master configuration file can be made available in all minion’s pillars. This makes global configuration of services and systems very easy but may not be desired if sensitive data is stored in the master configuration. This option is disabled by default.
To enable the master config from being added to the pillar set `pillar_opts` to `True`:

```
pillar_opts: True
```

### 5.11 Minion Config in Pillar

Minion configuration options can be set on pillars. Any option that you want to modify, should be in the first level of the pillars, in the same way you set the options in the config file. For example, to configure the MySQL root password to be used by MySQL Salt execution module, set the following pillar variable:

```
mysql.pass: hardtoguesspassword
```

### 5.12 Master Provided Pillar Error

By default if there is an error rendering a pillar, the detailed error is hidden and replaced with:

```
Rendering SLS 'my.sls' failed. Please see master log for details.
```

The error is protected because it's possible to contain templating data which would give that minion information it shouldn't know, like a password!

To have the master provide the detailed error that could potentially carry protected data set `pillar_safe_render_error` to `False`:

```
pillar_safe_render_error: True
```
Salt version 0.11.0 introduced the reactor system. The premise behind the reactor system is that with Salt’s events and the ability to execute commands, a logic engine could be put in place to allow events to trigger actions, or more accurately, reactions.

This system binds sls files to event tags on the master. These sls files then define reactions. This means that the reactor system has two parts. First, the reactor option needs to be set in the master configuration file. The reactor option allows for event tags to be associated with sls reaction files. Second, these reaction files use highdata (like the state system) to define reactions to be executed.

6.1 Event System

A basic understanding of the event system is required to understand reactors. The event system is a local ZeroMQ PUB interface which fires salt events. This event bus is an open system used for sending information notifying Salt and other systems about operations.

The event system fires events with a very specific criteria. Every event has a tag. Event tags allow for fast top level filtering of events. In addition to the tag, each event has a data structure. This data structure is a dict, which contains information about the event.

6.2 Mapping Events to Reactor SLS Files

Reactor SLS files and event tags are associated in the master config file. By default this is /etc/salt/master, or /etc/salt/master.d/reactor.conf.

New in version 2014.7.0: Added Reactor support for salt:// file paths.

In the master config section `reactor:` is a list of event tags to be matched and each event tag has a list of reactor SLS files to be run.

```bash
reactor:
  # Master config section "reactor"
  - 'salt/minion/*/start':
    # Match tag "salt/minion/*/start"
    # Things to do when a minion starts
    - /srv/reactor/start.sls
    - /srv/reactor/monitor.sls
    # Other things to do

  - 'salt/cloud/*/destroyed':
    # Globs can be used to matching tags
    # Globs can be used to match file names
    - /srv/reactor/destroy/*.sls
```

---

**Reactor System**

Salt version 0.11.0 introduced the reactor system. The premise behind the reactor system is that with Salt’s events and the ability to execute commands, a logic engine could be put in place to allow events to trigger actions, or more accurately, reactions.

This system binds sls files to event tags on the master. These sls files then define reactions. This means that the reactor system has two parts. First, the reactor option needs to be set in the master configuration file. The reactor option allows for event tags to be associated with sls reaction files. Second, these reaction files use highdata (like the state system) to define reactions to be executed.

6.1 Event System

A basic understanding of the event system is required to understand reactors. The event system is a local ZeroMQ PUB interface which fires salt events. This event bus is an open system used for sending information notifying Salt and other systems about operations.

The event system fires events with a very specific criteria. Every event has a tag. Event tags allow for fast top level filtering of events. In addition to the tag, each event has a data structure. This data structure is a dict, which contains information about the event.

6.2 Mapping Events to Reactor SLS Files

Reactor SLS files and event tags are associated in the master config file. By default this is /etc/salt/master, or /etc/salt/master.d/reactor.conf.

New in version 2014.7.0: Added Reactor support for salt:// file paths.

In the master config section `reactor:` is a list of event tags to be matched and each event tag has a list of reactor SLS files to be run.

```bash
reactor:
  # Master config section "reactor"
  - 'salt/minion/*/start':
    # Match tag "salt/minion/*/start"
    # Things to do when a minion starts
    - /srv/reactor/start.sls
    - /srv/reactor/monitor.sls
    # Other things to do

  - 'salt/cloud/*/destroyed':
    # Globs can be used to matching tags
    # Globs can be used to match file names
    - /srv/reactor/destroy/*.sls
```
Reactor sls files are similar to state and pillar sls files. They are by default yaml + Jinja templates and are passed familiar context variables.

They differ because of the addition of the tag and data variables.

• The tag variable is just the tag in the fired event.

• The data variable is the event's data dict.

Here is a simple reactor sls:

```yaml
{% if data['id'] == 'mysql1' %}
highstate_run:
  local.state.highstate:
    - tgt: mysql1
{% endif %}
```

This simple reactor file uses Jinja to further refine the reaction to be made. If the id in the event data is mysql1 (in other words, if the name of the minion is mysql1) then the following reaction is defined. The same data structure and compiler used for the state system is used for the reactor system. The only difference is that the data is matched up to the salt command API and the runner system. In this example, a command is published to the mysql1 minion with a function of state.highstate. Similarly, a runner can be called:

```yaml
{% if data['data']['orchestrate'] == 'refresh' %}
orchestrate_run:
  runner.state.orchestrate
{% endif %}
```

This example will execute the state.orchestrate runner and initiate an orchestrate execution.

### 6.3 Fire an event

To fire an event from a minion call event.send

```
salt-call event.send 'foo' '{orchestrate: refresh}'
```

After this is called, any reactor sls files matching event tag foo will execute with `{{ data['data']['orchestrate'] }}` equal to 'refresh'.

See `salt.modules.event` for more information.

### 6.4 Knowing what event is being fired

The best way to see exactly what events are fired and what data is available in each event is to use the state.event runner.

See also:

- *Common Salt Events*

Example usage:

```
salt-run state.event pretty=True
```

---

162 Chapter 6. Reactor System
Example output:

```yaml
salt/job/20150213001905721678/new {
   "_stamp": "2015-02-13T00:19:05.724583",
   "arg": [],
   "fun": "test.ping",
   "jid": "20150213001905721678",
   "minions": ["jerry"],
   "tgt": "*",
   "tgt_type": "glob",
   "user": "root"
}
salt/job/20150213001910749506/ret/jerry {
   "_stamp": "2015-02-13T00:19:11.136730",
   "cmd": "_return",
   "fun": "saltutil.find_job",
   "fun_args": ["20150213001905721678"
   ],
   "id": "jerry",
   "jid": "20150213001910749506",
   "retcode": 0,
   "return": {},
   "success": true
}
```

6.5 Debugging the Reactor

The best window into the Reactor is to run the master in the foreground with debug logging enabled. The output will include when the master sees the event, what the master does in response to that event, and it will also include the rendered SLS file (or any errors generated while rendering the SLS file).

1. Stop the master.
2. Start the master manually:
   ```bash
   salt-master -l debug
   ```
3. Look for log entries in the form:
   ```
   [DEBUG ] Gathering reactors for tag foo/bar
   [DEBUG ] Compiling reactions for tag foo/bar
   [DEBUG ] Rendered data from file: /path/to/the/reactor_file.sls:
   <... Rendered output appears here. ...>
   ```

   The rendered output is the result of the Jinja parsing and is a good way to view the result of referencing Jinja variables. If the result is empty then Jinja produced an empty result and the Reactor will ignore it.

6.6 Understanding the Structure of Reactor Formulas

I.e., when to use `arg` and `kavg` and when to specify the function arguments directly.

While the reactor system uses the same basic data structure as the state system, the functions that will be called using that data structure are different functions than are called via Salt's state system. The Reactor can call Runner
modules using the `runner` prefix, Wheel modules using the `wheel` prefix, and can also cause minions to run Execution modules using the `local` prefix.

Changed in version 2014.7.0: The `cmd` prefix was renamed to `local` for consistency with other parts of Salt. A backward-compatible alias was added for `cmd`.

The Reactor runs on the master and calls functions that exist on the master. In the case of Runner and Wheel functions the Reactor can just call those functions directly since they exist on the master and are run on the master.

In the case of functions that exist on minions and are run on minions, the Reactor still needs to call a function on the master in order to send the necessary data to the minion so the minion can execute that function.

The Reactor calls functions exposed in Salt's Python API documentation, and thus the structure of Reactor files very transparently reflects the function signatures of those functions.

### 6.6.1 Calling Execution modules on Minions

The Reactor sends commands down to minions in the exact same way Salt's CLI interface does. It calls a function locally on the master that sends the name of the function as well as a list of any arguments and a dictionary of any keyword arguments that the minion should use to execute that function.

Specifically, the Reactor calls the async version of this function. You can see that function has `arg` and `kwarg` parameters which are both values that are sent down to the minion.

Executing remote commands maps to the `LocalClient` interface which is used by the `salt` command. This interface more specifically maps to the `cmd_async` method inside of the `LocalClient` class. This means that the arguments passed are being passed to the `cmd_async` method, not the remote method. A field starts with `local` to use the `LocalClient` subsystem. The result is, to execute a remote command, a reactor formula would look like this:

```python
clean_tmp:
  local.cmd.run:
    - tgt: '*'
    - arg:
      - rm -rf /tmp/*
```

The `arg` option takes a list of arguments as they would be presented on the command line, so the above declaration is the same as running this salt command:

```bash
salt 'x' cmd.run 'rm -rf /tmp/*'
```

Use the `expr_form` argument to specify a matcher:

```python
clean_tmp:
  local.cmd.run:
    - tgt: 'os:Ubuntu'
    - expr_form: grain
      - arg:
        - rm -rf /tmp/*
```

```python
clean_tmp:
  local.cmd.run:
    - tgt: 'G@roles:hbase_master'
    - expr_form: compound
      - arg:
        - rm -rf /tmp/*
```

Any other parameters in the `LocalClient.cmd()` method can be specified as well.
6.6.2 Calling Runner modules and Wheel modules

Calling Runner modules and Wheel modules from the Reactor uses a more direct syntax since the function is being executed locally instead of sending a command to a remote system to be executed there. There are no `arg` or `kwarg` parameters (unless the Runner function or Wheel function accepts a parameter with either of those names.)

For example:

```python
clear_the_grains_cache_for_all_minions:
    runner.cache.clear_grains
```

If the runner takes arguments then they can be specified as well:

```python
spin_up_more_web_machines:
    runner.cloud.profile:
        - prof: centos_6
        - instances:
            - web11  # These VM names would be generated via Jinja in a
            - web12  # real-world example.
```

6.6.3 Passing event data to Minions or Orchestrate as Pillar

An interesting trick to pass data from the Reactor script to `state.highstate` or `state.sls` is to pass it as inline Pillar data since both functions take a keyword argument named `pillar`.

The following example uses Salt’s Reactor to listen for the event that is fired when the key for a new minion is accepted on the master using `salt-key`.

/etc/salt/master.d/reactor.conf:

```yaml
reactor:
    - 'salt/key':
        - /srv/salt/haproxy/react_new_minion.sls
```

The Reactor then fires a `state.sls` command targeted to the HAProxy servers and passes the ID of the new minion from the event to the state file via inline Pillar.

/srv/salt/haproxy/react_new_minion.sls:

```python
{% if data['act'] == 'accept' and data['id'].startswith('web') %}
add_new_minion_to_pool:
    local.state.sls:
        - tgt: 'haproxy*'
        - arg:
            - haproxy.refresh_pool
        - kwarg:
            pillar:
                new_minion: {{ data['id'] }}
{% endif %}
```

The above command is equivalent to the following command at the CLI:

```
salt 'haproxy*' state.sls haproxy.refresh_pool 'pillar={new_minion: minionid}'
```

This works with Orchestrate files as well:

```python
call_some_orchestrate_file:
    runner.state.orchestrate:
        - mods: some_orchestrate_file
```
Which is equivalent to the following command at the CLI:

```
salt-run state.orchestrate some_orchestrate_file pillar='{stuff: things}'
```

Finally, that data is available in the state file using the normal Pillar lookup syntax. The following example is grabbing web server names and IP addresses from *Salt Mine*. If this state is invoked from the Reactor then the custom Pillar value from above will be available and the new minion will be added to the pool but with the `disabled` flag so that HAProxy won't yet direct traffic to it.

```
/srv/salt/haproxy/refresh_pool.sls:
{% set new_minion = salt['pillar.get']('new_minion') %}
listen web *:80
  balance source
  {% for server,ip in salt['mine.get']('web*', 'network.interfaces', ['eth0']).items() %}
    {% if server == new_minion %}
      server {{ server }} {{ ip }}:80 disabled
    {% else %}
      server {{ server }} {{ ip }}:80 check
    {% endif %}
  {% endfor %}
```

### 6.7 A Complete Example

In this example, we're going to assume that we have a group of servers that will come online at random and need to have keys automatically accepted. We'll also add that we don't want all servers being automatically accepted. For this example, we'll assume that all hosts that have an id that starts with `ink` will be automatically accepted and have state.highstate executed. On top of this, we're going to add that a host coming up that was replaced (meaning a new key) will also be accepted.

Our master configuration will be rather simple. All minions that attempt to authenticate will match the tag of `salt/auth`. When it comes to the minion key being accepted, we get a more refined tag that includes the minion id, which we can use for matching.

```
/etc/salt/master.d/reactor.conf:
reactor:
  - 'salt/auth':
    - /srv/reactor/auth-pending.sls
  - 'salt/minion/ink*/start':
    - /srv/reactor/auth-complete.sls
```

In this sls file, we say that if the key was rejected we will delete the key on the master and then also tell the master to ssh in to the minion and tell it to restart the minion, since a minion process will die if the key is rejected.

We also say that if the key is pending and the id starts with ink we will accept the key. A minion that is waiting on a pending key will retry authentication every ten seconds by default.

```
/srv/reactor/auth-pending.sls:
{# Ink server failed to authenticate -- remove accepted key #}
{% if not data['result'] and data['id'].startswith('ink') %}
  minion_remove:
```

Chapter 6. Reactor System
wheel.key.delete:
  - match: {{ data['id'] }}

minion_rejoin:
  local.cmd.run:
    - tgt: salt-master.domain.tld
    - arg:
      - ssh -o UserKnownHostsFile=/dev/null -o StrictHostKeyChecking=no "{{ data['id'] }}" 'sleep 10

{% endif %}

{% if 'act' in data and data['act'] == 'pend' and data['id'].startswith('ink') %}

minion_add:
  wheel.key.accept:
    - match: {{ data['id'] }}

{% endif %}

No if statements are needed here because we already limited this action to just Ink servers in the master configuration.

/srv/reactor/auth-complete.sls:

{{# When an Ink server connects, run state.highstate. #}}
highstate_run:
  local.state.highstate:
    - tgt: {{ data['id'] }}
    - ret: smtp

The above will also return the highstate result data using the smtp_return returner (use virtualname like when using from the command line with --return). The returner needs to be configured on the minion for this to work. See salt.returners.smtp_return documentation for that.

### 6.8 Syncing Custom Types on Minion Start

Salt will sync all custom types (by running a saltutil.sync_all) on every highstate. However, there is a chicken-and-egg issue where, on the initial highstate, a minion will not yet have these custom types synced when the top file is first compiled. This can be worked around with a simple reactor which watches for minion_start events, which each minion fires when it first starts up and connects to the master.

On the master, create /srv/reactor/sync_grains.sls with the following contents:

sync_grains:
  local.saltutil.sync_grains:
    - tgt: {{ data['id'] }}

And in the master config file, add the following reactor configuration:

reactor:
  - 'minion_start':
    - /srv/reactor/sync_grains.sls

This will cause the master to instruct each minion to sync its custom grains when it starts, making these grains available when the initial highstate is executed.

Other types can be synced by replacing local.saltutil.sync_grains with local.saltutil.sync_modules, local.saltutil.sync_all, or whatever else suits the intended use case.
The Salt Mine is used to collect arbitrary data from minions and store it on the master. This data is then made available to all minions via the \texttt{salt.modules.mine} module.

The data is gathered on the minion and sent back to the master where only the most recent data is maintained (if long term data is required use returners or the external job cache).

### 7.1 Mine Functions

To enable the Salt Mine the \texttt{mine_functions} option needs to be applied to a minion. This option can be applied via the minion's configuration file, or the minion's Pillar. The \texttt{mine_functions} option dictates what functions are being executed and allows for arguments to be passed in. If no arguments are passed, an empty list must be added:

```yaml
mine_functions:
  test.ping: []
  network.ip_addrs:
    interface: eth0
    cidr: '10.0.0.0/8'
```

#### 7.1.1 Mine Functions Aliases

Function aliases can be used to provide friendly names, usage intentions or to allow multiple calls of the same function with different arguments. There is a different syntax for passing positional and key-value arguments. Mixing positional and key-value arguments is not supported.

New in version 2014.7.

```yaml
mine_functions:
  network.ip_addrs: [eth0]
  networkplus.internal_ip_addrs: []
  internal_ip_addrs:
    mine_function: network.ip_addrs
    cidr: 192.168.0.0/16
  ip_list:
    - mine_function: grains.get
    - ip_interfaces
```
7.2 Mine Interval

The Salt Mine functions are executed when the minion starts and at a given interval by the scheduler. The default interval is every 60 minutes and can be adjusted for the minion via the `mine_interval` option:

```
mine_interval: 60
```

7.3 Mine in Salt-SSH

As of the 2015.5.0 release of salt, salt-ssh supports `mine.get`. Because the minions cannot provide their own `mine_functions` configuration, we retrieve the args for specified mine functions in one of three places, searched in the following order:

1. Roster data
2. Pillar
3. Master config

The `mine_functions` are formatted exactly the same as in normal salt, just stored in a different location. Here is an example of a flat roster containing `mine_functions`:

```
test:
  host: 104.237.131.248
  user: root
  mine_functions:
    cmd.run: ['echo "hello!"']
    network.ip_addrs:
      interface: eth0
```

Note: Because of the differences in the architecture of salt-ssh, `mine.get` calls are somewhat inefficient. Salt must make a new salt-ssh call to each of the minions in question to retrieve the requested data, much like a publish call. However, unlike publish, it must run the requested function as a wrapper function, so we can retrieve the function args from the pillar of the minion in question. This results in a non-trivial delay in retrieving the requested data.

7.4 Example

One way to use data from Salt Mine is in a State. The values can be retrieved via Jinja and used in the SLS file. The following example is a partial HAProxy configuration file and pulls IP addresses from all minions with the `web` grain to add them to the pool of load balanced servers.

```
/srv/pillar/top.sls:

base:
  'G@roles:web':
    - web

/srv/pillar/web.sls:

mine_functions:
  network.ip_addrs: [eth0]
```

```
/etc/salt/minion.d/mine.conf:
```
mine_interval: 5

/srv/salt/haproxy.sls:

haproxy_config:
  file.managed:
    - name: /etc/haproxy/config
    - source: salt://haproxy_config
    - template: jinja

/srv/salt/haproxy_config:

...file contents snipped...

{% for server, addrs in salt['mine.get']('roles:web', 'network.ip_addrs', expr_form='pillar').items() %}
server {{ server }} {{ addrs[0] }}:80 check
{% endfor %}

...file contents snipped...
Salt’s External Authentication System (eAuth) allows for Salt to pass through command authorization to any external authentication system, such as PAM or LDAP.

Note: eAuth using the PAM external auth system requires salt-master to be run as root as this system needs root access to check authentication.

### 8.1 Access Control System

The external authentication system allows for specific users to be granted access to execute specific functions on specific minions. Access is configured in the master configuration file and uses the access control system:

```yaml
external_auth:
  pam:
    thatch:
      - 'web*':
        - test.*
        - network.*
    steve:
      - .*
```

The above configuration allows the user `thatch` to execute functions in the test and network modules on the minions that match the `web*` target. User `steve` is given unrestricted access to minion commands.

Salt respects the current PAM configuration in place, and uses the `login` service to authenticate.

Note: The PAM module does not allow authenticating as `root`.

To allow access to `wheel modules` or `runner modules` the following `@` syntax must be used:

```yaml
external_auth:
  pam:
    thatch:
      - '@wheel'  # to allow access to all wheel modules
      - '@runner' # to allow access to all runner modules
      - '@jobs'   # to allow access to the jobs runner and/or wheel module
```

Note: The runner/wheel markup is different, since there are no minions to scope the acl to.
Note: Globs will not match wheel or runners! They must be explicitly allowed with @wheel or @runner.

The external authentication system can then be used from the command-line by any user on the same system as the master with the -a option:

```
$ salt -a pam web\* test.ping
```

The system will ask the user for the credentials required by the authentication system and then publish the command.

To apply permissions to a group of users in an external authentication system, append a % to the ID:

```
external_auth:
  pam:
    admins%:
      - '*'
      - 'pkg.*'
```

**Warning**: All users that have external authentication privileges are allowed to run `saltutil.findjob`. Be aware that this could inadvertently expose some data such as minion IDs.

### 8.2 Tokens

With external authentication alone, the authentication credentials will be required with every call to Salt. This can be alleviated with Salt tokens.

Tokens are short term authorizations and can be easily created by just adding a -T option when authenticating:

```
$ salt -T -a pam web\* test.ping
```

Now a token will be created that has an expiration of 12 hours (by default). This token is stored in a file named `salt_token` in the active user's home directory.

Once the token is created, it is sent with all subsequent communications. User authentication does not need to be entered again until the token expires.

Token expiration time can be set in the Salt master config file.

#### 8.2.1 LDAP and Active Directory

**Note**: LDAP usage requires that you have installed python-ldap.

Salt supports both user and group authentication for LDAP (and Active Directory accessed via its LDAP interface)

### 8.3 OpenLDAP and similar systems

LDAP configuration happens in the Salt master configuration file.

Server configuration values and their defaults:

```
# Server to auth against
auth.ldap.server: localhost
```
There are two phases to LDAP authentication. First, Salt authenticates to search for a user’s Distinguished Name and group membership. The user it authenticates as in this phase is often a special LDAP system user with read-only access to the LDAP directory. After Salt searches the directory to determine the actual user’s DN and groups, it re-authenticates as the user running the Salt commands.

If you are already aware of the structure of your DN and permissions in your LDAP store are set such that users can look up their own group memberships, then the first and second users can be the same. To tell Salt this is the case, omit the `auth.ldap.bindpw` parameter. You can template the binddn like this:

```
auth.ldap.binddn: uid={{ username }},cn=users,cn=accounts,dc=saltstack,dc=com
```

Salt will use the password entered on the salt command line in place of the bindpw.

To use two separate users, specify the LDAP lookup user in the binddn directive, and include a bindpw like so

```
auth.ldap.binddn: uid=ldaplookup, cn=sysaccounts, cn=etc, dc=saltstack, dc=com
auth.ldap.bindpw: mypassword
```
As mentioned before, Salt uses a filter to find the DN associated with a user. Salt substitutes the `{{ username }}` value for the username when querying LDAP.

```yaml
auth.ldap.filter: uid={{ username }}
```

For OpenLDAP, to determine group membership, one can specify an OU that contains group data. This is prepended to the base DN to create a search path. Then the results are filtered against `auth.ldap.groupclass`, default `posixGroup`, and the account's 'name' attribute, `memberUid` by default.

```yaml
auth.ldap.groupou: Groups
```

### 8.4 Active Directory

Active Directory handles group membership differently, and does not utilize the `groupou` configuration variable. AD needs the following options in the master config:

```yaml
auth.ldap.activedirectory: True
auth.ldap.filter: sAMAccountName={{username}}
auth.ldap.accountattributename: sAMAccountName
auth.ldap.groupclass: group
auth.ldap.persontype: person
```

To determine group membership in AD, the username and password that is entered when LDAP is requested as the eAuth mechanism on the command line is used to bind to AD’s LDAP interface. If this fails, then it doesn’t matter what groups the user belongs to, he or she is denied access. Next, the distinguishedName of the user is looked up with the following LDAP search:

```perl
(&(<value of auth.ldap.accountattributename>=={{username}}))
  (objectClass=<value of auth.ldap.persontype>)
)
```

This should return a distinguishedName that we can use to filter for group membership. Then the following LDAP query is executed:

```perl
(&(<member=<distinguishedName from search above>>) )
  (objectClass=<value of auth.ldap.groupclass>)
)
```

To configure an LDAP group, append a `%` to the ID:

```yaml
test_ldap_user:
  - '*':
    - test.ping
```

```yaml
test_ldap_group%:
  - '*':
    - test.echo
```

To configure an LDAP group, append a `%` to the ID:
Access Control System

New in version 0.10.4.

Salt maintains a standard system used to open granular control to non administrative users to execute Salt commands. The access control system has been applied to all systems used to configure access to non administrative control interfaces in Salt. These interfaces include, the peer system, the external auth system and the client acl system.

The access control system mandated a standard configuration syntax used in all of the three aforementioned systems. While this adds functionality to the configuration in 0.10.4, it does not negate the old configuration.

Now specific functions can be opened up to specific minions from specific users in the case of external auth and client ACLs, and for specific minions in the case of the peer system.

The access controls are manifested using matchers in these configurations:

```plaintext
client_acl:
    fred:
        - web\*:
        - pkg.list_pkgs
        - test.*
        - apache.*
```

In the above example, fred is able to send commands only to minions which match the specified glob target. This can be expanded to include other functions for other minions based on standard targets.

```plaintext
external_auth:
    pam:
        dave:
            - test.ping
            - mongo\*:
            - network.*
        - log\*:
            - network.*
            - pkg.*
            - 'G@os:RedHat':
                - kmod.*
        steve:
            - *
```

The above allows for all minions to be hit by test.ping by dave, and adds a few functions that dave can execute on other minions. It also allows steve unrestricted access to salt commands.
New in version 0.9.7.

Since Salt executes jobs running on many systems, Salt needs to be able to manage jobs running on many systems.

## 10.1 The Minion proc System

Salt Minions maintain a proc directory in the Salt cachedir. The proc directory maintains files named after the executed job ID. These files contain the information about the current running jobs on the minion and allow for jobs to be looked up. This is located in the proc directory under the cachedir, with a default configuration it is under /var/cache/salt/proc.

## 10.2 Functions in the saltutil Module

Salt 0.9.7 introduced a few new functions to the saltutil module for managing jobs. These functions are:

1. **running** Returns the data of all running jobs that are found in the proc directory.
2. **find_job** Returns specific data about a certain job based on job id.
3. **signal_job** Allows for a given jid to be sent a signal.
4. **term_job** Sends a termination signal (SIGTERM, 15) to the process controlling the specified job.
5. **kill_job** Sends a kill signal (SIGKILL, 9) to the process controlling the specified job.

These functions make up the core of the back end used to manage jobs at the minion level.

## 10.3 The jobs Runner

A convenience runner front end and reporting system has been added as well. The jobs runner contains functions to make viewing data easier and cleaner.

The jobs runner contains a number of functions...
10.3.1 active

The active function runs saltutil.running on all minions and formats the return data about all running jobs in a much more usable and compact format. The active function will also compare jobs that have returned and jobs that are still running, making it easier to see what systems have completed a job and what systems are still being waited on.

```
# salt-run jobs.active
```

10.3.2 lookup_jid

When jobs are executed the return data is sent back to the master and cached. By default it is cached for 24 hours, but this can be configured via the `keep_jobs` option in the master configuration. Using the lookup_jid runner will display the same return data that the initial job invocation with the salt command would display.

```
# salt-run jobs.lookup_jid <job id number>
```

10.3.3 list_jobs

Before finding a historic job, it may be required to find the job id. list_jobs will parse the cached execution data and display all of the job data for jobs that have already, or partially returned.

```
# salt-run jobs.list_jobs
```

10.4 Scheduling Jobs

In Salt versions greater than 0.12.0, the scheduling system allows incremental executions on minions or the master. The schedule system exposes the execution of any execution function on minions or any runner on the master.

Scheduling is enabled via the `schedule` option on either the master or minion config files, or via a minion's pillar data. Schedules that are implemented via pillar data, only need to refresh the minion's pillar data, for example by using `saltutil.refresh_pillar`. Schedules implemented in the master or minion config have to restart the application in order for the schedule to be implemented.

**Note:** The scheduler executes different functions on the master and minions. When running on the master the functions reference runner functions, when running on the minion the functions specify execution functions.

A scheduled run has no output on the minion unless the config is set to info level or higher. Refer to `minion logging settings`.

Specify `maxrunning` to ensure that there are no more than N copies of a particular routine running. Use this for jobs that may be long-running and could step on each other or otherwise double execute. The default for `maxrunning` is 1.

States are executed on the minion, as all states are. You can pass positional arguments and provide a yaml dict of named arguments.

```
schedule:
    job1:
      function: state.sls
      seconds: 3600
      args:
        - httpd
```
This will schedule the command: `state.sls httpd test=True` every 3600 seconds (every hour)

```python
{kwars:
    test: True
}
```

New in version 2014.7.0.

Frequency of jobs can also be specified using date strings supported by the python dateutil library. This requires python-dateutil to be installed on the minion.

```python
{kwars:
    when:
        - Monday 5:00pm
        - Tuesday 3:00pm
        - Wednesday 5:00pm
}
```
This will schedule the command: `state.sls httpd test=True` at 5pm on Monday, Wednesday, and Friday, and 3pm on Tuesday and Thursday.

```python
schedule:
    job1:
        function: state.sls
        seconds: 3600
        args:
            - httpd
        kwargs:
            test: True
        range:
            start: 8:00am
            end: 5:00pm
```

This will schedule the command: `state.sls httpd test=True` every 3600 seconds (every hour) between the hours of 8am and 5pm. The range parameter must be a dictionary with the date strings using the dateutil format. This requires python-dateutil to be installed on the minion.

New in version 2014.7.0.

The scheduler also supports ensuring that there are no more than N copies of a particular routine running. Use this for jobs that may be long-running and could step on each other or pile up in case of infrastructure outage.

The default for maxrunning is 1.

```python
schedule:
    long_running_job:
        function: big_file_transfer
        jid_include: True
```

### 10.5 States

```python
schedule:
    log-loadavg:
        function: cmd.run
        seconds: 3660
        args:
            - 'logger -t salt < /proc/loadavg'
        kwargs:
            stateful: False
            shell: /bin/sh
```

### 10.6 Highstates

To set up a highstate to run on a minion every 60 minutes set this in the minion config or pillar:

```python
schedule:
    highstate:
        function: state.highstate
        minutes: 60
```
Time intervals can be specified as seconds, minutes, hours, or days.

### 10.7 Runners

Runner executions can also be specified on the master within the master configuration file:

```yaml
schedule:
  run_my_orch:
    function: state.orchestrate
    hours: 6
    splay: 600
    args:
      - orchestration.my_orch
```

The above configuration is analogous to running `salt-run state.orch orchestration.my_orch` every 6 hours.

### 10.8 Scheduler With Returner

The scheduler is also useful for tasks like gathering monitoring data about a minion, this schedule option will gather status data and send it to a MySQL returner database:

```yaml
schedule:
  uptime:
    function: status.uptime
    seconds: 60
    returner: mysql
  meminfo:
    function: status.meminfo
    minutes: 5
    returner: mysql
```

Since specifying the returner repeatedly can be tiresome, the `schedule_returner` option is available to specify one or a list of global returners to be used by the minions when scheduling.

In Salt versions greater than 0.12.0, the scheduling system allows incremental executions on minions or the master. The schedule system exposes the execution of any execution function on minions or any runner on the master.

Scheduling is enabled via the `schedule` option on either the master or minion config files, or via a minion's pillar data. Schedules that are implemented via pillar data, only need to refresh the minion's pillar data, for example by using `saltutil.refresh_pillar`. Schedules implemented in the master or minion config have to restart the application in order for the schedule to be implemented.

---

**Note:** The scheduler executes different functions on the master and minions. When running on the master the functions reference runner functions, when running on the minion the functions specify execution functions.

A scheduled run has no output on the minion unless the config is set to info level or higher. Refer to `minion logging settings`.

Specify `maxrunning` to ensure that there are no more than N copies of a particular routine running. Use this for jobs that may be long-running and could step on each other or otherwise double execute. The default for `maxrunning` is 1.

States are executed on the minion, as all states are. You can pass positional arguments and provide a yaml dict of named arguments.
```
schedule:
  job1:
    function: state.sls
    seconds: 3600
    args:
      - httpd
    kwargs:
      test: True
```

This will schedule the command: `state.sls httpd=test=True` every 3600 seconds (every hour)

```
schedule:
  job1:
    function: state.sls
    seconds: 3600
    args:
      - httpd
    kwargs:
      test: True
    splay: 15
```

This will schedule the command: `state.sls httpd=test=True` every 3600 seconds (every hour) splaying the time between 0 and 15 seconds

```
schedule:
  job1:
    function: state.sls
    seconds: 3600
    args:
      - httpd
    kwargs:
      test: True
    splay:
      start: 10
      end: 15
```

This will schedule the command: `state.sls httpd=test=True` every 3600 seconds (every hour) splaying the time between 10 and 15 seconds

New in version 2014.7.0.

Frequency of jobs can also be specified using date strings supported by the python dateutil library. This requires python-dateutil to be installed on the minion.

```
schedule:
  job1:
    function: state.sls
    args:
      - httpd
    kwargs:
      test: True
    when: 5:00pm
```

This will schedule the command: `state.sls httpd=test=True` at 5:00pm minion localtime.

```
schedule:
  job1:
    function: state.sls
    args:
      - httpd
```

This will schedule the command: `state.sls httpd=test=True`
This will schedule the command: state.sls httpd test=True at 5pm on Monday, Wednesday, and Friday, and 3pm on Tuesday and Thursday.

```
    function: state.sls
    seconds: 3600
    args:
        - httpd
    kwargs:
        test: True
    range:
        start: 8:00am
        end: 5:00pm
```

This will schedule the command: state.sls httpd test=True every 3600 seconds (every hour) between the hours of 8am and 5pm. The range parameter must be a dictionary with the date strings using the dateutil format. This requires python-dateutil to be installed on the minion.

New in version 2014.7.0.

The scheduler also supports ensuring that there are no more than N copies of a particular routine running. Use this for jobs that may be long-running and could step on each other or pile up in case of infrastructure outage.

The default for maxrunning is 1.

```
    function: big_file_transfer
    jid_include: True
```

### 10.8.1 States

```
    function: cmd.run
    seconds: 3660
    args:
        - 'logger -t salt < /proc/loadavg'
    kwargs:
        stateful: False
        shell: /bin/sh
```

### 10.8.2 Highstates

To set up a highstate to run on a minion every 60 minutes set this in the minion config or pillar:
### 10.8.3 Runners

Runner executions can also be specified on the master within the master configuration file:

```yaml
schedule:
  run_my_orch:
    function: state.orchestrate
    hours: 6
    splay: 600
    args:
      - orchestration.my_orch
```

The above configuration is analogous to running `salt-run state.orch orchestration.my_orch` every 6 hours.

### 10.8.4 Scheduler With Returner

The scheduler is also useful for tasks like gathering monitoring data about a minion, this schedule option will gather status data and send it to a MySQL returner database:

```yaml
schedule:
  uptime:
    function: status.uptime
    seconds: 60
    returner: mysql
  meminfo:
    function: status.meminfo
    minutes: 5
    returner: mysql
```

Since specifying the returner repeatedly can be tiresome, the `schedule_returner` option is available to specify one or a list of global returners to be used by the minions when scheduling.
Managing the Job Cache

The Salt Master maintains a job cache of all job executions which can be queried via the jobs runner. This job cache is called the Default Job Cache.

11.1 Default Job Cache

A number of options are available when configuring the job cache. The default caching system uses local storage on the Salt Master and can be found in the job cache directory (on Linux systems this is typically /var/cache/salt/master/jobs). The default caching system is suitable for most deployments as it does not typically require any further configuration or management.

The default job cache is a temporary cache and jobs will be stored for 24 hours. If the default cache needs to store jobs for a different period the time can be easily adjusted by changing the `keep_jobs` parameter in the Salt Master configuration file. The value passed in is measured via hours:

```
keep_jobs: 24
```

11.2 Additional Job Cache Options

Many deployments may wish to use an external database to maintain a long term register of executed jobs. Salt comes with two main mechanisms to do this, the master job cache and the external job cache.

See *Storing Job Results in an External System*. 
Storing Job Results in an External System

After a job executes, job results are returned to the Salt Master by each Salt Minion. These results are stored in the Default Job Cache.

In addition to the Default Job Cache, Salt provides two additional mechanisms to send job results to other systems (databases, local syslog, and others):

- External Job Cache
- Master Job Cache

The major difference between these two mechanism is from where results are returned (from the Salt Master or Salt Minion).

12.1 External Job Cache - Minion-Side Returner

When an External Job Cache is configured, data is returned to the Default Job Cache on the Salt Master like usual, and then results are also sent to an External Job Cache using a Salt returner module running on the Salt Minion.

- Advantages: Data is stored without placing additional load on the Salt Master.
- Disadvantages: Each Salt Minion connects to the external job cache, which can result in a large number of connections. Also requires additional configuration to get returner module settings on all Salt Minions.
12.2 Master Job Cache - Master-Side Returner

New in version 2014.7.0.

Instead of configuring an External Job Cache on each Salt Minion, you can configure the Master Job Cache to send job results from the Salt Master instead. In this configuration, Salt Minions send data to the Default Job Cache as usual, and then the Salt Master sends the data to the external system using a Salt returner module running on the Salt Master.

- Advantages: A single connection is required to the external system. This is preferred for databases and similar systems.
- Disadvantages: Places additional load on your Salt Master.

12.3 Configure an External or Master Job Cache

12.3.1 Step 1: Understand Salt Returners

Before you configure a job cache, it is essential to understand Salt returner modules (``returners``). Returners are pluggable Salt Modules that take the data returned by jobs, and then perform any necessary steps to send the data to an external system. For example, a returner might establish a connection, authenticate, and then format and transfer data.

The Salt Returner system provides the core functionality used by the External and Master Job Cache systems, and the same returners are used by both systems.

Salt currently provides many different returners that let you connect to a wide variety of systems. A complete list is available at all Salt returners. Each returner is configured differently, so make sure you read and follow the instructions linked from that page.

For example, the MySQL returner requires:

- A database created using provided schema (structure is available at MySQL returner)
- A user created with with privileges to the database
- Optional SSL configuration

A simpler returner, such as Slack or HipChat, requires:
- An API key/version
- The target channel/room
- The username that should be used to send the message

12.3.2 Step 2: Configure the Returner

After you understand the configuration and have the external system ready, add the returner configuration settings to the Salt Minion configuration file for the External Job Cache, or to the Salt Master configuration file for the Master Job Cache.

For example, MySQL requires:

```yaml
mysql.host: 'salt'
mysql.user: 'salt'
mysql.pass: 'salt'
mysql.db: 'salt'
mysql.port: 3306
```

Slack requires:

```yaml
slack.channel: 'channel'
slack.api_key: 'key'
slack.from_name: 'name'
```

After you have configured the returner and added settings to the configuration file, you can enable the External or Master Job Cache.

12.3.3 Step 3: Enable the External or Master Job Cache

Configuration is a single line that specifies an already-configured returner to use to send all job data to an external system.

**External Job Cache**

To enable a returner as the External Job Cache (Minion-side), add the following line to the Salt Master configuration file:

```yaml
ext_job_cache: <returner>
```

For example:

```yaml
ext_job_cache: mysql
```

**Note:** When configuring an External Job Cache (Minion-side), the returner settings are added to the Minion configuration file, but the External Job Cache setting is configured in the Master configuration file.

**Master Job Cache**

To enable a returner as a Master Job Cache (Master-side), add the following line to the Salt Master configuration file:

```yaml
master_job_cache: <returner>
```
For example:

```
master_job_cache: mysql
```

Verify that the returner configuration settings are in the Master configuration file, and be sure to restart the salt-master service after you make configuration changes. (service salt-master restart).
The SDB interface is designed to store and retrieve data that, unlike pillars and grains, is not necessarily minion-specific. The initial design goal was to allow passwords to be stored in a secure database, such as one managed by the keyring package, rather than as plain-text files. However, as a generic database interface, it could conceptually be used for a number of other purposes.

SDB was added to Salt in version 2014.7.0. SDB is currently experimental, and should probably not be used in production.

### 13.1 SDB Configuration

In order to use the SDB interface, a configuration profile must be set up in either the master or minion configuration file. The configuration stanza includes the name/ID that the profile will be referred to as, a `driver` setting, and any other arguments that are necessary for the SDB module that will be used. For instance, a profile called `mykeyring`, which uses the `system` service in the `keyring` module would look like:

```
mykeyring:
    driver: keyring
    service: system
```

It is recommended to keep the name of the profile simple, as it is used in the SDB URI as well.

### 13.2 SDB URIs

SDB is designed to make small database queries (hence the name, SDB) using a compact URL. This allows users to reference a database value quickly inside a number of Salt configuration areas, without a lot of overhead. The basic format of an SDB URI is:

```
sdb://<profile>/<args>
```

The profile refers to the configuration profile defined in either the master or the minion configuration file. The args are specific to the module referred to in the profile, but will typically only need to refer to the key of a key/value pair inside the database. This is because the profile itself should define as many other parameters as possible.

For example, a profile might be set up to reference credentials for a specific OpenStack account. The profile might look like:

```
kevinopenstack:
    driver: keyring
    service: salt.cloud.openstack.kevin
```
And the URI used to reference the password might look like:

```
sdb://kevinopenstack/password
```

### 13.3 Writing SDB Modules

There is currently one function that MUST exist in any SDB module (get()) and one that MAY exist (set()). If using a (set()) function, a `__func_alias__` dictionary MUST be declared in the module as well:

```python
__func_alias__ = {
    'set': 'set',
}
```

This is because `set` is a Python built-in, and therefore functions should not be created which are called `set()`. The `__func_alias__` functionality is provided via Salt's loader interfaces, and allows legally-named functions to be referred to using names that would otherwise be unwise to use.

The `get()` function is required, as it will be called via functions in other areas of the code which make use of the `sdb://` URI. For example, the `config.get` function in the `config` execution module uses this function.

The `set()` function may be provided, but is not required, as some sources may be read-only, or may be otherwise unwise to access via a URI (for instance, because of SQL injection attacks).

A simple example of an SDB module is `salt/sdb/keyring_db.py`, as it provides basic examples of most, if not all, of the types of functionality that are available not only for SDB modules, but for Salt modules in general.
The Salt Event System is used to fire off events enabling third party applications or external processes to react to behavior within Salt.

The event system is comprised of a two primary components:

- The event sockets which publishes events.
- The event library which can listen to events and send events into the salt system.

### 14.1 Event types

#### 14.1.1 Salt Master Events

These events are fired on the Salt Master event bus. This list is not comprehensive.

**Authentication events**

**salt/auth**

Fired when a minion performs an authentication check with the master.

**Variables**

- **id** -- The minion ID.
- **act** -- The current status of the minion key: accept, pend, reject.
- **pub** -- The minion public key.

**Note:** Minions fire auth events on fairly regular basis for a number of reasons. Writing reactors to respond to events through the auth cycle can lead to infinite reactor event loops (minion tries to auth, reactor responds by doing something that generates another auth event, minion sends auth event, etc.). Consider reacting to salt/key or salt/minion/<MID>/start or firing a custom event tag instead.

**Start events**

**salt/minion/<MID>/start**

Fired every time a minion connects to the Salt master.

**Variables**

- **id** -- The minion ID.
Key events

**salt/key**
Fired when accepting and rejecting minions keys on the Salt master.

Variables
- **id** -- The minion ID.
- **act** -- The new status of the minion key: accept, pend, reject.

**Warning:** If a master is in **auto_accept** mode, **salt/key** events will not be fired when the keys are accepted. In addition, pre-seeding keys (like happens through **Salt-Cloud**) will not cause firing of these events.

Job events

**salt/job/<JID>/new**
Fired as a new job is sent out to minions.

Variables
- **jid** -- The job ID.
- **tgt** -- The target of the job: *, a minion ID, G@os_family:RedHat, etc.
- **tgt_type** -- The type of targeting used: glob, grain, compound, etc.
- **fun** -- The function to run on minions: test.ping, network.interfaces, etc.
- **arg** -- A list of arguments to pass to the function that will be called.
- **minions** -- A list of minion IDs that Salt expects will return data for this job.
- **user** -- The name of the user that ran the command as defined in Salt’s Client ACL or external auth.

**salt/job/<JID>/ret/<MID>**
Fired each time a minion returns data for a job.

Variables
- **id** -- The minion ID.
- **jid** -- The job ID.
- **retcode** -- The return code for the job.
- **fun** -- The function the minion ran. E.g., test.ping.
- **return** -- The data returned from the execution module.

**salt/job/<JID>/prog/<MID>/<RUN NUM>**
Fired each time a each function in a state run completes execution. Must be enabled using the **state_events** option.

Variables
- **data** -- The data returned from the state module function.
- **id** -- The minion ID.
- **jid** -- The job ID.
Presence events

**salt/presence/present**

Events fired on a regular interval about currently connected, newly connected, or recently disconnected minions. Requires the `presence_events` setting to be enabled.

Variables

- **present** -- A list of minions that are currently connected to the Salt master.

**salt/presence/change**

Fired when the Presence system detects new minions connect or disconnect.

Variables

- **new** -- A list of minions that have connected since the last presence event.
- **lost** -- A list of minions that have disconnected since the last presence event.

Cloud Events

Unlike other Master events, `salt-cloud` events are not fired on behalf of a Salt Minion. Instead, `salt-cloud` events are fired on behalf of a VM. This is because the minion-to-be may not yet exist to fire events to or also may have been destroyed.

This behavior is reflected by the `name` variable in the event data for `salt-cloud` events as compared to the `id` variable for Salt Minion-triggered events.

**salt/cloud/<VM NAME>/creating**

Fired when salt-cloud starts the VM creation process.

Variables

- **name** -- the name of the VM being created.
- **event** -- description of the event.
- **provider** -- the cloud provider of the VM being created.
- **profile** -- the cloud profile for the VM being created.

**salt/cloud/<VM NAME>/deploying**

Fired when the VM is available and salt-cloud begins deploying Salt to the new VM.

Variables

- **name** -- the name of the VM being created.
- **event** -- description of the event.
- **kwargs** -- options available as the deploy script is invoked: `conf_file`, `deploy_command`, `display_ssh_output`, `host`, `keep_tmp`, `key_filename`, `make_minion`, `minion_conf`, `name`, `parallel`, `preseed_minion_keys`, `script`, `script_args`, `script_env`, `sock_dir`, `start_action`, `sudo`, `tmp_dir`, `tty`, `username`

**salt/cloud/<VM NAME>/requesting**

Fired when salt-cloud sends the request to create a new VM.

Variables

- **event** -- description of the event.
- **location** -- the location of the VM being requested.
• **kwargs** -- options available as the VM is being requested: Action, ImageId, InstanceType, KeyName, MaxCount, MinCount, SecurityGroup

**salt/cloud/<VM NAME>/querying**
Fired when salt-cloud queries data for a new instance.

Variables
- **event** -- description of the event.
- **instance_id** -- the ID of the new VM.

**salt/cloud/<VM NAME>/tagging**
Fired when salt-cloud tags a new instance.

Variables
- **event** -- description of the event.
- **tags** -- tags being set on the new instance.

**salt/cloud/<VM NAME>/waiting_for_ssh**
Fired while the salt-cloud deploy process is waiting for ssh to become available on the new instance.

Variables
- **event** -- description of the event.
- **ip_address** -- IP address of the new instance.

**salt/cloud/<VM NAME>/deploy_script**
Fired once the deploy script is finished.

Variables
- **event** -- description of the event.

**salt/cloud/<VM NAME>/created**
Fired once the new instance has been fully created.

Variables
- **name** -- the name of the VM being created.
- **event** -- description of the event.
- **instance_id** -- the ID of the new instance.
- **provider** -- the cloud provider of the VM being created.
- **profile** -- the cloud profile for the VM being created.

**salt/cloud/<VM NAME>/destroying**
Fired when salt-cloud requests the destruction of an instance.

Variables
- **name** -- the name of the VM being created.
- **event** -- description of the event.
- **instance_id** -- the ID of the new instance.

**salt/cloud/<VM NAME>/destroyed**
Fired when an instance has been destroyed.

Variables
- **name** -- the name of the VM being created.
- **event** -- description of the event.
• **instance_id** -- the ID of the new instance.

## 14.2 Listening for Events

Salt’s Event Bus is used heavily within Salt and it is also written to integrate heavily with existing tooling and scripts. There is a variety of ways to consume it.

### 14.2.1 From the CLI

The quickest way to watch the event bus is by calling the `state.event` runner:

```bash
salt-run state.event pretty=True
```

That runner is designed to interact with the event bus from external tools and shell scripts. See the documentation for more examples.

### 14.2.2 Remotely via the REST API

Salt’s event bus can be consumed `salt.netapi.rest_cherrypy.app.Events` as an HTTP stream from external tools or services.

```bash
curl -SsNk https://salt-api.example.com:8000/events?token=05A3
```

### 14.2.3 From Python

Python scripts can access the event bus only as the same system user that Salt is running as.

The event system is accessed via the event library and can only be accessed by the same system user that Salt is running as. To listen to events a SaltEvent object needs to be created and then the get_event function needs to be run. The SaltEvent object needs to know the location that the Salt Unix sockets are kept. In the configuration this is the `sock_dir` option. The `sock_dir` option defaults to `/var/run/salt/master` on most systems.

The following code will check for a single event:

```python
import salt.config
import salt.utils.event

opts = salt.config.client_config('/etc/salt/master')

event = salt.utils.event.get_event('master',
    'master',
    sock_dir=opts['sock_dir'],
    transport=opts['transport'],
    opts=opts)

data = event.get_event()
```

Events will also use a "tag". Tags allow for events to be filtered by prefix. By default all events will be returned. If only authentication events are desired, then pass the tag "salt/auth".

The `get_event` method has a default poll time assigned of 5 seconds. To change this time set the "wait" option.

The following example will only listen for auth events and will wait for 10 seconds instead of the default 5.
data = event.get_event(wait=10, tag='salt/auth')

To retrieve the tag as well as the event data, pass full=True:

evdata = event.get_event(wait=10, tag='salt/job', full=True)

tag, data = evdata['tag'], evdata['data']

Instead of looking for a single event, the iter_events method can be used to make a generator which will continually yield salt events.

The iter_events method also accepts a tag but not a wait time:

```python
for data in event.iter_events(tag='salt/auth'):
    print(data)
```

And finally event tags can be globbed, such as they can be in the Reactor, using the fnmatch library.

```python
import fnmatch
import salt.config
import salt.utils.event

opts = salt.config.client_config('/etc/salt/master')

sevent = salt.utils.event.get_event(
    'master',
    sock_dir=opts['sock_dir'],
    transport=opts['transport'],
    opts=opts)

while True:
    ret = sevnet.get_event(full=True)
    if ret is None:
        continue

    if fnmatch.fnmatch(ret['tag'], 'salt/job/*/ret/*'):
        do_something_with_job_return(ret['data'])
```

### 14.3 Firing Events

It is possible to fire events on either the minion's local bus or to fire events intended for the master.

To fire a local event from the minion on the command line call the `event.fire` execution function:

```bash
salt-call event.fire {'"data": "message to be sent in the event"'} 'tag'
```

To fire an event to be sent up to the master from the minion call the `event.send` execution function. Remember YAML can be used at the CLI in function arguments:

```bash
salt-call event.send 'myco/mytag/success' '{success: True, message: "It works!"}'
```

If a process is listening on the minion, it may be useful for a user on the master to fire an event to it:

```bash
# Job on minion
import salt.utils.event
```
event = salt.utils.event.MinionEvent(**__opts__)  

for evdata in event.iter_events(tag='customtag/'):  
    return evdata  # do your processing here...

salt minionname event.fire '{"data": "message for the minion"}' 'customtag/african/unladen'

14.4 Firing Events from Python

14.4.1 From Salt execution modules

Events can be very useful when writing execution modules, in order to inform various processes on the master when a certain task has taken place. This is easily done using the normal cross-calling syntax:

# /srv/salt/_modules/my_custom_module.py

def do_something():
    '''
    Do something and fire an event to the master when finished
    
    CLI Example::

    salt '*' my_custom_module:do_something
    '''
    # do something!
    __salt__['event.send']('myco/my_custom_module/finished', {
        'finished': True,
        'message': 'The something is finished!',
    })

14.4.2 From Custom Python Scripts

Firing events from custom Python code is quite simple and mirrors how it is done at the CLI:

```python
import salt.client
caller = salt.client.Caller()
caller.sminion.functions['event.send']('myco/myevent/success', {
    'success': True,
    'message': 'It works!',
})
```
Beacons

The beacon system allows the minion to hook into a variety of system processes and continually monitor these processes. When monitored activity occurs in a system process, an event is sent on the Salt event bus that can be used to trigger a reactor.

Salt beacons can currently monitor and send Salt events for many system activities, including:

- file system changes
- system load
- service status
- shell activity, such as user login
- network and disk usage

See beacon modules for a current list.

Note: Salt beacons are an event generation mechanism. Beacons leverage the Salt reactor system to make changes when beacon events occur.

15.1 Configuring Beacons

Salt beacons do not require any changes to the system process that is being monitored, everything is configured using Salt.

Beacons are typically enabled by placing a beacons: top level block in the minion configuration file:

```yaml
beacons:
  inotify:
    /etc/httpd/conf.d: {}
    /opt: {}  
```

The beacon system, like many others in Salt, can also be configured via the minion pillar, grains, or local config file.

15.1.1 Beacon Monitoring Interval

Beacons monitor on a 1-second interval by default. To set a different interval, provide an interval argument to a beacon. The following beacons run on 5- and 10-second intervals:
beacons:
  inotify:
    /etc/httpd/conf.d: {}
    /opt: {}
    interval: 5
load:
  - 1m:
    - 0.0
    - 2.0
  - 5m:
    - 0.0
    - 1.5
  - 15m:
    - 0.1
    - 1.0
  - interval: 10

15.2 Beacon Example

This example demonstrates configuring the inotify beacon to monitor a file for changes, and then create a backup each time a change is detected.

Note: The inotify beacon requires Pyinotify on the minion, install it using salt myminion pkg.install python-inotify.

First, on the Salt minion, add the following beacon configuration to /etc/salt/minion:

beacons:
  inotify:
    home/user/importantfile:
      mask:
        - modify

Replace user in the previous example with the name of your user account, and then save the configuration file and restart the minion service.

Next, create a file in your home directory named importantfile and add some simple content. The beacon is now set up to monitor this file for modifications.

15.2.1 View Events on the Master

On your Salt master, start the event runner using the following command:

```
salt-run state.event pretty=true
```

This runner displays events as they are received on the Salt event bus. To test the beacon you set up in the previous section, make and save a modification to the importantfile you created. You’ll see an event similar to the following on the event bus:

```
salt/beacon/minion1/inotify/home/user/importantfile {
    "_stamp": "2015-09-09T15:59:37.972753",
    "data": {
        "change": "IN_IGNORED",
        "id": "minion1",
```

"path": "/home/user/importantfile"
},
"tag": "salt/beacon/minion1/inotify/home/user/importantfile"
}

This indicates that the event is being captured and sent correctly. Now you can create a reactor to take action when this event occurs.

### 15.2.2 Create a Reactor

On your Salt master, create a file named `srv/reactor/backup.sls`. If the `reactor` directory doesn't exist, create it. Add the following to `backup.sls`:

```bash
backup file:
  cmd.file.copy:
    - tgt: {{ data['data'][id] }}
    - arg:
      - {{ data['data']['path'] }}
      - {{ data['data']['path'] }}.bak
```

Next, add the code to trigger the reactor to `ect/salt/master`:

```bash
reactor:
  - salt/beacon/*/inotify/*/importantfile:
    - /srv/reactor/backup.sls
```

This reactor creates a backup each time a file named `importantfile` is modified on a minion that has the `inotify` beacon configured as previously shown.

**Note:** You can have only one top level `reactor` section, so if one already exists, add this code to the existing section. See [Understanding the Structure of Reactor Formulas](#) to learn more about reactor SLS syntax.

### 15.2.3 Start the Salt Master in Debug Mode

To help with troubleshooting, start the Salt master in debug mode:

```bash
service salt-master stop
salt-master -l debug
```

When debug logging is enabled, event and reactor data are displayed so you can discover syntax and other issues.

### 15.2.4 Trigger the Reactor

On your minion, make and save another change to `importantfile`. On the Salt master, you'll see debug messages that indicate the event was received and the `file.copy` job was sent. When you list the directory on the minion, you'll now see `importantfile.bak`.

All beacons are configured using a similar process of enabling the beacon, writing a reactor SLS, and mapping a beacon event to the reactor SLS.
15.3 Writing Beacon Plugins

Beacon plugins use the standard Salt loader system, meaning that many of the constructs from other plugin systems holds true, such as the __virtual__ function.

The important function in the Beacon Plugin is the beacon function. When the beacon is configured to run, this function will be executed repeatedly by the minion. The beacon function therefore cannot block and should be as lightweight as possible. The beacon also must return a list of dicts, each dict in the list will be translated into an event on the master.

Please see the inotify beacon as an example.

15.3.1 The beacon Function

The beacons system will look for a function named beacon in the module. If this function is not present then the beacon will not be fired. This function is called on a regular basis and defaults to being called on every iteration of the minion, which can be tens to hundreds of times a second. This means that the beacon function cannot block and should not be CPU or IO intensive.

The beacon function will be passed in the configuration for the executed beacon. This makes it easy to establish a flexible configuration for each called beacon. This is also the preferred way to ingest the beacon's configuration as it allows for the configuration to be dynamically updated while the minion is running by configuring the beacon in the minion's pillar.

15.3.2 The Beacon Return

The information returned from the beacon is expected to follow a predefined structure. The returned value needs to be a list of dictionaries (standard python dictionaries are preferred, no ordered dicts are needed).

The dictionaries represent individual events to be fired on the minion and master event buses. Each dict is a single event. The dict can contain any arbitrary keys but the ‘tag’ key will be extracted and added to the tag of the fired event.

The return data structure would look something like this:

```
[{
    'changes': ['/foo/bar'],
    'tag': 'foo'
  },
  {
    'changes': ['/foo/baz'],
    'tag': 'bar'
  }]
```

15.3.3 Calling Execution Modules

Execution modules are still the preferred location for all work and system interaction to happen in Salt. For this reason the __salt__ variable is available inside the beacon.

Please be careful when calling functions in __salt__, while this is the preferred means of executing complicated routines in Salt not all of the execution modules have been written with beacons in mind. Watch out for execution modules that may be CPU intense or IO bound. Please feel free to add new execution modules and functions to back specific beacons.
Running Custom Master Processes

In addition to the processes that the Salt Master automatically spawns, it is possible to configure it to start additional custom processes. This is useful if a dedicated process is needed that should run throughout the life of the Salt Master. For periodic independent tasks, a scheduled runner may be more appropriate. Processes started in this way will be restarted if they die and will be killed when the Salt Master is shut down.

16.1 Example Configuration

Processes are declared in the master config file with the `ext_processes` option. Processes will be started in the order they are declared.

```yaml
ext_processes:
  - mymodule.TestProcess
  - mymodule.AnotherProcess
```

16.2 Example Process Class

```python
# Import python libs
import time
import logging
from multiprocessing import Process

# Import Salt libs
from salt.utils.event import SaltEvent

log = logging.getLogger(__name__)

class TestProcess(Process):
    def __init__(self, opts):
        Process.__init__(self)
        self.opts = opts

    def run(self):
        self.event = SaltEvent('master', self.opts['sock_dir'])
        i = 0
```
```python
while True:
    self.event.fire_event({'iteration': i}, 'ext_processes/test[0]')
    time.sleep(60)
```
High Availability Features in Salt

Salt supports several features for high availability and fault tolerance. Brief documentation for these features is listed alongside their configuration parameters in *Configuration file examples*.

### 17.1 Multimaster

Salt minions can connect to multiple masters at one time by configuring the `master` configuration parameter as a YAML list of all the available masters. By default, all masters are ```hot```, meaning that any master can direct commands to the Salt infrastructure.

In a multimaster configuration, each master must have the same cryptographic keys, and minion keys must be accepted on all masters separately. The contents of `file_roots` and `pillar_roots` need to be kept in sync with processes external to Salt as well.

A tutorial on setting up multimaster with ```hot``` masters is here:

*Multimaster Tutorial*

### 17.2 Multimaster with Failover

Changing the `master_type` parameter from `str` to `failover` will cause minions to connect to the first responding master in the list of masters. Every `master_alive_check` seconds the minions will check to make sure the current master is still responding. If the master does not respond, the minion will attempt to connect to the next master in the list. If the minion runs out of masters, the list will be recycled in case dead masters have been restored. Note that `master_alive_check` must be present in the minion configuration, or else the recurring job to check master status will not get scheduled.

Failover can be combined with PKI-style encrypted keys, but PKI is NOT REQUIRED to use failover.

Multimaster with PKI and Failover is discussed in *this tutorial*

`master_type: failover` can be combined with `master_shuffle: True` to spread minion connections across all masters (one master per minion, not each minion connecting to all masters). Adding Salt Syndics into the mix makes it possible to create a load-balanced Salt infrastructure. If a master fails, minions will notice and select another master from the available list.
17.3 Syndic

Salt's Syndic feature is a way to create differing infrastructure topologies. It is not strictly an HA feature, but can be treated as such.

With the syndic, a Salt infrastructure can be partitioned in such a way that certain masters control certain segments of the infrastructure, and ``Master of Masters'' nodes can control multiple segments underneath them.

Syndics are covered in depth in Salt Syndic.

17.4 Syndic with Multimaster

New in version 2015.5.0.

Syndic with Multimaster lets you connect a syndic to multiple masters to provide an additional layer of redundancy in a syndic configuration.

Syndics are covered in depth in Salt Syndic.
Salt Syndic

The most basic or typical Salt topology consists of a single Master node controlling a group of Minion nodes. An intermediate node type, called Syndic, when used offers greater structural flexibility and scalability in the construction of Salt topologies than topologies constructed only out of Master and Minion node types.

A Syndic node can be thought of as a special passthrough Minion node. A Syndic node consists of a salt-syndic daemon and a salt-master daemon running on the same system. The salt-master daemon running on the Syndic node controls a group of lower level Minion nodes and the salt-syndic daemon connects higher level Master node, sometimes called a Master of Masters.

The salt-syndic daemon relays publications and events between the Master node and the local salt-master daemon. This gives the Master node control over the Minion nodes attached to the salt-master daemon running on the Syndic node.

18.1 Configuring the Syndic

To setup a Salt Syndic you need to tell the Syndic node and its Master node about each other. If your Master node is located at 10.10.0.1, then your configurations would be:

On the Syndic node:

```bash
# /etc/salt/master
syndic_master: 10.10.0.1  # may be either an IP address or a hostname

# /etc/salt/minion

# id is shared by the salt-syndic daemon and a possible salt-minion daemon
# on the Syndic node
id: my_syndic
```

On the Master node:

```bash
# /etc/salt/master
order_masters: True
```

The `syndic_master` option tells the Syndic node where to find the Master node in the same way that the `master` option tells a Minion node where to find a Master node.

The `id` option is used by the salt-syndic daemon to identify with the Master node and if unset will default to the hostname or IP address of the Syndic just as with a Minion.

The `order_masters` option configures the Master node to send extra information with its publications that is needed by Syndic nodes connected directly to it.
Note: Each Syndic must provide its own file_roots directory. Files will not be automatically transferred from the Master node.

18.2 Configuring the Syndic with Multimaster

New in version 2015.5.0.

Syndic with Multimaster lets you connect a syndic to multiple masters to provide an additional layer of redundancy in a syndic configuration.

Higher level masters should first be configured in a multimaster configuration. See Multimaster Tutorial.

On the syndic, the syndic_master option is populated with a list of the higher level masters.

Since each syndic is connected to each master, jobs sent from any master are forwarded to minions that are connected to each syndic. If the master_id value is set in the master config on the higher level masters, job results are returned to the master that originated the request in a best effort fashion. Events/jobs without a master_id are returned to any available master.

18.3 Running the Syndic

The salt-syndic daemon is a separate process that needs to be started in addition to the salt-master daemon running on the Syndic node. Starting the salt-syndic daemon is the same as starting the other Salt daemons.

The Master node in many ways sees the Syndic as an ordinary Minion node. In particular, the Master will need to accept the Syndic’s Minion key as it would for any other Minion.

On the Syndic node:

```
# salt-syndic
or
# service salt-syndic start
```

On the Master node:

```
# salt-key -a my_syndic
```

The Master node will now be able to control the Minion nodes connected to the Syndic. Only the Syndic key will be listed in the Master node’s key registry but this also means that key activity between the Syndic’s Minions and the Syndic does not encumber the Master node. In this way, the Syndic’s key on the Master node can be thought of as a placeholder for the keys of all the Minion and Syndic nodes beneath it, giving the Master node a clear, high level structural view on the Salt cluster.

On the Master node:

```
# salt-key -L
Accepted Keys:
my_syndic
Denied Keys:
Unaccepted Keys:
Rejected Keys:

# salt '*' test.ping
minion_1:
    True
```
18.4 Topology

A Master node (a node which is itself not a Syndic to another higher level Master node) must run a salt-master daemon and optionally a salt-minion daemon.

A Syndic node must run salt-syndic and salt-master daemons and optionally a salt-minion daemon.

A Minion node must run a salt-minion daemon.

When a salt-master daemon issues a command, it will be received by the Syndic and Minion nodes directly connected to it. A Minion node will process the command in the way it ordinarily would. On a Syndic node, the salt-syndic daemon will relay the command to the salt-master daemon running on the Syndic node, which then propagates the command to to the Minions and Syndics connected to it.

When events and job return data are generated by salt-minion daemons, they are aggregated by the salt-master daemon they are connected to, which salt-master daemon then relays the data back through its salt-syndic daemon until the data reaches the Master or Syndic node that issued the command.

18.5 Syndic wait

**Note:** To reduce the amount of time the CLI waits for Minions to respond, install a Minion on the Syndic or tune the value of the syndic_wait configuration.

While it is possible to run a Syndic without a Minion installed on the same system, it is recommended, for a faster CLI response time, to do so. Without a Minion installed on the Syndic node, the timeout value of syndic_wait increases significantly - about three-fold. With a Minion installed on the Syndic, the CLI timeout resides at the value defined in syndic_wait.

**Note:** If you have a very large infrastructure or many layers of Syndics, you may find that the CLI doesn't wait long enough for the Syndics to return their events. If you think this is the case, you can set the syndic_wait value in the Master configs on the Master or Syndic nodes from which commands are executed. The default value is 5, and should work for the majority of deployments.

In order for a Master or Syndic node to return information from Minions that are below their Syndics, the CLI requires a short wait time in order to allow the Syndics to gather responses from their Minions. This value is defined in the syndic_wait config option and has a default of five seconds.

18.6 Syndic config options

These are the options that can be used to configure a Syndic node. Note that other than id, Syndic config options are placed in the Master config on the Syndic node.

- **id**: Syndic id (shared by the salt-syndic daemon with a potential salt-minion daemon on the same system)
• **syndic_master**: Master node IP address or hostname
• **syndic_master_port**: Master node ret_port
• **syndic_log_file**: path to the logfile (absolute or not)
• **syndic_pidfile**: path to the pidfile (absolute or not)
• **syndic_wait**: time in seconds to wait on returns from this syndic
Proxy minions are a developing Salt feature that enables controlling devices that, for whatever reason, cannot run a standard salt-minion. Examples include network gear that has an API but runs a proprietary OS, devices with limited CPU or memory, or devices that could run a minion, but for security reasons, will not.

Proxy minions are not an `out of the box` feature. Because there are an infinite number of controllable devices, you will most likely have to write the interface yourself. Fortunately, this is only as difficult as the actual interface to the proxied device. Devices that have an existing Python module (PyUSB for example) would be relatively simple to interface. Code to control a device that has an HTML REST-based interface should be easy. Code to control your typical housecat would be excellent source material for a PhD thesis.

Salt proxy-minions provide the 'plumbing' that allows device enumeration and discovery, control, status, remote execution, and state management.

See the Proxy Minion Walkthrough for an end-to-end demonstration of a working proxy minion.

19.1 New in 2015.8

Starting with the 2015.8 release of Salt, proxy processes are no longer forked off from a controlling minion. Instead, they have their own script salt-proxy which takes mostly the same arguments that the standard Salt minion does with the addition of --proxyid. This is the id that the salt-proxy will use to identify itself to the master. Proxy configurations are still best kept in Pillar and their format has not changed.

This change allows for better process control and logging. Proxy processes can now be listed with standard process management utilities (ps from the command line). Also, a full Salt minion is no longer required (though it is still strongly recommended) on machines hosting proxies.

19.2 Getting Started

The following diagram may be helpful in understanding the structure of a Salt installation that includes proxy-minions:
The key thing to remember is the left-most section of the diagram. Salt’s nature is to have a minion connect to a master, then the master may control the minion. However, for proxy minions, the target device cannot run a minion. After the proxy minion is started and initiates its connection to the ‘dumb’ device, it connects back to the salt-master and for all intents and purposes looks like just another minion to the Salt master.

To create support for a proxied device one needs to create four things:

1. The `proxy_connection_module` (located in salt/proxy).
2. The `grains support code` (located in salt/grains).
3. `Salt modules` specific to the controlled device.
4. `Salt states` specific to the controlled device.
19.2.1 Configuration parameters

Proxy minions require no configuration parameters in /etc/salt/master.

Salt’s Pillar system is ideally suited for configuring proxy-minions. Proxies can either be designated via a pillar file in pillar_roots, or through an external pillar. External pillars afford the opportunity for interfacing with a configuration management system, database, or other knowledgeable system that that may already contain all the details of proxy targets. To use static files in pillar_roots, pattern your files after the following examples, which are based on the diagram above:

/srv/pillar/top.sls

```yaml
base:
    dumbdevice1:
    - dumbdevice1
    dumbdevice2:
    - dumbdevice2
    dumbdevice3:
    - dumbdevice3
    dumbdevice4:
    - dumbdevice4
    dumbdevice5:
    - dumbdevice5
    dumbdevice6:
    - dumbdevice6
    dumbdevice7:
    - dumbdevice7
```

/srv/pillar/dumbdevice1.sls

proxy:
    proxitype: networkswitch
    host: 172.23.23.5
    username: root
    passwd: letmein

/srv/pillar/dumbdevice2.sls

proxy:
    proxitype: networkswitch
    host: 172.23.23.6
    username: root
    passwd: letmein

/srv/pillar/dumbdevice3.sls

proxy:
    proxitype: networkswitch
    host: 172.23.23.7
    username: root
    passwd: letmein

/srv/pillar/dumbdevice4.sls

proxy:
    proxitype: i2c_lightshow
    i2c_address: 1

/srv/pillar/dumbdevice5.sls
proxy:
  proxytype: i2c_lightshow
  i2c_address: 2

/srv/pillar/dumbdevice6.sls
proxy:
  proxytype: 433mhz_wireless

/srv/pillar/dumbdevice7.sls
proxy:
  proxytype: sms_serial
  deventry: /dev/tty04

Note the contents of each minioncontroller key may differ widely based on the type of device that the proxy-minion is managing.

In the above example

- dumbdevices 1, 2, and 3 are network switches that have a management interface available at a particular IP address.
- dumbdevices 4 and 5 are very low-level devices controlled over an i2c bus. In this case the devices are physically connected to machine 'minioncontroller2', and are addressable on the i2c bus at their respective i2c addresses.
- dumbdevice6 is a 433 MHz wireless transmitter, also physically connected to minioncontroller2
- dumbdevice7 is an SMS gateway connected to machine minioncontroller3 via a serial port.

Because of the way pillar works, each of the salt-proxy processes that fork off the proxy minions will only see the keys specific to the proxies it will be handling.

Also, in general, proxy-minions are lightweight, so the machines that run them could conceivably control a large number of devices. To run more than one proxy from a single machine, simply start an additional proxy process with --proxyid set to the id to which you want the proxy to bind. It is possible for the proxy services to be spread across many machines if necessary, or intentionally run on machines that need to control devices because of some physical interface (e.g. i2c and serial above). Another reason to divide proxy services might be security. In more secure environments only certain machines may have a network path to certain devices.

19.2.2 Proxymodules

A proxy module encapsulates all the code necessary to interface with a device. Proxymodules are located inside the salt.proxymodule. At a minimum a proxymodule object must implement the following functions:

__virtual__(): This function performs the same duty that it does for other types of Salt modules. Logic goes here to determine if the module can be loaded, checking for the presence of Python modules on which the proxy depends. Returning False will prevent the module from loading.

init(opts): Perform any initialization that the device needs. This is a good place to bring up a persistent connection to a device, or authenticate to create a persistent authorization token.

shutdown(): Code to cleanly shut down or close a connection to a controlled device goes here. This function must exist, but can contain only the keyword pass if there is no shutdown logic required.

ping(): While not required, it is highly recommended that this function also be defined in the proxymodule. The code for ping should contact the controlled device and make sure it is really available.

Pre 2015.8 the proxymodule also must have an id() function. 2015.8 and following don't use this function because the proxy's id is required on the command line.
id(opts): Returns a unique, unchanging id for the controlled device. This is the "name" of the device, and is used by the salt-master for targeting and key authentication.

Here is an example proxymodule used to interface to a very simple REST server. Code for the server is in the salt-contrib GitHub repository

This proxymodule enables "service" enumeration, starting, stopping, restarting, and status; "package" installation, and a ping.

```python
# -*- coding: utf-8 -*-

'''This is a simple proxy-minion designed to connect to and communicate with
the bottle-based web service contained in
https://github.com/saltstack/salt-contrib/proxyminion_rest_example
'''

from __future__ import absolute_import

# Import python libs
import logging
import salt.utils.http

HAS_REST_EXAMPLE = True

# This must be present or the Salt loader won't load this module
__proxyenabled__ = ['rest_sample']

# Variables are scoped to this module so we can have persistent data
# across calls to fns in here.
GRAINS_CACHE = {}
DETAILS = {}

# Want logging!
log = logging.getLogger(__file__)

# This does nothing, it's here just as an example and to provide a log
# entry when the module is loaded.
def __virtual__():
    '''
    Only return if all the modules are available
    '''
    log.debug('rest_sample proxy __virtual__() called...')
    return True

# Every proxy module needs an 'init', though you can
# just put a 'pass' here if it doesn't need to do anything.
def init(opts):
    log.debug('rest_sample proxy init() called...')

    # Save the REST URL
    DETAILS['url'] = opts['proxy']['url']

    # Make sure the REST URL ends with a '/'
    if not DETAILS['url'].endswith('/'):
        DETAILS['url'] += '/

def id(opts):
```
Return a unique ID for this proxy minion. This ID MUST NOT CHANGE. If it changes while the proxy is running the salt-master will get really confused and may stop talking to this minion

```python
r = salt.utils.http.query(opts['proxy']['url']+'id', decode_type='json', decode=True)
return r['dict']['id'].encode('ascii', 'ignore')
```

def grains():
    # Get the grains from the proxied device
    if not GRAINS_CACHE:
        r = salt.utils.http.query(DETAILS['url']+'info', decode_type='json', decode=True)
        GRAINS_CACHE = r['dict']
    return GRAINS_CACHE

def grains_refresh():
    # Refresh the grains from the proxied device
    GRAINS_CACHE = {}
    return grains()

def service_start(name):
    # Start a "service" on the REST server
    r = salt.utils.http.query(DETAILS['url']+'service/start/'+name, decode_type='json', decode=True)
    return r['dict']

def service_stop(name):
    # Stop a "service" on the REST server
    r = salt.utils.http.query(DETAILS['url']+'service/stop/'+name, decode_type='json', decode=True)
    return r['dict']

def service_restart(name):
    # Restart a "service" on the REST server
    r = salt.utils.http.query(DETAILS['url']+'service/restart/'+name, decode_type='json', decode=True)
    return r['dict']

def service_list():
    # List "services" on the REST server
    r = salt.utils.http.query(DETAILS['url']+'service/list', decode_type='json', decode=True)
    return r['dict']
def service_status(name):
    '''
    Check if a service is running on the REST server
    '''
    r = salt.utils.http.query(DETAILS['url']+'service/status/'+name, decode_type='json', decode=True)
    return r['dict']

def package_list():
    '''
    List "packages" installed on the REST server
    '''
    r = salt.utils.http.query(DETAILS['url']+'package/list', decode_type='json', decode=True)
    return r['dict']

def package_install(name, **kwargs):
    '''
    Install a "package" on the REST server
    '''
    cmd = DETAILS['url']+'package/install/'+name
    if 'version' in kwargs:
        cmd += '/' + kwargs['version']
    else:
        cmd += '/1.0'
    r = salt.utils.http.query(cmd, decode_type='json', decode=True)

def package_remove(name):
    '''
    Remove a "package" on the REST server
    '''
    r = salt.utils.http.query(DETAILS['url']+'package/remove/'+name, decode_type='json', decode=True)
    return r['dict']

def package_status(name):
    '''
    Check the installation status of a package on the REST server
    '''
    r = salt.utils.http.query(DETAILS['url']+'package/status/'+name, decode_type='json', decode=True)
    return r['dict']

def ping():
    '''
    Is the REST server up?
    '''
    r = salt.utils.http.query(DETAILS['url']+'ping', decode_type='json', decode=True)
    try:
        return r['dict'].get('ret', False)
    except Exception:
        return False

def shutdown(opts):
    '''

19.2. Getting Started
Grains are data about minions. Most proxied devices will have a paltry amount of data as compared to a typical Linux server. By default, a proxy minion will have several grains taken from the host. Salt core code requires values for `kernel`, `os`, and `os_family`—all of these are forced to be `proxy` for proxy-minions. To add others to your proxy minion for a particular device, create a file in `salt/grains` named `[proxytype].py` and place inside it the different functions that need to be run to collect the data you are interested in. Here's an example:

### 19.3 The `__proxyenabled__` directive

Salt execution modules, by, and large, cannot "automatically" work with proxied devices. Execution modules like `pkg` or `sqlite3` have no meaning on a network switch or a housecat. For an execution module to be available to a proxy-minion, the `__proxyenabled__` variable must be defined in the module as an array containing the names of all the proxytypes that this module can support. The array can contain the special value `*` to indicate that the module supports all proxies.

If no `__proxyenabled__` variable is defined, then by default, the execution module is unavailable to any proxy.

Here is an excerpt from a module that was modified to support proxy-minions:

```python
__proxyenabled__ = ['*']

def ping():
    if 'proxymodule' in __opts__:
        ping_cmd = __opts__['proxymodule'].loaded_base_name + '.ping'
        return __opts__['proxymodule'][ping_cmd]()
    else:
        return True
```

And then in `salt.proxy.rest_sample.py` we find

```python
def ping():
    """Is the REST server up?"
    """
    r = salt.utils.http.query(DETAILS['url']+'ping', decode_type='json', decode=True)
    try:
        return r['dict'].get('ret', False)
    except Exception:
        return False
```

### 19.3.1 Salt Proxy Minion End-to-End Example

The following is walkthrough that documents how to run a sample REST service and configure one or more proxy minions to talk to and control it.

1. Ideally, create a Python virtualenv in which to run the REST service. This is not strictly required, but without a virtualenv you will need to install `bottle` via pip globally on your system.
2. Clone https://github.com/saltstack/salt-contrib and copy the contents of the directory `proxyminion_rest_example` somewhere on a machine that is reachable from the machine on which you want to run the salt-proxy. This machine needs Python 2.7 or later.

3. Install bottle version 0.12.8 via pip or easy_install

```
pip install bottle==0.12.8
```

4. Run `python rest.py --help` for usage

5. Start the REST API on an appropriate port and IP.

6. Load the REST service's status page in your browser by going to the IP/port combination (e.g. `http://127.0.0.1:8000`)

7. You should see a page entitled "Salt Proxy Minion" with two sections, one for "services" and one for "packages" and you should see a log entry in the terminal where you started the REST process indicating that the index page was retrieved.

Now, configure your salt-proxy.

1. Edit `/etc/salt/proxy` and add an entry for your master's location

```
master: localhost
```

2. On your salt-master, ensure that pillar is configured properly. Select an ID for your proxy (in this example we will name the proxy with the letter 'p' followed by the port the proxy is answering on). In your pillar topfile, place an entry for your proxy:

```
base:
  'p8000':
    - p8000
```

This says that Salt's pillar should load some values for the proxy `p8000` from the file `/srv/pillar/p8000.sls` (if you have not changed your default pillar_roots)

3. In the pillar root for your base environment, create this file:

```
p8000.sls
-------

proxy:
  proxymodule: rest_sample
  url: http://<IP your REST listens on>:port
```

19.3. The `__proxyenabled__` directive
In other words, if your REST service is listening on port 8000 on 127.0.0.1 the `url` key above should say `url:
http://127.0.0.1:8000`

4. Make sure your salt-master is running.
5. Start the salt-proxy in debug mode

```
salt-proxy --proxyid=p8000 -l debug
```

6. Accept your proxy's key on your salt-master

```
salt-key -y -a p8000
The following keys are going to be accepted:
Unaccepted Keys:
p8000
Key for minion p8000 accepted.
```

7. Now you should be able to ping your proxy. When you ping, you should see a log entry in the terminal where the REST service is running.

```
salt p8000 test.ping
```

8. The REST service implements a degenerately simple pkg and service provider as well as a small set of grains. To ```install``` a package, use a standard `pkg.install`. If you pass ``==``` and a verrsion number after the package name then the service will parse that and accept that as the package's version.

9. Try running `salt p8000 grains.items` to see what grains are available. You can target proxies via grains if you like.

10. You can also start and stop the available services (apache, redbull, and postgresql with `service.start`, etc.

11. States can be written to target the proxy. Feel free to experiment with them.
The Salt Package Manager, or SPM, allows Salt formulas to be packaged, for ease of deployment. The design of SPM was influenced by other existing packaging systems including RPM, Yum, and Pacman.

### 20.1 Building Packages

Before SPM can install packages, they must be built. The source for these packages is often a Git repository, such as those found at the saltstack-formulas organization on GitHub.

#### 20.1.1 FORMULA

In addition to the formula itself, a FORMULA file must exist which describes the package. An example of this file is:

```text
name: apache
os: RedHat, Debian, Ubuntu, Suse, FreeBSD
os_family: RedHat, Debian, Suse, FreeBSD
dependencies: None
version: 201506
release: 2
summary: Formula for installing Apache
description: Formula for installing Apache
```

**Required Fields**

This file must contain at least the following fields:

- **name**

  The name of the package, as it will appear in the package filename, in the repository metadata, and the package database. Even if the source formula has `-formula` in its name, this name should probably not include that. For instance, when packaging the `apache-formula`, the name should be set to `apache`.

- **os**

  The value of the `os` grain that this formula supports. This is used to help users know which operating systems can support this package.
os_family

The value of the `os_family` grain that this formula supports. This is used to help users know which operating system families can support this package.

version

The version of the package. While it is up to the organization that manages this package, it is suggested that this version is specified in a YYYYMM format. For instance, if this version was released in June 2015, the package version should be 201506. If multiple released are made in a month, the `releasee` field should be used.

release

This field refers primarily to a release of a version, but also to multiple versions within a month. In general, if a version has been made public, and immediate updates need to be made to it, this field should also be updated.

summary

A one-line description of the package.

description

A more detailed description of the package which can contain more than one line.

Optional Fields

The following fields may also be present.

top_level_dir

This field is optional, but highly recommended. If it is not specified, the package name will be used.

Formula repositories typically do not store .sls files in the root of the repository; instead they are stored in a subdirectory. For instance, an `apache-formula` repository would contain a directory called `apache`, which would contain an `init.sls`, plus a number of other related files. In this instance, the `top_level_dir` should be set to `apache`.

Files outside the `top_level_dir`, such as readme.rst, FORMULA, and LICENSE will not be installed. The exceptions to this rule are files that are already treated specially, such as pillar.example and _modules/.

dependencies

A list of packages which must be installed before this package can function.

20.1.2 Building a Package

Once a FORMULA file has been created, it is placed into the root of the formula that is to be turned into a package. The `spm build` command is used to turn that formula into a package:

```
spm build /path/to/saltstack-formulas/apache-formula
```

The resulting file will be placed in the build directory. By default this directory is located at `/srv/spm/`. 

226 Chapter 20. Salt Package Manager
20.2 Building Repositories

Once one or more packages have been built, they can be made available to SPM via a package repository. Place the packages into the directory to be served and issue an `spm create_repo` command:

```
spm create_repo /srv/spm
```

This command is used, even if repository metadata already exists in that directory. SPM will regenerate the repository metadata again, using all of the packages in that directory.

20.3 Configuring Remote Repositories

Before SPM can use a repository, two things need to happen. First, SPM needs to know where the repositories are. Then it needs to pull down the repository metadata.

20.3.1 Repository Configuration Files

Normally repository configuration files are placed in the `/etc/salt/spm.repos.d`. These files contain the name of the repository, and the link to that repository:

```
my_repo:
  url: https://spm.example.com/
```

The URL can use http, https, ftp, or file.

```
local_repo:
  url: file:///srv/spm
```

20.3.2 Updating Local Repository Metadata

Once the repository is configured, its metadata needs to be downloaded. At the moment, this is a manual process, using the `spm update_repo` command.

```
spm update_repo
```

20.4 Installing Packages

Packages may be installed either from a local file, or from an SPM repository. To install from a repository, use the `spm install` command:

```
spm install apache
```

To install from a local file, use the `spm local_install` command:

```
spm local_install /srv/spm/apache-201506-1.spm
```

Currently, SPM does not check to see if files are already in place before installing them. That means that existing files will be overwritten without warning.
20.5 Pillars

Formula packages include a pillar.example file. Rather than being placed in the formula directory, this file is renamed to `<formula name>.sls.orig` and placed in the `pillar_path`, where it can be easily updated to meet the user's needs.

20.6 Loader Modules

When an execution module is placed in `<file_roots>/_modules/` on the master, it will automatically be synced to minions, the next time a sync operation takes place. Other modules are also propagated this way: state modules can be placed in `_states/`, and so on.

When SPM detects a file in a package which resides in one of these directories, that directory will be placed in `<file_roots>` instead of in the formula directory with the rest of the files.

20.7 Removing Packages

Packages may be removed once they are installed using the `spm remove` command.

```
spm remove apache
```

If files have been modified, they will not be removed. Empty directories will also be removed.

20.8 Technical Information

Packages are built using BZ2-compressed tarballs. By default, the package database is stored using the `sqlite3` driver (see Loader Modules below).

Support for these are built into Python, and so no external dependencies are needed.

All other files belonging to SPM use YAML, for portability and ease of use and maintainability.

20.9 SPM-Specific Loader Modules

SPM was designed to behave like traditional package managers, which apply files to the filesystem and store package metadata in a local database. However, because modern infrastructures often extend beyond those use cases, certain parts of SPM have been broken out into their own set of modules.

20.9.1 Package Database

By default, the package database is stored using the `sqlite3` module. This module was chosen because support for SQLite3 is built into Python itself.

Please see the SPM Development Guide for information on creating new modules for package database management.
20.9.2 Package Files

By default, package files are installed using the local module. This module applies files to the local filesystem, on the machine that the package is installed on.

Please see the SPM Development Guide for information on creating new modules for package file management.

20.10 SPM Configuration

There are a number of options that are specific to SPM. They may be configured in the master configuration file, or in SPM’s own spm configuration file (normally located at /etc/salt/spm). If configured in both places, the spm file takes precedence. In general, these values will not need to be changed from the defaults.

20.10.1 spm_logfile

Default: /var/log/salt/spm

Where SPM logs messages.

20.10.2 spm_repos_config

Default: /etc/salt/spm.repos

SPM repositories are configured with this file. There is also a directory which corresponds to it, which ends in .d. For instance, if the filename is /etc/salt/spm.repos, the directory will be /etc/salt/spm.repos.d/.

20.10.3 spm_cache_dir

Default: /var/cache/salt/spm

When SPM updates package repository metadata and downloads packaged, they will be placed in this directory. The package database, normally called packages.db, also lives in this directory.

20.10.4 spm_db

Default: /var/cache/salt/spm/packages.db

The location and name of the package database. This database stores the names of all of the SPM packages installed on the system, the files that belong to them, and the metadata for those files.

20.10.5 spm_build_dir

Default: /srv/spm

When packages are built, they will be placed in this directory.
20.10.6 spm_build_exclude

Default: ['\.git\']

When SPM builds a package, it normally adds all files in the formula directory to the package. Files listed here will be excluded from that package. This option requires a list to be specified.

```python
spm_build_exclude:
  - .git
  - .svn
```

20.11 Types of Packages

SPM supports different types of formula packages. The function of each package is denoted by its name. For instance, packages which end in `-formula` are considered to be Salt States (the most common type of formula). Packages which end in `-conf` contain configuration which is to be placed in the `/etc/salt/` directory. Packages which do not contain one of these names are treated as if they have a `-formula` name.

20.11.1 formula

By default, most files from this type of package live in the `/srv/spm/salt/` directory. The exception is the `pillar.example` file, which will be renamed to `<package_name>.sls` and placed in the pillar directory (`/srv/spm/pillar/` by default).

20.11.2 reactor

By default, files from this type of package live in the `/srv/spm/reactor/` directory.

20.11.3 conf

The files in this type of package are configuration files for Salt, which normally live in the `/etc/salt/` directory. Configuration files for packages other than Salt can and should be handled with a Salt State (using a `formula` type of package).

SPM Development Guide

This document discusses developing additional code for SPM.

SPM-Specific Loader Modules

SPM was designed to behave like traditional package managers, which apply files to the filesystem and store package metadata in a local database. However, because modern infrastructures often extend beyond those use cases, certain parts of SPM have been broken out into their own set of modules.

Each function that accepts arguments has a set of required and optional arguments. Take note that SPM will pass all arguments in, and therefore each function must accept each of those arguments. However, arguments that are marked as required are crucial to SPM’s core functionality, while arguments that are marked as optional are provided as a benefit to the module, if it needs to use them.
**Package Database** By default, the package database is stored using the `sqlite3` module. This module was chosen because support for SQLite3 is built into Python itself.

Modules for managing the package database are stored in the `salt/spm/pkgdb/` directory. A number of functions must exist to support database management.

**init()** Get a database connection, and initialize the package database if necessary.

This function accepts no arguments. If a database is used which supports a connection object, then that connection object is returned. For instance, the `sqlite3` module returns a `connect()` object from the `sqlite3` library:

```python
conn = sqlite3.connect(__opts__['spm_db'], isolation_level=None)
...
return conn
```

SPM itself will not use this connection object; it will be passed in as-is to the other functions in the module. Therefore, when you set up this object, make sure to do so in a way that is easily usable throughout the module.

**info()** Return information for a package. This generally consists of the information that is stored in the `FORMULA` file in the package.

The arguments that are passed in, in order, are `package` (required) and `conn` (optional).

`package` is the name of the package, as specified in the `FORMULA`. `conn` is the connection object returned from `init()`.

**list_files()** Return a list of files for an installed package. Only the filename should be returned, and no other information.

The arguments that are passed in, in order, are `package` (required) and `conn` (optional).

`package` is the name of the package, as specified in the `FORMULA`. `conn` is the connection object returned from `init()`.

**register_pkg()** Register a package in the package database. Nothing is expected to be returned from this function.

The arguments that are passed in, in order, are `name` (required), `formula_def` (required), and `conn` (optional).

`name` is the name of the package, as specified in the `FORMULA`. `formula_def` is the contents of the `FORMULA` file, as a dict. `conn` is the connection object returned from `init()`.

**register_file()** Register a file in the package database. Nothing is expected to be returned from this function.

The arguments that are passed in are `name` (required), `member` (required), `path` (required), `digest` (optional), and `conn` (optional).

`name` is the name of the package.

`member` is a `tarfile` object for the package file. It is included, because it contains most of the information for the file.

`path` is the location of the file on the local filesystem.

`digest` is the SHA1 checksum of the file.

`conn` is the connection object returned from `init()`.
unregister_pkg()  Unregister a package from the package database. This usually only involves removing the package's record from the database. Nothing is expected to be returned from this function.

The arguments that are passed in, in order, are name (required) and conn (optional).

name is the name of the package, as specified in the FORMULA. conn is the connection object returned from init().

unregister_file()  Unregister a package from the package database. This usually only involves removing the package's record from the database. Nothing is expected to be returned from this function.

The arguments that are passed in, in order, are name (required), pkg (optional) and conn (optional).

name is the path of the file, as it was installed on the filesystem.

pkg is the name of the package that the file belongs to.

conn is the connection object returned from init().

db_exists()  Check to see whether the package database already exists. This is the path to the package database file. This function will return True or False.

The only argument that is expected is db_, which is the package database file.

Package Files  By default, package files are installed using the local module. This module applies files to the local filesystem, on the machine that the package is installed on.

Modules for managing the package database are stored in the salt/spm/pkgfiles/ directory. A number of functions must exist to support file management.

init()  Initialize the installation location for the package files. Normally these will be directory paths, but other external destinations such as databases can be used. For this reason, this function will return a connection object, which can be a database object. However, in the default local module, this object is a dict containing the paths. This object will be passed into all other functions.

Three directories are used for the destinations: formula_path, pillar_path, and reactor_path.

formula_path is the location of most of the files that will be installed. The default is specific to the operating system, but is normally /srv/salt/.

pillar_path is the location that the pillar.example file will be installed to. The default is specific to the operating system, but is normally /srv/pillar/.

reactor_path is the location that reactor files will be installed to. The default is specific to the operating system, but is normally /srv/reactor/.

check_existing()  Check the filesystem for existing files. All files for the package will be checked, and if any are existing, then this function will normally state that SPM will refuse to install the package.

This function returns a list of the files that exist on the system.

The arguments that are passed into this function are, in order: package (required), pkg_files (required), formula_def (formula_def), and conn (optional).

package is the name of the package that is to be installed.

pkg_files is a list of the files to be checked.

formula_def is a copy of the information that is stored in the FORMULA file.
conn is the file connection object.

**install_file()**  Install a single file to the destination (normally on the filesystem). Nothing is expected to be returned from this function.

This function returns the final location that the file was installed to.

The arguments that are passed into this function are, in order, `package` (required), `formula_tar` (required), `member` (required), `formula_def` (required), and `conn` (optional).

- `package` is the name of the package that is to be installed.
- `formula_tar` is the tarfile object for the package. This is passed in so that the function can call `formula_tar.extract()` for the file.
- `member` is the tarfile object which represents the individual file. This may be modified as necessary, before being passed into `formula_tar.extract()`.
- `formula_def` is a copy of the information from the FORMULA file.
- `conn` is the file connection object.

**remove_file()**  Remove a single file from file system. Normally this will be little more than an `os.remove()`.

Nothing is expected to be returned from this function.

The arguments that are passed into this function are, in order, `path` (required) and `conn` (optional).

- `path` is the absolute path to the file to be removed.
- `conn` is the file connection object.

**hash_file()**  Returns the hexdigest hash value of a file.

The arguments that are passed into this function are, in order, `path` (required), `hashobj` (required), and `conn` (optional).

- `path` is the absolute path to the file.
- `hashobj` is a reference to `hashlib.sha1()`, which is used to pull the `hexdigest()` for the file.
- `conn` is the file connection object.

This function will not generally be more complex than:

```python
def hash_file(path, hashobj, conn=None):
    with salt.utils.fopen(path, 'r') as f:
        hashobj.update(f.read())
    return hashobj.hexdigest()
```

**path_exists()**  Check to see whether the file already exists on the filesystem. Returns `True` or `False`.

This function expects a `path` argument, which is the absolute path to the file to be checked.

**path_isdir()**  Check to see whether the path specified is a directory. Returns `True` or `False`.

This function expects a `path` argument, which is the absolute path to be checked.
Salt Transport

One of fundamental features of Salt is remote execution. Salt has two basic `channels` for communicating with minions. Each channel requires a client (minion) and a server (master) implementation to work within Salt. These pairs of channels will work together to implement the specific message passing required by the channel interface.

### 21.1 Pub Channel

The pub channel, or publish channel, is how a master sends a job (payload) to a minion. This is a basic pub/sub paradigm, which has specific targeting semantics. All data which goes across the publish system should be encrypted such that only members of the Salt cluster can decrypt the publishes.

### 21.2 Req Channel

The req channel is how the minions send data to the master. This interface is primarily used for fetching files and returning job returns. The req channels have two basic interfaces when talking to the master. `send` is the basic method that guarantees the message is encrypted at least so that only minions attached to the same master can read it-- but no guarantee of minion-master confidentiality, whereas the `encrypted_transfer_decode_dictentry` method does guarantee minion-master confidentiality.

#### 21.2.1 Zeromq Transport

**Note:** Zeromq is the current default transport within Salt

Zeromq is a messaging library with bindings into many languages. Zeromq implements a socket interface for message passing, with specific semantics for the socket type.

**Pub Channel**

The pub channel is implemented using zeromq’s pub/sub sockets. By default we don’t use zeromq’s filtering, which means that all publish jobs are sent to all minions and filtered minion side. Zeromq does have publisher side filtering which can be enabled in salt using `zmq_filtering`.
Req Channel

The req channel is implemented using zmq's req/rep sockets. These sockets enforce a send/recv pattern, which forces salt to serialize messages through these socket pairs. This means that although the interface is asynchronous on the minion we cannot send a second message until we have received the reply of the first message.

21.2.2 TCP Transport

The `tcp` transport is an implementation of Salt's channels using raw tcp sockets. Since this isn't using a pre-defined messaging library we will describe the wire protocol, message semantics, etc. in this document.

Wire Protocol

This implementation over TCP focuses on flexibility over absolute efficiency. This means we are okay to spend a couple of bytes of wire space for flexibility in the future. That being said, the wire framing is quite efficient and looks like:

\[
\text{len}(\text{payload}) \text{ msgpack}({'head': SOMEHEADER, 'body': SOMEBODY})
\]

The wire protocol is basically two parts, the length of the payload and a payload (which is a msgpack'd dict). Within that payload we have two items `head` and `body`. Head contains header information (such as `message id`). The Body contains the actual message that we are sending. With this flexible wire protocol we can implement any message semantics that we'd like-- including multiplexed message passing on a single socket.

Crypto

The current implementation uses the same crypto as the zmq transport.

Pub Channel

For the pub channel we send messages without `message ids` which the remote end interprets as a one-way send.

Note: As of today we send all publishes to all minions and rely on minion-side filtering.

Req Channel

For the req channel we send messages with a `message id`. This `message id` allows us to multiplex messages across the socket.

21.2.3 The RAET Transport

Note: The RAET transport is in very early development, it is functional but no promises are yet made as to its reliability or security. As for reliability and security, the encryption used has been audited and our tests show that raet is reliable. With this said we are still conducting more security audits and pushing the reliability. This document outlines the encryption used in RAET

New in version 2014.7.0.
The Reliable Asynchronous Event Transport, or RAET, is an alternative transport medium developed specifically with Salt in mind. It has been developed to allow queuing to happen up on the application layer and comes with socket layer encryption. It also abstracts a great deal of control over the socket layer and makes it easy to bubble up errors and exceptions.

RAET also offers very powerful message routing capabilities, allowing for messages to be routed between processes on a single machine all the way up to processes on multiple machines. Messages can also be restricted, allowing processes to be sent messages of specific types from specific sources allowing for trust to be established.

**Using RAET in Salt**

Using RAET in Salt is easy, the main difference is that the core dependencies change, instead of needing pycrypto, M2Crypto, ZeroMQ, and PYZMQ, the packages libsodium, libnacl, ioflo, and raet are required. Encryption is handled very cleanly by libnacl, while the queueing and flow control is handled by ioflo. Distribution packages are forthcoming, but libsodium can be easily installed from source, or many distributions do ship packages for it. The libnacl and ioflo packages can be easily installed from pypi, distribution packages are in the works.

Once the new deps are installed the 2014.7 release or higher of Salt needs to be installed.

Once installed, modify the configuration files for the minion and master to set the transport to raet:

**/etc/salt/master:**

```
transport: raet
```

**/etc/salt/minion:**

```
transport: raet
```

Now start salt as it would normally be started, the minion will connect to the master and share long term keys, which can then in turn be managed via salt-key. Remote execution and salt states will function in the same way as with Salt over ZeroMQ.

**Limitations**

The 2014.7 release of RAET is not complete! The Syndic and Multi Master have not been completed yet and these are slated for completion in the 2015.5.0 release.

Also, Salt-Raet allows for more control over the client but these hooks have not been implemented yet, therefore the client still uses the same system as the ZeroMQ client. This means that the extra reliability that RAET exposes has not yet been implemented in the CLI client.

**Why?**

**Customer and User Request**

Why make an alternative transport for Salt? There are many reasons, but the primary motivation came from customer requests, many large companies came with requests to run Salt over an alternative transport, the reasoning was varied, from performance and scaling improvements to licensing concerns. These customers have partnered with SaltStack to make RAET a reality.
More Capabilities

RAET has been designed to allow salt to have greater communication capabilities. It has been designed to allow for development into features which out ZeroMQ topologies can’t match.

Many of the proposed features are still under development and will be announced as they enter proof of concept phases, but these features include salt-fuse - a filesystem over salt, salt-vt - a parallel api driven shell over the salt transport and many others.

RAET Reliability

RAET is reliable, hence the name (Reliable Asynchronous Event Transport).

The concern posed by some over RAET reliability is based on the fact that RAET uses UDP instead of TCP and UDP does not have built in reliability.

RAET itself implements the needed reliability layers that are not natively present in UDP, this allows RAET to dynamically optimize packet delivery in a way that keeps it both reliable and asynchronous.

RAET and ZeroMQ

When using RAET, ZeroMQ is not required. RAET is a complete networking replacement. It is noteworthy that RAET is not a ZeroMQ replacement in a general sense, the ZeroMQ constructs are not reproduced in RAET, but they are instead implemented in such a way that is specific to Salt’s needs.

RAET is primarily an async communication layer over truly async connections, defaulting to UDP. ZeroMQ is over TCP and abstracts async constructs within the socket layer.

Salt is not dropping ZeroMQ support and has no immediate plans to do so.

Encryption

RAET uses Dan Bernstein's NACL encryption libraries and CurveCP handshake. The libnacl python binding binds to both libsodium and tweetnacl to execute the underlying cryptography. This allows us to completely rely on an externally developed cryptography system.

For more information on libsodium and CurveCP please see: http://doc.libsodium.org/ http://curvecp.org/

Programming Intro
Windows Software Repository

Note: Git repository management for the Windows Software Repository has changed in version 2015.8.0, and several master/minion config parameters have been renamed to make their naming more consistent with each other. Please see below for important details if upgrading from an earlier Salt release.

The Salt Windows Software Repository provides a package manager and software repository similar to what is provided by yum and apt on Linux.

It permits the installation of software using the installers on remote windows machines. In many senses, the operation is similar to that of the other package managers salt is aware of:

- the pkg.installed and similar states work on Windows.
- the pkg.install and similar module functions work on Windows.
- each windows machine needs to have pkg.refresh_db executed against it to pick up the latest version of the package database.

High level differences to yum and apt are:

- The repository metadata (sls files) is hosted through either salt or git.
- Packages can be downloaded from within the salt repository, a git repository or from http(s) or ftp urls.
- No dependencies are managed. Dependencies between packages needs to be managed manually.

22.1 Operation

The install state/module function of the windows package manager works roughly as follows:

1. Execute pkg.list_pkgs and store the result
2. Check if any action needs to be taken. (i.e. compare required package and version against pkg.list_pkgs results)
3. If so, run the installer command.
4. Execute pkg.list_pkgs and compare to the result stored from before installation.
5. Success/Failure/Changes will be reported based on the differences between the original and final pkg.list_pkgs results.

If there are any problems in using the package manager it is likely to be due to the data in your sls files not matching the difference between the pre and post pkg.list_pkgs results.
22.2 Usage

By default, the Windows software repository is found at /srv/salt/win/repo (C:salt\srv\salt\win\repo on standalone minions). This can be changed in the master config file by setting the `winrepo_dir` option (NOTE: this option was called `win_repo` in Salt versions prior to 2015.8.0). However, this path must reside somewhere inside the master's `file_roots`. Each piece of software should have its own directory which contains the installers and a package definition file. This package definition file is a YAML file named `init.sls`.

The package definition file should look similar to this example for Firefox:

```
/srv/salt/win/repo/firefox/init.sls
```

```yaml
definition:
  firefox:
    17.0.1:
      installer: 'salt://win/repo/firefox/English/Firefox Setup 17.0.1.exe'
      full_name: Mozilla Firefox 17.0.1 (x86 en-US)
      locale: en_US
      reboot: False
      install_flags: '-ms'
      uninstaller: '%ProgramFiles(x86)%/Mozilla Firefox/uninstall/helper.exe'
      uninstall_flags: '/S'
    16.0.2:
      installer: 'salt://win/repo/firefox/English/Firefox Setup 16.0.2.exe'
      full_name: Mozilla Firefox 16.0.2 (x86 en-US)
      locale: en_US
      reboot: False
      install_flags: '-ms'
      uninstaller: '%ProgramFiles(x86)%/Mozilla Firefox/uninstall/helper.exe'
      uninstall_flags: '/S'
    15.0.1:
      installer: 'salt://win/repo/firefox/English/Firefox Setup 15.0.1.exe'
      full_name: Mozilla Firefox 15.0.1 (x86 en-US)
      locale: en_US
      reboot: False
      install_flags: '-ms'
      uninstaller: '%ProgramFiles(x86)%/Mozilla Firefox/uninstall/helper.exe'
      uninstall_flags: '/S'
```

More examples can be found here: https://github.com/saltstack/salt-winrepo

The version number and `full_name` need to match the output from `pkg.list_pkgs` so that the status can be verified when running `highstate`. Note: It is still possible to successfully install packages using `pkg.install` even if they don’t match which can make this hard to troubleshoot.

```
salt 'test-2008' pkg.list_pkgs
salt 'test-2008' pkg.list_pkgs
```

```
test-2008
----------
7-Zip 9.20 (x64 edition):
  9.20.00.0
Microsoft .NET Framework 4 Client Profile:
  4.0.30319, 4.0.30319
Microsoft .NET Framework 4 Extended:
  4.0.30319, 4.0.30319
Microsoft Visual C++ 2008 Redistributable - x64 9.0.21022:
  9.0.21022
Mozilla Firefox 17.0.1 (x86 en-US):
  17.0.1
Mozilla Maintenance Service:
```
If any of these preinstalled packages already exist in winrepo the full_name will be automatically renamed to their package name during the next update (running highstate or installing another package).

```
7zip:
9.20.00.0
Microsoft .NET Framework 4 Client Profile:
  4.0.30319,4.0.30319
Microsoft .NET Framework 4 Extended:
  4.0.30319,4.0.30319
Microsoft Visual C++ 2008 Redistributable - x64 9.0.21022:
  9.0.21022
Mozilla Maintenance Service:
  17.0.1
Notepad++:
  6.4.2
Salt Minion 0.16.0:
  0.16.0
```

Add `msiexec: True` if using an MSI installer requiring the use of `msiexec /i` to install and `msiexec /x` to uninstall.

The `install_flags` and `uninstall_flags` are flags passed to the software installer to cause it to perform a silent install. These can often be found by adding `/?` or `/h` when running the installer from the command line. A great resource for finding these silent install flags can be found on the WPKG project's wiki:

```
7zip:
9.20.00.0:
  installer: salt://win/repo/7zip/7z920-x64.msi
  full_name: 7-Zip 9.20 (x64 edition)
  reboot: False
  install_flags: '/qn /norestart'
  msiexec: True
  uninstaller: '{23170F69-40C1-2702-0920-000001000000}'
  uninstall_flags: '/qn /norestart'
```

Alternatively the `uninstaller` can also simply repeat the URL of the `.msi` file.

```
7zip:
9.20.00.0:
  installer: salt://win/repo/7zip/7z920-x64.msi
  full_name: 7-Zip 9.20 (x64 edition)
  reboot: False
  install_flags: '/qn /norestart'
  msiexec: True
  uninstaller: salt://win/repo/7zip/7z920-x64.msi
```

22.2. Usage
uninstall_flags: 'qn /norestart'

Add cache_dir: True when the installer requires multiple source files. The directory containing the installer file will be recursively cached on the minion. Only applies to salt: installer URLs.

```python
sqlexpress:
12.0.2000.8:
    installer: 'salt://win/repo/sqlexpress/setup.exe'
    full_name: Microsoft SQL Server 2014 Setup (English)
    reboot: False
    install_flags: '/ACTION=install /IACCEPTSQLSERVERLICENSETERMS /Q'
    cache_dir: True
```

### 22.3 Generate Repo Cache File

Once the sls file has been created, generate the repository cache file with the winrepo runner:

```
salt-run winrepo.genrepo
```

Beginning with the 2015.8.0 Salt release the repository cache is compiled on the Salt Minion. This allows for easy templating on the minion which allows for pillar, grains and other things to be available during compilation time. From 2015.8.0 forward the above `salt-run winrepo.genrepo` is only required for older minions. New minions should execute `salt * pkg.refresh_db` to update from the latest from the master's repo.

Then update the repository cache file on your minions, exactly how it's done for the Linux package managers:

```
salt winminion pkg.refresh_db
```

### 22.4 Install Windows Software

Now you can query the available version of Firefox using the Salt pkg module.

```
salt winminion pkg.available_version firefox
```

```json
{'firefox': {'15.0.1': 'Mozilla Firefox 15.0.1 (x86 en-US)',
             '16.0.2': 'Mozilla Firefox 16.0.2 (x86 en-US)',
             '17.0.1': 'Mozilla Firefox 17.0.1 (x86 en-US)'}
```

As you can see, there are three versions of Firefox available for installation. You can refer a software package by its name or its full_name surround by single quotes.

```
salt winminion pkg.install 'firefox'
```

The above line will install the latest version of Firefox.

```
salt winminion pkg.install 'firefox' version=16.0.2
```

The above line will install version 16.0.2 of Firefox.

If a different version of the package is already installed it will be replaced with the version in the winrepo (only if the package itself supports live updating).

You can also specify the full name:
22.5 Uninstall Windows Software

Uninstall software using the pkg module:

```
salt winminion pkg.remove firefox
salt winminion pkg.purge firefox
```

pkg.purge just executes pkg.remove on Windows. At some point in the future pkg.purge may direct the installer to remove all configs and settings for software packages that support that option.

22.6 Managing Windows Software on a Standalone Windows Minion

The examples above for managing the winrepo using the winrepo runner apply to the master, but some use cases call for running a standalone (a.k.a. masterless) minion on a Windows server. For these cases, the runner functions are not available, so an execution module exists to provide the same functionality to standalone minions. The functions are named the same as the ones in the runner, and are used in the same way; the only difference is that salt-call is used instead of salt-run:

```
salt-call winrepo.genrepo
salt-call pkg.refresh_db
```

Package definition SLS files need to be in the correct location for winrepo.genrepo to find them. This location is governed by minion config parameters. With much of Salt's Windows Repo code having been rewritten for version 2015.8.0, the parameter names will differ depending on which version the minion is running. The following two sections include information on additional configuration required when running a standalone minion.

22.7 Minion Config Options for Releases Older Than 2015.8.0

If connected to a master, the minion will by default look for the winrepo cachefile (the file generated by the :py:func`winrepo.genrepo runner <salt.runners.winrepo.genrepo>`) at salt://win/repo/winrepo.p. If the cachefile is in a different path on the salt fileserver, then win_repo_cachefile will need to be updated to reflect the proper location.

Note: Additional Info for Standalone Minions

Additional configuration needs to be added to the minion config:

```
win_repo: 'C:\path\to\win\repo'
```

This path still needs to be within the minion's file_roots, just as when managing the Windows Repo on the master.

22.8 Minion Config Options for Releases 2015.8.0 and Newer

The winrepo_source_dir config parameter (default: salt://win/repo) controls where pkg.refresh_db looks for the cachefile (default: winrepo.p). This means that the default location for
the winrepo cachefile would be `salt://win/repo/winrepo.p`. Both `winrepo_source_dir` and `winrepo_cachefile` can be adjusted to match the actual location of this file on the Salt fileserver.

**Note:** Additional Info for Standalone Minions

The above still holds true regarding `winrepo_source_dir`, the differences are that the minion's `file_roots` is where that `salt://` URL will resolve, and the `winrepo` execution module must be used to generate this cachefile.

If `file_roots` has not been modified in the minion configuration, then no additional configuration needs to be added to the minion configuration. The `winrepo.genrepo` function from the `winrepo` execution module will by default look for the filename specified by `winrepo_cachefile` within `C:\salt\srv\salt\win\repo`. If the `file_roots` parameter has been modified, then `winrepo_dir` must be modified to fall within that path, at the proper relative path. For example, if the base environment in `file_roots` points to `D:\foo`, and `winrepo_source_dir` is `salt://win/repo`, then `winrepo_dir` must be set to `D:\foo\win\repo` to ensure that `winrepo.genrepo` puts the cachefile into right location.

### 22.9 Maintaining Windows Repo Definitions in Git Repositories

Windows software package definitions can also be hosted in one or more git repositories. The default repository configured is hosted on GitHub.com by SaltStack, Inc. It includes package definitions for various open source software projects.

This repo points to the HTTP or ftp locations of the installer files. Anyone is welcome to send a pull request to this repo to add new package definitions. Browse the repo here: [https://github.com/saltstack/salt-winrepo.git](https://github.com/saltstack/salt-winrepo.git).

Configure which git repositories the master can search for package definitions by modifying or extending the `winrepo_remotes` option (NOTE: this option was called `win_gitrepos` in Salt versions prior to 2015.8.0).

Use the `winrepo.update_git_repos` runner to clone/update the configured repos, then use `winrepo.genrepo` runner to compile the repository cache. Finally, use `pkg.refresh_db` on each minion to have them update their copy of the repository cache. Command examples are as follows:

```bash
salt-run winrepo.update_git_repos
salt-run winrepo.genrepo
salt winminion pkg.refresh_db
```

For standalone minions, the usage would be slightly different:

```bash
salt-call winrepo.update_git_repos
salt-call winrepo.genrepo
salt-call pkg.refresh_db
```

### 22.10 Changes in Version 2015.8.0

#### 22.10.1 Config Parameters Renamed

Many of the winrepo configuration parameters have changed in version 2015.8.0 to make the naming more consistent. The old parameter names will still work, but a warning will be logged indicating that the old name is deprecated. Below are the parameters which have changed for version 2015.8.0:
Master Config

<table>
<thead>
<tr>
<th>Old Name</th>
<th>New Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>win_repo</td>
<td>winrepo_dir</td>
</tr>
<tr>
<td>win_repo_mastercachefile</td>
<td>winrepo_cachefile</td>
</tr>
<tr>
<td>win_gitrepos</td>
<td>winrepo_remotes</td>
</tr>
</tbody>
</table>

See [here](#) for detailed information on all master config options for the Windows Repo.

Minion Config

<table>
<thead>
<tr>
<th>Old Name</th>
<th>New Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>win_repo</td>
<td>winrepo_dir</td>
</tr>
<tr>
<td>win_repo_cachefile</td>
<td>winrepo_cachefile</td>
</tr>
<tr>
<td>win_gitrepos</td>
<td>winrepo_remotes</td>
</tr>
</tbody>
</table>

See [here](#) for detailed information on all minion config options for the Windows Repo.

### 22.10.2 pygit2/GitPython Support for Maintaining Git Repos

The `winrepo.update_git_repos` runner (and the corresponding remote execution function for standalone minions) now makes use of the same underlying code used by the `Git Fileserver Backend` and `Git External Pillar` to maintain and update its local clones of git repositories. If a compatible version of either `pygit2` (0.20.3 and later) or `GitPython` (0.3.0 or later) is installed, then Salt will use it instead of the old method (which invokes the `git.latest` state).

**Note:** If compatible versions of both `pygit2` and `GitPython` are installed, then Salt will prefer `pygit2`, to override this behavior use the `winrepo_provider` configuration parameter:

```
winrepo_provider: gitpython
```

The `winrepo` execution module (discussed above in the Managing Windows Software on a Standalone Windows Minion section) does not yet officially support the new pygit2/GitPython functionality, but if either `pygit2` or `GitPython` is installed into Salt’s bundled Python then it should work. However, it should be considered experimental at this time.

To minimize potential issues, it is a good idea to remove any winrepo git repositories that were checked out by the old (pre-2015.8.0) winrepo code when upgrading the master to 2015.8.0 or later, and run `winrepo.update_git_repos` to clone them anew after the master is started.

Additional added features include the ability to access authenticated git repositories (**NOTE:** `pygit2` only), and to set per-remote config settings. An example of this would be the following:

```
winrepo_remotes:
  - https://github.com/saltstack/salt-winrepo.git
  - git@github.com:myuser/myrepo.git:
    - pubkey: /path/to/key.pub
    - privkey: /path/to/key
    - passphrase: myaw3s0m3pa$$phr4$3
  - https://github.com/myuser/privaterepo.git:
    - user: mygithubuser
    - password: CorrectHorseBatteryStaple
```

**Note:** Per-remote configuration settings work in the same fashion as they do in gitfs, with global parameters being overridden by their per-remote counterparts (for instance, setting `winrepo_passphrase` would set a global
passphrase for winrepo that would apply to all SSH-based remotes, unless overridden by a passphrase per-remote parameter).

See here for more a more in-depth explanation of how per-remote configuration works in gitfs, the same principles apply to winrepo.

There are a couple other changes in how Salt manages git repos using pygit2/GitPython. First of all, a clean argument has been added to the winrepo.update_git_repos runner, which (if set to True) will tell the runner to dispose of directories under the winrepo_dir which are not explicitly configured. This prevents the need to manually remove these directories when a repo is removed from the config file. To clean these old directories, just pass clean=True, like so:

```
salt-run winrepo.update_git_repos clean=True
```

However, if a mix of git and non-git Windows Repo definition files are being used, then this should not be used, as it will remove the directories containing non-git definitions.

The other major change is that collisions between repo names are now detected, and the winrepo.update_git_repos runner will not proceed if any are detected. Consider the following configuration:

```
winrepo_remotes:
  - https://foo.com/bar/baz.git
  - https://mydomain.tld/baz.git
  - https://github.com/foobar/baz
```

The winrepo.update_git_repos runner will refuse to update repos here, as all three of these repos would be checked out to the same directory. To work around this, a per-remote parameter called name can be used to resolve these conflicts:

```
winrepo_remotes:
  - https://foo.com/bar/baz.git
  - https://mydomain.tld/baz.git:
    - name: baz_junior
  - https://github.com/foobar/baz:
    - name: baz_the_third
```

### 22.11 Troubleshooting

#### 22.11.1 Incorrect name/version

If the package seems to install properly, but salt reports a failure then it is likely you have a version or full_name mismatch.

Check the exact full_name and version used by the package. Use pkg.list_pkgs to check that the names and version exactly match what is installed.

#### 22.11.2 Changes to sls files not being picked up

Ensure you have (re)generated the repository cache file and then updated the repository cache on the relevant minions:

```
salt-run winrepo.genrepo
salt winminion pkg.refresh_db
```
22.11.3 Packages management under Windows 2003

On windows server 2003, you need to install optional windows component `wmi windows installer provider` to have full list of installed packages. If you don't have this, salt-minion can't report some installed software.
Windows-specific Behaviour

Salt is capable of managing Windows systems, however due to various differences between the operating systems, there are some things you need to keep in mind.

This document will contain any quirks that apply across Salt or generally across multiple module functions. Any Windows-specific behavior for particular module functions will be documented in the module function documentation. Therefore this document should be read in conjunction with the module function documentation.

### 23.1 Group parameter for files

Salt was originally written for managing Unix-based systems, and therefore the file module functions were designed around that security model. Rather than trying to shoehorn that model on to Windows, Salt ignores these parameters and makes non-applicable module functions unavailable instead.

One of the commonly ignored parameters is the group parameter for managing files. Under Windows, while files do have a 'primary group' property, this is rarely used. It generally has no bearing on permissions unless intentionally configured and is most commonly used to provide Unix compatibility (e.g. Services For Unix, NFS services).

Because of this, any file module functions that typically require a group, do not under Windows. Attempts to directly use file module functions that operate on the group (e.g. `file.chgrp`) will return a pseudo-value and cause a log message to appear. No group parameters will be acted on.

If you do want to access and change the 'primary group' property and understand the implications, use the `file.get_pgid` or `file.get_pgroup` functions or the `pgroup` parameter on the `file.chown` module function.

### 23.2 Dealing with case-insensitive but case-preserving names

Windows is case-insensitive, but however preserves the case of names and it is this preserved form that is returned from system functions. This causes some issues with Salt because it assumes case-sensitive names. These issues generally occur in the state functions and can cause bizarre looking errors.

To avoid such issues, always pretend Windows is case-sensitive and use the right case for names, e.g. specify `user=Administrator` instead of `user=administrator`.

Follow issue 11801 for any changes to this behavior.
23.3 Dealing with various username forms

Salt does not understand the various forms that Windows usernames can come in, e.g. username, mydomain\username, username@mydomain.tld can all refer to the same user. In fact, Salt generally only considers the raw username value, i.e. the username without the domain or host information.

Using these alternative forms will likely confuse Salt and cause odd errors to happen. Use only the raw username value in the correct case to avoid problems.

Follow issue 11801 for any changes to this behavior.

23.4 Specifying the None group

Each Windows system has built-in _None_ group. This is the default `primary group' for files for users not on a domain environment.

Unfortunately, the word _None_ has special meaning in Python - it is a special value indicating `nothing', similar to `null' or `nil' in other languages.

To specify the None group, it must be specified in quotes, e.g. ./salt '*' file.chgrp C:\path\to\file "'None'".

23.5 Symbolic link loops

Under Windows, if any symbolic link loops are detected or if there are too many levels of symlinks (defaults to 64), an error is always raised.

For some functions, this behavior is different to the behavior on Unix platforms. In general, avoid symlink loops on either platform.

23.6 Modifying security properties (ACLs) on files

There is no support in Salt for modifying ACLs, and therefore no support for changing file permissions, besides modifying the owner/user.
24.1 Getting Started

Salt Cloud is built-in to Salt and is configured on and executed from your Salt Master.

24.1.1 Define a Provider

The first step is to add the credentials for your cloud host. Credentials and other settings provided by the cloud host are stored in provider configuration files. Provider configurations contain the details needed to connect to a cloud host such as EC2, GCE, Rackspace, etc., and any global options that you want set on your cloud minions (such as the location of your Salt Master).

On your Salt Master, browse to `/etc/salt/cloud.providers.d/` and create a file called `<provider>.provider.conf`, replacing `<provider>` with `ec2`, `softlayer`, and so on. The name helps you identify the contents, and is not important as long as the file ends in `.conf`.

Next, browse to the `Provider specifics` and add any required settings for your cloud host to this file. Here is an example for Amazon EC2:

```
my-ec2:
  driver: ec2
  # Set the EC2 access credentials (see below)
  #
  id: 'HJGRVICLJLKJYJG'
  key: 'kdjgfgsm;woormgl/aserigjksjdhasdfgn'
  # Make sure this key is owned by root with permissions 0400.
  #
  private_key: /etc/salt/my_test_key.pem
  keyname: my_test_key
  securitygroup: default
  # Optional: Set up the location of the Salt Master
  #
  minion:
    master: saltmaster.example.com
```

The required configuration varies between cloud hosts so make sure you read the provider specifics.

24.1.2 List Cloud Provider Options

You can now query the cloud provider you configured for available locations, images, and sizes. This information is used when you set up VM profiles.
24.1.3 Create VM Profiles

On your Salt Master, browse to /etc/salt/cloud.profiles.d/ and create a file called <provider>.profiles.conf, replacing <provider> with ec2, softlayer, and so on. The file must end in .conf.

You can now add any custom profiles you’d like to define to this file. Here are a few examples:

```yaml
micro_ec2:
  provider: my-ec2
  image: ami-d514f291
  size: t1.micro

medium_ec2:
  provider: my-ec2
  image: ami-d514f291
  size: m3.medium

large_ec2:
  provider: my-ec2
  image: ami-d514f291
  size: m3.large
```

Notice that the provider in our profile matches the provider name that we defined? That is how Salt Cloud knows how to connect to create a VM with these attributes.

24.1.4 Create VMs

VMs are created by calling salt-cloud with the following options:

```
salt-cloud -p <profile> <name1> <name2> ...
```

For example:

```
salt-cloud -p micro_ec2 minion1 minion2
```

24.1.5 Destroy VMs

Add a -d and the minion name you provided to destroy:

```
salt-cloud -d minion1 minion2
```

24.1.6 Query VMs

You can view details about the VMs you’ve created using --query:
24.2 Using Salt Cloud

24.2.1 salt-cloud

Provision virtual machines in the cloud with Salt

Synopsis

salt-cloud -m /etc/salt/cloud.map
salt-cloud -m /etc/salt/cloud.map NAME
salt-cloud -m /etc/salt/cloud.map NAME1 NAME2
salt-cloud -p PROFILE NAME
salt-cloud -p PROFILE NAME1 NAME2 NAME3 NAME4 NAME5 NAME6

Description

Salt Cloud is the system used to provision virtual machines on various public clouds via a cleanly controlled profile and mapping system.

Options

--version
Print the version of Salt that is running.

--versions-report
Show program's dependencies and version number, and then exit

-h, --help
Show the help message and exit

-c CONFIG_DIR, --config-dir=CONFIG_dir
The location of the Salt configuration directory. This directory contains the configuration files for Salt master and minions. The default location on most systems is /etc/salt.

Execution Options

-L LOCATION, --location=LOCATION
Specify which region to connect to.

-a ACTION, --action=ACTION
Perform an action that may be specific to this cloud provider. This argument requires one or more instance names to be specified.
-f <FUNC-NAME> <PROVIDER>, --function=<FUNC-NAME> <PROVIDER>
    Perform an function that may be specific to this cloud provider, that does not apply to an instance. This argument requires a provider to be specified (i.e.: nova).

-p PROFILE, --profile=PROFILE
    Select a single profile to build the named cloud VMs from. The profile must be defined in the specified profiles file.

-m MAP, --map=MAP
    Specify a map file to use. If used without any other options, this option will ensure that all of the mapped VMs are created. If the named VM already exists then it will be skipped.

-H, --hard
    When specifying a map file, the default behavior is to ensure that all of the VMs specified in the map file are created. If the --hard option is set, then any VMs that exist on configured cloud providers that are not specified in the map file will be destroyed. Be advised that this can be a destructive operation and should be used with care.

-d, --destroy
    Pass in the name(s) of VMs to destroy, salt-cloud will search the configured cloud providers for the specified names and destroy the VMs. Be advised that this is a destructive operation and should be used with care. Can be used in conjunction with the -m option to specify a map of VMs to be deleted.

-P, --parallel
    Normally when building many cloud VMs they are executed serially. The -P option will run each cloud vm build in a separate process allowing for large groups of VMs to be build at once.

Be advised that some cloud provider’s systems don’t seem to be well suited for this influx of vm creation. When creating large groups of VMs watch the cloud provider carefully.

-u, --update-bootstrap
    Update salt-bootstrap to the latest develop version on GitHub.

-y, --assume-yes
    Default yes in answer to all confirmation questions.

-k, --keep-tmp
    Do not remove files from /tmp/ after deploy.sh finishes.

--show-deploy-args
    Include the options used to deploy the minion in the data returned.

--script-args=SCRIPT_ARGS
    Script arguments to be fed to the bootstrap script when deploying the VM.

Query Options

-Q, --query
    Execute a query and return some information about the nodes running on configured cloud providers.

-F, --full-query
    Execute a query and print out all available information about all cloud VMs. Can be used in conjunction with -m to display only information about the specified map.

-S, --select-query
    Execute a query and print out selected information about all cloud VMs. Can be used in conjunction with -m to display only information about the specified map.

--list-providers
    Display a list of configured providers.
**--list-profiles**

New in version 2014.7.0.

Display a list of configured profiles. Pass in a cloud provider to view the provider's associated profiles, such as `digital_ocean`, or pass `all` to list all the configured profiles.

**Cloud Providers Listings**

**--list-locations=LIST_LOCATIONS**

Display a list of locations available in configured cloud providers. Pass the cloud provider that available locations are desired on, aka `linode`, or pass `all` to list locations for all configured cloud providers

**--list-images=LIST_IMAGES**

Display a list of images available in configured cloud providers. Pass the cloud provider that available images are desired on, aka `linode`, or pass `all` to list images for all configured cloud providers

**--list-sizes=LIST_SIZES**

Display a list of sizes available in configured cloud providers. Pass the cloud provider that available sizes are desired on, aka `AWS`, or pass `all` to list sizes for all configured cloud providers

**Cloud Credentials**

**--set-password=<USERNAME> <PROVIDER>**

Configure password for a cloud provider and save it to the keyring. PROVIDER can be specified with or without a driver, for example: `--set-password bob rackspace`` or more specific `--set-password bob rackspace:openstack`` DEPRECATED!

**Output Options**

**--out**

Pass in an alternative outputer to display the return of data. This outputer can be any of the available outputers:

```
grains, highstate, json, key, overstatestage, pprint, raw, txt, yaml```

Some outputers are formatted only for data returned from specific functions; for instance, the `grains` outputer will not work for non-grains data.

If an outputer is used that does not support the data passed into it, then Salt will fall back on the `pprint` outputer and display the return data using the Python `pprint` standard library module.

**Note:** If using `--out=json`, you will probably want `--static` as well. Without the static option, you will get a separate JSON string per minion which makes JSON output invalid as a whole. This is due to using an iterative outputer. So if you want to feed it to a JSON parser, use `--static` as well.

**--out-indent** OUTPUT_INDENT, **--output-indent** OUTPUT_INDENT

Print the output indented by the provided value in spaces. Negative values disable indentation. Only applicable in outputers that support indentation.

**--out-file=OUTPUT_FILE, --output-file=OUTPUT_FILE**

Write the output to the specified file.

**--no-color**

Disable all colored output
--force-color
Force colored output

Note: When using colored output the color codes are as follows:
green denotes success, red denotes failure, blue denotes changes and success and yellow denotes a
expected future change in configuration.

Examples

To create 4 VMs named web1, web2, db1, and db2 from specified profiles:

```
salt-cloud -p fedora_rackspace web1 web2 db1 db2
```

To read in a map file and create all VMs specified therein:

```
salt-cloud -m /path/to/cloud.map
```

To read in a map file and create all VMs specified therein in parallel:

```
salt-cloud -m /path/to/cloud.map -P
```

To delete any VMs specified in the map file:

```
salt-cloud -m /path/to/cloud.map -d
```

To delete any VMs NOT specified in the map file:

```
salt-cloud -m /path/to/cloud.map -H
```

To display the status of all VMs specified in the map file:

```
salt-cloud -m /path/to/cloud.map -Q
```

salt-cloud(7) salt(7) salt-master(1) salt-minion(1)

24.2.2 Salt Cloud basic usage

Salt Cloud needs, at least, one configured Provider and Profile to be functional.

Creating a VM

To create a VM with salt cloud, use command:

```
salt-cloud -p <profile> name_of_vm
```

Assuming there is a profile configured as following:

```
fedora_rackspace:
    provider: my-rackspace-config
    image: Fedora 17
    size: 256 server
    script: bootstrap-salt
```
Then, the command to create new VM named `fedora_http_01` is:

```bash
salt-cloud -p fedora_rackspace fedora_http_01
```

Destroying a VM

To destroy a created-by-salt-cloud VM, use command:

```bash
salt-cloud -d name_of_vm
```

For example, to delete the VM created on above example, use:

```bash
salt-cloud -d fedora_http_01
```

### 24.2.3 VM Profiles

Salt cloud designates virtual machines inside the profile configuration file. The profile configuration file defaults to `/etc/salt/cloud.profiles` and is a yaml configuration. The syntax for declaring profiles is simple:

```yaml
fedora_rackspace:
    provider: my-rackspace-config
    image: Fedora 17
    size: 256 server
    script: bootstrap-salt
```

It should be noted that the `script` option defaults to `bootstrap-salt`, and does not normally need to be specified. Further examples in this document will not show the `script` option.

A few key pieces of information need to be declared and can change based on the cloud provider. A number of additional parameters can also be inserted:

```yaml
centos_rackspace:
    provider: my-rackspace-config
    image: CentOS 6.2
    size: 1024 server
    minion:
        master: salt.example.com
        append_domain: webs.example.com
        grains:
            role: webserver
```

The image must be selected from available images. Similarly, sizes must be selected from the list of sizes. To get a list of available images and sizes use the following command:

```bash
salt-cloud --list-images openstack
salt-cloud --list-sizes openstack
```

Some parameters can be specified in the main Salt cloud configuration file and then are applied to all cloud profiles. For instance if only a single cloud provider is being used then the provider option can be declared in the Salt cloud configuration file.

### Multiple Configuration Files

In addition to `/etc/salt/cloud.profiles`, profiles can also be specified in any file matching `cloud.profiles.d/*conf` which is a sub-directory relative to the profiles configuration file(with the above
configuration file as an example, /etc/salt/cloud.profiles.d/*.*conf). This allows for more extensible configuration, and plays nicely with various configuration management tools as well as version control systems.

**Larger Example**

```
rhel_ec2:
  provider: my-ec2-config
  image: ami-e565ba8c
  size: t1.micro
  minion:
    cheese: edam

ubuntu_ec2:
  provider: my-ec2-config
  image: ami-7e2da54e
  size: t1.micro
  minion:
    cheese: edam

ubuntu_rackspace:
  provider: my-rackspace-config
  image: Ubuntu 12.04 LTS
  size: 256 server
  minion:
    cheese: edam

fedora_rackspace:
  provider: my-rackspace-config
  image: Fedora 17
  size: 256 server
  minion:
    cheese: edam

cent_linode:
  provider: my-linode-config
  image: CentOS 6.2 64bit
  size: Linode 512

cent_gogrid:
  provider: my-gogrid-config
  image: 12834
  size: 512MB

cent_joyent:
  provider: my-joyent-config
  image: centos-6
  size: Small 1GB
```

### 24.2.4 Cloud Map File

A number of options exist when creating virtual machines. They can be managed directly from profiles and the command line execution, or a more complex map file can be created. The map file allows for a number of virtual machines to be created and associated with specific profiles.

Map files have a simple format, specify a profile and then a list of virtual machines to make from said profile:
This map file can then be called to roll out all of these virtual machines. Map files are called from the salt-cloud command with the -m option:

```bash
$ salt-cloud -m /path/to/mapfile
```

Remember, that as with direct profile provisioning the -P option can be passed to create the virtual machines in parallel:

```bash
$ salt-cloud -m /path/to/mapfile -P
```

**Note:** Due to limitations in the GoGrid API, instances cannot be provisioned in parallel with the GoGrid driver. Map files will work with GoGrid, but the -P argument should not be used on maps referencing GoGrid instances.

A map file can also be enforced to represent the total state of a cloud deployment by using the --hard option. When using the hard option any vms that exist but are not specified in the map file will be destroyed:

```bash
$ salt-cloud -m /path/to/mapfile -P -H
```

Be careful with this argument, it is very dangerous! In fact, it is so dangerous that in order to use it, you must explicitly enable it in the main configuration file.

```
enable_hard_maps: True
```

A map file can include grains and minion configuration options:

```
fedora_small:
- web1:
  minion:
    log_level: debug
  grains:
    cheese: tasty
    omelet: du fromage
- web2:
  minion:
    log_level: warn
  grains:
    cheese: more tasty
    omelet: with peppers
```

A map file may also be used with the various query options:

```bash
$ salt-cloud -m /path/to/mapfile -Q

{'ec2': {'web1': {'id': 'i-e6aqfegb',
  'image': None,
  'private_ips': []},
```
```python

'public_ips': [],
'size': None,
'state': 0},
'web2': {'Absent'}}

...or with the delete option:

```
$ salt-cloud -m /path/to/mapfile -d
```

The following virtual machines are set to be destroyed:

```
web1
web2
```

Proceed? [N/y]

**Warning**: Specifying Nodes with Maps on the Command Line

Specifying the name of a node or nodes with the maps options on the command line is not supported. This is especially important to remember when using `--destroy` with maps; `salt-cloud` will ignore any arguments passed in which are not directly relevant to the map file. *When using `--destroy` with a map, every node in the map file will be deleted!* Maps don’t provide any useful information for destroying individual nodes, and should not be used to destroy a subset of a map.

### Setting up New Salt Masters

Bootstrapping a new master in the map is as simple as:

```yaml
fedora_small:
  - web1:
    make_master: True
  - web2
  - web3
```

Notice that **ALL** bootstrapped minions from the map will answer to the newly created salt-master.

To make any of the bootstrapped minions answer to the bootstrapping salt-master as opposed to the newly created salt-master, as an example:

```yaml
fedora_small:
  - web1:
    make_master: True
    minion:
      master: <the local master ip address>
      local_master: True
  - web2
  - web3
```

The above says the minion running on the newly created salt-master responds to the local master, ie, the master used to bootstrap these VMs.

Another example:

```yaml
fedora_small:
  - web1:
    make_master: True
  - web2
  - web3:
    minion:
      master: <the local master ip address>
      local_master: True
```
The above example makes the web3 minion answer to the local master, not the newly created master.

### 24.2.5 Cloud Actions

Once a VM has been created, there are a number of actions that can be performed on it. The "reboot" action can be used across all providers, but all other actions are specific to the cloud provider. In order to perform an action, you may specify it from the command line, including the name(s) of the VM to perform the action on:

```
$ salt-cloud -a reboot vm_name
$ salt-cloud -a reboot vm1 vm2 vm2
```

Or you may specify a map which includes all VMs to perform the action on:

```
$ salt-cloud -a reboot -m /path/to/mapfile
```

The following is a list of actions currently supported by salt-cloud:

<table>
<thead>
<tr>
<th>Provider</th>
<th>Actions</th>
</tr>
</thead>
<tbody>
<tr>
<td>All</td>
<td>reboot</td>
</tr>
<tr>
<td>EC2</td>
<td>start, stop</td>
</tr>
<tr>
<td>Joyent</td>
<td>stop</td>
</tr>
<tr>
<td>Linode</td>
<td>start, stop</td>
</tr>
</tbody>
</table>

Another useful reference for viewing more salt-cloud actions is the [Salt Cloud Feature Matrix](salt-cloud-feature-matrix).

### 24.2.6 Cloud Functions

Cloud functions work much the same way as cloud actions, except that they don't perform an operation on a specific instance, and so do not need a machine name to be specified. However, since they perform an operation on a specific cloud provider, that provider must be specified.

```
$ salt-cloud -f show_image ec2 image=ami-fd20ad94
```

There are three universal salt-cloud functions that are extremely useful for gathering information about instances on a provider basis:

- **list_nodes**: Returns some general information about the instances for the given provider.
- **list_nodes_full**: Returns all information about the instances for the given provider.
- **list_nodes_select**: Returns select information about the instances for the given provider.

```
$ salt-cloud -f list_nodes linode
$ salt-cloud -f list_nodes_full linode
$ salt-cloud -f list_nodes_select linode
```

Another useful reference for viewing salt-cloud functions is the [Salt Cloud Feature Matrix](salt-cloud-feature-matrix).
24.3 Core Configuration

24.3.1 Install Salt Cloud

Salt Cloud is now part of Salt proper. It was merged in as of Salt version 2014.1.0.

On Ubuntu, install Salt Cloud by using following command:

```bash
sudo add-apt-repository ppa:saltstack/salt
sudo apt-get update
sudo apt-get install salt-cloud
```

If using Salt Cloud on OS X, `curl-ca-bundle` must be installed. Presently, this package is not available via `brew`, but it is available using MacPorts:

```bash
sudo port install curl-ca-bundle
```

Salt Cloud depends on `apache-libcloud`. Libcloud can be installed via `pip` with `pip install apache-libcloud`.

Installing Salt Cloud for development

Installing Salt for development enables Salt Cloud development as well, just make sure `apache-libcloud` is installed as per above paragraph.

See these instructions: Installing Salt for development.

24.3.2 Core Configuration

A number of core configuration options and some options that are global to the VM profiles can be set in the cloud configuration file. By default this file is located at `/etc/salt/cloud`.

**Thread Pool Size**

When salt cloud is operating in parallel mode via the `-P` argument, you can control the thread pool size by specifying the `pool_size` parameter with a positive integer value.

By default, the thread pool size will be set to the number of VMs that salt cloud is operating on.

```yaml
pool_size: 10
```

**Minion Configuration**

The default minion configuration is set up in this file. Minions created by salt-cloud derive their configuration from this file. Almost all parameters found in Configuring the Salt Minion can be used here.

```yaml
minion:
  master: saltmaster.example.com
```

In particular, this is the location to specify the location of the salt master and its listening port, if the port is not set to the default.
Cloud Configuration Syntax

The data specific to interacting with public clouds is set up here.

Cloud provider configuration settings can live in several places. The first is in /etc/salt/cloud:

```bash
# /etc/salt/cloud
providers:
  my-aws-migrated-config:
    id: HJGRYCILJKJYG
    key: kdjgfsgm;woormgl/aserigjksjhasdfgn
    keyname: test
    securitygroup: quick-start
    private_key: /root/test.pem
    driver: ec2
```

Cloud provider configuration data can also be housed in /etc/salt/cloud.providers or any file matching /etc/salt/cloud.providers.d/*.conf. All files in any of these locations will be parsed for cloud provider data.

Using the example configuration above:

```bash
# /etc/salt/cloud.providers
# or could be /etc/salt/cloud.providers.d/*.conf
my-aws-config:
  id: HJGRYCILJKJYG
  key: kdjgfsgm;woormgl/aserigjksjhasdfgn
  keyname: test
  securitygroup: quick-start
  private_key: /root/test.pem
  driver: ec2
```

**Note:** Salt Cloud provider configurations within /etc/cloud.provider.d/ should not specify the `providers` starting key.

It is also possible to have multiple cloud configuration blocks within the same alias block. For example:

```bash
production-config:
  - id: HJGRYCILJKJYG
    key: kdjgfsgm;woormgl/aserigjksjhasdfgn
    keyname: test
    securitygroup: quick-start
    private_key: /root/test.pem
    driver: ec2

  - user: example_user
    apikey: 123984bjjas87034
    driver: rackspace
```

However, using this configuration method requires a change with profile configuration blocks. The provider alias needs to have the provider key value appended as in the following example:

```bash
rhel_aws_dev:
  provider: production-config:ec2
  image: ami-e565ba8c
  size: t1.micro

rhel_aws_prod:
  provider: production-config:ec2
```

24.3. Core Configuration 263
Notice that because of the multiple entries, one has to be explicit about the provider alias and name, from the above example, `production-config: ec2`.

This data interacts with the `salt-cloud` binary regarding its `--list-location`, `--list-images`, and `--list-sizes` which needs a cloud provider as an argument. The argument used should be the configured cloud provider alias. If the provider alias has multiple entries, `<provider-alias>`: `<provider-name>` should be used.

To allow for a more extensible configuration, `--providers-config`, which defaults to `/etc/salt/cloud.providers`, was added to the cli parser. It allows for the providers’ configuration to be added on a per-file basis.

**Pillar Configuration**

It is possible to configure cloud providers using pillars. This is only used when inside the cloud module. You can setup a variable called `cloud` that contains your profile and provider to pass that information to the cloud servers instead of having to copy the full configuration to every minion. In your pillar file, you would use something like this:

```yaml
cloud:
  ssh_key_name: saltstack
  ssh_key_file: /root/.ssh/id_rsa
  update_cachedir: True
  diff_cache_events: True
  change_password: True

providers:
  my-nova:
    identity_url: https://identity.api.rackspacecloud.com/v2.0/
    compute_region: IAD
    user: myuser
    api_key: apikey
    tenant: 123456
    driver: nova

  my-openstack:
    identity_url: https://identity.api.rackspacecloud.com/v2.0/tokens
    user: user2
    apikey: apikey2
    tenant: 654321
    compute_region: DFW
    driver: openstack
    compute_name: cloudServersOpenStack

profiles:
  ubuntu-nova:
    provider: my-nova
    size: performance1-8
    image: bb02b1a3-bc77-4d17-ab5b-421d89850fca
```
Cloud Configurations

Scaleway

To use Salt Cloud with Scaleway, you need to get an access key and an API token. API tokens are unique identifiers associated with your Scaleway account. To retrieve your access key and API token, log-in to the Scaleway control panel, open the pull-down menu on your account name and click on "My Credentials" link.

If you do not have API token you can create one by clicking the "Create New Token" button on the right corner.

my-scaleway-config:
  access_key: 15cf404d-4560-41b1-9a0c-21c3d5c4ff1f
  token: a7347ec8-5de1-4024-a5e3-24b77d1ba91d
  driver: scaleway

Note: In the cloud profile that uses this provider configuration, the syntax for the provider required field would be provider: my-scaleway-config.

Rackspace

Rackspace cloud requires two configuration options; a user and an apikey:

my-rackspace-config:
  user: example_user
  apikey: 123984bjjas87034
  driver: rackspace

Note: In the cloud profile that uses this provider configuration, the syntax for the provider required field would be provider: my-rackspace-config.

Amazon AWS

A number of configuration options are required for Amazon AWS including id, key, keyname, security-group, and private_key:

my-aws-quick-start:
  id: HJGRYCILLJLKJVG
  key: 'kdjgfsmg;woormgl/aserigjksjdhhasdfgn'
  keyname: test
  securitygroup: quick-start
  private_key: /root/test.pem
  driver: ec2
my-aws-default:
  id: HJGRYCILJLKJYG
  key: 'kdjgfsmg;woormgl/aserigjksjdhasdfgn'
  keyname: test
  securitygroup: default
  private_key: /root/test.pem
  driver: ec2

Note: In the cloud profile that uses this provider configuration, the syntax for the provider required field would be either provider: my-aws-quick-start or provider: my-aws-default.

Linode

Linode requires a single API key, but the default root password also needs to be set:

my-linode-config:
  apikey: asldkgfakl;sdfjsjaslfjaklsdjf;askldjfaaksjdflhsalsdfgfhdfk
  password: F00barbaz
  ssh_pubkey: ssh-ed25519 AAAAC3NzaC1lZDI1NTE5AAAIAIKHEOLLbeXgaqRQT9NBAopVz366SdYc0KKX33WAnq+2R user@host
  ssh_key_file: ~/.ssh/id_ed25519
  driver: linode

The password needs to be 8 characters and contain lowercase, uppercase, and numbers.

Note: In the cloud profile that uses this provider configuration, the syntax for the provider required field would be provider: my-linode-config

Joyent Cloud

The Joyent cloud requires three configuration parameters: The username and password that are used to log into the Joyent system, as well as the location of the private SSH key associated with the Joyent account. The SSH key is needed to send the provisioning commands up to the freshly created virtual machine.

my-joyent-config:
  user: fred
  password: saltybacon
  private_key: /root/joyent.pem
  driver: joyent

Note: In the cloud profile that uses this provider configuration, the syntax for the provider required field would be provider: my-joyent-config

GoGrid

To use Salt Cloud with GoGrid, log into the GoGrid web interface and create an API key. Do this by clicking on "My Account" and then going to the API Keys tab.

The apikey and the sharedsecret configuration parameters need to be set in the configuration file to enable interfacing with GoGrid:
my-gogrid-config:
  apikey: asdff7896asdh789
  sharedsecret: saltybacon
  driver: gogrid

Note: In the cloud profile that uses this provider configuration, the syntax for the provider required field would be provider: my-gogrid-config.

OpenStack

OpenStack configuration differs between providers, and at the moment several options need to be specified. This module has been officially tested against the HP and the Rackspace implementations, and some examples are provided for both.

# For HP
my-openstack-hp-config:
  compute_name: Compute
  compute_region: 'az-1.region-a.geo-1'
  tenant: myuser-tenant1
  user: myuser
  ssh_key_name: mykey
  ssh_key_file: '/etc/salt/hpcloud/mykey.pem'
  password: mypass
  driver: openstack

# For Rackspace
my-openstack-rackspace-config:
  identity_url: 'https://identity.api.rackspacecloud.com/v2.0/tokens'
  compute_name: cloudServersOpenStack
  protocol: ipv4
  compute_region: DFW
  protocol: ipv4
  user: myuser
  tenant: 5555555
  password: mypass
  driver: openstack

If you have an API key for your provider, it may be specified instead of a password:

my-openstack-hp-config:
  apikey: 901d3f579h23c8v73q9

my-openstack-rackspace-config:
  apikey: 901d3f579h23c8v73q9

Note: In the cloud profile that uses this provider configuration, the syntax for the provider required field would be either provider: my-openstack-hp-config or provider: my-openstack-rackspace-config.

You will certainly need to configure the user, tenant, and either password or apikey.

If your OpenStack instances only have private IP addresses and a CIDR range of private addresses are not reachable from the salt-master, you may set your preference to have Salt ignore it.
my-openstack-config:
  ignore_cidr: 192.168.0.0/16

For in-house OpenStack Essex installation, libcloud needs the service_type:

my-openstack-config:
  identity_url: 'http://control.openstack.example.org:5000/v2.0/
  compute_name : Compute Service
  service_type : compute

DigitalOcean

Using Salt for DigitalOcean requires a client_key and an api_key. These can be found in the DigitalOcean web interface, in the ```My Settings``` section, under the API Access tab.

my-digitalocean-config:
  driver: digital_ocean
  personal_access_token: xxx
  location: New York 1

Note: In the cloud profile that uses this provider configuration, the syntax for the provider required field would be 
  ```provider: my-digital-ocean-config```.

Parallels

Using Salt with Parallels requires a user, password and URL. These can be obtained from your cloud provider.

my-parallels-config:
  user: myuser
  password: xyzzy
  url: https://api.cloud.xmission.com:4465/paci/v1.0/
  driver: parallels

Note: In the cloud profile that uses this provider configuration, the syntax for the provider required field would be 
  ```provider: my-parallels-config```.

Proxmox

Using Salt with Proxmox requires a user, password, and URL. These can be obtained from your cloud host. Both 
PAM and PVE users can be used.

my-proxmox-config:
  driver: proxmox
  user: saltcloud@pve
  password: xyzzy
  url: your.proxmox.host

Note: In the cloud profile that uses this provider configuration, the syntax for the provider required field would be 
  ```provider: my-proxmox-config```.
LXC

The lxc driver uses saltify to install salt and attach the lxc container as a new lxc minion. As soon as we can, we manage baremetal operation over SSH. You can also destroy those containers via this driver.

```
devhost10-lxc:
  target: devhost10
  driver: lxc
```

And in the map file:

```
devhost10-lxc:
  provider: devhost10-lxc
  from_container: ubuntu
  backing: lvm
  sudo: True
  size: 3g
  ip: 10.0.3.9
  minion:
    master: 10.5.0.1
    master_port: 4506
  lxc_conf:
    - lxc.utsname: superlxc
```

Note: In the cloud profile that uses this provider configuration, the syntax for the provider required field would be `provider: devhost10-lxc`.

Saltify

The Saltify driver is a new, experimental driver designed to install Salt on a remote machine, virtual or bare metal, using SSH. This driver is useful for provisioning machines which are already installed, but not Salted. For more information about using this driver and for configuration examples, please see the Getting Started with Saltify documentation.

Extending Profiles and Cloud Providers Configuration

As of 0.8.7, the option to extend both the profiles and cloud providers configuration and avoid duplication was added. The extends feature works on the current profiles configuration, but, regarding the cloud providers configuration, only works in the new syntax and respective configuration files, i.e. `/etc/salt/salt/cloud.providers` or `/etc/salt/cloud.providers.d/*.conf`.

Note: Extending cloud profiles and providers is not recursive. For example, a profile that is extended by a second profile is possible, but the second profile cannot be extended by a third profile.

Also, if a profile (or provider) is extending another profile and each contains a list of values, the lists from the extending profile will override the list from the original profile. The lists are not merged together.

Extending Profiles

Some example usage on how to use `extends` with profiles. Consider `/etc/salt/salt/cloud.profiles` containing:
development-instances:
  provider: my-ec2-config
  size: t1.micro
  ssh_username: ec2_user
  securitygroup:
    - default
  deploy: False

Amazon-Linux-AMI-2012.09-64bit:
  image: ami-54cf5c3d
  extends: development-instances

Fedora-17:
  image: ami-08d97e61
  extends: development-instances

CentOS-5:
  provider: my-aws-config
  image: ami-09b61d60
  extends: development-instances

The above configuration, once parsed would generate the following profiles data:

```json
[{
  'deploy': False,
  'image': 'ami-08d97e61',
  'profile': 'Fedora-17',
  'provider': 'my-ec2-config',
  'securitygroup': ['default'],
  'size': 't1.micro',
  'ssh_username': 'ec2_user'},
{
  'deploy': False,
  'image': 'ami-09b61d60',
  'profile': 'CentOS-5',
  'provider': 'my-aws-config',
  'securitygroup': ['default'],
  'size': 't1.micro',
  'ssh_username': 'ec2_user'},
{
  'deploy': False,
  'image': 'ami-54cf5c3d',
  'profile': 'Amazon-Linux-AMI-2012.09-64bit',
  'provider': 'my-ec2-config',
  'securitygroup': ['default'],
  'size': 't1.micro',
  'ssh_username': 'ec2_user'},
{
  'deploy': False,
  'profile': 'development-instances',
  'provider': 'my-ec2-config',
  'securitygroup': ['default'],
  'size': 't1.micro',
  'ssh_username': 'ec2_user']
```

Pretty cool right?

## Extending Providers

Some example usage on how to use `extends` within the cloud providers configuration. Consider `/etc/salt/salt/cloud.providers` containing:
my-develop-envs:
- id: HJGRYCIILJKJYG
  key: 'kdjgfsgm;woormgl/aserigksjdhasdfgn'
  keyname: test
  securitygroup: quick-start
  private_key: /root/test.pem
  location: ap-southeast-1
  availability_zone: ap-southeast-1b
  driver: ec2
- user: myuser@mycorp.com
  password: mypass
  ssh_key_name: mykey
  ssh_key_file: '/etc/salt/ibm/mykey.pem'
  location: Raleigh
  driver: ibmsce

my-productions-envs:
- extends: my-develop-envs:ibmsce
  user: my-production-user@mycorp.com
  location: us-east-1
  availability_zone: us-east-1

The above configuration, once parsed would generate the following providers data:

```python
'providers': {
    'my-develop-envs': [
        {'availability_zone': 'ap-southeast-1b',
         'id': 'HJGRYCIILJKJYG',
         'key': 'kdjgfsgm;woormgl/aserigksjdhasdfgn',
         'keyname': 'test',
         'location': 'ap-southeast-1',
         'private_key': '/root/test.pem',
         'driver': 'aws',
         'securitygroup': 'quick-start'},
        {'location': 'Raleigh',
         'password': 'mypass',
         'driver': 'ibmsce',
         'ssh_key_file': '/etc/salt/ibm/mykey.pem',
         'ssh_key_name': 'mykey',
         'user': 'myuser@mycorp.com'},
    ],
    'my-productions-envs': [
        {'availability_zone': 'us-east-1',
         'location': 'us-east-1',
         'password': 'mypass',
         'driver': 'ibmsce',
         'ssh_key_file': '/etc/salt/ibm/mykey.pem',
         'ssh_key_name': 'mykey',
         'user': 'my-production-user@mycorp.com'}
    ]
}
```
24.4 Windows Configuration

24.4.1 Spinning up Windows Minions

It is possible to use Salt Cloud to spin up Windows instances, and then install Salt on them. This functionality is available on all cloud providers that are supported by Salt Cloud. However, it may not necessarily be available on all Windows images.

Requirements

Salt Cloud makes use of `impacket` and `winexe` to set up the Windows Salt Minion installer.

`impacket` is usually available as either the `impacket` or the `python-impacket` package, depending on the distribution. More information on `impacket` can be found at the project home:

- `impacket` project home

`winexe` is less commonly available in distribution-specific repositories. However, it is currently being built for various distributions in 3rd party channels:

- RPMs at phone.net
- OpenSuse Build Service

Optionally WinRM can be used instead of `winexe` if the python module `pywinrm` is available and WinRM is supported on the target Windows version. Information on `pywinrm` can be found at the project home:

- `pywinrm` project home

Additionally, a copy of the Salt Minion Windows installer must be present on the system on which Salt Cloud is running. This installer may be downloaded from saltstack.com:

- SaltStack Download Area

Firewall Settings

Because Salt Cloud makes use of `smbclient` and `winexe`, port 445 must be open on the target image. This port is not generally open by default on a standard Windows distribution, and care must be taken to use an image in which this port is open, or the Windows firewall is disabled.

If supported by the cloud provider, a PowerShell script may be used to open up this port automatically, using the cloud provider’s `userdata`. The following script would open up port 445, and apply the changes:

```powershell
New-NetFirewallRule -Name "SMB445" -DisplayName "SMB445" -Protocol TCP -LocalPort 445
Set-Item (dir wsman:\localhost\Listener\*\Port -Recurse).pspath 445 -Force
Restart-Service winrm
</powershell>
```

For EC2, this script may be saved as a file, and specified in the provider or profile configuration as `userdata_file`. For instance:

```
userdata_file: /etc/salt/windows-firewall.ps1
```
Configuration

Configuration is set as usual, with some extra configuration settings. The location of the Windows installer on the machine that Salt Cloud is running on must be specified. This may be done in any of the regular configuration files (main, providers, profiles, maps). For example:

Setting the installer in `/etc/salt/cloud.providers`:

```
my-softlayer:
    driver: softlayer
    user: MYUSER1138
    apikey: 'e3b68aa711e6deadc62d5b76355674beef7cc3116062ddbaa6e5f7e4655bdfdc9'
    minion:
        master: saltmaster.example.com
    win_installer: /root/Salt-Minion-2014.7.0-AMD64-Setup.exe
    win_username: Administrator
    win_password: letmein
    smb_port: 445
```

The default Windows user is *Administrator*, and the default Windows password is blank.

If WinRM is to be used `use_winrm` needs to be set to *True*.

Auto-Generated Passwords on EC2

On EC2, when the `win_password` is set to *auto*, Salt Cloud will query EC2 for an auto-generated password. This password is expected to take at least 4 minutes to generate, adding additional time to the deploy process.

When the EC2 API is queried for the auto-generated password, it will be returned in a message encrypted with the specified `keyname`. This requires that the appropriate `private_key` file is also specified. Such a profile configuration might look like:

```
windows-server-2012:
    provider: my-ec2-config
    image: ami-c49c0dac
    size: m1.small
    securitygroup: windows
    keyname: mykey
    private_key: /root/mykey.pem
    userdata_file: /etc/salt/windows-firewall.ps1
    win_installer: /root/Salt-Minion-2014.7.0-AMD64-Setup.exe
    win_username: Administrator
    win_password: auto
```

24.5 Cloud Provider Specifics

24.5.1 Getting Started With Aliyun ECS

The Aliyun ECS (Elastic Computer Service) is one of the most popular public cloud hosts in China. This cloud host can be used to manage aliyun instance using salt-cloud.

http://www.aliyun.com/
Dependencies

This driver requires the Python requests library to be installed.

Configuration

Using Salt for Aliyun ECS requires aliyun access key id and key secret. These can be found in the aliyun web interface, in the `User Center` section, under `My Service` tab.

```
# Note: This example is for /etc/salt/cloud.providers or any file in the
# /etc/salt/cloud.providers.d/ directory.

my-aliyun-config:
  # aliyun Access Key ID
  id: wDGzWregedg3435gDgxd
  # aliyun Access Key Secret
  key: GDd45t43RDBTrkkkg43934t34qT43t4dgegerGEgg
  location: cn-qingdao
  driver: aliyun
```

**Note:** Changed in version 2015.8.0.

The `provider` parameter in cloud provider definitions was renamed to `driver`. This change was made to avoid confusion with the `provider` parameter that is used in cloud profile definitions. Cloud provider definitions now use `driver` to refer to the Salt cloud module that provides the underlying functionality to connect to a cloud host, while cloud profiles continue to use `provider` to refer to provider configurations that you define.

Profiles

Cloud Profiles

Set up an initial profile at `/etc/salt/cloud.profiles` or in the `/etc/salt/cloud.profiles.d/` directory:

```
aliyun_centos:
  provider: my-aliyun-config
  size: ecs.t1.small
  location: cn-qingdao
  securitygroup: G1989096784427999
  image: centos6u3_64_20G_aliaegis_20130816.vhd
```

Sizes can be obtained using the `--list-sizes` option for the `salt-cloud` command:

```
# salt-cloud --list-sizes my-aliyun-config
my-aliyun-config:
  --------
  aliyun:
  --------
  ecs.c1.large:
  ---------
  CpuCoreCount:
  8
  InstanceTypeId:
  ecs.c1.large
  MemorySize:
```

Chapter 24. Salt Cloud
Images can be obtained using the `--list-images` option for the `salt-cloud` command:

```bash
# salt-cloud --list-images my-aliyun-config
my-aliyun-config:
    ---------
    aliyun:
    ---------
    centos5u8_64_20G_aliaegis_20131231.vhd:
    ---------
    Architecture: x86_64
    Description:
    ImageId: centos5u8_64_20G_aliaegis_20131231.vhd
    ImageName: CentOS 5.8 64
    ImageOwnerAlias: system
    ImageVersion: 1.0
    OSName: CentOS 5.8 64
    Platform: CENTOS5
    Size: 20
    Visibility: public
```

Locations can be obtained using the `--list-locations` option for the `salt-cloud` command:

```bash
my-aliyun-config:
    ---------
    aliyun:
    ---------
    cn-beijing:
    ---------
    LocalName: 
    RegionId: cn-beijing
    cn-hangzhou:
    ---------
    LocalName: 
    RegionId: cn-hangzhou
    cn-hongkong:
    ---------
    LocalName: 
    RegionId: cn-hongkong
```
cn-qingdao:
    --------
    LocalName: cn-qingdao
    RegionId: cn-qingdao

Security Group can be obtained using the `-f list_securitygroup` option for the `salt-cloud` command:

```bash
# salt-cloud --location=cn-qingdao -f list_securitygroup my-aliyun-config
my-aliyun-config:
    --------
    aliyun:
        --------
        G1989096784427999:
            --------
            Description: G1989096784427999
            SecurityGroupId: G1989096784427999
```

Note: Aliyun ECS REST API documentation is available from [Aliyun ECS API](http://www.aliyun.com/).

### 24.5.2 Getting Started With Azure

New in version 2014.1.0.

Azure is a cloud service by Microsoft providing virtual machines, SQL services, media services, and more. This document describes how to use Salt Cloud to create a virtual machine on Azure, with Salt installed.

**Dependencies**

- The [Azure Python SDK] >= 0.11.1.
- The `python-requests` library, for Python < 2.7.9.
- A Microsoft Azure account
- OpenSSL (to generate the certificates)
- Salt

**Configuration**

Set up the provider config at `/etc/salt/cloud.providers.d/azure.conf`:

```bash
# Note: This example is for /etc/salt/cloud.providers.d/azure.conf
my-azure-config:
    driver: azure
    subscription_id: 3287abc8-f98a-c678-3bde-326766fd3617
    certificate_path: /etc/salt/azure.pem

    # Set up the location of the salt master
```
```
#
minion:
    master: saltmaster.example.com

# Optional
management_host: management.core.windows.net
```

The certificate used must be generated by the user. OpenSSL can be used to create the management certificates. Two certificates are needed: a .cer file, which is uploaded to Azure, and a .pem file, which is stored locally.

To create the .pem file, execute the following command:

```bash
openssl req -x509 -nodes -days 365 -newkey rsa:1024 -keyout /etc/salt/azure.pem -out /etc/salt/azure.pem
```

To create the .cer file, execute the following command:

```bash
openssl x509 -inform pem -in /etc/salt/azure.pem -outform der -out /etc/salt/azure.cer
```

After creating these files, the .cer file will need to be uploaded to Azure via the ``Upload a Management Certificate`` action of the ``Management Certificates`` tab within the ``Settings`` section of the management portal.

Optionally, a `management_host` may be configured, if necessary for the region.

**Note:** Changed in version 2015.8.0.

The `provider` parameter in cloud provider definitions was renamed to `driver`. This change was made to avoid confusion with the `provider` parameter that is used in cloud profile definitions. Cloud provider definitions now use `driver` to refer to the Salt cloud module that provides the underlying functionality to connect to a cloud host, while cloud profiles continue to use `provider` to refer to provider configurations that you define.

**Cloud Profiles**

Set up an initial profile at `/etc/salt/cloud.profiles`:

```
azure-ubuntu:
    provider: my-azure-config
    image: 'b39f27a8b8c64d52b05eac6a62ebad85__Ubuntu-12_04_3-LTS-amd64-server-20131003-en-us-30GB'
    size: Small
    location: 'East US'
    ssh_username: azureuser
    ssh_password: verybadpass
    slot: production
    media_link: 'http://portalvhdabcdefghijklmn.blob.core.windows.net/vhds'
```

These options are described in more detail below. Once configured, the profile can be realized with a salt command:

```bash
salt-cloud -p azure-ubuntu newinstance
```

This will create an salt minion instance named `newinstance` in Azure. If the command was executed on the salt-master, its Salt key will automatically be signed on the master.

Once the instance has been created with salt-minion installed, connectivity to it can be verified with Salt:

```bash
salt newinstance test.ping
```
Profile Options

The following options are currently available for Azure.

**provider**

The name of the provider as configured in `/etc/salt/cloud.providers.d/azure.conf`.

**image**

The name of the image to use to create a VM. Available images can be viewed using the following command:

```
salt-cloud --list-images my-azure-config
```

**size**

The name of the size to use to create a VM. Available sizes can be viewed using the following command:

```
salt-cloud --list-sizes my-azure-config
```

**location**

The name of the location to create a VM in. Available locations can be viewed using the following command:

```
salt-cloud --list-locations my-azure-config
```

**affinity_group**

The name of the affinity group to create a VM in. Either a location or an affinity_group may be specified, but not both. See Affinity Groups below.

**ssh_username**

The user to use to log into the newly-created VM to install Salt.

**ssh_password**

The password to use to log into the newly-created VM to install Salt.

**slot**

The environment to which the hosted service is deployed. Valid values are staging or production. When set to production, the resulting URL of the new VM will be `<vm_name>.cloudapp.net`. When set to staging, the resulting URL will contain a generated hash instead.
media_link

This is the URL of the container that will store the disk that this VM uses. Currently, this container must already exist. If a VM has previously been created in the associated account, a container should already exist. In the web interface, go into the Storage area and click one of the available storage selections. Click the Containers link, and then copy the URL from the container that will be used. It generally looks like:

```
http://portalvhdabcdefghijklmnop.blob.core.windows.net/vhds
```

service_name

The name of the service in which to create the VM. If this is not specified, then a service will be created with the same name as the VM.

Show Instance

This action is a thin wrapper around `--full-query`, which displays details on a single instance only. In an environment with several machines, this will save a user from having to sort through all instance data, just to examine a single instance.

```
salt-cloud -a show_instance myinstance
```

Destroying VMs

There are certain options which can be specified in the global cloud configuration file (usually `/etc/salt/cloud`) which affect Salt Cloud’s behavior when a VM is destroyed.

cleanup_disks

New in version 2015.8.0.
Default is `False`. When set to `True`, Salt Cloud will wait for the VM to be destroyed, then attempt to destroy the main disk that is associated with the VM.

cleanup_vhds

New in version 2015.8.0.
Default is `False`. Requires `cleanup_disks` to be set to `True`. When also set to `True`, Salt Cloud will ask Azure to delete the VHD associated with the disk that is also destroyed.

cleanup_services

New in version 2015.8.0.
Default is `False`. Requires `cleanup_disks` to be set to `True`. When also set to `True`, Salt Cloud will wait for the disk to be destroyed, then attempt to remove the service that is associated with the VM. Because the disk belongs to the service, the disk must be destroyed before the service can be.
Managing Hosted Services

New in version 2015.8.0.

An account can have one or more hosted services. A hosted service is required in order to create a VM. However, as mentioned above, if a hosted service is not specified when a VM is created, then one will automatically be created with the name of the name. The following functions are also available.

create_service

Create a hosted service. The following options are available.

name  Required. The name of the hosted service to create.

label  Required. A label to apply to the hosted service.

description  Optional. A longer description of the hosted service.

location  Required, if affinity_group is not set. The location in which to create the hosted service. Either the location or the affinity_group must be set, but not both.

affinity_group  Required, if location is not set. The affinity group in which to create the hosted service. Either the location or the affinity_group must be set, but not both.

extended_properties  Optional. Dictionary containing name/value pairs of hosted service properties. You can have a maximum of 50 extended property name/value pairs. The maximum length of the Name element is 64 characters, only alphanumeric characters and underscores are valid in the Name, and the name must start with a letter. The value has a maximum length of 255 characters.

CLI Example  The following example illustrates creating a hosted service.

```
salt-cloud -f create_service my-azure name=my-service label=my-service location='West US'
```

show_service

Return details about a specific hosted service. Can also be called with get_service.

```
salt-cloud -f show_storage my-azure name=my-service
```

list_services

List all hosted services associates with the subscription.

```
salt-cloud -f list_services my-azure-config
```
**delete_service**

Delete a specific hosted service.

```
salt-cloud -f delete_service my-azure name=my-service
```

**Managing Storage Accounts**

New in version 2015.8.0.

Salt Cloud can manage storage accounts associated with the account. The following functions are available. Deprecated marked as deprecated are marked as such as per the SDK documentation, but are still included for completeness with the SDK.

**create_storage**

Create a storage account. The following options are supported.

- **name**  Required. The name of the storage account to create.
- **label**  Required. A label to apply to the storage account.
- **description**  Optional. A longer description of the storage account.
- **location**  Required, if **affinity_group** is not set. The location in which to create the storage account. Either the **location** or the **affinity_group** must be set, but not both.
- **affinity_group**  Required, if **location** is not set. The affinity group in which to create the storage account. Either the **location** or the **affinity_group** must be set, but not both.
- **extended_properties**  Optional. Dictionary containing name/value pairs of storage account properties. You can have a maximum of 50 extended property name/value pairs. The maximum length of the Name element is 64 characters, only alphanumeric characters and underscores are valid in the Name, and the name must start with a letter. The value has a maximum length of 255 characters.
- **geo_replication_enabled**  Deprecated. Replaced by the **account_type** parameter.
- **account_type**  Specifies whether the account supports locally-redundant storage, geo-redundant storage, zone-redundant storage, or read access geo-redundant storage. Possible values are:
  - Standard_LRS
  - Standard_ZRS
  - Standard_GRS
  - Standard_RAGRS
CLI Example  The following example illustrates creating a storage account.

```
salt-cloud -f create_storage my-azure name=my-storage label=my-storage location='West US'
```

**list_storage**

List all storage accounts associates with the subscription.

```
salt-cloud -f list_storage my-azure-config
```

**show_storage**

Return details about a specific storage account. Can also be called with get_storage.

```
salt-cloud -f show_storage my-azure name=my-storage
```

**update_storage**

Update details concerning a storage account. Any of the options available in create_storage can be used, but the name cannot be changed.

```
salt-cloud -f update_storage my-azure name=my-storage label=my-storage
```

**delete_storage**

Delete a specific storage account.

```
salt-cloud -f delete_storage my-azure name=my-storage
```

**show_storage_keys**

Returns the primary and secondary access keys for the specified storage account.

```
salt-cloud -f show_storage_keys my-azure name=my-storage
```

**regenerate_storage_keys**

Regenerate storage account keys. Requires a key_type (``primary'' or ``secondary'') to be specified.

```
salt-cloud -f regenerate_storage_keys my-azure name=my-storage key_type=primary
```

**Managing Disks**

New in version 2015.8.0.

When a VM is created, a disk will also be created for it. The following functions are available for managing disks. Deprecated marked as deprecated are marked as such as per the SDK documentation, but are still included for completeness with the SDK.
show_disk

Return details about a specific disk. Can also be called with get_disk.

```
salt-cloud -f show_disk my-azure name=my-disk
```

list_disks

List all disks associates with the account.

```
salt-cloud -f list_disks my-azure
```

update_disk

Update details for a disk. The following options are available.

- name  Required. The name of the disk to update.
- has_operating_system  Deprecated.
- label  Required. The label for the disk.
- media_link  Deprecated. The location of the disk in the account, including the storage container that it is in. This should not need to be changed.
- new_name  Deprecated. If renaming the disk, the new name.
- os  Deprecated.

**CLI Example**  The following example illustrates updating a disk.

```
salt-cloud -f update_disk my-azure name=my-disk label=my-disk
```

delete_disk

Delete a specific disk.

```
salt-cloud -f delete_disk my-azure name=my-disk
```

Managing Service Certificates

New in version 2015.8.0.

Stored at the cloud service level, these certificates are used by your deployed services. For more information on service certificates, see the following link:

- Manage Certificates
The following functions are available.

**list_service_certificates**

List service certificates associated with the account.

```bash
salt-cloud -f list_service_certificates my-azure
```

**show_service_certificate**

Show the data for a specific service certificate associated with the account. The name, thumbprint, and thumbalgorithm can be obtained from `list_service_certificates`. Can also be called with `get_service_certificate`.

```bash
salt-cloud -f show_service_certificate my-azure name=my_service_certificate \   thumbalgorithm=sha1 thumbprint=0123456789ABCDEF
```

**add_service_certificate**

Add a service certificate to the account. This requires that a certificate already exists, which is then added to the account. For more information on creating the certificate itself, see:

- Create a Service Certificate for Azure

The following options are available.

- **name** Required. The name of the hosted service that the certificate will belong to.

- **data** Required. The base-64 encoded form of the pfx file.

- **certificate_format** Required. The service certificate format. The only supported value is pfx.

- **password** The certificate password.

```bash
salt-cloud -f add_service_certificate my-azure name=my-cert \   data='...CERT_DATA...' certificate_format=pfx password=verybadpass
```

**delete_service_certificate**

Delete a service certificate from the account. The name, thumbprint, and thumbalgorithm can be obtained from `list_service_certificates`.

```bash
salt-cloud -f delete_service_certificate my-azure \   name=my_service_certificate \   thumbalgorithm=sha1 thumbprint=0123456789ABCDEF
```
Managing Management Certificates

New in version 2015.8.0.

A Azure management certificate is an X.509 v3 certificate used to authenticate an agent, such as Visual Studio Tools for Windows Azure or a client application that uses the Service Management API, acting on behalf of the subscription owner to manage subscription resources. Azure management certificates are uploaded to Azure and stored at the subscription level. The management certificate store can hold up to 100 certificates per subscription. These certificates are used to authenticate your Windows Azure deployment.

For more information on management certificates, see the following link.

- Manage Certificates

The following functions are available.

list_management_certificates

List management certificates associated with the account.

```
salt-cloud -f list_management_certificates my-azure
```

show_management_certificate

Show the data for a specific management certificate associated with the account. The name, thumbprint, and thumbalgorithm can be obtained from list_management_certificates. Can also be called with get_management_certificate.

```
salt-cloud -f show_management_certificate my-azure name=my_management_certificate \ 
   thumbalgorithm=sha1 thumbprint=0123456789ABCDEF
```

add_management_certificate

Management certificates must have a key length of at least 2048 bits and should reside in the Personal certificate store. When the certificate is installed on the client, it should contain the private key of the certificate. To upload to the certificate to the Microsoft Azure Management Portal, you must export it as a .cer format file that does not contain the private key. For more information on creating management certificates, see the following link:

- Create and Upload a Management Certificate for Azure

The following options are available.

```
public_key  A base64 representation of the management certificate public key.

thumbprint  The thumbprint that uniquely identifies the management certificate.

data  The certificate's raw data in base-64 encoded .cer format.
```

```
salt-cloud -f add_management_certificate my-azure public_key='...PUBKEY...' \ 
   thumbprint=0123456789ABCDEF data='...CERT_DATA...'
```
delete_management_certificate

Delete a management certificate from the account. The thumbprint can be obtained from list_management_certificates.

```
salt-cloud -f delete_management_certificate my-azure thumbprint=0123456789ABCDEF
```

Virtual Network Management

New in version 2015.8.0.
The following are functions for managing virtual networks.

list_virtual_networks

List input endpoints associated with the deployment.

```
salt-cloud -f list_virtual_networks my-azure service=myservice deployment=mydeployment
```

Managing Input Endpoints

New in version 2015.8.0.
Input endpoints are used to manage port access for roles. Because endpoints cannot be managed by the Azure Python SDK, Salt Cloud uses the API directly. With versions of Python before 2.7.9, the requests-python package needs to be installed in order for this to work. Additionally, the following needs to be set in the master’s configuration file:

```
requests_lib: True
```

The following functions are available.

list_input_endpoints

List input endpoints associated with the deployment

```
salt-cloud -f list_input_endpoints my-azure service=myservice deployment=mydeployment
```

show_input_endpoint

Show an input endpoint associated with the deployment

```
salt-cloud -f show_input_endpoint my-azure service=myservice deployment=mydeployment name=SSH
```

add_input_endpoint

Add an input endpoint to the deployment. Please note that there may be a delay before the changes show up. The following options are available.

```
service  Required. The name of the hosted service which the VM belongs to.
```
deployment Required. The name of the deployment that the VM belongs to. If the VM was created with Salt Cloud, the deployment name probably matches the VM name.

role Required. The name of the role that the VM belongs to. If the VM was created with Salt Cloud, the role name probably matches the VM name.

name Required. The name of the input endpoint. This typically matches the port that the endpoint is set to. For instance, port 22 would be called SSH.

port Required. The public (Internet-facing) port that is used for the endpoint.

local_port Optional. The private port on the VM itself that will be matched with the port. This is typically the same as the port. If this value is not specified, it will be copied from port.

protocol Required. Either tcp or udp.

enable_direct_server_return Optional. If an internal load balancer exists in the account, it can be used with a direct server return. The default value is False. Please see the following article for an explanation of this option.

- Load Balancing for Azure Infrastructure Services

timeout_for_tcp_idle_connection Optional. The default value is 4. Please see the following article for an explanation of this option.

- Configurable Idle Timeout for Azure Load Balancer

CLI Example The following example illustrates adding an input endpoint.

```bash
salt-cloud -f add_input_endpoint my-azure service=myservice \
    deployment=mydeployment role=myrole name=HTTP local_port=80 \
    port=80 protocol=tcp enable_direct_server_return=False \
    timeout_for_tcp_idle_connection=4
```

update_input_endpoint

Updates the details for a specific input endpoint. All options from add_input_endpoint are supported.

```bash
salt-cloud -f update_input_endpoint my-azure service=myservice \
    deployment=mydeployment role=myrole name=HTTP local_port=80 \
    port=80 protocol=tcp enable_direct_server_return=False \
    timeout_for_tcp_idle_connection=4
```

delete_input_endpoint

Delete an input endpoint from the deployment. Please note that there may be a delay before the changes show up. The following items are required.

CLI Example The following example illustrates deleting an input endpoint.
service  The name of the hosted service which the VM belongs to.

deployment  The name of the deployment that the VM belongs to. If the VM was created with Salt Cloud, the deployment name probably matches the VM name.

role  The name of the role that the VM belongs to. If the VM was created with Salt Cloud, the role name probably matches the VM name.

name  The name of the input endpoint. This typically matches the port that the endpoint is set to. For instance, port 22 would be called SSH.

Managing Affinity Groups

New in version 2015.8.0.

Affinity groups allow you to group your Azure services to optimize performance. All services and VMs within an affinity group will be located in the same region. For more information on Affinity groups, see the following link:

- Create an Affinity Group in the Management Portal

The following functions are available.

list_affinity_groups

List input endpoints associated with the account

salt-cloud -f list_affinity_groups my-azure

show_affinity_group

Show an affinity group associated with the account

salt-cloud -f show_affinity_group my-azure service=myservice \\
    deployment=mydeployment role=myrole name=HTTP

create_affinity_group

Create a new affinity group. The following options are supported.

name  Required. The name of the new affinity group.

location  Required. The region in which the affinity group lives.

label  Required. A label describing the new affinity group.
description  Optional. A longer description of the affinity group.

```
salt-cloud -f create_affinity_group my-azure name=my_affinity_group 
   label=my-affinity-group location='West US'
```

update_affinity_group

Update an affinity group's properties

```
salt-cloud -f update_affinity_group my-azure name=my_group label=my_group
```

delete_affinity_group

Delete a specific affinity group associated with the account

```
salt-cloud -f delete_affinity_group my-azure name=my_affinity_group
```

Managing Blob Storage

New in version 2015.8.0.

Azure storage containers and their contents can be managed with Salt Cloud. This is not as elegant as using one of the other available clients in Windows, but it benefits Linux and Unix users, as there are fewer options available on those platforms.

Blob Storage Configuration

Blob storage must be configured differently than the standard Azure configuration. Both a `storage_account` and a `storage_key` must be specified either through the Azure provider configuration (in addition to the other Azure configuration) or via the command line.

```
storage_account: mystorage
storage_key: ffhj334fDSGFEGDFDewr34fwfsFSDFwe==
```

`storage_account`  This is one of the storage accounts that is available via the `list_storage` function.

`storage_key`  Both a primary and a secondary `storage_key` can be obtained by running the `show_storage_keys` function. Either key may be used.

Blob Functions

The following functions are made available through Salt Cloud for managing blob storage.

```
make_blob_url  Creates the URL to access a blob

salt-cloud -f make_blob_url my-azure container=mycontainer blob=myblob
```

`container`  Name of the container.
blob Name of the blob.

account Name of the storage account. If not specified, derives the host base from the provider configuration.

protocol Protocol to use: 'http' or 'https'. If not specified, derives the host base from the provider configuration.

host_base Live host base URL. If not specified, derives the host base from the provider configuration.

list_storage_containers List containers associated with the storage account

```
salt-cloud -f list_storage_containers my-azure
```

create_storage_container Create a storage container

```
salt-cloud -f create_storage_container my-azure name=mycontainer
```

name Name of container to create.

meta_name_values Optional. A dict with name_value pairs to associate with the container as metadata. Example:{'Category': 'test'}

blob_public_access Optional. Possible values include: container, blob

fail_on_exist Specify whether to throw an exception when the container exists.

show_storage_container Show a container associated with the storage account

```
salt-cloud -f show_storage_container my-azure name=myservice
```

name Name of container to show.

show_storage_container_metadata Show a storage container’s metadata

```
salt-cloud -f show_storage_container_metadata my-azure name=myservice
```

name Name of container to show.

lease_id If specified, show_storage_container_metadata only succeeds if the container’s lease is active and matches this ID.

set_storage_container_metadata Set a storage container’s metadata

```
salt-cloud -f set_storage_container my-azure name=mycontainer
   x_ms_meta_name_values='{"my_name": "my_value"}'
```
**name**  Name of existing container.  `meta_name_values`  A dict containing name, value for metadata.  Example:  `{"category":"test"}`  

**lease_id**  If specified, `set_storage_container_metadata` only succeeds if the container’s lease is active and matches this ID.

**show_storage_container_acl**  Show a storage container’s acl

```
salt-cloud -f show_storage_container_acl my-azure name=myservice
```

**name**  Name of existing container.

**lease_id**  If specified, `show_storage_container_acl` only succeeds if the container’s lease is active and matches this ID.

**set_storage_container_acl**  Set a storage container’s acl

```
salt-cloud -f set_storage_container my-azure name=mycontainer
```

**name**  Name of existing container.

**signed_identifiers**  SignedIdentifiers instance

**blob_public_access**  Optional. Possible values include: container, blob

**lease_id**  If specified, `set_storage_container_acl` only succeeds if the container’s lease is active and matches this ID.

**delete_storage_container**  Delete a container associated with the storage account

```
salt-cloud -f delete_storage_container my-azure name=mycontainer
```

**name**  Name of container to create.

**fail_not_exist**  Specify whether to throw an exception when the container exists.

**lease_id**  If specified, `delete_storage_container` only succeeds if the container’s lease is active and matches this ID.

**lease_storage_container**  Lease a container associated with the storage account

```
salt-cloud -f lease_storage_container my-azure name=mycontainer
```

**name**  Name of container to create.

**lease_action**  Required. Possible values: acquire|renew|release|break|change

**lease_id**  Required if the container has an active lease.
lease_duration  Specifies the duration of the lease, in seconds, or negative one (-1) for a lease that never expires. A non-infinite lease can be between 15 and 60 seconds. A lease duration cannot be changed using renew or change. For backwards compatibility, the default is 60, and the value is only used on an acquire operation.

lease_break_period  Optional. For a break operation, this is the proposed duration of seconds that the lease should continue before it is broken, between 0 and 60 seconds. This break period is only used if it is shorter than the time remaining on the lease. If longer, the time remaining on the lease is used. A new lease will not be available before the break period has expired, but the lease may be held for longer than the break period. If this header does not appear with a break operation, a fixed-duration lease breaks after the remaining lease period elapses, and an infinite lease breaks immediately.

proposed_lease_id  Optional for acquire, required for change. Proposed lease ID, in a GUID string format.

list_blobs  List blobs associated with the container

salt-cloud -f list_blobs my-azure container=mycontainer

container  The name of the storage container

prefix  Optional. Filters the results to return only blobs whose names begin with the specified prefix.

marker  Optional. A string value that identifies the portion of the list to be returned with the next list operation. The operation returns a marker value within the response body if the list returned was not complete. The marker value may then be used in a subsequent call to request the next set of list items. The marker value is opaque to the client.

maxresults  Optional. Specifies the maximum number of blobs to return, including all BlobPrefix elements. If the request does not specify maxresults or specifies a value greater than 5,000, the server will return up to 5,000 items. Setting maxresults to a value less than or equal to zero results in error response code 400 (Bad Request).

include  Optional. Specifies one or more datasets to include in the response. To specify more than one of these options on the URI, you must separate each option with a comma. Valid values are:

- snapshots:
  Specifies that snapshots should be included in the enumeration. Snapshots are listed from oldest to newest in the response.
- metadata:
  Specifies that blob metadata be returned in the response.
- uncommittedblobs:
  Specifies that blobs for which blocks have been uploaded, but which have not been committed using Put Block List (REST API), be included in the response.
- copy:
  Version 2012-02-12 and newer. Specifies that metadata related to any current or previous Copy Blob operation should be included in the response.
delimiter

Optional. When the request includes this parameter, the operation returns a BlobPrefix element in the response body that acts as a placeholder for all blobs whose names begin with the same substring up to the appearance of the delimiter character. The delimiter may be a single character or a string.

**show_blob_service_properties**  
Show a blob’s service properties

```
salt-cloud -f show_blob_service_properties my-azure
```

**set_blob_service_properties**  
Sets the properties of a storage account's Blob service, including Windows Azure Storage Analytics. You can also use this operation to set the default request version for all incoming requests that do not have a version specified.

```
salt-cloud -f set_blob_service_properties my-azure
```

**properties**  
a StorageServiceProperties object.

**timeout**  
Optional. The timeout parameter is expressed in seconds.

**show_blob_properties**  
Returns all user-defined metadata, standard HTTP properties, and system properties for the blob.

```
salt-cloud -f show_blob_properties my-azure container=mycontainer blob=myblob
```

**container**  
Name of existing container.

**blob**  
Name of existing blob.

**lease_id**  
Required if the blob has an active lease.

**set_blob_properties**  
Set a blob’s properties

```
salt-cloud -f set_blob_properties my-azure
```

**container**  
Name of existing container.

**blob**  
Name of existing blob.

**blob_cache_control**  
Optional. Modifies the cache control string for the blob.

**blob_content_type**  
Optional. Sets the blob’s content type.

**blob_content_md5**  
Optional. Sets the blob’s MD5 hash.

**blob_content_encoding**  
Optional. Sets the blob’s content encoding.
**blob_content_language**  Optional. Sets the blob's content language.

**lease_id**  Required if the blob has an active lease.

**blob_content_disposition**  Optional. Sets the blob's Content-Disposition header. The Content-Disposition response header field conveys additional information about how to process the response payload, and also can be used to attach additional metadata. For example, if set to attachment, it indicates that the user-agent should not display the response, but instead show a Save As dialog with a filename other than the blob name specified.

**put_blob**  Upload a blob

```
salt-cloud -f put_blob my-azure container=base name=top.sls blob_path=/srv/salt/top.sls
salt-cloud -f put_blob my-azure container=base name=content.txt blob_content='Some content'
```

**container**  Name of existing container.

**name**  Name of existing blob.

**blob_path**  The path on the local machine of the file to upload as a blob. Either this or blob_content must be specified.

**blob_content**  The actual content to be uploaded as a blob. Either this or blob_path must me specified.

**cache_control**  Optional. The Blob service stores this value but does not use or modify it.

**content_language**  optional. Specifies the natural languages used by this resource.

**content_md5**  Optional. An MD5 hash of the blob content. This hash is used to verify the integrity of the blob during transport. When this header is specified, the storage service checks the hash that has arrived with the one that was sent. If the two hashes do not match, the operation will fail with error code 400 (Bad Request).

**blob_content_type**  Optional. Set the blob's content type.

**blob_content_encoding**  Optional. Set the blob's content encoding.

**blob_content_language**  Optional. Set the blob's content language.

**blob_content_md5**  Optional. Set the blob's MD5 hash.

**blob_cache_control**  Optional. Sets the blob's cache control.

**meta_name_values**  A dict containing name, value for metadata.
lease_id  Required if the blob has an active lease.

get_blob  Download a blob

salt-cloud -f get_blob my-azure container=base name=top.sls local_path=/srv/salt/top.sls
salt-cloud -f get_blob my-azure container=base name=content.txt return_content=True

container  Name of existing container.

name  Name of existing blob.

local_path  The path on the local machine to download the blob to. Either this or return_content must be specified.

return_content  Whether or not to return the content directly from the blob. If specified, must be True or False. Either this or the local_path must be specified.

snapshot  Optional. The snapshot parameter is an opaque DateTime value that, when present, specifies the blob snapshot to retrieve.

lease_id  Required if the blob has an active lease.

progress_callback  callback for progress with signature function(current, total) where current is the number of bytes transferred so far, and total is the size of the blob.

max_connections  Maximum number of parallel connections to use when the blob size exceeds 64MB. Set to 1 to download the blob chunks sequentially. Set to 2 or more to download the blob chunks in parallel. This uses more system resources but will download faster.

max_retries  Number of times to retry download of blob chunk if an error occurs.

retry_wait  Sleep time in secs between retries.

24.5.3 Getting Started With DigitalOcean

DigitalOcean is a public cloud host that specializes in Linux instances.

Configuration

Using Salt for DigitalOcean requires a personal_access_token, an ssh_key_file, and at least one SSH key name in ssh_key_names. More ssh_key_names can be added by separating each key with a comma. The personal_access_token can be found in the DigitalOcean web interface in the "Apps & API" section. The SSH key name can be found under the "SSH Keys" section.
# Note: This example is for /etc/salt/cloud.providers or any file in the
# /etc/salt/cloud.providers.d/ directory.

my-digitalocean-config:
  driver: digital_ocean
  personal_access_token: xxx
  ssh_key_file: /path/to/ssh/key/file
  ssh_key_names: my-key-name,my-key-name-2
  location: New York 1

Note: Changed in version 2015.8.0.

The provider parameter in cloud provider definitions was renamed to driver. This change was made to avoid confusion with the provider parameter that is used in cloud profile definitions. Cloud provider definitions now use driver to refer to the Salt cloud module that provides the underlying functionality to connect to a cloud host, while cloud profiles continue to use provider to refer to provider configurations that you define.

Profiles

Cloud Profiles

Set up an initial profile at /etc/salt/cloud.profiles or in the /etc/salt/cloud.profiles.d/ directory:

digitalocean-ubuntu:
  provider: my-digitalocean-config
  image: Ubuntu 14.04 x32
  size: 512MB
  location: New York 1
  private_networking: True
  backups_enabled: True
  ipv6: True

Locations can be obtained using the --list-locations option for the salt-cloud command:

# salt-cloud --list-locations my-digitalocean-config
my-digitalocean-config:
  ---------
  digital_ocean:
  ---------
  Amsterdam 1:
  ---------
  available:
  False
  features:
    [u'backups']
  name:
    Amsterdam 1
  sizes:
    []
  slug:
    ams1

...SNIP...

Sizes can be obtained using the --list-sizes option for the salt-cloud command:
Images can be obtained using the `--list-images` option for the `salt-cloud` command:

```bash
# salt-cloud --list-images my-digitalocean-config
my-digitalocean-config:
  digital_ocean:
    Arch Linux 2013.05 x64:
      distribution: Arch Linux
      id: 350424
      name: Arch Linux 2013.05 x64
      public: True
      slug: None
```

**Note:** DigitalOcean's concept of Applications is nothing more than a pre-configured instance (same as a normal Droplet). You will find examples such as Docker 0.7 Ubuntu 13.04 x64 and Wordpress on Ubuntu 12.10 when using the `--list-images` option. These names can be used just like the rest of the standard instances when specifying an image in the cloud profile configuration.

**Note:** If your domain's DNS is managed with DigitalOcean, you can automatically create A-records for newly created droplets. Use `create_dns_record: True` in your config to enable this. Add `delete_dns_record: True` to also delete records when a droplet is destroyed.

**Note:** Additional documentation is available from DigitalOcean.
24.5.4 Getting Started With AWS EC2

Amazon EC2 is a very widely used public cloud platform and one of the core platforms Salt Cloud has been built to support.

Previously, the suggested driver for AWS EC2 was the `aws` driver. This has been deprecated in favor of the `ec2` driver. Configuration using the old `aws` driver will still function, but that driver is no longer in active development.

Dependencies

This driver requires the Python `requests` library to be installed.

Configuration

The following example illustrates some of the options that can be set. These parameters are discussed in more detail below.

```yaml
# Note: This example is for /etc/salt/cloud.providers or any file in the
# /etc/salt/cloud.providers.d/ directory.

my-ec2-southeast-public-ips:
    # Set up the location of the salt master
    #
    minion:
        master: saltmaster.example.com

    # Set up grains information, which will be common for all nodes
    # using this provider
    grains:
        node_type: broker
        release: 1.0.1

    # Specify whether to use public or private IP for deploy script.
    #
    # Valid options are:
    #   private_ips - The salt-cloud command is run inside the EC2
    #   public_ips - The salt-cloud command is run outside of EC2
    #
    ssh_interface: public_ips

    # Optionally configure the Windows credential validation number of
    # retries and delay between retries. This defaults to 10 retries
    # with a one second delay between retries
    win_deploy_auth_retries: 10
    win_deploy_auth_retry_delay: 1

    # Set the EC2 access credentials (see below)
    #
    id: 'use-instance-role-credentials'
    key: 'use-instance-role-credentials'

    # Make sure this key is owned by root with permissions 0400.
```

private_key: /etc/salt/my_test_key.pem
driver: ec2

my-ec2-southeast-private-ips:
  # Set up the location of the salt master
  #
  minion:
    master: saltmaster.example.com

  # Specify whether to use public or private IP for deploy script.
  #
  # Valid options are:
  #   private_ips - The salt-master is also hosted with EC2
  #   public_ips - The salt-master is hosted outside of EC2
  #
  ssh_interface: private_ips

  # Optionally configure the Windows credential validation number of
  # retries and delay between retries. This defaults to 10 retries
  # with a one second delay between retries
  win_deploy_auth_retries: 10
  win_deploy_auth_retry_delay: 1

  # Set the EC2 access credentials (see below)
  #
  id: 'use-instance-role-credentials'
  key: 'use-instance-role-credentials'

  # Make sure this key is owned by root with permissions 0400.
  #
  private_key: /etc/salt/my_test_key.pem
  keyname: my_test_key
This one should NOT be specified if VPC was not configured in AWS to be the default. It might cause an error message which says that network interfaces and an instance-level security groups may not be specified on the same request.

```
securitygroup: default
```

# Optionally configure default region

```
location: ap-southeast-1
availability_zone: ap-southeast-1b
```

Configure which user to use to run the deploy script. This setting is dependent upon the AMI that is used to deploy. It is usually safer to configure this individually in a profile, than globally. Typical users are:

```
# Amazon Linux -> ec2-user
# RHEL            -> ec2-user
# CentOS          -> ec2-user
# Ubuntu          -> ubuntu
```

```
ssh_username: ec2-user
```

# Optionally add an IAM profile

```
iam_profile: 'my other profile name'
```

```
driver: ec2
```

**Note:** Changed in version 2015.8.0.

The `provider` parameter in cloud provider definitions was renamed to `driver`. This change was made to avoid confusion with the `provider` parameter that is used in cloud profile definitions. Cloud provider definitions now use `driver` to refer to the Salt cloud module that provides the underlying functionality to connect to a cloud host, while cloud profiles continue to use `provider` to refer to provider configurations that you define.

## Access Credentials

The `id` and `key` settings may be found in the Security Credentials area of the AWS Account page:

https://portal.aws.amazon.com/gp/aws/securityCredentials

Both are located in the Access Credentials area of the page, under the Access Keys tab. The `id` setting is labeled Access Key ID, and the `key` setting is labeled Secret Access Key.

Note: if either `id` or `key` is set to `use-instance-role-credentials` it is assumed that Salt is running on an AWS instance, and the instance role credentials will be retrieved and used. Since both the `id` and `key` are required parameters for the AWS ec2 provider, it is recommended to set both to `use-instance-role-credentials` for this functionality.

A `static` and `permanent` Access Key ID and Secret Key can be specified, but this is not recommended. Instance role keys are rotated on a regular basis, and are the recommended method of specifying AWS credentials.
Windows Deploy Timeouts

For Windows instances, it may take longer than normal for the instance to be ready. In these circumstances, the provider configuration can be configured with a `win_deploy_auth_retries` and/or a `win_deploy_auth_retry_delay` setting, which default to 10 retries and a one second delay between retries. These retries and timeouts relate to validating the Administrator password once AWS provides the credentials via the AWS API.

Key Pairs

In order to create an instance with Salt installed and configured, a key pair will need to be created. This can be done in the EC2 Management Console, in the Key Pairs area. These key pairs are unique to a specific region. Keys in the us-east-1 region can be configured at:

https://console.aws.amazon.com/ec2/home?region=us-east-1#s=KeyPairs

Keys in the us-west-1 region can be configured at

https://console.aws.amazon.com/ec2/home?region=us-west-1#s=KeyPairs

...and so on. When creating a key pair, the browser will prompt to download a pem file. This file must be placed in a directory accessible by Salt Cloud, with permissions set to either 0400 or 0600.

Security Groups

An instance on EC2 needs to belong to a security group. Like key pairs, these are unique to a specific region. These are also configured in the EC2 Management Console. Security groups for the us-east-1 region can be configured at:

https://console.aws.amazon.com/ec2/home?region=us-east-1#s=SecurityGroups

...and so on.

A security group defines firewall rules which an instance will adhere to. If the salt-master is configured outside of EC2, the security group must open the SSH port (usually port 22) in order for Salt Cloud to install Salt.

IAM Profile

Amazon EC2 instances support the concept of an instance profile, which is a logical container for the IAM role. At the time that you launch an EC2 instance, you can associate the instance with an instance profile, which in turn corresponds to the IAM role. Any software that runs on the EC2 instance is able to access AWS using the permissions associated with the IAM role.

Scaffolding the profile is a 2-step configuration process:

1. Configure an IAM Role from the IAM Management Console.
2. Attach this role to a new profile. It can be done with the AWS CLI:
Once the profile is created, you can use the **PROFILE_NAME** to configure your cloud profiles.

**Cloud Profiles**

Set up an initial profile at `/etc/salt/cloud.profiles`:

```
base_ec2_private:
  provider: my-ec2-southeast-private-ips
  image: ami-e565ba8c
  size: t2.micro
  ssh_username: ec2-user

base_ec2_public:
  provider: my-ec2-southeast-public-ips
  image: ami-e565ba8c
  size: t2.micro
  ssh_username: ec2-user

base_ec2_db:
  provider: my-ec2-southeast-public-ips
  image: ami-e565ba8c
  size: m1.xlarge
  ssh_username: ec2-user
  volumes:
    - { size: 10, device: /dev/sdf }
    - { size: 10, device: /dev/sdg, type: io1, iops: 1000 }
    - { size: 10, device: /dev/sdh, type: io1, iops: 1000 }
  # optionally add tags to profile:
  tag: { 'Environment': 'production', 'Role': 'database' }
  # force grains to sync after install
  sync_after_install: grains

base_ec2_vpc:
  provider: my-ec2-southeast-public-ips
  image: ami-a73264ce
  size: m1.xlarge
  ssh_username: ec2-user
  script: /etc/salt/cloud.deploy.d/user_data.sh
  network_interfaces:
    - DeviceIndex: 0
      PrivateIpAddresses:
        - Primary: True
          #auto assign public ip (not EIP)
          AssociatePublicIpAddress: True
          SubnetId: subnet-813d4bbf
          SecurityGroupId:
            - sg-750af413
  volumes:
    - { size: 10, device: /dev/sdf }
    - { size: 10, device: /dev/sdg, type: io1, iops: 1000 }
    - { size: 10, device: /dev/sdh, type: io1, iops: 1000 }
  del_root_vol_on_destroy: True
  del_all_vol_on_destroy: True
  tag: { 'Environment': 'production', 'Role': 'database' }
```
The profile can now be realized with a salt command:

```bash
# salt-cloud -p base_ec2 ami.example.com
# salt-cloud -p base_ec2_public ami.example.com
# salt-cloud -p base_ec2_private ami.example.com
```

This will create an instance named `ami.example.com` in EC2. The minion that is installed on this instance will have an id of `ami.example.com`. If the command was executed on the salt-master, its Salt key will automatically be signed on the master.

Once the instance has been created with salt-minion installed, connectivity to it can be verified with Salt:

```bash
# salt 'ami.example.com' test.ping
```

### Required Settings

The following settings are always required for EC2:

```yaml
# Set the EC2 login data
my-ec2-config:
  id: HJGRYCILJLKJYG
  key: 'kdjgfsmg;woormgl/asericjksjhsadfgn'
  keyname: test
  securitygroup: quick-start
  private_key: /root/test.pem
  driver: ec2
```

### Optional Settings

EC2 allows a location to be set for servers to be deployed in. Availability zones exist inside regions, and may be added to increase specificity.

```yaml
# Optionally configure default region
location: ap-southeast-1
availability_zone: ap-southeast-1b
```

EC2 instances can have a public or private IP, or both. When an instance is deployed, Salt Cloud needs to log into it via SSH to run the deploy script. By default, the public IP will be used for this. If the salt-cloud command is run from another EC2 instance, the private IP should be used.

```yaml
# Specify whether to use public or private IP for deploy script
# private_ips or public_ips
ssh_interface: public_ips
```

Many EC2 instances do not allow remote access to the root user by default. Instead, another user must be used to run the deploy script using sudo. Some common usernames include ec2-user (for Amazon Linux), ubuntu (for Ubuntu instances), admin (for official Debian) and bitnami (for images provided by Bitnami).

```yaml
# Configure which user to use to run the deploy script
ssh_username: ec2-user
```
Multiple usernames can be provided, in which case Salt Cloud will attempt to guess the correct username. This is mostly useful in the main configuration file:

```yaml
my-ec2-config:
  ssh_username:
    - ec2-user
    - ubuntu
    - admin
    - bitnami
```

Multiple security groups can also be specified in the same fashion:

```yaml
my-ec2-config:
  securitygroup:
    - default
    - extra
```

Your instances may optionally make use of EC2 Spot Instances. The following example will request that spot instances be used and your maximum bid will be $0.10. Keep in mind that different spot prices may be needed based on the current value of the various EC2 instance sizes. You can check current and past spot instance pricing via the EC2 API or AWS Console.

```yaml
my-ec2-config:
  spot_config:
    spot_price: 0.10
```

By default, the spot instance type is set to `one-time', meaning it will be launched and, if it's ever terminated for whatever reason, it will not be recreated. If you would like your spot instances to be relaunched after a termination (by your or AWS), set the `type` to `persistent'.

NOTE: Spot instances are a great way to save a bit of money, but you do run the risk of losing your spot instances if the current price for the instance size goes above your maximum bid.

The following parameters may be set in the cloud configuration file to control various aspects of the spot instance launching:

- `wait_for_spot_timeout`: seconds to wait before giving up on spot instance launch (default=600)
- `wait_for_spot_interval`: seconds to wait in between polling requests to determine if a spot instance is available (default=30)
- `wait_for_spot_interval_multiplier`: a multiplier to add to the interval in between requests, which is useful if AWS is throttling your requests (default=1)
- `wait_for_spot_max_failures`: maximum number of failures before giving up on launching your spot instance (default=10)

If you find that you're being throttled by AWS while polling for spot instances, you can set the following in your core cloud configuration file that will double the polling interval after each request to AWS.

```yaml
wait_for_spot_interval: 1
wait_for_spot_interval_multiplier: 2
```

See the [AWS Spot Instances](https://aws.amazon.com/media/doc/AWSSpotInstances.pdf) documentation for more information.

Block device mappings enable you to specify additional EBS volumes or instance store volumes when the instance is launched. This setting is also available on each cloud profile. Note that the number of instance stores varies by instance type. If more mappings are provided than are supported by the instance type, mappings will be created in the order provided and additional mappings will be ignored. Consult the [AWS documentation](https://aws.amazon.com/documentation/s3/) for a listing of the available instance stores, and device names.
You can also use block device mappings to change the size of the root device at the provisioning time. For example, assuming the root device is `/dev/sda', you can set its size to 100G by using the following configuration.

```
my-ec2-config:
  block_device_mappings:
  - DeviceName: /dev/sda
    Ebs.VolumeSize: 100
    Ebs.VolumeType: gp2
    Ebs.SnapshotId: dummy0
```

Existing EBS volumes may also be attached (not created) to your instances or you can create new EBS volumes based on EBS snapshots. To simply attach an existing volume use the `volume_id` parameter.

```
device: /dev/xvdj
volume_id: vol-12345abcd
```

Or, to create a volume from an EBS snapshot, use the `snapshot` parameter.

```
device: /dev/xvdj
snapshot: snap-abcd12345
```

Note that `volume_id` will take precedence over the `snapshot` parameter.

Tags can be set once an instance has been launched.

```
my-ec2-config:
  tag:
    tag0: value
    tag1: value
```

Modify EC2 Tags

One of the features of EC2 is the ability to tag resources. In fact, under the hood, the names given to EC2 instances by salt-cloud are actually just stored as a tag called Name. Salt Cloud has the ability to manage these tags:

```
salt-cloud -a get_tags mymachine
salt-cloud -a set_tags mymachine tag1=somestuff tag2='Other stuff'
salt-cloud -a del_tags mymachine tag1,tag2,tag3
```

It is possible to manage tags on any resource in EC2 with a Resource ID, not just instances:

```
salt-cloud -f get_tags my_ec2 resource_id=af5467ba
salt-cloud -f set_tags my_ec2 resource_id=af5467ba tag1=somestuff
salt-cloud -f del_tags my_ec2 resource_id=af5467ba tag1,tag2,tag3
```

Rename EC2 Instances

As mentioned above, EC2 instances are named via a tag. However, renaming an instance by renaming its tag will cause the salt keys to mismatch. A rename function exists which renames both the instance, and the salt keys.
salt-cloud -a rename mymachine newname=yourmachine

**EC2 Termination Protection**

EC2 allows the user to enable and disable termination protection on a specific instance. An instance with this protection enabled cannot be destroyed.

salt-cloud -a enable_term_protect mymachine
salt-cloud -a disable_term_protect mymachine

**Rename on Destroy**

When instances on EC2 are destroyed, there will be a lag between the time that the action is sent, and the time that Amazon cleans up the instance. During this time, the instance still retains a Name tag, which will cause a collision if the creation of an instance with the same name is attempted before the cleanup occurs. In order to avoid such collisions, Salt Cloud can be configured to rename instances when they are destroyed. The new name will look something like:

myinstance-DEL20f5b8ad4eb64ed88f2c428df80a1a0c

In order to enable this, add rename_on_destroy line to the main configuration file:

```
my-ec2-config:
  rename_on_destroy: True
```

**Listing Images**

Normally, images can be queried on a cloud provider by passing the --list-images argument to Salt Cloud. This still holds true for EC2:

salt-cloud --list-images my-ec2-config

However, the full list of images on EC2 is extremely large, and querying all of the available images may cause Salt Cloud to behave as if frozen. Therefore, the default behavior of this option may be modified, by adding an owner argument to the provider configuration:

```
owner: aws-marketplace
```

The possible values for this setting are amazon, aws-marketplace, self, <AWS account ID> or all. The default setting is amazon. Take note that all and aws-marketplace may cause Salt Cloud to appear as if it is freezing, as it tries to handle the large amount of data.

It is also possible to perform this query using different settings without modifying the configuration files. To do this, call the avail_images function directly:

salt-cloud -f avail_images my-ec2-config owner=aws-marketplace

**EC2 Images**

The following are lists of available AMI images, generally sorted by OS. These lists are on 3rd-party websites, are not managed by Salt Stack in any way. They are provided here as a reference for those who are interested, and contain no warranty (express or implied) from anyone affiliated with Salt Stack. Most of them have never been used, much less tested, by the Salt Stack team.
• Arch Linux
• FreeBSD
• Fedora
• CentOS
• Ubuntu
• Debian
• OmniOS
• All Images on Amazon

**show_image**

This is a function that describes an AMI on EC2. This will give insight as to the defaults that will be applied to an instance using a particular AMI.

```
salt-cloud -f show_image ec2 image=ami-fd20ad94
```

**show_instance**

This action is a thin wrapper around `--full-query`, which displays details on a single instance only. In an environment with several machines, this will save a user from having to sort through all instance data, just to examine a single instance.

```
salt-cloud -a show_instance myinstance
```

**ebs_optimized**

This argument enables switching of the EbsOptimized setting which default to `false`. Indicates whether the instance is optimized for EBS I/O. This optimization provides dedicated throughput to Amazon EBS and an optimized configuration stack to provide optimal Amazon EBS I/O performance. This optimization isn't available with all instance types. Additional usage charges apply when using an EBS-optimized instance.

This setting can be added to the profile or map file for an instance.

If set to True, this setting will enable an instance to be EbsOptimized

```
ebs_optimized: True
```

This can also be set as a cloud provider setting in the EC2 cloud configuration:

```
my-ec2-config:
  ebs_optimized: True
```

**del_root_vol_on_destroy**

This argument overrides the default DeleteOnTermination setting in the AMI for the EBS root volumes for an instance. Many AMIs contain `false` as a default, resulting in orphaned volumes in the EC2 account, which may unknowingly be charged to the account. This setting can be added to the profile or map file for an instance.

If set, this setting will apply to the root EBS volume
del_root_vol_on_destroy: True

This can also be set as a cloud provider setting in the EC2 cloud configuration:

```yaml
my-ec2-config:
  del_root_vol_on_destroy: True
```

**del_all_vols_on_destroy**

This argument overrides the default DeleteOnTermination setting in the AMI for the not-root EBS volumes for an instance. Many AMIs contain 'false' as a default, resulting in orphaned volumes in the EC2 account, which may unknowingly be charged to the account. This setting can be added to the profile or map file for an instance.

If set, this setting will apply to any (non-root) volumes that were created by salt-cloud using the `volumes` setting.

The volumes will not be deleted under the following conditions:
* If a volume is detached before terminating the instance
* If a volume is created without this setting and attached to the instance

**del_all_vols_on_destroy: True**

This can also be set as a cloud provider setting in the EC2 cloud configuration:

```yaml
my-ec2-config:
  del_all_vols_on_destroy: True
```

The setting for this may be changed on all volumes of an existing instance using one of the following commands:

```
salt-cloud -a delvol_on_destroy myinstance
salt-cloud -a keepvol_on_destroy myinstance
salt-cloud -a show_delvol_on_destroy myinstance
```

The setting for this may be changed on a volume on an existing instance using one of the following commands:

```
salt-cloud -a delvol_on_destroy myinstance device=/dev/sda1
salt-cloud -a delvol_on_destroy myinstance volume_id=vol-1a2b3c4d
salt-cloud -a keepvol_on_destroy myinstance device=/dev/sda1
salt-cloud -a keepvol_on_destroy myinstance volume_id=vol-1a2b3c4d
salt-cloud -a show_delvol_on_destroy myinstance device=/dev/sda1
salt-cloud -a show_delvol_on_destroy myinstance volume_id=vol-1a2b3c4d
```

**EC2 Termination Protection**

EC2 allows the user to enable and disable termination protection on a specific instance. An instance with this protection enabled cannot be destroyed. The EC2 driver adds a show_term_protect action to the regular EC2 functionality.

```
salt-cloud -a show_term_protect mymachine
salt-cloud -a enable_term_protect mymachine
salt-cloud -a disable_term_protect mymachine
```

**Alternate Endpoint**

Normally, EC2 endpoints are build using the region and the service_url. The resulting endpoint would follow this pattern:
This results in an endpoint that looks like:

```plaintext
ec2.us-east-1.amazonaws.com
```

There are other projects that support an EC2 compatibility layer, which this scheme does not account for. This can be overridden by specifying the endpoint directly in the main cloud configuration file:

```plaintext
my-ec2-config:
  endpoint: myendpoint.example.com:1138/services/Cloud
```

## Volume Management

The EC2 driver has several functions and actions for management of EBS volumes.

### Creating Volumes

A volume may be created, independent of an instance. A zone must be specified. A size or a snapshot may be specified (in GiB). If neither is given, a default size of 10 GiB will be used. If a snapshot is given, the size of the snapshot will be used.

```plaintext
salt-cloud -f create_volume ec2 zone=us-east-1b
salt-cloud -f create_volume ec2 zone=us-east-1b size=10
salt-cloud -f create_volume ec2 zone=us-east-1b snapshot=snap12345678
salt-cloud -f create_volume ec2 size=10 type=standard
salt-cloud -f create_volume ec2 size=10 type=io1 iops=1000
```

### Attaching Volumes

Unattached volumes may be attached to an instance. The following values are required; name or instance_id, volume_id, and device.

```plaintext
salt-cloud -a attach_volume myinstance volume_id=vol-12345 device=/dev/sdb1
```

### Show a Volume

The details about an existing volume may be retrieved.

```plaintext
salt-cloud -a show_volume myinstance volume_id=vol-12345
salt-cloud -f show_volume ec2 volume_id=vol-12345
```

### Detaching Volumes

An existing volume may be detached from an instance.

```plaintext
salt-cloud -a detach_volume myinstance volume_id=vol-12345
```
Deleting Volumes

A volume that is not attached to an instance may be deleted.

```
salt-cloud -f delete_volume ec2 volume_id=vol-12345
```

Managing Key Pairs

The EC2 driver has the ability to manage key pairs.

Creating a Key Pair

A key pair is required in order to create an instance. When creating a key pair with this function, the return data will contain a copy of the private key. This private key is not stored by Amazon, will not be obtainable past this point, and should be stored immediately.

```
salt-cloud -f create_keypair ec2 keyname=mykeypair
```

Show a Key Pair

This function will show the details related to a key pair, not including the private key itself (which is not stored by Amazon).

```
salt-cloud -f show_keypair ec2 keyname=mykeypair
```

Delete a Key Pair

This function removes the key pair from Amazon.

```
salt-cloud -f delete_keypair ec2 keyname=mykeypair
```

Launching instances into a VPC

Simple launching into a VPC

In the amazon web interface, identify the id of the subnet into which your image should be created. Then, edit your cloud.profiles file like so:-

```
profile-id:
    provider: provider-name
    subnetid: subnet-XXXXXXXX
    image: ami-XXXXXXXX
    size: m1.medium
    ssh_username: ubuntu
    securitygroupid:  
        - sg-XXXXXXXX
```
Specifying interface properties

New in version 2014.7.0.

Launching into a VPC allows you to specify more complex configurations for the network interfaces of your virtual machines, for example:-

```
profile-id:
  provider: provider-name
  image: ami-XXXXXXXX
  size: m1.medium
  ssh_username: ubuntu

# Do not include either 'subnetid' or 'securitygroupid' here if you are
# going to manually specify interface configuration
#
network_interfaces:
  - DeviceIndex: 0
    SubnetId: subnet-XXXXXXXX
    SecurityGroupId:
      - sg-XXXXXXXX

# Uncomment this line if you would like to set an explicit private
# IP address for the ec2 instance
#
# PrivateIpAddress: 192.168.1.66

# Uncomment this to associate an existing Elastic IP Address with
# this network interface:
#
# associate_eip: eni-XXXXXXXX

# You can allocate more than one IP address to an interface. Use the
# 'ip addr list' command to see them.
#
# SecondaryPrivateIpAddressCount: 2

# Uncomment this to allocate a new Elastic IP Address to this
# interface (will be associated with the primary private ip address
# of the interface
#
# allocate_new_eip: True

# Uncomment this instead to allocate a new Elastic IP Address to
# both the primary private ip address and each of the secondary ones
#
# allocate_new_eips: True

# Uncomment this if you're creating NAT instances. Allows an instance
# to accept IP packets with destinations other than itself.
# SourceDestCheck: False
```

Note that it is an error to assign a 'subnetid' or 'securitygroupid' to a profile where the interfaces are manually configured like this. These are both really properties of each network interface, not of the machine itself.

### 24.5.5 Getting Started With GoGrid

GoGrid is a public cloud host that supports Linux and Windows.
Configuration

To use Salt Cloud with GoGrid log into the GoGrid web interface and create an API key. Do this by clicking on `My Account` and then going to the API Keys tab.

The `apikey` and the `sharedsecret` configuration parameters need to be set in the configuration file to enable interfacing with GoGrid:

```bash
# Note: This example is for /etc/salt/cloud.providers or any file in the # /etc/salt/cloud.providers.d/ directory.

my-gogrid-config:
  driver: gogrid
  apikey: asdff7896asdh789
  sharedsecret: saltybacon
```

Note: A Note about using Map files with GoGrid:

Due to limitations in the GoGrid API, instances cannot be provisioned in parallel with the GoGrid driver. Map files will work with GoGrid, but the `-P` argument should not be used on maps referencing GoGrid instances.

Note: Changed in version 2015.8.0.

The `provider` parameter in cloud provider definitions was renamed to `driver`. This change was made to avoid confusion with the `provider` parameter that is used in cloud profile definitions. Cloud provider definitions now use `driver` to refer to the Salt cloud module that provides the underlying functionality to connect to a cloud host, while cloud profiles continue to use `provider` to refer to provider configurations that you define.

Profiles

Cloud Profiles

Set up an initial profile at `/etc/salt/cloud.profiles` or in the `/etc/salt/cloud.profiles.d/` directory:

```bash
gogrid_512:
  provider: my-gogrid-config
  size: 512MB
  image: CentOS 6.2 (64-bit) w/ None
```

Sizes can be obtained using the `--list-sizes` option for the `salt-cloud` command:

```bash
# salt-cloud --list-sizes my-gogrid-config
my-gogrid-config:
  ----------
  gogrid:
  ----------
  512MB:
  ----------
  bandwidth:
    None
disk:
  30
driver:
get_uuid:
id:
```
Images can be obtained using the --list-images option for the salt-cloud command:

```
# salt-cloud --list-images my-gogrid-config
my-gogrid-config:
    --------
    gogrid:
    --------
    CentOS 6.4 (64-bit) w/ None:
    --------
    driver:
    extra:
    --------
    get_uuid:
    id: 18094
    name: CentOS 6.4 (64-bit) w/ None
    uuid: bfd405539919e01aa6261828a96cf54c8dce2c4
```

Assigning IPs

New in version 2015.8.0.

The GoGrid API allows IP addresses to be manually assigned. Salt Cloud supports this functionality by allowing an IP address to be specified using the assign_public_ip argument. This likely makes the most sense inside a map file, but it may also be used inside a profile.

```
gogrid_512:
    provider: my-gogrid-config
    size: 512MB
    image: CentOS 6.2 (64-bit) w/ None
    assign_public_ip: 11.38.257.42
```

24.5.6 Getting Started With Google Compute Engine

Google Compute Engine (GCE) is Google-infrastructure as a service that lets you run your large-scale computing workloads on virtual machines. This document covers how to use Salt Cloud to provision and manage your virtual machines hosted within Google's infrastructure.

You can find out more about GCE and other Google Cloud Platform services at https://cloud.google.com.
Dependencies

- Libcloud >= 0.14.0-beta3
- PyCrypto >= 2.1.
- A Google Cloud Platform account with Compute Engine enabled
- A registered Service Account for authorization
- Oh, and obviously you’ll need salt

Google Compute Engine Setup

1. Sign up for Google Cloud Platform
   Go to https://cloud.google.com and use your Google account to sign up for Google Cloud Platform and complete the guided instructions.

2. Create a Project
   Next, go to the console at https://cloud.google.com/console and create a new Project. Make sure to select your new Project if you are not automatically directed to the Project.

   Projects are a way of grouping together related users, services, and billing. You may opt to create multiple Projects and the remaining instructions will need to be completed for each Project if you wish to use GCE and Salt Cloud to manage your virtual machines.

3. Enable the Google Compute Engine service
   In your Project, either just click Compute Engine to the left, or go to the APIs & auth section and APIs link and enable the Google Compute Engine service.

4. Create a Service Account
   To set up authorization, navigate to APIs & auth section and then the Credentials link and click the CREATE NEW CLIENT ID button. Select Service Account and click the Create Client ID button. This will automatically download a .json file which can be ignored.

   Look for a new Service Account section in the page and record the generated email address for the matching key/fingerprint. The email address will be used in the service_account_email_address of the /etc/salt/cloud file.

5. Key Format
   If you are using `libcloud > 0.17.0` it is recommended that you use the `JSON format` file you downloaded above and skip to the `Configuration` section below, using the JSON file `"_in place of `NEW.pem`_` in the documentation. If you are using an older version of libcloud or are unsure of the version you have, please follow the instructions below to generate and format a new P12 key.

   In the new Service Account section, click Generate new P12 key, which will automatically download a .p12 private key file. The .p12 private key needs to be converted to a format compatible with libcloud. This new Google-generated private key was encrypted using notasecret as a passphrase. Use the following command and record the location of the converted private key and record the location for use in the service_account_private_key of the /etc/salt/cloud file:

   ```bash
   openssl pkcs12 -in ORIG.p12 -passin pass:notasecret \
   -nodes -nocerts | openssl rsa -out NEW.pem
   ```
Configuration

Set up the cloud config at /etc/salt/cloud:

```yaml
# Note: This example is for /etc/salt/cloud

providers:
gce-config:
    # Set up the Project name and Service Account authorization
    #
    project: "your-project-id"
    service_account_email_address: "123-a5gt@developer.gserviceaccount.com"
    service_account_private_key: "/path/to/your/NEW.pem"

    # Set up the location of the salt master
    #
    minion:
        master: saltmaster.example.com

    # Set up grains information, which will be common for all nodes
    # using this provider
    grains:
        node_type: broker
        release: 1.0.1

        driver: gce
```

**Note:** The value provided for `project` must not contain underscores or spaces and is labeled as ```Project ID''` on the Google Developers Console.

**Note:** Changed in version 2015.8.0.

The `provider` parameter in cloud provider definitions was renamed to `driver`. This change was made to avoid confusion with the `provider` parameter that is used in cloud profile definitions. Cloud provider definitions now use `driver` to refer to the Salt cloud module that provides the underlying functionality to connect to a cloud host, while cloud profiles continue to use `provider` to refer to provider configurations that you define.

Cloud Profiles

Set up an initial profile at /etc/salt/cloud.profiles:

```yaml
all_settings:
    image: centos-6
    size: n1-standard-1
    location: europe-west1-b
    network: default
    tags: ['"one", "two", "three"]'
    metadata: {'"one": 1, "2": "two"'}
    use_persistent_disk: True
    delete_boot_pd: False
    deploy: True
    make_master: False
    provider: gce-config
```

The profile can be realized now with a salt command:
salt-cloud -p all_settings gce-instance

This will create an salt minion instance named gce-instance in GCE. If the command was executed on the salt-master, its Salt key will automatically be signed on the master.

Once the instance has been created with salt-minion installed, connectivity to it can be verified with Salt:

```
salt 'ami.example.com' test.ping
```

**GCE Specific Settings**

Consult the sample profile below for more information about GCE specific settings. Some of them are mandatory and are properly labeled below but typically also include a hard-coded default.

```
all_settings:
  # Image is used to define what Operating System image should be used to for the instance. Examples are Debian 7 (wheezy) and CentOS 6.
  #
  # MANDATORY
  #
  # image: centos-6

  # A 'size', in GCE terms, refers to the instance's 'machine type'. See the on-line documentation for a complete list of GCE machine types.
  #
  # MANDATORY
  #
  # size: n1-standard-1

  # A 'location', in GCE terms, refers to the instance's 'zone'. GCE has the notion of both Regions (e.g. us-central1, europe-west1, etc) and Zones (e.g. us-central1-a, us-central1-b, etc).
  #
  # MANDATORY
  #
  # location: europe-west1-b

  # Use this setting to define the network resource for the instance. All GCE projects contain a network named 'default' but it's possible to use this setting to create instances belonging to a different network resource.
  #
  # network: default

  # GCE supports instance/network tags and this setting allows you to set custom tags. It should be a list of strings and must be parse-able by the python ast.literal_eval() function to convert it to a python list.
  #
  # tags: ['one', 'two', 'three']

  # GCE supports instance metadata and this setting allows you to set custom metadata. It should be a hash of key/value strings and parse-able by the python ast.literal_eval() function to convert it to a python dictionary.
```

316 Chapter 24. Salt Cloud
metadata: '{"one": "1", "2": "two"}'

# Use this setting to ensure that when new instances are created,
# they will use a persistent disk to preserve data between instance
# terminations and re-creations.
# use_persistent_disk: True

# In the event that you wish the boot persistent disk to be permanently
# deleted when you destroy an instance, set delete_boot_pd to True.
# delete_boot_pd: False

# Specify whether to use public or private IP for deploy script.
# Valid options are:
#    private_ips - The salt-master is also hosted with GCE
#    public_ips - The salt-master is hosted outside of GCE
ssh_interface: public_ips

# Per instance setting: Used a named fixed IP address to this host.
# Valid options are:
#    ephemeral - The host will use a GCE ephemeral IP
#    None - No external IP will be configured on this host.
# Optionally, pass the name of a GCE address to use a fixed IP address.
# If the address does not already exist, it will be created.
external_ip: "ephemeral"

GCE instances do not allow remote access to the root user by default. Instead, another user must be used to run the deploy script using sudo. Append something like this to /etc/salt/cloud.profiles:

all_settings:
...

    # SSH to GCE instances as gceuser
    ssh_username: gceuser

    # Use the local private SSH key file located here
    ssh_keyfile: /etc/cloud/google_compute_engine

If you have not already used this SSH key to login to instances in this GCE project you will also need to add the public key to your projects metadata at https://cloud.google.com/console. You could also add it via the metadata setting too:

all_settings:
...

metadata: '{"one": "1", "2": "two",
    "sshKeys": "gceuser:ssh-rsa <Your SSH Public Key> gceuser@host"}"

Single instance details

This action is a thin wrapper around --full-query, which displays details on a single instance only. In an environment with several machines, this will save a user from having to sort through all instance data, just to examine a single instance.

salt-cloud -a show_instance myinstance
Destroy, persistent disks, and metadata

As noted in the provider configuration, it’s possible to force the boot persistent disk to be deleted when you destroy the instance. The way that this has been implemented is to use the instance metadata to record the cloud profile used when creating the instance. When destroy is called, if the instance contains a `salt-cloud-profile` key, its value is used to reference the matching profile to determine if `delete_boot_pd` is set to `True`.

Be aware that any GCE instances created with salt cloud will contain this custom `salt-cloud-profile` metadata entry.

List various resources

It’s also possible to list several GCE resources similar to what can be done with other providers. The following commands can be used to list GCE zones (locations), machine types (sizes), and images.

```
salt-cloud --list-locations gce
salt-cloud --list-sizes gce
salt-cloud --list-images gce
```

Persistent Disk

The Compute Engine provider provides functions via salt-cloud to manage your Persistent Disks. You can create and destroy disks as well as attach and detach them from running instances.

Create

When creating a disk, you can create an empty disk and specify its size (in GB), or specify either an `image` or `snapshot`.

```
salt-cloud -f create_disk gce disk_name=pd location=us-central1-b size=200
```

Delete

Deleting a disk only requires the name of the disk to delete

```
salt-cloud -f delete_disk gce disk_name=old-backup
```

Attach

Attaching a disk to an existing instance is really an `action` and requires both an instance name and disk name. It’s possible to use this action to create bootable persistent disks if necessary. Compute Engine also supports attaching a persistent disk in READ_ONLY mode to multiple instances at the same time (but then cannot be attached in READ_WRITE to any instance).

```
salt-cloud -a attach_disk myinstance disk_name=pd mode=READ_WRITE boot=yes
```
Detach

Detaching a disk is also an action against an instance and only requires the name of the disk. Note that this does not safely sync and umount the disk from the instance. To ensure no data loss, you must first make sure the disk is unmounted from the instance.

```
salt-cloud -a detach_disk myinstance disk_name=pd
```

Show disk

It’s also possible to look up the details for an existing disk with either a function or an action.

```
salt-cloud -a show_disk myinstance disk_name=pd
salt-cloud -f show_disk gce disk_name=pd
```

Create snapshot

You can take a snapshot of an existing disk’s content. The snapshot can then in turn be used to create other persistent disks. Note that to prevent data corruption, it is strongly suggested that you unmount the disk prior to taking a snapshot. You must name the snapshot and provide the name of the disk.

```
salt-cloud -f create_snapshot gce name=backup-20140226 disk_name=pd
```

Delete snapshot

You can delete a snapshot when it’s no longer needed by specifying the name of the snapshot.

```
salt-cloud -f delete_snapshot gce name=backup-20140226
```

Show snapshot

Use this function to look up information about the snapshot.

```
salt-cloud -f show_snapshot gce name=backup-20140226
```

Networking

Compute Engine supports multiple private networks per project. Instances within a private network can easily communicate with each other by an internal DNS service that resolves instance names. Instances within a private network can also communicate with either directly without needing special routing or firewall rules even if they span different regions/zones.

Networks also support custom firewall rules. By default, traffic between instances on the same private network is open to all ports and protocols. Inbound SSH traffic (port 22) is also allowed but all other inbound traffic is blocked.

Create network

New networks require a name and CIDR range. New instances can be created and added to this network by setting the network name during create. It is not possible to add/remove existing instances to a network.
salt-cloud -f create_network gce name=mynet cidr=10.10.10.0/24

**Destroy network**

Destroy a network by specifying the name. Make sure that there are no instances associated with the network prior to deleting it or you'll have a bad day.

salt-cloud -f delete_network gce name=mynet

**Show network**

Specify the network name to view information about the network.

salt-cloud -f show_network gce name=mynet

**Create address**

Create a new named static IP address in a region.

salt-cloud -f create_address gce name=my-fixed-ip region=us-central1

**Delete address**

Delete an existing named fixed IP address.

salt-cloud -f delete_address gce name=my-fixed-ip region=us-central1

**Show address**

View details on a named address.

salt-cloud -f show_address gce name=my-fixed-ip region=us-central1

**Create firewall**

You'll need to create custom firewall rules if you want to allow other traffic than what is described above. For instance, if you run a web service on your instances, you'll need to explicitly allow HTTP and/or SSL traffic. The firewall rule must have a name and it will use the `default` network unless otherwise specified with a `network` attribute. Firewalls also support instance tags for source/destination.

salt-cloud -f create_fwrule gce name=web allow=tcp:80,tcp:443,icmp

**Delete firewall**

Deleting a firewall rule will prevent any previously allowed traffic for the named firewall rule.
Show firewall

Use this function to review an existing firewall rule’s information.

```
salt-cloud -f show_fwrule gce name=web
```

Load Balancer

Compute Engine possess a load-balancer feature for splitting traffic across multiple instances. Please reference the documentation for a more complete discription.

The load-balancer functionality is slightly different than that described in Google’s documentation. The concept of TargetPool and ForwardingRule are consolidated in salt-cloud/libcloud. HTTP Health Checks are optional.

HTTP Health Check

HTTP Health Checks can be used as a means to toggle load-balancing across instance members, or to detect if an HTTP site is functioning. A common use-case is to set up a health check URL and if you want to toggle traffic on/off to an instance, you can temporarily have it return a non-200 response. A non-200 response to the load-balancer’s health check will keep the LB from sending any new traffic to the “down” instance. Once the instance’s health check URL beings returning 200-responses, the LB will again start to send traffic to it. Review Compute Engine’s documentation for allowable parameters. You can use the following salt-cloud functions to manage your HTTP health checks.

```
salt-cloud -f create_hc gce name=myhc path=/ port=80
salt-cloud -f delete_hc gce name=myhc
salt-cloud -f show_hc gce name=myhc
```

Load-balancer

When creating a new load-balancer, it requires a name, region, port range, and list of members. There are other optional parameters for protocol, and list of health checks. Deleting or showing details about the LB only requires the name.

```
salt-cloud -f create_lb gce name=lb region=... ports=80 members=w1,w2,w3
salt-cloud -f delete_lb gce name=lb
salt-cloud -f show_lb gce name=lb
```

You can also create a load balancer using a named fixed IP address by specifying the name of the address. If the address does not exist yet it will be created.

```
salt-cloud -f create_lb gce name=my-lb region=us-central1 ports=234 members=s1,s2,s3 address=my-lb-ip
```

Attach and Detach LB

It is possible to attach or detach an instance from an existing load-balancer. Both the instance and load-balancer must exist before using these functions.
24.5.7 Getting Started With HP Cloud

HP Cloud is a major public cloud platform and uses the libcloud openstack driver. The current version of OpenStack that HP Cloud uses is Havana. When an instance is booted, it must have a floating IP added to it in order to connect to it and further below you will see an example that adds context to this statement.

Set up a cloud provider configuration file

To use the openstack driver for HP Cloud, set up the cloud provider configuration file as in the example shown below:

```
/etc/salt/cloud.providers.d/hpcloud.conf:

hpcloud-config:
    # Set the location of the salt-master
    #
    minion:
        master: saltmaster.example.com

    # Configure HP Cloud using the OpenStack plugin
    #
    identity_url: https://region-b.geo-1.identity.hpcloudsvc.com:35357/v2.0/tokens
    compute_name: Compute
    protocol: ipv4

    # Set the compute region:
    #
    compute_region: region-b.geo-1

    # Configure HP Cloud authentication credentials
    #
    user: myname
    tenant: myname-project1
    password: xxxxxxxxxx

    # keys to allow connection to the instance launched
    #
    ssh_key_name: yourkey
    ssh_key_file: /path/to/key/yourkey.priv

    driver: openstack
```

The subsequent example that follows is using the openstack driver.

**Note:** Changed in version 2015.8.0.

The provider parameter in cloud provider definitions was renamed to driver. This change was made to avoid confusion with the provider parameter that is used in cloud profile definitions. Cloud provider definitions now use driver to refer to the Salt cloud module that provides the underlying functionality to connect to a cloud host, while cloud profiles continue to use provider to refer to provider configurations that you define.
**Compute Region**

Originally, HP Cloud, in its OpenStack Essex version (1.0), had 3 availability zones in one region, US West (region-a.geo-1), which each behaved each as a region.

This has since changed, and the current OpenStack Havana version of HP Cloud (1.1) now has simplified this and now has two regions to choose from:

<table>
<thead>
<tr>
<th>Region</th>
<th>Location</th>
</tr>
</thead>
<tbody>
<tr>
<td>region-a.geo-1</td>
<td>US West</td>
</tr>
<tr>
<td>region-b.geo-1</td>
<td>US East</td>
</tr>
</tbody>
</table>

**Authentication**

The **user** is the same user as is used to log into the HP Cloud management UI. The **tenant** can be found in the upper left under "Project/Region/Scope". It is often named the same as **user** albeit with a `-project1` appended. The **password** is of course what you created your account with. The management UI also has other information such as being able to select US East or US West.

**Set up a cloud profile config file**

The profile shown below is a know working profile for an Ubuntu instance. The profile configuration file is stored in the following location:

```
/etc/salt/cloud.profiles.d/hp_ae1_ubuntu.conf
```

```
hp_ae1_ubuntu:
    provider: hp_ae1
    image: 9302692b-b787-4b52-a3a6-daebb79cb498
    ignore_cidr: 10.0.0.1/24
    networks:
        - floating: Ext-Net
    size: standard.small
    ssh_key_file: /root/keys/test.key
    ssh_key_name: test
    ssh_username: ubuntu
```

Some important things about the example above:

- The **image** parameter can use either the image name or image ID which you can obtain by running in the example below (this case US East):

  ```
  # salt-cloud --list-images hp_ae1
  ```

- The parameter **ignore_cidr** specifies a range of addresses to ignore when trying to connect to the instance. In this case, it's the range of IP addresses used for an private IP of the instance.

- The parameter **networks** is very important to include. In previous versions of Salt Cloud, this is what made it possible for salt-cloud to be able to attach a floating IP to the instance in order to connect to the instance and set up the minion. The current version of salt-cloud doesn't require it, though having it is of no harm either. Newer versions of salt-cloud will use this, and without it, will attempt to find a list of floating IP addresses to use regardless.

- The **ssh_key_file** and **ssh_key_name** are the keys that will make it possible to connect to the instance to set up the minion

- The **ssh_username** parameter, in this case, being that the image used will be ubuntu, will make it possible to not only log in but install the minion
Launch an instance

To instantiate a machine based on this profile (example):

```
# salt-cloud -p hp_a1_ubuntu ubuntu_instance_1
```

After several minutes, this will create an instance named ubuntu_instance_1 running in HP Cloud in the US East region and will set up the minion and then return information about the instance once completed.

Manage the instance

Once the instance has been created with salt-minion installed, connectivity to it can be verified with Salt:

```
# salt ubuntu_instance_1 ping
```

SSH to the instance

Additionally, the instance can be accessed via SSH using the floating IP assigned to it

```
# ssh ubuntu@<floating ip>
```

Using a private IP

Alternatively, in the cloud profile, using the private IP to log into the instance to set up the minion is another option, particularly if salt-cloud is running within the cloud on an instance that is on the same network with all the other instances (minions)

The example below is a modified version of the previous example. Note the use of `ssh_interface`:

```
hp_a1_ubuntu:
    provider: hp_a1
    image: 9302692b-b787-4b52-a3a6-daebb79cb498
    size: standard.small
    ssh_key_file: /root/keys/test.key
    ssh_key_name: test
    ssh_username: ubuntu
    ssh_interface: private_ips
```

With this setup, salt-cloud will use the private IP address to ssh into the instance and set up the salt-minion

### 24.5.8 Getting Started With Joyent

Joyent is a public cloud host that supports SmartOS, Linux, FreeBSD, and Windows.

**Dependencies**

This driver requires the Python `requests` library to be installed.
**Configuration**

The Joyent cloud requires three configuration parameters. The user name and password that are used to log into the Joyent system, and the location of the private ssh key associated with the Joyent account. The ssh key is needed to send the provisioning commands up to the freshly created virtual machine.

```yaml
# Note: This example is for /etc/salt/cloud.providers or any file in the
# /etc/salt/cloud.providers.d/ directory.
my-joyent-config:
  driver: joyent
  user: fred
  password: saltybacon
  private_key: /root/mykey.pem
  keyname: mykey
```

**Note:** Changed in version 2015.8.0.

The `provider` parameter in cloud provider definitions was renamed to `driver`. This change was made to avoid confusion with the `provider` parameter that is used in cloud profile definitions. Cloud provider definitions now use `driver` to refer to the Salt cloud module that provides the underlying functionality to connect to a cloud host, while cloud profiles continue to use `provider` to refer to provider configurations that you define.

**Profiles**

**Cloud Profiles**

Set up an initial profile at `/etc/salt/cloud.profiles` or in the `/etc/salt/cloud.profiles.d/` directory:

```yaml
joyent_512
  provider: my-joyent-config
  size: Extra Small 512 MB
  image: Arch Linux 2013.06
```

Sizes can be obtained using the `--list-sizes` option for the `salt-cloud` command:

```bash
# salt-cloud --list-sizes my-joyent-config
my-joyent-config:
  ________
  joyent:
  ________
  Extra Small 512 MB:
  ____________
  default:
  false
disk:
  15360
id:
  Extra Small 512 MB
memory:
  512
name:
  Extra Small 512 MB
swap:
  1024
```
Images can be obtained using the --list-images option for the salt-cloud command:

```
# salt-cloud --list-images my-joyent-config
my-joyent-config:
    --------
    joyent:
    --------
    base:
    --------
    description:
    A 32-bit SmartOS image with just essential packages installed. Ideal for users who are comfortable with setting up their own environment and tools.
    disabled:
    False
    files:
    --------
    - compression:
      bzip2
    - sha1:
      48dc6457c237cf6306103c74b5f45f5bf2d9bbe
    - size:
      82492182
    name:
    base
    os:
    smartos
    owner:
    352971aa-31ba-496c-9ade-a379feaed52
    public:
    True
```

**SmartDataCenter**

This driver can also be used with the Joyent SmartDataCenter project. More details can be found at:

Using SDC requires that an api_host_suffix is set. The default value for this is `.api.joyentcloud.com`. All characters, including the leading `.`, should be included:

```
api_host_suffix: .api.myhostname.com
```

**Miscellaneous Configuration**

The following configuration items can be set in either provider or profile configuration files.

**use_ssl**

When set to True (the default), attach https:// to any URL that does not already have http:// or https:// included at the beginning. The best practice is to leave the protocol out of the URL, and use this setting to manage it.
verify_ssl

When set to True (the default), the underlying web library will verify the SSL certificate. This should only be set to False for debugging.

24.5.9 Getting Started With LXC

The LXC module is designed to install Salt in an LXC container on a controlled and possibly remote minion. In other words, Salt will connect to a minion, then from that minion:

- Provision and configure a container for networking access
- Use those modules to deploy salt and re-attach to master.
  - lxc runner
  - lxc module
  - seed

Limitations

- You can only act on one minion and one provider at a time.
- Listing images must be targeted to a particular LXC provider (nothing will be outputted with all)

Operation

Salt’s LXC support does use lxc.init via the lxc.cloud_init_interface and seeds the minion via seed.mkconfig.

You can provide to those lxc VMs a profile and a network profile like if you were directly using the minion module.

Order of operation:

- Create the LXC container on the desired minion (clone or template)
- Change LXC config options (if any need to be changed)
- Start container
- Change base passwords if any
- Change base DNS configuration if necessary
- Wait for LXC container to be up and ready for ssh
- Test SSH connection and bailout in error
- Upload deploy script and seeds, then re-attach the minion.

Provider configuration

Here is a simple provider configuration:
Profile configuration

Please read LXC Management with Salt before anything else. And specially Profiles.

Here are the options to configure your containers:

- **target** Host minion id to install the lxc Container into
- **lxc_profile** Name of the profile or inline options for the LXC vm creation/cloning, please see Container Profiles.
- **network_profile** Name of the profile or inline options for the LXC vm network settings, please see Network Profiles.
- **nic_opts** Totally optionnal. Per interface new-style configuration options mappings which will override any profile default option:

  ```
  eth0: {'mac': '00:16:3e:01:29:40',
         'gateway': None, (default)
         'link': 'br0', (default)
         'gateway': None, (default)
         'netmask': '', (default)
         'ip': '22.1.4.25'}
  ```
- **password** password for root and sysadmin users
- **dnsservers** List of DNS servers to use. This is optional.
- **minion** minion configuration (see Minion Configuration in Salt Cloud)
- **bootstrap_shell** shell for bootstraping script (default: /bin/sh)
- **script** defaults to salt-bootstrap
- **script_args** arguments which are given to the bootstrap script. the {0} placeholder will be replaced by the path which contains the minion config and key files, eg:

  ```python
  script_args="-c {0}"
  ```

Using profiles:

```bash
# Note: This example would go in /etc/salt/cloud.profiles or any file in the
# /etc/salt/cloud.profiles.d/ directory.
devhost10-lxc:
    provider: devhost10-lxc
    lxc_profile: foo
    network_profile: bar
```
Using inline profiles (eg to override the network bridge):

```yaml
devhost11-lxc:
  provider: devhost10-lxc
  lxc_profile:
    clone_from: foo
  network_profile:
    eth0:
      link: lxcbr0
  minion:
    master: 10.5.0.1
    master_port: 4506
```

Template instead of a clone:

```yaml
devhost11-lxc:
  provider: devhost10-lxc
  lxc_profile:
    template: ubuntu
  network_profile:
    eth0:
      link: lxcbr0
  minion:
    master: 10.5.0.1
    master_port: 4506
```

Static ip:

```yaml
# Note: This example would go in /etc/salt/cloud.profiles or any file in the
# /etc/salt/cloud.profiles.d/ directory.
devhost10-lxc:
  provider: devhost10-lxc
  nic_opts:
    eth0:
      ipv4: 10.0.3.9
  minion:
    master: 10.5.0.1
    master_port: 4506
```

DHCP:

```yaml
# Note: This example would go in /etc/salt/cloud.profiles or any file in the
# /etc/salt/cloud.profiles.d/ directory.
devhost10-lxc:
  provider: devhost10-lxc
  minion:
    master: 10.5.0.1
    master_port: 4506
```

Driver Support

- Container creation
- Image listing (LXC templates)
• Running container information (IP addresses, etc.)

24.5.10 Getting Started With Linode

Linode is a public cloud host with a focus on Linux instances.
Starting with the 2015.8.0 release of Salt, the Linode driver uses Linode's native REST API. There are no external dependencies required to use the Linode driver.

Configuration

Linode requires a single API key, but the default root password for new instances also needs to be set:

```bash
# Note: This example is for /etc/salt/cloud.providers or any file in the
# /etc/salt/cloud.providers.d/ directory.

my-linode-config:
  apikey: asldkgfakl;sdfljasldflsdjfl;askldjfaaklsjdfsldasdfsdfghdks
  password: F00barbaz
  ssh_pubkey: ssh-ed25519 AAAAC3NzaC1lZDI1NTE5AAAAIHEOLLbeXgaqRQT9NBAopVz366SdYc0KKX33VAnq+2R user@host
  ssh_key_file: ~/.ssh/id_ed25519
  driver: linode
```

The password needs to be 8 characters and contain lowercase, uppercase, and numbers.

**Note:** Changed in version 2015.8.0.
The `provider` parameter in cloud provider definitions was renamed to `driver`. This change was made to avoid confusion with the `provider` parameter that is used in cloud profile definitions. Cloud provider definitions now use `driver` to refer to the Salt cloud module that provides the underlying functionality to connect to a cloud host, while cloud profiles continue to use `provider` to refer to provider configurations that you define.

Profiles

Cloud Profiles

Set up an initial profile at `/etc/salt/cloud.profiles` or in the `/etc/salt/cloud.profiles.d/` directory:

```yaml
linode_1024:
  provider: my-linode-config
  size: Linode 1024
  image: Arch Linux 2013.06
  location: london
```

Sizes can be obtained using the `--list-sizes` option for the `salt-cloud` command:

```bash
# salt-cloud --list-sizes my-linode-config
my-linode-config:
  ----------
  linode:
    Linode 1024:
      ----------
      bandwidth:
```

330 Chapter 24. Salt Cloud
Images can be obtained using the --list-images option for the salt-cloud command:

```
# salt-cloud --list-images my-linode-config
my-linode-config:
        linode:
             Arch Linux 2013.06:
            driver:
            extra:
                 64bit:
                         1
                 pvops:
                         1
            get_uuid:
            id:
                     112
            name:
                     Arch Linux 2013.06
            uuid:
                     8457f92eaffc92b7666b6734a96ad7abe1a8a6dd
```

Locations can be obtained using the --list-locations option for the salt-cloud command:

```
# salt-cloud --list-locations my-linode-config
my-linode-config:
        linode:
             Atlanta, GA, USA:
                abbreviation: atlanta
                id:
                         4
             Dallas, TX, USA:
                abbreviation: dallas
```
Cloning

When salt-cloud accesses Linode via linode-python it can clone machines.

It is safest to clone a stopped machine. To stop a machine run

```
salt-cloud -a stop machine_to_clone
```

To create a new machine based on another machine, add an entry to your linode cloud profile that looks like this:

```
li-clone:
    provider: my-linode-config
    clonefrom: machine_to_clone
    script_args: -C
```

Then run salt-cloud as normal, specifying `-p li-clone`. The profile name can be anything; It doesn't have to be `li-clone`.

`Clonefrom:` is the name of an existing machine in Linode from which to clone. `Script args: -C` is necessary to avoid re-deploying Salt via salt-bootstrap. `-C` will just re-deploy keys so the new minion will not have a duplicate key or minion_id on the master.

24.5.11 Getting Started With OpenStack

OpenStack is one of the most popular cloud projects. It's an open source project to build public and/or private clouds. You can use Salt Cloud to launch OpenStack instances.

Dependencies

- Libcloud >= 0.13.2

Configuration

- Using the new format, set up the cloud configuration at `/etc/salt/cloud.providers` or `/etc/salt/cloud.providers.d/openstack.conf`:

```
my-openstack-config:
  # Set the location of the salt-master
  #
  minion:
    master: saltmaster.example.com

  # Configure the OpenStack driver
  #
  identity_url: http://identity.youopenstack.com/v2.0/tokens
  compute_name: nova
  protocol: ipv4

  compute_region: RegionOne

  # Configure Openstack authentication credentials
```
#
user: myname
password: 123456
# tenant is the project name
tenant: myproject
driver: openstack

# skip SSL certificate validation (default false)
insecure: false

Note: Changed in version 2015.8.0.
The provider parameter in cloud provider definitions was renamed to driver. This change was made to avoid confusion with the provider parameter that is used in cloud profile definitions. Cloud provider definitions now use driver to refer to the Salt cloud module that provides the underlying functionality to connect to a cloud host, while cloud profiles continue to use provider to refer to provider configurations that you define.

Using nova client to get information from OpenStack

One of the best ways to get information about OpenStack is using the novaclient python package (available in pip as python-novaclient). The client configuration is a set of environment variables that you can get from the Dashboard. Log in and then go to Project -> Access & security -> API Access and download the "OpenStack RC file". Then:

source /path/to/your/rcfile
nova credentials
nova endpoints

In the nova endpoints output you can see the information about compute_region and compute_name.

Compute Region

It depends on the OpenStack cluster that you are using. Please, have a look at the previous sections.

Authentication

The user and password is the same user as is used to log into the OpenStack Dashboard.

Profiles

Here is an example of a profile:

openstack_512:
    provider: my-openstack-config
    size: m1.tiny
    image: cirros-0.3.1-x86_64-uec
    ssh_key_file: /tmp/test.pem
    ssh_key_name: test
    ssh_interface: private_ips

The following list explains some of the important properties.
size can be one of the options listed in the output of nova flavor-list.
image can be one of the options listed in the output of nova image-list.

ssh_key_file The SSH private key that the salt-cloud uses to SSH into the VM after its first booted in order to execute a command or script. This private key's public key must be the openstack public key inserted into the authorized_key's file of the VM's root user account.

ssh_key_name The name of the openstack SSH public key that is inserted into the authorized_keys file of the VM's root user account. Prior to using this public key, you must use openstack commands or the horizon web UI to load that key into the tenant's account. Note that this openstack tenant must be the one you defined in the cloud provider.

ssh_interface This option allows you to create a VM without a public IP. If this option is omitted and the VM does not have a public IP, then the salt-cloud waits for a certain period of time and then destroys the VM. With the nova drive, private cloud networks can be defined here.

For more information concerning cloud profiles, see here.

change_password

If no ssh_key_file is provided, and the server already exists, change_password will use the api to change the root password of the server so that it can be bootstrapped.

change_password: True

userdata_file

Use userdata_file to specify the userdata file to upload for use with cloud-init if available.

userdata_file: /etc/salt/cloud-init/packages.yml

24.5.12 Getting Started With Parallels

Parallels Cloud Server is a product by Parallels that delivers a cloud hosting solution. The PARALLELS module for Salt Cloud enables you to manage instances hosted using PCS. Further information can be found at:

http://www.parallels.com/products/pcs/

- Using the old format, set up the cloud configuration at /etc/salt/cloud:

```yaml
# Set up the location of the salt master
#
minion:
  master: saltmaster.example.com

# Set the PARALLELS access credentials (see below)
#
PARALLELS.user: myuser
PARALLELS.password: badpass

# Set the access URL for your PARALLELS host
#
PARALLELS.url: https://api.cloud.xmission.com:4465/paci/v1.0/
```

- Using the new format, set up the cloud configuration at /etc/salt/cloud.providers or /etc/salt/cloud.providers.d/parallels.conf:
my-parallels-config:
  # Set up the location of the salt master
  #
  minion:
    master: saltmaster.example.com

  # Set the PARALLELS access credentials (see below)
  #
  user: myuser
  password: badpass

  # Set the access URL for your PARALLELS provider
  #
  url: https://api.cloud.xmission.com:4465/paci/v1.0/
  driver: parallels

Note: Changed in version 2015.8.0.
The provider parameter in cloud provider definitions was renamed to driver. This change was made to avoid confusion with the provider parameter that is used in cloud profile definitions. Cloud provider definitions now use driver to refer to the Salt cloud module that provides the underlying functionality to connect to a cloud host, while cloud profiles continue to use provider to refer to provider configurations that you define.

Access Credentials

The user, password, and url will be provided to you by your cloud host. These are all required in order for the PARALLELS driver to work.

Cloud Profiles

Set up an initial profile at /etc/salt/cloud.profiles or /etc/salt/cloud.profiles.d/parallels.conf:

parallels-ubuntu:
  provider: my-parallels-config
  image: ubuntu-12.04-x86_64

The profile can be realized now with a salt command:

# salt-cloud -p parallels-ubuntu myubuntu

This will create an instance named myubuntu on the cloud host. The minion that is installed on this instance will have an id of myubuntu. If the command was executed on the salt-master, its Salt key will automatically be signed on the master.

Once the instance has been created with salt-minion installed, connectivity to it can be verified with Salt:

# salt myubuntu test.ping

Required Settings

The following settings are always required for PARALLELS:

- Using the old cloud configuration format:
PARALLELS.user: myuser
PARALLELS.password: badpass
PARALLELS.url: https://api.cloud.xmission.com:4465/paci/v1.0/

- Using the new cloud configuration format:

```makefile
my-parallels-config:
    user: myuser
    password: badpass
    url: https://api.cloud.xmission.com:4465/paci/v1.0/
    driver: parallels
```

Optional Settings

Unlike other cloud providers in Salt Cloud, Parallels does not utilize a size setting. This is because Parallels allows the end-user to specify a more detailed configuration for their instances than is allowed by many other cloud hosts. The following options are available to be used in a profile, with their default settings listed.

```makefile
# Description of the instance. Defaults to the instance name.
desc: <instance_name>

# How many CPU cores, and how fast they are (in MHz)
cpu_number: 1
cpu_power: 1000

# How many megabytes of RAM
ram: 256

# Bandwidth available, in kbps
bandwidth: 100

# How many public IPs will be assigned to this instance
ip_num: 1

# Size of the instance disk (in GiB)
disk_size: 10

# Username and password
ssh_username: root
password: <value from PARALLELS.password>

# The name of the image, from `salt-cloud --list-images parallels`
image: ubuntu-12.04-x86_64
```

24.5.13 Getting Started With Proxmox

Proxmox Virtual Environment is a complete server virtualization management solution, based on KVM virtualization and OpenVZ containers. Further information can be found at:

http://www.proxmox.org/

Dependencies

- IPy >= 0.81
• requests >= 2.2.1

Please note: This module allows you to create both OpenVZ and KVM but installing Salt on it will only be done when the VM is an OpenVZ container rather than a KVM virtual machine.

• Set up the cloud configuration at /etc/salt/cloud.providers or /etc/salt/cloud.providers.d/proxmox.conf:

my-proxmox-config:

# Set up the location of the salt master
#
minion:
  master: saltmaster.example.com

# Set the PROXMOX access credentials (see below)
#
user: myuser@pve
password: badpass

# Set the access URL for your PROXMOX host
#
url: your.proxmox.host

driver: proxmox

Note: Changed in version 2015.8.0.
The provider parameter in cloud provider definitions was renamed to driver. This change was made to avoid confusion with the provider parameter that is used in cloud profile definitions. Cloud provider definitions now use driver to refer to the Salt cloud module that provides the underlying functionality to connect to a cloud host, while cloud profiles continue to use provider to refer to provider configurations that you define.

Access Credentials

The user, password, and url will be provided to you by your cloud host. These are all required in order for the PROXMOX driver to work.

Cloud Profiles

Set up an initial profile at /etc/salt/cloud.profiles or /etc/salt/cloud.profiles.d/proxmox.conf:

• Configure a profile to be used:

proxmox-ubuntu:

  provider: my-proxmox-config
  image: local:vztmpl/ubuntu-12.04-standard_12.04-1_amd64.tar.gz
  technology: openvz
  host: myvmhost
  ip_address: 192.168.100.155
  password: topsecret

The profile can be realized now with a salt command:

# salt-cloud -p proxmox-ubuntu myubuntu

This will create an instance named myubuntu on the cloud host. The minion that is installed on this instance will have a hostname of myubuntu. If the command was executed on the salt-master, its Salt key will automatically be signed on the master.
Once the instance has been created with salt-minion installed, connectivity to it can be verified with Salt:

```
# salt myubuntu test.ping
```

### Required Settings

The following settings are always required for PROXMOX:

- Using the new cloud configuration format:

```yaml
my-proxmox-config:
  driver: proxmox
  user: saltcloud@pve
  password: xyzzy
  url: your.proxmox.host
```

### Optional Settings

Unlike other cloud providers in Salt Cloud, Proxmox does not utilize a `size` setting. This is because Proxmox allows the end-user to specify a more detailed configuration for their instances, than is allowed by many other cloud providers. The following options are available to be used in a profile, with their default settings listed.

```
# Description of the instance.
desc: <instance_name>

# How many CPU cores, and how fast they are (in MHz)
cpus: 1
cpuunits: 1000

# How many megabytes of RAM
memory: 256

# How much swap space in MB
swap: 256

# Whether to auto boot the vm after the host reboots
onboot: 1

# Size of the instance disk (in GiB)
disk: 10

# Host to create this vm on
host: myvmhost

# Nameservers. Defaults to host
nameserver: 8.8.8.8 8.8.4.4

# Username and password
ssh_username: root
password: <value from PROXMOX.password>

# The name of the image, from `salt-cloud --list-images proxmox`
image: local:vztmpl/ubuntu-12.04-standard_12.04-1_amd64.tar.gz
```
24.5.14 Getting Started With Rackspace

Rackspace is a major public cloud platform which may be configured using either the rackspace or the openstack driver, depending on your needs.

Please note that the rackspace driver is intended only for 1st gen instances, aka, "the old cloud" at Rackspace. It is required for 1st gen instances, but will not work with OpenStack-based instances. Unless you explicitly have a reason to use it, it is highly recommended that you use the openstack driver instead.

Dependencies

- Libcloud >= 0.13.2

Configuration

To use the openstack driver (recommended), set up the cloud configuration at /etc/salt/cloud.providers or /etc/salt/cloud.providers.d/rackspace.conf:

```yaml
my-rackspace-config:
  # Set the location of the salt-master
  #
  minion:
    master: saltmaster.example.com

  # Configure Rackspace using the OpenStack plugin
  #
  identity_url: https://identity.api.rackspacecloud.com/v2.0/tokens
  compute_name: cloudServersOpenStack
  protocol: ipv4

  # Set the compute region:
  #
  compute_region: DFW

  # Configure Rackspace authentication credentials
  #
  user: myname
  tenant: 123456
  apikey: xxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

  driver: openstack
```

To use the rackspace driver, set up the cloud configuration at /etc/salt/cloud.providers or /etc/salt/cloud.providers.d/rackspace.conf:

```yaml
my-rackspace-config:
  driver: rackspace
  # The Rackspace login user
  user: fred
  # The Rackspace user's apikey
  apikey: 901d3f579h23c8v73q9
```

The settings that follow are for using Rackspace with the openstack driver, and will not work with the rackspace driver.

Note: Changed in version 2015.8.0.
The `provider` parameter in cloud provider definitions was renamed to `driver`. This change was made to avoid confusion with the `provider` parameter that is used in cloud profile definitions. Cloud provider definitions now use `driver` to refer to the Salt cloud module that provides the underlying functionality to connect to a cloud host, while cloud profiles continue to use `provider` to refer to provider configurations that you define.

**Compute Region**

Rackspace currently has six compute regions which may be used:

- DFW -> Dallas/Forth Worth
- ORD -> Chicago
- SYD -> Sydney
- LON -> London
- IAD -> Northern Virginia
- HKG -> Hong Kong

Note: Currently the LON region is only available with a UK account, and UK accounts cannot access other regions.

**Authentication**

The `user` is the same user as is used to log into the Rackspace Control Panel. The `tenant` and `apikey` can be found in the API Keys area of the Control Panel. The `apikey` will be labeled as API Key (and may need to be generated), and `tenant` will be labeled as Cloud Account Number.

An initial profile can be configured in `/etc/salt/cloud.profiles` or `/etc/salt/cloud.profiles.d/rackspace.conf`:

```
openstack_512:
    provider: my-rackspace-config
    size: 512 MB Standard
    image: Ubuntu 12.04 LTS (Precise Pangolin)
```

To instantiate a machine based on this profile:

```
# salt-cloud -p openstack_512 myinstance
```

This will create a virtual machine at Rackspace with the name `myinstance`. This operation may take several minutes to complete, depending on the current load at the Rackspace data center.

Once the instance has been created with salt-minion installed, connectivity to it can be verified with Salt:

```
# salt myinstance test.ping
```

**RackConnect Environments**

Rackspace offers a hybrid hosting configuration option called RackConnect that allows you to use a physical firewall appliance with your cloud servers. When this service is in use the public_ip assigned by nova will be replaced by a NAT ip on the firewall. For salt-cloud to work properly it must use the newly assigned `access ip` instead of the Nova assigned public ip. You can enable that capability by adding this to your profiles:

```
openstack_512:
    provider: my-openstack-config
    size: 512 MB Standard
    image: Ubuntu 12.04 LTS (Precise Pangolin)
    rackconnect: True
```
Managed Cloud Environments

Rackspace offers a managed service level of hosting. As part of the managed service level you have the ability to choose from base of lamp installations on cloud server images. The post build process for both the base and the lamp installations used Chef to install things such as the cloud monitoring agent and the cloud backup agent. It also takes care of installing the lamp stack if selected. In order to prevent the post installation process from stomping over the bootstrapping you can add the below to your profiles.

```
openstack_512:
  provider: my-rackspace-config
  size: 512 MB Standard
  image: Ubuntu 12.04 LTS (Precise Pangolin)
  managedcloud: True
```

First and Next Generation Images

Rackspace provides two sets of virtual machine images, first, and next generation. As of 0.8.9 salt-cloud will default to using the next generation images. To force the use of first generation images, on the profile configuration please add:

```
FreeBSD-9.0-512:
  provider: my-rackspace-config
  size: 512 MB Standard
  image: FreeBSD 9.0
  force_first_gen: True
```

Private Subnets

By default salt-cloud will not add Rackspace private networks to new servers. To enable a private network to a server instantiated by salt cloud, add the following section to the provider file (typically /etc/salt/cloud.providers.d/rackspace.conf)

```
networks:
  - fixed:
    # This is the private network
    - private-network-id
    # This is Rackspace's "PublicNet"
    - 00000000-0000-0000-0000-000000000000
    # This is Rackspace's "ServiceNet"
    - 11111111-1111-1111-1111-111111111111
```

To get the Rackspace private network ID, go to Networking, Networks and hover over the private network name.

The order of the networks in the above code block does not map to the order of the ethernet devices on newly created servers. Public IP will always be first (eth0 ) followed by servicenet (eth1 ) and then private networks.

Enabling the private network per above gives the option of using the private subnet for all master-minion communication, including the bootstrap install of salt-minion. To enable the minion to use the private subnet, update the master: line in the minion: section of the providers file. To configure the master to only listen on the private subnet IP, update the interface: line in the /etc/salt/master file to be the private subnet IP of the salt master.

24.5.15 Getting Started With Saltify

The Saltify driver is a new, experimental driver for installing Salt on existing machines (virtual or bare metal).
Dependencies

The Saltify driver has no external dependencies.

Configuration

Because the Saltify driver does not use an actual cloud provider host, it has a simple provider configuration. The only thing that is required to be set is the driver name, and any other potentially useful information, like the location of the salt-master:

```bash
# Note: This example is for /etc/salt/cloud.providers file or any file in
# the /etc/salt/cloud.providers.d/ directory.

my-saltify-config:
    minion:
        master: 111.222.333.444
    provider: saltify
```

Profiles

Saltify requires a profile to be configured for each machine that needs Salt installed. The initial profile can be set up at /etc/salt/cloud.profiles or in the /etc/salt/cloud.profiles.d/ directory. Each profile requires both an `ssh_host` and an `ssh_username` key parameter as well as either an `key_filename` or a `password`.

Profile configuration example:

```bash
# /etc/salt/cloud.profiles.d/saltify.conf

salt-this-machine:
    ssh_host: 12.34.56.78
    ssh_username: root
    key_filename: '/etc/salt/mysshkey.pem'
    provider: my-saltify-config
```

The machine can now be ``Salted'' with the following command:

```bash
salt-cloud -p salt-this-machine my-machine
```

This will install salt on the machine specified by the cloud profile, `salt-this-machine`, and will give the machine the minion id of `my-machine`. If the command was executed on the salt-master, its Salt key will automatically be signed on the master.

Once a salt-minion has been successfully installed on the instance, connectivity to it can be verified with Salt:

```bash
salt my-machine test.ping
```

Using Map Files

The settings explained in the section above may also be set in a map file. An example of how to use the Saltify driver with a map file follows:

```bash
# /etc/salt/saltify-map

make_salty:
```
- my-instance-0:
  ssh_host: 12.34.56.78
  ssh_username: root
  password: very-bad-password
- my-instance-1:
  ssh_host: 44.33.22.11
  ssh_username: root
  password: another-bad-pass

Note: When using a cloud map with the Saltify driver, the name of the profile to use, in this case make_salary, must be defined in a profile config. For example:

```
# /etc/salt/cloud.profiles.d/saltify.conf
make_salary:
  provider: my-saltify-config
```

The machines listed in the map file can now be ``Salted'' by applying the following salt map command:

```
salt-cloud -m /etc/salt/saltify-map
```

This command will install salt on the machines specified in the map and will give each machine their minion id of my-instance-0 and my-instance-1, respectively. If the command was executed on the salt-master, its Salt key will automatically be signed on the master.

Connectivity to the new ``Salted'' instances can now be verified with Salt:

```
salt 'my-instance-*' test.ping
```

24.5.16 Getting Started With Scaleway

Scaleway is the first IaaS host worldwide to offer an ARM based cloud. It's the ideal platform for horizontal scaling with BareMetal SSD servers. The solution provides on demand resources: it comes with on-demand SSD storage, movable IPs, images, security group and an Object Storage solution. https://scaleway.com

Configuration

Using Salt for Scaleway, requires an access key and an API token. API tokens are unique identifiers associated with your Scaleway account. To retrieve your access key and API token, log-in to the Scaleway control panel, open the pull-down menu on your account name and click on ``My Credentials'' link.

If you do not have API token you can create one by clicking the ``Create New Token'' button on the right corner.

```
# Note: This example is for /etc/salt/cloud.providers or any file in the
# /etc/salt/cloud.providers.d/ directory.

my-scaleway-config:
  access_key: 15cf404d-4560-41b1-9a0c-21c3d5c4ff1f
  token: a7347ec8-5de1-4024-a5e3-24b77d1ba91d
  driver: scaleway
```

Note: Changed in version 2015.8.0.

The provider parameter in cloud provider definitions was renamed to driver. This change was made to avoid confusion with the provider parameter that is used in cloud profile definitions. Cloud provider definitions now
use `driver` to refer to the Salt cloud module that provides the underlying functionality to connect to a cloud host, while cloud profiles continue to use `provider` to refer to provider configurations that you define.

## Profiles

### Cloud Profiles

Set up an initial profile at `/etc/salt/cloud.profiles` or in the `/etc/salt/cloud.profiles.d/` directory:

```bash
scalewa-ubuntu:
    provider: my-scaleway-config
    image: Ubuntu Trusty (14.04 LTS)
```

Images can be obtained using the `--list-images` option for the `salt-cloud` command:

```bash
# salt-cloud --list-images my-scaleway-config
my-scaleway-config:
    --------------
    scaleway:
        ----------
        069fd876-eb04-44ab-a9cd-47e2fa3e5309:
            ---------
            arch: arm
            creation_date: 2015-03-12T09:35:45.764477+00:00
            default_bootscript: 
                {'kernel': {'dtb': '', 'title': 'Pimouss 3.2.34-30-std', 'id': 'cfda4308-cd6f-4e51-9744-905fc0da370f', 'path': 'kernel/pimouss-uImage-3.2.34-30-std'}, 'title': '3.2.34-std #30 (stable)', 'id': 'c5af0215-2516-4316-befc-5da1cfad609c', 'initrd': 
                    {'path': 'initrd/c1-uInitrd', 'id': '1be14b1b-e24c-48e5-b0b6-7ba452e42b92', 'title': 'C1 initrd'}, 
                    'bootcmdargs': 
                        {'id': 'd22c4dde-e5a4-47ad-abb9-d23b54d542ff', 'value': 'ip=dhcp boot=local root=/dev/nbd0 USE_XNBD=1 nbd.max_parts=8'}, 
                        'organization': '11111111-1111-4111-8111-111111111111', 
                        'public': True}
extra_volumes: 
    []
    id: 069fd876-eb04-44ab-a9cd-47e2fa3e5309
    modification_date: 2015-04-24T12:02:16.820256+00:00
    name: Ubuntu Vivid (15.04)
    organization: a283af0b-d13e-42e1-a43f-855ffbf281ab
    public: True
    root_volume: 
        {'name': 'distrib-ubuntu-vivid-2015-03-12_10:32-snapshot', 'id': 'a6d9e2e63-8dee-4b0d-9b47-fc24f5f5eab2', 'volume_type': 'l_ssd', 'size': 50000000000L}
```

... Execute a query and return all information about the nodes running on configured cloud providers using the `-Q` option for the `salt-cloud` command:

```bash
# salt-cloud -F
[INFO ] salt-cloud starting
[INFO ] Starting new HTTPS connection (1): api.scaleway.com
my-scaleway-config:
    --------------
    scaleway:
        ------------
        salt-manager:
            ----------
            creation_date:
```

Chapter 24. Salt Cloud
24.5.17 Getting Started With SoftLayer

SoftLayer is a public cloud host, and baremetal hardware hosting service.

Dependencies

The SoftLayer driver for Salt Cloud requires the softlayer package, which is available at PyPI:
https://pypi.python.org/pypi/SoftLayer

This package can be installed using pip or easy_install:

# pip install softlayer
# easy_install softlayer

Configuration

Set up the cloud config at /etc/salt/cloud.providers:

# Note: These examples are for /etc/salt/cloud.providers

my-softlayer:
    # Set up the location of the salt master
    minion:
        master: saltmaster.example.com

    # Set the SoftLayer access credentials (see below)
    user: MYUSER1138
    apikey: 'e3b68aa711e6deadc62d5b76355674beef7cc3116062dbacafe5f7e465bf0c9'

    driver: softlayer

my-softlayer-hw:
    # Set up the location of the salt master
    minion:
        master: saltmaster.example.com

    # Set the SoftLayer access credentials (see below)
    user: MYUSER1138
    apikey: 'e3b68aa711e6deadc62d5b76355674beef7cc3116062dbacafe5f7e465bf0c9'

    driver: softlayer_h喜悦

Note: Changed in version 2015.8.0.

The provider parameter in cloud provider definitions was renamed to driver. This change was made to avoid confusion with the provider parameter that is used in cloud profile definitions. Cloud provider definitions now
use `driver` to refer to the Salt cloud module that provides the underlying functionality to connect to a cloud host, while cloud profiles continue to use `provider` to refer to provider configurations that you define.

**Access Credentials**

The `user` setting is the same user as is used to log into the SoftLayer Administration area. The `apikey` setting is found inside the Admin area after logging in:

- Hover over the `Account` menu item.
- Click the `Users` link.
- Find the API Key column and click View.

**Profiles**

**Cloud Profiles**

Set up an initial profile at `/etc/salt/cloud.profiles`:

```yaml
base_softlayer_ubuntu:
  provider: my-softlayer
  image: UBUNTU_LATEST
  cpu_number: 1
  ram: 1024
  disk_size: 100
  local_disk: True
  hourly_billing: True
  domain: example.com
  location: sjc01
  # Optional
  max_net_speed: 1000
  private_vlan: 396
  private_network: True
  private_ssh: True
  # May be used _instead_of_ image
  global_identifier: 320d8be5-46c0-dead-cafe-13e3c51
```

Most of the above items are required; optional items are specified below.

**image** Images to build an instance can be found using the `--list-images` option:

```
# salt-cloud --list-images my-softlayer
```

The setting used will be labeled as `template`.

**cpu_number** This is the number of CPU cores that will be used for this instance. This number may be dependent upon the image that is used. For instance:

```
Red Hat Enterprise Linux 6 - Minimal Install (64 bit) (1 - 4 Core):
    _________
    name:
    Red Hat Enterprise Linux 6 - Minimal Install (64 bit) (1 - 4 Core)
    template:
```
Note that the template (meaning, the image option) for both of these is the same, but the names suggest how many CPU cores are supported.

**ram**  This is the amount of memory, in megabytes, that will be allocated to this instance.

**disk_size**  The amount of disk space that will be allocated to this image, in megabytes.

**local_disk**  When true the disks for the computing instance will be provisioned on the host which it runs, otherwise SAN disks will be provisioned.

**hourly_billing**  When true the computing instance will be billed on hourly usage, otherwise it will be billed on a monthly basis.

**domain**  The domain name that will be used in the FQDN (Fully Qualified Domain Name) for this instance. The domain setting will be used in conjunction with the instance name to form the FQDN.

**location**  Images to build an instance can be found using the `--list-locations` option:

```
# salt-cloud --list-location my-softlayer
```

**max_net_speed**  Specifies the connection speed for the instance's network components. This setting is optional. By default, this is set to 10.

**public_vlan**  If it is necessary for an instance to be created within a specific frontend VLAN, the ID for that VLAN can be specified in either the provider or profile configuration.

This ID can be queried using the `list_vlans` function, as described below. This setting is optional.

**private_vlan**  If it is necessary for an instance to be created within a specific backend VLAN, the ID for that VLAN can be specified in either the provider or profile configuration.

This ID can be queried using the `list_vlans` function, as described below. This setting is optional.

**private_network**  If a server is to only be used internally, meaning it does not have a public VLAN associated with it, this value would be set to True. This setting is optional. The default is False.

**private_ssh**  Whether to run the deploy script on the server using the public IP address or the private IP address. If set to True, Salt Cloud will attempt to SSH into the new server using the private IP address. The default is False. This setting is optional.
global_identifier When creating an instance using a custom template, this option is set to the corresponding value obtained using the list_custom_images function. This option will not be used if an image is set, and if an image is not set, it is required.

The profile can be realized now with a salt command:

```
# salt-cloud -p base_softlayer_ubuntu myserver
```

Using the above configuration, this will create myserver.example.com.

Once the instance has been created with salt-minion installed, connectivity to it can be verified with Salt:

```
# salt 'myserver.example.com' test.ping
```

Cloud Profiles

Set up an initial profile at /etc/salt/cloud.profiles:

```
base_softlayer_hw_centos:
  provider: my-softlayer-hw
  # CentOS 6.0 - Minimal Install (64 bit)
  image: 13963
  # 2 x 2.0 GHz Core Bare Metal Instance - 2 GB Ram
  size: 1921
  # 250GB SATA II
  hdd: 19
  # San Jose 01
  location: 168642
  domain: example.com
  # Optional
  vlan: 396
  port_speed: 273
  bandwidth: 248
```

Most of the above items are required; optional items are specified below.

image Images to build an instance can be found using the --list-images option:

```
# salt-cloud --list-images my-softlayer-hw
```

A list of id’s and names will be provided. The `name` will describe the operating system and architecture. The id will be the setting to be used in the profile.

size Sizes to build an instance can be found using the --list-sizes option:

```
# salt-cloud --list-sizes my-softlayer-hw
```

A list of id’s and names will be provided. The `name` will describe the speed and quantity of CPU cores, and the amount of memory that the hardware will contain. The id will be the setting to be used in the profile.

hdd There are currently two sizes of hard disk drive (HDD) that are available for hardware instances on SoftLayer:

```
19: 250GB SATA II
1267: 500GB SATA II
```

The hdd setting in the profile will be either 19 or 1267. Other sizes may be added in the future.
**location**  Locations to build an instance can be found using the `--list-images` option:

```bash
# salt-cloud --list-locations my-softlayer-hw
```

A list of IDs and names will be provided. The `location` will describe the location in human terms. The `id` will be the setting to be used in the profile.

**domain**  The domain name that will be used in the FQDN (Fully Qualified Domain Name) for this instance. The `domain` setting will be used in conjunction with the instance name to form the FQDN.

**vlan**  If it is necessary for an instance to be created within a specific VLAN, the ID for that VLAN can be specified in either the provider or profile configuration.

This ID can be queried using the `list_vlans` function, as described below.

**port_speed**  Specifies the speed for the instance’s network port. This setting refers to an ID within the SoftLayer API, which sets the port speed. This setting is optional. The default is 273, or, 100 Mbps Public & Private Networks. The following settings are available:

- 273: 100 Mbps Public & Private Networks
- 274: 1 Gbps Public & Private Networks
- 21509: 10 Mbps Dual Public & Private Networks (up to 20 Mbps)
- 21513: 100 Mbps Dual Public & Private Networks (up to 200 Mbps)
- 2314: 1 Gbps Dual Public & Private Networks (up to 2 Gbps)
- 272: 10 Mbps Public & Private Networks

**bandwidth**  Specifies the network bandwidth available for the instance. This setting refers to an ID within the SoftLayer API, which sets the bandwidth. This setting is optional. The default is 248, or, 5000 GB Bandwidth. The following settings are available:

- 248: 5000 GB Bandwidth
- 129: 6000 GB Bandwidth
- 130: 8000 GB Bandwidth
- 131: 10000 GB Bandwidth
- 36: Unlimited Bandwidth (10 Mbps Uplink)
- 125: Unlimited Bandwidth (100 Mbps Uplink)

**Actions**

The following actions are currently supported by the SoftLayer Salt Cloud driver.

**show_instance**

This action is a thin wrapper around `--full-query`, which displays details on a single instance only. In an environment with several machines, this will save a user from having to sort through all instance data, just to examine a single instance.
$ salt-cloud -a show_instance myinstance

Functions

The following functions are currently supported by the SoftLayer Salt Cloud driver.

list_vlans

This function lists all VLANs associated with the account, and all known data from the SoftLayer API concerning those VLANs.

$ salt-cloud -f list_vlans my-softlayer
$ salt-cloud -f list_vlans my-softlayer-hw

The id returned in this list is necessary for the vlan option when creating an instance.

list_custom_images

This function lists any custom templates associated with the account, that can be used to create a new instance.

$ salt-cloud -f list_custom_images my-softlayer

The globalIdentifier returned in this list is necessary for the global_identifier option when creating an image using a custom template.

Optional Products for SoftLayer HW

The softlayer_hw driver supports the ability to add optional products, which are supported by SoftLayer's API. These products each have an ID associated with them, that can be passed into Salt Cloud with the optional_products option:

```yaml
softlayer_hw_test:
    provider: my-softlayer-hw
    # CentOS 6.0 - Minimal Install (64 bit)
    image: 13963
    # 2 x 2.0 GHz Core Bare Metal Instance - 2 GB Ram
    size: 1921
    # 250GB SATA II
    hdd: 19
    # San Jose 01
    location: 168642
    domain: example.com
    optional_products:
        # MySQL for Linux
        - id: 28
        # Business Continuance Insurance
        - id: 104
```

These values can be manually obtained by looking at the source of an order page on the SoftLayer web interface. For convenience, many of these values are listed here:
Public Secondary IP Addresses

- 22: 4 Public IP Addresses
- 23: 8 Public IP Addresses

Primary IPv6 Addresses

- 17129: 1 IPv6 Address

Public Static IPv6 Addresses

- 1481: /64 Block Static Public IPv6 Addresses

OS-Specific Addon

- 17139: XenServer Advanced for XenServer 6.x
- 17141: XenServer Enterprise for XenServer 6.x
- 2334: XenServer Advanced for XenServer 5.6
- 2335: XenServer Enterprise for XenServer 5.6
- 13915: Microsoft WebMatrix
- 21276: VMware vCenter 5.1 Standard

Control Panel Software

- 121: cPanel/WHM with Fantastico and RVskin
- 20778: Parallels Plesk Panel 11 (Linux) 100 Domain w/ Power Pack
- 20786: Parallels Plesk Panel 11 (Windows) 100 Domain w/ Power Pack
- 20787: Parallels Plesk Panel 11 (Linux) Unlimited Domain w/ Power Pack
- 20792: Parallels Plesk Panel 11 (Windows) Unlimited Domain w/ Power Pack
- 2340: Parallels Plesk Panel 10 (Linux) 100 Domain w/ Power Pack
- 2339: Parallels Plesk Panel 10 (Linux) Unlimited Domain w/ Power Pack
- 13704: Parallels Plesk Panel 10 (Windows) Unlimited Domain w/ Power Pack

Database Software

- 29: MySQL 5.0 for Windows
- 28: MySQL for Linux
- 21501: Riak 1.x
- 20893: MongoDB

24.5.18 Getting Started with VEXXHOST

VEXXHOST is a cloud computing host which provides Canadian cloud computing services which are based in Montreal and use the libcloud OpenStack driver. VEXXHOST currently runs the Havana release of OpenStack. When provisioning new instances, they automatically get a public IP and private IP address. Therefore, you do not need to assign a floating IP to access your instance after it’s booted.

Cloud Provider Configuration

To use the openstack driver for the VEXXHOST public cloud, you will need to set up the cloud provider configuration file as in the example below:

```
/my-vexxhost-config:
  # Set the location of the salt-master
  #
  minion:
    master: saltmaster.example.com

  # Configure VEXXHOST using the OpenStack plugin
  #
  identity_url: http://auth.api.thenebulacloud.com:5000/v2.0/tokens
  compute_name: nova

  # Set the compute region:
  #
  compute_region: na-yul-nhs1

  # Configure VEXXHOST authentication credentials
```

24.5. Cloud Provider Specifics
Authentication

All of the authentication fields that you need can be found by logging into your VEXXHOST customer center. Once you've logged in, you will need to click on `"CloudConsole"` and then click on `"API Credentials"`.

Cloud Profile Configuration

In order to get the correct image UUID and the instance type to use in the cloud profile, you can run the following command respectively:

```
# salt-cloud --list-images=vexxhost-config
# salt-cloud --list-sizes=vexxhost-config
```

Once you have that, you can go ahead and create a new cloud profile. This profile will build an Ubuntu 12.04 LTS nb.2G instance.

```
/etc/salt/cloud.profiles.d/vh_ubuntu1204_2G.conf:

vh_ubuntu1204_2G:
    provider: my-vexxhost-config
    image: 4051139f-750d-4d72-8ef0-074f2ccc7e5a
    size: nb.2G
```

Provision an instance

To create an instance based on the sample profile that we created above, you can run the following `salt-cloud` command.

```
# salt-cloud -p vh_ubuntu1204_2G vh_instance1
```

Typically, instances are provisioned in under 30 seconds on the VEXXHOST public cloud. After the instance provisions, it will be set up a minion and then return all the instance information once it's complete.

Once the instance has been setup, you can test connectivity to it by running the following command:
# salt vh_instance1 test.ping

You can now continue to provision new instances and they will all automatically be set up as minions of the master you’ve defined in the configuration file.

## 24.5.19 Getting Started With VMware

New in version 2015.5.4.

**Author:** Nitin Madhok &lt;nmadhok@clemson.edu&gt;

The VMware cloud module allows you to manage VMware ESX, ESXi, and vCenter.

### Dependencies

The vmware module for Salt Cloud requires the *pyVmomi* package, which is available at PyPI: https://pypi.python.org/pypi/pyvmomi

This package can be installed using *pip* or *easy_install*:

```bash
pip install pyvmomi
easy_install pyvmomi
```

### Configuration

The VMware cloud module needs the vCenter URL, username and password to be set up in the cloud configuration at /etc/salt/cloud.providers or /etc/salt/cloud.providers.d/vmware.conf:

```yaml
my-vmware-config:
    driver: vmware
    user: 'DOMAIN\user'
    password: 'verybadpass'
    url: '10.20.30.40'

vcenter01:
    driver: vmware
    user: 'DOMAIN\user'
    password: 'verybadpass'
    url: 'vcenter01.domain.com'
    protocol: 'https'
    port: 443

vcenter02:
    driver: vmware
    user: 'DOMAIN\user'
    password: 'verybadpass'
    url: 'vcenter02.domain.com'
    protocol: 'http'
    port: 80
```

Note: Optionally, protocol and port can be specified if the vCenter server is not using the defaults. Default is protocol: https and port: 443.

Note: Changed in version 2015.8.0.
The `provider` parameter in cloud provider definitions was renamed to `driver`. This change was made to avoid confusion with the `provider` parameter that is used in cloud profile definitions. Cloud provider definitions now use `driver` to refer to the Salt cloud module that provides the underlying functionality to connect to a cloud host, while cloud profiles continue to use `provider` to refer to provider configurations that you define.

Profiles

Set up an initial profile at `/etc/salt/cloud.profiles` or `/etc/salt/cloud.profiles.d/vmware.conf`:

```
vmware-centos6.5:
  provider: vcenter01
  clonefrom: test-vm

  ## Optional arguments
  num_cpus: 4
  memory: 8GB

  devices:
    cd:
      CD/DVD drive 1:
        device_type: datastore_iso_file
        iso_path: "[nap004-1] vmimages/tools-isoimages/linux.iso"
      CD/DVD drive 2:
        device_type: client_device
        mode: atapi
      CD/DVD drive 3:
        device_type: client_device
        mode: passthrough

  disk:
    Hard disk 1:
      size: 30
    Hard disk 2:
      size: 20
    Hard disk 3:
      size: 5

  network:
    Network adapter 1:
      name: 10.20.30-400-Test
      switch_type: standard
      ip: 10.20.30.123
      gateway: [10.20.30.110]
      subnet_mask: 255.255.255.128
      domain: mycompany.com
    Network adapter 2:
      name: 10.30.40-500-Dev-DHCP
      adapter_type: e1000
      switch_type: distributed
    Network adapter 3:
      name: 10.40.50-600-Prod
      adapter_type: vmxnet3
      switch_type: distributed
      ip: 10.40.50.123
      gateway: [10.40.50.110]
      subnet_mask: 255.255.255.128
      domain: mycompany.com

  scsi:
    SCSI controller 1:
      type: lsilogic
```
SCSI controller 2:
  type: lsilogic_sas
  bus_sharing: virtual
SCSI controller 3:
  type: paravirtual
  bus_sharing: physical

domain: mycompany.com
dns_servers:
  - 123.127.255.240
  - 123.127.255.241
  - 123.127.255.242

# If cloning from template, either resourcepool or cluster MUST be specified!
resourcepool: Resources
cluster: Prod
datastore: HUGE-DATASTORE-Cluster
type: Development
datacenter: DC1
host: c4212n-002.domain.com
template: False
power_on: True
extra_config:
  mem.hotadd: 'yes'
guestinfo.foo: bar
guestinfo.domain: foobar.com
guestinfo.customVariable: customValue
deploy: True
private_key: /root/.ssh/mykey.pem
ssh_username: cloud-user
password: veryVeryBadPassword
minion:
  master: 123.127.193.105

file_map:
  /path/to/local/custom/script: /path/to/remote/script
  /path/to/local/file: /path/to/remote/file
  /srv/salt/yum/epel.repo: /etc/yum.repos.d/epel.repo

hardware_version: 10

provider Enter the name that was specified when the cloud provider config was created.
clonefrom Enter the name of the VM/template to clone from.
num_cpus Enter the number of vCPUS that you want the VM/template to have. If not specified, the current
  VM/template's vCPU count is used.
memory Enter the memory size (in MB or GB) that you want the VM/template to have. If not specified, the current
  VM/template's memory size is used. Example memory: 8GB or memory: 8192MB.
devices Enter the device specifications here. Currently, the following devices can be created or reconfigured:
  cd Enter the CD/DVD drive specification here. If the CD/DVD drive doesn't exist, it will be created with the
    specified configuration. If the CD/DVD drive already exists, it will be reconfigured with the specifications.
    The following options can be specified per CD/DVD drive:
      device_type Specify how the CD/DVD drive should be used. Currently supported types

24.5. Cloud Provider Specifics 357
are client_device and datastore_iso_file. Default is device_type: client_device

iso_path Enter the path to the iso file present on the datastore only if device_type: datastore_iso_file. The syntax to specify this is iso_path: "[datastoreName] vmimages/tools-isoimages/linux.iso". This field is ignored if device_type: client_device

mode Enter the mode of connection only if device_type: client_device. Currently supported modes are passthrough and atapi. This field is ignored if device_type: datastore_iso_file. Default is mode: passthrough

disk Enter the disk specification here. If the hard disk doesn't exist, it will be created with the provided size. If the hard disk already exists, it will be expanded if the provided size is greater than the current size of the disk.

network Enter the network adapter specification here. If the network adapter doesn't exist, a new network adapter will be created with the specified network name, type and other configuration. If the network adapter already exists, it will be reconfigured with the specifications. The following additional options can be specified per network adapter (See example above):

name Enter the network name you want the network adapter to be mapped to.

adapter_type Enter the network adapter type you want to create. Currently supported types are vmxnet, vmxnet2, vmxnet3, e1000 and e1000e. If no type is specified, by default vmxnet3 will be used.

switch_type Enter the type of switch to use. This decides whether to use a standard switch network or a distributed virtual portgroup. Currently supported types are standard for standard portgroups and distributed for distributed virtual portgroups.

ip Enter the static IP you want the network adapter to be mapped to. If the network specified is DHCP enabled, you do not have to specify this.

gateway Enter the gateway for the network as a list. If the network specified is DHCP enabled, you do not have to specify this.

subnet_mask Enter the subnet mask for the network. If the network specified is DHCP enabled, you do not have to specify this.

domain Enter the domain to be used with the network adapter. If the network specified is DHCP enabled, you do not have to specify this.

scsi Enter the SCSI adapter specification here. If the SCSI adapter doesn't exist, a new SCSI adapter will be created of the specified type. If the SCSI adapter already exists, it will be reconfigured with the specifications. The following additional options can be specified per SCSI adapter:

type Enter the SCSI adapter type you want to create. Currently supported types are lsilogic, lsilogic_sas and paravirtual. Type must be specified when creating a new SCSI adapter.

bus_sharing Specify this if sharing of virtual disks between virtual machines is desired. The following can be specified:

  virtual Virtual disks can be shared between virtual machines on the same server.

  physical Virtual disks can be shared between virtual machines on any server.

  no Virtual disks cannot be shared between virtual machines.

domain Enter the global domain name to be used for DNS. If not specified and if the VM name is a FQDN, domain is set to the domain from the VM name. Default is local.

dns_servers Enter the list of DNS servers to use in order of priority.
**resourcepool** Enter the name of the resourcepool to which the new virtual machine should be attached. This determines what compute resources will be available to the clone.

Note:
- For a clone operation from a virtual machine, it will use the same resourcepool as the original virtual machine unless specified.
- For a clone operation from a template to a virtual machine, specifying either this or cluster is required. If both are specified, the resourcepool value will be used.
- For a clone operation to a template, this argument is ignored.

**cluster** Enter the name of the cluster whose resource pool the new virtual machine should be attached to.

Note:
- For a clone operation from a virtual machine, it will use the same cluster's resourcepool as the original virtual machine unless specified.
- For a clone operation from a template to a virtual machine, specifying either this or resourcepool is required. If both are specified, the resourcepool value will be used.
- For a clone operation to a template, this argument is ignored.

**datastore** Enter the name of the datastore or the datastore cluster where the virtual machine should be located on physical storage. If not specified, the current datastore is used.

Note:
- If you specify a datastore cluster name, DRS Storage recommendation is automatically applied.
- If you specify a datastore name, DRS Storage recommendation is disabled.

**folder** Enter the name of the folder that will contain the new virtual machine.

Note:
- For a clone operation from a VM/template, the new VM/template will be added to the same folder that the original VM/template belongs to unless specified.
- If both folder and datacenter are specified, the folder value will be used.

**datacenter** Enter the name of the datacenter that will contain the new virtual machine.

Note:
- For a clone operation from a VM/template, the new VM/template will be added to the same folder that the original VM/template belongs to unless specified.
- If both folder and datacenter are specified, the folder value will be used.

**host** Enter the name of the target host where the virtual machine should be registered.

If not specified:

Note:
- If resource pool is not specified, current host is used.
- If resource pool is specified, and the target pool represents a stand-alone host, the host is used.
• If resource pool is specified, and the target pool represents a DRS-enabled cluster, a host selected by DRS is used.
• If resource pool is specified and the target pool represents a cluster without DRS enabled, an InvalidArgument exception be thrown.

**template** Specifies whether the new virtual machine should be marked as a template or not. Default is `template: False`.

**power_on** Specifies whether the new virtual machine should be powered on or not. If `template: True` is set, this field is ignored. Default is `power_on: True`.

**extra_config** Specifies the additional configuration information for the virtual machine. This describes a set of modifications to the additional options. If the key is already present, it will be reset with the new value provided. Otherwise, a new option is added. Keys with empty values will be removed.

**deploy** Specifies if salt should be installed on the newly created VM. Default is `True` so salt will be installed using the bootstrap script. If `template: True` or `power_on: False` is set, this field is ignored and salt will not be installed.

**private_key** Specify the path to the private key to use to be able to ssh to the VM.

**ssh_username** Specify the username to use in order to ssh to the VM. Default is `root`.

**password** Specify a password to use in order to ssh to the VM. If `private_key` is specified, you do not need to specify this.

**minion** Specify custom minion configuration you want the salt minion to have. A good example would be to specify the `master` as the IP/DNS name of the master.

**file_map** Specify file/files you want to copy to the VM before the bootstrap script is run and salt is installed. A good example of using this would be if you need to put custom repo files on the server in case your server will be in a private network and cannot reach external networks.

**hardware_version** Specify the virtual hardware version for the vm/template that is supported by the host.

### 24.5.20 Getting Started With vSphere

**Note:** Deprecated since version Carbon: The `vsphere` cloud driver has been deprecated in favor of the `vmware` cloud driver and will be removed in Salt Carbon. Please refer to **Getting started with VMware** instead to get started with the configuration.

VMware vSphere is a management platform for virtual infrastructure and cloud computing.

**Dependencies**

The vSphere module for Salt Cloud requires the PySphere package, which is available at PyPI:

https://pypi.python.org/pypi/pysphere

This package can be installed using `pip` or `easy_install`:

```
# pip install pysphere
# easy_install pysphere
```
Configuration

Set up the cloud config at `/etc/salt/cloud.providers` or in the `/etc/salt/cloud.providers.d/` directory:

```yaml
my-vsphere-config:
  driver: vsphere
  # Set the vSphere access credentials
  user: marco
  password: polo
  # Set the URL of your vSphere server
  url: 'vsphere.example.com'
```

**Note:** Changed in version 2015.8.0.

The `provider` parameter in cloud provider definitions was renamed to `driver`. This change was made to avoid confusion with the `provider` parameter that is used in cloud profile definitions. Cloud provider definitions now use `driver` to refer to the Salt cloud module that provides the underlying functionality to connect to a cloud host, while cloud profiles continue to use `provider` to refer to provider configurations that you define.

Profiles

Cloud Profiles

vSphere uses a Managed Object Reference to identify objects located in vCenter. The MOR ID's are used when configuring a vSphere cloud profile. Use the following reference when locating the MOR's for the cloud profile.

http://kb.vmware.com/selfservice/microsites/search.do?cmd=displayKC&docType=kc&externalId=1017126&sliceId=1&docTypeID=DT_KB_1_1&dialogID=520386078&stateId=1%200%20520388386

Set up an initial profile at `/etc/salt/cloud.profiles` or in the `/etc/salt/cloud.profiles.d/` directory:

```yaml
vsphere-centos:
  provider: my-vsphere-config
  image: centos
  # Optional
  datastore: datastore-15
  resourcepool: resgroup-8
  folder: salt-cloud
  host: host-9
  template: False
```

**provider** Enter the name that was specified when the cloud provider profile was created.

**image** Images available to build an instance can be found using the `--list-images` option:

```
# salt-cloud --list-images my-vsphere-config
```

**datastore** The MOR of the datastore where the virtual machine should be located. If not specified, the current datastore is used.

**resourcepool** The MOR of the resourcepool to be used for the new vm. If not set, it will use the same resourcepool as the original vm.
folder  Name of the folder that will contain the new VM. If not set, the VM will be added to the folder the original VM belongs to.

host  The MOR of the host where the vm should be registered.

If not specified:

- if resourcepool is not specified, the current host is used.
- if resourcepool is specified, and the target pool represents a stand-alone host, the host is used.
- if resourcepool is specified, and the target pool represents a DRS-enabled cluster, a host selected by DRS is used.
- if resourcepool is specified, and the target pool represents a cluster without DRS enabled, an InvalidArgument exception will be thrown.

template  Specifies whether or not the new virtual machine should be marked as a template. Default is False.

### 24.6 Miscellaneous Options

#### 24.6.1 Miscellaneous Salt Cloud Options

This page describes various miscellaneous options available in Salt Cloud.

**Deploy Script Arguments**

Custom deploy scripts are unlikely to need custom arguments to be passed to them, but salt-bootstrap has been extended quite a bit, and this may be necessary. `script_args` can be specified in either the profile or the map file, to pass arguments to the deploy script:

```yaml
ec2-amazon:
  provider: my-ec2-config
  image: ami-1624987f
  size: t1.micro
  ssh_username: ec2-user
  script: bootstrap-salt
  script_args: -c /tmp/

This has also been tested to work with pipes, if needed:

```yaml
script_args: | head
```

**Selecting the File Transport**

By default, Salt Cloud uses SFTP to transfer files to Linux hosts. However, if SFTP is not available, or specific SCP functionality is needed, Salt Cloud can be configured to use SCP instead.

```yaml
file_transport: sftp
file_transport: scp
```
Sync After Install

Salt allows users to create custom modules, grains, and states which can be synchronised to minions to extend Salt with further functionality.

This option will inform Salt Cloud to synchronise your custom modules, grains, states or all these to the minion just after it has been created. For this to happen, the following line needs to be added to the main cloud configuration file:

```
sync_after_install: all
```

The available options for this setting are:

- modules
- grains
- states
- all

Setting up New Salt Masters

It has become increasingly common for users to set up multi-hierarchal infrastructures using Salt Cloud. This sometimes involves setting up an instance to be a master in addition to a minion. With that in mind, you can now lay down master configuration on a machine by specifying master options in the profile or map file.

```
make_master: True
```

This will cause Salt Cloud to generate master keys for the instance, and tell salt-bootstrap to install the salt-master package, in addition to the salt-minion package.

The default master configuration is usually appropriate for most users, and will not be changed unless specific master configuration has been added to the profile or map:

```
master:
  user: root
  interface: 0.0.0.0
```

Delete SSH Keys

When Salt Cloud deploys an instance, the SSH pub key for the instance is added to the known_hosts file for the user that ran the salt-cloud command. When an instance is deployed, a cloud host generally recycles the IP address for the instance. When Salt Cloud attempts to deploy an instance using a recycled IP address that has previously been accessed from the same machine, the old key in the known_hosts file will cause a conflict.

In order to mitigate this issue, Salt Cloud can be configured to remove old keys from the known_hosts file when destroying the node. In order to do this, the following line needs to be added to the main cloud configuration file:

```
delete_sshkeys: True
```

Keeping /tmp/ Files

When Salt Cloud deploys an instance, it uploads temporary files to /tmp/ for salt-bootstrap to put in place. After the script has run, they are deleted. To keep these files around (mostly for debugging purposes), the --keep-tmp option can be added:
salt-cloud -p myprofile mymachine --keep-tmp

For those wondering why /tmp/ was used instead of /root/, this had to be done for images which require the use of sudo, and therefore do not allow remote root logins, even for file transfers (which makes /root/ unavailable).

**Hide Output From Minion Install**

By default Salt Cloud will stream the output from the minion deploy script directly to STDOUT. Although this can been very useful, in certain cases you may wish to switch this off. The following config option is there to enable or disable this output:

```plaintext
display_ssh_output: False
```

**Connection Timeout**

There are several stages when deploying Salt where Salt Cloud needs to wait for something to happen. The VM getting it’s IP address, the VM’s SSH port is available, etc.

If you find that the Salt Cloud defaults are not enough and your deployment fails because Salt Cloud did not wait log enough, there are some settings you can tweak.

**Note**

All values should be provided in seconds

You can tweak these settings globally, per cloud provider, or event per profile definition.

**wait_for_ip_timeout**

The amount of time Salt Cloud should wait for a VM to start and get an IP back from the cloud host. Default: varies by cloud provider (between 5 and 25 minutes)

**wait_for_ip_interval**

The amount of time Salt Cloud should sleep while querying for the VM's IP. Default: varies by cloud provider (between .5 and 10 seconds)

**ssh_connect_timeout**

The amount of time Salt Cloud should wait for a successful SSH connection to the VM. Default: varies by cloud provider (between 5 and 15 minutes)

**wait_for_passwd_timeout**

The amount of time until an ssh connection can be established via password or ssh key. Default: varies by cloud provider (mostly 15 seconds)
wait_for_passwd_maxtries

The number of attempts to connect to the VM until we abandon. Default: 15 attempts

wait_for_fun_timeout

Some cloud drivers check for an available IP or a successful SSH connection using a function, namely, SoftLayer, and SoftLayer-HW. So, the amount of time Salt Cloud should retry such functions before failing. Default: 15 minutes.

wait_for_spot_timeout

The amount of time Salt Cloud should wait before an EC2 Spot instance is available. This setting is only available for the EC2 cloud driver. Default: 10 minutes

Salt Cloud Cache

Salt Cloud can maintain a cache of node data, for supported providers. The following options manage this functionality.

update_cachedir

On supported cloud providers, whether or not to maintain a cache of nodes returned from a --full-query. The data will be stored in msgpack format under <SALT_CACHEDIR>/cloud/active/<DRIVER>/<PROVIDER>/<NODE_NAME>.p. This setting can be True or False.

diff_cache_events

When the cloud cachedir is being managed, if differences are encountered between the data that is returned live from the cloud host and the data in the cache, fire events which describe the changes. This setting can be True or False.

Some of these events will contain data which describe a node. Because some of the fields returned may contain sensitive data, the cache_event_strip_fields configuration option exists to strip those fields from the event return.

```yaml
cache_event_strip_fields:
  - password
  - priv_key
```

The following are events that can be fired based on this data.

salt/cloud/minionid/cache_node_new  A new node was found on the cloud host which was not listed in the cloud cachedir. A dict describing the new node will be contained in the event.

salt/cloud/minionid/cache_node_missing  A node that was previously listed in the cloud cachedir is no longer available on the cloud host.

salt/cloud/minionid/cache_node_diff  One or more pieces of data in the cloud cachedir has changed on the cloud host. A dict containing both the old and the new data will be contained in the event.
SSH Known Hosts

Normally when bootstrapping a VM, salt-cloud will ignore the SSH host key. This is because it does not know what the host key is before starting (because it doesn't exist yet). If strict host key checking is turned on without the key in the known_hosts file, then the host will never be available, and cannot be bootstrapped.

If a provider is able to determine the host key before trying to bootstrap it, that provider's driver can add it to the known_hosts file, and then turn on strict host key checking. This can be set up in the main cloud configuration file (normally /etc/salt/cloud) or in the provider-specific configuration file:

| known_hosts_file: /path/to/.ssh/known_hosts |

If this is not set, it will default to /dev/null, and strict host key checking will be turned off.

It is highly recommended that this option is not set, unless the user has verified that the provider supports this functionality, and that the image being used is capable of providing the necessary information. At this time, only the EC2 driver supports this functionality.

SSH Agent

New in version 2015.5.0.

If the ssh key is not stored on the server salt-cloud is being run on, set ssh_agent, and salt-cloud will use the forwarded ssh-agent to authenticate.

| ssh_agent: True |

File Map Upload

New in version 2014.7.0.

The file_map option allows an arbitrary group of files to be uploaded to the target system before running the deploy script. This functionality requires a provider uses salt.utils.cloud.bootstrap(), which is currently limited to the ec2, gce, openstack and nova drivers.

The file_map can be configured globally in /etc/salt/cloud, or in any cloud provider or profile file. For example, to upload an extra package or a custom deploy script, a cloud profile using file_map might look like:

<table>
<thead>
<tr>
<th>ubuntu14:</th>
</tr>
</thead>
<tbody>
<tr>
<td>provider: ec2-config</td>
</tr>
<tr>

24.7 Troubleshooting Steps

24.7.1 Troubleshooting Salt Cloud

This page describes various steps for troubleshooting problems that may arise while using Salt Cloud.
Virtual Machines Are Created, But Do Not Respond

Are TCP ports 4505 and 4506 open on the master? This is easy to overlook on new masters. Information on how to open firewall ports on various platforms can be found here.

Generic Troubleshooting Steps

This section describes a set of instructions that are useful to a large number of situations, and are likely to solve most issues that arise.

Version Compatibility

One of the most common issues that Salt Cloud users run into is import errors. These are often caused by version compatibility issues with Salt.

Salt 0.16.x works with Salt Cloud 0.8.9 or greater.
Salt 0.17.x requires Salt Cloud 0.8.11.
Releases after 0.17.x (0.18 or greater) should not encounter issues as Salt Cloud has been merged into Salt itself.

Debug Mode

Frequently, running Salt Cloud in debug mode will reveal information about a deployment which would otherwise not be obvious:

```
salt-cloud -p myprofile myinstance -l debug
```

Keep in mind that a number of messages will appear that look at first like errors, but are in fact intended to give developers factual information to assist in debugging. A number of messages that appear will be for cloud providers that you do not have configured; in these cases, the message usually is intended to confirm that they are not configured.

Salt Bootstrap

By default, Salt Cloud uses the Salt Bootstrap script to provision instances:

This script is packaged with Salt Cloud, but may be updated without updating the Salt package:

```
salt-cloud -u
```

The Bootstrap Log

If the default deploy script was used, there should be a file in the /tmp/ directory called bootstrap-salt.log. This file contains the full output from the deployment, including any errors that may have occurred.

Keeping Temp Files

Salt Cloud uploads minion-specific files to instances once they are available via SSH, and then executes a deploy script to put them into the correct place and install Salt. The --keep-tmp option will instruct Salt Cloud not to remove those files when finished with them, so that the user may inspect them for problems:
salt-cloud -p myprofile myinstance --keep-tmp

By default, Salt Cloud will create a directory on the target instance called /tmp/.saltcloud/. This directory should be owned by the user that is to execute the deploy script, and should have permissions of 0700.

Most cloud hosts are configured to use root as the default initial user for deployment, and as such, this directory and all files in it should be owned by the root user.

The /tmp/.saltcloud/ directory should have the following files:

- A deploy.sh script. This script should have permissions of 0755.
- A .pem and .pub key named after the minion. The .pem file should have permissions of 0600. Ensure that the .pem and .pub files have been properly copied to the /etc/salt/pki/minion/ directory.
- A file called minion. This file should have been copied to the /etc/salt/ directory.
- Optionally, a file called grains. This file, if present, should have been copied to the /etc/salt/ directory.

Unprivileged Primary Users

Some cloud hosts, most notably EC2, are configured with a different primary user. Some common examples are ec2-user, ubuntu, fedora, and bitnami. In these cases, the /tmp/.saltcloud/ directory and all files in it should be owned by this user.

Some cloud hosts, such as EC2, are configured to not require these users to provide a password when using the sudo command. Because it is more secure to require sudo users to provide a password, other hosts are configured that way.

If this instance is required to provide a password, it needs to be configured in Salt Cloud. A password for sudo to use may be added to either the provider configuration or the profile configuration:

```
sudo_password: mypassword
```

/tmp/ is Mounted as noexec

It is more secure to mount the /tmp/ directory with a noexec option. This is uncommon on most cloud hosts, but very common in private environments. To see if the /tmp/ directory is mounted this way, run the following command:

```
mount | grep tmp
```

If the output of this command includes a line that looks like this, then the /tmp/ directory is mounted as noexec:

```
tmpfs on /tmp type tmpfs (rw,noexec)
```

If this is the case, then the deploy_command will need to be changed in order to run the deploy script through the sh command, rather than trying to execute it directly. This may be specified in either the provider or the profile config:

```
deploy_command: sh /tmp/.saltcloud/deploy.sh
```

Please note that by default, Salt Cloud will place its files in a directory called /tmp/.saltcloud/. This may be also be changed in the provider or profile configuration:
tmp_dir: /tmp/.saltcloud/

If this directory is changed, then the deploy_command need to be changed in order to reflect the tmp_dir configuration.

Executing the Deploy Script Manually

If all of the files needed for deployment were successfully uploaded to the correct locations, and contain the correct permissions and ownerships, the deploy script may be executed manually in order to check for other issues:

```bash
cd /tmp/.saltcloud/
./deploy.sh
```

24.8 Extending Salt Cloud

24.8.1 Writing Cloud Driver Modules

Salt Cloud runs on a module system similar to the main Salt project. The modules inside saltcloud exist in the salt/cloud/clouds directory of the salt source.

There are two basic types of cloud modules. If a cloud host is supported by libcloud, then using it is the fastest route to getting a module written. The Apache Libcloud project is located at:

http://libcloud.apache.org/

Not every cloud host is supported by libcloud. Additionally, not every feature in a supported cloud host is necessarily supported by libcloud. In either of these cases, a module can be created which does not rely on libcloud.

All Driver Modules

The following functions are required by all driver modules, whether or not they are based on libcloud.

The __virtual__() Function

This function determines whether or not to make this cloud module available upon execution. Most often, it uses get_configured_provider() to determine if the necessary configuration has been set up. It may also check for necessary imports, to decide whether to load the module. In most cases, it will return a True or False value.

If the name of the driver used does not match the filename, then that name should be returned instead of True. An example of this may be seen in the Azure module:

https://github.com/saltstack/salt/tree/develop/salt/cloud/clouds/msazure.py

The get_configured_provider() Function

This function uses config.is_provider_configured() to determine whether all required information for this driver has been configured. The last value in the list of required settings should be followed by a comma.
Libcloud Based Modules

Writing a cloud module based on libcloud has two major advantages. First of all, much of the work has already been done by the libcloud project. Second, most of the functions necessary to Salt have already been added to the Salt Cloud project.

The create() Function

The most important function that does need to be manually written is the create() function. This is what is used to request a virtual machine to be created by the cloud host, wait for it to become available, and then (optionally) log in and install Salt on it.

A good example to follow for writing a cloud driver module based on libcloud is the module provided for Linode: https://github.com/saltstack/salt/tree/develop/salt/cloud/clouds/linode.py

The basic flow of a create() function is as follows:

- Send a request to the cloud host to create a virtual machine.
- Wait for the virtual machine to become available.
- Generate kwargstobe used to deploy Salt.
- Log into the virtual machine and deploy Salt.
- Return a data structure that describes the newly-created virtual machine.

At various points throughout this function, events may be fired on the Salt event bus. Four of these events, which are described below, are required. Other events may be added by the user, where appropriate.

When the create() function is called, it is passed a data structure called vm_. This dict contains a composite of information describing the virtual machine to be created. A dict called __opts__ is also provided by Salt, which contains the options used to run Salt Cloud, as well as a set of configuration and environment variables.

The first thing the create() function must do is fire an event stating that it has started the create process. This event is tagged salt/cloud/<vm name>/creating. The payload contains the names of the VM, profile, and provider.

A set of kwargs is then usually created, to describe the parameters required by the cloud host to request the virtual machine.

An event is then fired to state that a virtual machine is about to be requested. It is tagged as salt/cloud/<vm name>/requesting. The payload contains most or all of the parameters that will be sent to the cloud host. Any private information (such as passwords) should not be sent in the event.

After a request is made, a set of deploy kwargs will be generated. These will be used to install Salt on the target machine. Windows options are supported at this point, and should be generated, even if the cloud host does not currently support Windows. This will save time in the future if the host does eventually decide to support Windows.

An event is then fired to state that the deploy process is about to begin. This event is tagged salt/cloud/<vm name>/deploying. The payload for the event will contain a set of deploy kwargs, useful for debugging purposes. Any private data, including passwords and keys (including public keys) should be stripped from the deploy kwargs before the event is fired.

If any Windows options have been passed in, the salt.utils.cloud.deploy_windows() function will be called. Otherwise, it will be assumed that the target is a Linux or Unix machine, and the salt.utils.cloud.deploy_script() will be called.

Both of these functions will wait for the target machine to become available, then the necessary port to log in, then a successful login that can be used to install Salt. Minion configuration and keys will then be uploaded to a temporary
directory on the target by the appropriate function. On a Windows target, the Windows Minion Installer will be run in silent mode. On a Linux/Unix target, a deploy script (bootstrap-salt.sh, by default) will be run, which will auto-detect the operating system, and install Salt using its native package manager. These do not need to be handled by the developer in the cloud module.

The `salt.utils.cloud.validate_windows_cred()` function has been extended to take the number of retries and retry_delay parameters in case a specific cloud host has a delay between providing the Windows credentials and the credentials being available for use. In their `create()` function, or as a sub-function called during the creation process, developers should use the `win_deploy_auth_retries` and `win_deploy_auth_retry_delay` parameters from the provider configuration to allow the end-user the ability to customize the number of tries and delay between tries for their particular host.

After the appropriate deploy function completes, a final event is fired which describes the virtual machine that has just been created. This event is tagged `salt/cloud/<vm name>/created`. The payload contains the names of the VM, profile, and provider.

Finally, a dict (queried from the provider) which describes the new virtual machine is returned to the user. Because this data is not fired on the event bus it can, and should, return any passwords that were returned by the cloud host. In some cases (for example, Rackspace), this is the only time that the password can be queried by the user; post-creation queries may not contain password information (depending upon the host).

**The libcloudfuncs Functions**

A number of other functions are required for all cloud hosts. However, with libcloud-based modules, these are all provided for free by the libcloudfuncs library. The following two lines set up the imports:

```python
from salt.cloud.libcloudfuncs import *  # pylint: disable=W0614,W0401
from salt.utils import namespaced_function
```

And then a series of declarations will make the necessary functions available within the cloud module.

```python
get_size = namespaced_function(get_size, globals())
get_image = namespaced_function(get_image, globals())
avail_locations = namespaced_function(avail_locations, globals())
avail_images = namespaced_function(avail_images, globals())
avail_sizes = namespaced_function(avail_sizes, globals())
script = namespaced_function(script, globals())
destroy = namespaced_function(destroy, globals())
list_nodes = namespaced_function(list_nodes, globals())
list_nodes_full = namespaced_function(list_nodes_full, globals())
list_nodes_select = namespaced_function(list_nodes_select, globals())
show_instance = namespaced_function(show_instance, globals())
```

If necessary, these functions may be replaced by removing the appropriate declaration line, and then adding the function as normal.

These functions are required for all cloud modules, and are described in detail in the next section.

**Non-Libcloud Based Modules**

In some cases, using libcloud is not an option. This may be because libcloud has not yet included the necessary driver itself, or it may be that the driver that is included with libcloud does not contain all of the necessary features required by the developer. When this is the case, some or all of the functions in `libcloudfuncs` may be replaced. If they are all replaced, the libcloud imports should be absent from the Salt Cloud module.

A good example of a non-libcloud driver is the DigitalOcean driver:
The `create()` Function

The `create()` function must be created as described in the libcloud-based module documentation.

The `get_size()` Function

This function is only necessary for libcloud-based modules, and does not need to exist otherwise.

The `get_image()` Function

This function is only necessary for libcloud-based modules, and does not need to exist otherwise.

The `avail_locations()` Function

This function returns a list of locations available, if the cloud host uses multiple data centers. It is not necessary if the cloud host uses only one data center. It is normally called using the `--list-locations` option.

```
salt-cloud --list-locations my-cloud-provider
```

The `avail_images()` Function

This function returns a list of images available for this cloud provider. There are not currently any known cloud providers that do not provide this functionality, though they may refer to images by a different name (for example, `templates`). It is normally called using the `--list-images` option.

```
salt-cloud --list-images my-cloud-provider
```

The `avail_sizes()` Function

This function returns a list of sizes available for this cloud provider. Generally, this refers to a combination of RAM, CPU, and/or disk space. This functionality may not be present on some cloud providers. For example, the Parallels module breaks down RAM, CPU, and disk space into separate options, whereas in other providers, these options are baked into the image. It is normally called using the `--list-sizes` option.

```
salt-cloud --list-sizes my-cloud-provider
```

The `script()` Function

This function builds the deploy script to be used on the remote machine. It is likely to be moved into the `salt.utils.cloud` library in the near future, as it is very generic and can usually be copied wholesale from another module. An excellent example is in the Azure driver.
The destroy() Function

This function irreversibly destroys a virtual machine on the cloud provider. Before doing so, it should fire an event on the Salt event bus. The tag for this event is `salt/cloud/<vm name>/destroying`. Once the virtual machine has been destroyed, another event is fired. The tag for that event is `salt/cloud/<vm name>/destroyed`.

This function is normally called with the `-d` options:

```
salt-cloud -d myinstance
```

The list_nodes() Function

This function returns a list of nodes available on this cloud provider, using the following fields:

- id (str)
- image (str)
- size (str)
- state (str)
- private_ips (list)
- public_ips (list)

No other fields should be returned in this function, and all of these fields should be returned, even if empty. The private_ips and public_ips fields should always be of a list type, even if empty, and the other fields should always be of a str type. This function is normally called with the `-Q` option:

```
salt-cloud -Q
```

The list_nodes_full() Function

All information available about all nodes should be returned in this function. The fields in the list_nodes() function should also be returned, even if they would not normally be provided by the cloud provider. This is because some functions both within Salt and 3rd party will break if an expected field is not present. This function is normally called with the `-F` option:

```
salt-cloud -F
```

The list_nodes_select() Function

This function returns only the fields specified in the `query.selection` option in `/etc/salt/cloud`. Because this function is so generic, all of the heavy lifting has been moved into the `salt.utils.cloud` library.

A function to call `list_nodes_select()` still needs to be present. In general, the following code can be used as-is:

```python
def list_nodes_select(call=None):
    ""
    Return a list of the VMs that are on the provider, with select fields
    ""
    return salt.utils.cloud.list_nodes_select(
        list_nodes_full('function'), __opts__['query.selection'], call,
    )
```

24.8. Extending Salt Cloud 373
However, depending on the cloud provider, additional variables may be required. For instance, some modules use a `conn` object, or may need to pass other options into `list_nodes_full()`. In this case, be sure to update the function appropriately:

```python
def list_nodes_select(conn=None, call=None):
    '''
    Return a list of the VMs that are on the provider, with select fields
    '''
    if not conn:
        conn = get_conn()  # pylint: disable=E0602
    return salt.utils.cloud.list_nodes_select(
        list_nodes_full(conn, 'function'),
        __opts__['query.selection'],
        call,
    )
```

This function is normally called with the `-S` option:

```
salt-cloud -S
```

The `show_instance()` Function

This function is used to display all of the information about a single node that is available from the cloud provider. The simplest way to provide this is usually to call `list_nodes_full()`, and return just the data for the requested node. It is normally called as an action:

```
salt-cloud -a show_instance myinstance
```

Actions and Functions

Extra functionality may be added to a cloud provider in the form of an `--action` or a `--function`. Actions are performed against a cloud instance/virtual machine, and functions are performed against a cloud provider.

Actions

Actions are calls that are performed against a specific instance or virtual machine. The `show_instance` action should be available in all cloud modules. Actions are normally called with the `-a` option:

```
salt-cloud -a show_instance myinstance
```

Actions must accept a `name` as a first argument, may optionally support any number of `kwargs` as appropriate, and must accept an argument of `call`, with a default of `None`.

Before performing any other work, an action should normally verify that it has been called correctly. It may then perform the desired feature, and return useful information to the user. A basic action looks like:

```python
def show_instance(name, call=None):
    '''
    Show the details from EC2 concerning an AMI
    '''
    if call != 'action':
        raise SaltCloudSystemExit(  
            'The show_instance action must be called with -a or --action.'
        )
```
Please note that generic kwargs, if used, are passed through to actions as kwargs and not **kwargs. An example of this is seen in the Functions section.

### Functions

Functions are called that are performed against a specific cloud provider. An optional function that is often useful is `show_image`, which describes an image in detail. Functions are normally called with the `-f` option:

```bash
salt-cloud -f show_image my-cloud-provider image='Ubuntu 13.10 64-bit'
```

A function may accept any number of kwargs as appropriate, and must accept an argument of `call` with a default of `None`.

Before performing any other work, a function should normally verify that it has been called correctly. It may then perform the desired feature, and return useful information to the user. A basic function looks like:

```python
def show_image(kwargs, call=None):
    '''
    Show the details from EC2 concerning an AMI
    '''
    if call != 'function':
        raise SaltCloudSystemExit(  
            'The show_image action must be called with -f or --function.'
        )
    params = {
        'ImageId.1': kwargs['image'],  
        'Action': 'DescribeImages'
    }  
    result = query(params)
    log.info(result)

    return result
```

Take note that generic kwargs are passed through to functions as kwargs and not **kwargs.

#### 24.8.2 OS Support for Cloud VMs

Salt Cloud works primarily by executing a script on the virtual machines as soon as they become available. The script that is executed is referenced in the cloud profile as the `script`. In older versions, this was the `os` argument. This was changed in 0.8.2.

A number of legacy scripts exist in the deploy directory in the saltcloud source tree. The preferred method is currently to use the salt-bootstrap script. A stable version is included with each release tarball starting with 0.8.4. The most updated version can be found at:

https://github.com/saltstack/salt-bootstrap

If you do not specify a script argument, this script will be used at the default.

If the Salt Bootstrap script does not meet your needs, you may write your own. The script should be written in bash and is a Jinja template. Deploy scripts need to execute a number of functions to do a complete salt setup. These functions include:

1. Install the salt minion. If this can be done via system packages this method is HIGHLY preferred.
2. Add the salt minion keys before the minion is started for the first time. The minion keys are available as strings that can be copied into place in the Jinja template under the dict named "vm".

3. Start the salt-minion daemon and enable it at startup time.

4. Set up the minion configuration file from the "minion" data available in the Jinja template.

A good, well commented, example of this process is the Fedora deployment script:

https://github.com/saltstack/salt-cloud/blob/master/saltcloud/deploy/Fedora.sh

A number of legacy deploy scripts are included with the release tarball. None of them are as functional or complete as Salt Bootstrap, and are still included for academic purposes.

Other Generic Deploy Scripts

If you want to be assured of always using the latest Salt Bootstrap script, there are a few generic templates available in the deploy directory of your saltcloud source tree:

```
curl-bootstrap
curl-bootstrap-git
python-bootstrap
wget-bootstrap
wget-bootstrap-git
```

These are example scripts which were designed to be customized, adapted, and refit to meet your needs. One important use of them is to pass options to the salt-bootstrap script, such as updating to specific git tags.

Post-Deploy Commands

Once a minion has been deployed, it has the option to run a salt command. Normally, this would be the state.highstate command, which would finish provisioning the VM. Another common option is state.sls, or for just testing, test.ping. This is configured in the main cloud config file:

```
start_action: state.highstate
```

This is currently considered to be experimental functionality, and may not work well with all cloud hosts. If you experience problems with Salt Cloud hanging after Salt is deployed, consider using Startup States instead:

http://docs.saltstack.com/ref/states/startup.html

Skipping the Deploy Script

For whatever reason, you may want to skip the deploy script altogether. This results in a VM being spun up much faster, with absolutely no configuration. This can be set from the command line:

```
salt-cloud --no-deploy -p micro_aws my_instance
```

Or it can be set from the main cloud config file:

```
deploy: False
```

Or it can be set from the provider’s configuration:

```
RACKSPACE.user: example_user
RACKSPACE.apikey: 123984bjjas87034
RACKSPACE.deploy: False
```
Or even on the VM's profile settings:

```yaml
ubuntu_aws:
    provider: my-ec2-config
    image: ami-7e2da54e
    size: t1.micro
    deploy: False
```

The default for deploy is True.

In the profile, you may also set the script option to None:

```yaml
script: None
```

This is the slowest option, since it still uploads the None deploy script and executes it.

**Updating Salt Bootstrap**

Salt Bootstrap can be updated automatically with salt-cloud:

```bash
salt-cloud -u
salt-cloud --update-bootstrap
```

Bear in mind that this updates to the latest (unstable) version, so use with caution.

**Keeping /tmp/ Files**

When Salt Cloud deploys an instance, it uploads temporary files to /tmp/ for salt-bootstrap to put in place. After the script has run, they are deleted. To keep these files around (mostly for debugging purposes), the --keep-tmp option can be added:

```bash
salt-cloud -p myprofile mymachine --keep-tmp
```

For those wondering why /tmp/ was used instead of /root/, this had to be done for images which require the use of sudo, and therefore do not allow remote root logins, even for file transfers (which makes /root/ unavailable).

**Deploy Script Arguments**

Custom deploy scripts are unlikely to need custom arguments to be passed to them, but salt-bootstrap has been extended quite a bit, and this may be necessary. script_args can be specified in either the profile or the map file, to pass arguments to the deploy script:

```yaml
aws-amazon:
    provider: my-ec2-config
    image: ami-1624987f
    size: t1.micro
    ssh_username: ec2-user
    script: bootstrap-salt
    script_args: -c /tmp/
```

This has also been tested to work with pipes, if needed:

```yaml
script_args: | head
```
24.9 Using Salt Cloud from Salt

24.9.1 Using the Salt Modules for Cloud

In addition to the `salt-cloud` command, Salt Cloud can be called from Salt, in a variety of different ways. Most users will be interested in either the execution module or the state module, but it is also possible to call Salt Cloud as a runner.

Because the actual work will be performed on a remote minion, the normal Salt Cloud configuration must exist on any target minion that needs to execute a Salt Cloud command. Because Salt Cloud now supports breaking out configuration into individual files, the configuration is easily managed using Salt's own `file.managed` state function. For example, the following directories allow this configuration to be managed easily:

```
/etc/salt/cloud.providers.d/
/etc/salt/cloud.profiles.d/
```

Minion Keys

Keep in mind that when creating minions, Salt Cloud will create public and private minion keys, upload them to the minion, and place the public key on the machine that created the minion. It will *not* attempt to place any public minion keys on the master, unless the minion which was used to create the instance is also the Salt Master. This is because granting arbitrary minions access to modify keys on the master is a serious security risk, and must be avoided.

Execution Module

The `cloud` module is available to use from the command line. At the moment, almost every standard Salt Cloud feature is available to use. The following commands are available:

```
list_images
```

This command is designed to show images that are available to be used to create an instance using Salt Cloud. In general they are used in the creation of profiles, but may also be used to create an instance directly (see below). Listing images requires a provider to be configured, and specified:

```
salt myminion cloud.list_images my-cloud-provider
```

```
list_sizes
```

This command is designed to show sizes that are available to be used to create an instance using Salt Cloud. In general they are used in the creation of profiles, but may also be used to create an instance directly (see below). This command is not available for all cloud providers; see the provider-specific documentation for details. Listing sizes requires a provider to be configured, and specified:

```
salt myminion cloud.list_sizes my-cloud-provider
```

```
list_locations
```

This command is designed to show locations that are available to be used to create an instance using Salt Cloud. In general they are used in the creation of profiles, but may also be used to create an instance directly (see below).
This command is not available for all cloud providers; see the provider-specific documentation for details. Listing locations requires a provider to be configured, and specified:

```bash
salt myminion cloud.list_locations my-cloud-provider
```

**query**

This command is used to query all configured cloud providers, and display all instances associated with those accounts. By default, it will run a standard query, returning the following fields:

- **id** The name or ID of the instance, as used by the cloud provider.
- **image** The disk image that was used to create this instance.
- **private_ips** Any public IP addresses currently assigned to this instance.
- **public_ips** Any private IP addresses currently assigned to this instance.
- **size** The size of the instance; can refer to RAM, CPU(s), disk space, etc., depending on the cloud provider.
- **state** The running state of the instance; for example, `running`, `stopped`, `pending`, etc. This state is dependent upon the provider.

This command may also be used to perform a full query or a select query, as described below. The following usages are available:

```bash
salt myminion cloud.query
salt myminion cloud.query list_nodes
salt myminion cloud.query list_nodes_full
```

**full_query**

This command behaves like the `query` command, but lists all information concerning each instance as provided by the cloud provider, in addition to the fields returned by the `query` command.

```bash
salt myminion cloud.full_query
```

**select_query**

This command behaves like the `query` command, but only returned select fields as defined in the `/etc/salt/cloud` configuration file. A sample configuration for this section of the file might look like:

```yaml
query.selection:
  - id
  - key_name
```

This configuration would only return the `id` and `key_name` fields, for those cloud providers that support those two fields. This would be called using the following command:

```bash
salt myminion cloud.select_query
```

**profile**

This command is used to create an instance using a profile that is configured on the target minion. Please note that the profile must be configured before this command can be used with it.

---

24.9. Using Salt Cloud from Salt
Please note that the execution module does not run in parallel mode. Using multiple minions to create instances can effectively perform parallel instance creation.

**create**

This command is similar to the `profile` command, in that it is used to create a new instance. However, it does not require a profile to be pre-configured. Instead, all of the options that are normally configured in a profile are passed directly to Salt Cloud to create the instance:

```
salt myminion cloud.create my-ec2-config my-new-instance

  image=ami-1624987f size=t1.micro ssh_username=ec2-user
  securitygroup=default delvol_on_destroy=True
```

Please note that the execution module does not run in parallel mode. Using multiple minions to create instances can effectively perform parallel instance creation.

**destroy**

This command is used to destroy an instance or instances. This command will search all configured providers and remove any instance(s) which matches the name(s) passed in here. The results of this command are non-reversible and should be used with caution.

```
salt myminion cloud.destroy myinstance
salt myminion cloud.destroy myinstance1,myinstance2
```

**action**

This command implements both the `action` and the `function` commands used in the standard salt-cloud command. If one of the standard `action` commands is used, an instance name must be provided. If one of the standard function commands is used, a provider configuration must be named.

```
salt myminion cloud.action start instance=myinstance
salt myminion cloud.action show_image provider=my-ec2-config

  image=ami-1624987f
```

The actions available are largely dependent upon the module for the specific cloud provider. The following actions are available for all cloud providers:

**list_nodes** This is a direct call to the `query` function as described above, but is only performed against a single cloud provider. A provider configuration must be included.

**list_nodes_select** This is a direct call to the `full_query` function as described above, but is only performed against a single cloud provider. A provider configuration must be included.

**list_nodes_select** This is a direct call to the `select_query` function as described above, but is only performed against a single cloud provider. A provider configuration must be included.

**show_instance** This is a thin wrapper around `list_nodes`, which returns the full information about a single instance. An instance name must be provided.
State Module

A subset of the execution module is available through the cloud state module. Not all functions are currently included, because there is currently insufficient code for them to perform statefully. For example, a command to create an instance may be issued with a series of options, but those options cannot currently be statefully managed. Additional states to manage these options will be released at a later time.

cloud.present

This state will ensure that an instance is present inside a particular cloud provider. Any option that is normally specified in the cloud.create execution module and function may be declared here, but only the actual presence of the instance will be managed statefully.

```yaml
my-instance-name:
  cloud.present:
    - provider: my-ec2-config
    - image: ami-1624987f
    - size: 't1.micro'
    - ssh_username: ec2-user
    - securitygroup: default
    - delvol_on_destroy: True
```

cloud.profile

This state will ensure that an instance is present inside a particular cloud provider. This function calls the cloud.profile execution module and function, but as with cloud.present, only the actual presence of the instance will be managed statefully.

```yaml
my-instance-name:
  cloud.profile:
    - profile: ec2-centos64-x64
```

cloud.absent

This state will ensure that an instance (identified by name) does not exist in any of the cloud providers configured on the target minion. Please note that this state is non-reversible and may be considered especially destructive when issued as a cloud state.

```yaml
my-instance-name:
  cloud.absent
```

Runner Module

The cloud runner module is executed on the master, and performs actions using the configuration and Salt modules on the master itself. This means that any public minion keys will also be properly accepted by the master.

Using the functions in the runner module is no different than using those in the execution module, outside of the behavior described in the above paragraph. The following functions are available inside the runner:

- list_images
- list_sizes
- list_locations

24.9. Using Salt Cloud from Salt
Outside of the standard usage of `salt-run` itself, commands are executed as usual:

```bash
salt-run cloud.profile ec2-centos64-x86_64 my-instance-name
```

**CloudClient**

The execution, state, and runner modules ultimately all use the CloudClient library that ships with Salt. To use the CloudClient library locally (either on the master or a minion), create a client object and issue a command against it:

```python
import salt.cloud
import pprint
client = salt.cloud.CloudClient('/etc/salt/cloud')
nodes = client.query()
pprint.pprint(nodes)
```

## 24.10 Feature Comparison

### 24.10.1 Feature Matrix

A number of features are available in most cloud hosts, but not all are available everywhere. This may be because the feature isn’t supported by the cloud host itself, or it may only be that the feature has not yet been added to Salt Cloud. In a handful of cases, it is because the feature does not make sense for a particular cloud provider (Saltify, for instance).

This matrix shows which features are available in which cloud hosts, as far as Salt Cloud is concerned. This is not a comprehensive list of all features available in all cloud hosts, and should not be used to make business decisions concerning choosing a cloud host. In most cases, adding support for a feature to Salt Cloud requires only a little effort.

**Legacy Drivers**

Both AWS and Rackspace are listed as “Legacy”. This is because those drivers have been replaced by other drivers, which are generally the preferred method for working with those hosts.

The EC2 driver should be used instead of the AWS driver, when possible. The OpenStack driver should be used instead of the Rackspace driver, unless the user is dealing with instances in “the old cloud” in Rackspace.

**Note for Developers**

When adding new features to a particular cloud host, please make sure to add the feature to this table. Additionally, if you notice a feature that is not properly listed here, pull requests to fix them is appreciated.
### Standard Features

These are features that are available for almost every cloud host.

### 24.11 Tutorials

#### 24.11.1 Using Salt Cloud with the Event Reactor

One of the most powerful features of the Salt framework is the Event Reactor. As the Reactor was in development, Salt Cloud was regularly updated to take advantage of the Reactor upon completion. As such, various aspects of both the creation and destruction of instances with Salt Cloud fire events to the Salt Master, which can be used by the Event Reactor.

**Event Structure**

As of this writing, all events in Salt Cloud have a tag, which includes the ID of the instance being managed, and a payload which describes the task that is currently being handled. A Salt Cloud tag looks like:

```
salt/cloud/<minion_id>/<task>
```

For instance, the first event fired when creating an instance named `web1` would look like:
```
salt/cloud/web1/creating
```

Assuming this instance is using the `ec2-centos` profile, which is in turn using the `ec2-config` provider, the payload for this tag would look like:

```json
{
    'name': 'web1',
    'profile': 'ec2-centos',
    'provider': 'ec2-config:ec2'
}
```
Available Events

When an instance is created in Salt Cloud, whether by map, profile, or directly through an API, a minimum of five events are normally fired. More may be available, depending upon the cloud provider being used. Some of the common events are described below.

salt/cloud/<minion_id>/creating

This event states simply that the process to create an instance has begun. At this point in time, no actual work has begun. The payload for this event includes:

name profile provider

salt/cloud/<minion_id>/requesting

Salt Cloud is about to make a request to the cloud provider to create an instance. At this point, all of the variables required to make the request have been gathered, and the payload of the event will reflect those variables which do not normally pose a security risk. What is returned here is dependent upon the cloud provider. Some common variables are:

name image size location

salt/cloud/<minion_id>/querying

The instance has been successfully requested, but the necessary information to log into the instance (such as IP address) is not yet available. This event marks the beginning of the process to wait for this information.

The payload for this event normally only includes the instance_id.

salt/cloud/<minion_id>/waiting_for_ssh

The information required to log into the instance has been retrieved, but the instance is not necessarily ready to be accessed. Following this event, Salt Cloud will wait for the IP address to respond to a ping, then wait for the specified port (usually 22) to respond to a connection, and on Linux systems, for SSH to become available. Salt Cloud will attempt to issue the date command on the remote system, as a means to check for availability. If no ssh_username has been specified, a list of usernames (starting with root) will be attempted. If one or more usernames was configured for ssh_username, they will be added to the beginning of the list, in order.

The payload for this event normally only includes the ip_address.

salt/cloud/<minion_id>/deploying

The necessary port has been detected as available, and now Salt Cloud can log into the instance, upload any files used for deployment, and run the deploy script. Once the script has completed, Salt Cloud will log back into the instance and remove any remaining files.

A number of variables are used to deploy instances, and the majority of these will be available in the payload. Any keys, passwords or other sensitive data will be scraped from the payload. Most of the variables returned will be related to the profile or provider config, and any default values that could have been changed in the profile or provider, but weren't.
salt/cloud/<minion_id>/created

The deploy sequence has completed, and the instance is now available, Salted, and ready for use. This event is the final task for Salt Cloud, before returning instance information to the user and exiting.

The payload for this event contains little more than the initial creating event. This event is required in all cloud providers.

Configuring the Event Reactor

The Event Reactor is built into the Salt Master process, and as such is configured via the master configuration file. Normally this will be a YAML file located at /etc/salt/master. Additionally, master configuration items can be stored, in YAML format, inside the /etc/salt/master.d/ directory.

These configuration items may be stored in either location; however, they may only be stored in one location. For organizational and security purposes, it may be best to create a single configuration file, which contains only Event Reactor configuration, at /etc/salt/master.d/reactor.

The Event Reactor uses a top-level configuration item called reactor. This block contains a list of tags to be watched for, each of which also includes a list of sls files. For instance:

```
reactor:
  - 'salt/minion/*/start':
  - '/srv/reactor/custom-reactor.sls'
  - 'salt/cloud/*/created':
  - '/srv/reactor/cloud-alert.sls'
  - 'salt/cloud/*/destroyed':
  - '/srv/reactor/cloud-destroy-alert.sls'
```

The above configuration configures reactors for three different tags: one which is fired when a minion process has started and is available to receive commands, one which is fired when a cloud instance has been created, and one which is fired when a cloud instance is destroyed.

Note that each tag contains a wildcard (*) in it. For each of these tags, this will normally refer to a minion_id. This is not required of event tags, but is very common.

Reactor SLS Files

Reactor sls files should be placed in the /srv/reactor/ directory for consistency between environments, but this is not currently enforced by Salt.

Reactor sls files follow a similar format to other sls files in Salt. By default they are written in YAML and can be templated using jinja, but since they are processed through Salt's rendering system, any available renderer (JSON, Mako, Cheetah, etc.) can be used.

As with other sls files, each stanza will start with a declaration ID, followed by the function to run, and then any arguments for that function. For example:

```
# /srv/reactor/cloud-alert.sls
new_instance_alert:
  cmd.pagerduty.create_event:
    - tgt: alertserver
    - kwarg:
      description: "New instance: {{ data['name'] }}"
      details: "New cloud instance created on {{ data['provider'] }}"
      service_key: 1626dead5ecafe46231e968eb1be29c4
      profile: my-pagerduty-account
```
When the Event Reactor receives an event notifying it that a new instance has been created, this SLS will create a new incident in PagerDuty, using the configured PagerDuty account.

The declaration ID in this example is `new_instance_alert`. The function called is `cmd.pagerduty.create_event`. The `cmd` portion of this function specifies that an execution module and function will be called, in this case, the `pagerduty.create_event` function.

Because an execution module is specified, a target (tgt) must be specified on which to call the function. In this case, a minion called `alertserver` has been used. Any arguments passed through to the function are declared in the kwarg block.

**Example: Reactor-Based Highstate**

When Salt Cloud creates an instance, by default it will install the Salt Minion onto the instance, along with any specified minion configuration, and automatically accept that minion’s keys on the master. One of the configuration options that can be specified is `startup_states`, which is commonly set to `highstate`. This will tell the minion to immediately apply a highstate, as soon as it is able to do so.

This can present a problem with some system images on some cloud hosts. For instance, Salt Cloud can be configured to log in as either the `root` user, or a user with `sudo` access. While some hosts commonly use images that lock out remote `root` access and require a user with `sudo` privileges to log in (notably EC2, with their `ec2-user` login), most cloud hosts fall back to `root` as the default login on all images, including for operating systems (such as Ubuntu) which normally disallow remote `root` login.

For users of these operating systems, it is understandable that a highstate would include configuration to block remote `root` logins again. However, Salt Cloud may not have finished cleaning up its deployment files by the time the minion process has started, and kicked off a highstate run. Users have reported errors from Salt Cloud getting locked out while trying to clean up after itself.

The goal of a startup state may be achieved using the Event Reactor. Because a minion fires an event when it is able to receive commands, this event can effectively be used inside the reactor system instead. The following will point the reactor system to the right `SLS` file:

```
reactor:
  - 'salt/cloud/*/created':
    - '/srv/reactor/startup_highstate.sls'
```

And the following `SLS` file will start a highstate run on the target minion:

```
# /srv/reactor/startup_highstate.sls
reactor_highstate:
  cmd.state.highstate:
    tgt: {{ data['name'] }}
```

Because this event will not be fired until Salt Cloud has cleaned up after itself, the highstate run will not step on Salt Cloud’s toes. And because every file on the minion is configurable, including `/etc/salt/minion`, the `startup_states` can still be configured for future minion restarts, if desired.
25.1 Writing netapi modules

netapi modules, put simply, bind a port and start a service. They are purposefully open-ended and can be used to present a variety of external interfaces to Salt, and even present multiple interfaces at once.

See also:
* The full list of netapi modules

25.1.1 Configuration

All netapi configuration is done in the Salt master config and takes a form similar to the following:

```yaml
rest_cherrypy:
  port: 8000
  debug: True
  ssl_crt: /etc/pki/tls/certs/localhost.crt
  ssl_key: /etc/pki/tls/certs/localhost.key
```

25.1.2 The __virtual__ function

Like all module types in Salt, netapi modules go through Salt’s loader interface to determine if they should be loaded into memory and then executed.

The __virtual__ function in the module makes this determination and should return False or a string that will serve as the name of the module. If the module raises an ImportError or any other errors, it will not be loaded.

25.1.3 The start function

The start() function will be called for each netapi module that is loaded. This function should contain the server loop that actually starts the service. This is started in a multiprocess.

25.1.4 Inline documentation

As with the rest of Salt, it is a best-practice to include liberal inline documentation in the form of a module docstring and docstrings on any classes, methods, and functions in your netapi module.
25.1.5 Loader “magic” methods

The loader makes the __opts__ data structure available to any function in a netapi module.

25.2 Introduction to netapi modules

netapi modules provide API-centric access to Salt. Usually externally-facing services such as REST or WebSockets, XMPP, XMLRPC, etc.

In general netapi modules bind to a port and start a service. They are purposefully open-ended. A single module can be configured to run as well as multiple modules simultaneously.

netapi modules are enabled by adding configuration to your Salt Master config file and then starting the salt-api daemon. Check the docs for each module to see external requirements and configuration settings.

Communication with Salt and Salt satellite projects is done using Salt’s own Python API. A list of available client interfaces is below.

salt-api

Prior to Salt’s 2014.7.0 release, netapi modules lived in the separate sister project salt-api. That project has been merged into the main Salt project.

See also:
The full list of netapi modules

25.3 Client interfaces

Salt’s client interfaces expose executing functions by crafting a dictionary of values that are mapped to function arguments. This allows calling functions simply by creating a data structure. (And this is exactly how much of Salt’s own internals work!)

class salt.netapi.NetapiClient(opts)

    Provide a uniform method of accessing the various client interfaces in Salt in the form of low-data data structures. For example:

    >>> client = NetapiClient(__opts__)
    >>> lowstate = {'client': 'local', 'tgt': '*', 'fun': 'test.ping', 'arg': ''}
    >>> client.run(lowstate)

local(*args, **kwargs)
    Run execution modules synchronously
    See salt.client.LocalClient.cmd() for all available parameters.
    Sends a command from the master to the targeted minions. This is the same interface that Salt’s own CLI uses. Note the arg and kwarg parameters are sent down to the minion(s) and the given function, fun, is called with those parameters.

        Returns Returns the result from the execution module

local_async(*args, **kwargs)
    Run execution modules asynchronously
    Wraps salt.client.LocalClient.run_job().
local_batch(*args, **kwargs)
    Run execution modules against batches of minions
    New in version 0.8.4.
    Wraps salt.client.LocalClient.cmd_batch()
    Returns Returns the result from the execution module for each batch of returns

runner(fun, timeout=None, **kwargs)
    Run runner modules <all-salt.runners> synchronously
    Wraps salt.runner.RunnerClient.cmd_sync().
    Note that runner functions must be called using keyword arguments. Positional arguments are not supported.
    Returns Returns the result from the runner module

wheel(fun, **kwargs)
    Run wheel modules synchronously
    Wraps salt.wheel.WheelClient.master_call().
    Note that wheel functions must be called using keyword arguments. Positional arguments are not supported.
    Returns Returns the result from the wheel module
The Salt Virt cloud controller capability was initially added to Salt in version 0.14.0 as an alpha technology. The initial Salt Virt system supports core cloud operations:

- Virtual machine deployment
- Inspection of deployed VMs
- Virtual machine migration
- Network profiling
- Automatic VM integration with all aspects of Salt
- Image Pre-seeding

Many features are currently under development to enhance the capabilities of the Salt Virt systems.

**Note:** It is noteworthy that Salt was originally developed with the intent of using the Salt communication system as the backbone to a cloud controller. This means that the Salt Virt system is not an afterthought, simply a system that took the back seat to other development. The original attempt to develop the cloud control aspects of Salt was a project called butter. This project never took off, but was functional and proves the early viability of Salt to be a cloud controller.

### 26.1 Salt Virt Tutorial

A tutorial about how to get Salt Virt up and running has been added to the tutorial section:

*Cloud Controller Tutorial*

### 26.2 The Salt Virt Runner

The point of interaction with the cloud controller is the `virt` runner. The `virt` runner comes with routines to execute specific virtual machine routines.

Reference documentation for the `virt` runner is available with the runner module documentation:

*Virt Runner Reference*
26.3 Based on Live State Data

The Salt Virt system is based on using Salt to query live data about hypervisors and then using the data gathered to make decisions about cloud operations. This means that no external resources are required to run Salt Virt, and that the information gathered about the cloud is live and accurate.

26.4 Deploy from Network or Disk

26.4.1 Virtual Machine Disk Profiles

Salt Virt allows for the disks created for deployed virtual machines to be finely configured. The configuration is a simple data structure which is read from the `config.option` function, meaning that the configuration can be stored in the minion config file, the master config file, or the minion's pillar.

This configuration option is called `virt.disk`. The default `virt.disk` data structure looks like this:

```
virt.disk:
  default:
    - system:
      size: 8192
      format: qcow2
      model: virtio
```

**Note:** The format and model does not need to be defined, Salt will default to the optimal format used by the underlying hypervisor, in the case of kvm this is `qcow2` and `virtio`.

This configuration sets up a disk profile called default. The default profile creates a single system disk on the virtual machine.

Define More Profiles

Many environments will require more complex disk profiles and may require more than one profile, this can be easily accomplished:

```
virt.disk:
  default:
    - system:
      size: 8192
  database:
    - system:
      size: 8192
    - data:
      size: 30720
  web:
    - system:
      size: 1024
    - logs:
      size: 5120
```

This configuration allows for one of three profiles to be selected, allowing virtual machines to be created with different storage needs of the deployed vm.
26.4.2 Virtual Machine Network Profiles

Salt Virt allows for the network devices created for deployed virtual machines to be finely configured. The configuration is a simple data structure which is read from the `config.option` function, meaning that the configuration can be stored in the minion config file, the master config file, or the minion’s pillar.

This configuration option is called `virt.nic`. By default the `virt.nic` option is empty but defaults to a data structure which looks like this:

```yaml
virt.nic:
  default:
    eth0:
    bridge: br0
    model: virtio
```

**Note:** The model does not need to be defined, Salt will default to the optimal model used by the underlying hypervisor; in the case of kvm this model is virtio.

This configuration sets up a network profile called default. The default profile creates a single Ethernet device on the virtual machine that is bridged to the hypervisor’s `br0` interface. This default setup does not require setting up the `virt.nic` configuration, and is the reason why a default install only requires setting up the `br0` bridge device on the hypervisor.

**Define More Profiles**

Many environments will require more complex network profiles and may require more than one profile, this can be easily accomplished:

```yaml
virt.nic:
  dual:
    eth0:
    bridge: service_br
    eth1:
    bridge: storage_br
  single:
    eth0:
    bridge: service_br
  triple:
    eth0:
    bridge: service_br
    eth1:
    bridge: storage_br
    eth2:
    bridge: dmz_br
  all:
    eth0:
    bridge: service_br
    eth1:
    bridge: storage_br
    eth2:
    bridge: dmz_br
    eth3:
    bridge: database_br
  dmz:
    eth0:
    bridge: service_br
    eth1:
```

26.4. Deploy from Network or Disk
bridge: dmz_br

database:
  eth0:
    bridge: service_br
  eth1:
    bridge: database_br

This configuration allows for one of six profiles to be selected, allowing virtual machines to be created which attach to different network depending on the needs of the deployed vm.
Understanding YAML

The default renderer for SLS files is the YAML renderer. YAML is a markup language with many powerful features. However, Salt uses a small subset of YAML that maps over very commonly used data structures, like lists and dictionaries. It is the job of the YAML renderer to take the YAML data structure and compile it into a Python data structure for use by Salt.

Though YAML syntax may seem daunting and terse at first, there are only three very simple rules to remember when writing YAML for SLS files.

### 27.1 Rule One: Indentation

YAML uses a fixed indentation scheme to represent relationships between data layers. Salt requires that the indentation for each level consists of exactly two spaces. Do not use tabs.

### 27.2 Rule Two: Colons

Python dictionaries are, of course, simply key-value pairs. Users from other languages may recognize this data type as hashes or associative arrays.

Dictionary keys are represented in YAML as strings terminated by a trailing colon. Values are represented by either a string following the colon, separated by a space:

```
my_key: my_value
```

In Python, the above maps to:

```
{ 'my_key': 'my_value' }
```

Alternatively, a value can be associated with a key through indentation.

```
my_key:
  my_value
```

Note: The above syntax is valid YAML but is uncommon in SLS files because most often, the value for a key is not singular but instead is a list of values.

In Python, the above maps to:
Dictionaries can be nested:
```
{ 'first_level_dict_key':
    { 'second_level_dict_key': 'value_in_second_level_dict' }
}
```

And in Python:
```
{
    'first_level_dict_key': {
        'second_level_dict_key': 'value_in_second_level_dict'
    }
}
```

### 27.3 Rule Three: Dashes

To represent lists of items, a single dash followed by a space is used. Multiple items are a part of the same list as a function of their having the same level of indentation.

```
- list_value_one
- list_value_two
- list_value_three
```

Lists can be the value of a key-value pair. This is quite common in Salt:
```
my_dictionary:
- list_value_one
- list_value_two
- list_value_three
```

In Python, the above maps to:
```
{ 'my_dictionary': ['list_value_one', 'list_value_two', 'list_value_three']}
```

### 27.4 Learning More

One easy way to learn more about how YAML gets rendered into Python data structures is to use an online YAML parser to see the Python output.

One excellent choice for experimenting with YAML parsing is: [http://yaml-online-parser.appspot.com/](http://yaml-online-parser.appspot.com/)
In 0.10.4 the `external_nodes` system was upgraded to allow for modular subsystems to be used to generate the top file data for a highstate run on the master.

The old `external_nodes` option has been removed. The master tops system contains a number of subsystems that are loaded via the Salt loader interfaces like modules, states, returners, runners, etc.

Using the new `master_top` option is simple:

```yaml
master_top:
  ext_nodes: cobbler-external-nodes
```

for **Cobbler** or:

```yaml
master_top:
  reclass:
    inventory_base_uri: /etc/reclass
    classes_uri: roles
```

for **Reclass**.

It's also possible to create custom master_top modules. These modules must go in a subdirectory called `tops` in the `extension_modules` directory. The `extension_modules` directory is not defined by default (the default `/srv/salt/_modules` will NOT work as of this release)

Custom tops modules are written like any other execution module, see the source for the two modules above for examples of fully functional ones. Below is a degenerate example:

```bash
/etc/salt/master:
extension_modules: /srv/salt/modules
master_top:
  custom_top: True

/srv/salt/modules/tops/customtop.py:

```python
import logging
import sys
# Define the module's virtual name
__virtualname__ = 'customtop'

log = logging.getLogger(__name__)

def __virtual__():
    return __virtualname__
```
```python
def top(**kwargs):
    log.debug('Calling top in customtop')
    return {'base': ['test']}
```

`salt minion state.show_top` should then display something like:

```
salt minion state.show_top

minion
    ----------
    base:
        - test
```
29.1 Getting Started

Salt SSH is very easy to use, simply set up a basic roster file of the systems to connect to and run `salt-ssh` commands in a similar way as standard `salt` commands.

- Salt ssh is considered production ready in version 2014.7.0
- Python is required on the remote system (unless using the `-r` option to send raw ssh commands)
- On many systems, the `salt-ssh` executable will be in its own package, usually named `salt-ssh`
- The Salt SSH system does not supercede the standard Salt communication systems, it simply offers an SSH-based alternative that does not require ZeroMQ and a remote agent. Be aware that since all communication with Salt SSH is executed via SSH it is substantially slower than standard Salt with ZeroMQ.
- At the moment fileserver operations must be wrapped to ensure that the relevant files are delivered with the `salt-ssh` commands. The state module is an exception, which compiles the state run on the master, and in the process finds all the references to `salt://` paths and copies those files down in the same tarball as the state run. However, needed fileserver wrappers are still under development.

29.2 Salt SSH Roster

The roster system in Salt allows for remote minions to be easily defined.

**Note:** See the *Roster documentation* for more details.

Simply create the roster file, the default location is `/etc/salt/roster`:

```plaintext
web1: 192.168.42.1
```

This is a very basic roster file where a Salt ID is being assigned to an IP address. A more elaborate roster can be created:

```plaintext
web1: 192.168.42.1 # The IP addr or DNS hostname
  host: 192.168.42.1  # Remote executions will be executed as user fred
  user: fred
  passwd: foobarbaz # The password to use for login, if omitted, keys are used
  sudo: True # Whether to sudo to root, not enabled by default
web2: 192.168.42.2
```
29.3 Calling Salt SSH

The `salt-ssh` command can be easily executed in the same way as a salt command:

```
salt-ssh '*' test.ping
```

Commands with `salt-ssh` follow the same syntax as the `salt` command.

The standard salt functions are available! The output is the same as `salt` and many of the same flags are available. Please see [http://docs.saltstack.com/ref/cli/salt-ssh.html](http://docs.saltstack.com/ref/cli/salt-ssh.html) for all of the available options.

29.3.1 Raw Shell Calls

By default `salt-ssh` runs Salt execution modules on the remote system, but `salt-ssh` can also execute raw shell commands:

```
salt-ssh '*' -r 'ifconfig'
```

29.4 States Via Salt SSH

The Salt State system can also be used with `salt-ssh`. The state system abstracts the same interface to the user in `salt-ssh` as it does when using standard `salt`. The intent is that Salt Formulas defined for standard `salt` will work seamlessly with `salt-ssh` and vice-versa.

The standard Salt States walkthroughs function by simply replacing `salt` commands with `salt-ssh`.

29.5 Targeting with Salt SSH

Due to the fact that the targeting approach differs in `salt-ssh`, only glob and regex targets are supported as of this writing, the remaining target systems still need to be implemented.

Note: By default, Grains are settable through `salt-ssh`. By default, these grains will not be persisted across reboots.

See the `"thin_dir"` setting in [Roster documentation](http://docs.saltstack.com) for more details.

29.6 Configuring Salt SSH

Salt SSH takes its configuration from a master configuration file. Normally, this file is in `/etc/salt/master`. If one wishes to use a customized configuration file, the `-c` option to Salt SSH facilitates passing in a directory to look inside for a configuration file named `master`.
29.6.1 Minion Config

New in version 2015.5.1.

Minion config options can be defined globally using the master configuration option `ssh_minion_opts`. It can also be defined on a per-minion basis with the `minion_opts` entry in the roster.

29.7 Running Salt SSH as non-root user

By default, Salt reads all the configuration from `/etc/salt/`. If you are running Salt SSH with a regular user you have to modify some paths or you will get "Permission denied" messages. You have to modify two parameters: `pki_dir` and `cachedir`. Those should point to a full path writable for the user.

It's recommended not to modify `/etc/salt` for this purpose. Create a private copy of `/etc/salt` for the user and run the command with `-c /new/config/path`.

29.8 Define CLI Options with Saltfile

If you are commonly passing in CLI options to `salt-ssh`, you can create a Saltfile to automatically use these options. This is common if you’re managing several different salt projects on the same server.

So you can `cd` into a directory that has a Saltfile with the following YAML contents:

```
salt-ssh:
  config_dir: path/to/config/dir
  max_procs: 30
  wipe_ssh: True
```

Instead of having to call `salt-ssh --config-dir=path/to/config/dir --max-procs=30 --wipe \
* test.ping` you can call `salt-ssh * test.ping`.

Boolean-style options should be specified in their YAML representation.

**Note:** The option keys specified must match the destination attributes for the options specified in the parser `salt.utils.parsers.SaltSSHOptionParser`. For example, in the case of the `--wipe` command line option, its `dest` is configured to be `wipe_ssh` and thus this is what should be configured in the Saltfile. Using the names of flags for this option, being `wipe: True` or `w: True`, will not work.
Salt rosters are pluggable systems added in Salt 0.17.0 to facilitate the salt-ssh system. The roster system was created because salt-ssh needs a means to identify which systems need to be targeted for execution.

See also:

*Full list of builtin roster modules*

Note: The Roster System is not needed or used in standard Salt because the master does not need to be initially aware of target systems, since the Salt Minion checks itself into the master.

Since the roster system is pluggable, it can be easily augmented to attach to any existing systems to gather information about what servers are presently available and should be attached to by salt-ssh. By default the roster file is located at /etc/salt/roster.

### 30.1 How Rosters Work

The roster system compiles a data structure internally referred to as targets. The targets is a list of target systems and attributes about how to connect to said systems. The only requirement for a roster module in Salt is to return the targets data structure.

#### 30.1.1 Targets Data

The information which can be stored in a roster target is the following:

```plaintext
<Salt ID>:  # The id to reference the target system with
host:      # The IP address or DNS name of the remote host
user:      # The user to log in as
passwd:    # The password to log in with

# Optional parameters
port:      # The target system's ssh port number
sudo:      # Boolean to run command via sudo
priv:      # File path to ssh private key, defaults to salt-ssh.rsa
timeout:   # Number of seconds to wait for response when establishing
            # an SSH connection
timeout:   # Number of seconds to wait for response
minion_opts:  # Dictionary of minion opts
thin_dir:   # The target system's storage directory for Salt
            # components. Defaults to /tmp/salt-<hash>
```
30.1.2 thin_dir

Salt needs to upload a standalone environment to the target system, and this defaults to /tmp/salt-<hash>. This directory will be cleaned up per normal systems operation.

If you need a persistent Salt environment, for instance to set persistent grains, this value will need to be changed.
31.1 Full list of builtin auth modules

<table>
<thead>
<tr>
<th>Module</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>auto</td>
<td>An &quot;Always Approved&quot; auth interface to test against, not intended for production use.</td>
</tr>
<tr>
<td>django</td>
<td>Provide authentication using Django Web Framework</td>
</tr>
<tr>
<td>keystone</td>
<td>Provide authentication using OpenStack Keystone</td>
</tr>
<tr>
<td>ldap</td>
<td>Provide authentication using simple LDAP binds</td>
</tr>
<tr>
<td>mysql</td>
<td>Provide authentication using MySQL.</td>
</tr>
<tr>
<td>pam</td>
<td>Authenticate against PAM</td>
</tr>
<tr>
<td>pki</td>
<td>Authenticate via a PKI certificate.</td>
</tr>
<tr>
<td>stormpath</td>
<td>Provide authentication using Stormpath.</td>
</tr>
<tr>
<td>yubico</td>
<td>Provide authentication using YubiKey.</td>
</tr>
</tbody>
</table>

31.1.1 salt.auth.auto

An "Always Approved" auth interface to test against, not intended for production use.

```
salt.auth.auto.auth(username, password)
```

Authenticate!

31.1.2 salt.auth.django

Provide authentication using Django Web Framework

```
depends
  - Django Web Framework
```

Django authentication depends on the presence of the django framework in the PYTHONPATH, the Django project's settings.py file being in the PYTHONPATH and accessible via the DJANGO_SETTINGS_MODULE environment variable.

Django auth can be defined like any other auth module:

```
external_auth:
  django:
    fred:
      - .*
      - '@runner'
```
This will authenticate Fred via Django and allow him to run any execution module and all runners.

The authorization details can optionally be located inside the Django database. The relevant entry in the models.py file would look like this:

```python
class SaltExternalAuthModel(models.Model):
    user_fk = models.ForeignKey(auth.User)
    minion_matcher = models.CharField()
    minion_fn = models.CharField()
```

The `external_auth` clause in the master config would then look like this:

```yaml
external_auth:
    django:
        ^model: <fully-qualified reference to model class>
```

When a user attempts to authenticate via Django, Salt will import the package indicated via the keyword `^model`. That model must have the fields indicated above, though the model DOES NOT have to be named `SaltExternalAuthModel`.

```python
salt.auth.django.auth(username, password)
    Simple Django auth
salt.auth.django.django_auth_setup()  
    Prepare the connection to the Django authentication framework
salt.auth.django.retrieve_auth_entries(u=None)
```

Parameters **u** -- Username to filter for

Returns Dictionary that can be slotted into the `__opts__` structure for eauth that designates the user associated ACL

Database records such as:

<table>
<thead>
<tr>
<th>username</th>
<th>minion_or_fn_matcher</th>
<th>minion_fn</th>
</tr>
</thead>
<tbody>
<tr>
<td>fred</td>
<td>test.ping</td>
<td></td>
</tr>
<tr>
<td>fred</td>
<td>server1</td>
<td>network.interfaces</td>
</tr>
<tr>
<td>fred</td>
<td>server1</td>
<td>raid.list</td>
</tr>
<tr>
<td>fred</td>
<td>server2</td>
<td>.*</td>
</tr>
<tr>
<td>guru</td>
<td>.*</td>
<td></td>
</tr>
<tr>
<td>smartadmin</td>
<td>server1</td>
<td>.*</td>
</tr>
</tbody>
</table>

Should result in an eauth config such as:

```yaml
fred:
    - test.ping
    - server1:
        - network.interfaces
        - raid.list
    - server2:
        - *
guru:
    - *
smartadmin:
    - server1:
        - *
```
31.1.3 salt.auth.keystone

Provide authentication using OpenStack Keystone

```python
depends
  - keystoneclient Python module

salt.auth.keystone.auth(username, password)
  Try and authenticate

salt.auth.keystone.get_auth_url()
  Try and get the URL from the config, else return localhost
```

31.1.4 salt.auth.ldap

Provide authentication using simple LDAP binds

```python
depends
  - ldap Python module

salt.auth.ldap.auth(username, password)
  Simple LDAP auth

salt.auth.ldap.groups(username, **kwargs)
  Authenticate against an LDAP group

  Behavior is highly dependent on if Active Directory is in use.

  AD handles group membership very differently than OpenLDAP. See the External Authentication documentation for a thorough discussion of available parameters for customizing the search.

  OpenLDAP allows you to search for all groups in the directory and returns members of those groups. Then we check against the username entered.
```

31.1.5 salt.auth.mysql

Provide authentication using MySQL.

When using MySQL as an authentication backend, you will need to create or use an existing table that has a username and a password column.

To get started, create a simple table that holds just a username and a password. The password field will hold a SHA256 checksum.

```sql
CREATE TABLE `users` (
  `id` int(11) NOT NULL AUTO_INCREMENT,
  `username` varchar(25) DEFAULT NULL,
  `password` varchar(70) DEFAULT NULL,
  PRIMARY KEY (`id`)
) ENGINE=InnoDB AUTO_INCREMENT=2 DEFAULT CHARSET=latin1;
```

To create a user within MySQL, execute the following statement.

```sql
INSERT INTO users VALUES (NULL, 'diana', SHA2('secret', 256))
```
mysql_auth:
  hostname: localhost
  database: SaltStack
  username: root
  password: letmein
  auth_sql: 'SELECT username FROM users WHERE username = "{0}" AND password = SHA2("{1}", 256)'

The auth_sql contains the SQL that will validate a user to ensure they are correctly authenticated. This is where you can specify other SQL queries to authenticate users.

Enable MySQL authentication.

external_auth:
  mysql:
    damian:
      - test.*

  depends
    • MySQL-python Python module

salt.auth.mysql.auth(username, password)
  Authenticate using a MySQL user table

31.1.6 salt.auth.pam

Authenticate against PAM

Provides an authenticate function that will allow the caller to authenticate a user against the Pluggable Authentication Modules (PAM) on the system.

Implemented using ctypes, so no compilation is necessary.

Note: PAM authentication will not work for the root user.

The Python interface to PAM does not support authenticating as root.

class salt.auth.pam.PamConv
  Wrapper class for pam_conv structure

  appdata_ptr
    Structure/Union member

  conv
    Structure/Union member

class salt.auth.pam.PamHandle
  Wrapper class for pam_handle_t

  handle
    Structure/Union member

class salt.auth.pam.PamMessage
  Wrapper class for pam_message structure

  msg
    Structure/Union member

  msg_style
    Structure/Union member
class salt.auth.pam.PamResponse
    Wrapper class for pam_response structure

    resp
        Structure/Union member

    resp_retcode
        Structure/Union member

salt.auth.pam.auth(username, password, **kwargs)
    Authenticate via pam

salt.auth.pam.authenticate(username, password, service='login')
    Returns True if the given username and password authenticate for the given service. Returns False otherwise
    username: the username to authenticate
    password: the password in plain text
    service: the PAM service to authenticate against. Defaults to `login`

salt.auth.pam.groups(username, *args, **kwargs)
    Retrieve groups for a given user for this auth provider
    Uses system groups

31.1.7 salt.auth.pki

Authenticate via a PKI certificate.

Note: This module is Experimental and should be used with caution

Provides an authenticate function that will allow the caller to authenticate a user via their public cert against a pre-defined Certificate Authority.

TODO: Add a `ca_dir` option to configure a directory of CA files, a la Apache.

depends
    - pyOpenSSL module

salt.auth.pki.auth(pem, **kwargs)
    Returns True if the given user cert was issued by the CA. Returns False otherwise.
    pem: a pem-encoded user public key (certificate)

Configure the CA cert in the master config file:

external_auth:
    pkI:
        ca_file: /etc/pki/tls/ca_certs/trusted-ca.crt

31.1.8 salt.auth.stormpath

Provide authentication using Stormpath.

This driver requires some extra configuration beyond that which Stormpath normally requires.
New in version 2015.8.0.

salt.auth.stormpath.auth(username, password)
Authenticate using a Stormpath directory or application

31.1.9 salt.auth.yubico

Provide authentication using YubiKey.
New in version 2015.5.0.

depends yubico-client Python module

To get your YubiKey API key you will need to visit the website below.
https://upgrade.yubico.com/getapikey/

The resulting page will show the generated Client ID (aka AuthID or API ID) and the generated API key (Secret Key). Make a note of both and use these two values in your /etc/salt/master configuration.

/etc/salt/master

  yubico_users:
    damian:
      id: 12345
      key: ABCDEFGHIJKLMNOPQRSTUVWXYZ
  
  external_auth:
    yubico:
      damian:
        - test.*

Please wait five to ten minutes after generating the key before testing so that the API key will be updated on all the YubiCloud servers.

salt.auth.yubico.auth(username, password)
Authenticate against yubico server

31.2 Command Line Reference

Salt can be controlled by a command line client by the root user on the Salt master. The Salt command line client uses the Salt client API to communicate with the Salt master server. The Salt client is straightforward and simple to use.

Using the Salt client commands can be easily sent to the minions.

Each of these commands accepts an explicit --config option to point to either the master or minion configuration file. If this option is not provided and the default configuration file does not exist then Salt falls back to use the environment variables SALT_MASTER_CONFIG and SALT_MINION_CONFIG.
See also:

*Configuration*

### 31.2.1 Using the Salt Command

The Salt command needs a few components to send information to the Salt minions. The target minions need to be defined, the function to call and any arguments the function requires.

#### Defining the Target Minions

The first argument passed to salt, defines the target minions, the target minions are accessed via their hostname. The default target type is a bash glob:

```
salt '*foo.com' sys.doc
```

Salt can also define the target minions with regular expressions:

```
salt -E '*.foo' cmd.run 'ls -l | grep foo'
```

Or to explicitly list hosts, salt can take a list:

```
salt -L foo.bar.baz,quo.qux cmd.run 'ps aux | grep foo'
```

#### More Powerful Targets

The simple target specifications, glob, regex, and list will cover many use cases, and for some will cover all use cases, but more powerful options exist.

#### Targeting with Grains

The Grains interface was built into Salt to allow minions to be targeted by system properties. So minions running on a particular operating system can be called to execute a function, or a specific kernel.

Calling via a grain is done by passing the -G option to salt, specifying a grain and a glob expression to match the value of the grain. The syntax for the target is the grain key followed by a glob expression: `os:Arch*`.

```
salt -G 'os:Fedora' test.ping
```

Will return True from all of the minions running Fedora.

To discover what grains are available and what the values are, execute the grains.item salt function:

```
salt '*' grains.items
```

more info on using targeting with grains can be found [here](#).

#### Targeting with Executions

As of 0.8.8 targeting with executions is still under heavy development and this documentation is written to reference the behavior of execution matching in the future.

Execution matching allows for a primary function to be executed, and then based on the return of the primary function the main function is executed.
Execution matching allows for matching minions based on any arbitrary running data on the minions.

**Compound Targeting**

New in version 0.9.5.

Multiple target interfaces can be used in conjunction to determine the command targets. These targets can then be combined using and or or statements. This is well defined with an example:

```shell
salt -C 'G@os:Debian and webser* or E@db.*' test.ping
```

In this example any minion who's id starts with `webser` and is running Debian, or any minion who's id starts with db will be matched.

The type of matcher defaults to glob, but can be specified with the corresponding letter followed by the @ symbol. In the above example a grain is used with G@ as well as a regular expression with E@. The `webser*` target does not need to be prefaced with a target type specifier because it is a glob.

More info on using compound targeting can be found [here](#).

**Node Group Targeting**

New in version 0.9.5.

For certain cases, it can be convenient to have a predefined group of minions on which to execute commands. This can be accomplished using what are called nodegroups. Nodegroups allow for predefined compound targets to be declared in the master configuration file, as a sort of shorthand for having to type out complicated compound expressions.

```yaml
nodegroups:
  group1: 'L@foo.domain.com,bar.domain.com,baz.domain.com and bl*.domain.com'
  group2: 'G@os:Debian and foo.domain.com'
  group3: 'G@os:Debian and N@group1'
```

**Calling the Function**

The function to call on the specified target is placed after the target specification.

New in version 0.9.8.

Functions may also accept arguments, space-delimited:

```shell
salt '*' cmd.exec_code python 'import sys; print sys.version'
```

Optional, keyword arguments are also supported:

```shell
salt '*' pip.install salt timeout=5 upgrade=True
```

They are always in the form of kwarg=argument.

Arguments are formatted as YAML:

```shell
salt '*' cmd.run 'echo "Hello: $FIRST_NAME"' env='{{FIRST_NAME: "Joe"}}'
```

Note: dictionaries must have curly braces around them (like the env keyword argument above). This was changed in 0.15.1: in the above example, the first argument used to be parsed as the dictionary {'echo "Hello": "$FIRST_NAME"'}. This was generally not the expected behavior.
If you want to test what parameters are actually passed to a module, use the `test.arg_repr` command:

```
salt '*' test.arg_repr 'echo "Hello: $FIRST_NAME"' env='{FIRST_NAME: "Joe"}';
```

Finding available minion functions

The Salt functions are self documenting, all of the function documentation can be retrieved from the minions via the `sys.doc()` function:

```
salt '*' sys.doc
```

### Compound Command Execution

If a series of commands needs to be sent to a single target specification then the commands can be sent in a single publish. This can make gathering groups of information faster, and lowers the stress on the network for repeated commands.

Compound command execution works by sending a list of functions and arguments instead of sending a single function and argument. The functions are executed on the minion in the order they are defined on the command line, and then the data from all of the commands are returned in a dictionary. This means that the set of commands are called in a predictable way, and the returned data can be easily interpreted.

Executing compound commands if done by passing a comma delimited list of functions, followed by a comma delimited list of arguments:

```
salt '*' cmd.run,test.ping,test.echo 'cat /proc/cpuinfo',,foo
```

The trick to look out for here, is that if a function is being passed no arguments, then there needs to be a placeholder for the absent arguments. This is why in the above example, there are two commas right next to each other. `test.ping` takes no arguments, so we need to add another comma, otherwise Salt would attempt to pass `"foo"` to `test.ping`.

If you need to pass arguments that include commas, then make sure you add spaces around the commas that separate arguments. For example:

```
salt '*' cmd.run,test.ping,test.echo 'echo "1,2,3"', , foo
```

You may change the arguments separator using the `--args-separator` option:

```
salt --args-separator=:: '*' some.fun,test.echo params with , comma :: foo
```

### 31.2.2 salt-call

#### salt-call

**Synopsis**

```
salt-call [options]
```
Description

The salt-call command is used to run module functions locally on a minion instead of executing them from the master. Salt-call is used to run a Standalone Minion, and was originally created for troubleshooting.

The Salt Master is contacted to retrieve state files and other resources during execution unless the --local option is specified.

Note: salt-call commands execute from the current user's shell context, while salt commands execute from the system's default context.

Options

--version
Print the version of Salt that is running.

--versions-report
Show program's dependencies and version number, and then exit

-h, --help
Show the help message and exit

-c CONFIG_DIR, --config-dir=CONFIG_dir
The location of the Salt configuration directory. This directory contains the configuration files for Salt master and minions. The default location on most systems is /etc/salt.

--hard-crash
Raise any original exception rather than exiting gracefully Default: False

-g, --grains
Return the information generated by the Salt grains

-m MODULE_DIRS, --module-dirs=MODULE_DIRS
Specify an additional directory to pull modules from. Multiple directories can be provided by passing -m /--module-dirs multiple times.

-d, --doc, --documentation
Return the documentation for the specified module or for all modules if none are specified

--master=MASTER
Specify the master to use. The minion must be authenticated with the master. If this option is omitted, the master options from the minion config will be used. If multi masters are set up the first listed master that responds will be used.

--return RETURNER
Set salt-call to pass the return data to one or many returner interfaces. To use many returner interfaces specify a comma delimited list of returners.

--local
Run salt-call locally, as if there was no master running.

--file-root=FILE_ROOT
Set this directory as the base file root.

--pillar-root=PILLAR_ROOT
Set this directory as the base pillar root.

--retcode-passthrough
Exit with the salt call retcode and not the salt binary retcode
--metadata
  Print out the execution metadata as well as the return. This will print out the outputter data, the return code, etc.

--id=ID
  Specify the minion id to use. If this option is omitted, the id option from the minion config will be used.

--skip-grains
  Do not load grains.

--refresh-grains-cache
  Force a refresh of the grains cache

Logging Options
  Logging options which override any settings defined on the configuration files.

-\l LOG_LEVEL, --log-level=LOG_LEVEL
  Console logging log level. One of all, garbage, trace, debug, info, warning, error, quiet. Default: info.

--log-file=LOG_FILE
  Log file path. Default: /var/log/salt/minion.

--log-file-level=LOG_LEVEL_LOGFILE
  Logfile logging log level. One of all, garbage, trace, debug, info, warning, error, quiet. Default: info.

Output Options
--out
  Pass in an alternative outputter to display the return of data. This outputter can be any of the available outputters:

  grains, highstate, json, key, overstatetest, pprint, raw, txt, yaml

  Some outputters are formatted only for data returned from specific functions; for instance, the grains outputter will not work for non-grains data.

  If an outputter is used that does not support the data passed into it, then Salt will fall back on the pprint outputter and display the return data using the Python pprint standard library module.

  Note: If using --out=json, you will probably want --static as well. Without the static option, you will get a separate JSON string per minion which makes JSON output invalid as a whole. This is due to using an iterative outputter. So if you want to feed it to a JSON parser, use --static as well.

--out-indent OUTPUT_INDENT, --output-indent OUTPUT_INDENT
  Print the output indented by the provided value in spaces. Negative values disable indentation. Only applicable in outputters that support indentation.

--out-file=OUTPUT_FILE, --output-file=OUTPUT_FILE
  Write the output to the specified file.

--no-color
  Disable all colored output

--force-color
  Force colored output

  Note: When using colored output the color codes are as follows:

  green denotes success, red denotes failure, blue denotes changes and success and yellow denotes a expected future change in configuration.

`salt(1) salt-master(1) salt-minion(1)`

### 31.2.3 `salt`

**Synopsis**

```
salt `*` [options] sys.doc
salt `-E` `*` [options] sys.doc cmd
salt `-G` `*` [options] test.ping
salt `-C` `*` `G@os:Arch.*` and `webserv*` or `G@kernel:FreeBSD` [options] test.ping
```

**Description**

Salt allows for commands to be executed across a swath of remote systems in parallel. This means that remote systems can be both controlled and queried with ease.

**Options**

- `--version`
  Print the version of Salt that is running.

- `--versions-report`
  Show program's dependencies and version number, and then exit

- `-h`, `--help`
  Show the help message and exit

- `-c CONFIG_DIR, --config-dir=CONFIG_dir`
  The location of the Salt configuration directory. This directory contains the configuration files for Salt master and minions. The default location on most systems is `/etc/salt`.

- `-t TIMEOUT, --timeout=TIMEOUT`
  The timeout in seconds to wait for replies from the Salt minions. The timeout number specifies how long the command line client will wait to query the minions and check on running jobs. Default: 5

- `-s, --static`
  By default as of version 0.9.8 the salt command returns data to the console as it is received from minions, but previous releases would return data only after all data was received. Use the static option to only return the data with a hard timeout and after all minions have returned. Without the static option, you will get a separate JSON string per minion which makes JSON output invalid as a whole.

- `--async`
  Instead of waiting for the job to run on minions only print the job id of the started execution and complete.
--state-output=STATE_OUTPUT
New in version 0.17.
Override the configured state_output value for minion output. One of full, terse, mixed, changes or filter. Default: full.

--subset=SUBSET
Execute the routine on a random subset of the targeted minions. The minions will be verified that they have the named function before executing.

-v VERBOSE, --verbose
Turn on verbosity for the salt call, this will cause the salt command to print out extra data like the job id.

--hide-timeout
Instead of showing the return data for all minions. This option prints only the online minions which could be reached.

-b BATCH, --batch-size=BATCH
Instead of executing on all targeted minions at once, execute on a progressive set of minions. This option takes an argument in the form of an explicit number of minions to execute at once, or a percentage of minions to execute on.

-a EAUTH, --auth=EAUTH
Pass in an external authentication medium to validate against. The credentials will be prompted for. The options are auto, keystone, ldap, pam, and stormpath. Can be used with the -T option.

-T, --make-token
Used in conjunction with the -a option. This creates a token that allows for the authenticated user to send commands without needing to re-authenticate.

--return=RETURNER
Choose an alternative returner to call on the minion, if an alternative returner is used then the return will not come back to the command line but will be sent to the specified return system. The options are carbon, cassandra, couchbase, couchdb, elasticsearch, etcd, hipchat, local, local_cache, memcache, mongo, mysql, odbc, postgres, redis, sentry, slack, sms, smtp, sqlite3, syslog, and xmpp.

-d, --doc, --documentation
Return the documentation for the module functions available on the minions

--args-separator=ARGS_SEPARATOR
Set the special argument used as a delimiter between command arguments of compound commands. This is useful when one wants to pass commas as arguments to some of the commands in a compound command.

Logging Options
Logging options which override any settings defined on the configuration files.

-l LOG_LEVEL, --log-level=LOG_LEVEL
Console logging log level. One of all, garbage, trace, debug, info, warning, error, quiet. Default: warning.

--log-file=LOG_FILE

--log-file-level=LOG_LEVEL_LOGFILE
Logfile logging log level. One of all, garbage, trace, debug, info, warning, error, quiet. Default: warning.

Target Selection
-E, --pcre
The target expression will be interpreted as a PCRE regular expression rather than a shell glob.
**--list**  
The target expression will be interpreted as a comma-delimited list; example:  
server1.foo.bar,server2.foo.bar,example7.quo.qux

**--grain**  
The target expression matches values returned by the Salt grains system on the minions. The target expression is in the format of `<grain value>:<glob expression>`; example: `os:Arch`

This was changed in version 0.9.8 to accept glob expressions instead of regular expression. To use regular expression matching with grains, use the `--grain-pcre` option.

**--grain-pcre**  
The target expression matches values returned by the Salt grains system on the minions. The target expression is in the format of `<grain value>:<regular expression>`; example: `os:Arch.*`

**--nodegroup**  
Use a predefined compound target defined in the Salt master configuration file.

**--range**  
Instead of using shell globs to evaluate the target, use a range expression to identify targets. Range expressions look like `%cluster`.

Using the Range option requires that a range server is set up and the location of the range server is referenced in the master configuration file.

**--compound**  
Utilize many target definitions to make the call very granular. This option takes a group of targets separated by `and` or `or`. The default matcher is a glob as usual. If something other than a glob is used, preface it with the letter denoting the type; example: `webserv* and G@os:Debian or E@db*` Make sure that the compound target is encapsulated in quotes.

**--pillar**  
Instead of using shell globs to evaluate the target, use a pillar value to identify targets. The syntax for the target is the pillar key followed by a glob expression: `role:production*`

**--ipcidr**  
Match based on Subnet (CIDR notation) or IPv4 address.

**Output Options**

**--out**  
Pass in an alternative outputer to display the return of data. This outputer can be any of the available outputters:

```
grains, highstate, json, key, overstatetage, pprint, raw, txt, yaml
```

Some outputters are formatted only for data returned from specific functions; for instance, the grains outputer will not work for non-grains data.

If an outputter is used that does not support the data passed into it, then Salt will fall back on the pprint outputter and display the return data using the Python `pprint` standard library module.

**Note:** If using `--out=json`, you will probably want `--static` as well. Without the static option, you will get a separate JSON string per minion which makes JSON output invalid as a whole. This is due to using an iterative outputter. So if you want to feed it to a JSON parser, use `--static` as well.

**--out-indent**  
Print the output indented by the provided value in spaces. Negative values disable indentation. Only applicable in outputters that support indentation.
**--out-file**=OUTPUT_FILE, **--output-file**=OUTPUT_FILE
Write the output to the specified file.

**--no-color**
Disable all colored output

**--force-color**
Force colored output

Note: When using colored output the color codes are as follows:
green denotes success, red denotes failure, blue denotes changes and success and yellow denotes an expected future change in configuration.

salt(7) salt-master(1) salt-minion(1)

31.2.4 salt-cloud

**salt-cloud**

Provision virtual machines in the cloud with Salt

**Synopsis**

salt-cloud -m /etc/salt/cloud.map
salt-cloud -m /etc/salt/cloud.map NAME
salt-cloud -m /etc/salt/cloud.map NAME1 NAME2
salt-cloud -p PROFILE NAME
salt-cloud -p PROFILE NAME1 NAME2 NAME3 NAME4 NAME5 NAME6

**Description**

Salt Cloud is the system used to provision virtual machines on various public clouds via a cleanly controlled profile and mapping system.

**Options**

**--version**
Print the version of Salt that is running.

**--versions-report**
Show program's dependencies and version number, and then exit

- **h**, **--help**
  Show the help message and exit
-c CONFIG_DIR, --config-dir=CONFIG_dir
   The location of the Salt configuration directory. This directory contains the configuration files for Salt master and minions. The default location on most systems is /etc/salt.

Execution Options
-L LOCATION, --location=LOCATION
   Specify which region to connect to.
-a ACTION, --action=ACTION
   Perform an action that may be specific to this cloud provider. This argument requires one or more instance names to be specified.
-f <FUNC-NAME> <PROVIDER>, --function=<FUNC-NAME> <PROVIDER>
   Perform an function that may be specific to this cloud provider, that does not apply to an instance. This argument requires a provider to be specified (i.e.: nova).
-p PROFILE, --profile=PROFILE
   Select a single profile to build the named cloud VMs from. The profile must be defined in the specified profiles file.
-m MAP, --map=MAP
   Specify a map file to use. If used without any other options, this option will ensure that all of the mapped VMs are created. If the named VM already exists then it will be skipped.
-H, --hard
   When specifying a map file, the default behavior is to ensure that all of the VMs specified in the map file are created. If the --hard option is set, then any VMs that exist on configured cloud providers that are not specified in the map file will be destroyed. Be advised that this can be a destructive operation and should be used with care.
-d, --destroy
   Pass in the name(s) of VMs to destroy, salt-cloud will search the configured cloud providers for the specified names and destroy the VMs. Be advised that this is a destructive operation and should be used with care. Can be used in conjunction with the -m option to specify a map of VMs to be deleted.
-P, --parallel
   Normally when building many cloud VMs they are executed serially. The -P option will run each cloud vm build in a separate process allowing for large groups of VMs to be build at once.
   Be advised that some cloud provider's systems don't seem to be well suited for this influx of vm creation. When creating large groups of VMs watch the cloud providers carefully.
-u, --update-bootstrap
   Update salt-bootstrap to the latest develop version on GitHub.
-y, --assume-yes
   Default yes in answer to all confirmation questions.
-k, --keep-tmp
   Do not remove files from /tmp/ after deploy.sh finishes.
--show-deploy-args
   Include the options used to deploy the minion in the data returned.
--script-args=SCRIPT_ARGS
   Script arguments to be fed to the bootstrap script when deploying the VM.

Query Options
-Q, --query
   Execute a query and return some information about the nodes running on configured cloud providers
-F, --full-query
   Execute a query and print out all available information about all cloud VMs. Can be used in conjunction with -m to display only information about the specified map.

-S, --select-query
   Execute a query and print out selected information about all cloud VMs. Can be used in conjunction with -m to display only information about the specified map.

--list-providers
   Display a list of configured providers.

--list-profiles
   New in version 2014.7.0.

   Display a list of configured profiles. Pass in a cloud provider to view the provider's associated profiles, such as digital_ocean, or pass in all to list all the configured profiles.

Cloud Providers Listings

--list-locations=LIST_LOCATIONS
   Display a list of locations available in configured cloud providers. Pass the cloud provider that available locations are desired on, aka 'linode', or pass 'all' to list locations for all configured cloud providers

--list-images=LIST_IMAGES
   Display a list of images available in configured cloud providers. Pass the cloud provider that available images are desired on, aka 'linode', or pass 'all' to list images for all configured cloud providers

--list-sizes=LIST_SIZES
   Display a list of sizes available in configured cloud providers. Pass the cloud provider that available sizes are desired on, aka 'AWS', or pass 'all' to list sizes for all configured cloud providers

Cloud Credentials

--set-password=<USERNAME> <PROVIDER>
   Configure password for a cloud provider and save it to the keyring. PROVIDER can be specified with or without a driver, for example: `--set-password bob rackspace` or more specific `--set-password bob rackspace:openstack` DEPRECATED!

Output Options

--out
   Pass in an alternative outputter to display the return of data. This outputter can be any of the available outputters:

   grains, highstate, json, key, overstatestage, pprint, raw, txt, yaml

   Some outputters are formatted only for data returned from specific functions; for instance, the grains outputter will not work for non-grains data.

   If an outputter is used that does not support the data passed into it, then Salt will fall back on the pprint outputter and display the return data using the Python pprint standard library module.

   Note: If using --out=json, you will probably want --static as well. Without the static option, you will get a separate JSON string per minion which makes JSON output invalid as a whole. This is due to using an iterative outputter. So if you want to feed it to a JSON parser, use --static as well.

--out-indent OUTPUT_INDENT, --output-indent OUTPUT_INDENT
   Print the output indented by the provided value in spaces. Negative values disable indentation. Only applicable in outputters that support indentation.
**--out-file**=OUTPUT_FILE, **--output-file**=OUTPUT_FILE
Write the output to the specified file.

**--no-color**
Disable all colored output

**--force-color**
Force colored output

Note: When using colored output the color codes are as follows:
green denotes success, red denotes failure, blue denotes changes and success and yellow denotes a expected future change in configuration.

**Examples**

To create 4 VMs named web1, web2, db1, and db2 from specified profiles:
```
salt-cloud -p fedora_rackspace web1 web2 db1 db2
```

To read in a map file and create all VMs specified therein:
```
salt-cloud -m /path/to/cloud.map
```

To read in a map file and create all VMs specified therein in parallel:
```
salt-cloud -m /path/to/cloud.map -P
```

To delete any VMs specified in the map file:
```
salt-cloud -m /path/to/cloud.map -d
```

To delete any VMs NOT specified in the map file:
```
salt-cloud -m /path/to/cloud.map -H
```

To display the status of all VMs specified in the map file:
```
salt-cloud -m /path/to/cloud.map -Q
```

salt-cloud(7) salt(7) salt-master(1) salt-minion(1)

---

**31.2.5 salt-cp**

**salt-cp**

Copy a file to a set of systems

**Synopsis**
Description

Salt copy copies a local file out to all of the Salt minions matched by the given target.

Note: salt-cp uses salt's publishing mechanism. This means the privacy of the contents of the file on the wire are completely dependant upon the transport in use. In addition, if the salt-master is running with debug logging it is possible that the contents of the file will be logged to disk.

Options

--version
Print the version of Salt that is running.

--versions-report
Show program's dependencies and version number, and then exit

-h, --help
Show the help message and exit

-c CONFIG_DIR, --config-dir=CONFIG_dir
The location of the Salt configuration directory. This directory contains the configuration files for Salt master and minions. The default location on most systems is /etc/salt.

-t TIMEOUT, --timeout=TIMEOUT
The timeout in seconds to wait for replies from the Salt minions. The timeout number specifies how long the command line client will wait to query the minions and check on running jobs. Default: 5

Logging Options
Logging options which override any settings defined on the configuration files.

-l LOG_LEVEL, --log-level=LOG_LEVEL
Console logging log level. One of all, garbage, trace, debug, info, warning, error, quiet. Default: warning.

--log-file=LOG_FILE

--log-file-level=LOG_LEVEL_LOGFILE
Log file logging log level. One of all, garbage, trace, debug, info, warning, error, quiet. Default: warning.

Target Selection

-E, --pcre
The target expression will be interpreted as a PCRE regular expression rather than a shell glob.

-L, --list
The target expression will be interpreted as a comma-delimited list; example: server1.foo.bar,server2.foo.bar,example7.quo.qux
-G, --grain
The target expression matches values returned by the Salt grains system on the minions. The target expression is in the format of `<grain value>:<glob expression>`; example: `os:Arch`

This was changed in version 0.9.8 to accept glob expressions instead of regular expression. To use regular expression matching with grains, use the --grain-pcre option.

--grain-pcre
The target expression matches values returned by the Salt grains system on the minions. The target expression is in the format of `<grain value>:<regular expression>`; example: `os:Arch`.

-N, --nodegroup
Use a predefined compound target defined in the Salt master configuration file.

-R, --range
Instead of using shell globs to evaluate the target, use a range expression to identify targets. Range expressions look like %cluster.

Using the Range option requires that a range server is set up and the location of the range server is referenced in the master configuration file.

salt(1) salt-master(1) salt-minion(1)

31.2.6 salt-key

salt-key

Synopsis

salt-key [ options ]

Description

Salt-key executes simple management of Salt server public keys used for authentication.

On initial connection, a Salt minion sends its public key to the Salt master. This key must be accepted using the salt-key command on the Salt master.

Salt minion keys can be in one of the following states:

- **unaccepted**: key is waiting to be accepted.
- **accepted**: key was accepted and the minion can communicate with the Salt master.
- **rejected**: key was rejected using the salt-key command. In this state the minion does not receive any communication from the Salt master.
- **denied**: key was rejected automatically by the Salt master. This occurs when a minion has a duplicate ID, or when a minion was rebuilt or had new keys generated and the previous key was not deleted from the Salt master. In this state the minion does not receive any communication from the Salt master.

To change the state of a minion key, use -d to delete the key and then accept or reject the key.
Options

--version
Print the version of Salt that is running.

--versions-report
Show program's dependencies and version number, and then exit

-h, --help
Show the help message and exit

-c CONFIG_DIR, --config-dir=CONFIG_dir
The location of the Salt configuration directory. This directory contains the configuration files for Salt master and minions. The default location on most systems is /etc/salt.

-u USER, --user=USER
Specify user to run salt-key

--hard-crash
Raise any original exception rather than exiting gracefully. Default is False.

-q, --quiet
Suppress output

-y, --yes
Answer 'Yes' to all questions presented, defaults to False

--rotate-aes-key=ROTATE_AES_KEY
Setting this to False prevents the master from refreshing the key session when keys are deleted or rejected, this lowers the security of the key deletion/rejection operation. Default is True.

Logging Options  Logging options which override any settings defined on the configuration files.

--log-file=LOG_FILE
Log file path. Default: /var/log/salt/minion.

--log-file-level=LOG_LEVEL_LOGFILE
Logfile logging log level. One of all, garbage, trace, debug, info, warning, error, quiet. Default: warning.

Output Options

--out
Pass in an alternative outputter to display the return of data. This outputter can be any of the available outputters:

grains, highstate, json, key, overstatestage, pprint, raw, txt, yaml

Some outputters are formatted only for data returned from specific functions; for instance, the grains outputter will not work for non-grains data.

If an outputter is used that does not support the data passed into it, then Salt will fall back on the pprint outputter and display the return data using the Python pprint standard library module.

Note: If using --out=json, you will probably want --static as well. Without the static option, you will get a separate JSON string per minion which makes JSON output invalid as a whole. This is due to using an iterative outputter. So if you want to feed it to a JSON parser, use --static as well.
--out-indent OUTPUT_INDENT, --output-indent OUTPUT_INDENT
Print the output indented by the provided value in spaces. Negative values disable indentation. Only applicable in outputters that support indentation.

--out-file=OUTPUT_FILE, --output-file=OUTPUT_FILE
Write the output to the specified file.

--no-color
Disable all colored output

--force-color
Force colored output

Note: When using colored output the color codes are as follows:
green denotes success, red denotes failure, blue denotes changes and success and yellow denotes a expected future change in configuration.

Actions
-1 ARG, --list=ARG
List the public keys. The args pre, un, and unaccepted will list unaccepted/unsigned keys. acc or accepted will list accepted/signed keys. rej or rejected will list rejected keys. Finally, all will list all keys.
-L, --list-all
List all public keys. (Deprecated: use --list all)

-a ACCEPT, --accept=ACCEPT
Accept the specified public key (use --include-all to match rejected keys in addition to pending keys). Globs are supported.
-A, --accept-all
Accepts all pending keys.

-r REJECT, --reject=REJECT
Reject the specified public key (use --include-all to match accepted keys in addition to pending keys). Globs are supported.
-R, --reject-all
Rejects all pending keys.

--include-all
Include non-pending keys when accepting/rejecting.

-p PRINT, --print=PRINT
Print the specified public key.
-P, --print-all
Print all public keys

-d DELETE, --delete=DELETE
Delete the specified key. Globs are supported.

-D, --delete-all
Delete all keys.

-f FINGER, --finger=FINGER
Print the specified key's fingerprint.
-F, --finger-all
Print all keys' fingerprints.
Key Generation Options

`--gen-keys=GEN_KEYS`
Set a name to generate a keypair for use with salt

`--gen-keys-dir=GEN_KEYS_DIR`
Set the directory to save the generated keypair. Only works with `gen_keys_dir` option; default is the current directory.

`--keysize=KEYSIZE`
Set the keysize for the generated key, only works with the `--gen-keys' option, the key size must be 2048 or higher, otherwise it will be rounded up to 2048. The default is 2048.

`--gen-signature`
Create a signature file of the masters public-key named master_pubkey_signature. The signature can be send to a minion in the masters auth-reply and enables the minion to verify the masters public-key cryptographically. This requires a new signing-key- pair which can be auto-created with the `--auto-create` parameter.

`--priv=PRIV`
The private-key file to create a signature with

`--signature-path=SIGNATURE_PATH`
The path where the signature file should be written

`--pub=PUB`
The public-key file to create a signature for

`--auto-create`
Auto-create a signing key-pair if it does not yet exist

salt(7) salt-master(1) salt-minion(1)

31.2.7 salt-master

salt-master

The Salt master daemon, used to control the Salt minions

Synopsis

```
salt-master [ options ]
```

Description

The master daemon controls the Salt minions

Options

`--version`
Print the version of Salt that is running.
--versions-report
    Show program's dependencies and version number, and then exit

-h, --help
    Show the help message and exit

-c CONFIG_DIR, --config-dir=CONFIG_dir
    The location of the Salt configuration directory. This directory contains the configuration files for Salt master
    and minions. The default location on most systems is /etc/salt.

-u USER, --user=USER
    Specify user to run salt-master

-d, --daemon
    Run salt-master as a daemon

--pid-file PIDFILE
    Specify the location of the pidfile. Default: /var/run/salt-master.pid

Logging Options  Logging options which override any settings defined on the configuration files.

-l LOG_LEVEL, --log-level=LOG_LEVEL
    Console logging log level. One of all, garbage, trace, debug, info, warning, error, quiet. Default: warning.

--log-file=LOG_FILE

--log-file-level=LOG_LEVEL_LOGFILE
    Logfile logging log level. One of all, garbage, trace, debug, info, warning, error, quiet. Default: warning.

See also

tsalt(1) salt(7) salt-minion(1)

31.2.8 salt-minion

salt-minion

The Salt minion daemon, receives commands from a remote Salt master.

Synopsis

    salt-minion [ options ]

Description

The Salt minion receives commands from the central Salt master and replies with the results of said commands.
Options

--version
Print the version of Salt that is running.

--versions-report
Show program's dependencies and version number, and then exit

-h, --help
Show the help message and exit

-c CONFIG_DIR, --config-dir=CONFIG_dir
The location of the Salt configuration directory. This directory contains the configuration files for Salt master and minions. The default location on most systems is /etc/salt.

-u USER, --user=USER
Specify user to run salt-minion

-d, --daemon
Run salt-minion as a daemon

--pid-file PIDFILE
Specify the location of the pidfile. Default: /var/run/salt-minion.pid

Logging Options
Logging options which override any settings defined on the configuration files.

-l LOG_LEVEL, --log-level=LOG_LEVEL
Console logging log level. One of all, garbage, trace, debug, info, warning, error, quiet. Default: warning.

--log-file=LOG_FILE
Log file path. Default: /var/log/salt/minion.

--log-file-level=LOG_LEVEL_LOGFILE
Logfile logging log level. One of all, garbage, trace, debug, info, warning, error, quiet. Default: warning.

See also

salt(1) salt(7) salt-master(1)

31.2.9 salt-proxy

salt-proxy

Receives commands from a Salt master and proxies these commands to devices that are unable to run a full minion.

Synopsis

salt-proxy [ options ]
Description

The Salt proxy minion receives commands from a Salt master, transmits appropriate commands to devices that are unable to run a minion, and replies with the results of said commands.

Options

--proxyid
The minion id that this proxy will assume. This is required.

--version
Print the version of Salt that is running.

--versions-report
Show program's dependencies and version number, and then exit

-h, --help
Show the help message and exit

-c CONFIG_DIR, --config-dir=CONFIG_dir
The location of the Salt configuration directory. This directory contains the configuration files for Salt master and minions. The default location on most systems is /etc/salt.

-u USER, --user=USER
Specify user to run salt-proxy

-d, --daemon
Run salt-proxy as a daemon

--pid-file PIDFILE
Specify the location of the pidfile. Default: /var/run/salt-proxy-<id>.pid

Logging Options
Logging options which override any settings defined on the configuration files.

-l LOG_LEVEL, --log-level=LOG_LEVEL
Console logging log level. One of all, garbage, trace, debug, info, warning, error, quiet. Default: warning.

--log-file=LOG_FILE
Log file path. Default: /var/log/salt/minion.

--log-file-level=LOG_LEVEL_LOGFILE
Logfile logging log level. One of all, garbage, trace, debug, info, warning, error, quiet. Default: warning.

See also

salt(1) salt(7) salt-master(1) salt-minion(1)

31.2.10 salt-run

salt-run

Execute a Salt runner
Synopsis

salt-run RUNNER

Description

salt-run is the frontend command for executing Salt Runners. Salt runners are simple modules used to execute convenience functions on the master

Options

--version
Print the version of Salt that is running.

--versions-report
Show program's dependencies and version number, and then exit

-h, --help
Show the help message and exit

-c CONFIG_DIR, --config-dir=CONFIG_dir
The location of the Salt configuration directory. This directory contains the configuration files for Salt master and minions. The default location on most systems is /etc/salt.

-t TIMEOUT, --timeout=TIMEOUT
The timeout in seconds to wait for replies from the Salt minions. The timeout number specifies how long the command line client will wait to query the minions and check on running jobs. Default: 1

--hard-crash
Raise any original exception rather than exiting gracefully. Default is False.

-d, --doc, --documentation
Display documentation for runners, pass a module or a runner to see documentation on only that module/runner.

Logging Options
Logging options which override any settings defined on the configuration files.

-l LOG_LEVEL, --log-level=LOG_LEVEL
Console logging log level. One of all, garbage, trace, debug, info, warning, error, quiet. Default: warning.

--log-file=LOG_FILE

--log-file-level=LOG_LEVEL_LOGFILE
Logfile logging log level. One of all, garbage, trace, debug, info, warning, error, quiet. Default: warning.

salt(1) salt-master(1) salt-minion(1)
31.2.11 salt-ssh

**salt-ssh**

Synopsis

```
salt-ssh 'x' [ options ] sys.doc
salt-ssh -E '.*' [ options ] sys.doc cmd
```

Description

Salt SSH allows for salt routines to be executed using only SSH for transport

Options

```
-r, --raw, --raw-shell
    Execute a raw shell command.
--priv
    Specify the SSH private key file to be used for authentication.
--roster
    Define which roster system to use, this defines if a database backend, scanner, or custom roster system is used. Default is the flat file roster.
--roster-file
    Define an alternative location for the default roster file location. The default roster file is called roster and is found in the same directory as the master config file.
    New in version 2014.1.0.
--refresh, --refresh-cache
    Force a refresh of the master side data cache of the target’s data. This is needed if a target’s grains have been changed and the auto refresh timeframe has not been reached.
--max-procs
    Set the number of concurrent minions to communicate with. This value defines how many processes are opened up at a time to manage connections, the more running process the faster communication should be, default is 25.
-i, --ignore-host-keys
    Ignore the ssh host keys which by default are honored and connections would ask for approval.
--passwd
    Set the default password to attempt to use when authenticating.
--key-deploy
    Set this flag to attempt to deploy the authorized ssh key with all minions. This combined with --passwd can make initial deployment of keys very fast and easy.
--version
    Print the version of Salt that is running.
--versions-report
    Show program’s dependencies and version number, and then exit
Salt Documentation, Release 2015.8.0

-h, --help
Show the help message and exit

-c CONFIG_DIR, --config-dir=CONFIG_dir
The location of the Salt configuration directory. This directory contains the configuration files for Salt master and minions. The default location on most systems is /etc/salt.

Target Selection
-E, --pcre
The target expression will be interpreted as a PCRE regular expression rather than a shell glob.

-L, --list
The target expression will be interpreted as a comma-delimited list; example: server1.foo.bar,server2.foo.bar.example7.quo.qux

-G, --grain
The target expression matches values returned by the Salt grains system on the minions. The target expression is in the format of `<grain value>:<glob expression>'; example: `os:Arch`

This was changed in version 0.9.8 to accept glob expressions instead of regular expression. To use regular expression matching with grains, use the --grain-pcre option.

--grain-pcre
The target expression matches values returned by the Salt grains system on the minions. The target expression is in the format of `<grain value>:<regular expression>'; example: `os:Arch.*'

-N, --nodegroup
Use a predefined compound target defined in the Salt master configuration file.

-R, --range
Instead of using shell globs to evaluate the target, use a range expression to identify targets. Range expressions look like %cluster.

Using the Range option requires that a range server is set up and the location of the range server is referenced in the master configuration file.

Logging Options
Logging options which override any settings defined on the configuration files.

-l LOG_LEVEL, --log-level=LOG_LEVEL
Console logging log level. One of all, garbage, trace, debug, info, warning, error, quiet. Default: warning.

--log-file=LOG_FILE

--log-file-level=LOG_LEVEL_LOGFILE
Logfile logging log level. One of all, garbage, trace, debug, info, warning, error, quiet. Default: warning.

Output Options
--out
Pass in an alternative outputter to display the return of data. This outputter can be any of the available out-putters:

grains, highstate, json, key, overstatestage, pprint, raw, txt, yaml

Some outputters are formatted only for data returned from specific functions; for instance, the grains outputter will not work for non-grains data.
If an outputter is used that does not support the data passed into it, then Salt will fall back on the `pprint` outputter and display the return data using the Python `pprint` standard library module.

**Note:** If using `--out=json`, you will probably want `--static` as well. Without the static option, you will get a separate JSON string per minion which makes JSON output invalid as a whole. This is due to using an iterative outputter. So if you want to feed it to a JSON parser, use `--static` as well.

```
--out-indent OUTPUT_INDENT, --output-indent OUTPUT_INDENT
Print the output indented by the provided value in spaces. Negative values disable indentation. Only applicable in outputters that support indentation.
```

```
--out-file=OUTPUT_FILE, --output-file=OUTPUT_FILE
Write the output to the specified file.
```

```
--no-color
Disable all colored output
```

```
--force-color
Force colored output
```

**Note:** When using colored output the color codes are as follows:
- **green** denotes success,
- **red** denotes failure,
- **blue** denotes changes and success
- **yellow** denotes a.

### 31.2.12 salt-syndic

#### salt-syndic

The Salt syndic daemon, a special minion that passes through commands from a higher master.

**Synopsis**

```
salt-syndic [ options ]
```

**Description**

The Salt syndic daemon, a special minion that passes through commands from a higher master.

**Options**

```
--version
Print the version of Salt that is running.
```

```
--versions-report
Show program's dependencies and version number, and then exit
```
-h, --help
    Show the help message and exit
-c CONFIG_DIR, --config-dir=CONFIG_dir
    The location of the Salt configuration directory. This directory contains the configuration files for Salt master and minions. The default location on most systems is /etc/salt.
-u USER, --user=USER
    Specify user to run salt-syndic
-d, --daemon
    Run salt-syndic as a daemon
--pid-file PIDFILE
    Specify the location of the pidfile. Default: /var/run/salt-syndic.pid

Logging Options
Logging options which override any settings defined on the configuration files.
-l LOG_LEVEL, --log-level=LOG_LEVEL
    Console logging log level. One of all, garbage, trace, debug, info, warning, error, quiet. Default: warning.
--log-file=LOG_FILE
--log-file-level=LOG_LEVEL_LOGFILE
    Logfile logging log level. One of all, garbage, trace, debug, info, warning, error, quiet. Default: warning.

salt(1) salt-master(1) salt-minion(1)

31.2.13 salt-api

salt-api
Start interfaces used to remotely connect to the salt master

Synopsis

salt-api

Description
The Salt API system manages network api connectors for the Salt Master

Options

--version
    Print the version of Salt that is running.
--versions-report
  Show program's dependencies and version number, and then exit

-h, --help
  Show the help message and exit

-c CONFIG_DIR, --config-dir=CONFIG_dir
  The location of the Salt configuration directory. This directory contains the configuration files for Salt master
  and minions. The default location on most systems is /etc/salt.

-d, --daemon
  Run the salt-api as a daemon

--pid-file=PIDFILE
  Specify the location of the pidfile. Default: /var/run/salt-api.pid

Logging Options  Logging options which override any settings defined on the configuration files.

-l LOG_LEVEL, --log-level=LOG_LEVEL
  Console logging log level. One of all, garbage, trace, debug, info, warning, error, quiet. Default: warning.

--log-file=LOG_FILE

--log-file-level=LOG_LEVEL_LOGFILE
  Logfile logging log level. One of all, garbage, trace, debug, info, warning, error, quiet. Default: warning.

See also

salt-api(7) salt(7) salt-master(1)

31.2.14  spm

spm

Salt Package Manager

Synopsis

  spm <command> [argument]

Description

  spm is the frontend command for managing Salt packages. Packages normally only include formulas, meaning a
  group of SLS files that install into the file_roots on the Salt Master, but Salt modules can also be installed.
Options

-y, --assume-yes
Assume yes instead of prompting the other whether or not to proceed with a particular command. Default is False.

-f, --force
When presented with a course of action that spm would normally refuse to perform, that action will be performed anyway. This is often destructive, and should be used with caution.

Logging Options Logging options which override any settings defined on the configuration files.

-l LOG_LEVEL, --log-level=LOG_LEVEL
Console logging log level. One of all, garbage, trace, debug, info, warning, error, quiet. Default: warning.

--log-file=LOG_FILE

--log-file-level=LOG_LEVEL_LOGFILE
Logfile logging log level. One of all, garbage, trace, debug, info, warning, error, quiet. Default: warning.

Commands

update_repo
Connect to remote repositories locally configured on the system and download their metadata.

install
Install a package from a configured SPM repository. Requires a package name.

remove
Remove an installed package from the system. Requires a package name.

info
List information about an installed package. Requires a package name.

files
List files belonging to an installed package. Requires a package name.

local
Perform one of the above options (except for remove) on a package file, instead of on a package in a repository, or an installed package. Requires a valid path to a local file on the system.

build
Build a package from a directory containing a FORMULA file. Requires a valid path to a local directory on the system.

create_repo
Scan a directory for valid SPM package files and build an SPM-METADATA file in that directory which describes them.

See also

salt(1) salt-master(1) salt-minion(1)
31.3 Client ACL system

The salt client ACL system is a means to allow system users other than root to have access to execute select salt commands on minions from the master.

The client ACL system is configured in the master configuration file via the `client_acl` configuration option. Under the `client_acl` configuration option the users open to send commands are specified and then a list of regular expressions which specify the minion functions which will be made available to specified user. This configuration is much like the `peer` configuration:

```yaml
client_acl:
  # Allow thatch to execute anything.
  thatch:
    - *
  # Allow fred to use test and pkg, but only on "web*" minions.
  fred:
    - web*:
      - test.*
      - pkg.*
```

31.3.1 Permission Issues

Directories required for `client_acl` must be modified to be readable by the users specified:

```bash
chmod 755 /var/cache/salt /var/cache/salt/master /var/cache/salt/master/jobs /var/run/salt /var/run/salt/master
```

**Note:** In addition to the changes above you will also need to modify the permissions of `/var/log/salt` and the existing log file to be writable by the user(s) which will be running the commands. If you do not wish to do this then you must disable logging or Salt will generate errors as it cannot write to the logs as the system users.

If you are upgrading from earlier versions of salt you must also remove any existing user keys and re-start the Salt master:

```bash
rm /var/cache/salt/.*key
service salt-master restart
```

31.4 Python client API

Salt provides several entry points for interfacing with Python applications. These entry points are often referred to as `*Client()` APIs. Each client accesses different parts of Salt, either from the master or from a minion. Each client is detailed below.

**See also:**

There are many ways to access Salt programmatically.

Salt can be used from CLI scripts as well as via a REST interface.

See Salt's `outputter system` to retrieve structured data from Salt as JSON, or as shell-friendly text, or many other formats.

See the `state.event` runner to utilize Salt's event bus from shell scripts.

Salt's `netapi module` provides access to Salt externally via a REST interface. Review the `netapi module` documentation for more information.
31.4.1 Salt’s opts dictionary

Some clients require access to Salt’s opts dictionary. (The dictionary representation of the master or minion config files.)

A common pattern for fetching the opts dictionary is to defer to environment variables if they exist or otherwise fetch the config from the default location.

```python
salt.config.client_config(path, env_var='SALT_CLIENT_CONFIG', defaults=None)
```

Load Master configuration data

Usage:

```python
import salt.config
master_opts = salt.config.client_config('/etc/salt/master')
```

Returns a dictionary of the Salt Master configuration file with necessary options needed to communicate with a locally-running Salt Master daemon. This function searches for client specific configurations and adds them to the data from the master configuration.

This is useful for master-side operations like LocalClient.

```python
salt.config.minion_config(path, env_var='SALT_MINION_CONFIG', defaults=None, cache_minion_id=False)
```

Reads in the minion configuration file and sets up special options

This is useful for Minion-side operations, such as the Caller class, and manually running the loader interface.

```python
import salt.client
minion_opts = salt.config.minion_config('/etc/salt/minion')
```

31.4.2 Salt’s Loader Interface

Modules in the Salt ecosystem are loaded into memory using a custom loader system. This allows modules to have conditional requirements (OS, OS version, installed libraries, etc) and allows Salt to inject special variables (__salt__, __opts__, etc).

Most modules can be manually loaded. This is often useful in third-party Python apps or when writing tests. However some modules require and expect a full, running Salt system underneath. Notably modules that facilitate master-to-minion communication such as the mine, publish, and peer execution modules. The error KeyError: 'master_uri' is a likely indicator for this situation. In those instances use the Caller class to execute those modules instead.

Each module type has a corresponding loader function.

```python
salt.loader.minionMods(opts, context=None, utils=None, whitelist=None, include_errors=False, initial_load=False, loaded_base_name=None, notify=False)
```

Load execution modules

Returns a dictionary of execution modules appropriate for the current system by evaluating the __virtual__() function in each module.

Parameters

- **opts (dict)** -- The Salt options dictionary

- **context (dict)** -- A Salt context that should be made present inside generated modules in __context__

- **utils (dict)** -- Utility functions which should be made available to Salt modules in __utils__. See utils_dir in salt.config for additional information about configuration.
- **whitelist** *(list)* -- A list of modules which should be whitelisted.
- **include_errors** *(bool)* -- Deprecated flag! Unused.
- **initial_load** *(bool)* -- Deprecated flag! Unused.
- **loaded_base_name** *(str)* -- A string marker for the loaded base name.
- **notify** *(bool)* -- Flag indicating that an event should be fired upon completion of module loading.

```python
import salt.config
import salt.loader

__opts__ = salt.config.minion_config('/etc/salt/minion')
__grains__ = salt.loader.grains(__opts__)
__opts__['grains'] = __grains__
__salt__ = salt.loader.minion_mods(__opts__)
__salt__['test.ping']()
```

salt.loader.raw_mod*(opts, name, functions, mod='modules')*
Returns a single module loaded raw and bypassing the __virtual__ function

```python
import salt.config
import salt.loader

__opts__ = salt.config.minion_config('/etc/salt/minion')
testmod = salt.loader.raw_mod(__opts__, 'test', None)
testmod['test.ping']()
```

salt.loader.states*(opts, functions, utils, whitelist=None)*
Returns the state modules

Parameters
- **opts** *(dict)* -- The Salt options dictionary
- **functions** *(dict)* -- A dictionary of minion modules, with module names as keys and func as values.

```python
import salt.config
import salt.loader

__opts__ = salt.config.minion_config('/etc/salt/minion')
statemods = salt.loader.states(__opts__, None, None)
```

salt.loader.grains*(opts, force_refresh=False)*
Return the functions for the dynamic grains and the values for the static grains.

```python
import salt.config
import salt.loader

__opts__ = salt.config.minion_config('/etc/salt/minion')
__grains__ = salt.loader.grains(__opts__)
print __grains__['id']
```

salt.loader.grain_funcs*(opts)*
Returns the grain functions

```python
import salt.config
import salt.loader
```

442 Chapter 31. Reference
Salt Documentation, Release 2015.8.0

```python
__opts__ = salt.config.minion_config('/etc/salt/minion')
grainfuncs = salt.loader.grain_funcs(__opts__)
```

# 31.4.3 Salt’s Client Interfaces

**LocalClient**

class salt.client.LocalClient(c_path='/etc/salt/master', mopts=None, skip_perm_errors=False)

The interface used by the `salt` CLI tool on the Salt Master

LocalClient is used to send a command to Salt minions to execute execution modules and return the results to the Salt Master.

Importing and using LocalClient must be done on the same machine as the Salt Master and it must be done using the same user that the Salt Master is running as. (Unless external_auth is configured and authentication credentials are included in the execution).

```python
import salt.client
local = salt.client.LocalClient()
local.cmd('*', 'test.fib', [10])
```

**cmd** *(tgt, fun, arg=(), timeout=None, expr_form='glob', ret='', jid='', kwarg=None, **kwargs)*

Synchronously execute a command on targeted minions

The cmd method will execute and wait for the timeout period for all minions to reply, then it will return all minion data at once.

```python
>>> import salt.client
>>> local = salt.client.LocalClient()
>>> local.cmd('*', 'cmd.run', ['whoami'])
{'jerry': 'root'}
```

With extra keyword arguments for the command function to be run:

```python
local.cmd('*', 'test.arg', ['arg1', 'arg2'], kwarg={'foo': 'bar'})
```

Compound commands can be used for multiple executions in a single publish. Function names and function arguments are provided in separate lists but the index values must correlate and an empty list must be used if no arguments are required.

```python
>>> local.cmd('*', ['grains.items', 'sys.doc', 'cmd.run'], ['[', [
                [],
                [],
                ['uptime'],
                ]])
```

## Parameters

- **tgt** *(string or list)* -- Which minions to target for the execution. Default is shell glob. Modified by the `expr_form` option.
• **fun** *(string or list of strings)* -- The module and function to call on the specified minions of the form module.function. For example *test.ping* or *grains.items*.

**Compound commands** Multiple functions may be called in a single publish by passing a list of commands. This can dramatically lower overhead and speed up the application communicating with Salt.

This requires that the *arg* param is a list of lists. The *fun* list and the *arg* list must correlate by index meaning a function that does not take arguments must still have a corresponding empty list at the expected index.

• **arg** *(list or list-of-lists)* -- A list of arguments to pass to the remote function. If the function takes no arguments *arg* may be omitted except when executing a compound command.

• **timeout** -- Seconds to wait after the last minion returns but before all minions return.

• **expr_form** -- The type of *tgt*. Allowed values:
  - glob - Bash glob completion - Default
  - pcre - Perl style regular expression
  - list - Python list of hosts
  - grains - Match based on a grain comparison
  - grain_pcre - Grain comparison with a regex
  - pillargroup - Pillar data comparison
  - pillargroup_pcre - Pillar data comparison with a regex
  - nodegroup - Match on nodegroup
  - range - Use a Range server for matching
  - compound - Pass a compound match string

• **ret** -- The returner to use. The value passed can be single returner, or a comma delimited list of returners to call in order on the minions

• **kwarg** -- A dictionary with keyword arguments for the function.

• **kwargs** -- Optional keyword arguments. Authentication credentials may be passed when using *external_auth*.

For example: `local.cmd('*','test.ping', username='saltdev', password='saltdev', eauth='pam')`. Or: `local.cmd('*','test.ping', token='5871821ea51754fdce8153c1c745433')`

**Returns** A dictionary with the result of the execution, keyed by minion ID. A compound command will return a sub-dictionary keyed by function name.

```python
cmd_async(tgt, fun, arg=(), expr_form='glob', ret='ret', jid='', kwarg=None, **kwargs)
```

Asynchronously send a command to connected minions

The function signature is the same as *cmd()* with the following exceptions.

**Returns** A job ID or 0 on failure.

```python
>>> local.cmd_async('*','test.sleep', [300])
'20131219215921857715'
```
**cmd_batch** *(tgt, fun, arg=(), expr_form='glob', ret='\', kwarg=None, batch='10%', **kwargs)*

Iteratively execute a command on subsets of minions at a time. The function signature is the same as `cmd()` with the following exceptions.

**Parameters**

- **batch** -- The batch identifier of systems to execute on

**Returns**

A generator of minion returns

```python
>>> returns = local.cmd_batch('*', 'state.highstate', bat='10%')
```

```python
>>> for ret in returns:
...   print(ret)
{'jerry': {...}}
{'dave': {...}}
{'stewart': {...}}
```

**cmd_iter** *(tgt, fun, arg=(), timeout=None, expr_form='glob', ret='\', kwarg=None, **kwargs)*

Yields the individual minion returns as they come in. The function signature is the same as `cmd()` with the following exceptions.

**Returns**

A generator yielding the individual minion returns

```python
>>> ret = local.cmd_iter('*', 'test.ping')
```

```python
>>> for i in ret:
...   print(i)
{'jerry': {'ret': True}}
{'dave': {'ret': True}}
{'stewart': {'ret': True}}
```

**cmd_iter_no_block** *(tgt, fun, arg=(), timeout=None, expr_form='glob', ret='\', kwarg=None, **kwargs)*

Yields the individual minion returns as they come in, or `None` when no returns are available. The function signature is the same as `cmd()` with the following exceptions.

**Returns**

A generator yielding the individual minion returns, or `None` when no returns are available. This allows for actions to be injected in between minion returns.

```python
>>> ret = local.cmd_iter_no_block('*', 'test.ping')
```

```python
>>> for i in ret:
...   print(i)
None
{'jerry': {'ret': True}}
{'dave': {'ret': True}}
None
{'stewart': {'ret': True}}
```

**cmd_subset** *(tgt, fun, arg=(), expr_form='glob', ret='\', kwarg=None, sub=3, cli=False, progress=False, **kwargs)*

Execute a command on a random subset of the targeted systems. The function signature is the same as `cmd()` with the following exceptions.

**Parameters**

- **sub** -- The number of systems to execute on

```python
>>> SLC.cmd_subset('*', 'test.ping', sub=1)
{'jerry': True}
```

**get_cli_returns** *(jid, minions, timeout=None, tgt='\', tgt_type='glob', verbose=False, show_jid=False, **kwargs)*

Starts a watcher looking at the return data for a specified JID.
**Returns** all of the information for the JID

```python
def get_event_iter_returns(jid, minions, timeout=None):
    """Gather the return data from the event system, break hard when timeout is reached."
    pass
```

```python
def run_job(tgt, fun, arg=(), expr_form='glob', ret='*', timeout=None, jid='*', kwarg=None, **kwargs):
    """Asynchronously send a command to connected minions"
    pass
```

```python
>>> local.run_job('x', 'test.sleep', [300])
{'jid': '20131219215650131543', 'minions': ['jerry']}
```

### Salt Caller

**class** `salt.client.Caller(c_path='/etc/salt/minion', mopts=None)`

**Caller** is the same interface used by the `salt-call` command-line tool on the Salt Minion.

Changed in version 2015.8.0: Added the `cmd` method for consistency with the other Salt clients. The existing `function` and `sminion.functions` interfaces still exist but have been removed from the docs.

Importing and using `Caller` must be done on the same machine as a Salt Minion and it must be done using the same user that the Salt Minion is running as.

**Usage:**

```python
import salt.client
caller = salt.client.Caller()
caller.cmd('test.ping')
```

Note, a running master or minion daemon is not required to use this class. Running `salt-call --local` simply sets `file_client` to `local`. The same can be achieved at the Python level by including that setting in a minion config file.

New in version 2014.7.0: Pass the minion config as the `mopts` dictionary.

```python
import salt.client
import salt.config
__opts__ = salt.config.minion_config('/etc/salt/minion')
__opts__['file_client'] = 'local'
caller = salt.client.Caller(mopts=__opts__)
```

```python
def cmd(fun, *args, **kwargs):
    """Call an execution module with the given arguments and keyword arguments"
    pass
```

Changed in version 2015.8.0: Added the `cmd` method for consistency with the other Salt clients. The existing `function` and `sminion.functions` interfaces still exist but have been removed from the docs.

```python
caller.cmd('test.arg', 'Foo', 'Bar', baz='Baz')

caller.cmd('event.send', 'myco/myevent/something',
           data={'foo': 'Foo'}, with_env=['GIT_COMMIT'], with_grains=True)
```
RunnerClient

class salt.runner.RunnerClient(opts)
    The interface used by the `salt-run` CLI tool on the Salt Master

    It executes runner modules which run on the Salt Master.

    Importing and using RunnerClient must be done on the same machine as the Salt Master and it must be
done using the same user that the Salt Master is running as.

    Salt's external_auth can be used to authenticate calls. The eauth user must be authorized to execute
runner modules: (@runner). Only the `master_call()` below supports eauth.

    async (fun, low, user='UNKNOWN')
        Execute the function in a multiprocess and return the event tag to use to watch for the return

    cmd (fun, arg=None, pub_data=None, kwarg=None)
        Execute a function

>>> opts = salt.config.master_config('/etc/salt/master')
>>> runner = salt.runner.RunnerClient(opts)
>>> runner.cmd('jobs.list_jobs', [])
{
    '20131219215650131543': {
        'Arguments': [300],
        'Function': 'test.sleep',
        'StartTime': '2013, Dec 19 21:56:50.131543',
        'Target': '*',
        'Target-type': 'glob',
        'User': 'saltdev'
    },
    '20131219215921857715': {
        'Arguments': [300],
        'Function': 'test.sleep',
        'Target': '*',
        'Target-type': 'glob',
        'User': 'saltdev'
    }
}

cmd_async (low)
    Execute a runner function asynchronously; eauth is respected

    This function requires that external_auth is configured and the user is authorized to execute runner
functions: (@runner).

    runner.eauth_async({
        'fun': 'jobs.list_jobs',
        'username': 'saltdev',
        'password': 'saltdev',
        'eauth': 'pam',
    })

cmd_sync (low, timeout=None)
    Execute a runner function synchronously; eauth is respected

    This function requires that external_auth is configured and the user is authorized to execute runner
functions: (@runner).
```python
def runner.eauth_sync(
    fun='jobs.list_jobs',
    username='saltdev',
    password='saltdev',
    eauth='pam',
)
```

**WheelClient**

class salt.wheel.WheelClient(\n    opts=None\n)

An interface to Salt's wheel modules

Wheel modules interact with various parts of the Salt Master.

Importing and using WheelClient must be done on the same machine as the Salt Master and it must be done using the same user that the Salt Master is running as. Unless external_auth is configured and the user is authorized to execute wheel functions: (@wheel).

Usage:

```python
import salt.config
import salt.wheel

def _client():
    return WheelClient(salt.config.master_config('/etc/salt/master'))

t = _client()
```

```python
def _execute(jid, fun, arg, pub_data, kwarg):
    # Execute the function and return the event tag to watch for the return
    return t.cmd(jid, fun, arg, pub_data, kwarg)
```

```python
def wheel.eauth_sync(
    fun='jobs.list_jobs',
    username='saltdev',
    password='saltdev',
    eauth='pam',
)
```
CloudClient

```python
class salt.cloud.CloudClient(path=None, opts=None, config_dir=None, pillars=None):
    The client class to wrap cloud interactions

    action(fun=None, cloudmap=None, names=None, provider=None, instance=None, kwargs=None)
    Execute a single action via the cloud plugin backend
    Examples:
    client.action(fun='show_instance', names=['myinstance'])
    client.action(fun='show_image', provider='my-ec2-config',
                  kwargs={'image': 'ami-10314d79'})

create(provider, names, **kwargs)
    Create the named VMs, without using a profile
    Example:
    client.create(names=['myinstance'], provider='my-ec2-config',
                  kwargs={'image': 'ami-1624987f', 'size': 't1.micro',
                          'ssh_username': 'ec2-user', 'securitygroup': 'default',
                          'delvol_on_destroy': True})

destroy(names)
    Destroy the named VMs

distinct(key, names, **kwargs)
    Distinct action
    Example:
    client.distinct(names=['myinstance'], key='size',
                     provider='my-ec2-config',
                     kwargs={'value': 't1.micro'})

extra_action(names, provider, action, **kwargs)
    Perform actions with block storage devices
    Example:
    client.extra_action(names=['myblock'], action='volume_create',
                         provider='my-nova',
                         kwargs={'voltype': 'SSD', 'size': 1000})
    client.extra_action(names=['salt-net'], action='network_create',
                         provider='my-nova',
                         kwargs={'cidr': '192.168.100.0/24'})

full_query(query_type='list_nodes_full')
    Query all instance information

list_images(provider=None)
    List all available images in configured cloud systems

list_locations(provider=None)
    List all available locations in configured cloud systems

list_sizes(provider=None)
    List all available sizes in configured cloud systems

low(fun, low)
    Pass the cloud function and low data structure to run
```

map_run(path, **kwargs)
    Pass in a location for a map to execute

min_query(query_type='list_nodes_min')
    Query select instance information

profile(profile, names, vm_overrides=None, **kwargs)
    Pass in a profile to create, names is a list of vm names to allocate
    vm_overrides is a special dict that will be per node options overrides

Example:

```python
>>> client = salt.cloud.CloudClient(path='/etc/salt/cloud')
>>> client.profile('do_512_git', names=['minion01',])
{'minion01': {u'backups_active': 'False',
            u'created_at': '2014-09-04T18:10:15Z',
            u'droplet': {u'event_id': 31000502,
                         u'id': 2530006,
                         u'image_id': 5140006,
                         u'name': 'minion01',
                         u'size_id': 66},
            u'id': '2530006',
            u'image_id': '5140006',
            u'ip_address': '107.XXX.XXX.XXX',
            u'locked': 'True',
            u'name': 'minion01',
            u'private_ip_address': None,
            u'region_id': '4',
            u'size_id': '66',
            u'status': 'new'}}
```

query(query_type='list_nodes')
    Query basic instance information

select_query(query_type='list_nodes_select')
    Query select instance information

SSHClient

class salt.client.ssh.client.SSHClient(c_path=’/etc/salt/master’, mopts=None)
    Create a client object for executing routines via the salt-ssh backend

    New in version 2015.5.0.

cmd(tgt, fun, arg=(), timeout=None, expr_form='glob', kwarg=None, **kwargs)
    Execute a single command via the salt-ssh subsystem and return all routines at once

    New in version 2015.5.0.

cmd_iter(tgt, fun, arg=(), timeout=None, expr_form='glob', ret='`, kwarg=None, **kwargs)
    Execute a single command via the salt-ssh subsystem and return a generator

    New in version 2015.5.0.

31.5 Full list of Salt Cloud modules
### 31.5.1 salt.cloud.clouds.aliyun

**AliYun ECS Cloud Module**

New in version 2014.7.0.

The Aliyun cloud module is used to control access to the aliyun ECS. [http://www.aliyun.com/](http://www.aliyun.com/)

Use of this module requires the `id` and `key` parameter to be set. Set up the cloud configuration at `/etc/salt/cloud.providers` or `/etc/salt/cloud.providers.d/aliyun.conf`:

```yaml
my-aliyun-config:
    # aliyun Access Key ID
    id: wFGEwgregeqw3435gDger
    # aliyun Access Key Secret
    key: GDE43t43REGTrkilg43934t34qT43t4dgegerGEgg
    location: cn-qingdao
    driver: aliyun
```

**depends** requests

salt.cloud.clouds.aliyun.available_images(**kwargs=None, call=None**)  
Return a list of the images that are on the provider

salt.cloud.clouds.aliyun.available_locations(**call=None**)  
Return a dict of all available VM locations on the cloud provider with relevant data

salt.cloud.clouds.aliyun.available_sizes(**call=None**)  
Return a list of the image sizes that are on the provider
salt.cloud.clouds.aliyun.create(vm_)
Create a single VM from a data dict

salt.cloud.clouds.aliyun.create_node(kwargs)
Convenience function to make the rest api call for node creation.

salt.cloud.clouds.aliyun.destroy(name, call=None)
Destroy a node.

CLI Example:

salt-cloud -a destroy myinstance
salt-cloud -d myinstance

salt.cloud.clouds.aliyun.get_configured_provider()
Return the first configured instance.

salt.cloud.clouds.aliyun.get_dependencies()
Warn if dependencies aren't met.

salt.cloud.clouds.aliyun.get_image(vm_)
Return the image object to use

salt.cloud.clouds.aliyun.get_location(vm_=None)
Return the aliyun region to use, in this order:
- CLI parameter
- VM parameter
- Cloud profile setting

salt.cloud.clouds.aliyun.get_securitygroup(vm_)
Return the security group

salt.cloud.clouds.aliyun.get_size(vm_)
Return the VM's size. Used by create_node().

salt.cloud.clouds.aliyun.list_availability_zones(call=None)
List all availability zones in the current region

salt.cloud.clouds.aliyun.list_monitor_data(kwargs=None, call=None)
Get monitor data of the instance. If instance name is missing, will show all the instance monitor data on the region.

CLI Examples:

salt-cloud -f list_monitor_data aliyun
salt-cloud -f list_monitor_data aliyun name=AY14051311071990225bd

salt.cloud.clouds.aliyun.list_nodes(call=None)
Return a list of the VMs that are on the provider

salt.cloud.clouds.aliyun.list_nodes_full(call=None)
Return a list of the VMs that are on the provider

salt.cloud.clouds.aliyun.list_nodes_min(call=None)
Return a list of the VMs that are on the provider. Only a list of VM names, and their state, is returned. This is the minimum amount of information needed to check for existing VMs.

salt.cloud.clouds.aliyun.list_nodes_select(call=None)
Return a list of the VMs that are on the provider, with select fields
salt.cloud.clouds.aliyun.list_securitygroup(call=None)
    Return a list of security group

salt.cloud.clouds.aliyun.query(params=None)
    Make a web call to aliyun ECS REST API

salt.cloud.clouds.aliyun.reboot(name, call=None)
    Reboot a node
    CLI Examples:
    salt-cloud -a reboot myinstance

salt.cloud.clouds.aliyun.script(vm_)
    Return the script deployment object

salt.cloud.clouds.aliyun.show_disk(name, call=None)
    Show the disk details of the instance
    CLI Examples:
    salt-cloud -a show_disk aliyun myinstance

salt.cloud.clouds.aliyun.show_image(kwargs, call=None)
    Show the details from aliyun image

salt.cloud.clouds.aliyun.show_instance(name, call=None)
    Show the details from aliyun instance

salt.cloud.clouds.aliyun.start(name, call=None)
    Start a node
    CLI Examples:
    salt-cloud -a start myinstance

salt.cloud.clouds.aliyun.stop(name, force=False, call=None)
    Stop a node
    CLI Examples:
    salt-cloud -a stop myinstance
    salt-cloud -a stop myinstance force=True

31.5.2 salt.cloud.clouds.botoCore_aws

The AWS Cloud Module

The AWS cloud module is used to interact with the Amazon Web Services system.

This module has been replaced by the EC2 cloud module, and is no longer supported. The documentation shown here is for reference only; it is highly recommended to change all usages of this driver over to the EC2 driver.

If this driver is still needed, set up the cloud configuration at /etc/salt/cloud.providers or /etc/salt/cloud.providers.d/aws.conf:

```bash
my-aws-botoCore-config:
    # The AWS API authentication id
    id: GKTADJGHEIQSXMKKRBJ08H
    # The AWS API authentication key
```

31.5. Full list of Salt Cloud modules
### salt.cloud.clouds.botocore_aws.disable_term_protect

Disable termination protection on a node

**CLI Example:**
```
salt-cloud -a disable_term_protect mymachine
```

### salt.cloud.clouds.botocore_aws.enable_term_protect

Enable termination protection on a node

**CLI Example:**
```
salt-cloud -a enable_term_protect mymachine
```

### salt.cloud.clouds.botocore_aws.get_configured_provider

Return the first configured instance.

### salt.cloud.clouds.botocore_aws.get_dependencies

Warn if dependencies aren’t met.

## 31.5.3 salt.cloud.clouds.cloudstack

### CloudStack Cloud Module

The CloudStack cloud module is used to control access to a CloudStack based Public Cloud.

#### depends

**libcloud**

Use of this module requires the `apikey`, `secretkey`, `host` and `path` parameters.

**my-cloudstack-cloud-config:**
```
apikey: <your api key >
secretkey: <your secret key >
host: localhost
path: /client/api
driver: cloudstack
```

### salt.cloud.clouds.cloudstack.avail_images

Return a dict of all available VM images on the cloud provider with relevant data

### salt.cloud.clouds.cloudstack.avail_locations

Return a dict of all available VM locations on the cloud provider with relevant data

### salt.cloud.clouds.cloudstack.avail_sizes

Return a dict of all available VM images on the cloud provider with relevant data

### salt.cloud.clouds.cloudstack.block_device_mappings

Return the block device mapping:
```
[['DeviceName': '/dev/sdb', 'VirtualName': 'ephemeral0'],
 {'DeviceName': '/dev/sdc', 'VirtualName': 'ephemeral1']
```
salt.cloud.clouds.cloudstack.cloudstack_displayname(vm_)
    Return display name of VM:
    = \"minion1\"
salt.cloud.clouds.cloudstack.create(vm_)
    Create a single VM from a data dict
salt.cloud.clouds.cloudstack.destroy(name, conn=None, call=None)
    Delete a single VM, and all of its volumes
salt.cloud.clouds.cloudstack.get_configured_provider()
    Return the first configured instance.
salt.cloud.clouds.cloudstack.get_conn()
    Return a conn object for the passed VM data
salt.cloud.clouds.cloudstack.get_dependencies()
    Warn if dependencies aren't met.
salt.cloud.clouds.cloudstack.get_image(conn, vm_)
    Return the image object to use
salt.cloud.clouds.cloudstack.get_ip(data)
    Return the IP address of the VM. If the VM has public IP as defined by libcloud module then use it. Otherwise try to extract the private IP and use that one.
salt.cloud.clouds.cloudstack.get_key()
    Returns the ssh private key for VM access
salt.cloud.clouds.cloudstack.get_keypair(vm_)
    Return the keypair to use
salt.cloud.clouds.cloudstack.get_location(conn, vm_)
    Return the node location to use
salt.cloud.clouds.cloudstack.get_networkid(vm_)
    Return the networkid to use, only valid for Advanced Zone
salt.cloud.clouds.cloudstack.get_node(conn, name)
    Return a libcloud node for the named VM
salt.cloud.clouds.cloudstack.get_password(vm_)
    Return the password to use
salt.cloud.clouds.cloudstack.get_project(conn, vm_)
    Return the project to use.
salt.cloud.clouds.cloudstack.get_size(conn, vm_)
    Return the VM's size object
salt.cloud.clouds.cloudstack.list_nodes(conn=None, call=None)
    Return a list of the VMs that are on the provider
salt.cloud.clouds.cloudstack.list_nodes_full(conn=None, call=None)
    Return a list of the VMs that are on the provider, with all fields
salt.cloud.clouds.cloudstack.list_nodes_select(conn=None, call=None)
    Return a list of the VMs that are on the provider, with select fields
salt.cloud.clouds.cloudstack.script(vm_)
    Return the script deployment object
salt.cloud.clouds.cloudstack.show_instance(name, call=None)
    Show the details from the provider concerning an instance

31.5.4 salt.cloud.clouds.digital_ocean

DigitalOcean Cloud Module

The DigitalOcean cloud module is used to control access to the DigitalOcean VPS system.

Use of this module requires a personal_access_token, an ssh_key_file, and at least one SSH key name in ssh_key_names. More ssh_key_names can be added by separating each key with a comma. The personal_access_token can be found in the DigitalOcean web interface in the "Apps & API" section. The SSH key name can be found under the "SSH Keys" section.

```
# Note: This example is for /etc/salt/cloud.providers or any file in the
# /etc/salt/cloud.providers.d/ directory.

my-digital-ocean-config:
  personal_access_token: xxx
  ssh_key_file: /path/to/ssh/key/file
  ssh_key_names: my-key-name,my-key-name-2
  driver: digital_ocean

  depends requests

salt.cloud.clouds.digital_ocean.avail_images(call=None)
    Return a list of the images that are on the provider

salt.cloud.clouds.digital_ocean.avail_locations(call=None)
    Return a dict of all available VM locations on the cloud provider with relevant data

salt.cloud.clouds.digital_ocean.avail_sizes(call=None)
    Return a list of the image sizes that are on the provider

salt.cloud.clouds.digital_ocean.create(vm_)
    Create a single VM from a data dict

salt.cloud.clouds.digital_ocean.create_dns_record(hostname, ip_address)
    Creates a DNS record for the given hostname if the domain is managed with DO.

salt.cloud.clouds.digital_ocean.create_key(kwars=None, call=None)
    Upload a public key

salt.cloud.clouds.digital_ocean.create_node(args)
    Create a node

salt.cloud.clouds.digital_ocean.delete_dns_record(hostname)
    Deletes a DNS for the given hostname if the domain is managed with DO.

salt.cloud.clouds.digital_ocean.destroy(name, call=None)
    Destroy a node. Will check termination protection and warn if enabled.

    CLI Example:
    salt-cloud --destroy mymachine

salt.cloud.clouds.digital_ocean.get_configured_provider()
    Return the first configured instance.

salt.cloud.clouds.digital_ocean.get_dependencies()
    Warn if dependencies aren't met.
salt.cloud.clouds.digital_ocean.get_image(vm_)
    Return the image object to use
salt.cloud.clouds.digital_ocean.get_keyid(keyname)
    Return the ID of the keyname
salt.cloud.clouds.digital_ocean.get_location(vm_)
    Return the VM's location
salt.cloud.clouds.digital_ocean.get_size(vm_)
    Return the VM's size. Used by create_node().
salt.cloud.clouds.digital_ocean.list_keypairs(call=None)
    Return a dict of all available VM locations on the cloud provider with relevant data
salt.cloud.clouds.digital_ocean.list_nodes(call=None)
    Return a list of the VMs that are on the provider
salt.cloud.clouds.digital_ocean.list_nodes_full(call=None, forOutput=True)
    Return a list of the VMs that are on the provider
salt.cloud.clouds.digital_ocean.list_nodes_select(call=None)
    Return a list of the VMs that are on the provider, with select fields
salt.cloud.clouds.digital_ocean.query(method='droplets', droplet_id=None, command=None, args=None, http_method='get')
    Make a web call to DigitalOcean
salt.cloud.clouds.digital_ocean.remove_key(kwargs=None, call=None)
    Delete public key
salt.cloud.clouds.digital_ocean.script(vm_)
    Return the script deployment object
salt.cloud.clouds.digital_ocean.show_instance(name, call=None)
    Show the details from DigitalOcean concerning a droplet
salt.cloud.clouds.digital_ocean.show_keypair(kwargs=None, call=None)
    Show the details of an SSH keypair
salt.cloud.clouds.digital_ocean.show_pricing(kwargs=None, call=None)
    Show pricing for a particular profile. This is only an estimate, based on unofficial pricing sources.
    New in version 2015.8.0.
    CLI Examples:
    ```
    salt-cloud -f show_pricing my-digitalocean-config profile=my-profile
    ```

31.5.5 salt.cloud.clouds.ec2

The EC2 Cloud Module

The EC2 cloud module is used to interact with the Amazon Elastic Cloud Computing.

To use the EC2 cloud module, set up the cloud configuration at /etc/salt/cloud.providers or /etc/salt/cloud.providers.d/ec2.conf:

```
my-ec2-config:
    # The EC2 API authentication id, set this and/or key to
    # 'use-instance-role-credentials' to use the instance role credentials
```

31.5. Full list of Salt Cloud modules
# from the meta-data if running on an AWS instance
id: GKTADJGHEIQSXMKKRBJ08H
# The EC2 API authentication key, set this and/or id to
# 'use-instance-role-credentials' to use the instance role credentials
# from the meta-data if running on an AWS instance
key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
# The ssh keyname to use
keyname: default
# The amazon security group
securitygroup: ssh_open
# The location of the private key which corresponds to the keyname
private_key: /root/default.pem

# Be default, service_url is set to amazonaws.com. If you are using this
# driver for something other than Amazon EC2, change it here:
service_url: amazonaws.com

# The endpoint that is ultimately used is usually formed using the region
# and the service_url. If you would like to override that entirely, you
# can explicitly define the endpoint:
endpoint: myendpoint.example.com:1138/services/Cloud

# SSH Gateways can be used with this provider. Gateways can be used
# when a salt-master is not on the same private network as the instance
# that is being deployed.

# Defaults to None
# Required
ssh_gateway: gateway.example.com

# Defaults to port 22
# Optional
ssh_gateway_port: 22

# Defaults to root
# Optional
ssh_gateway_username: root

# One authentication method is required. If both
# are specified, Private key wins.

# Private key defaults to None
ssh_gateway_private_key: /path/to/key.pem

# Password defaults to None
ssh_gateway_password: ExamplePasswordHere

driver: ec2

depends requests

salt.cloud.clouds.ec2.attach_volume(name=None, kwargs=None, instance_id=None, call=None)
Attach a volume to an instance

salt.cloud.clouds.ec2.avail_images(kwargs=None, call=None)
Return a dict of all available VM images on the cloud provider.

salt.cloud.clouds.ec2.avail_locations(call=None)
List all available locations

```python
salt.cloud.clouds.ec2.avail_sizes(call=None)
```

Return a dict of all available VM sizes on the cloud provider with relevant data. Latest version can be found at:

```python
salt.cloud.clouds.ec2.block_device_mappings(vm_)
```

Return the block device mapping:

```python
[]
```

```python
salt.cloud.clouds.ec2.copy_snapshot(kwargs=None, call=None)
```

Copy a snapshot

```python
salt.cloud.clouds.ec2.create(vm_=None, call=None)
```

Create a single VM from a data dict

```python
salt.cloud.clouds.ec2.create_attach_volumes(name, kwargs, call=None, wait_to_finish=True)
```

Create and attach volumes to created node

```python
salt.cloud.clouds.ec2.create_keypair(kwargs=None, call=None)
```

Create an SSH keypair

```python
salt.cloud.clouds.ec2.create_snapshot(kwargs=None, call=None, wait_to_finish=False)
```

Create a snapshot.

```python
volume_id The ID of the Volume from which to create a snapshot.
description The optional description of the snapshot.
```

CLI Exampes:

```bash
salt-cloud -f create_snapshot my-ec2-config volume_id=vol-351d8826
salt-cloud -f create_snapshot my-ec2-config volume_id=vol-351d8826 \
    description="My Snapshot Description"
```

```python
salt.cloud.clouds.ec2.create_volume(kwargs=None, call=None, wait_to_finish=False)
```

Create a volume

CLI Examples:

```bash
salt-cloud -f create_volume my-ec2-config zone=us-east-1b
salt-cloud -f create_volume my-ec2-config zone=us-east-1b tags='{"tag1": "val1", "tag2", "val2"}"
```

```python
salt.cloud.clouds.ec2.del_tags(name=None, kwargs=None, call=None, instance_id=None, resource_id=None)
```

Delete tags for a resource. Normally a VM name or instance_id is passed in, but a resource_id may be passed instead. If both are passed in, the instance_id will be used.

CLI Examples:

```bash
salt-cloud -a del_tags mymachine tags=mytag,
salt-cloud -a del_tags mymachine tags=tag1,tag2,tag3
salt-cloud -a del_tags resource_id=vol-3267ab32 tags=tag1,tag2,tag3
```

```python
salt.cloud.clouds.ec2.delete_keypair(kwargs=None, call=None)
```

Delete an SSH keypair
salt.cloud.clouds.ec2.delete_snapshot(**kwargs=None, call=None)**

Delete a snapshot

salt.cloud.clouds.ec2.delete_volume(name=None, **kwargs=None, instance_id=None, call=None)**

Delete a volume

salt.cloud.clouds.ec2.delvol_on_destroy(name, **kwargs=None, call=None)**

Delete all/specified EBS volumes upon instance termination

CLI Example:

```bash
salt-cloud -a delvol_on_destroy mymachine
```

salt.cloud.clouds.ec2.describe_snapshots(**kwargs=None, call=None)**

Describe a snapshot (or snapshots)

- snapshot_id: One or more snapshot IDs. Multiple IDs must be separated by ",".
- owner: Return the snapshots owned by the specified owner. Valid values include: self, amazon, <AWS Account ID>. Multiple values must be separated by ",".
- restorable_by: One or more AWS accounts IDs that can create volumes from the snapshot. Multiple aws account IDs must be separated by ",".

TODO: Add all of the filters.

salt.cloud.clouds.ec2.describe_volumes(**kwargs=None, call=None)**

Describe a volume (or volumes)

- volume_id: One or more volume IDs. Multiple IDs must be separated by ",".

TODO: Add all of the filters.

salt.cloud.clouds.ec2.destroy(name, call=None)**

Destroy a node. Will check termination protection and warn if enabled.

CLI Example:

```bash
salt-cloud --destroy mymachine
```

salt.cloud.clouds.ec2.detach_volume(name=None, **kwargs=None, instance_id=None, call=None)**

Detach a volume from an instance

salt.cloud.clouds.ec2.disable_term_protect(name, call=None)**

Disable termination protection on a node

CLI Example:

```bash
salt-cloud -a disable_term_protect mymachine
```

salt.cloud.clouds.ec2.enable_term_protect(name, call=None)**

Enable termination protection on a node

CLI Example:

```bash
salt-cloud -a enable_term_protect mymachine
```

salt.cloud.clouds.ec2.get_availability_zone(vm_)

Return the availability zone to use

salt.cloud.clouds.ec2.get_configured_provider()

Return the first configured instance.
salt.cloud.clouds.ec2.get_console_output(name=None, location=None, instance_id=None, call=None, kwargs=None)

    Show the console output from the instance.
    By default, returns decoded data, not the Base64-encoded data that is actually returned from the EC2 API.

salt.cloud.clouds.ec2.get_dependencies()

    Warn if dependencies aren't met.

salt.cloud.clouds.ec2.get_location(vm_=None)

    Return the EC2 region to use, in this order:
        • CLI parameter
        • VM parameter
        • Cloud profile setting

salt.cloud.clouds.ec2.get_password_data(name=None, kwargs=None, instance_id=None, call=None)

    Return password data for a Windows instance.
    By default only the encrypted password data will be returned. However, if a key_file is passed in, then a
decrypted password will also be returned.
    Note that the key_file references the private key that was used to generate the keypair associated with this
instance. This private key will _not_ be transmitted to Amazon; it is only used internally inside of Salt Cloud
to decrypt data _after_ it has been received from Amazon.

    CLI Examples:
    
    ```
    salt-cloud -a get_password_data mymachine
    salt-cloud -a get_password_data mymachine key_file=/root/ec2key.pem
    ```
    
    Note: PKCS1_v1_5 was added in PyCrypto 2.5

salt.cloud.clouds.ec2.get_placementgroup(vm_)

    Returns the PlacementGroup to use

salt.cloud.clouds.ec2.get_provider(vm_=None)

    Extract the provider name from vm

salt.cloud.clouds.ec2.get_spot_config(vm_)

    Returns the spot instance configuration for the provided vm

salt.cloud.clouds.ec2.get_ssh_gateway_config(vm_)

    Return the ssh_gateway configuration.

salt.cloud.clouds.ec2.get_subnetid(vm_)

    Returns the SubnetId to use

salt.cloud.clouds.ec2.get_tags(name=None, instance_id=None, call=None, location=None, kwargs=None, resource_id=None)

    Retrieve tags for a resource. Normally a VM name or instance_id is passed in, but a resource_id may be passed
instead. If both are passed in, the instance_id will be used.

    CLI Examples:
    
    ```
    salt-cloud -a get_tags mymachine
    salt-cloud -a get_tags resource_id=vol-3267ab32
    ```

salt.cloud.clouds.ec2.get_tenancy(vm_)

    Returns the Tenancy to use.

31.5. Full list of Salt Cloud modules 461
Can be ’dedicated’ or ’default’. Cannot be present for spot instances.

salt.cloud.clouds.ec2.iam_profile(vm_)

Return the IAM profile.

The IAM instance profile to associate with the instances. This is either the Amazon Resource Name (ARN) of the instance profile or the name of the role.

Type: String
Default: None
Required: No
Example: arn:aws:iam::111111111111:instance-profile/s3access
Example: s3access

salt.cloud.clouds.ec2.keepvol_on_destroy(name, kwargs=None, call=None)

Do not delete all/specified EBS volumes upon instance termination

CLI Example:

   salt-cloud -a keepvol_on_destroy mymachine

salt.cloud.clouds.ec2.keyname(vm_)

Return the keyname

salt.cloud.clouds.ec2.list_nodes(call=None)

Return a list of the VMs that are on the provider

salt.cloud.clouds.ec2.list_nodes_full(location=None, call=None)

Return a list of the VMs that are on the provider

salt.cloud.clouds.ec2.list_nodes_min(location=None, call=None)

Return a list of the VMs that are on the provider. Only a list of VM names, and their state, is returned. This is the minimum amount of information needed to check for existing VMs.

salt.cloud.clouds.ec2.list_nodes_select(call=None)

Return a list of the VMs that are on the provider, with select fields

salt.cloud.clouds.ec2.optimize_providers(providers)

Return an optimized list of providers.

   We want to reduce the duplication of querying the same region.

   If a provider is using the same credentials for the same region the same data will be returned for each provider, thus causing un-wanted duplicate data and API calls to EC2.

salt.cloud.clouds.ec2.query(params=None, setname=None, requesturl=None, location=None, return_url=False, return_root=False)

salt.cloud.clouds.ec2.query_instance(vm_=None, call=None)

Query an instance upon creation from the EC2 API

salt.cloud.clouds.ec2.queue_instances(instances)

Queue a set of instances to be provisioned later. Expects a list.

Currently this only queries node data, and then places it in the cloud cache (if configured). If the salt-cloud-reactor is being used, these instances will be automatically provisioned using that.

For more information about the salt-cloud-reactor, see:

   https://github.com/saltstack-formulas/salt-cloud-reactor
salt.cloud.clouds.ec2.reboot(name, call=None)
    Reboot a node.
    CLI Example:
    >>> salt-cloud -a reboot mymachine

salt.cloud.clouds.ec2.rename(name, kwargs, call=None)
    Properly rename a node. Pass in the new name as `new name`.
    CLI Example:
    >>> salt-cloud -a rename mymachine newname=yourmachine

salt.cloud.clouds.ec2.request_instance(vm_=None, call=None)
    Put together all of the information necessary to request an instance on EC2, and then fire off the request the
    instance.
    Returns data about the instance

salt.cloud.clouds.ec2.script(vm_)
    Return the script deployment object

salt.cloud.clouds.ec2.securitygroup(vm_)
    Return the security group

salt.cloud.clouds.ec2.securitygroupid(vm_)
    Returns the SecurityGroupId

salt.cloud.clouds.ec2.set_tags(name=None, tags=None, call=None, location=None, instance_id=None, resource_id=None, kwargs=None)
    Set tags for a resource. Normally a VM name or instance_id is passed in, but a resource_id may be passed
    instead. If both are passed in, the instance_id will be used.
    CLI Examples:
    >>> salt-cloud -a set_tags mymachine tag1=somestuff tag2='Other stuff'
    >>> salt-cloud -a set_tags resource_id=vol-3267ab32 tag=somestuff

salt.cloud.clouds.ec2.show_delvol_on_destroy(name, kwargs=None, call=None)
    Do not delete all/specified EBS volumes upon instance termination
    CLI Example:
    >>> salt-cloud -a show_delvol_on_destroy mymachine

salt.cloud.clouds.ec2.show_image(kwargs, call=None)
    Show the details from EC2 concerning an AMI

salt.cloud.clouds.ec2.show_instance(name=None, instance_id=None, call=None, kwargs=None)
    Show the details from EC2 concerning an AMI.
    Can be called as an action (which requires a name):
    >>> salt-cloud -a show_instance myinstance
    ...or as a function (which requires either a name or instance_id):
    >>> salt-cloud -f show_instance my-ec2 name=myinstance
    >>> salt-cloud -f show_instance my-ec2 instance_id=i-d34db33f
salt.cloud.clouds.ec2.show_keypair(kwargs=None, call=None)
Show the details of an SSH keypair

salt.cloud.clouds.ec2.show_pricing(kwargs=None, call=None)
Show pricing for a particular profile. This is only an estimate, based on unofficial pricing sources.

CLI Examples:
```
salt-cloud -f show_pricing my-ec2-config profile=my-profile
```

If pricing sources have not been cached, they will be downloaded. Once they have been cached, they will not be updated automatically. To manually update all prices, use the following command:
```
salt-cloud -f update_pricing <provider>
```

New in version 2015.8.0.

salt.cloud.clouds.ec2.show_term_protect(name=None, instance_id=None, call=None, quiet=False)
Show the details from EC2 concerning an AMI

salt.cloud.clouds.ec2.show_volume(kwargs=None, call=None)
Wrapper around describe_volumes. Here just to keep functionality. Might be depreciated later.

salt.cloud.clouds.ec2.sign(key, msg)

salt.cloud.clouds.ec2.ssh_interface(vm_)
Return the ssh_interface type to connect to. Either 'public_ips' (default) or 'private_ips'.

salt.cloud.clouds.ec2.start(name, call=None)
Start a node

salt.cloud.clouds.ec2.stop(name, call=None)
Stop a node

salt.cloud.clouds.ec2.update_pricing(kwargs=None, call=None)
Download most recent pricing information from AWS and convert to a local JSON file.

CLI Examples:
```
salt-cloud -f update_pricing my-ec2-config
salt-cloud -f update_pricing my-ec2-config type=linux
```

New in version 2015.8.0.

salt.cloud.clouds.ec2.wait_for_instance(vm_=None, data=None, ip_address=None, display_ssh_output=True, call=None)
Wait for an instance upon creation from the EC2 API, to become available

Google Compute Engine Module

The Google Compute Engine module. This module interfaces with Google Compute Engine. To authenticate to GCE, you will need to create a Service Account.

Setting up Service Account Authentication:

- Go to the Cloud Console at: https://cloud.google.com/console.
- Create or navigate to your desired Project.
- Make sure Google Compute Engine service is enabled under the Services section.
- Go to "APIs and auth" section, and then the "Credentials" link.
- Click the "CREATE NEW CLIENT ID" button.
- Select "Service Account" and click "Create Client ID" button.
- This will automatically download a .json file; ignore it.
- Look for a new "Service Account" section in the page, click on the "Generate New P12 key" button.
- Copy the Email Address for inclusion in your /etc/salt/cloud file in the `service_account_email_address` setting.
- Download the Private Key
- The key that you download is a PKCS12 key. It needs to be converted to the PEM format.
- Convert the key using OpenSSL (the default password is `notasecret`): C{openssl pkcs12 -in PRIVKEY.p12 -passin pass:notasecret -nodes -nocerts | openssl rsa -out ~/PRIVKEY.pem}
- Add the full path name of the converted private key to your /etc/salt/cloud file as `service_account_private_key` setting.
- Consider using a more secure location for your private key.

my-gce-config:

```yaml
# The Google Cloud Platform Project ID
project: "my-project-id"
# The Service Account client ID
service_account_email_address: 1234567890@developer.gserviceaccount.com
# The location of the private key (PEM format)
service_account_private_key: /home/erjohnso/PRIVKEY.pem
driver: gce
# Specify whether to use public or private IP for deploy script.
# Valid options are:
#    private_ips - The salt-master is also hosted with GCE
#    public_ips - The salt-master is hosted outside of GCE
ssh_interface: public_ips
```

maintainer Eric Johnson <erjohnso@google.com>
depends libcloud >= 0.14.1

depends pycrypto >= 2.1

salt.cloud.clouds.gce.attach_disk(name=None, kwargs=None, call=None)

Attach an existing disk to an existing instance.

CLI Example:

```
salt-cloud -a attach_disk myinstance disk_name=mydisk mode=READ_WRITE
```
**salt.cloud.clouds.gce.attach_lb** *(kwargs=None, call=None)*

Add an existing node/member to an existing load-balancer configuration.

**CLI Example:**
```
salt-cloud -f attach_lb gce name=lb member=myinstance
```

**salt.cloud.clouds.gce.avail_images** *(conn=None)*

Return a dict of all available VM images on the cloud provider with relevant data

Note that for GCE, there are custom images within the project, but the generic images are in other projects. This returns a dict of images in the project plus images in `debian-cloud` and `centos-cloud` (if there is overlap in names, the one in the current project is used.)

**salt.cloud.clouds.gce.avail_locations** *(conn=None, call=None)*

Return a dict of all available VM locations on the cloud provider with relevant data

**salt.cloud.clouds.gce.avail_sizes** *(conn=None)*

Return a dict of available instances sizes (a.k.a machine types) and convert them to something more serializable.

**salt.cloud.clouds.gce.create** *(vm_=None, call=None)*

Create a single GCE instance from a data dict.

**salt.cloud.clouds.gce.create_address** *(kwargs=None, call=None)*

Create a static address in a region.

**CLI Example:**
```
salt-cloud -f create_address gce name=my-ip region=us-central1 address=IP
```

**salt.cloud.clouds.gce.create_disk** *(kwargs=None, call=None)*

Create a new persistent disk. Must specify `disk_name` and `location`. Can also specify an `image` or `snapshot` but if neither of those are specified, a `size` (in GB) is required.

**CLI Example:**
```
salt-cloud -f create_disk gce disk_name=pd size=300 location=us-central1-b
```

**salt.cloud.clouds.gce.create_fwrule** *(kwargs=None, call=None)*

Create a GCE firewall rule. The `default` network is used if not specified.

**CLI Example:**
```
salt-cloud -f create_fwrule gce name=allow-http allow=tcp:80
```

**salt.cloud.clouds.gce.create_hc** *(kwargs=None, call=None)*

Create an HTTP health check configuration.

**CLI Example:**
```
salt-cloud -f create_hc gce name=hc path=/healthy port=80
```

**salt.cloud.clouds.gce.create_lb** *(kwargs=None, call=None)*

Create a load-balancer configuration.

**CLI Example:**
```
salt-cloud -f create_lb gce name=lb region=us-central1 ports=80
```

**salt.cloud.clouds.gce.create_network** *(kwargs=None, call=None)*

Create a GCE network.

**CLI Example:**
salt.cloud.clouds.gce.create_network(name='mynet', cidr='10.10.10.0/24')

Create a new network. Must specify `name` and `cidr`.

CLI Example:

```
salt-cloud -f create_network gce name=mynet cidr=10.10.10.0/24
```

salt.cloud.clouds.gce.create_snapshot(**kwargs=None, call=None)**

Create a new disk snapshot. Must specify `name` and `disk_name`.

CLI Example:

```
salt-cloud -f create_snapshot gce name=snap1 disk_name=pd
```

salt.cloud.clouds.gce.delete_address(**kwargs=None, call=None)**

Permanently delete a static address.

CLI Example:

```
salt-cloud -f delete_address gce name=my-ip
```

salt.cloud.clouds.gce.delete_disk(**kwargs=None, call=None)**

Permanently delete a persistent disk.

CLI Example:

```
salt-cloud -f delete_disk gce disk_name=pd
```

salt.cloud.clouds.gce.delete_fwrule(**kwargs=None, call=None)**

Permanently delete a firewall rule.

CLI Example:

```
salt-cloud -f delete_fwrule gce name=allow-http
```

salt.cloud.clouds.gce.delete_HC(**kwargs=None, call=None)**

Permanently delete a health check.

CLI Example:

```
salt-cloud -f delete_HC gce name=hc
```

salt.cloud.clouds.gce.delete_lb(**kwargs=None, call=None)**

Permanently delete a load-balancer.

CLI Example:

```
salt-cloud -f delete_lb gce name=lb
```

salt.cloud.clouds.gce.delete_network(**kwargs=None, call=None)**

Permanently delete a network.

CLI Example:

```
salt-cloud -f delete_network gce name=mynet
```

salt.cloud.clouds.gce.delete_snapshot(**kwargs=None, call=None)**

Permanently delete a disk snapshot.

CLI Example:

```
salt-cloud -f delete_snapshot gce name=disk-snap-1
```

salt.cloud.clouds.gce.destroy(*vm_name, call=None)**

Call `destroy` on the instance. Can be called with `-a destroy` or -d

CLI Example:

```
salt-cloud -f destroy gce
```
salt-cloud -a destroy myinstance1 myinstance2 ...
salt-cloud -d myinstance1 myinstance2 ...

```
salt.cloud.clouds.gce.detach_disk(name=None, kwargs=None, call=None)
```

Detach a disk from an instance.

CLI Example:
```
salt-cloud -a detach_disk myinstance disk_name=mydisk
```

```
salt.cloud.clouds.gce.detach_lb(kwargs=None, call=None)
```

Remove an existing node/member from an existing load-balancer configuration.

CLI Example:
```
salt-cloud -f detach_lb gce name=lb member=myinstance
```

```
salt.cloud.clouds.gce.get_configured_provider()
```

Return the first configured instance.

```
salt.cloud.clouds.gce.get_conn()
```

Return a conn object for the passed VM data

```
salt.cloud.clouds.gce.get_dependencies()
```

Warn if dependencies aren't met.

```
salt.cloud.clouds.gce.get_lb_conn(gce_driver=None)
```

Return a load-balancer conn object

```
salt.cloud.clouds.gce.list_nodes(conn=None, call=None)
```

Return a list of the VMs that are on the provider

```
salt.cloud.clouds.gce.list_nodes_full(conn=None, call=None)
```

Return a list of the VMs that are on the provider, with all fields

```
salt.cloud.clouds.gce.list_nodes_select(conn=None, call=None)
```

Return a list of the VMs that are on the provider, with select fields

```
salt.cloud.clouds.gce.reboot(vm_name, call=None)
```

Call GCE 'reset' on the instance.

CLI Example:
```
salt-cloud -a reboot myinstance
```

```
salt.cloud.clouds.gce.script(vm_)
```

Return the script deployment object

```
salt.cloud.clouds.gce.show_address(kwargs=None, call=None)
```

Show the details of an existing static address.

CLI Example:
```
salt-cloud -f show_address gce name=mysnapshot region=us-central1
```

```
salt.cloud.clouds.gce.show_disk(name=None, kwargs=None, call=None)
```

Show the details of an existing disk.

CLI Example:
```
salt-cloud -a show_disk myinstance disk_name=mydisk
salt-cloud -f show_disk gce disk_name=mydisk
```
salt.cloud.clouds.gce.show_fwrule(**kwargs=None, call=None)**
Show the details of an existing firewall rule.

CLI Example:

```
salt-cloud -f show_fwrule gce name=allow-http
```

salt.cloud.clouds.gce.show_hc(**kwargs=None, call=None)**
Show the details of an existing health check.

CLI Example:

```
salt-cloud -f show_hc gce name=hc
```

salt.cloud.clouds.gce.show_instance(**vm_name, call=None)**
Show the details of the existing instance.

salt.cloud.clouds.gce.show_lb(**kwargs=None, call=None)**
Show the details of an existing load-balancer.

CLI Example:

```
salt-cloud -f show_lb gce name=lb
```

salt.cloud.clouds.gce.show_network(**kwargs=None, call=None)**
Show the details of an existing network.

CLI Example:

```
salt-cloud -f show_network gce name=mynet
```

salt.cloud.clouds.gce.show_pricing(**kwargs=None, call=None)**
Show pricing for a particular profile. This is only an estimate, based on unofficial pricing sources.

New in version 2015.8.0.

CLI Examples:

```
salt-cloud -f show_pricing my-gce-config profile=my-profile
```

salt.cloud.clouds.gce.show_snapshot(**kwargs=None, call=None)**
Show the details of an existing snapshot.

CLI Example:

```
salt-cloud -f show_snapshot gce name=mysnapshot
```

salt.cloud.clouds.gce.update_pricing(**kwargs=None, call=None)**
Download most recent pricing information from GCE and save locally

CLI Examples:

```
salt-cloud -f update_pricing my-gce-config
```

New in version 2015.8.0.
31.5.7 salt.cloud.clouds.gogrid

GoGrid Cloud Module

The GoGrid cloud module. This module interfaces with the gogrid public cloud service. To use Salt Cloud with GoGrid log into the GoGrid web interface and create an api key. Do this by clicking on `My Account` and then going to the API Keys tab.

Set up the cloud configuration at `/etc/salt/cloud.providers` or `/etc/salt/cloud.providers.d/gogrid.conf`:

```yaml
my-gogrid-config:
  # The generated api key to use
  apikey: asdff7896asdh789
  # The apikey's shared secret
  sharedsecret: saltybacon
  driver: gogrid
```

**Note:** A Note about using Map files with GoGrid:

Due to limitations in the GoGrid API, instances cannot be provisioned in parallel with the GoGrid driver. Map files will work with GoGrid, but the `-P` argument should not be used on maps referencing GoGrid instances.

**Note:** A Note about using Map files with GoGrid:

Due to limitations in the GoGrid API, instances cannot be provisioned in parallel with the GoGrid driver. Map files will work with GoGrid, but the `-P` argument should not be used on maps referencing GoGrid instances.

### Methods

- `salt.cloud.clouds.gogrid.avail_images()`: Available images
- `salt.cloud.clouds.gogrid.avail_locations()`: Available locations
- `salt.cloud.clouds.gogrid.avail_sizes()`: Available sizes
- `salt.cloud.clouds.gogrid.create(vm_)`: Create a single VM from a data dict
- `salt.cloud.clouds.gogrid.destroy(name, call=None)`: Destroy a machine by name
  
  CLI Example:
  ```
  salt-cloud -d vm_name
  ```
- `salt.cloud.clouds.gogrid.get_configured_provider()`: Return the first configured instance.
- `salt.cloud.clouds.gogrid.list_common_lookups(kwargs=None, call=None)`: List common lookups for a particular type of item
  
  New in version 2015.8.0.
- `salt.cloud.clouds.gogrid.list_nodes(full=False, call=None)`: List of nodes, keeping only a brief listing
  
  CLI Example:
salt-cloud -Q

salt.cloud.clouds.gogrid.list_nodes_full(call=None)
    List nodes, with all available information
    CLI Example:
    
    salt-cloud -F

salt.cloud.clouds.gogrid.list_nodes_select(call=None)
    Return a list of the VMs that are on the provider, with select fields
    CLI Example:

    salt-cloud -S

salt.cloud.clouds.gogrid.list_passwords(kwargs=None, call=None)
    List all password on the account
    New in version 2015.8.0.

salt.cloud.clouds.gogrid.list_public_ips(kwargs=None, call=None)
    List all available public IPs.
    CLI Example: .. code-block:: bash
                  
                  salt-cloud -f list_public_ips <provider>
                  To list unavailable (assigned) IPs, use:
                  CLI Example: .. code-block:: bash
                  
                  salt-cloud -f list_public_ips <provider> state=assigned
    New in version 2015.8.0.

salt.cloud.clouds.gogrid.reboot(name, call=None)
    Reboot a machine by name
    CLI Example:

    salt-cloud -a reboot vm_name
    New in version 2015.8.0.

salt.cloud.clouds.gogrid.show_instance(name, call=None)
    Start a machine by name
    CLI Example:

    salt-cloud -a show_instance vm_name
    New in version 2015.8.0.

salt.cloud.clouds.gogrid.start(name, call=None)
    Start a machine by name
    CLI Example:

    salt-cloud -a start vm_name
    New in version 2015.8.0.

31.5. Full list of Salt Cloud modules
salt.cloud.clouds.gogrid.stop(name, call=\None)
Stop a machine by name

CLI Example:
```
salt-cloud -a stop vm_name
```

New in version 2015.8.0.

31.5.8  salt.cloud.clouds.joyent

Joyent Cloud Module

The Joyent Cloud module is used to interact with the Joyent cloud system.

Set up the cloud configuration at /etc/salt/cloud.providers or /etc/salt/cloud.providers.d/joyent.conf:

```
my-joyent-config:
  driver: joyent
  # The Joyent login user
  user: fred
  # The Joyent user's password
  password: saltybacon
  # The location of the ssh private key that can log into the new VM
  private_key: /root/mykey.pem
  # The name of the private key
  private_key: mykey
```

When creating your profiles for the joyent cloud, add the location attribute to the profile, this will automatically get picked up when performing tasks associated with that vm. An example profile might look like:

```
joyent_512:
  provider: my-joyent-config
  size: Extra Small 512 MB
  image: centos-6
  location: us-east-1
```

This driver can also be used with the Joyent SmartDataCenter project. More details can be found at:

Using SDC requires that an api_host_suffix is set. The default value for this is .api.joyentcloud.com. All characters, including the leading ., should be included:

```
api_host_suffix: .api.myhostname.com
```

**depends**  PyCrypto

salt.cloud.clouds.joyent.avail_images(call=\None)
Get list of available images

CLI Example:
```
salt-cloud --list-images
```

Can use a custom URL for images. Default is:
```
image_url: images.joyent.com/image
```

salt.cloud.clouds.joyent.avail_locations(call=\None)
List all available locations
salt.cloud.clouds.joyent.avail_sizes(call=None)
   get list of available packages
   CLI Example:
      salt-cloud --list-sizes

salt.cloud.clouds.joyent.create(vm_)
   Create a single VM from a data dict
   CLI Example:
      salt-cloud -p profile_name vm_name

salt.cloud.clouds.joyent.create_node(**kwargs)
   convenience function to make the rest api call for node creation.

salt.cloud.clouds.joyent.delete_key(kwargs=None, call=None)
   List the keys available
   CLI Example:
      salt-cloud -f delete_key joyent keyname=mykey

salt.cloud.clouds.joyent.destroy(name, call=None)
   destroy a machine by name
   Parameters
   - name -- name given to the machine
   - call -- call value in this case is 'action'
   Returns array of booleans, true if successfully stopped and true if successfully removed
   CLI Example:
      salt-cloud -d vm_name

salt.cloud.clouds.joyent.get_configured_provider()
   Return the first configured instance.

salt.cloud.clouds.joyent.get_image(vm_)
   Return the image object to use

salt.cloud.clouds.joyent.get_location(vm_=None)
   Return the joyent data center to use, in this order:
   - CLI parameter
   - VM parameter
   - Cloud profile setting

salt.cloud.clouds.joyent.get_location_path(location='us-east-1',
   api_host_suffix='api.joyentcloud.com')
   create url from location variable :param location: joyent data center location :return: url

salt.cloud.clouds.joyent.get_node(name)
   gets the node from the full node list by name :param name: name of the vm :return: node object

salt.cloud.clouds.joyent.get_size(vm_)
   Return the VM's size object
salt.cloud.clouds.joyent.has_method(obj, method_name)
    Find if the provided object has a specific method

salt.cloud.clouds.joyent.import_key(kwargs=None, call=None)
    List the keys available
    CLI Example:
    salt-cloud -f import_key joyent keyname=mykey keyfile=/tmp/mykey.pub

salt.cloud.clouds.joyent.joyent_node_state(id_)
    Convert joyent returned state to state common to other data center return values for consistency
    Parameters id -- joyent state value
    Returns state value

salt.cloud.clouds.joyent.key_list(items=None)
    convert list to dictionary using the key as the identifier :param items: array to iterate over :return: dictionary

salt.cloud.clouds.joyent.list_keys(kwargs=None, call=None)
    List the keys available

salt.cloud.clouds.joyent.list_nodes(full=False, call=None)
    list of nodes, keeping only a brief listing
    CLI Example:
    salt-cloud -Q

salt.cloud.clouds.joyent.list_nodes_full(call=None)
    list of nodes, maintaining all content provided from joyent listings
    CLI Example:
    salt-cloud -F

salt.cloud.clouds.joyent.list_nodes_select(call=None)
    Return a list of the VMs that are on the provider, with select fields

salt.cloud.clouds.joyent.query(action=None, command=None, args=None, method='GET', location=None, data=None)
    Make a web call to Joyent

salt.cloud.clouds.joyent.query_instance(vm_=None, call=None)
    Query an instance upon creation from the Joyent API

salt.cloud.clouds.joyent.reboot(name, call=None)
    reboot a machine by name :param name: name given to the machine :param call: call value in this case is 'action':return: true if successful
    CLI Example:
    salt-cloud -a reboot vm_name

salt.cloud.clouds.joyent.reformat_node(item=None, full=False)
    Reformat the returned data from joyent, determine public/private IPs and strip out fields if necessary to provide either full or brief content.
    Parameters
    • item -- node dictionary
    • full -- full or brief output
Returns  dict

```
salt.cloud.clouds.joyent.show_instance(name, call=None)
    get details about a machine
    :param name: name given to the machine
    :param call: call value in this case is `action`
    :return: machine information

    CLI Example:
    
    salt-cloud -a show_instance vm_name
```

```
salt.cloud.clouds.joyent.show_key(**kwargs, call=None)
    List the keys available
```

```
salt.cloud.clouds.joyent.ssh_interface(vm_)
    Return the ssh_interface type to connect to. Either `public_ips` (default) or `private_ips`.
```

```
salt.cloud.clouds.joyent.start(name, call=None)
    start a machine by name
    :param name: name given to the machine
    :param call: call value in this case is `action`
    :return: true if successful

    CLI Example:
    
    salt-cloud -a start vm_name
```

```
salt.cloud.clouds.joyent.stop(name, call=None)
    stop a machine by name
    :param name: name given to the machine
    :param call: call value in this case is `action`
    :return: true if successful

    CLI Example:
    
    salt-cloud -a stop vm_name
```

```
salt.cloud.clouds.joyent.take_action(name=None, call=None, command=None, data=None, method='GET', location='us-east-1')
    take action call used by start, stop, reboot
    :param name: name given to the machine
    :param call: call value in this case is `action`
    :param command: api path
    :param data: any data to be passed to the api, must be in json format
    :param method: GET, POST, or DELETE
    :param location: data center to execute the command on
    :return: true if successful
```

### 31.5.9 salt.cloud.clouds.libcloud_aws

The AWS Cloud Module

The AWS cloud module is used to interact with the Amazon Web Services system.

This module has been replaced by the EC2 cloud module, and is no longer supported. The documentation shown here is for reference only; it is highly recommended to change all usages of this driver over to the EC2 driver.

If this driver is still needed, set up the cloud configuration at /etc/salt/cloud.providers or /etc/salt/cloud.providers.d/aws.conf:

```
my-aws-config:
    # The AWS API authentication id
    id: GKTADJGHEIQSXMKKRBJ08H
    # The AWS API authentication key
    key: askdjghsdfjkghWuwUjasdflkdfklgjhsdjfajkghs
    # The ssh keyname to use
    keyname: default
    # The amazon security group
    securitygroup: ssh_open
    # The location of the private key which corresponds to the keyname
```

31.5. Full list of Salt Cloud modules 475
private_key: /root/default.pem

driver: aws

salt.cloud.clouds.libcloud_aws.block_device_mappings(vm_)
Return the block device mapping:

```
[{
'DeviceName': '/dev/sdb', 'VirtualName': 'ephemeral0'},
{'DeviceName': '/dev/sdc', 'VirtualName': 'ephemeral1'}]
```

salt.cloud.clouds.libcloud_aws.create(vm_)
Create a single VM from a data dict

salt.cloud.clouds.libcloud_aws.create_attach_volumes(volumes, location, data)
Create and attach volumes to created node

salt.cloud.clouds.libcloud_aws.del_tags(name, kwargs, call=None)
Delete tags for a node

CLI Example:

```
salt-cloud -a del_tags mymachine tag1,tag2,tag3
```

salt.cloud.clouds.libcloud_aws.destroy(name)
Wrap core libcloud funs destroy method, adding check for termination protection

salt.cloud.clouds.libcloud_aws.get_availability_zone(conn, vm_)
Return the availability zone to use

salt.cloud.clouds.libcloud_aws.get_configured_provider()
Return the first configured instance.

salt.cloud.clouds.libcloud_aws.get_conn(**kwargs)
Return a conn object for the passed VM data

salt.cloud.clouds.libcloud_aws.get_dependencies()
Warn if dependencies aren’t met.

salt.cloud.clouds.libcloud_aws.get_location(vm_=None)
Return the AWS region to use, in this order:
- CLI parameter
- Cloud profile setting
- Global salt-cloud config

salt.cloud.clouds.libcloud_aws.get_tags(name, call=None)
Retrieve tags for a node

salt.cloud.clouds.libcloud_aws.iam_profile(vm_)
Return the IAM role

salt.cloud.clouds.libcloud_aws.keyname(vm_)
Return the keyname

salt.cloud.clouds.libcloud_aws.rename(name, kwargs, call=None)
Properly rename a node. Pass in the new name as ”new name”.

CLI Example:

```
salt-cloud -a rename mymachine newname=yourmachine
```
salt.cloud.clouds.libcloud_aws.securitygroup(vm_)
    Return the security group

salt.cloud.clouds.libcloud_aws.set_tags(name, tags, call=None)
    Set tags for a node

    CLI Example:
    salt-cloud -a set_tags mymachine tag1=somestuff tag2='Other stuff'

salt.cloud.clouds.libcloud_aws.ssh_interface(vm_)
    Return the ssh_interface type to connect to. Either 'public_ips' (default) or 'private_ips'.

salt.cloud.clouds.libcloud_aws.ssh_username(vm_)
    Return the ssh_username. Defaults to 'ec2-user'.

salt.cloud.clouds.libcloud_aws.start(name, call=None)
    Start a node

salt.cloud.clouds.libcloud_aws.stop(name, call=None)
    Stop a node

31.5.10 salt.cloud.clouds.linode

Linode Cloud Module using Linode’s REST API

The Linode cloud module is used to control access to the Linode VPS system.

Use of this module only requires the apikey parameter. However, the default root password for new instances also needs to be set. The password needs to be 8 characters and contain lowercase, uppercase, and numbers.

Set up the cloud configuration at /etc/salt/cloud.providers or /etc/salt/cloud.providers.d/linode.conf:

```yaml
my-linode-provider:
    apikey: f4ZsmwtB1c7f8S5Jodu43RgXVDFlNjuJaeIYV8QMftTqKScEB2vSosFSr...
    password: F00barbaz
    driver: linode
    ssh_key_file: /tmp/salt-cloud_pubkey
    ssh_pubkey: ssh-rsa AAAAB3NzaC1yc2EA...

linode-profile:
    provider: my-linode-provider
    size: Linode 1024
    image: CentOS 7
    location: London, England, UK
    private_ip: true
```

To clone, add a profile with a clonefrom key, and a script_args: -C. clonefrom should be the name of the VM (linode) that is the source for the clone. script_args: -C passes a -C to the bootstrap script, which only configures the minion and doesn’t try to install a new copy of salt-minion. This way the minion gets new keys and the keys get pre-seeded on the master, and the /etc/salt/minion file has the right ‘id:’ declaration.

Cloning requires a post 2015-02-01 salt-bootstrap.

salt.cloud.clouds.linode.avail_images(call=None)
    Return available Linode images.

    CLI Example:
salt-cloud --list-images my-linode-config
salt-cloud -f avail_images my-linode-config

salt.cloud.clouds.linode.avail_locations(call=None)

Return available Linode datacenter locations.

CLI Example:
salt-cloud --list-locations my-linode-config
salt-cloud -f avail_locations my-linode-config

salt.cloud.clouds.linode.avail_sizes(call=None)

Return available Linode sizes.

CLI Example:
salt-cloud --list-sizes my-linode-config
salt-cloud -f avail_sizes my-linode-config

salt.cloud.clouds.linode.boot(name=None, kwargs=None, call=None)

Boots a Linode.

- **name** The name of the Linode to boot. Can be used instead of linode_id.
- **linode_id** The ID of the Linode to boot. If provided, will be used as an alternative to name and reduces the number of API calls to Linode by one. Will be preferred over name.
- **config_id** The ID of the Config to boot. Required.
- **check_running** Defaults to True. If set to False, overrides the call to check if the VM is running before calling the linode.boot API call. Change check_running to True is useful during the boot call in the create function, since the new VM will not be running yet.

Can be called as an action (which requires a name):
salt-cloud -a boot my-instance config_id=10

...or as a function (which requires either a name or linode_id):
salt-cloud -f boot my-linode-config name=my-instance config_id=10
salt-cloud -f boot my-linode-config linode_id=1225876 config_id=10

salt.cloud.clouds.linode.clone(kwargs=None, call=None)

Clone a Linode.

- **linode_id** The ID of the Linode to clone. Required.
- **datacenter_id** The ID of the Datacenter where the Linode will be placed. Required.
- **plan_id** The ID of the plan (size) of the Linode. Required.

CLI Example:
salt-cloud -f clone my-linode-config linode_id=1234567 datacenter_id=2 plan_id=5

salt.cloud.clouds.linode.create(vm_)

Create a single Linode VM.

salt.cloud.clouds.linode.create_config(kwargs=None, call=None)

Creates a Linode Configuration Profile.

- **name** The name of the VM to create the config for.
linode_id  The ID of the Linode to create the configuration for.

root_disk_id  The Root Disk ID to be used for this config.

swap_disk_id  The Swap Disk ID to be used for this config.

kernel_id  The ID of the kernel to use for this configuration profile.

\[
\text{salt.cloud.clouds.linode.create_disk_from_distro}(\text{vm}, \text{linode_id}, \text{swap_size=\text{None}})
\]
Creates the disk for the Linode from the distribution.

\[
\text{vm} \quad \text{The VM profile to create the disk for.}
\]

\[
\text{linode_id} \quad \text{The ID of the Linode to create the distribution disk for. Required.}
\]

\[
\text{swap_size} \quad \text{The size of the disk, in MB.}
\]

\[
\text{salt.cloud.clouds.linode.create_private_ip}(\text{vm}, \text{linode_id})
\]
Creates a private IP for the specified Linode.

\[
\text{vm} \quad \text{The VM profile to create the swap disk for.}
\]

\[
\text{linode_id} \quad \text{The ID of the Linode to create the IP address for.}
\]

\[
\text{salt.cloud.clouds.linode.create_swap_disk}(\text{vm}, \text{linode_id}, \text{swap_size=\text{None}})
\]
Creates the disk for the specified Linode.

\[
\text{vm} \quad \text{The VM profile to create the swap disk for.}
\]

\[
\text{linode_id} \quad \text{The ID of the Linode to create the swap disk for.}
\]

\[
\text{swap_size} \quad \text{The size of the disk, in MB.}
\]

\[
\text{salt.cloud.clouds.linode.destroy}(\text{name}, \text{call=\text{None}})
\]
Destroys a Linode by name.

\[
\text{name} \quad \text{The name of VM to be destroyed.}
\]

CLI Example:

```
salt-cloud -d vm_name
```

\[
\text{salt.cloud.clouds.linode.get_config_id}(\text{kwargs=\text{None}}, \text{call=\text{None}})
\]
Returns a config_id for a given linode.

New in version 2015.8.0.

\[
\text{name} \quad \text{The name of the Linode for which to get the config_id. Can be used instead of linode_id.}
\]

\[
\text{linode_id} \quad \text{The ID of the Linode for which to get the config_id. Can be used instead of name.}
\]

CLI Example:

```
salt-cloud -f get_config_id my-linode-config name=my-linode
salt-cloud -f get_config_id my-linode-config linode_id=1234567
```

\[
\text{salt.cloud.clouds.linode.get_configured_provider}()
\]
Return the first configured instance.

\[
\text{salt.cloud.clouds.linode.get_datacenter_id}(\text{location})
\]
Returns the Linode Datacenter ID.

\[
\text{location} \quad \text{The location, or name, of the datacenter to get the ID from.}
\]

\[
\text{salt.cloud.clouds.linode.get_disk_size}(\text{vm}, \text{swap})
\]
Returns the size of of the root disk in MB.

\[
\text{vm} \quad \text{The VM to get the disk size for.}
\]

31.5. Full list of Salt Cloud modules
salt.cloud.clouds.linode.get_distribution_id(vm_)
    Returns the distribution ID for a VM
    vm_  The VM to get the distribution ID for

salt.cloud.clouds.linode.get_ips(linode_id=None)
    Returns public and private IP addresses.
    linode_id  Limits the IP addresses returned to the specified Linode ID.

salt.cloud.clouds.linode.get_linode(kwargs=None, call=None)
    Returns data for a single named Linode.
    name  The name of the Linode for which to get data. Can be used instead
          of linode_id. Note this will induce
          an additional API call compared to using linode_id.
    linode_id  The ID of the Linode for which to get data. Can be used instead of name.

    CLI Example:
    salt-cloud -f get_linode my-linode-config
    name=my-instance
    salt-cloud -f get_linode my-linode-config linode_id=1234567

salt.cloud.clouds.linode.get_linode_id_from_name(name)
    Returns the Linode ID for a VM from the provided name.
    name  The name of the Linode from which to get the Linode ID. Required.

salt.cloud.clouds.linode.get_password(vm_)
    Return the password to use for a VM.
    vm_  The configuration to obtain the password from.

salt.cloud.clouds.linode.get_plan_id(kwargs=None, call=None)
    Returns the Linode Plan ID.
    label  The label, or name, of the plan to get the ID from.

    CLI Example:
    salt-cloud -f get_plan_id linode label="Linode 1024"

salt.cloud.clouds.linode.get_private_ip(vm_)
    Return True if a private ip address is requested

salt.cloud.clouds.linode.get_pub_key(vm_)
    Return the SSH pub key.
    vm_  The configuration to obtain the public key from.

salt.cloud.clouds.linode.get_swap_size(vm_)
    Returns the amount of swap space to be used in MB.
    vm_  The VM profile to obtain the swap size from.

salt.cloud.clouds.linode.get_vm_size(vm_)
    Returns the VM's size.
    vm_  The VM to get the size for.

salt.cloud.clouds.linode.list_nodes(call=None)
    Returns a list of linodes, keeping only a brief listing.

    CLI Example:
salt-cloud -Q
salt-cloud --query
salt-cloud -f list_nodes my-linode-config

**Note:** The image label only displays information about the VM’s distribution vendor, such as `Debian` or `RHEL` and does not display the actual image name. This is due to a limitation of the Linode API.

### salt.cloud.clouds.linode.list_nodes_full(call=None)

List linodes, with all available information.

**CLI Example:**
salt-cloud -F
salt-cloud --full-query
salt-cloud -f list_nodes_full my-linode-config

**Note:** The image label only displays information about the VM’s distribution vendor, such as `Debian` or `RHEL` and does not display the actual image name. This is due to a limitation of the Linode API.

### salt.cloud.clouds.linode.list_nodes_min(call=None)

Return a list of the VMs that are on the provider. Only a list of VM names and their state is returned. This is the minimum amount of information needed to check for existing VMs.

New in version 2015.8.0.

**CLI Example:**
salt-cloud -f list_nodes_min my-linode-config
salt-cloud --function list_nodes_min my-linode-config

### salt.cloud.clouds.linode.reboot(name, call=None)

Reboot a linode.

New in version 2015.8.0.

**name** The name of the VM to reboot.

**CLI Example:**
salt-cloud -a reboot vm_name

### salt.cloud.clouds.linode.show_instance(name, call=None)

Displays details about a particular Linode VM. Either a name or a linode_id must be provided.

New in version 2015.8.0.

**name** The name of the VM for which to display details.

**CLI Example:**
salt-cloud -a show_instance vm_name

**Note:** The image label only displays information about the VM’s distribution vendor, such as `Debian` or `RHEL` and does not display the actual image name. This is due to a limitation of the Linode API.

### salt.cloud.clouds.linode.show_pricing(kwargs=None, call=None)

Show pricing for a particular profile. This is only an estimate, based on unofficial pricing sources.

New in version 2015.8.0.
CLI Example:
```
salt-cloud -f show_pricing my-linode-config profile=my-linode-profile
```

```
salt.cloud.clouds.linode.start(name, call=None)
```
Start a VM in Linode.

- **name** The name of the VM to start.

CLI Example:
```
salt-cloud -a stop vm_name
```

```
salt.cloud.clouds.linode.stop(name, call=None)
```
Stop a VM in Linode.

- **name** The name of the VM to stop.

CLI Example:
```
salt-cloud -a stop vm_name
```

```
salt.cloud.clouds.linode.update_linode(linode_id, update_args=None)
```
Updates a Linode's properties.

- **linode_id** The ID of the Linode to shutdown. Required.
- **update_args** The args to update the Linode with. Must be in dictionary form.

### 31.5.11 salt.cloud.clouds.lxc

**Install Salt on an LXC Container**

New in version 2014.7.0.

Please read [core config documentation](#).

```
salt.cloud.clouds.lxc.avail_images()
```

```
salt.cloud.clouds.lxc.create(vm_, call=None)
```
Create an lxc Container. This function is idempotent and will try to either provision or finish the provision of an lxc container.

NOTE: Most of the initialization code has been moved and merged with the lxc runner and lxc.init functions

```
salt.cloud.clouds.lxc.destroy(vm_, call=None)
```
Destroy a lxc container

```
salt.cloud.clouds.lxc.get_configured_provider(vm_=None)
```
Return the contextual provider of None if no configured one can be found.

```
salt.cloud.clouds.lxc.get_provider(name)
```

```
salt.cloud.clouds.lxc.list_nodes(conn=None, call=None)
```

```
salt.cloud.clouds.lxc.list_nodes_full(conn=None, call=None)
```

```
salt.cloud.clouds.lxc.list_nodes_select(call=None)
```
Return a list of the VMs that are on the provider, with select fields

```
salt.cloud.clouds.lxc.show_instance(name, call=None)
```
Show the details from the provider concerning an instance
31.5.12 salt.cloud.clouds.msazure

Azure Cloud Module

The Azure cloud module is used to control access to Microsoft Azure

depends

- Microsoft Azure SDK for Python >= 0.11.1
- python-requests, for Python < 2.7.9

configuration Required provider parameters:

- apikey
- certificate_path
- subscription_id
- requests_lib

A Management Certificate (.pem and .crt files) must be created and the .pem file placed on the same machine that salt-cloud is run from. Information on creating the pem file to use, and uploading the associated cer file can be found at:

For users with Python < 2.7.9, requests_lib must currently be set to True.

Example /etc/salt/cloud.providers or /etc/salt/cloud.providers.d/azure.conf configuration:

```
my-azure-config:
  driver: azure
  subscription_id: 3287abc8-f98a-c678-3bde-326766fd3617
  certificate_path: /etc/salt/azure.pem
  management_host: management.core.windows.net
```

salt.cloud.clouds.msazure.add_input_endpoint(kwags=None, conn=None, call=None)

New in version 2015.8.0.

Add an input endpoint to the deployment. Please note that there may be a delay before the changes show up.

CLI Example:

```
salt-cloud -f add_input_endpoint my-azure service=myservice \
  deployment=mydeployment role=myrole name=HTTP local_port=80 \
  port=80 protocol=tcp enable_direct_server_return=False \
  timeout_for_tcp_idle_connection=4
```

salt.cloud.clouds.msazure.add_management_certificate(kwags=None, conn=None, call=None)

New in version 2015.8.0.

Add a new management certificate

CLI Example:

```
salt-cloud -f add_management_certificate my-azure public_key='...PUBKEY...' \
  thumbprint=0123456789ABCDEF data='...CERT_DATA...'```
salt.cloud.clouds.msazure.add_service_certificate(kwars=None, conn=None, call=None)

New in version 2015.8.0.
Add a new service certificate

CLI Example:
```
salt-cloud -f add_service_certificate my-azure name=my_service_certificate \
data='...CERT_DATA...' certificate_format=sha1 password=verybadpass
```

salt.cloud.clouds.msazure.avail_images(conn=None, call=None)
List available images for Azure

salt.cloud.clouds.msazure.avail_locations(conn=None, call=None)
List available locations for Azure

salt.cloud.clouds.msazure.avail_sizes(call=None)
Return a list of sizes from Azure

salt.cloud.clouds.msazure.cleanup_unattached_disks(kwars=None, conn=None, call=None)
New in version 2015.8.0.
Cleans up all disks associated with the account, which are not attached. *CAUTION* This is a destructive function with no undo button, and no ```Are you sure?``` confirmation!

CLI Examples:
```
salt-cloud -f cleanup_unattached_disks my-azure name=my_disk
salt-cloud -f cleanup_unattached_disks my-azure name=my_disk delete_vhd=True
```

salt.cloud.clouds.msazure.create(vm_)
Create a single VM from a data dict

salt.cloud.clouds.msazure.create_affinity_group(kwars=None, conn=None, call=None)
New in version 2015.8.0.
Create a new affinity group

CLI Example:
```
salt-cloud -f create_affinity_group my-azure name=my_affinity_group
```

salt.cloud.clouds.msazure.create_attach_volumes(name, kwars=None, conn=None, call=None, wait_to_finish=True)
Create and attach volumes to created node

salt.cloud.clouds.msazure.create_service(kwars=None, conn=None, call=None)
New in version 2015.8.0.
Create a new hosted service

CLI Example:
```
salt-cloud -f create_service my-azure name=my_service label=my_service location='West US'
```

salt.cloud.clouds.msazure.create_storage(kwars=None, conn=None, call=None)
New in version 2015.8.0.
Create a new storage account

CLI Example:
salt-cloud -f create_storage my-azure name=my_storage label=my_storage location='West US'

salt.cloud.clouds.msazure.create_storage_container(kwargs=None, storage_conn=None, call=None)

New in version 2015.8.0.
Create a storage container
CLI Example:
salt-cloud -f create_storage_container my-azure name=mycontainer

name: Name of container to create.
meta_name_values: Optional. A dict with name_value pairs to associate with the container as metadata.
Example:{'Category':'test'}
blob_public_access: Optional. Possible values include: container, blob
fail_on_exist: Specify whether to throw an exception when the container exists.

salt.cloud.clouds.msazure.delete_affinity_group(kwargs=None, conn=None, call=None)

New in version 2015.8.0.
Delete a specific affinity group associated with the account
CLI Examples:
salt-cloud -f delete_affinity_group my-azure name=my_affinity_group

salt.cloud.clouds.msazure.delete_disk(kwargs=None, conn=None, call=None)

New in version 2015.8.0.
Delete a specific disk associated with the account
CLI Examples:
salt-cloud -f delete_disk my-azure name=my_disk
salt-cloud -f delete_disk my-azure name=my_disk delete_vhd=True

salt.cloud.clouds.msazure.delete_input_endpoint(kwargs=None, conn=None, call=None)

New in version 2015.8.0.
Delete an input endpoint from the deployment. Please note that there may be a delay before the changes show up.
CLI Example:
salt-cloud -f delete_input_endpoint my-azure service=myservice \
    deployment=mydeployment role=myrole name=HTTP

salt.cloud.clouds.msazure.delete_management_certificate(kwargs=None, conn=None, call=None)

New in version 2015.8.0.
Delete a specific certificate associated with the management
CLI Examples:
salt-cloud -f delete_management_certificate my-azure name=my_management_certificate \
    thumbalgorithm=sha1 thumbprint=0123456789ABCDEF

31.5. Full list of Salt Cloud modules
salt.cloud.clouds.msazure.delete_service(kwargs=None, conn=None, call=None)

New in version 2015.8.0.
Delete a specific service associated with the account

CLI Examples:

```
salt-cloud -f delete_service my-azure name=my_service
```

salt.cloud.clouds.msazure.delete_service_certificate(kwargs=None, conn=None, call=None)

New in version 2015.8.0.
Delete a specific certificate associated with the service

CLI Examples:

```
salt-cloud -f delete_service_certificate my-azure name=my_service_certificate \
    thumbalgorithm=sha1 thumbprint=0123456789ABCDEF
```

salt.cloud.clouds.msazure.delete_storage(kwargs=None, conn=None, call=None)

New in version 2015.8.0.
Delete a specific storage account

CLI Examples:

```
salt-cloud -f delete_storage my-azure name=my_storage
```

salt.cloud.clouds.msazure.delete_storage_container(kwargs=None, storage_conn=None, call=None)

New in version 2015.8.0.
Delete a container associated with the storage account

CLI Example:

```
salt-cloud -f delete_storage_container my-azure name=mycontainer
```

- **name**: Name of container to create.
- **fail_not_exist**: Specify whether to throw an exception when the container exists.
- **lease_id**: If specified, delete_storage_container only succeeds if the container's lease is active and matches this ID.

salt.cloud.clouds.msazure.destroy(name, conn=None, call=None, kwargs=None)

Destroy a VM

CLI Examples:

```
salt-cloud -d myminion
salt-cloud -a destroy myminion service_name=myservice
```

salt.cloud.clouds.msazure.get_affinity_group(kwargs=None, conn=None, call=None)

New in version 2015.8.0.
Show an affinity group associated with the account

CLI Example:

```
salt-cloud -f show_affinity_group my-azure service=myservice \ 
    deployment=mydeployment name=SSH
```
salt.cloud.clouds.msazure.get_blob(kwags=\textit{None}, storage\_conn=\textit{None}, call=\textit{None})

New in version 2015.8.0.

Download a blob

CLI Example:

```
salt-cloud -f get_blob my-azure container=base name=top.sls local\_path=/srv/salt/top.sls
salt-cloud -f get_blob my-azure container=base name=content.txt return\_content=True
```

**container**: Name of existing container.

**name**: Name of existing blob.

**local\_path**: The path on the local machine to download the blob to. Either this or return\_content must be specified.

**return\_content**: Whether or not to return the content directly from the blob. If specified, must be True or False. Either this or the local\_path must be specified.

**snapshot**: Optional. The snapshot parameter is an opaque DateTime value that, when present, specifies the blob snapshot to retrieve.

**lease\_id**: Required if the blob has an active lease.

**progress\_callback**: callback for progress with signature function\(\text{current, total}\) where current is the number of bytes transferred so far, and total is the size of the blob.

**max\_connections**: Maximum number of parallel connections to use when the blob size exceeds 64MB. Set to 1 to download the blob chunks sequentially. Set to 2 or more to download the blob chunks in parallel. This uses more system resources but will download faster.

**max\_retries**: Number of times to retry download of blob chunk if an error occurs.

**retry\_wait**: Sleep time in secs between retries.

salt.cloud.clouds.msazure.get_blob\_properties(kwags=\textit{None}, storage\_conn=\textit{None}, call=\textit{None})

New in version 2015.8.0.

Returns all user-defined metadata, standard HTTP properties, and system properties for the blob.

CLI Example:

```
salt-cloud -f show\_blob\_properties my-azure container=mycontainer blob=myblob
```

**container**: Name of existing container.

**blob**: Name of existing blob.

**lease\_id**: Required if the blob has an active lease.

salt.cloud.clouds.msazure.get_blob\_service\_properties(kwags=\textit{None}, storage\_conn=\textit{None}, call=\textit{None})

New in version 2015.8.0.

Show a blob’s service properties

CLI Example:

```
salt-cloud -f show\_blob\_service\_properties my-azure
```
Salt Documentation, Release 2015.8.0

salt.cloud.clouds.msazure.get_configured_provider()
   Return the first configured instance.

salt.cloud.clouds.msazure.get_conn()
   Return a conn object for the passed VM data

salt.cloud.clouds.msazure.get_dependencies()
   Warn if dependencies aren't met.

salt.cloud.clouds.msazure.get_deployment(**kwargs=None, conn=None, call=None)
   New in version 2015.8.0.
   Return information about a deployment
   CLI Example:
   ```
   salt-cloud -f show_deployment my-azure name=my_deployment
   ```

salt.cloud.clouds.msazure.get_disk(**kwargs=None, conn=None, call=None)
   New in version 2015.8.0.
   Return information about a disk
   CLI Example:
   ```
   salt-cloud -f show_disk my-azure name=my_disk
   ```

salt.cloud.clouds.msazure.get_input_endpoint(**kwargs=None, conn=None, call=None)
   New in version 2015.8.0.
   Show an input endpoint associated with the deployment
   CLI Example:
   ```
   salt-cloud -f show_input_endpoint my-azure service=myservice \
   deployment=mydeployment name=SSH
   ```

salt.cloud.clouds.msazure.get_management_certificate(**kwargs=None, conn=None, call=None)
   New in version 2015.8.0.
   Return information about a management_certificate
   CLI Example:
   ```
   salt-cloud -f get_management_certificate my-azure name=my_management_certificate \
   thumbalgorithm=sha1 thumbprint=0123456789abcdef
   ```

salt.cloud.clouds.msazure.get_operation_status(**kwargs=None, conn=None, call=None)
   New in version 2015.2.
   Get Operation Status, based on a request ID
   CLI Example:
   ```
   salt-cloud -f get_operation_status my-azure id=0123456789abcdef0123456789abcdef
   ```

salt.cloud.clouds.msazure.get_service_certificate(**kwargs=None, conn=None, call=None)
   New in version 2015.8.0.
   Return information about a service certificate
   CLI Example:
salt.cloud -f show_service_certificate my-azure name=my_service_certificate \
    thumbalgorithm=sha1 thumbprint=0123456789ABCDEF

salt.cloud.clouds.msazure.get_storage(kwars=None, conn=None, call=None)
New in version 2015.8.0.
List storage service properties
CLI Example:
salt-cloud -f show_storage my-azure name=my_storage

salt.cloud.clouds.msazure.get_storage_conn(storage_account=None, storage_key=None, storage_conn=None, conn_kwargs=None)
New in version 2015.8.0.
Return a storage_conn object for the storage account

salt.cloud.clouds.msazure.get_storage_container(kwars=None, conn_kwargs=None, storage_conn=None, call=None)
New in version 2015.8.0.
Show a container associated with the storage account
CLI Example:
salt-cloud -f show_storage_container my-azure name=myservice

    name: Name of container to show.

salt.cloud.clouds.msazure.get_storage_container_acl(kwars=None, storage_conn=None, call=None)
New in version 2015.8.0.
Show a storage container's acl
CLI Example:
salt-cloud -f show_storage_container_acl my-azure name=myservice

    name: Name of existing container.
    lease_id: If specified, show_storage_container_acl only succeeds if the container's lease is active and matches this ID.

salt.cloud.clouds.msazure.get_storage_container_metadata(kwars=None, storage_conn=None, call=None)
New in version 2015.8.0.
Show a storage container's metadata
CLI Example:
salt-cloud -f show_storage_container_metadata my-azure name=myservice

    name: Name of container to show.
    lease_id: If specified, show_storage_container_metadata only succeeds if the container's lease is active and matches this ID.
salt.cloud.clouds.msazure.get_storage_keys(kwars=None, conn=None, call=None)
    New in version 2015.8.0.
    Show storage account keys
    CLI Example:
    
    salt-cloud -f show_storage_keys my-azure name=my_storage

salt.cloud.clouds.msazure.lease_storage_container(kwars=None, storage_conn=None, call=None)
    New in version 2015.8.0.
    Lease a container associated with the storage account
    CLI Example:
    
    salt-cloud -f lease_storage_container my-azure name=mycontainer

    name: Name of container to create.
    lease_action: Required. Possible values: acquire|renew|release|break|change
    lease_id: Required if the container has an active lease.
    lease_duration: Specifies the duration of the lease, in seconds, or negative one (-1) for a lease that never
        expires. A non-infinite lease can be between 15 and 60 seconds. A lease duration cannot be changed
        using renew or change. For backwards compatibility, the default is 60, and the value is only used on an
        acquire operation.
    lease_break_period: Optional. For a break operation, this is the proposed duration of seconds that the lease
        should continue before it is broken, between 0 and 60 seconds. This break period is only used if it is
        shorter than the time remaining on the lease. If longer, the time remaining on the lease is used. A new
        lease will not be available before the break period has expired, but the lease may be held for longer than
        the break period. If this header does not appear with a break operation, a fixed-duration lease breaks
        after the remaining lease period elapses, and an infinite lease breaks immediately.
    proposed_lease_id: Optional for acquire, required for change. Proposed lease ID, in a GUID string format.

salt.cloud.clouds.msazure.list_affinity_groups(kwars=None, conn=None, call=None)
    New in version 2015.8.0.
    List input endpoints associated with the deployment
    CLI Example:
    
    salt-cloud -f list_affinity_groups my-azure

salt.cloud.clouds.msazure.list_blobs(kwars=None, storage_conn=None, call=None)
    New in version 2015.8.0.
    List blobs associated with the container
    CLI Example:
    
    salt-cloud -f list_blobs my-azure container=mycontainer

    container: The name of the storage container
    prefix: Optional. Filters the results to return only blobs whose names begin with the specified prefix.
**marker:** Optional. A string value that identifies the portion of the list to be returned with the next list operation. The operation returns a marker value within the response body if the list returned was not complete. The marker value may then be used in a subsequent call to request the next set of list items. The marker value is opaque to the client.

**maxresults:** Optional. Specifies the maximum number of blobs to return, including all BlobPrefix elements. If the request does not specify maxresults or specifies a value greater than 5,000, the server will return up to 5,000 items. Setting maxresults to a value less than or equal to zero results in error response code 400 (Bad Request).

**include:** Optional. Specifies one or more datasets to include in the response. To specify more than one of these options on the URI, you must separate each option with a comma. Valid values are:

- **snapshots:** Specifies that snapshots should be included in the enumeration. Snapshots are listed from oldest to newest in the response.
- **metadata:** Specifies that blob metadata be returned in the response.
- **uncommittedblobs:** Specifies that blobs for which blocks have been uploaded, but which have not been committed using Put Block List (REST API), be included in the response.
- **copy:** Version 2012-02-12 and newer. Specifies that metadata related to any current or previous Copy Blob operation should be included in the response.

**delimiter:** Optional. When the request includes this parameter, the operation returns a BlobPrefix element in the response body that acts as a placeholder for all blobs whose names begin with the same substring up to the appearance of the delimiter character. The delimiter may be a single character or a string.

```python
salt.cloud.clouds.msazure.list_disks(kwargs=None, conn=None, call=None)
New in version 2015.8.0.
List disks associated with the account

CLI Example:
```
salt-cloud -f list_disks my-azure
```

```pythonsalt.cloud.clouds.msazure.list_hosted_services(conn=None, call=None)
List VMs on this Azure account, with full information
```

```python
salt.cloud.clouds.msazure.list_input_endpoints(kwargs=None, conn=None, call=None)
New in version 2015.8.0.
List input endpoints associated with the deployment

CLI Example:
```
salt-cloud -f list_input_endpoints my-azure service=myservice deployment=mydeployment
```

```python
salt.cloud.clouds.msazure.list_management_certificates(kwargs=None, conn=None, call=None)
New in version 2015.8.0.
List management certificates associated with the subscription

CLI Example:
```
salt-cloud -f list_management_certificates my-azure name=my_management
```

```python
salt.cloud.clouds.msazure.list_nodes(conn=None, call=None)
List VMs on this Azure account
```
salt.cloud.clouds.msazure.list_nodes_full(conn=None, call=None)
List VMs on this Azure account, with full information

salt.cloud.clouds.msazure.list_nodes_select(conn=None, call=None)
Return a list of the VMs that are on the provider, with select fields

salt.cloud.clouds.msazure.list_service_certificates(kwargs=None, conn=None, call=None)
New in version 2015.8.0.
List certificates associated with the service
CLI Example:
salt-cloud -f list_service_certificates my-azure name=my_service

salt.cloud.clouds.msazure.list_services(kwargs=None, conn=None, call=None)
New in version 2015.8.0.
List hosted services associated with the account
CLI Example:
salt-cloud -f list_services my-azure

salt.cloud.clouds.msazure.list_storage(kwargs=None, conn=None, call=None)
New in version 2015.8.0.
List storage accounts associated with the account
CLI Example:
salt-cloud -f list_storage my-azure

salt.cloud.clouds.msazure.list_storage_containers(kwargs=None, storage_conn=None, call=None)
New in version 2015.8.0.
List containers associated with the storage account
CLI Example:
salt-cloud -f list_storage_containers my-azure

salt.cloud.clouds.msazure.list_storage_services(conn=None, call=None)
List VMs on this Azure account, with full information

salt.cloud.clouds.msazure.list_virtual_networks(kwargs=None, conn=None, call=None)
New in version 2015.8.0.
List input endpoints associated with the deployment
CLI Example:
salt-cloud -f list_virtual_networks my-azure service=myservice deployment=mydeployment

salt.cloud.clouds.msazure.make_blob_url(kwargs=None, storage_conn=None, call=None)
New in version 2015.8.0.
Create the URL to access a blob
CLI Example:
salt-cloud -f make_blob_url my-azure container=mycontainer blob=myblob

container: Name of the container.

blob: Name of the blob.

account: Name of the storage account. If not specified, derives the host base from the provider configuration.

protocol: Protocol to use: 'http' or 'https'. If not specified, derives the host base from the provider configuration.

host_base: Live host base URL. If not specified, derives the host base from the provider configuration.

salt.cloud.clouds.msazure.put_blob(_kwargs=None, storage_conn=None, call=None)
New in version 2015.8.0.

Upload a blob

CLI Examples:

```
salt-cloud -f put_blob my-azure container=base name=top.sls blob_path=/srv/salt/top.sls
salt-cloud -f put_blob my-azure container=base name=content.txt blob_content='Some content'
```

container: Name of existing container.

name: Name of existing blob.

blob_path: The path on the local machine of the file to upload as a blob. Either this or blob_content must be specified.

blob_content: The actual content to be uploaded as a blob. Either this or blob_path must me specified.

cache_control: Optional. The Blob service stores this value but does not use or modify it.

content_language: Optional. Specifies the natural languages used by this resource.

cache_content_md5: Optional. An MD5 hash of the blob content. This hash is used to verify the integrity of the blob during transport. When this header is specified, the storage service checks the hash that has arrived with the one that was sent. If the two hashes do not match, the operation will fail with error code 400 (Bad Request).

blob_content_type: Optional. Set the blob's content type.

blob_content_encoding: Optional. Set the blob's content encoding.

blob_content_language: Optional. Set the blob's content language.

blob_content_md5: Optional. Set the blob's MD5 hash.

blob_cache_control: Optional. Set the blob's cache control.

meta_name_values: A dict containing name, value for metadata.

lease_id: Required if the blob has an active lease.

salt.cloud.clouds.msazure.query(path, method='GET', data=None, params=None, header_dict=None, decode=True)
Perform a query directly against the Azure REST API

salt.cloud.clouds.msazure.regenerate_storage_keys( kwargs=None, conn=None, call=None)
New in version 2015.8.0.

Regenerate storage account keys. Requires a key_type ("primary" or "secondary") to be specified.
CLI Example:

```
salt-cloud -f regenerate_storage_keys my-azure name=my_storage key_type=primary
```

```
salt.cloud.clouds.msazure.script(vm_)
    Return the script deployment object
```

```
salt.cloud.clouds.msazure.set_blob_properties(kwargs=None, storage_conn=None, call=None)
    New in version 2015.8.0.
    Set a blob's properties
    CLI Example:

```
salt-cloud -f set_blob_properties my-azure
```

- **container**: Name of existing container.
- **blob**: Name of existing blob.
- **blob_cache_control**: Optional. Modifies the cache control string for the blob.
- **blob_content_type**: Optional. Sets the blob's content type.
- **blob_content_md5**: Optional. Sets the blob's MD5 hash.
- **blob_content_encoding**: Optional. Sets the blob's content encoding.
- **blob_content_language**: Optional. Sets the blob's content language.
- **lease_id**: Required if the blob has an active lease.
- **blob_content_disposition**: Optional. Sets the blob's Content-Disposition header. The Content-Disposition response header field conveys additional information about how to process the response payload, and also can be used to attach additional metadata. For example, if set to attachment, it indicates that the user-agent should not display the response, but instead show a Save As dialog with a filename other than the blob name specified.

```
salt.cloud.clouds.msazure.set_blob_service_properties(kwargs=None, storage_conn=None, call=None)
    New in version 2015.8.0.
    Sets the properties of a storage account's Blob service, including Windows Azure Storage Analytics. You can also use this operation to set the default request version for all incoming requests that do not have a version specified.
    CLI Example:

```
salt-cloud -f set_blob_service_properties my-azure
```

- **properties**: a StorageServiceProperties object.
- **timeout**: Optional. The timeout parameter is expressed in seconds.

```
salt.cloud.clouds.msazure.set_storage_container_acl(kwargs=None, storage_conn=None, call=None)
    New in version 2015.8.0.
    Set a storage container's acl
    CLI Example:
```
```bash
salt-cloud -f set_storage_container my-azure name=mycontainer
```

**name**: Name of existing container.

**signed_identifiers**: SignedIdentifiers instance

**blob_public_access**: Optional. Possible values include: container, blob

**lease_id**: If specified, set_storage_container_acl only succeeds if the container's lease is active and matches this ID.

```python
salt.cloud.clouds.msazure.set_storage_container_metadata(kwargs=None, storage_conn=None, call=None)
```

New in version 2015.8.0.

Set a storage container's metadata

CLI Example:

```bash
salt-cloud -f set_storage_container my-azure name=mycontainer \
            x_ms_meta_name_values='{"my_name": "my_value"}';
```

**name**: Name of existing container.

**meta_name_values**: A dict containing name, value for metadata. Example: {'category':'test'}

**lease_id**: If specified, set_storage_container_metadata only succeeds if the container's lease is active and matches this ID.

```python
salt.cloud.clouds.msazure.show_affinity_group(kwargs=None, conn=None, call=None)
```

New in version 2015.8.0.

Show an affinity group associated with the account

CLI Example:

```bash
salt-cloud -f show_affinity_group my-azure service=myservice \
            deployment=mydeployment name=SSH
```

```python
salt.cloud.clouds.msazure.show_blob_properties(kwargs=None, storage_conn=None, call=None)
```

New in version 2015.8.0.

Returns all user-defined metadata, standard HTTP properties, and system properties for the blob.

CLI Example:

```bash
salt-cloud -f show_blob_properties my-azure container=mycontainer blob=myblob
```

**container**: Name of existing container.

**blob**: Name of existing blob.

**lease_id**: Required if the blob has an active lease.

```python
salt.cloud.clouds.msazure.show_blob_service_properties(kwargs=None, storage_conn=None, call=None)
```

New in version 2015.8.0.

Show a blob's service properties
CLI Example:
```
salt-cloud -f show_blob_service_properties my-azure
```

salt.cloud.clouds.msazure.show_deployment(*kwargs=None, conn=None, call=None*)
New in version 2015.8.0.
Return information about a deployment
CLI Example:
```
salt-cloud -f show_deployment my-azure name=my_deployment
```

salt.cloud.clouds.msazure.show_disk(*kwargs=None, conn=None, call=None*)
New in version 2015.8.0.
Return information about a disk
CLI Example:
```
salt-cloud -f show_disk my-azure name=my_disk
```

salt.cloud.clouds.msazure.show_input_endpoint(*kwargs=None, conn=None, call=None*)
New in version 2015.8.0.
Show an input endpoint associated with the deployment
CLI Example:
```
salt-cloud -f show_input_endpoint my-azure service=myservice \ 
deployment=mydeployment name=SSH
```

salt.cloud.clouds.msazure.show_instance(name, call=None)
Show the details from the provider concerning an instance

salt.cloud.clouds.msazure.show_management_certificate(*kwargs=None, conn=None, call=None*)
New in version 2015.8.0.
Return information about a management_certificate
CLI Example:
```
salt-cloud -f get_management_certificate my-azure name=my_management_certificate \ 
thumbalgorithm=sha1 thumbprint=0123456789ABCDEF
```

salt.cloud.clouds.msazure.show_service(*kwargs=None, conn=None, call=None*)
New in version 2015.8.0.
List hosted service properties
CLI Example:
```
salt-cloud -f show_service my-azure name=my_service
```

salt.cloud.clouds.msazure.show_service_certificate(*kwargs=None, conn=None, call=None*)
New in version 2015.8.0.
Return information about a service certificate
CLI Example:
salt.cloud -f show_service_certificate my-azure name=my_service_certificate \ 
  thumbalgorithm=sha1 thumbprint=0123456789ABCDEF

salt.cloud.clouds.msazure.show_storage(kwargs=None, conn=None, call=None)
New in version 2015.8.0.
List storage service properties
CLI Example:
  salt-cloud -f show_storage my-azure name=my_storage

salt.cloud.clouds.msazure.show_storage_container(kwargs=None, storage_conn=None, call=None)
New in version 2015.8.0.
Show a container associated with the storage account
CLI Example:
  salt-cloud -f show_storage_container my-azure name=myservice

  name: Name of container to show.

salt.cloud.clouds.msazure.show_storage_container_acl(kwargs=None, storage_conn=None, call=None)
New in version 2015.8.0.
Show a storage container's acl
CLI Example:
  salt-cloud -f show_storage_container_acl my-azure name=myservice

  name: Name of existing container.
  lease_id: If specified, show_storage_container_acl only succeeds if the container's lease is active and matches this ID.

salt.cloud.clouds.msazure.show_storage_container_metadata(kwargs=None, storage_conn=None, call=None)
New in version 2015.8.0.
Show a storage container's metadata
CLI Example:
  salt-cloud -f show_storage_container_metadata my-azure name=myservice

  name: Name of container to show.
  lease_id: If specified, show_storage_container_metadata only succeeds if the container's lease is active and matches this ID.

salt.cloud.clouds.msazure.show_storage_keys(kwargs=None, conn=None, call=None)
New in version 2015.8.0.
Show storage account keys
CLI Example:
salt.cloud -f show_storage_keys my-azure name=my_storage

```python
salt.cloud.clouds.msazure.update_affinity_group(kwags=) None, conn=None, call=None)
    Update an affinity group’s properties
    CLI Example:
    salt-cloud -f update_affinity_group my-azure name=my_group label=my_group
```

salt.cloud.clouds.msazure.update_disk(kwags=) None, conn=None, call=None)
    Update a disk’s properties
    CLI Example:
    salt-cloud -f update_disk my-azure name=my_disk label=my_disk
    salt-cloud -f update_disk my-azure name=my_disk new_name=another_disk

salt.cloud.clouds.msazure.update_input_endpoint(kwags=) None, conn=None, call=None,
    activity='update')
    Update an input endpoint associated with the deployment. Please note that there may be a delay before the changes show up.
    CLI Example:
    salt-cloud -f update_input_endpoint my-azure service=myservice \
    deployment=mydeployment role=myrole name=HTTP local_port=80 \ 
    port=80 protocol=tcp enable_direct_server_return=False \ 
    timeout_for_tcp_idle_connection=4

salt.cloud.clouds.msazure.update_storage(kwags=) None, conn=None, call=None)
    Update a storage account’s properties
    CLI Example:
    salt-cloud -f update_storage my-azure name=my_storage label=my_storage

31.5.13 salt.cloud.clouds.nova

OpenStack Nova Cloud Module

OpenStack is an open source project that is in use by a number a cloud providers, each of which have their own ways of using it.

The OpenStack Nova module for Salt Cloud was bootstrapped from the OpenStack module for Salt Cloud, which uses a libcloud-based connection. The Nova module is designed to use the nova and glance modules already built into Salt.

These modules use the Python novaclient and glanceclient libraries, respectively. In order to use this module, the proper salt configuration must also be in place. This can be specified in the master config, the minion config, a set of grains or a set of pillars.
my_openstack_profile:
  keystone.user: admin
  keystone.password: verybadpass
  keystone.tenant: admin
  keystone.auth_url: 'http://127.0.0.1:5000/v2.0/

Note that there is currently a dependency upon netaddr. This can be installed on Debian-based systems by means of the python-netaddr package.

This module currently requires the latest develop branch of Salt to be installed.

This module has been tested to work with HP Cloud and Rackspace. See the documentation for specific options for either of these providers. These examples could be set up in the cloud configuration at /etc/salt/cloud.providers or /etc/salt/cloud.providers.d/openstack.conf:

my-openstack-config:
  # The ID of the minion that will execute the salt nova functions
  auth_minion: myminion
  # The name of the configuration profile to use on said minion
  config_profile: my_openstack_profile

  ssh_key_name: mykey

  driver: nova
  userdata_file: /tmp/userdata.txt

For local installations that only use private IP address ranges, the following option may be useful. Using the old syntax:

Note: For api use, you will need an auth plugin. The base novaclient does not support apikeys, but some providers such as rackspace have extended keystone to accept them

my-openstack-config:
  # Ignore IP addresses on this network for bootstrap
  ignore_cidr: 192.168.50.0/24

my-nova:
  identity_url: 'https://identity.api.rackspacecloud.com/v2.0/
  compute_region: IAD
  user: myusername
  password: mypassword
  tenant: <userid>
  driver: nova

my-api:
  identity_url: 'https://identity.api.rackspacecloud.com/v2.0/
  compute_region: IAD
  user: myusername
  api_key: <api_key>
  os_auth_plugin: rackspace
  tenant: <userid>
  driver: nova
  networks:
    - net-id: 47a38ff2-fe21-4800-8604-42bd1848e743
    - net-id: 00000000-0000-0000-0000-000000000000
    - net-id: 11111111-1111-1111-1111-111111111111

Note: You must include the default net-ids when setting networks or the server will be created without the rest of the interfaces
Note: For rackconnect v3, rackconnectv3 needs to be specified with the rackconnect v3 cloud network as its variable.

```python
salt.cloud.clouds.nova.attach_volume(name, server_name, device='/dev/xvdb', **kwargs)
    Attach block volume

salt.cloud.clouds.nova.avail_images()
    Return a dict of all available VM images on the cloud provider.

salt.cloud.clouds.nova.avail_locations(conn=None, call=None)
    Return a list of locations

salt.cloud.clouds.nova.avail_sizes()
    Return a dict of all available VM sizes on the cloud provider.

salt.cloud.clouds.nova.cloudnetwork(vm_)
    Determine if we should use an extranetwork to bootstrap Either 'False' (default) or 'True'.

salt.cloud.clouds.nova.create(vm_)
    Create a single VM from a data dict

salt.cloud.clouds.nova.create_attach_volumes(name, call=None, **kwargs)
    Create and attach volumes to created node

salt.cloud.clouds.nova.create_volume(name, size=100, snapshot=None, voltype=None, **kwargs)
    Create block storage device

salt.cloud.clouds.nova.destroy(name, conn=None, call=None)
    Delete a single VM

salt.cloud.clouds.nova.get_configured_provider()
    Return the first configured instance.

salt.cloud.clouds.nova.get_conn()
    Return a conn object for the passed VM data

salt.cloud.clouds.nova.get_dependencies()
    Warn if dependencies aren't met.

salt.cloud.clouds.nova.get_image(conn, vm_)
    Return the image object to use

salt.cloud.clouds.nova.get_size(conn, vm_)
    Return the VM's size object

salt.cloud.clouds.nova.ignore_cidr(vm_, ip)
    Return True if we are to ignore the specified IP. Compatible with IPv4.

salt.cloud.clouds.nova.list_nodes(call=None, **kwargs)
    Return a list of the VMs that in this location

salt.cloud.clouds.nova.list_nodes_full(call=None, **kwargs)
    Return a list of the VMs that in this location

salt.cloud.clouds.nova.list_nodes_select(call=None)
    Return a list of the VMs that are on the provider, with select fields

salt.cloud.clouds.nova.managedcloud(vm_)
    Determine if we should wait for the managed cloud automation before running. Either 'False' (default) or 'True'.

salt.cloud.clouds.nova.network_create(name, **kwargs)
    Create private networks
```
salt.cloud.clouds.nova.network_list(call=None, **kwargs)
List private networks
	salt.cloud.clouds.nova.preferred_ip(vm_, ips)
Return the preferred Internet protocol. Either `ipv4` (default) or `ipv6`.
	salt.cloud.clouds.nova.rackconnect(vm_)
Determine if we should wait for rackconnect automation before running. Either `False` (default) or `True`.
	salt.cloud.clouds.nova.reboot(name, conn=None)
Reboot a single VM
	salt.cloud.clouds.nova.request_instance(vm_=None, call=None)
Put together all of the information necessary to request an instance through Novaclient and then fire off the request the instance.

Returns data about the instance
	salt.cloud.clouds.nova.script(vm_)
Return the script deployment object
	salt.cloud.clouds.nova.show_instance(name, call=None)
Show the details from the provider concerning an instance
	salt.cloud.clouds.nova.ssh_interface(vm_)
Return the ssh_interface type to connect to. Either `public_ips` (default) or `private_ips`.
	salt.cloud.clouds.nova.virtual_interface_create(name, net_name, **kwargs)
Create private networks
	salt.cloud.clouds.nova.virtual_interface_list(name, **kwargs)
Create private networks
	salt.cloud.clouds.nova.volume_attach(name, server_name, device='/dev/xvdb', **kwargs)
Attach block volume
	salt.cloud.clouds.nova.volume_create(name, size=100, snapshot=None, voltype=None, **kwargs)
Create block storage device
	salt.cloud.clouds.nova.volume_create_attach(name, call=None, **kwargs)
Create and attach volumes to created node
	salt.cloud.clouds.nova.volume_delete(name, **kwargs)
Delete block storage device
	salt.cloud.clouds.nova.volume_detach(name, **kwargs)
Detach block volume
	salt.cloud.clouds.nova.volume_list(**kwargs)
List block devices

31.5.14 salt.cloud.clouds.opennebula

OpenNebula Cloud Module

The OpenNebula cloud module is used to control access to an OpenNebula cloud.

depends lxml

Use of this module requires the xml_rpc, user and password parameter to be set. Set up the cloud configuration at /etc/salt/cloud.providers or /etc/salt/cloud.providers.d/opennebula.conf:

31.5. Full list of Salt Cloud modules
my-opennebula-config:
  xml_rpc: http://localhost:2633/RPC2
  user: oneadmin
  password: JHGhgsayu32jsa
  driver: opennebula

salt.cloud.clouds.opennebula.avail_images(call=None)
  Return a list of the templates that are on the provider

salt.cloud.clouds.opennebula.avail_locations(call=None)
  Return a dict of all available VM locations on the cloud provider with relevant data

salt.cloud.clouds.opennebula.avail_sizes(call=None)
  Because sizes are built into templates with OpenNebula, there will be no sizes to return here

salt.cloud.clouds.opennebula.create(vm_)
  Create a single VM from a data dict

salt.cloud.clouds.opennebula.destroy(name, call=None)
  Destroy a node. Will check termination protection and warn if enabled.

  CLI Example:
  salt-cloud --destroy mymachine

salt.cloud.clouds.opennebula.get_configured_provider()
  Return the first configured instance.

salt.cloud.clouds.opennebula.get_dependencies()
  Warn if dependencies aren't met.

salt.cloud.clouds.opennebula.get_image(vm_)
  Return the image object to use

salt.cloud.clouds.opennebula.get_location(vm_)
  Return the VM's location

salt.cloud.clouds.opennebula.list_nodes(call=None)
  Return a list of the VMs that are on the provider

salt.cloud.clouds.opennebula.list_nodes_full(call=None)
  Return a list of the VMs that are on the provider

salt.cloud.clouds.opennebula.list_nodes_select(call=None)
  Return a list of the VMs that are on the provider, with select fields

salt.cloud.clouds.opennebula.script(vm_)
  Return the script deployment object

salt.cloud.clouds.opennebula.show_instance(name, call=None)
  Show the details from OpenNebula concerning a VM

31.5.15 salt.cloud.clouds.openstack

OpenStack Cloud Module

OpenStack is an open source project that is in use by a number a cloud providers, each of which have their own ways of using it.

  depends libcloud >= 0.13.2
OpenStack provides a number of ways to authenticate. This module uses password-based authentication, using auth v2.0. It is likely to start supporting other methods of authentication provided by OpenStack in the future.

Note that there is currently a dependency upon netaddr. This can be installed on Debian-based systems by means of the python-netaddr package.

This module has been tested to work with HP Cloud and Rackspace. See the documentation for specific options for either of these providers. Some examples, using the old cloud configuration syntax, are provided below:

Set up in the cloud configuration at `/etc/salt/cloud.providers` or `/etc/salt/cloud.providers.d/openstack.conf`:

```yaml
my-openstack-config:
  # The OpenStack identity service url
  identity_url: https://region-b.geo-1.identity.hpcloudsvc.com:35357/v2.0/
  # The OpenStack compute region
  compute_region: region-b.geo-1
  # The OpenStack compute service name
  compute_name: Compute
  # The OpenStack tenant name (not tenant ID)
  tenant: myuser-tenant1
  # The OpenStack user name
  user: myuser
  # The OpenStack keypair name
  ssh_key_name: mykey
  # Skip SSL certificate validation
  insecure: false
  # The ssh key file
  ssh_key_file: /path/to/keyfile/test.pem
  # The OpenStack network UUIDs
  networks:
    - fixed:
      - 4402cd51-37ee-435e-a966-8245956dc0e6
    - floating:
      - Ext-Net
  files:
    /path/to/dest.txt:
      /local/path/to/src.txt
      # Skips the service catalog API endpoint, and uses the following
  driver: openstack
  userdata_file: /tmp/userdata.txt
  # config_drive is required for userdata at rackspace
  config_drive: True
```

For in-house Openstack Essex installation, libcloud needs the `service_type`:

```yaml
my-openstack-config:
  identity_url: http://control.openstack.example.org:5000/v2.0/
  compute_name: Compute Service
  service_type: compute
```

Either a password or an API key must also be specified:

```yaml
my-openstack-password-or-api-config:
  # The OpenStack password
  password: letmein
  # The OpenStack API key
  apikey: 901d3f579h23c8v73q9
```

31.5. Full list of Salt Cloud modules
Optionally, if you don’t want to save plain-text password in your configuration file, you can use keyring:

```
my-openstack-keyring-config:
    # The OpenStack password is stored in keyring
    # don't forget to set the password by running something like:
    # salt-cloud --set-password=myuser my-openstack-keyring-config
    password: USE_KEYRING
```

For local installations that only use private IP address ranges, the following option may be useful. Using the old syntax:

```
my-openstack-config:
    # Ignore IP addresses on this network for bootstrap
    ignore_cidr: 192.168.50.0/24
```

It is possible to upload a small set of files (no more than 5, and nothing too large) to the remote server. Generally this should not be needed, as salt itself can upload to the server after it is spun up, with nowhere near the same restrictions.

```
my-openstack-config:
    files:
        /path/to/dest.txt:
            /local/path/to/src.txt
```

Alternatively, one could use the private IP to connect by specifying:

```
my-openstack-config:
    ssh_interface: private_ips
```

Salt provides several functions to interact with OpenStack cloud provider:

```python
salt.cloud.clouds.openstack.avail_images(conn=None, call=None)
    Return a dict of all available VM images on the cloud provider with relevant data

salt.cloud.clouds.openstack.avail_locations(conn=None, call=None)
    Return a dict of all available VM locations on the cloud provider with relevant data

salt.cloud.clouds.openstack.avail_sizes(conn=None, call=None)
    Return a dict of all available VM images on the cloud provider with relevant data

salt.cloud.clouds.openstack.create(vm_)
    Create a single VM from a data dict

salt.cloud.clouds.openstack.destroy(name, conn=None, call=None)
    Delete a single VM

salt.cloud.clouds.openstack.get_configured_provider()
    Return the first configured instance.

salt.cloud.clouds.openstack.get_conn()
    Return a conn object for the passed VM data

salt.cloud.clouds.openstack.get_dependencies()
    Warn if dependencies aren’t met.

salt.cloud.clouds.openstack.get_image(conn, vm_)
    Return the image object to use

salt.cloud.clouds.openstack.get_node(conn, name)
    Return a libcloud node for the named VM

salt.cloud.clouds.openstack.get_size(conn, vm_)
    Return the VM’s size object
```
salt.cloud.clouds.openstack.ignore_cidr(vm_, ip)
    Return True if we are to ignore the specified IP. Compatible with IPv4.

salt.cloud.clouds.openstack.list_nodes(conn=None, call=None)
    Return a list of the VMs that are on the provider

salt.cloud.clouds.openstack.list_nodes_full(conn=None, call=None)
    Return a list of the VMs that are on the provider, with all fields

salt.cloud.clouds.openstack.list_nodes_select(conn=None, call=None)
    Return a list of the VMs that are on the provider, with select fields

salt.cloud.clouds.openstack.managedcloud(vm_)
    Determine if we should wait for the managed cloud automation before running. Either 'False' (default) or 'True'.

salt.cloud.clouds.openstack.networks(vm_, kwargs=None)

salt.cloud.clouds.openstack.preferred_ip(vm_, ips)
    Return the preferred Internet protocol. Either 'ipv4' (default) or 'ipv6'.

salt.cloud.clouds.openstack.rackconnect(vm_)
    Determine if we should wait for rackconnect automation before running. Either 'False' (default) or 'True'.

salt.cloud.clouds.openstack.reboot(name, conn=None)
    Reboot a single VM

salt.cloud.clouds.openstack.request_instance(vm_=None, call=None)
    Put together all of the information necessary to request an instance on Openstack and then fire off the request
    the instance.

    Returns data about the instance

salt.cloud.clouds.openstack.script(vm_)
    Return the script deployment object

salt.cloud.clouds.openstack.show_instance(name, call=None)
    Show the details from the provider concerning an instance

salt.cloud.clouds.openstack.ssh_interface(vm_)
    Return the ssh_interface type to connect to. Either 'public_ips' (default) or 'private_ips'.

31.5.16 salt.cloud.clouds.parallels

Parallels Cloud Module

The Parallels cloud module is used to control access to cloud providers using the Parallels VPS system.

Set up the cloud configuration at /etc/salt/cloud.providers or /etc/salt/cloud.providers.d/parallels.conf:

```
my-parallels-config:
  # Parallels account information
  user: myuser
  password: mypassword
  url: https://api.cloud.xmission.com:4465/paci/v1.0/
  driver: parallels
```

salt.cloud.clouds.parallels.avail_images(call=None)
    Return a list of the images that are on the provider

31.5. Full list of Salt Cloud modules
salt.cloud.clouds.parallels.create(vm_)
    Create a single VM from a data dict

salt.cloud.clouds.parallels.create_node(vm_)
    Build and submit the XML to create a node

salt.cloud.clouds.parallels.destroy(name, call=None)
    Destroy a node.
    CLI Example:
    ```
    salt-cloud --destroy mymachine
    ```

salt.cloud.clouds.parallels.get_configured_provider()
    Return the first configured instance.

salt.cloud.clouds.parallels.get_image(vm_)
    Return the image object to use

salt.cloud.clouds.parallels.list_nodes(call=None)
    Return a list of the VMs that are on the provider

salt.cloud.clouds.parallels.list_nodes_full(call=None)
    Return a list of the VMs that are on the provider

salt.cloud.clouds.parallels.list_nodes_select(call=None)
    Return a list of the VMs that are on the provider, with select fields

salt.cloud.clouds.parallels.query(action=None, command=None, args=None, method='GET', data=None)
    Make a web call to a Parallels provider

salt.cloud.clouds.parallels.script(vm_)
    Return the script deployment object

salt.cloud.clouds.parallels.show_image(kwargs, call=None)
    Show the details from Parallels concerning an image

salt.cloud.clouds.parallels.show_instance(name, call=None)
    Show the details from Parallels concerning an instance

salt.cloud.clouds.parallels.start(name, call=None)
    Start a node.
    CLI Example:
    ```
    salt-cloud -a start mymachine
    ```

salt.cloud.clouds.parallels.stop(name, call=None)
    Stop a node.
    CLI Example:
    ```
    salt-cloud -a stop mymachine
    ```

salt.cloud.clouds.parallels.wait_until(name, state, timeout=300)
    Wait until a specific state has been reached on a node
31.5.17 salt.cloud.clouds.proxmox

Proxmox Cloud Module

New in version 2014.7.0.

The Proxmox cloud module is used to control access to cloud providers using the Proxmox system (KVM / OpenVZ).

Set up the cloud configuration at `/etc/salt/cloud.providers` or `/etc/salt/cloud.providers.d/proxmox.conf`:

```
my-proxmox-config:
    # Proxmox account information
    user: myuser@pam or myuser@pve
    password: mypassword
    url: hypervisor.domain.tld
    driver: proxmox
    verify_ssl: True
```

**maintainer** Frank Klaassen <frank@cloudright.nl>

**depends** requests >= 2.2.1

**depends** IPy >= 0.81

**salt.cloud.clouds.proxmox.avail_images** *(call=None, location='local')*

Return a list of the images that are on the provider

CLI Example:

```
salt-cloud --list-images my-proxmox-config
```

**salt.cloud.clouds.proxmox.avail_locations** *(call=None)*

Return a list of the hypervisors (nodes) which this Proxmox PVE machine manages

CLI Example:

```
salt-cloud --list-locations my-proxmox-config
```

**salt.cloud.clouds.proxmox.create** *(vm_)*

Create a single VM from a data dict

CLI Example:

```
salt-cloud -p proxmox-ubuntu vmhostname
```

**salt.cloud.clouds.proxmox.create_node** *(vm_)*

Build and submit the requestdata to create a new node

**salt.cloud.clouds.proxmox.destroy** *(name, call=None)*

Destroy a node.

CLI Example:

```
salt-cloud --destroy mymachine
```

**salt.cloud.clouds.proxmox.get_configured_provider** *

Return the first configured instance.

**salt.cloud.clouds.proxmox.get_dependencies** *

Warn if dependencies aren’t met.
salt.cloud.clouds.proxmox.get_resources_nodes(call=None, resFilter=None)
Retrieve all hypervisors (nodes) available on this environment
CLI Example:
    salt-cloud -f get_resources_nodes my-proxmox-config

salt.cloud.clouds.proxmox.get_resources_vms(call=None, resFilter=None, includeConfig=True)
Retrieve all VMs available on this environment
CLI Example:
    salt-cloud -f get_resources_vms my-proxmox-config

salt.cloud.clouds.proxmox.get_vm_status(vmid=None, name=None)
Get the status for a VM, either via the ID or the hostname

salt.cloud.clouds.proxmox.get_vmconfig(vmid, node=None, node_type='openvz')
Get VM configuration

salt.cloud.clouds.proxmox.list_nodes(call=None)
Return a list of the VMs that are managed by the provider
CLI Example:
    salt-cloud -Q my-proxmox-config

salt.cloud.clouds.proxmox.list_nodes_full(call=None)
Return a list of the VMs that are on the provider
CLI Example:
    salt-cloud -F my-proxmox-config

salt.cloud.clouds.proxmox.list_nodes_select(call=None)
Return a list of the VMs that are on the provider, with select fields
CLI Example:
    salt-cloud -S my-proxmox-config

salt.cloud.clouds.proxmox.query(conn_type, option, post_data=None)
Execute the HTTP request to the API

salt.cloud.clouds.proxmox.script(vm_)
Return the script deployment object

salt.cloud.clouds.proxmox.set_vm_status(status, name=None, vmid=None)
Convenience function for setting VM status

salt.cloud.clouds.proxmox.show_instance(name, call=None)
Show the details from Proxmox concerning an instance

salt.cloud.clouds.proxmox.shutdown(name=None, vmid=None, call=None)
Shutdown a node via ACPI.
CLI Example:
    salt-cloud -a shutdown mymachine

salt.cloud.clouds.proxmox.start(name, vmid=None, call=None)
Start a node.
CLI Example:
salt-cloud -a start mymachine

salt.cloud.clouds.proxmox.stop(name, vmid=None, call=None)
   Stop a node ("pulling the plug").
   CLI Example:
   
salt-cloud -a stop mymachine

salt.cloud.clouds.proxmox.wait_for_created(upid, timeout=300)
   Wait until a the vm has been created successfully
salt.cloud.clouds.proxmox.wait_for_state(vmid, state, timeout=300)
   Wait until a specific state has been reached on a node

31.5.18 salt.cloud.clouds.pyrax

Pyrax Cloud Module

PLEASE NOTE: This module is currently in early development, and considered to be experimental and unstable. It is not recommended for production use. Unless you are actively developing code in this module, you should use the OpenStack module instead.

salt.cloud.clouds.pyrax.get_configured_provider()
   Return the first configured instance.

salt.cloud.clouds.pyrax.get_conn(conn_type)
   Return a conn object for the passed VM data

salt.cloud.clouds.pyrax.get_dependencies()
   Warn if dependencies aren't met.

salt.cloud.clouds.pyraxqueues_create(call, kwargs)

salt.cloud.clouds.pyrax.queue_delete(call, kwargs)

salt.cloud.clouds.pyrax.queue_exists(call, kwargs)

salt.cloud.clouds.pyrax.queue_show(call, kwargs)

31.5.19 salt.cloud.clouds.rackspace

Rackspace Cloud Module

The Rackspace cloud module. This module uses the preferred means to set up a libcloud based cloud module and should be used as the general template for setting up additional libcloud based modules.

  depends libcloud >= 0.13.2

Please note that the rackspace driver is only intended for 1st gen instances, aka, "the old cloud" at Rackspace. It is required for 1st gen instances, but will not work with OpenStack-based instances. Unless you explicitly have a reason to use it, it is highly recommended that you use the openstack driver instead.

The rackspace cloud module interfaces with the Rackspace public cloud service and requires that two configuration parameters be set for use, user and apikey.

Set up the cloud configuration at /etc/salt/cloud.providers or /etc/salt/cloud.providers.d/rackspace.conf
my-rackspace-config:
  driver: rackspace
  # The Rackspace login user
  user: fred
  # The Rackspace user's apikey
  apikey: 901d3f579h23c8v73q9

salt.cloud.clouds.rackspace.avail_images(conn=None, call=None)
  Return a dict of all available VM images on the cloud provider with relevant data

salt.cloud.clouds.rackspace.avail_locations(conn=None, call=None)
  Return a dict of all available VM locations on the cloud provider with relevant data

salt.cloud.clouds.rackspace.avail_sizes(conn=None, call=None)
  Return a dict of all available VM images on the cloud provider with relevant data

salt.cloud.clouds.rackspace.create(vm_)
  Create a single VM from a data dict

salt.cloud.clouds.rackspace.destroy(name, conn=None, call=None)
  Delete a single VM

salt.cloud.clouds.rackspace.get_configured_provider()
  Return the first configured instance.

salt.cloud.clouds.rackspace.get_conn()
  Return a conn object for the passed VM data

salt.cloud.clouds.rackspace.get_dependencies()
  Warn if dependencies aren't met.

salt.cloud.clouds.rackspace.get_image(conn, vm_)
  Return the image object to use

salt.cloud.clouds.rackspace.get_size(conn, vm_)
  Return the VM's size object

salt.cloud.clouds.rackspace.list_nodes(conn=None, call=None)
  Return a list of the VMs that are on the provider

salt.cloud.clouds.rackspace.list_nodes_full(conn=None, call=None)
  Return a list of the VMs that are on the provider, with all fields

salt.cloud.clouds.rackspace.list_nodes_select(conn=None, call=None)
  Return a list of the VMs that are on the provider, with select fields

salt.cloud.clouds.rackspace.preferred_ip(vm_, ips)
  Return the preferred Internet protocol. Either 'ipv4' (default) or 'ipv6'.

salt.cloud.clouds.rackspace.script(vm_)
  Return the script deployment object

salt.cloud.clouds.rackspace.show_instance(name, call=None)
  Show the details from the provider concerning an instance

salt.cloud.clouds.rackspace.ssh_interface(vm_)
  Return the ssh_interface type to connect to. Either 'public_ips' (default) or 'private_ips'.
31.5.20 salt.cloud.clouds.saltify

Saltify Module

The Saltify module is designed to install Salt on a remote machine, virtual or bare metal, using SSH. This module is useful for provisioning machines which are already installed, but not Salted.

Use of this module requires some configuration in cloud profile and provider files as described in the *Getting Started with Saltify* documentation.

```python
salt.cloud.clouds.saltify.create(vm_)
    Provision a single machine

salt.cloud.clouds.saltify.get_configured_provider()
    Return the first configured instance.

salt.cloud.clouds.saltify.list_nodes()
    Because this module is not specific to any cloud providers, there will be no nodes to list.

salt.cloud.clouds.saltify.list_nodes_full()
    Because this module is not specific to any cloud providers, there will be no nodes to list.

salt.cloud.clouds.saltify.list_nodes_select()
    Because this module is not specific to any cloud providers, there will be no nodes to list.
```

31.5.21 salt.cloud.clouds.softlayer

SoftLayer Cloud Module

The SoftLayer cloud module is used to control access to the SoftLayer VPS system.

Use of this module only requires the `apikey` parameter. Set up the cloud configuration at:

```
/etc/salt/cloud.providers or /etc/salt/cloud.providers.d/softlayer.conf:
```

```yaml
my-softlayer-config:
  # SoftLayer account api key
  user: MYLOGIN
  apikey: JVkbSJDGHSKUKSDJfhsdklfjgsjdjkflhjlsdfhgdgjkenrtuin
  driver: softlayer
```

The SoftLayer Python Library needs to be installed in order to use the SoftLayer salt.cloud modules. See: https://pypi.python.org/pypi/SoftLayer

```python
depends softlayer

salt.cloud.clouds.softlayer.avail_images(call=None)
    Return a dict of all available VM images on the cloud provider.

salt.cloud.clouds.softlayer.avail_locations(call=None)
    List all available locations

salt.cloud.clouds.softlayer.avail_sizes(call=None)
    Return a dict of all available VM sizes on the cloud provider with relevant data. This data is provided in three dicts.

salt.cloud.clouds.softlayer.create(vm_)
    Create a single VM from a data dict
```
salt.cloud.clouds.softlayer.destroy(name, call=None)
    Destroy a node.

    CLI Example:
    salt-cloud --destroy mymachine

salt.cloud.clouds.softlayer.get_configured_provider()
    Return the first configured instance.

salt.cloud.clouds.softlayer.get_conn(service='SoftLayer_Virtual_Guest')
    Return a conn object for the passed VM data

salt.cloud.clouds.softlayer.get_dependencies()
    Warn if dependencies aren’t met.

salt.cloud.clouds.softlayer.get_location(vm_=None)
    Return the location to use, in this order:
    - CLI parameter
    - VM parameter
    - Cloud profile setting

salt.cloud.clouds.softlayer.list_custom_images(call=None)
    Return a dict of all custom VM images on the cloud provider.

salt.cloud.clouds.softlayer.list_nodes(call=None)
    Return a list of the VMs that are on the provider

salt.cloud.clouds.softlayer.list_nodes_full(mask='mask[id]', call=None)
    Return a list of the VMs that are on the provider

salt.cloud.clouds.softlayer.list_nodes_select(call=None)
    Return a list of the VMs that are on the provider, with select fields

salt.cloud.clouds.softlayer.list_vlans(call=None)
    List all VLANs associated with the account

salt.cloud.clouds.softlayer.script(vm_)
    Return the script deployment object

salt.cloud.clouds.softlayer.show_instance(name, call=None)
    Show the details from SoftLayer concerning a guest

### 31.5.22 salt.cloud.clouds.softlayer_hw

**SoftLayer HW Cloud Module**

The SoftLayer HW cloud module is used to control access to the SoftLayer hardware cloud system

Use of this module only requires the apikey parameter. Set up the cloud configuration at:

```
/etc/salt/cloud.providers or /etc/salt/cloud.providers.d/softlayer.conf:
```

```
my-softlayer-config:
    # SoftLayer account api key
    user: MYLOGIN
    apikey: JVkb5JDGHSKUKSDJfhsdklfgsjdkfhlhjlsdfhghdgjkenrtuin
    driver: softlayer_hw
```
The SoftLayer Python Library needs to be installed in order to use the SoftLayer salt.cloud modules. See: https://pypi.python.org/pypi/SoftLayer

```python
depends softlayer

salt.cloud.clouds.softlayer_hw.avail_images(call=None)
Return a dict of all available VM images on the cloud provider.

salt.cloud.clouds.softlayer_hw.avail_locations(call=None)
List all available locations

salt.cloud.clouds.softlayer_hw.avail_sizes(call=None)
Return a dict of all available VM sizes on the cloud provider with relevant data. This data is provided in three dicts.

salt.cloud.clouds.softlayer_hw.create(vm_)
Create a single VM from a data dict

salt.cloud.clouds.softlayer_hw.destroy(name, call=None)
Destroy a node.

CLI Example:

```salt-cloud --destroy mymachine```

salt.cloud.clouds.softlayer_hw.get_configured_provider()
Return the first configured instance.

salt.cloud.clouds.softlayer_hw.get_conn(service='SoftLayer_Hardware')
Return a conn object for the passed VM data

salt.cloud.clouds.softlayer_hw.get_dependencies()
Warn if dependencies aren't met.

salt.cloud.clouds.softlayer_hw.get_location(vm_=None)
Return the location to use, in this order:

- CLI parameter
- VM parameter
- Cloud profile setting

salt.cloud.clouds.softlayer_hw.list_nodes(call=None)
Return a list of the VMs that are on the provider

salt.cloud.clouds.softlayer_hw.list_nodes_full(mask='mask[id, hostname, primaryIpAddress, primaryBackendIpAddress, processorPhysicalCoreAmount, memoryCount]', call=None)

Return a list of the VMs that are on the provider

salt.cloud.clouds.softlayer_hw.list_nodes_select(call=None)
Return a list of the VMs that are on the provider, with select fields

salt.cloud.clouds.softlayer_hw.list_vlans(call=None)
List all VLANs associated with the account

salt.cloud.clouds.softlayer_hw.script(vm_)
Return the script deployment object

salt.cloud.clouds.softlayer_hw.show_all_prices(call=None, kwargs=None)
Return a dict of all available VM images on the cloud provider.

31.5. Full list of Salt Cloud modules
salt.cloud.clouds.softlayer_hw.show_instance(name, call=None)
Show the details from SoftLayer concerning a guest

salt.cloud.clouds.softlayer_hw.show_pricing(kwargs=None, call=None)
Show pricing for a particular profile. This is only an estimate, based on unofficial pricing sources.

CLI Examples:

salt-cloud -f show_pricing my-softlayerhw-config profile=my-profile

If pricing sources have not been cached, they will be downloaded. Once they have been cached, they will not
be updated automatically. To manually update all prices, use the following command:

salt-cloud -f update_pricing <provider>

New in version 2015.8.0.

31.5.23 salt.cloud.clouds.vmware

VMware Cloud Module

New in version 2015.5.4.

The VMware cloud module allows you to manage VMware ESX, ESXi, and vCenter.

See Getting started with VMware to get started.

codeauthor Nitin Madhok <nmadhok@clemson.edu>
depends pyVmomi Python module

Note: Ensure python pyVmomi module is installed by running following one-liner check. The output should be 0.

python -c "import pyVmomi" ; echo $? 

To use this module, set up the vCenter URL, username and password in the cloud configuration at
/etc/salt/cloud.providers or /etc/salt/cloud.providers.d/vmware.conf:

my-vmware-config:
  driver: vmware
  user: 'DOMAIN\user'
  password: 'verybadpass'
  url: '10.20.30.40'

vcenter01:
  driver: vmware
  user: 'DOMAIN\user'
  password: 'verybadpass'
  url: 'vcenter01.domain.com'
  protocol: 'https'
  port: 443

vcenter02:
  driver: vmware
  user: 'DOMAIN\user'
  password: 'verybadpass'
  url: 'vcenter02.domain.com'
  protocol: 'http'
  port: 80
Note: Optionally, protocol and port can be specified if the vCenter server is not using the defaults. Default is protocol: https and port: 443.

To test the connection for my-vmware-config specified in the cloud configuration, run

test_vcenter_connection()

salt.cloud.clouds.vmware.add_host(kwargs=None, call=None)

Add a host system to the specified cluster or datacenter in this VMware environment

Note: To use this function, you need to specify esxi_host_user and esxi_host_password under your provider configuration set up at /etc/salt/cloud.providers or /etc/salt/cloud.providers.d/vmware.conf:

vcenter01:
    driver: vmware
    user: 'DOMAIN\user'
    password: 'verybadpass'
    url: 'vcenter01.domain.com'

    # Required when adding a host system
    esxi_host_user: 'root'
    esxi_host_password: 'myhostpassword'

    # Optional fields that can be specified when adding a host system

The SSL thumbprint of the host system can be optionally specified by setting esxi_host_ssl_thumbprint under your provider configuration. To get the SSL thumbprint of the host system, execute the following command from a remote server:

```
echo -n | openssl s_client -connect <YOUR-HOSTSYSTEM-DNS/IP>:443 2>/dev/null | openssl x509 -noout -fingerprint -sha1
```

CLI Example:

```
salt-cloud -f add_host my-vmware-config host="myHostSystemName" cluster="myClusterName"
salt-cloud -f add_host my-vmware-config host="myHostSystemName" datacenter="myDatacenterName"
```

salt.cloud.clouds.vmware.avail_images(call=None)

Return a list of all the templates present in this VMware environment with basic details

CLI Example:

```
salt-cloud --list-images my-vmware-config
```

salt.cloud.clouds.vmware.avail_locations(call=None)

Return a list of all the available locations/datacenters in this VMware environment

CLI Example:

```
salt-cloud --list-locations my-vmware-config
```

salt.cloud.clouds.vmware.avail_sizes(call=None)

Return a list of all the available sizes in this VMware environment.

CLI Example:

```
salt-cloud --list-sizes my-vmware-config
```

Note: Since sizes are built into templates, this function will return an empty dictionary.
salt.cloud.clouds.vmware.connect_host(kwags=None, call=None)
    Connect the specified host system in this VMware environment
    
    CLI Example:
    
    salt-cloud -f connect_host my-vmware-config host="myHostSystemName"

salt.cloud.clouds.vmware.create(vm_)
    To create a single VM in the VMware environment.
    
    Sample profile and arguments that can be specified in it can be found here.
    
    CLI Example:
    
    salt-cloud -p vmware-centos6.5 vmname

salt.cloud.clouds.vmware.create_cluster(kwags=None, call=None)
    Create a new cluster under the specified datacenter in this VMware environment
    
    CLI Example:
    
    salt-cloud -f create_cluster my-vmware-config name="myNewCluster" datacenter="datacenterName"

salt.cloud.clouds.vmware.create_datacenter(kwags=None, call=None)
    Create a new data center in this VMware environment
    
    CLI Example:
    
    salt-cloud -f create_datacenter my-vmware-config name="MyNewDatacenter"

salt.cloud.clouds.vmware.create_datastore_cluster(kwags=None, call=None)
    Create a new datastore cluster for the specified datacenter in this VMware environment
    
    CLI Example:
    
    salt-cloud -f create_datastore_cluster my-vmware-config name="datastoreClusterName" datacenter="datacenterName"

salt.cloud.clouds.vmware.create_folder(kwags=None, call=None)
    Create the specified folder path in this VMware environment
    
    Note: To create a Host and Cluster Folder under a Datacenter, specify path="/yourDatacenterName/host/yourFolderName"
    
    To create a Network Folder under a Datacenter, specify path="/yourDatacenterName/network/yourFolderName"
    
    To create a Storage Folder under a Datacenter, specify path="/yourDatacenterName/datastore/yourFolderName"
    
    To create a VM and Template Folder under a Datacenter, specify path="/yourDatacenterName/vm/yourFolderName"
    
    CLI Example:
    
    salt-cloud -f create_folder my-vmware-config path="/Local/a/b/c"
    salt-cloud -f create_folder my-vmware-config path="/MyDatacenter/vm/MyVMFolder"
    salt-cloud -f create_folder my-vmware-config path="/MyDatacenter/host/MyHostFolder"
    salt-cloud -f create_folder my-vmware-config path="/MyDatacenter/network/MyNetworkFolder"
    salt-cloud -f create_folder my-vmware-config path="/MyDatacenter/storage/MyStorageFolder"

salt.cloud.clouds.vmware.create_snapshot(name, kwags=None, call=None)
    Create a snapshot of the specified virtual machine in this VMware environment
Note: If the VM is powered on, the internal state of the VM (memory dump) is included in the snapshot by default which will also set the power state of the snapshot to ‘powered on’. You can set memdump=False to override this. This field is ignored if the virtual machine is powered off or if the VM does not support snapshots with memory dumps. Default is memdump=True

Note: If the VM is powered on when the snapshot is taken, VMware Tools can be used to quiesce the file system in the virtual machine by setting quiesce=True. This field is ignored if the virtual machine is powered off; if VMware Tools are not available or if memdump=True. Default is quiesce=False

CLI Example:

```
salt-cloud -a create_snapshot vmname snapshot_name="mySnapshot"
salt-cloud -a create_snapshot vmname snapshot_name="mySnapshot" [description="My Snapshot"] [memdump=False] [quiesce=True]
```

salt.cloud.clouds.vmware.destroy(name, call=None)
To destroy a VM from the VMware environment

CLI Example:

```
salt-cloud -d vmname
salt-cloud --destroy vmname
salt-cloud -a destroy vmname
```

salt.cloud.clouds.vmware.disconnect_host(kwargs=None, call=None)
Disconnect the specified host system in this VMware environment

CLI Example:

```
salt-cloud -f disconnect_host my-vmware-config host="myHostSystemName"
```

salt.cloud.clouds.vmware.enter_maintenance_mode(kwargs=None, call=None)
To put the specified host system in maintenance mode in this VMware environment

CLI Example:

```
salt-cloud -f enter_maintenance_mode my-vmware-config host="myHostSystemName"
```

salt.cloud.clouds.vmware.exit_maintenance_mode(kwargs=None, call=None)
To take the specified host system out of maintenance mode in this VMware environment

CLI Example:

```
salt-cloud -f exit_maintenance_mode my-vmware-config host="myHostSystemName"
```

salt.cloud.clouds.vmware.get_dependencies()
Warn if dependencies aren’t met.

salt.cloud.clouds.vmware.get_vcenter_version(kwargs=None, call=None)
Show the vCenter Server version with build number.

CLI Example:

```
salt-cloud -f get_vcenter_version my-vmware-config
```

salt.cloud.clouds.vmware.list_clusters(kwargs=None, call=None)
List all the clusters for this VMware environment

CLI Example:
salt.cloud -f list_clusters my-vmware-config

salt.cloud.clouds.vmware.list_clusters_by_datacenter(kwargs=None, call=None)
List clusters for each datacenter; or clusters for a specified datacenter in this VMware environment

To list clusters for each datacenter:
CLI Example:
salt-cloud -f list_clusters_by_datacenter my-vmware-config

To list clusters for a specified datacenter:
CLI Example:
salt-cloud -f list_clusters_by_datacenter my-vmware-config datacenter="datacenterName"

salt.cloud.clouds.vmware.list_datacenters(kwargs=None, call=None)
List all the data centers for this VMware environment

CLI Example:
salt-cloud -f list_datacenters my-vmware-config

salt.cloud.clouds.vmware.list_datastore_clusters(kwargs=None, call=None)
List all the datastore clusters for this VMware environment

CLI Example:
salt-cloud -f list_datastore_clusters my-vmware-config

salt.cloud.clouds.vmware.list_datastores(kwargs=None, call=None)
List all the datastores for this VMware environment

CLI Example:
salt-cloud -f list_datastores my-vmware-config

salt.cloud.clouds.vmware.list_dvs(kwargs=None, call=None)
List all the distributed virtual switches for this VMware environment

CLI Example:
salt-cloud -f list_dvs my-vmware-config

salt.cloud.clouds.vmware.list_folders(kwargs=None, call=None)
List all the folders for this VMware environment

CLI Example:
salt-cloud -f list_folders my-vmware-config

salt.cloud.clouds.vmware.list_hbas(kwargs=None, call=None)
List all HBAs for each host system; or all HBAs for a specified host system; or HBAs of specified type for each
host system; or HBAs of specified type for a specified host system in this VMware environment

Note: You can specify type as either parallel, iscsi, block or fibre.

To list all HBAs for each host system:
CLI Example:
salt-cloud -f list_hbas my-vmware-config

To list all HBAs for a specified host system:
CLI Example:
salt-cloud -f list_hbas my-vmware-config host="hostSystemName"

To list HBAs of specified type for each host system:
CLI Example:
salt-cloud -f list_hbas my-vmware-config type="HBAType"

To list HBAs of specified type for a specified host system:
CLI Example:
salt-cloud -f list_hbas my-vmware-config host="hostSystemName" type="HBAType"

salt.cloud.clouds.vmware.list_hosts (kwargs=None, call=None)
List all the hosts for this VMware environment
CLI Example:
salt-cloud -f list_hosts my-vmware-config

salt.cloud.clouds.vmware.list_hosts_by_cluster (kwargs=None, call=None)
List hosts for each cluster; or hosts for a specified cluster in this VMware environment
To list hosts for each cluster:
CLI Example:
salt-cloud -f list_hosts_by_cluster my-vmware-config

To list hosts for a specified cluster:
CLI Example:
salt-cloud -f list_hosts_by_cluster my-vmware-config cluster="clusterName"

salt.cloud.clouds.vmware.list_hosts_by_datacenter (kwargs=None, call=None)
List hosts for each datacenter; or hosts for a specified datacenter in this VMware environment
To list hosts for each datacenter:
CLI Example:
salt-cloud -f list_hosts_by_datacenter my-vmware-config

To list hosts for a specified datacenter:
CLI Example:
salt-cloud -f list_hosts_by_datacenter my-vmware-config datacenter="datacenterName"

salt.cloud.clouds.vmware.list_networks (kwargs=None, call=None)
List all the standard networks for this VMware environment
CLI Example:
salt-cloud -f list_networks my-vmware-config

`salt.cloud.clouds.vmware.list_nodes`(kwargs=None, call=None)
Return a list of all VMs and templates that are on the specified provider, with basic fields

CLI Example:
salt-cloud -f list_nodes my-vmware-config

to return a list of all VMs and templates present on ALL configured providers, with basic fields:

CLI Example:
salt-cloud -Q

`salt.cloud.clouds.vmware.list_nodes_full`(kwargs=None, call=None)
Return a list of all VMs and templates that are on the specified provider, with full details

CLI Example:
salt-cloud -f list_nodes_full my-vmware-config

to return a list of all VMs and templates present on ALL configured providers, with full details:

CLI Example:
salt-cloud -F

`salt.cloud.clouds.vmware.list_nodes_min`(kwargs=None, call=None)
Return a list of all VMs and templates that are on the specified provider, with no details

CLI Example:
salt-cloud -f list_nodes_min my-vmware-config

`salt.cloud.clouds.vmware.list_nodes_select`(call=None)
Return a list of all VMs and templates that are on the specified provider, with fields specified under query.selection in /etc/salt/cloud

CLI Example:
salt-cloud -f list_nodes_select my-vmware-config

to return a list of all VMs and templates present on ALL configured providers, with fields specified under query.selection in /etc/salt/cloud:

CLI Example:
salt-cloud -S

`salt.cloud.clouds.vmware.list_resourcepools`(kwargs=None, call=None)
List all the resource pools for this VMware environment

CLI Example:
salt-cloud -f list_resourcepools my-vmware-config

`salt.cloud.clouds.vmware.list_snapshots`(kwargs=None, call=None)
List snapshots either for all VMs and templates or for a specific VM/template in this VMware environment

To list snapshots for all VMs and templates:

CLI Example:
To list snapshots for a specific VM/template:

**CLI Example:**

```bash
salt-cloud -f list_snapshots my-vmware-config name="vmname"
```

### `salt.cloud.clouds.vmware.list_templates` (kwargs=None, call=None)

List all the templates present in this VMware environment

**CLI Example:**

```bash
salt-cloud -f list_templates my-vmware-config
```

### `salt.cloud.clouds.vmware.list_vapps` (kwargs=None, call=None)

List all the vApps for this VMware environment

**CLI Example:**

```bash
salt-cloud -f list_vapps my-vmware-config
```

### `salt.cloud.clouds.vmware.reboot_host` (kwargs=None, call=None)

Reboot the specified host system in this VMware environment

**Note:** If the host system is not in maintenance mode, it will not be rebooted. If you want to reboot the host system regardless of whether it is in maintenance mode, set `force=True`. Default is `force=False`.

**CLI Example:**

```bash
salt-cloud -f reboot_host my-vmware-config host="myHostSystemName" [force=True]
```

### `salt.cloud.clouds.vmware.remove_all_snapshots` (name, kwargs=None, call=None)

Remove all the snapshots present for the specified virtual machine.

**Note:** All the snapshots higher up in the hierarchy of the current snapshot tree are consolidated and their virtual disks are merged. To override this behavior and only remove all snapshots, set `merge_snapshots=False`. Default is `merge_snapshots=True`.

**CLI Example:**

```bash
salt-cloud -a remove_all_snapshots vmname [merge_snapshots=False]
```

### `salt.cloud.clouds.vmware.remove_host` (kwargs=None, call=None)

Remove the specified host system from this VMware environment

**CLI Example:**

```bash
salt-cloud -f remove_host my-vmware-config host="myHostSystemName"
```

### `salt.cloud.clouds.vmware.rescan_hba` (kwargs=None, call=None)

To rescan a specified HBA or all the HBAs on the Host System

**CLI Example:**

```bash
salt-cloud -f rescan_hba my-vmware-config host="hostSystemName"
salt-cloud -f rescan_hba my-vmware-config hba="hbaDeviceName" host="hostSystemName"
```
salt.cloud.clouds.vmware.reset(name, call=None)

To reset a VM using its name

CLI Example:
```
salt-cloud -a reset vmname
```

salt.cloud.clouds.vmware.revert_to_snapshot(name, kwargs=None, call=None)

Revert virtual machine to its current snapshot. If no snapshot exists, the state of the virtual machine remains unchanged.

**Note:** The virtual machine will be powered on if the power state of the snapshot when it was created was set to "Powered On". Set `power_off=True` so that the virtual machine stays powered off regardless of the power state of the snapshot when it was created. Default is `power_off=False`.

If the power state of the snapshot when it was created was "Powered On" and if `power_off=True`, the VM will be put in suspended state after it has been reverted to the snapshot.

CLI Example:
```
salt-cloud -a revert_to_snapshot vmname [power_off=True]
```

salt.cloud.clouds.vmware.show_instance(name, call=None)

List all available details of the specified VM

CLI Example:
```
salt-cloud -a show_instance vmname
```

salt.cloud.clouds.vmware.start(name, call=None)

To start/power on a VM using its name

CLI Example:
```
salt-cloud -a start vmname
```

salt.cloud.clouds.vmware.stop(name, call=None)

To stop/power off a VM using its name

CLI Example:
```
salt-cloud -a stop vmname
```

salt.cloud.clouds.vmware.suspend(name, call=None)

To suspend a VM using its name

CLI Example:
```
salt-cloud -a suspend vmname
```

salt.cloud.clouds.vmware.terminate(name, call=None)

To do an immediate power off of a VM using its name. A SIGKILL is issued to the vmx process of the VM

CLI Example:
```
salt-cloud -a terminate vmname
```

salt.cloud.clouds.vmware.test_vcenter_connection(kwargs=None, call=None)

Test if the connection can be made to the vCenter server using the specified credentials inside `/etc/salt/cloud.providers` or `/etc/salt/cloud.providers.d/vmware.conf`

CLI Example:
salt-cloud -f test_vcenter_connection my-vmware-config

```
salt.cloud.clouds.vmware.upgrade_tools(name, reboot=False, call=None)
```
To upgrade VMware Tools on a specified virtual machine.

**Note:** If the virtual machine is running Windows OS, use `reboot=True` to reboot the virtual machine after VMware tools upgrade. Default is `reboot=False`

**CLI Example:**
```
salt-cloud -a upgrade_tools vmname
salt-cloud -a upgrade_tools vmname reboot=True
```

```
salt.cloud.clouds.vmware.upgrade_tools_all(call=None)
```
To upgrade VMware Tools on all virtual machines present in the specified provider.

**Note:** If the virtual machine is running Windows OS, this function will attempt to suppress the automatic reboot caused by a VMware Tools upgrade.

**CLI Example:**
```
salt-cloud -f upgrade_tools_all my-vmware-config
```

### 31.5.24 salt.cloud.clouds.vsphere

**vSphere Cloud Module**

**Note:** Deprecated since version Carbon: The `vsphere` cloud driver has been deprecated in favor of the `vmware` cloud driver and will be removed in Salt Carbon. Please refer to [Getting started with VMware](#) to get started and convert your vsphere provider configurations to use the vmware driver.

The vSphere cloud module is used to control access to VMware vSphere.

**depends** PySphere Python module >= 0.1.8

Note: Ensure python pysphere module is installed by running following one-liner check. The output should be 0.
```
python -c "import pysphere" ; echo $?  
# if this fails install using
pip install https://pysphere.googlecode.com/files/pysphere-0.1.8.zip
```

Use of this module only requires a URL, username and password. Set up the cloud configuration at:

```
/etc/salt/cloud.providers or /etc/salt/cloud.providers.d/vsphere.conf:
```

```
my-vsphere-config:
  driver: vsphere
  user: myuser
  password: verybadpass
  template_user: root
  template_password: mybadVMpassword
  url: 'https://10.1.1.1:443'
```

Note: Your URL may or may not look like any of the following, depending on how your VMWare installation is configured:

---

### 31.5. Full list of Salt Cloud modules

523
folder Name of the folder that will contain the new VM. If not set, the VM will be added to the folder the original VM belongs to.

resourcepool MOR of the resourcepool to be used for the new vm. If not set, it uses the same resourcepool than the original vm.

datastore MOR of the datastore where the virtual machine should be located. If not specified, the current datastore is used.

host MOR of the host where the virtual machine should be registered.

   **Id not specified:**
   - if resourcepool is not specified, current host is used.
   - if resourcepool is specified, and the target pool represents a stand-alone host, the host is used.
   - if resourcepool is specified, and the target pool represents a DRS-enabled cluster, a host selected by DRS is used.
   - if resourcepool is specified and the target pool represents a cluster without DRS enabled, an InvalidArgument exception will be thrown.

template Specifies whether or not the new virtual machine should be marked as a template. Default is False.

template_user Specifies the user to access the VM. Should be

template_password The password with which to access the VM.

sudo The user to access the VM with sudo privileges.

   New in version 2015.5.2.

sudo_password The password corresponding to the sudo user to access the VM with sudo privileges.

   New in version 2015.5.2.

salt.cloud.clouds.vsphere.avail_images() Return a dict of all available VM images on the cloud provider.

salt.cloud.clouds.vsphere.avail_locations() Return a dict of all available VM locations on the cloud provider with relevant data

salt.cloud.clouds.vsphere.create(vm_) Create a single VM from a data dict

salt.cloud.clouds.vsphere.create_snapshot(**kwargs=\{None, call=None\}) Create a snapshot

   @name: Name of the virtual machine to snapshot @snapshot: Name of the snapshot @description: Description of the snapshot (optional) @memory: Dump of the internal state of the virtual machine (optional)

   New in version 2015.8.0.

   CLI Example:

```
salt-cloud -f create_snapshot [PROVIDER] name=myvm.example.com snapshot=mysnapshot
salt-cloud -f create_snapshot [PROVIDER] name=myvm.example.com snapshot=mysnapshot description=''
```
**salt.cloud.clouds.vsphere.delete_snapshot** *(kwargs=\text{None}, \text{call}=\text{None})*
Delete snapshot

New in version 2015.8.0.

CLI Example:
```
salt-cloud -f delete_snapshot [PROVIDER] name=myvm.example.com snapshot=mysnapshot
```

**salt.cloud.clouds.vsphere.destroy**(name, \text{call}=\text{None})*
Destroy a node.

CLI Example:
```
salt-cloud --destroy mymachine
```

**salt.cloud.clouds.vsphere.get_configured_provider()**
Return the first configured instance.

**salt.cloud.clouds.vsphere.get_conn()**
Return a conn object for the passed VM data

**salt.cloud.clouds.vsphere.get_dependencies()**
Warn if dependencies aren’t met.

**salt.cloud.clouds.vsphere.list_clusters**(kwargs=\text{None}, \text{call}=\text{None})*
List the clusters for this VMware environment

**salt.cloud.clouds.vsphere.list_datacenters**(kwargs=\text{None}, \text{call}=\text{None})*
List the data centers for this VMware environment

**salt.cloud.clouds.vsphere.list_datastores**(kwargs=\text{None}, \text{call}=\text{None})*
List the datastores for this VMware environment

**salt.cloud.clouds.vsphere.list_folders**(kwargs=\text{None}, \text{call}=\text{None})*
List the folders for this VMware environment

**salt.cloud.clouds.vsphere.list_hosts**(kwargs=\text{None}, \text{call}=\text{None})*
List the hosts for this VMware environment

**salt.cloud.clouds.vsphere.list_nodes**(kwargs=\text{None}, \text{call}=\text{None})*
Return a list of the VMs that are on the provider, with basic fields

**salt.cloud.clouds.vsphere.list_nodes_full**(kwargs=\text{None}, \text{call}=\text{None})*
Return a list of the VMs that are on the provider with full details

**salt.cloud.clouds.vsphere.list_nodes_min**(kwargs=\text{None}, \text{call}=\text{None})*
Return a list of the nodes in the provider, with no details

**salt.cloud.clouds.vsphere.list_nodes_select()**
Return a list of the VMs that are on the provider, with select fields

**salt.cloud.clouds.vsphere.list_resourcepools**(kwargs=\text{None}, \text{call}=\text{None})*
List the hosts for this VMware environment

**salt.cloud.clouds.vsphere.reset**(name, \text{call}=\text{None})*
To reset a VM using its name

CLI Example:
```
salt-cloud -a reset vmname
```

**salt.cloud.clouds.vsphere.script**(vm_)*
Return the script deployment object
salt.cloud.clouds.vsphere.show_instance(name, call=None)
    Show the details from vSphere concerning a guest

salt.cloud.clouds.vsphere.snapshot_list(kwarg=None, call=None)
    List virtual machines with snapshots
    New in version 2015.8.0.
    CLI Example:
    ```
salt-cloud -f snapshot_list
    ```

salt.cloud.clouds.vsphere.start(name, call=None)
    To start/power on a VM using its name
    CLI Example:
    ```
salt-cloud -a start vmname
    ```

salt.cloud.clouds.vsphere.status(name, call=None)
    To check the status of a VM using its name
    CLI Example:
    ```
salt-cloud -a status vmname
    ```

salt.cloud.clouds.vsphere.stop(name, call=None)
    To stop/power off a VM using its name
    CLI Example:
    ```
salt-cloud -a stop vmname
    ```

salt.cloud.clouds.vsphere.suspend(name, call=None)
    To suspend a VM using its name
    CLI Example:
    ```
salt-cloud -a suspend vmname
    ```

salt.cloud.clouds.vsphere.wait_for_ip(vm_)

31.6 Configuration file examples

- Example master configuration file
- Example minion configuration file

31.6.1 Example master configuration file

```
##### Primary configuration settings #####
###############################################################
# This configuration file is used to manage the behavior of the Salt Master. #
# Values that are commented out but have an empty line after the comment are #
# defaults that do not need to be set in the config. If there is no blank line #
# after the comment then the value is presented as an example and is not the #
# default.
```
# Per default, the master will automatically include all config files
# from master.d/*.conf (master.d is a directory in the same directory
# as the main master config file).
#default_include: master.d/*.conf

# The address of the interface to bind to:
#interface: 0.0.0.0

# Whether the master should listen for IPv6 connections. If this is set to True,
# the interface option must be adjusted, too. (For example: "interface: '::")
#ipv6: False

# The tcp port used by the publisher:
#publish_port: 4505

# The user under which the salt master will run. Salt will update all
# permissions to allow the specified user to run the master. The exception is
# the job cache, which must be deleted if this user is changed. If the
# modified files cause conflicts, set verify_env to False.
#user: root

# Max open files
#
# Each minion connecting to the master uses AT LEAST one file descriptor, the
# master subscription connection. If enough minions connect you might start
# seeing on the console (and then salt-master crashes):
# Too many open files (tcp_listener.cpp:335)
# Aborted (core dumped)
#
# By default this value will be the one of `ulimit -Hn`, ie, the hard limit for
# max open files.
#
# If you wish to set a different value than the default one, uncomment and
# configure this setting. Remember that this value CANNOT be higher than the
# hard limit. Raising the hard limit depends on your OS and/or distribution,
# a good way to find the limit is to search the internet. For example:
# raise max open files hard limit debian
#
#max_open_files: 100000

# The number of worker threads to start. These threads are used to manage
# return calls made from minions to the master. If the master seems to be
# running slowly, increase the number of threads. This setting can not be
# set lower than 3.
#worker_threads: 5

# The port used by the communication interface. The ret (return) port is the
# interface used for the file server, authentication, job returns, etc.
#ret_port: 4506

# Specify the location of the daemon process ID file:
#pidfile: /var/run/salt-master.pid

# The root directory prepended to these options: pki_dir, cachedir,
# sock_dir, log_file, autosign_file, autoreject_file, extension_modules,
# key_logfile, pidfile:
#root_dir: /
# Directory used to store public key data:
#pki_dir: /etc/salt/pki/master

# Directory to store job and cache data:
# This directory may contain sensitive data and should be protected accordingly.
#
#cachedir: /var/cache/salt/master

# Directory for custom modules. This directory can contain subdirectories for
# each of Salt's module types such as "runners", "output", "wheel", "modules",
# "states", "returners", etc.
#extension_modules: <no default>

# Directory for custom modules. This directory can contain subdirectories for
# each of Salt's module types such as "runners", "output", "wheel", "modules",
# "states", "returners", etc.
# Like 'extension_modules' but can take an array of paths
#module_dirs: <no default>
# - /var/cache/salt/minion/extmods

# Verify and set permissions on configuration directories at startup:
#verify_env: True

# Set the number of hours to keep old job information in the job cache:
#keep_jobs: 24

# Set the default timeout for the salt command and api. The default is 5
# seconds.
#timeout: 5

# The loop_interval option controls the seconds for the master's maintenance
# process check cycle. This process updates file server backends, cleans the
# job cache and executes the scheduler.
#loop_interval: 60

# Set the default outputter used by the salt command. The default is "nested".
#output: nested

# Return minions that timeout when running commands like test.ping
#show_timeout: True

# By default, output is colored. To disable colored output, set the color value
# to False.
#color: True

# Do not strip off the colored output from nested results and state outputs
# (true by default).
#strip_colors: False

# Set the directory used to hold unix sockets:
#sock_dir: /var/run/salt/master

# The master can take a while to start up when lspci and/or dmidecode is used
# to populate the grains for the master. Enable if you want to see GPU hardware
# data for your master.
#enable_gpu_grains: False

# The master maintains a job cache. While this is a great addition, it can be
# a burden on the master for larger deployments (over 5000 minions).
Disabling the job cache will make previously executed jobs unavailable to
the jobs system and is not generally recommended.

```
#job_cache: True
```

# Cache minion grains and pillar data in the cachedir.
```
#minion_data_cache: True
```

# Store all returns in the given returner.
Setting this option requires that any returner-specific configuration also
be set. See various returners in salt/returners for details on required
configuration values. (See also, event_return_queue below.)
```
#event_return: mysql
```

On busy systems, enabling event_returns can cause a considerable load on
the storage system for returners. Events can be queued on the master and
stored in a batched fashion using a single transaction for multiple events.
By default, events are not queued.

```
#event_return_queue: 0
```

# Only events returns matching tags in a whitelist
```
#event_return_whitelist:
#    - salt/master/a_tag
#    - salt/master/another_tag
```

# Store all event returns _except_ the tags in a blacklist
```
#event_return_blacklist:
#    - salt/master/not_this_tag
#    - salt/master/or_this_one
```

Passing very large events can cause the minion to consume large amounts of
memory. This value tunes the maximum size of a message allowed onto the
master event bus. The value is expressed in bytes.
```
#max_event_size: 1048576
```

By default, the master AES key rotates every 24 hours. The next command
following a key rotation will trigger a key refresh from the minion which may
result in minions which do not respond to the first command after a key refresh.

```
#ping_on_rotate: False
```

To tell the master to ping all minions immediately after an AES key refresh, set
`ping_on_rotate` to True. This should mitigate the issue where a minion does not
appear to initially respond after a key is rotated.

```
# Note that ping_on_rotate may cause high load on the master immediately after
# the key rotation event as minions reconnect. Consider this carefully if this
# salt master is managing a large number of minions.
```

If disabled, it is recommended to handle this event by listening for the
'aes_key_rotate' event with the 'key' tag and acting appropriately.
```
# WARNING: This may have security implications if compromised minions auth with
# a previous deleted minion ID.
```
#preserve_minion_cache: False

# If max_minions is used in large installations, the master might experience
# high-load situations because of having to check the number of connected
# minions for every authentication. This cache provides the minion-ids of
# all connected minions to all MWorker-processes and greatly improves the
# performance of max_minions.
# con_cache: False

# The master can include configuration from other files. To enable this,
# pass a list of paths to this option. The paths can be either relative or
# absolute; if relative, they are considered to be relative to the directory
# the main master configuration file lives in (this file). Paths can make use
# of shell-style globbing. If no files are matched by a path passed to this
# option, then the master will log a warning message.
#
# Include a config file from some other path:
# include: /etc/salt/extra_config
#
# Include config from several files and directories:
# include:
# - /etc/salt/extra_config

####### Security settings #######

Security settings

# Enable "open mode", this mode still maintains encryption, but turns off
# authentication, this is only intended for highly secure environments or for
# the situation where your keys end up in a bad state. If you run in open mode
# you do so at your own risk!
#open_mode: False

# Enable auto_accept, this setting will automatically accept all incoming
# public keys from the minions. Note that this is insecure.
#auto_accept: False

# Time in minutes that a incoming public key with a matching name found in
# pki_dir/minion_autosign/keyid is automatically accepted. Expired autosign keys
# are removed when the master checks the minion_autosign directory.
# 0 equals no timeout
# autosign_timeout: 120

# If the autosign_file is specified, incoming keys specified in the
# autosign_file will be automatically accepted. This is insecure. Regular
# expressions as well as globing lines are supported.
# autosign_file: /etc/salt/autosign.conf

# Works like autosign_file, but instead allows you to specify minion IDs for
# which keys will automatically be rejected. Will override both membership in
# the autosign_file and the auto_accept setting.
# autoreject_file: /etc/salt/autoreject.conf

# Enable permissive access to the salt keys. This allows you to run the
# master or minion as root, but have a non-root group be given access to
# your pki_dir. To make the access explicit, root must belong to the group
# you've given access to. This is potentially quite insecure. If an autosign_file
# is specified, enabling permissive_pki_access will allow group access to that
# specific file.
#permissive_pki_access: False

# Allow users on the master access to execute specific commands on minions.
# This setting should be treated with care since it opens up execution
# capabilities to non root users. By default this capability is completely
# disabled.
#client_acl:
# larry:
#  - test.ping
#  - network.*
#
# Blacklist any of the following users or modules
#
# This example would blacklist all non sudo users, including root from
# running any commands. It would also blacklist any use of the "cmd"
# module. This is completely disabled by default.
#client_acl_blacklist:
# users:
#  - root
#  - '^(?![?!sudo_]).*$' # all non sudo users
# modules:
#  - cmd

# Enforce client_acl & client_acl_blacklist when users have sudo
# access to the salt command.
#
#sudo_acl: False

# The external auth system uses the Salt auth modules to authenticate and
# validate users to access areas of the Salt system.
#external_auth:
# pam:
#  fred:
#   - test.*
#
# Time (in seconds) for a newly generated token to live. Default: 12 hours
#token_expire: 43200

# Allow minions to push files to the master. This is disabled by default, for
# security purposes.
#file_recv: False

# Set a hard-limit on the size of the files that can be pushed to the master.
# It will be interpreted as megabytes. Default: 100
#file_recv_max_size: 100

# Signature verification on messages published from the master.
# This causes the master to cryptographically sign all messages published to its event
# bus, and minions then verify that signature before acting on the message.
#
# This is False by default.
#
# Note that to facilitate interoperability with masters and minions that are different
# versions, if sign_pub_messages is True but a message is received by a minion with
# no signature, it will still be accepted, and a warning message will be logged.
# Conversely, if sign_pub_messages is False, but a minion receives a signed
# message it will be accepted, the signature will not be checked, and a warning message
# will be logged. This behavior went away in Salt 2014.1.0 and these two situations
# will cause minion to throw an exception and drop the message.
# sign_pub_messages: False

##### Salt-SSH Configuration #####

# Pass in an alternative location for the salt-ssh roster file
#roster_file: /etc/salt/roster

# Pass in minion option overrides that will be inserted into the SHIM for
# salt-ssh calls. The local minion config is not used for salt-ssh. Can be
# overridden on a per-minion basis in the roster (`minion_opts`)
#ssh_minion_opts:
#  gpg_keydir: /root/gpg

##### Master Module Management #####

# Manage how master side modules are loaded.

# Add any additional locations to look for master runners:
#runner_dirs: []

# Enable Cython for master side modules:
#cython_enable: False

##### State System settings #####

# The state system uses a "top" file to tell the minions what environment to
# use and what modules to use. The state_top file is defined relative to the
# root of the base environment as defined in "File Server settings" below.
#state_top: top.sls

# The master_tops option replaces the external_nodes option by creating
# a pluggable system for the generation of external top data. The external_nodes
# option is deprecated by the master_tops option.
#master_tops:
#  ext_nodes: <Shell command which returns yaml>
#master_tops: {}
# (block, not variable tag!). Defaults to False, corresponds to the Jinja
# environment init variable "trim_blocks".
#jinja_trim_blocks: False
#
# If this is set to True leading spaces and tabs are stripped from the start
# of a line to a block. Defaults to False, corresponds to the Jinja
# environment init variable "lstrip_blocks".
#jinja_lstrip_blocks: False
#
# The failhard option tells the minions to stop immediately after the first
# failure detected in the state execution, defaults to False
#failhard: False
#
# The state_verbose and state_output settings can be used to change the way
# state system data is printed to the display. By default all data is printed.
# The state_verbose setting can be set to True or False, when set to False
# all data that has a result of True and no changes will be suppressed.
#state_verbose: True
#
# The state_output setting changes if the output is the full multi line
# output for each changed state if set to 'full', but if set to 'terse'
# the output will be shortened to a single line. If set to 'mixed', the output
# will be terse unless a state failed, in which case that output will be full.
# If set to 'changes', the output will be full unless the state didn't change.
#state_output: full
#
# Automatically aggregate all states that have support for mod_aggregate by
# setting to 'True'. Or pass a list of state module names to automatically
# aggregate just those types.
#
# state_aggregate:
# - pkg
#
#state_aggregate: False
#
# Send progress events as each function in a state run completes execution
# by setting to 'True'. Progress events are in the format
# 'salt/job/<JID>/prog/<MID>/<RUN NUM>'
#state_events: False
#
##### File Server settings #####
##########################################
# Salt runs a lightweight file server written in zeromq to deliver files to
# minions. This file server is built into the master daemon and does not
# require a dedicated port.
#
# The file server works on environments passed to the master, each environment
# can have multiple root directories, the subdirectories in the multiple file
# roots cannot match, otherwise the downloaded files will not be able to be
# reliably ensured. A base environment is required to house the top file.
# Example:
# file_roots:
# base:
# - /srv/salt/
# dev:
# - /srv/salt/dev/services
# - /srv/salt/dev/states
# prod:
# - /srv/salt/prod/services
# - /srv/salt/prod/states
#
#file_roots:
# base:
# - /srv/salt
#

# When using multiple environments, each with their own top file, the
# default behaviour is an unordered merge. To prevent top files from
# being merged together and instead to only use the top file from the
# requested environment, set this value to 'same'.
#top_file_merging_strategy: merge
#
# To specify the order in which environments are merged, set the ordering
# in the env_order option. Given a conflict, the last matching value will
# win.
#env_order: ['base', 'dev', 'prod']
#
# If top_file_merging_strategy is set to 'same' and an environment does not
# contain a top file, the top file in the environment specified by default_top
# will be used instead.
#default_top: base
#
# The hash_type is the hash to use when discovering the hash of a file on
# the master server. The default is md5, but sha1, sha224, sha256, sha384
# and sha512 are also supported.
#
# Prior to changing this value, the master should be stopped and all Salt
# caches should be cleared.
#hash_type: md5
#
# The buffer size in the file server can be adjusted here:
#file_buffer_size: 1048576
#
# A regular expression (or a list of expressions) that will be matched
# against the file path before syncing the modules and states to the minions.
# This includes files affected by the file.recurse state.
# For example, if you manage your custom modules and states in subversion
# and don't want all the '.svn' folders and content synced to your minions,
# you could set this to '/\./svn($|/)'. By default nothing is ignored.
#file_ignore_regex:
# - '/\./svn($|/)'
# - '/\./git($|/)'
#
# A file glob (or list of file globs) that will be matched against the file
# path before syncing the modules and states to the minions. This is similar
# to file_ignore_regex above, but works on globs instead of regex. By default
# nothing is ignored.
#file_ignore_glob:
# - '*.pyc'
# - '*somefolder/*.bak'
# - '*.swp'

# File Server Backend
#
# Salt supports a modular fileserver backend system, this system allows
# the salt master to link directly to third party systems to gather and
# manage the files available to minions. Multiple backends can be
# configured and will be searched for the requested file in the order in which
# they are defined here. The default setting only enables the standard backend
# "roots" which uses the "file_roots" option.
#fileserver_backend:
# - roots
#
# To use multiple backends list them in the order they are searched:
#fileserver_backend:
# - git
# - roots
#
# Uncomment the line below if you do not want the file_server to follow
# symlinks when walking the filesystem tree. This is set to True
# by default. Currently this only applies to the default roots
#fileserver_followsymlinks: False
#
# Uncomment the line below if you do not want symlinks to be
# treated as the files they are pointing to. By default this is set to
# False. By uncommenting the line below, any detected symlink while listing
# files on the Master will not be returned to the Minion.
#fileserver_ignoresymlinks: True
#
# By default, the Salt fileserver recurses fully into all defined environments
# to attempt to find files. To limit this behavior so that the fileserver only
# traverses directories with SLS files and special Salt directories like _modules,
# enable the option below. This might be useful for installations where a file root
# has a very large number of files and performance is impacted. Default is False.
#fileserver_limit_traversal: False
#
# The fileserver can fire events off every time the fileserver is updated,
# these are disabled by default, but can be easily turned on by setting this
# flag to True
#fileserver_events: False

# Git File Server Backend Configuration
#
# Gitfs can be provided by one of two python modules: GitPython or pygit2. If
# using pygit2, both libgit2 and git must also be installed.
#gitfs_provider: gitpython
#
# When using the git fileserver backend at least one git remote needs to be
# defined. The user running the salt master will need read access to the repo.
# The repos will be searched in order to find the file requested by a client
# and the first repo to have the file will return it.
# When using the git backend branches and tags are translated into salt
# environments.
# Note: file:// repos will be treated as a remote, so refs you want used must
# exist in that repo as *local* refs.
#gitfs_remotes:
# - git://github.com/saltstack/salt-states.git
# - file:///var/git/saltmaster
#
# The gitfs_ssl_verify option specifies whether to ignore ssl certificate
# errors when contacting the gitfs backend. You might want to set this to
# false if you're using a git backend that uses a self-signed certificate but
# keep in mind that setting this flag to anything other than the default of True
# is a security concern, you may want to try using the ssh transport.
#gitfs_ssl_verify: True
#
# The gitfs_root option gives the ability to serve files from a subdirectory
# within the repository. The path is defined relative to the root of the
# repository and defaults to the repository root.
#gitfs_root: somefolder/otherfolder
#
### Pillar settings ###
Salt Pillars allow for the building of global data that can be made selectively
available to different minions based on minion grain filtering. The Salt
Pillar is laid out in the same fashion as the file server, with environments,
a top file and sls files. However, pillar data does not need to be in the
highstate format, and is generally just key/value pairs.
#pillar_roots:
#  base:
#  - /srv/pillar
#ext_pillar:
#  - hiera: /etc/hiera.yaml
#  - cmd_yaml: cat /etc/salt/yaml

# The ext_pillar_first option allows for external pillar sources to populate
# before file system pillar. This allows for targeting file system pillar from
# ext_pillar.
#ext_pillar_first: False

# The pillar_gitfs_ssl_verify option specifies whether to ignore ssl certificate
# errors when contacting the pillar gitfs backend. You might want to set this to
# false if you're using a git backend that uses a self-signed certificate but
# keep in mind that setting this flag to anything other than the default of True
# is a security concern, you may want to try using the ssh transport.
#pillar_gitfs_ssl_verify: True

# The pillar_opts option adds the master configuration file data to a dict in
# the pillar called "master". This is used to set simple configurations in the
# master config file that can then be used on minions.
#pillar_opts: False

# The pillar_safe_render_error option prevents the master from passing pillar
# render errors to the minion. This is set on by default because the error could
# contain templating data which would give that minion information it shouldn't
# have, like a password! When set true the error message will only show:
#  Rendering SLS 'my.sls' failed. Please see master log for details.
#pillar_safe_render_error: True

# The pillar_source_merging_strategy option allows you to configure merging strategy
# between different sources. It accepts four values: recurse, aggregate, overwrite,
# or smart. Recurse will merge recursively mapping of data. Aggregate instructs
# aggregation of elements between sources that use the `!yamlex` renderer. Overwrite
# will overwrite elements according the order in which they are processed. This is
# behavior of the 2014.1 branch and earlier. Smart guesses the best strategy based
# on the "renderer" setting and is the default value.
#pillar_source_merging_strategy: smart
# Syndic settings

The Salt syndic is used to pass commands through a master from a higher master. Using the syndic is simple. If this is a master that will have syndic servers(s) below it, then set the "order_masters" setting to True. If this is a master that will be running a syndic daemon for passthrough, then the "syndic_master" setting needs to be set to the location of the master server to receive commands from.

Set the order_masters setting to True if this master will command lower masters' syndic interfaces.

```yaml
#order_masters: False
```

If this master will be running a salt syndic daemon, syndic_master tells this master where to receive commands from.

```yaml
#syndic_master: masterofmaster
```

This is the 'ret_port' of the MasterOfMaster:

```yaml
#syndic_master_port: 4506
```

PID file of the syndic daemon:

```yaml
#syndic_pidfile: /var/run/salt-syndic.pid
```

LOG file of the syndic daemon:

```yaml
#syndic_log_file: syndic.log
```

# Peer Publish settings

Salt minions can send commands to other minions, but only if the minion is allowed to. By default "Peer Publication" is disabled, and when enabled it is enabled for specific minions and specific commands. This allows secure compartmentalization of commands based on individual minions.

The configuration uses regular expressions to match minions and then a list of regular expressions to match functions. The following will allow the minion authenticated as foo.example.com to execute functions from the test and pkg modules.

```yaml
#peer:
# foo.example.com:
# - test.*
# - pkg.*
```

This will allow all minions to execute all commands:

```yaml
#peer:
# .*:
# - .*
```

This is not recommended, since it would allow anyone who gets root on any single minion to instantly have root on all of the minions!

Minions can also be allowed to execute runners from the salt master. Since executing a runner from the minion could be considered a security risk, it needs to be enabled. This setting functions just like the peer setting except that it opens up runners instead of module functions.

```yaml
# All peer runner support is turned off by default and must be enabled before
```
# using. This will enable all peer runners for all minions:
#peer_run:
#  .*:
#    - .*
#    
# To enable just the manage.up runner for the minion foo.example.com:
#peer_run:
#  foo.example.com:
#    - manage.up
#
##### Mine settings #####
##########################################
# Restrict mine.get access from minions. By default any minion has a full access
# to get all mine data from master cache. In acl definition below, only pcre matches
# are allowed.
#mine_get:
#  .*:
#    - .*
#    
# The example below enables minion foo.example.com to get 'network.interfaces' mine
data only, minions web* to get all network.* and disk.* mine data and all other
# minions won't get any mine data.
#mine_get:
#  foo.example.com:
#    - network.interfaces
#  web.*:
#    - network.*
#    - disk.*

##### Logging settings #####
##########################################
# The location of the master log file
# The master log can be sent to a regular file, local path name, or network
# location. Remote logging works best when configured to use rsyslogd(8) (e.g.:
# `file:///dev/log`), with rsyslogd(8) configured for network logging. The URI
# format is: <file|udp|tcp>:<host|socketpath>:<port-if-required>/<log-facility>
#log_file: /var/log/salt/master
#log_file: file:///dev/log
#log_file: udp://loghost:10514

#log_file: /var/log/salt/master
#key_logfile: /var/log/salt/key

# The level of messages to send to the console.
# One of 'garbage', 'trace', 'debug', 'info', 'warning', 'error', 'critical'.
#log_level: warning

# The level of messages to send to the log file.
# One of 'garbage', 'trace', 'debug', 'info', 'warning', 'error', 'critical'.
# If using 'log_granular_levels' this must be set to the highest desired level.
#log_level_logfile: warning

# The date and time format used in log messages. Allowed date/time formatting
# can be seen here: http://docs.python.org/library/time.html#time.strftime
#log_datefmt: '%H:%M:%S'
#log_datefmt_logfile: '%Y-%m-%d %H:%M:%S'
# The format of the console logging messages. Allowed formatting options can
# be seen here: http://docs.python.org/library/logging.html#logrecord-attributes
#
# Console log colors are specified by these additional formatters:
#
# %(colorlevel)s
# %(colormsg)s
#
# Since it is desirable to include the surrounding brackets, '[' and ']', in
# the coloring of the messages, these color formatters also include padding as
# well. Color LogRecord attributes are only available for console logging.
#
#log_fmt_console: '%(colorlevel)s %(colormsg)s'
#log_fmt_console: '
#log_fmt_logfile: '%(asctime)s,%(msecs)03.0f [%(name)-17s][%(levelname)-8s] %(message)s'
#
# This can be used to control logging levels more specifically. This
# example sets the main salt library at the 'warning' level, but sets
# 'salt.modules' to log at the 'debug' level:
#log_granular_levels:
#   'salt': 'warning'
#   'salt.modules': 'debug'
#
#log_granular_levels: {}

##### Node Groups ####
############################################################
# Node groups allow for logical groupings of minion nodes. A group consists of a group
# name and a compound target.
#nodegroups:
#   group1: 'L@foo.domain.com,bar.domain.com,baz.domain.com and bl*.domain.com'
#   group2: 'G@os:Debian and foo.domain.com'

##### Range Cluster settings ####
############################################################
# The range server (and optional port) that serves your cluster information
# https://github.com/ytoolshed/range/wiki/%22yamlfile%22-module-file-spec
#range_server: range:80

##### Windows Software Repo settings ####
############################################################
# Location of the repo on the master:
#win_repo: '/srv/salt/win/repo'
#
# Location of the master's repo cache file:
#win_repo_mastercachefile: '/srv/salt/win/repo/winrepo.p'
#
# List of git repositories to include with the local repo:
#win_gitrepos:
# - 'https://github.com/saltstack/salt-winrepo.git'
##### Returner settings ######

# Which returner(s) will be used for minion's result:
#return: mysql

## 31.6.2 Example minion configuration file

##### Primary configuration settings #####

# This configuration file is used to manage the behavior of the Salt Minion.
# With the exception of the location of the Salt Master Server, values that are
# commented out but have an empty line after the comment are defaults that need
# not be set in the config. If there is no blank line after the comment, the
# value is presented as an example and is not the default.

# Per default the minion will automatically include all config files
# from minion.d/*.conf (minion.d is a directory in the same directory
# as the main minion config file).
#default_include: minion.d/*.conf

# Set the location of the salt master server. If the master server cannot be
# resolved, then the minion will fail to start.
#master: salt

# If multiple masters are specified in the 'master' setting, the default behavior
# is to always try to connect to them in the order they are listed. If random_master is
# set to True, the order will be randomized instead. This can be helpful in distributing
# the load of many minions executing salt-call requests, for example, from a cron job.
# If only one master is listed, this setting is ignored and a warning will be logged.
#random_master: False

# Minions can connect to multiple masters simultaneously (all masters
# are "hot"), or can be configured to failover if a master becomes
# unavailable. Multiple hot masters are configured by setting this
# value to "str". Failover masters can be requested by setting
# to "failover". MAKE SURE TO SET master_alive_interval if you are
# using failover.
#master_type: str

# Poll interval in seconds for checking if the master is still there. Only
# respected if master_type above is "failover".
#master_alive_interval: 30

# Set whether the minion should connect to the master via IPv6:
#ipv6: False

# Set the number of seconds to wait before attempting to resolve
# the master hostname if name resolution fails. Defaults to 30 seconds.
# Set to zero if the minion should shutdown and not retry.
#retry_dns: 30

# Set the port used by the master reply and authentication server.
#master_port: 4506

# The user to run salt.
#user: root
# Setting sudo_user will cause salt to run all execution modules under an sudo
# to the user given in sudo_user. The user under which the salt minion process
# itself runs will still be that provided in the user config above, but all
# execution modules run by the minion will be rerouted through sudo.
#sudo_user: saltdev

# Specify the location of the daemon process ID file.
#pidfile: /var/run/salt-minion.pid

# The root directory prepended to these options: pki_dir, cachedir, log_file,
# sock_dir, pidfile.
#root_dir:

# The directory to store the pki information in
#pki_dir: /etc/salt/pki/minion

# Explicitly declare the id for this minion to use, if left commented the id
# will be the hostname as returned by the python call: socket.getfqdn()
# Since salt uses detached ids it is possible to run multiple minions on the
# same machine but with different ids, this can be useful for salt compute
# clusters.
#id:

# Append a domain to a hostname in the event that it does not exist. This is
# useful for systems where socket.getfqdn() does not actually result in a
# FQDN (for instance, Solaris).
#append_domain:

# Custom static grains for this minion can be specified here and used in SLS
# files just like all other grains. This example sets 4 custom grains, with
# the 'roles' grain having two values that can be matched against.
#grains:
#  roles:
#    - webserver
#    - memcache
#  deployment: datacenter4
#  cabinet: 13
#  cab_u: 14-15
#
# Where cache data goes.
# This data may contain sensitive data and should be protected accordingly.
cachedir: /var/cache/salt/minion

# Verify and set permissions on configuration directories at startup.
#verify_env: True

# The minion can locally cache the return data from jobs sent to it, this
# can be a good way to keep track of jobs the minion has executed
# (on the minion side). By default this feature is disabled, to enable, set
# cache_jobs to True.
#cache_jobs: False

# Set the directory used to hold unix sockets.
#sock_dir: /var/run/salt/minion

# Set the default outputter used by the salt-call command. The default is
# "nested".
#output: nested
# By default output is colored. To disable colored output, set the color value # to False.
#color: True

# Do not strip off the colored output from nested results and state outputs
# (true by default).
# strip_colors: False

# Backup files that are replaced by file.managed and file.recurse under 
# 'cachedir'/file_backups relative to their original location and appended 
# with a timestamp. The only valid setting is "minion". Disabled by default.
# Alternatively this can be specified for each file in state files: 
#/etc/ssh/sshd_config:
# file.managed:
#   - source: salt://ssh/sshd_config
#   - backup: minion
#
# backup_mode: minion

# When waiting for a master to accept the minion's public key, salt will 
# continuously attempt to reconnect until successful. This is the time, in 
# seconds, between those reconnection attempts.
# acceptance_wait_time: 10

# If this is nonzero, the time between reconnection attempts will increase by 
# acceptance_wait_time seconds per iteration, up to this maximum. If this is 
# set to zero, the time between reconnection attempts will stay constant.
# acceptance_wait_time_max: 0

# If the master rejects the minion's public key, retry instead of exiting.
# Rejected keys will be handled the same as waiting on acceptance.
# rejected_retry: False

# When the master key changes, the minion will try to re-auth itself to receive
# the new master key. In larger environments this can cause a SYN flood on the
# master because all minions try to re-auth immediately. To prevent this and
# have a minion wait for a random amount of time, use this optional parameter.
# The wait-time will be a random number of seconds between 0 and the defined value.
# random_reauth_delay: 60

# When waiting for a master to accept the minion's public key, salt will 
# continuously attempt to reconnect until successful. This is the timeout value, 
# in seconds, for each individual attempt. After this timeout expires, the minion 
# will wait for acceptance_wait_time seconds before trying again. Unless your master 
# is under unusually heavy load, this should be left at the default.
# auth_timeout: 60

# Number of consecutive SaltReqTimeoutError that are acceptable when trying to 
# authenticate.
# auth_tries: 7

# If authentication fails due to SaltReqTimeoutError during a ping_interval, 
# cause sub minion process to restart.
# auth_safemode: False

# Ping Master to ensure connection is alive (minutes).
#ping_interval: 0

# To auto recover minions if master changes IP address (DDNS)
# auth_tries: 10
# auth_safemode: False
# ping_interval: 90
#
# Minions won't know master is missing until a ping fails. After the ping fail,
# the minion will attempt authentication and likely fails out and cause a restart.
# When the minion restarts it will resolve the masters IP and attempt to reconnect.

# If you don't have any problems with syn-floods, don't bother with the
# three recon_* settings described below, just leave the defaults!
# The ZeroMQ pull-socket that binds to the masters publishing interface tries
# to reconnect immediately, if the socket is disconnected (for example if
# the master processes are restarted). In large setups this will have all
# minions reconnect immediately which might flood the master (the ZeroMQ-default
# is usually a 100ms delay). To prevent this, these three recon_* settings
# can be used.
# recon_default: the interval in milliseconds that the socket should wait before
# trying to reconnect to the master (1000ms = 1 second)
#
# recon_max: the maximum time a socket should wait. each interval the time to wait
# is calculated by doubling the previous time. if recon_max is reached,
# it starts again at recon_default. Short example:
#
# reconnect 1: the socket will wait 'recon_default' milliseconds
# reconnect 2: 'recon_default' * 2
# reconnect 3: ('recon_default' * 2) * 2
# reconnect 4: value from previous interval * 2
# reconnect 5: value from previous interval * 2
# reconnect x: if value >= recon_max, it starts again with recon_default
#
# recon_randomize: generate a random wait time on minion start. The wait time will
# be a random value between recon_default and recon_default +
# recon_max. Having all minions reconnect with the same recon_default
# and recon_max value kind of defeats the purpose of being able to
# change these settings. If all minions have the same values and your
# setup is quite large (several thousand minions), they will still
# flood the master. The desired behavior is to have timeframe within
# all minions try to reconnect.
#
# Example on how to use these settings. The goal: have all minions reconnect within a
# 60 second timeframe on a disconnect.
# recon_default: 1000
# recon_max: 59000
# recon_randomize: True
#
# Each minion will have a randomized reconnect value between 'recon_default'
# and 'recon_default + recon_max', which in this example means between 1000ms
# 60000ms (or between 1 and 60 seconds). The generated random-value will be
# doubled after each attempt to reconnect. Lets say the generated random
# value is 11 seconds (or 11000ms).
# reconnect 1: wait 11 seconds
# reconnect 2: wait 22 seconds
# reconnect 3: wait 33 seconds
# reconnect 4: wait 44 seconds
# reconnect 5: wait 55 seconds
# reconnect 6: wait time is bigger than 60 seconds (recon_default + recon_max)
# reconnect 7: wait 11 seconds
# reconnect 8: wait 22 seconds
# reconnect 9: wait 33 seconds
# reconnect x: etc.
#
# In a setup with ~6000 thousand hosts these settings would average the reconnects
to about 100 per second and all hosts would be reconnected within 60 seconds.
# recon_default: 100
# recon_max: 5000
# recon_randomize: False
#
# The loop_interval sets how long in seconds the minion will wait between
# evaluating the scheduler and running cleanup tasks. This defaults to a
# sane 60 seconds, but if the minion scheduler needs to be evaluated more
# often lower this value
#loop_interval: 60

# The grains_refresh_every setting allows for a minion to periodically check
# its grains to see if they have changed and, if so, to inform the master
# of the new grains. This operation is moderately expensive, therefore
# care should be taken not to set this value too low.
#
# Note: This value is expressed in __minutes__!
#
# A value of 10 minutes is a reasonable default.
#
# If the value is set to zero, this check is disabled.
#grains_refresh_every: 1

# Cache grains on the minion. Default is False.
#grains_cache: False

# Grains cache expiration, in seconds. If the cache file is older than this
# number of seconds then the grains cache will be dumped and fully re-populated
# with fresh data. Defaults to 5 minutes. Will have no effect if 'grains_cache'
# is not enabled.
#grains_cache_expiration: 300

# Windows platforms lack posix IPC and must rely on slower TCP based inter-
# process communications. Set ipc_mode to 'tcp' on such systems
#ipc_mode: ipc

# Overwrite the default tcp ports used by the minion when in tcp mode
#tcp_pub_port: 4510
#tcp_pull_port: 4511

# Passing very large events can cause the minion to consume large amounts of
# memory. This value tunes the maximum size of a message allowed onto the
# minion event bus. The value is expressed in bytes.
#max_event_size: 1048576

# To detect failed master(s) and fire events on connect/disconnect, set
# master_alive_interval to the number of seconds to poll the masters for
# connection events.
#
#master_alive_interval: 30

# The minion can include configuration from other files. To enable this, # pass a list of paths to this option. The paths can be either relative or # absolute; if relative, they are considered to be relative to the directory # the main minion configuration file lives in (this file). Paths can make use # of shell-style globbing. If no files are matched by a path passed to this # option then the minion will log a warning message.

# Include a config file from some other path:
# include: /etc/salt/extra_config

# Include config from several files and directories:
# include:
#   - /etc/salt/extra_config
#   - /etc/roles/webserver
#
#
######## Minion module management ########
#################################################################################################################
# Disable specific modules. This allows the admin to limit the level of # access the master has to the minion.
#disable_modules: [cmd,test]
#disable_returners: []

# Modules can be loaded from arbitrary paths. This enables the easy deployment # of third party modules. Modules for returners and minions can be loaded. # Specify a list of extra directories to search for minion modules and # returners. These paths must be fully qualified!
#module_dirs: []
#returner_dirs: []
#states_dirs: []
#render_dirs: []
#utils_dirs: []

# A module provider can be statically overwritten or extended for the minion # via the providers option, in this case the default module will be # overwritten by the specified module. In this example the pkg module will # be provided by the yumpkg5 module instead of the system default.
#providers:
#   pkg: yumpkg5

# Enable Cython modules searching and loading. (Default: False)
cython_enable: False

# Specify a max size (in bytes) for modules on import. This feature is currently # only supported on *nix operating systems and requires psutil.
#modules_max_memory: -1

##### State Management Settings ######
#################################################################################################################
# The state management system executes all of the state templates on the minion # to enable more granular control of system state management. The type of # template and serialization used for state management needs to be configured # on the minion, the default renderer is yaml_jinja. This is a yaml file # rendered from a jinja template, the available options are:
# renderer: yaml_jinja
#
# The failhard option tells the minions to stop immediately after the first
# failure detected in the state execution. Defaults to False.
#failhard: False
#
# Reload the modules prior to a highstate run.
#autoload_dynamic_modules: True
#
# clean_dynamic_modules keeps the dynamic modules on the minion in sync with
# the dynamic modules on the master, this means that if a dynamic module is
# not on the master it will be deleted from the minion. By default, this is
# enabled and can be disabled by changing this value to False.
#clean_dynamic_modules: True
#
# Normally, the minion is not isolated to any single environment on the master
# when running states, but the environment can be isolated on the minion side
# by statically setting it. Remember that the recommended way to manage
# environments is to isolate via the top file.
#environment: None
#
# If using the local file directory, then the state top file name needs to be
# defined, by default this is top.sls.
#state_top: top.sls
#
# Run states when the minion daemon starts. To enable, set startup_states to:
# 'highstate' -- Execute state.highstate
# 'sls' -- Read in the sls_list option and execute the named sls files
# 'top' -- Read top_file option and execute based on that file on the Master
#startup_states: ''
#
# List of states to run when the minion starts up if startup_states is 'sls':
#sls_list:
#  - edit.vim
#  - hyper
#
# Top file to execute if startup_states is 'top':
top_file: ''
#
# Automatically aggregate all states that have support for mod_aggregate by
# setting to True. Or pass a list of state module names to automatically
# aggregate just those types.
#
# state_aggregate:
#  - pkg
#
#state_aggregate: False

##### File Directory Settings #####
##########################################
# The Salt Minion can redirect all file server operations to a local directory,
# this allows for the same state tree that is on the master to be used if
# copied completely onto the minion. This is a literal copy of the settings on
# the master but used to reference a local directory on the minion.

# Set the file client. The client defaults to looking on the master server for
# files, but can be directed to look at the local file directory setting
# defined below by setting it to local.
#file_client: remote

# The file directory works on environments passed to the minion, each environment
# can have multiple root directories, the subdirectories in the multiple file
# roots cannot match, otherwise the downloaded files will not be able to be
# reliably ensured. A base environment is required to house the top file.
# Example:
# file_roots:
#   base:
#     - /srv/salt/
#   dev:
#     - /srv/salt/dev/services
#     - /srv/salt/dev/states
#   prod:
#     - /srv/salt/prod/services
#     - /srv/salt/prod/states
#
#file_roots:
# base:
# - /srv/salt

# By default, the Salt fileserver recurses fully into all defined environments
# to attempt to find files. To limit this behavior so that the fileserver only
# traverses directories with SLS files and special Salt directories like _modules,
# enable the option below. This might be useful for installations where a file root
# has a very large number of files and performance is negatively impacted. Default
# is False.
#fileserver_limit_traversal: False

# The hash_type is the hash to use when discovering the hash of a file in
# the local fileserver. The default is md5, but sha1, sha224, sha256, sha384
# and sha512 are also supported.
#
# Warning: Prior to changing this value, the minion should be stopped and all
# Salt caches should be cleared.
#hash_type: md5

# The Salt pillar is searched for locally if file_client is set to local. If
# this is the case, and pillar data is defined, then the pillar_roots need to
# also be configured on the minion:
#pillar_roots:
# base:
# - /srv/pillar
#
#
# Security settings

# Enable "open mode", this mode still maintains encryption, but turns off
# authentication, this is only intended for highly secure environments or for
# the situation where your keys end up in a bad state. If you run in open mode
# you do so at your own risk!
#open_mode: False

# Enable permissive access to the salt keys. This allows you to run the master or minion as root, but have a non-root group be given access to your pki_dir. To make the access explicit, root must belong to the group you've given access to. This is potentially quite insecure.
#permissive_pki_access: False

# The state_verbose and state_output settings can be used to change the way state system data is printed to the display. By default all data is printed. The state_verbose setting can be set to True or False, when set to False all data that has a result of True and no changes will be suppressed.
#state_verbose: True

# The state_output setting changes if the output is the full multi line output for each changed state if set to 'full', but if set to 'terse' the output will be shortened to a single line.
#state_output: full

# The state_output_diff setting changes whether or not the output from successful states is returned. Useful when even the terse output of these states is cluttering the logs. Set it to True to ignore them.
#state_output_diff: False

# The state_output_profile setting changes whether profile information will be shown for each state run.
#state_output_profile: True

# Fingerprint of the master public key to validate the identity of your Salt master before the initial key exchange. The master fingerprint can be found by running "salt-key -F master" on the Salt master.
#master_finger: ''

##### Thread settings #####
###########################################
# Disable multiprocessing support, by default when a minion receives a publication a new process is spawned and the command is executed therein.
#multiprocessing: True

##### Logging settings #####
##########################################
# The location of the minion log file
# The minion log can be sent to a regular file, local path name, or network location. Remote logging works best when configured to use rsyslogd(8) (e.g.: `file:///dev/log`), with rsyslogd(8) configured for network logging. The URI format is: <file|udp|tcp>://<host|socketpath>:<port-if-required>/<log-facility>
#log_file: /var/log/salt/minion
#log_file: file:///dev/log
#log_file: udp://loghost:10514
#log_file: /var/log/salt/minion
#key_logfile: /var/log/salt/key

# The level of messages to send to the console. One of 'garbage', 'trace', 'debug', 'info', 'warning', 'error', 'critical'. Default: 'warning'
#log_level: warning

# The level of messages to send to the log file.  
# One of 'garbage', 'trace', 'debug', info', 'warning', 'error', 'critical'.  
# If using 'log_granular_levels' this must be set to the highest desired level.  
# Default: 'warning'

#log_level_logfile:

# The date and time format used in log messages. Allowed date/time formatting  
# can be seen here: http://docs.python.org/library/time.html#time.strftime  
#log_datefmt: '%H:%M:%S'  
#log_datefmt_logfile: '%Y-%m-%d %H:%M:%S'

# The format of the console logging messages. Allowed formatting options can  
# be seen here: http://docs.python.org/library/logging.html#logrecord-attributes  
# Console log colors are specified by these additional formatters:  
#  
#  %%(colorlevel)s  
#  %%(colormessage)s  
#  %%(colorprocess)s  
#  %%(colormessage)s  
#  
# Since it is desirable to include the surrounding brackets, '[' and ']', in  
# the coloring of the messages, these color formatters also include padding as  
# well. Color LogRecord attributes are only available for console logging.  
#  
#log_fmt_console: '%(colorlevel)s %(colormessage)s'  
#log_fmt_console: '[%(levelname)-8s] %%(message)s'  
#log_fmt_logfile: '%(asctime)s,%(msecs)03.0f [%(name)-17s][%(levelname)-8s] %%(message)s'

# This can be used to control logging levels more specifically. This  
# example sets the main salt library at the 'warning' level, but sets  
# 'salt.modules' to log at the 'debug' level:  
#  
#log_granular_levels:  
#  'salt': 'warning'  
#  'salt.modules': 'debug'

#log_granular_levels: {}

# To diagnose issues with minions disconnecting or missing returns, ZeroMQ  
# supports the use of monitor sockets # to log connection events. This  
# feature requires ZeroMQ 4.0 or higher.  
# To enable ZeroMQ monitor sockets, set 'zmq_monitor' to 'True' and log at a  
# debug level or higher.  
# A sample log event is as follows:  
#  
#  [DEBUG ] ZeroMQ event: {'endpoint': 'tcp://127.0.0.1:4505', 'event': 512,  
#  'value': 27, 'description': 'EVENT_DISCONNECTED'}  
# All events logged will include the string 'ZeroMQ event'. A connection event  
# should be logged on the as the minion starts up and initially connects to the  
# master. If not, check for debug log level and that the necessary version of  
# ZeroMQ is installed.
#zmq_monitor: False

##### Module configuration #####

Salt allows for modules to be passed arbitrary configuration data, any data passed here in valid yaml format will be passed on to the salt minion modules for use. It is STRONGLY recommended that a naming convention be used in which the module name is followed by a . and then the value. Also, all top level data must be applied via the yaml dict construct, some examples:

# You can specify that all modules should run in test mode:
#test: True
#
# A simple value for the test module:
#test.foo: foo
#
# A list for the test module:
#test.bar: [baz, quo]
#
# A dict for the test module:
#test.baz: {spam: sausage, cheese: bread}
#

##### Update settings #####

Using the features in Esky, a salt minion can both run as a frozen app and be updated on the fly. These options control how the update process (saltutil.update()) behaves.

# The url for finding and downloading updates. Disabled by default.
#update_url: False
#
# The list of services to restart after a successful update. Empty by default.
#update_restart_services: []

##### Keepalive settings #####

ZeroMQ now includes support for configuring SO_KEEPALIVE if supported by the OS. If connections between the minion and the master pass through a state tracking device such as a firewall or VPN gateway, there is the risk that it could tear down the connection the master and minion without informing either party that their connection has been taken away. Enabling TCP Keepalives prevents this from happening.

# Overall state of TCP Keepalives, enable (1 or True), disable (0 or False)
# or leave to the OS defaults (-1), on Linux, typically disabled. Default True, enabled.
tcp_keepalive: True
#
# How long before the first keepalive should be sent in seconds. Default 300
# to send the first keepalive after 5 minutes, OS default (-1) is typically 7200 seconds.
# on Linux see /proc/sys/net/ipv4/tcp_keepalive_time.
tcp_keepalive_idle: 300
#
# How many lost probes are needed to consider the connection lost. Default -1
# to use OS defaults, typically 9 on Linux, see /proc/sys/net/ipv4/tcp_keepalive_probes.
tcp_keepalive_cnt: -1

550 Chapter 31. Reference
31.7 Configuring Salt

Salt configuration is very simple. The default configuration for the master will work for most installations and the only requirement for setting up a minion is to set the location of the master in the minion configuration file.

The configuration files will be installed to /etc/salt and are named after the respective components, /etc/salt/master, and /etc/salt/minion.

31.7.1 Master Configuration

By default the Salt master listens on ports 4505 and 4506 on all interfaces (0.0.0.0). To bind Salt to a specific IP, redefine the `interface` directive in the master configuration file, typically /etc/salt/master, as follows:

```
- #interface: 0.0.0.0
+ interface: 10.0.0.1
```

After updating the configuration file, restart the Salt master. See the master configuration reference for more details about other configurable options.

31.7.2 Minion Configuration

Although there are many Salt Minion configuration options, configuring a Salt Minion is very simple. By default a Salt Minion will try to connect to the DNS name `salt`; if the Minion is able to resolve that name correctly, no configuration is needed.

If the DNS name `salt` does not resolve to point to the correct location of the Master, redefine the `master` directive in the minion configuration file, typically /etc/salt/minion, as follows:

```
- #master: salt
+ master: 10.0.0.1
```

After updating the configuration file, restart the Salt minion. See the minion configuration reference for more details about other configurable options.
31.7.3 Running Salt

1. Start the master in the foreground (to daemonize the process, pass the `-d` flag):
   ```bash
   salt-master
   ```

2. Start the minion in the foreground (to daemonize the process, pass the `-d` flag):
   ```bash
   salt-minion
   ```

**Having trouble?**

The simplest way to troubleshoot Salt is to run the master and minion in the foreground with `log level` set to `debug`:

```bash
salt-master --log-level=debug
```

For information on salt's logging system please see the [logging document](#).

**Run as an unprivileged (non-root) user**

To run Salt as another user, set the `user` parameter in the master config file.

Additionally, ownership, and permissions need to be set such that the desired user can read from and write to the following directories (and their subdirectories, where applicable):

- `/etc/salt`
- `/var/cache/salt`
- `/var/log/salt`
- `/var/run/salt`

More information about running salt as a non-privileged user can be found [here](#).

There is also a full troubleshooting guide available.

31.7.4 Key Identity

Salt provides commands to validate the identity of your Salt master and Salt minions before the initial key exchange. Validating key identity helps avoid inadvertently connecting to the wrong Salt master, and helps prevent a potential MiTM attack when establishing the initial connection.

**Master Key Fingerprint**

Print the master key fingerprint by running the following command on the Salt master:

```bash
salt-key -F master
```

Copy the `master.pub` fingerprint from the `Local Keys` section, and then set this value as the `master_finger` in the minion configuration file. Save the configuration file and then restart the Salt minion.

**Minion Key Fingerprint**

Run the following command on each Salt minion to view the minion key fingerprint:
salt-call --local key.finger

Compare this value to the value that is displayed when you run the `salt-key --finger <MINION_ID>` command on the Salt master.

### 31.7.5 Key Management

Salt uses AES encryption for all communication between the Master and the Minion. This ensures that the commands sent to the Minions cannot be tampered with, and that communication between Master and Minion is authenticated through trusted, accepted keys.

Before commands can be sent to a Minion, its key must be accepted on the Master. Run the `salt-key` command to list the keys known to the Salt Master:

```
[root@master ~]# salt-key -L
Unaccepted Keys:
alpha
bravo
charlie
delta
Accepted Keys:
```

This example shows that the Salt Master is aware of four Minions, but none of the keys has been accepted. To accept the keys and allow the Minions to be controlled by the Master, again use the `salt-key` command:

```
[root@master ~]# salt-key -A
[root@master ~]# salt-key -L
Unaccepted Keys:
Accepted Keys:
alpha
bravo
charlie
delta
```

The `salt-key` command allows for signing keys individually or in bulk. The example above, using `-A` bulk-accepts all pending keys. To accept keys individually use the lowercase of the same option, `-a keyname`.

See also:

`salt-key manpage`

### 31.7.6 Sending Commands

Communication between the Master and a Minion may be verified by running the `test.ping` command:

```
[root@master ~]# salt alpha test.ping
alpha: True
```

Communication between the Master and all Minions may be tested in a similar way:

```
[root@master ~]# salt '*' test.ping
alpha:
   True
bravo:
   True
charlie:
```
Each of the Minions should send a True response as shown above.

### 31.7.7 What's Next?

Understanding targeting is important. From there, depending on the way you wish to use Salt, you should also proceed to learn about States and Execution Modules.

### 31.8 Configuring the Salt Master

The Salt system is amazingly simple and easy to configure, the two components of the Salt system each have a respective configuration file. The salt-master is configured via the master configuration file, and the salt-minion is configured via the minion configuration file.

See also:

example master configuration file

The configuration file for the salt-master is located at /etc/salt/master by default. A notable exception is FreeBSD, where the configuration file is located at /usr/local/etc/salt. The available options are as follows:

#### 31.8.1 Primary Master Configuration

**interface**

Default: 0.0.0.0 (all interfaces)

The local interface to bind to.

interface: 192.168.0.1

**ipv6**

Default: False

Whether the master should listen for IPv6 connections. If this is set to True, the interface option must be adjusted too (for example: `interface: '::'`)

ipv6: True

**publish_port**

Default: 4505

The network port to set up the publication interface.

publish_port: 4505
**master_id**

Default: None

The id to be passed in the publish job to minions. This is used for MultiSyndics to return the job to the requesting master.

*Note:* This must be the same string as the syndic is configured with.

```
master_id: MasterOfMaster
```

**user**

Default: root

The user to run the Salt processes

```
user: root
```

**max_open_files**

Default: 100000

Each minion connecting to the master uses AT LEAST one file descriptor, the master subscription connection. If enough minions connect you might start seeing on the console(and then salt-master crashes):

```
Too many open files (tcp_listener.cpp:335)
Aborted (core dumped)
```

```
max_open_files: 100000
```

By default this value will be the one of `ulimit -Hn`, i.e., the hard limit for max open files.

To set a different value than the default one, uncomment, and configure this setting. Remember that this value CANNOT be higher than the hard limit. Raising the hard limit depends on the OS and/or distribution, a good way to find the limit is to search the internet for something like this:

```
raise max open files hard limit debian
```

**worker_threads**

Default: 5

The number of threads to start for receiving commands and replies from minions. If minions are stalling on replies because you have many minions, raise the worker_threads value.

Worker threads should not be put below 3 when using the peer system, but can drop down to 1 worker otherwise.

*Note:* When the master daemon starts, it is expected behaviour to see multiple salt-master processes, even if `worker_threads` is set to `1`. At a minimum, a controlling process will start along with a Publisher, an Event-Publisher, and a number of MWorker processes will be started. The number of MWorker processes is tuneable by the `worker_threads` configuration value while the others are not.
worker_threads: 5

**ret_port**
Default: 4506
The port used by the return server, this is the server used by Salt to receive execution returns and command executions.
ret_port: 4506

**pidfile**
Default: /var/run/salt-master.pid
Specify the location of the master pidfile.
pidfile: /var/run/salt-master.pid

**root_dir**
Default: /
The system root directory to operate from, change this to make Salt run from an alternative root.
root_dir: /

Note: This directory is prepended to the following options: pki_dir, cachedir, sock_dir, log_file, autosign_file, autoreject_file, pidfile.

**pki_dir**
Default: /etc/salt/pki
The directory to store the pki authentication keys.
pki_dir: /etc/salt/pki

**extension_modules**
Directory for custom modules. This directory can contain subdirectories for each of Salt's module types such as `runners`, `output`, `wheel`, `modules`, `states`, `returners`, etc. This path is appended to root_dir.
extension_modules: srv/modules

**module_dirs**
Default: []
Like extension_modules, but a list of extra directories to search for Salt modules.
module_dirs:
- /var/cache/salt/minion/extmods

cachedir

Default: /var/cache/salt
The location used to store cache information, particularly the job information for executed salt commands.
This directory may contain sensitive data and should be protected accordingly.
cachedir: /var/cache/salt

verify_env

Default: True
Verify and set permissions on configuration directories at startup.
verify_env: True

keep_jobs

Default: 24
Set the number of hours to keep old job information.

timeout

Default: 5
Set the default timeout for the salt command and api.

loop_interval

Default: 60
The loop_interval option controls the seconds for the master’s maintenance process check cycle. This process updates file server backends, cleans the job cache and executes the scheduler.

output

Default: nested
Set the default outputter used by the salt command.
color

Default: True
By default output is colored, to disable colored output set the color value to False.

<table>
<thead>
<tr>
<th>color</th>
</tr>
</thead>
<tbody>
<tr>
<td>color: False</td>
</tr>
</tbody>
</table>

sock_dir

Default: /var/run/salt/master
Set the location to use for creating Unix sockets for master process communication.

<table>
<thead>
<tr>
<th>sock_dir</th>
</tr>
</thead>
<tbody>
<tr>
<td>sock_dir: /var/run/salt/master</td>
</tr>
</tbody>
</table>

enable_gpu_grains

Default: True
Enable GPU hardware data for your master. Be aware that the master can take a while to start up when lspci and/or dmidecode is used to populate the grains for the master.

job_cache

Default: True
The master maintains a job cache, while this is a great addition it can be a burden on the master for larger deployments (over 5000 minions). Disabling the job cache will make previously executed jobs unavailable to the jobs system and is not generally recommended. Normally it is wise to make sure the master has access to a faster IO system or a tmpfs is mounted to the jobs dir.

<table>
<thead>
<tr>
<th>minion_data_cache</th>
</tr>
</thead>
<tbody>
<tr>
<td>minion_data_cache: True</td>
</tr>
</tbody>
</table>

minion_data_cache

Default: True
The minion data cache is a cache of information about the minions stored on the master, this information is primarily the pillar and grains data. The data is cached in the Master cachedir under the name of the minion and used to predetermine what minions are expected to reply from executions.

ext_job_cache

Default: ''
Used to specify a default returner for all minions, when this option is set the specified returner needs to be properly configured and the minions will always default to sending returns to this returner. This will also disable the local job cache on the master.

<table>
<thead>
<tr>
<th>ext_job_cache</th>
</tr>
</thead>
<tbody>
<tr>
<td>ext_job_cache: redis</td>
</tr>
</tbody>
</table>
**event_return**

New in version 2015.5.0.

Default: ' '  

Specify the returner to use to log events. A returner may have installation and configuration requirements. Read the returner's documentation.

**Note:** Not all returners support event returns. Verify that a returner has an `event_return()` function before configuring this option with a returner.

```
event_return: cassandra_cql
```

**master_job_cache**

New in version 2014.7.

Default: `local_cache`

Specify the returner to use for the job cache. The job cache will only be interacted with from the salt master and therefore does not need to be accessible from the minions.

```
master_job_cache: redis
```

**enforce_mine_cache**

Default: False

By-default when disabling the minion_data_cache mine will stop working since it is based on cached data, by enabling this option we explicitly enabling only the cache for the mine system.

```
enforce_mine_cache: False
```

**max_minions**

Default: 0

The number of minions the master should allow to connect. Use this to accommodate the number of minions per master if you have different types of hardware serving your minions. The default of 0 means unlimited connections. Please note, that this can slow down the authentication process a bit in large setups.

```
max_minions: 100
```

**con_cache**

Default: False

If `max_minions` is used in large installations, the master might experience high-load situations because of having to check the number of connected minions for every authentication. This cache provides the minion-ids of all connected minions to all MWorker-processes and greatly improves the performance of `max_minions`.

```
con_cache: True
```
**presence_events**

Default: False

Causes the master to periodically look for actively connected minions. *Presence events* are fired on the event bus on a regular interval with a list of connected minions, as well as events with lists of newly connected or disconnected minions. This is a master-only operation that does not send executions to minions. Note, this does not detect minions that connect to a master via localhost.

```plaintext
presence_events: False
```

### 31.8.2 Salt-SSH Configuration

**roster_file**

Default: `/etc/salt/roster`

Pass in an alternative location for the salt-ssh roster file.

```plaintext
roster_file: /root/roster
```

**ssh_minion_opts**

Default: None

Pass in minion option overrides that will be inserted into the SHIM for salt-ssh calls. The local minion config is not used for salt-ssh. Can be overridden on a per-minion basis in the roster (`minion_opts`)

```plaintext
minion_opts:
    gpg_keydir: /root/gpg
```

### 31.8.3 Master Security Settings

**open_mode**

Default: False

Open mode is a dangerous security feature. One problem encountered with pki authentication systems is that keys can become `mixed up` and authentication begins to fail. Open mode turns off authentication and tells the master to accept all authentication. This will clean up the pki keys received from the minions. Open mode should not be turned on for general use. Open mode should only be used for a short period of time to clean up pki keys. To turn on open mode set this value to `True`.

```plaintext
open_mode: False
```

**auto_accept**

Default: False

Enable auto_accept. This setting will automatically accept all incoming public keys from minions.

```plaintext
auto_accept: False
```
**autosign_timeout**

New in version 2014.7.0.

Default: 120

Time in minutes that a incoming public key with a matching name found in pki_dir/minion_autosign/keyid is automatically accepted. Expired autosign keys are removed when the master checks the minion_autosign directory. This method to auto accept minions can be safer than an autosign_file because the keyid record can expire and is limited to being an exact name match. This should still be considered a less than secure option, due to the fact that trust is based on just the requesting minion id.

**autosign_file**

Default: not defined

If the autosign_file is specified incoming keys specified in the autosign_file will be automatically accepted. Matches will be searched for first by string comparison, then by globbing, then by full-string regex matching. This should still be considered a less than secure option, due to the fact that trust is based on just the requesting minion id.

**autoreject_file**

New in version 2014.1.0.

Default: not defined

Works like autosign_file, but instead allows you to specify minion IDs for which keys will automatically be rejected. Will override both membership in the autosign_file and the auto_accept setting.

**client_acl**

Default: {}

Enable user accounts on the master to execute specific modules. These modules can be expressed as regular expressions.

```
client_acl:
    fred:
        - test.ping
        - pkg.*
```

**client_acl_blacklist**

Default: {}

Blacklist users or modules

This example would blacklist all non sudo users, including root from running any commands. It would also blacklist any use of the `cmd` module.

This is completely disabled by default.
client_acl_blacklist:
  users:
    - root
    - '^(?!sudo_).*'$  # all non sudo users
modules:
  - cmd

external_auth

Default: {}

The external auth system uses the Salt auth modules to authenticate and validate users to access areas of the Salt system.

external_auth:
  pam:
    fred:
      - test.*

token_expire

Default: 43200

Time (in seconds) for a newly generated token to live.

Default: 12 hours

token_expire: 43200

file_recv

Default: False

Allow minions to push files to the master. This is disabled by default, for security purposes.

file_recv: False

master_sign_pubkey

Default: False

Sign the master auth-replies with a cryptographic signature of the masters public key. Please see the tutorial how to use these settings in the Multimaster-PKI with Failover Tutorial

master_sign_pubkey: True

master_sign_key_name

Default: master_sign

The customizable name of the signing-key-pair without suffix.

master_sign_key_name: <filename_without_suffix>
master_pubkey_signature

Default: master_pubkey_signature
The name of the file in the masters pki-directory that holds the pre-calculated signature of the masters public-key.

\[\text{master_pubkey_signature: <filename>}\]

master_use_pubkey_signature

Default: False
Instead of computing the signature for each auth-reply, use a pre-calculated signature. The master_pubkey_signature must also be set for this.

\[\text{master_use_pubkey_signature: True}\]

rotate_aes_key

Default: True
Rotate the salt-masters AES-key when a minion-public is deleted with salt-key. This is a very important security-setting. Disabling it will enable deleted minions to still listen in on the messages published by the salt-master. Do not disable this unless it is absolutely clear what this does.

\[\text{rotate_aes_key: True}\]

31.8.4 Master Module Management

runner_dirs

Default: []
Set additional directories to search for runner modules.

cython_enable

Default: False
Set to true to enable Cython modules (.pyx files) to be compiled on the fly on the Salt master.

\[\text{cython_enable: False}\]

31.8.5 Master State System Settings

state_top

Default: top.sls
The state system uses a `top` file to tell the minions what environment to use and what modules to use. The state_top file is defined relative to the root of the base environment.
state_top: top.sls

**master_tops**

Default: {}

The master_tops option replaces the external_nodes option by creating a pluggable system for the generation of external top data. The external_nodes option is deprecated by the master_tops option. To gain the capabilities of the classic external_nodes system, use the following configuration:

```yaml
master_tops:
  ext_nodes: <Shell command which returns yaml>
```

**external_nodes**

Default: None

The external_nodes option allows Salt to gather data that would normally be placed in a top file from an external node controller. The external_nodes option is the executable that will return the ENC data. Remember that Salt will look for external nodes AND top files and combine the results if both are enabled and available!

```yaml
external_nodes: cobbler-ext-nodes
```

**renderer**

Default: yaml_jinja

The renderer to use on the minions to render the state data.

```yaml
renderer: yaml_jinja
```

**failhard**

Default: False

Set the global failhard flag, this informs all states to stop running states at the moment a single state fails.

```yaml
failhard: False
```

**state_verbose**

Default: True

Controls the verbosity of state runs. By default, the results of all states are returned, but setting this value to False will cause Salt to only display output for states which either failed, or succeeded without making any changes to the minion.

```yaml
state_verbose: False
```
**state_output**

Default: full

The state_output setting changes if the output is the full multi line output for each changed state if set to 'full', but if set to 'terse' the output will be shortened to a single line. If set to 'mixed', the output will be terse unless a state failed, in which case that output will be full. If set to 'changes', the output will be full unless the state didn't change.

```
state_output: full
```

**state_aggregate**

Default: False

Automatically aggregate all states that have support for mod_aggregate by setting to True. Or pass a list of state module names to automatically aggregate just those types.

```
state_aggregate:
  - pkg

state_aggregate: True
```

**state_events**

Default: False

Send progress events as each function in a state run completes execution by setting to True. Progress events are in the format salt/job/<JID>/prog/<MID>/<RUN NUM>.

```
state_events: True
```

**yaml_utf8**

Default: False

Enable extra routines for YAML renderer used states containing UTF characters.

```
yaml_utf8: False
```

**test**

Default: False

Set all state calls to only test if they are going to actually make changes or just post what changes are going to be made.

```
test: False
```

31.8.6 Master File Server Settings

**fileservr_backend**

Default: ['roots']
Salt supports a modular fileserver backend system, this system allows the salt master to link directly to third party systems to gather and manage the files available to minions. Multiple backends can be configured and will be searched for the requested file in the order in which they are defined here. The default setting only enables the standard backend roots, which is configured using the `file_roots` option.

Example:

```yaml
fileserver_backend:
  - roots
  - git
```

**hash_type**

Default: md5

The hash_type is the hash to use when discovering the hash of a file on the master server. The default is md5, but sha1, sha224, sha256, sha384, and sha512 are also supported.

```yaml
hash_type: md5
```

**file_buffer_size**

Default: 1048576

The buffer size in the file server in bytes.

```yaml
file_buffer_size: 1048576
```

**file_ignore_regex**

Default: ''

A regular expression (or a list of expressions) that will be matched against the file path before syncing the modules and states to the minions. This includes files affected by the file.recurse state. For example, if you manage your custom modules and states in subversion and don’t want all the `.svn` folders and content synced to your minions, you could set this to `'/\.svn($|/)'. By default nothing is ignored.

```yaml
file_ignore_regex:
  - '/\.svn($|)'
  - '/\.git($|)'
```

**file_ignore_glob**

Default: ''

A file glob (or list of file globs) that will be matched against the file path before syncing the modules and states to the minions. This is similar to `file_ignore_regex` above, but works on globs instead of regex. By default nothing is ignored.

```yaml
file_ignore_glob:
  - '*.pyc'
  - '*/somefolder/*.bak'
  - '*/.swp'
```
Note: Vim’s .swp files are a common cause of Unicode errors in file.recurse states which use templating. Unless there is a good reason to distribute them via the fileserver, it is good practice to include ‘\*\.swp’ in the file_ignore_glob.

roots: Master’s Local File Server

file_roots

Default:

base:
    - /srv/salt

Salt runs a lightweight file server written in ZeroMQ to deliver files to minions. This file server is built into the master daemon and does not require a dedicated port.

The file server works on environments passed to the master. Each environment can have multiple root directories. The subdirectories in the multiple file roots cannot match, otherwise the downloaded files will not be able to be reliably ensured. A base environment is required to house the top file.

Example:

file_roots:
    base:
        - /srv/salt
    dev:
        - /srv/salt/dev/services
        - /srv/salt/dev/states
    prod:
        - /srv/salt/prod/services
        - /srv/salt/prod/states

git: Git Remote File Server Backend

gitfs_remotes

Default: []

When using the git fileserver backend at least one git remote needs to be defined. The user running the salt master will need read access to the repo.

The repos will be searched in order to find the file requested by a client and the first repo to have the file will return it. Branches and tags are translated into salt environments.

gitfs_remotes:
    - git://github.com/saltstack/salt-states.git
    - file:///var/git/saltmaster

Note: file:// repos will be treated as a remote and copied into the master’s gitfs cache, so only the local refs for those repos will be exposed as fileserver environments.

As of 2014.7.0, it is possible to have per-repo versions of several of the gitfs configuration parameters. For more information, see the GitFS Walkthrough.
gitfs_provider

New in version 2014.7.0.
Optional parameter used to specify the provider to be used for gitfs. More information can be found in the *GitFS Walkthrough*.
Must be one of the following: pygit2, gitpython, or dulwich. If unset, then each will be tried in that same order, and the first one with a compatible version installed will be the provider that is used.

```yaml
gitfs_provider: dulwich
```

gitfs_ssl_verify

Default: True
Specifies whether or not to ignore SSL certificate errors when contacting the remote repository. You might want to set this to `False` if you're using a git repo that uses a self-signed certificate. However, keep in mind that setting this to anything other `True` is a considered insecure, and using an SSH-based transport (if available) may be a better option.

```yaml
gitfs_ssl_verify: True
```

gitfs_mountpoint

New in version 2014.7.0.
Default: ''
Specifies a path on the salt fileserver from which gitfs remotes are served. Can be used in conjunction with `gitfs_root`. Can also be configured on a per-remote basis, see here for more info.

```yaml
gitfs_mountpoint: salt://foo/bar
```

Note: The `salt://` protocol designation can be left off (in other words, `foo/bar` and `salt://foo/bar` are equivalent).

gitfs_root

Default: ''
Serve files from a subdirectory within the repository, instead of the root. This is useful when there are files in the repository that should not be available to the Salt fileserver. Can be used in conjunction with `gitfs_mountpoint`.

```yaml
gitfs_root: somefolder/otherfolder
```

Changed in version 2014.7.0: Ability to specify gitfs roots on a per-remote basis was added. See here for more info.

gitfs_base

Default: master
Defines which branch/tag should be used as the base environment.
**gitfs_base**: `salt`

Changed in version 2014.7.0: Ability to specify the base on a per-remote basis was added. See [here](#) for more info.

**gitfs_env_whitelist**

New in version 2014.7.0.

Default: `[]`

Used to restrict which environments are made available. Can speed up state runs if the repos in `gitfs_remotes` contain many branches/tags. More information can be found in the *GitFS Walkthrough*.

```yaml
gitfs_env_whitelist:
  - base
  - v1.*
  - 'mybranch\d+'
```

**gitfs_env_blacklist**

New in version 2014.7.0.

Default: `[]`

Used to restrict which environments are made available. Can speed up state runs if the repos in `gitfs_remotes` contain many branches/tags. More information can be found in the *GitFS Walkthrough*.

```yaml
gitfs_env_blacklist:
  - base
  - v1.*
  - 'mybranch\d+'
```

**GitFS Authentication Options**

These parameters only currently apply to the pygit2 gitfs provider. Examples of how to use these can be found in the *GitFS Walkthrough*.

**gitfs_user**  New in version 2014.7.0.

Default: `''`

Along with `gitfs_password`, is used to authenticate to HTTPS remotes.

```yaml
gitfs_user: git
```

**gitfs_password**  New in version 2014.7.0.

Default: `''`

Along with `gitfs_user`, is used to authenticate to HTTPS remotes. This parameter is not required if the repository does not use authentication.

```yaml
gitfs_password: mypassword
```
**gitfs_insecure_auth**  New in version 2014.7.0.
Default: False
By default, Salt will not authenticate to an HTTP (non-HTTPS) remote. This parameter enables authentication over HTTP. Enable this at your own risk.

```yaml
gitfs_insecure_auth: True
```

**gitfs_pubkey**  New in version 2014.7.0.
Default: ''
Along with `gitfs_privkey` (and optionally `gitfs_passphrase`), is used to authenticate to SSH remotes. This parameter (or its per-remote counterpart) is required for SSH remotes.

```yaml
gitfs_pubkey: /path/to/key.pub
```

**gitfs_privkey**  New in version 2014.7.0.
Default: ''
Along with `gitfs_pubkey` (and optionally `gitfs_passphrase`), is used to authenticate to SSH remotes. This parameter (or its per-remote counterpart) is required for SSH remotes.

```yaml
gitfs_privkey: /path/to/key
```

**gitfs_passphrase**  New in version 2014.7.0.
Default: ''
This parameter is optional, required only when the SSH key being used to authenticate is protected by a passphrase.

```yaml
gitfs_passphrase: mypassphrase
```

**hg: Mercurial Remote File Server Backend**

**hgfs_remotes**

New in version 0.17.0.
Default: []
When using the hg fileserver backend at least one mercurial remote needs to be defined. The user running the salt master will need read access to the repo.
The repos will be searched in order to find the file requested by a client and the first repo to have the file will return it. Branches and/or bookmarks are translated into salt environments, as defined by the `hgfs_branch_method` parameter.

```yaml
hgfs_remotes:
  - https://username@bitbucket.org/username/reponame
```

Note:  As of 2014.7.0, it is possible to have per-repo versions of the `hgfs_root`, `hgfs_mountpoint`, `hgfs_base`, and `hgfs_branch_method` parameters. For example:
hgfs_remotes:
- https://username@bitbucket.org/username/repo1
  - base: saltstates
- https://username@bitbucket.org/username/repo2:
  - root: salt
  - mountpoint: salt://foo/bar/baz
- https://username@bitbucket.org/username/repo3:
  - root: salt/states
  - branch_method: mixed

**hgfs_branch_method**

New in version 0.17.0.
Default: branches
Defines the objects that will be used as fileserver environments.

- **branches** - Only branches and tags will be used
- **bookmarks** - Only bookmarks and tags will be used
- **mixed** - Branches, bookmarks, and tags will be used

**hgfs_branch_method**: mixed

**Note**: Starting in version 2014.1.0, the value of the `hgfs_base` parameter defines which branch is used as the base environment, allowing for a base environment to be used with an `hgfs_branch_method` of bookmarks. Prior to this release, the default branch will be used as the base environment.

**hgfs_mountpoint**

New in version 2014.7.0.
Default: ''
Specifies a path on the salt fileserver from which hgfs remotes are served. Can be used in conjunction with `hgfs_root`. Can also be configured on a per-remote basis, see here for more info.

**hgfs_mountpoint**: salt://foo/bar

**Note**: The salt:// protocol designation can be left off (in other words, foo/bar and salt://foo/bar are equivalent).

**hgfs_root**

New in version 0.17.0.
Default: ''
Serve files from a subdirectory within the repository, instead of the root. This is useful when there are files in the repository that should not be available to the Salt fileserver. Can be used in conjunction with `hgfs_mountpoint`.

31.8. Configuring the Salt Master
**hgfs_root: somefolder/otherfolder**

Changed in version 2014.7.0: Ability to specify hgfs roots on a per-remote basis was added. See here for more info.

**hgfs_base**

New in version 2014.1.0.

Default: default

Defines which branch should be used as the base environment. Change this if `hgfs_branch_method` is set to bookmarks to specify which bookmark should be used as the base environment.

`hgfs_base: salt`

**hgfs_env_whitelist**

New in version 2014.7.0.

Default: []

Used to restrict which environments are made available. Can speed up state runs if your hgfs remotes contain many branches/bookmarks/tags. Full names, globs, and regular expressions are supported. If using a regular expression, the expression must match the entire minion ID.

If used, only branches/bookmarks/tags which match one of the specified expressions will be exposed as fileserver environments.

If used in conjunction with `hgfs_env_blacklist`, then the subset of branches/bookmarks/tags which match the whitelist but do not match the blacklist will be exposed as fileserver environments.

`hgfs_env_whitelist:
  - base
  - v1.*
  - 'mybranch\d+'`

**hgfs_env_blacklist**

New in version 2014.7.0.

Default: []

Used to restrict which environments are made available. Can speed up state runs if your hgfs remotes contain many branches/bookmarks/tags. Full names, globs, and regular expressions are supported. If using a regular expression, the expression must match the entire minion ID.

If used, branches/bookmarks/tags which match one of the specified expressions will not be exposed as fileserver environments.

If used in conjunction with `hgfs_env_whitelist`, then the subset of branches/bookmarks/tags which match the whitelist but do not match the blacklist will be exposed as fileserver environments.

`hgfs_env_blacklist:
  - base
  - v1.*
  - 'mybranch\d+'`
svn: Subversion Remote File Server Backend

**svnfs_remotes**

New in version 0.17.0.

Default: `[]`

When using the `svn` fileserver backend at least one subversion remote needs to be defined. The user running the salt master will need read access to the repo.

The repos will be searched in order to find the file requested by a client and the first repo to have the file will return it. The trunk, branches, and tags become environments, with the trunk being the base environment.

```
svnfs_remotes:
  - svn://foo.com/svn/myproject
```

**Note:** As of 2014.7.0, it is possible to have per-repo versions of the following configuration parameters:

- `svnfs_root`
- `svnfs_mountpoint`
- `svnfs_trunk`
- `svnfs_branches`
- `svnfs_tags`

For example:

```
svnfs_remotes:
  - svn://foo.com/svn/project1
  - svn://foo.com/svn/project2:
    - root: salt
    - mountpoint: salt://foo/bar/baz
  - svn://foo.com/svn/project3:
    - root: salt/states
    - branches: branch
    - tags: tag
```

**svnfs_mountpoint**

New in version 2014.7.0.

Default: `''

Specifies a path on the salt fileserver from which svnfs remotes are served. Can be used in conjunction with `svnfs_root`. Can also be configured on a per-remote basis, see here for more info.

```
svnfs_mountpoint: salt://foo/bar
```

**Note:** The `salt://` protocol designation can be left off (in other words, `foo/bar` and `salt://foo/bar` are equivalent).
**svnfs_root**

New in version 0.17.0.

Default: ''

Serve files from a subdirectory within the repository, instead of the root. This is useful when there are files in the repository that should not be available to the Salt fileserver. Can be used in conjunction with `svnfs_mountpoint`.

```
svnfs_root: somefolder/otherfolder
```

Changed in version 2014.7.0: Ability to specify svnfs roots on a per-remote basis was added. See [here](#) for more info.

**svnfs_trunk**

New in version 2014.7.0.

Default: trunk

Path relative to the root of the repository where the trunk is located. Can also be configured on a per-remote basis, see [here](#) for more info.

```
svnfs_trunk: trunk
```

**svnfs_branches**

New in version 2014.7.0.

Default: branches

Path relative to the root of the repository where the branches are located. Can also be configured on a per-remote basis, see [here](#) for more info.

```
svnfs_branches: branches
```

**svnfs_tags**

New in version 2014.7.0.

Default: tags

Path relative to the root of the repository where the tags are located. Can also be configured on a per-remote basis, see [here](#) for more info.

```
svnfs_tags: tags
```

**svnfs_env_whitelist**

New in version 2014.7.0.

Default: []

Used to restrict which environments are made available. Can speed up state runs if your svnfs remotes contain many branches/tags. Full names, globs, and regular expressions are supported. If using a regular expression, the expression must match the entire minion ID.
If used, only branches/tags which match one of the specified expressions will be exposed as fileserver environments.

If used in conjunction with `svnfs_env_blacklist`, then the subset of branches/tags which match the whitelist but do not match the blacklist will be exposed as fileserver environments.

```plaintext
svnfs_env_whitelist:
  - base
  - v1.*
  - 'mybranch\d+
```

```
svnfs_env_blacklist:
  - base
  - v1.*
  - 'mybranch\d+
```

### `svnfs_env_blacklist`

New in version 2014.7.0.

Default: `[]`

Used to restrict which environments are made available. Can speed up state runs if your svnfs remotes contain many branches/tags. Full names, globs, and regular expressions are supported. If using a regular expression, the expression must match the entire minion ID.

If used, branches/tags which match one of the specified expressions will *not* be exposed as fileserver environments.

If used in conjunction with `svnfs_env_whitelist`, then the subset of branches/tags which match the whitelist but do not match the blacklist will be exposed as fileserver environments.

```plaintext
svnfs_env_blacklist:
  - base
  - v1.*
  - 'mybranch\d+
```

### Minion: MinionFS Remote File Server Backend

#### `minionfs_env`

New in version 2014.7.0.

Default: `base`

Environment from which MinionFS files are made available.

```plaintext
minionfs_env: minionfs
```

### `minionfs_mountpoint`

New in version 2014.7.0.

Default: `'`

Specifies a path on the salt fileserver from which minionfs files are served.

```plaintext
minionfs_mountpoint: salt://foo/bar
```

Note: The `salt://` protocol designation can be left off (in other words, `foo/bar` and `salt://foo/bar` are equivalent).
**minionfs_whitelist**

New in version 2014.7.0.

Default: `[]`

Used to restrict which minions' pushed files are exposed via minionfs. If using a regular expression, the expression must match the entire minion ID.

If used, only the pushed files from minions which match one of the specified expressions will be exposed.

If used in conjunction with `minionfs_blacklist`, then the subset of hosts which match the whitelist but do not match the blacklist will be exposed.

```
minionfs_whitelist:
  - base
  - v1.*
  - 'mybranch\d+'
```

**minionfs_blacklist**

New in version 2014.7.0.

Default: `[]`

Used to restrict which minions' pushed files are exposed via minionfs. If using a regular expression, the expression must match the entire minion ID.

If used, only the pushed files from minions which match one of the specified expressions will not be exposed.

If used in conjunction with `minionfs_whitelist`, then the subset of hosts which match the whitelist but do not match the blacklist will be exposed.

```
minionfs_blacklist:
  - base
  - v1.*
  - 'mybranch\d+'
```

### 31.8.7 Pillar Configuration

**pillar_roots**

Default:

```
pillar_roots:
  base:
    - /srv/pillar
```

Set the environments and directories used to hold pillar sls data. This configuration is the same as `file_roots`:

```
pillar_roots:
  base:
    - /srv/pillar
  dev:
    - /srv/pillar/dev
  prod:
    - /srv/pillar/prod
```
**ext_pillar**

The ext_pillar option allows for any number of external pillar interfaces to be called when populating pillar data. The configuration is based on ext_pillar functions. The available ext_pillar functions can be found herein:

https://github.com/saltstack/salt/blob/develop/salt/pillar

By default, the ext_pillar interface is not configured to run.

Default: None

```yaml
ext_pillar:
  - hiera: /etc/hiera.yaml
  - cmd_yaml: cat /etc/salt/yaml
  - reclass:
    - inventory_base_uri: /etc/reclass
```

There are additional details at Pillars

**ext_pillar_first**

New in version 2015.5.0.

Default: False

This option allows for external pillar sources to be evaluated before pillar_roots. This allows for targeting file system pillar from ext_pillar.

```
ext_pillar_first: False
```

**Git External Pillar (git_pillar) Configuration Options**

**git_pillar_provider**

New in version 2015.8.0.

Specify the provider to be used for git_pillar. Must be either pygit2 or gitpython. If unset, then both will be tried in that same order, and the first one with a compatible version installed will be the provider that is used.

```
git_pillar_provider: gitpython
```

**git_pillar_base**

New in version 2015.8.0.

Default: master

If the desired branch matches this value, and the environment is omitted from the git_pillar configuration, then the environment for that git_pillar remote will be base. For example, in the configuration below, the foo branch/tag would be assigned to the base environment, while bar would be mapped to the bar environment.

```
git_pillar_base: foo
```

```yaml
ext_pillar:
  - git:
    - foo https://mygitserver/git-pillar.git
    - bar https://mygitserver/git-pillar.git
```
**git_pillar_branch**

New in version 2015.8.0.

Default: `master`

If the branch is omitted from a git_pillar remote, then this branch will be used instead. For example, in the configuration below, the first two remotes would use the `pillardata` branch/tag, while the third would use the `foo` branch/tag.

```
git_pillar_branch: pillardata

ext_pillar:
  - git:
    - https://mygitserver/pillar1.git
    - https://mygitserver/pillar2.git:
      - root: pillar
    - foo https://mygitserver/pillar3.git
```

**git_pillar_env**

New in version 2015.8.0.

Default: `''` (unset)

Environment to use for git_pillar remotes. This is normally derived from the branch/tag (or from a per-remote env parameter), but if set this will override the process of deriving the env from the branch/tag name. For example, in the configuration below the `foo` branch would be assigned to the `base` environment, while the `bar` branch would need to explicitly have `bar` configured as it's environment to keep it from also being mapped to the `base` environment.

```
git_pillar_env: base

ext_pillar:
  - git:
    - foo https://mygitserver/git-pillar.git
    - bar https://mygitserver/git-pillar.git:
      - env: bar
```

For this reason, this option is recommended to be left unset, unless the use case calls for all (or almost all) of the git_pillar remotes to use the same environment irrespective of the branch/tag being used.

**git_pillar_root**

New in version 2015.8.0.

Default: `''`

Path relative to the root of the repository where the git_pillar top file and SLS files are located. In the below configuration, the pillar top file and SLS files would be looked for in a subdirectory called `pillar`.

```
git_pillar_root: pillar

ext_pillar:
  - git:
    - master https://mygitserver/pillar1.git
    - master https://mygitserver/pillar2.git
```
Note: This is a global option. If only one or two repos need to have their files sourced from a subdirectory, then `git_pillar_root` can be omitted and the root can be specified on a per-remote basis, like so:

```
ext_pillar:
  - git:
    - master https://mygitserver/pillar1.git
    - master https://mygitserver/pillar2.git:
      - root: pillar
```

In this example, for the first remote the top file and SLS files would be looked for in the root of the repository, while in the second remote the pillar data would be retrieved from the `pillar` subdirectory.

**git_pillar_ssl_verify**

New in version 2015.8.0.

Default: True

Specifies whether or not to ignore SSL certificate errors when contacting the remote repository. You might want to set this to `False` if you're using a git repo that uses a self-signed certificate. However, keep in mind that setting this to anything other than `True` is considered insecure, and using an SSH-based transport (if available) may be a better option.

```
git_pillar_ssl_verify: True
```

**Git External Pillar Authentication Options**

These parameters only currently apply to the `pygit2 git_pillar_provider`. Authentication works the same as it does in `gitfs`, as outlined in the `GitFS Walkthrough`, though the global configuration options are named differently to reflect that they are for `gitpillar` instead of `gitfs`.

**git_pillar_user**  New in version 2015.8.0.

Default: ''

Along with `git_pillar_password`, is used to authenticate to HTTPS remotes.

```
git_pillar_user: git
```

**git_pillar_password**  New in version 2015.8.0.

Default: ''

Along with `git_pillar_user`, is used to authenticate to HTTPS remotes. This parameter is not required if the repository does not use authentication.

```
git_pillar_password: mypassword
```

**git_pillar_insecure_auth**  New in version 2015.8.0.

Default: False
By default, Salt will not authenticate to an HTTP (non-HTTPS) remote. This parameter enables authentication over HTTP. Enable this at your own risk.

```
git_pillar_insecure_auth: True
```

**git_pillar_pubkey**  New in version 2015.8.0.

Default: ''

Along with `git_pillar_privkey` (and optionally `git_pillar_passphrase`), is used to authenticate to SSH remotes.

```
git_pillar_pubkey: /path/to/key.pub
```

**git_pillar_privkey**  New in version 2015.8.0.

Default: ''

Along with `git_pillar_pubkey` (and optionally `git_pillar_passphrase`), is used to authenticate to SSH remotes.

```
git_pillar_privkey: /path/to/key
```

**git_pillar_passphrase**  New in version 2015.8.0.

Default: ''

This parameter is optional, required only when the SSH key being used to authenticate is protected by a passphrase.

```
git_pillar_passphrase: mypassphrase
```

**pillar_source_merging_strategy**

New in version 2014.7.0.

Default: `smart`

The pillar_source_merging_strategy option allows you to configure merging strategy between different sources. It accepts 4 values:

- `recurse`:

  it will merge recursively mapping of data. For example, theses 2 sources:

  ```
  foo: 42
  bar:
    element1: True

  bar:
    element2: True
  baz: quux
  ```

  will be merged as:

  ```
  foo: 42
  bar:
    element1: True
    element2: True
  baz: quux
  ```
• aggregate:
  instructs aggregation of elements between sources that use the `#!yamlex renderer.
  For example, these two documents:

  ```yaml
  #!yamlex
  foo: 42
  bar: !aggregate {
    element1: True
  }
  baz: !aggregate quux
  ```

  ```yaml
  #!yamlex
  bar: !aggregate {
    element2: True
  }
  baz: !aggregate quux2
  ```

  will be merged as:

  ```yaml
  foo: 42
  bar:
    element1: True
    element2: True
  baz:
    - quux
    - quux2
  ```

• overwrite:
  Will use the behaviour of the 2014.1 branch and earlier.
  Overwrites elements according the order in which they are processed.

  First pillar processed:

  ```yaml
  A:
    first_key: blah
    second_key: blah
  ```

  Second pillar processed:

  ```yaml
  A:
    third_key: blah
    fourth_key: blah
  ```

  will be merged as:

  ```yaml
  A:
    third_key: blah
    fourth_key: blah
  ```

• smart (default):
  Guesses the best strategy based on the `renderer` setting.
31.8.8 Syndic Server Settings

A Salt syndic is a Salt master used to pass commands from a higher Salt master to minions below the syndic. Using the syndic is simple. If this is a master that will have syndic servers(s) below it, set the `order_masters` setting to True.

If this is a master that will be running a syndic daemon for passthrough the `syndic_master` setting needs to be set to the location of the master server.

Do not forget that, in other words, it means that it shares with the local minions its ID and PKI_DIR.

**order_masters**

Default: False

Extra data needs to be sent with publications if the master is controlling a lower level master via a syndic minion. If this is the case the order_masters value must be set to True

| order_masters: False |

**syndic_master**

Default: None

If this master will be running a salt-syndic to connect to a higher level master, specify the higher level master with this configuration value.

| syndic_master: masterofmasters |

You can optionally connect a syndic to multiple higher level masters by setting the `syndic_master` value to a list:

<table>
<thead>
<tr>
<th>syndic_master:</th>
</tr>
</thead>
<tbody>
<tr>
<td>masterofmasters1</td>
</tr>
<tr>
<td>masterofmasters2</td>
</tr>
</tbody>
</table>

Each higher level master must be set up in a multimaster configuration.

**syndic_master_port**

Default: 4506

If this master will be running a salt-syndic to connect to a higher level master, specify the higher level master port with this configuration value.

| syndic_master_port: 4506 |

**syndic_pidfile**

Default: salt-syndic.pid

If this master will be running a salt-syndic to connect to a higher level master, specify the pidfile of the syndic daemon.

| syndic_pidfile: syndic.pid |
syndic_log_file

Default: syndic.log

If this master will be running a salt-syndic to connect to a higher level master, specify the log_file of the syndic daemon.

syndic_log_file: salt-syndic.log

31.8.9 Peer Publish Settings

Salt minions can send commands to other minions, but only if the minion is allowed to. By default "Peer Publication" is disabled, and when enabled it is enabled for specific minions and specific commands. This allows secure compartmentalization of commands based on individual minions.

peer

Default: {}

The configuration uses regular expressions to match minions and then a list of regular expressions to match functions. The following will allow the minion authenticated as foo.example.com to execute functions from the test and pkg modules.

peer:
  foo.example.com:
    - test.*
    - pkg.*

This will allow all minions to execute all commands:

peer:
  .*:
    - *

This is not recommended, since it would allow anyone who gets root on any single minion to instantly have root on all of the minions!

By adding an additional layer you can limit the target hosts in addition to the accessible commands:

peer:
  foo.example.com:
    "db*":
      - test.*
      - pkg.*

peer_run

Default: {}

The peer_run option is used to open up runners on the master to access from the minions. The peer_run configuration matches the format of the peer configuration.

The following example would allow foo.example.com to execute the manage.up runner:

peer_run:
  foo.example.com:
    - manage.up
### 31.8.10 Master Logging Settings

**log_file**

Default: `/var/log/salt/master`

The master log can be sent to a regular file, local path name, or network location. See also `log_file`.

Examples:

<table>
<thead>
<tr>
<th>log_file</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>/var/log/salt/master</code></td>
</tr>
<tr>
<td><code>file:///dev/log</code></td>
</tr>
<tr>
<td><code>udp://loghost:10514</code></td>
</tr>
</tbody>
</table>

**log_level**

Default: `warning`

The level of messages to send to the console. See also `log_level`.

<table>
<thead>
<tr>
<th>log_level</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>warning</code></td>
</tr>
</tbody>
</table>

**log_level_logfile**

Default: `warning`

The level of messages to send to the log file. See also `log_level_logfile`. When it is not set explicitly it will inherit the level set by `log_level` option.

<table>
<thead>
<tr>
<th>log_level_logfile</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>warning</code></td>
</tr>
</tbody>
</table>

**log_datefmt**

Default: `%H:%M:%S`

The date and time format used in console log messages. See also `log_datefmt`.

<table>
<thead>
<tr>
<th>log_datefmt</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>%H:%M:%S</code></td>
</tr>
</tbody>
</table>

**log_datefmt_logfile**

Default: `%Y-%m-%d %H:%M:%S`

The date and time format used in log file messages. See also `log_datefmt_logfile`.

<table>
<thead>
<tr>
<th>log_datefmt_logfile</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>%Y-%m-%d %H:%M:%S</code></td>
</tr>
</tbody>
</table>
**log_fmt_console**

Default: `[%{(levelname)-8s}] %(message)s`

The format of the console logging messages. See also `log_fmt_console`.

**Note:** Log colors are enabled in `log_fmt_console` rather than the `color` config since the logging system is loaded before the master config.

Console log colors are specified by these additional formatters:

`%(colorlevel)s %(colorname)s %(colorprocess)s %(colormsg)s`

Since it is desirable to include the surrounding brackets, `[' and ']`, in the coloring of the messages, these color formatters also include padding as well. Color LogRecord attributes are only available for console logging.

```
log_fmt_console: '(%(colorlevel)s%(colormsg)s')
```

```
log_fmt_console: '(%(levelname)-8s)%(message)s'
```

**log_fmt_logfile**

Default: `%(%asctime)s,%(msecs)03.0f [%(name)-17s][%(levelname)-8s] %(message)s`

The format of the log file logging messages. See also `log_fmt_logfile`.

```
log_fmt_logfile: '%(asctime)s,%(msecs)03.0f [%(name)-17s][%(levelname)-8s] %(message)s'
```

**log_granular_levels**

Default: `{}`

This can be used to control logging levels more specifically. See also `log_granular_levels`.

### 31.8.11 Node Groups

Default: `{}`

Node groups allow for logical groupings of minion nodes. A group consists of a group name and a compound target.

```
nodegroups:
  group1: 'L@foo.domain.com,bar.domain.com,baz.domain.com or bl*.domain.com'
  group2: 'G@os:Debian and foo.domain.com'
  group3: 'G@os:Debian and N@group1'
```

More information on using nodegroups can be found [here](#).

### 31.8.12 Range Cluster Settings

**range_server**

Default: `'`

The range server (and optional port) that serves your cluster information

`https://github.com/ytoolshed/range/wiki/%22yamlfile%22-module-file-spec`
31.8.13 Include Configuration

**default_include**

Default: `master.d/*.conf`

The master can include configuration from other files. Per default the master will automatically include all config files from `master.d/*.conf` where `master.d` is relative to the directory of the master configuration file.

**include**

Default: `not defined`

The master can include configuration from other files. To enable this, pass a list of paths to this option. The paths can be either relative or absolute; if relative, they are considered to be relative to the directory the main minion configuration file lives in. Paths can make use of shell-style globbing. If no files are matched by a path passed to this option then the master will log a warning message.

```bash
# Include files from a master.d directory in the same
directory as the master config file
include: master.d/*/ 

# Include a single extra file into the configuration
include: /etc/roles/webserver

# Include several files and the master.d directory
include:
  - extra_config
  - master.d/*
  - /etc/roles/webserver
```

31.8.14 Windows Software Repo Settings

**winrepo_provider**

New in version 2015.8.0.

Specify the provider to be used for winrepo. Must be either pygit2 or gitpython. If unset, then both will be tried in that same order, and the first one with a compatible version installed will be the provider that is used.

```bash
winrepo_provider: gitpython
```

**winrepo_dir**

Changed in version 2015.8.0: Renamed from `win_repo` to `winrepo_dir`

Default: `/srv/salt/win/repo`

Location on the master where the `winrepo_remotes` are checked out.
**winrepo_dir**

Path relative to `winrepo_dir` where the winrepo cache should be created.

```
winrepo_dir: /srv/salt/win/repo
```

**winrepo_cachefile**

Changed in version 2015.8.0: Renamed from `win_repo_mastercachefile` to `winrepo_cachefile`

Default: `winrepo.p`

```
winrepo_cachefile: winrepo.p
```

**winrepo_remotes**

Changed in version 2015.8.0: Renamed from `win_gitrepos` to `winrepo_remotes`

Default: `['https://github.com/saltstack/salt-winrepo.git']`

List of git repositories to checkout and include in the winrepo

```
winrepo_remotes:
  - https://github.com/saltstack/salt-winrepo.git
```

To specify a specific revision of the repository, prepend a commit ID to the URL of the the repository:

```
winrepo_remotes:
  - '<commit_id> https://github.com/saltstack/salt-winrepo.git'
```

Replace `<commit_id>` with the SHA1 hash of a commit ID. Specifying a commit ID is useful in that it allows one to revert back to a previous version in the event that an error is introduced in the latest revision of the repo.

**winrepo_branch**

New in version 2015.8.0.

Default: `master`

If the branch is omitted from a winrepo remote, then this branch will be used instead. For example, in the configuration below, the first two remotes would use the `winrepo` branch/tag, while the third would use the `foo` branch/tag.

```
winrepo_branch: winrepo
```

```
ext_pillar:
  - git:
    - https://mygitserver/winrepo1.git
    - https://mygitserver/winrepo2.git:
      - foo https://mygitserver/winrepo3.git
```

**winrepo_ssl_verify**

New in version 2015.8.0.

Default: `True`
Specifies whether or not to ignore SSL certificate errors when contacting the remote repository. You might want to set this to `False` if you’re using a git repo that uses a self-signed certificate. However, keep in mind that setting this to anything other `True` is a considered insecure, and using an SSH-based transport (if available) may be a better option.

```
winrepo_ssl_verify: True
```

### Winrepo Authentication Options

These parameters only currently apply to the `pygit2` `winrepo_provider`. Authentication works the same as it does in gitfs, as outlined in the `GitFS Walkthrough`, though the global configuration options are named differently to reflect that they are for winrepo instead of gitfs.

**winrepo_user**

New in version 2015.8.0.

Default: `''`

Along with `winrepo_password`, is used to authenticate to HTTPS remotes.

```
winrepo_user: git
```

**winrepo_password**

New in version 2015.8.0.

Default: `''`

Along with `winrepo_user`, is used to authenticate to HTTPS remotes. This parameter is not required if the repository does not use authentication.

```
winrepo_password: mypassword
```

**winrepo_insecure_auth**

New in version 2015.8.0.

Default: `False`

By default, Salt will not authenticate to an HTTP (non-HTTPS) remote. This parameter enables authentication over HTTP. **Enable this at your own risk.**

```
winrepo_insecure_auth: True
```

**winrepo_pubkey**

New in version 2015.8.0.

Default: `''`

Along with `winrepo_privkey` (and optionally `winrepo_passphrase`), is used to authenticate to SSH remotes.
**winrepo_pubkey**: /path/to/key.pub

**winrepo_privkey**

New in version 2015.8.0.
Default: ''
Along with **winrepo_pubkey** (and optionally **winrepo_passphrase**), is used to authenticate to SSH remotes.

**winrepo_passphrase**

New in version 2015.8.0.
Default: ''
This parameter is optional, required only when the SSH key being used to authenticate is protected by a passphrase.

31.9 Configuring the Salt Minion

The Salt system is amazingly simple and easy to configure. The two components of the Salt system each have a respective configuration file. The **salt-master** is configured via the master configuration file, and the **salt-minion** is configured via the minion configuration file.

See also:

*example minion configuration file*

The Salt Minion configuration is very simple. Typically, the only value that needs to be set is the master value so the minion knows where to locate its master.

By default, the salt-minion configuration will be in /etc/salt/minion. A notable exception is FreeBSD, where the configuration will be in /usr/local/etc/salt/minion.

### 31.9.1 Minion Primary Configuration

**master**

Default: salt
The hostname or ipv4 of the master.
Default: salt

```yaml
master: salt
```

The option can also be set to a list of masters, enabling **multi-master** mode.

```yaml
master:
  - address1
  - address2
```
Changed in version 2014.7.0: The master can be dynamically configured. The `master` value can be set to an module function which will be executed and will assume that the returning value is the ip or hostname of the desired master. If a function is being specified, then the `master_type` option must be set to `func`, to tell the minion that the value is a function to be run and not a fully-qualified domain name.

```
master: module.function
master_type: func
```

In addition, instead of using multi-master mode, the minion can be configured to use the list of master addresses as a failover list, trying the first address, then the second, etc. until the minion successfully connects. To enable this behavior, set `master_type` to `failover`:

```
master:
  - address1
  - address2
master_type: failover
```

**master_type**

New in version 2014.7.0.

Default: `str`

The type of the `master` variable. Can be `str`, `failover` or `func`.

```
master_type: failover
```

If this option is set to `failover`, `master` must be a list of master addresses. The minion will then try each master in the order specified in the list until it successfully connects. `master_alive_interval` must also be set, this determines how often the minion will verify the presence of the master.

```
master_type: func
```

If the master needs to be dynamically assigned by executing a function instead of reading in the static master value, set this to `func`. This can be used to manage the minion’s master setting from an execution module. By simply changing the algorithm in the module to return a new master ip/fqdn, restart the minion and it will connect to the new master.

**master_alive_interval**

```
master_alive_interval: 30
```

Configures how often, in seconds, the minion will verify that the current master is alive and responding. The minion will try to establish a connection to the next master in the list if it finds the existing one is dead.

**master_shuffle**

New in version 2014.7.0.

Default: `False`

If `master` is a list of addresses, shuffle them before trying to connect to distribute the minions over all available masters. This uses Python's `random.shuffle` method.

```
master_shuffle: True
```
**retry_dns**

Default: 30

Set the number of seconds to wait before attempting to resolve the master hostname if name resolution fails. Defaults to 30 seconds. Set to zero if the minion should shutdown and not retry.

retry_dns: 30

**master_port**

Default: 4506

The port of the master ret server, this needs to coincide with the ret_port option on the Salt master.

master_port: 4506

**user**

Default: root

The user to run the Salt processes

user: root

**sudo_runas**

Default: None

The user to run salt remote execution commands as via sudo. If this option is enabled then sudo will be used to change the active user executing the remote command. If enabled the user will need to be allowed access via the sudoers file for the user that the salt minion is configured to run as. The most common option would be to use the root user. If this option is set the user option should also be set to a non-root user. If migrating from a root minion to a non root minion the minion cache should be cleared and the minion pki directory will need to be changed to the ownership of the new user.

sudo_runas: root

**sudo_user**

Default: ''

Setting sudo_user will cause salt to run all execution modules under an sudo to the user given in sudo_user. The user under which the salt minion process itself runs will still be that provided in user above, but all execution modules run by the minion will be rerouted through sudo.

sudo_user: saltadm

**pidfile**

Default: /var/run/salt-minion.pid

The location of the daemon's process ID file
pidfile: /var/run/salt-minion.pid

root_dir
Default: /
This directory is prepended to the following options: pki_dir, cachedir, log_file, sock_dir, and pid-file.
root_dir: /

pki_dir
Default: /etc/salt/pki
The directory used to store the minion's public and private keys.
pki_dir: /etc/salt/pki

id
Default: the system's hostname
See also:
Salt Walkthrough
The Setting up a Salt Minion section contains detailed information on how the hostname is determined.
Explicitly declare the id for this minion to use. Since Salt uses detached ids it is possible to run multiple minions on
the same machine but with different ids.
id: foo.bar.com

append_domain
Default: None
Append a domain to a hostname in the event that it does not exist. This is useful for systems where
socket.getfqdn() does not actually result in a FQDN (for instance, Solaris).
append_domain: foo.org

cachedir
Default: /var/cache/salt
The location for minion cache data.
This directory may contain sensitive data and should be protected accordingly.
cachedir: /var/cache/salt
**verify_env**

Default: True
Verify and set permissions on configuration directories at startup.

| verify_env: True |

**Note:** When marked as True the verify_env option requires WRITE access to the configuration directory (/etc/salt/). In certain situations such as mounting /etc/salt/ as read-only for templating this will create a stack trace when state.highstate is called.

**cache_jobs**

Default: False
The minion can locally cache the return data from jobs sent to it, this can be a good way to keep track of the minion side of the jobs the minion has executed. By default this feature is disabled, to enable set cache_jobs to True.

| cache_jobs: False |

**grains_cache**

Default: False
The minion can locally cache grain data instead of refreshing the data each time the grain is referenced. By default this feature is disabled, to enable set grains_cache to True.

| grains_cache: False |

**sock_dir**

Default: /var/run/salt/minion
The directory where Unix sockets will be kept.

| sock_dir: /var/run/salt/minion |

**backup_mode**

Default: []
Backup files replaced by file.managed and file.recurse under cachedir.

| backup_mode: minion |

**acceptance_wait_time**

Default: 10
The number of seconds to wait until attempting to re-authenticate with the master.
**random_reauth_delay**

When the master key changes, the minion will try to re-auth itself to receive the new master key. In larger environments this can cause a syn-flood on the master because all minions try to re-auth immediately. To prevent this and have a minion wait for a random amount of time, use this optional parameter. The wait-time will be a random number of seconds between 0 and the defined value.

| random_reauth_delay: 60 |

**acceptance_wait_time_max**

Default: None

The maximum number of seconds to wait until attempting to re-authenticate with the master. If set, the wait will increase by acceptance_wait_time_seconds each iteration.

| acceptance_wait_time_max: None |

**recon_default**

Default: 1000

The interval in milliseconds that the socket should wait before trying to reconnect to the master (1000ms = 1 second).

| recon_default: 1000 |

**recon_max**

Default: 10000

The maximum time a socket should wait. Each interval the time to wait is calculated by doubling the previous time. If recon_max is reached, it starts again at the recon_default.

**Short example:**

- reconnect 1: the socket will wait `recon_default` milliseconds
- reconnect 2: `recon_default` * 2
- reconnect 3: (`recon_default` * 2) * 2
- reconnect 4: value from previous interval * 2
- reconnect 5: value from previous interval * 2
- reconnect x: if value >= recon_max, it starts again with recon_default

| recon_max: 10000 |
**recon_randomize**

Default: True

Generate a random wait time on minion start. The wait time will be a random value between recon_default and recon_default and recon_max. Having all minions reconnect with the same recon_default and recon_max value kind of defeats the purpose of being able to change these settings. If all minions have the same values and the setup is quite large (several thousand minions), they will still flood the master. The desired behavior is to have time-frame within all minions try to reconnect.

| recon_randomize: True |

**cache_sreqs**

Default: True

The connection to the master ret_port is kept open. When set to False, the minion creates a new connection for every return to the master. environment, set this value to False.

| cache_sreqs: True |

**ipc_mode**

Default: ipc

Windows platforms lack POSIX IPC and must rely on slower TCP based inter-process communications. Set ipc_mode to tcp on such systems.

| ipc_mode: ipc |

**tcp_pub_port**

Default: 4510

Publish port used when ipc_mode is set to tcp.

| tcp_pub_port: 4510 |

**tcp_pull_port**

Default: 4511

Pull port used when ipc_mode is set to tcp.

| tcp_pull_port: 4511 |

### 31.9.2 Minion Module Management

**disable_modules**

Default: [] (all modules are enabled by default)
The event may occur in which the administrator desires that a minion should not be able to execute a certain module. The sys module is built into the minion and cannot be disabled. This setting can also tune the minion, as all modules are loaded into ram disabling modules will lower the minion’s ram footprint.

<table>
<thead>
<tr>
<th>disable_modules:</th>
</tr>
</thead>
<tbody>
<tr>
<td>- test</td>
</tr>
<tr>
<td>- solr</td>
</tr>
</tbody>
</table>

**disable_returners**

Default: [] (all returners are enabled by default)

If certain returners should be disabled, this is the place

<table>
<thead>
<tr>
<th>disable_returners:</th>
</tr>
</thead>
<tbody>
<tr>
<td>- mongo_return</td>
</tr>
</tbody>
</table>

**module_dirs**

Default: []

A list of extra directories to search for Salt modules

<table>
<thead>
<tr>
<th>module_dirs:</th>
</tr>
</thead>
<tbody>
<tr>
<td>- /var/lib/salt/modules</td>
</tr>
</tbody>
</table>

**returner_dirs**

Default: []

A list of extra directories to search for Salt returners

<table>
<thead>
<tr>
<th>returners_dirs:</th>
</tr>
</thead>
<tbody>
<tr>
<td>- /var/lib/salt/returners</td>
</tr>
</tbody>
</table>

**states_dirs**

Default: []

A list of extra directories to search for Salt states

<table>
<thead>
<tr>
<th>states_dirs:</th>
</tr>
</thead>
<tbody>
<tr>
<td>- /var/lib/salt/states</td>
</tr>
</tbody>
</table>

**grains_dirs**

Default: []

A list of extra directories to search for Salt grains

<table>
<thead>
<tr>
<th>grains_dirs:</th>
</tr>
</thead>
<tbody>
<tr>
<td>- /var/lib/salt/grains</td>
</tr>
</tbody>
</table>
**render_dirs**

Default: []
A list of extra directories to search for Salt renderers

```yaml
render_dirs:
  - /var/lib/salt/renderers
```

**cython_enable**

Default: False
Set this value to true to enable auto-loading and compiling of `.pyx` modules. This setting requires that `gcc` and `cython` are installed on the minion

```yaml
cython_enable: False
```

**enable_zip_modules**

New in version 2015.8.0.
Default: False
Set this value to true to enable loading of zip archives as extension modules. This allows for packing module code with specific dependencies to avoid conflicts and/or having to install specific modules' dependencies in system libraries.

```yaml
enable_zip_modules: False
```

**providers**

Default: (empty)
A module provider can be statically overwritten or extended for the minion via the `providers` option. This can be done on an individual basis in an SLS file, or globally here in the minion config, like below.

```yaml
providers:
  service: systemd
```

### 31.9.3 State Management Settings

**renderer**

Default: `yaml_jinja`
The default renderer used for local state executions

```yaml
renderer: yaml_jinja
```
state_verbose

Default: False

state_verbose allows for the data returned from the minion to be more verbose. Normally only states that fail or states that have changes are returned, but setting `state_verbose` to True will return all states that were checked.

```
state_verbose: True
```

state_output

Default: full

The state_output setting changes if the output is the full multi line output for each changed state if set to `full`, but if set to `terse` the output will be shortened to a single line.

```
state_output: full
```

autoload_dynamic_modules

Default: True

autoload_dynamic_modules Turns on automatic loading of modules found in the environments on the master. This is turned on by default, to turn off auto-loading modules when states run set this value to False.

```
autoload_dynamic_modules: True
```

Default: True

clean_dynamic_modules keeps the dynamic modules on the minion in sync with the dynamic modules on the master, this means that if a dynamic module is not on the master it will be deleted from the minion. By default this is enabled and can be disabled by changing this value to False.

```
clean_dynamic_modules: True
```

evironment

Default: None

Normally the minion is not isolated to any single environment on the master when running states, but the environment can be isolated on the minion side by statically setting it. Remember that the recommended way to manage environments is to isolate via the top file.

```
environment: None
```

31.9.4 File Directory Settings

file_client

Default: remote

The client defaults to looking on the master server for files, but can be directed to look on the minion by setting this parameter to local.
file_client: remote

**use_master_when_local**

Default: False

When using a local `file_client`, this parameter is used to allow the client to connect to a master for remote execution.

use_master_when_local: False

**file_roots**

Default:

```plaintext
base: /srv/salt
```

When using a local `file_client`, this parameter is used to setup the fileserver’s environments. This parameter operates identically to the `master config parameter` of the same name.

```plaintext
file_roots:
   base:
      - /srv/salt
   dev:
      - /srv/salt/dev/services
      - /srv/salt/dev/states
   prod:
      - /srv/salt/prod/services
      - /srv/salt/prod/states
```

**hash_type**

Default: md5

The `hash_type` is the hash to use when discovering the hash of a file on the local fileserver. The default is md5, but sha1, sha224, sha256, sha384, and sha512 are also supported.

hash_type: md5

**pillar_roots**

Default:

```plaintext
base: /srv/pillar
```

When using a local `file_client`, this parameter is used to setup the pillar environments.

```plaintext
pillar_roots:
   base:
      - /srv/pillar
   dev:
      - /srv/pillar/dev
```
31.9.5 Security Settings

open_mode

Default: False
Open mode can be used to clean out the PKI key received from the Salt master, turn on open mode, restart the minion, then turn off open mode and restart the minion to clean the keys.

open_mode: False

master_finger

Default: ''
Fingerprint of the master public key to validate the identity of your Salt master before the initial key exchange. The master fingerprint can be found by running ``salt-key -F master'' on the Salt master.

verify_master_pubkey_sign

Default: False
Enables verification of the master-public-signature returned by the master in auth-replies. Please see the tutorial on how to configure this properly Multimaster-PKI with Failover Tutorial
New in version 2014.7.0.

verify_master_pubkey_sign: True

If this is set to True, master_sign_pubkey must be also set to True in the master configuration file.

master_sign_key_name

Default: master_sign
The filename without the .pub suffix of the public key that should be used for verifying the signature from the master. The file must be located in the minion's pki directory.
New in version 2014.7.0.

master_sign_key_name: <filename_without_suffix>

always_verify_signature

Default: False
If verify_master_pubkey_sign is enabled, the signature is only verified, if the public-key of the master changes. If the signature should always be verified, this can be set to True.
New in version 2014.7.0.

always_verify_signature: True

### 31.9.6 Thread Settings

Default: True

Disable multiprocessing support by default when a minion receives a publication a new process is spawned and the command is executed therein.

multiprocessing: True

### 31.9.7 Minion Logging Settings

**log_file**

Default: /var/log/salt/minion

The minion log can be sent to a regular file, local path name, or network location. See also log_file.

Examples:

<table>
<thead>
<tr>
<th>log_file</th>
</tr>
</thead>
<tbody>
<tr>
<td>/var/log/salt/minion</td>
</tr>
<tr>
<td>file:///dev/log</td>
</tr>
<tr>
<td>udp://loghost:10514</td>
</tr>
</tbody>
</table>

**log_level**

Default: warning

The level of messages to send to the console. See also log_level.

<table>
<thead>
<tr>
<th>log_level</th>
</tr>
</thead>
<tbody>
<tr>
<td>warning</td>
</tr>
</tbody>
</table>

**log_level_logfile**

Default: warning

The level of messages to send to the log file. See also log_level_logfile. When it is not set explicitly it will inherit the level set by log_level option.

<table>
<thead>
<tr>
<th>log_level_logfile</th>
</tr>
</thead>
<tbody>
<tr>
<td>warning</td>
</tr>
</tbody>
</table>

**log_datefmt**

Default: %H:%M:%S

The date and time format used in console log messages. See also log_datefmt.
log_datefmt: \'%H:%M:%S\'

**log_datefmt_logfile**

Default: \%Y-\%m-\%d \%H:\%M:\%S

The date and time format used in log file messages. See also log_datefmt_logfile.

log_datefmt_logfile: \'%Y-\%m-\%d \%H:\%M:\%S\'

**log_fmt_console**

Default: \[\%(levelname)-8s\] \%(message)s

The format of the console logging messages. See also log_fmt_console.

Note: Log colors are enabled in log_fmt_console rather than the color config since the logging system is loaded before the minion config.

Console log colors are specified by these additional formatters:

\%(colorlevel)s \%(colormsg)s

Since it is desirable to include the surrounding brackets, '[' and ']', in the coloring of the messages, these color formatters also include padding as well. Color LogRecord attributes are only available for console logging.

log_fmt_console: \'(colorlevel)s \(colormsg)s\'
log_fmt_console: \'[%(levelname)-8s] \%(message)s\'

**log_fmt_logfile**

Default: \%(asctime)s,\%(msecs)03.0f \[\%(name)-17s]\%(levelname)-8s \%(message)s

The format of the log file logging messages. See also log_fmt_logfile.

log_fmt_logfile: \'(asctime)s,\%(msecs)03.0f \[\%(name)-17s]\%(levelname)-8s \%(message)s\'

**log_granular_levels**

Default: \{

This can be used to control logging levels more specifically. See also log_granular_levels.

**failhard**

Default: False

Set the global failhard flag, this informs all states to stop running states at the moment a single state fails.

failhard: False
31.9.8 Include Configuration

**default_include**

Default: minion.d/*.conf

The minion can include configuration from other files. Per default the minion will automatically include all config files from **minion.d/*.conf** where minion.d is relative to the directory of the minion configuration file.

**include**

Default: not defined

The minion can include configuration from other files. To enable this, pass a list of paths to this option. The paths can be either relative or absolute; if relative, they are considered to be relative to the directory the main minion configuration file lives in. Paths can make use of shell-style globbing. If no files are matched by a path passed to this option then the minion will log a warning message.

```bash
# Include files from a minion.d directory in the same directory as the minion config file
include: minion.d/*.conf

# Include a single extra file into the configuration
include: /etc/roles/webserver

# Include several files and the minion.d directory
include:
  - extra_config
  - minion.d/*
  - /etc/roles/webserver
```

31.9.9 Frozen Build Update Settings

These options control how `salt.modules.saltutil.update()` works with esky frozen apps. For more information look at https://github.com/cloudmatrix/esky/.

**update_url**

Default: False (Update feature is disabled)

The url to use when looking for application updates. Esky depends on directory listings to search for new versions. A webserver running on your Master is a good starting point for most setups.

```bash
update_url: 'http://salt.example.com/minion-updates'
```

**update_restart_services**

Default: [] (service restarting on update is disabled)

A list of services to restart when the minion software is updated. This would typically just be a list containing the minion's service name, but you may have other services that need to go with it.

```bash
update_restart_services: ['salt-minion']
```
31.9.10 Standalone Minion Windows Software Repo Settings

**Important:** To use these config options, the minion must be running in masterless mode (set file_client to local).

---

**winrepo_dir**

Changed in version 2015.8.0: Renamed from win_repo to winrepo_dir. Also, this option did not have a default value until this version.

Default: C:\salt\srv\salt\win\repo

Location on the minion where the winrepo_remotes are checked out.

```
winrepo_dir: 'D:\winrepo'
```

---

**winrepo_cachefile**

Changed in version 2015.8.0: Renamed from win_repo_cachefile to winrepo_cachefile. Also, this option did not have a default value until this version.

Default: winrepo.p

Path relative to winrepo_dir where the winrepo cache should be created.

```
winrepo_cachefile: winrepo.p
```

---

**winrepo_remotes**

Changed in version 2015.8.0: Renamed from win_gitrepos to winrepo_remotes. Also, this option did not have a default value until this version.

New in version 2015.8.0.

Default: ['https://github.com/saltstack/salt-winrepo.git']

List of git repositories to checkout and include in the winrepo

```
winrepo_remotes:
  - https://github.com/saltstack/salt-winrepo.git
```

To specify a specific revision of the repository, prepend a commit ID to the URL of the the repository:

```
winrepo_remotes:
  - '<commit_id> https://github.com/saltstack/salt-winrepo.git'
```

Replace <commit_id> with the SHA1 hash of a commit ID. Specifying a commit ID is useful in that it allows one to revert back to a previous version in the event that an error is introduced in the latest revision of the repo.

---

31.10 Running the Salt Master/Minion as an Unprivileged User

While the default setup runs the master and minion as the root user, some may consider it an extra measure of security to run the master as a non-root user. Keep in mind that doing so does not change the master's capability
to access minions as the user they are running as. Due to this many feel that running the master as a non-root user does not grant any real security advantage which is why the master has remained as root by default.

**Note:** Some of Salt's operations cannot execute correctly when the master is not running as root, specifically the pam external auth system, as this system needs root access to check authentication.

As of Salt 0.9.10 it is possible to run Salt as a non-root user. This can be done by setting the `user` parameter in the master configuration file, and restarting the `salt-master` service.

The minion has its own `user` parameter as well, but running the minion as an unprivileged user will keep it from making changes to things like users, installed packages, etc. unless access controls (sudo, etc.) are setup on the minion to permit the non-root user to make the needed changes.

In order to allow Salt to successfully run as a non-root user, ownership, and permissions need to be set such that the desired user can read from and write to the following directories (and their subdirectories, where applicable):

- `/etc/salt`
- `/var/cache/salt`
- `/var/log/salt`
- `/var/run/salt`

Ownership can be easily changed with `chown`, like so:

```
# chown -R user /etc/salt /var/cache/salt /var/log/salt /var/run/salt
```

**Warning:** Running either the master or minion with the `root_dir` parameter specified will affect these paths, as will setting options like `pki_dir`, `cachedir`, `log_file`, and other options that normally live in the above directories.

### 31.11 Logging

The salt project tries to get the logging to work for you and help us solve any issues you might find along the way.

If you want to get some more information on the nitty-gritty of salt's logging system, please head over to the [logging development document](https://docs.saltstack.com/en/latest/ref/logging.html), if all you're after is salt's logging configurations, please continue reading.

### 31.11.1 Available Configuration Settings

**log_file**

The log records can be sent to a regular file, local path name, or network location. Remote logging works best when configured to use rsyslogd(8) (e.g.: `file:///dev/log`), with rsyslogd(8) configured for network logging. The format for remote addresses is: `<file|udp|tcp>://<host|socketpath>:<port-if-required>>/<log-facility>.

Default: Dependent of the binary being executed, for example, for `salt-master`, `/var/log/salt/master`.

Examples:

<table>
<thead>
<tr>
<th>log_file</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>/var/log/salt/master</code></td>
</tr>
<tr>
<td><code>/var/log/salt/minion</code></td>
</tr>
</tbody>
</table>
log_file: file:///dev/log
log_file: udp://loghost:10514

**log_level**

Default: warning

The level of log record messages to send to the console. One of all, garbage, trace, debug, info, warning, error, critical, quiet.

log_level: warning

**log_level_logfile**

Default: warning

The level of messages to send to the log file. One of all, garbage, trace, debug, info, warning, error, critical, quiet.

log_level_logfile: warning

**log_datefmt**

Default: %H:%M:%S

The date and time format used in console log messages. Allowed date/time formatting can be seen on `time.strftime`.

log_datefmt: '%H:%M:%S'

**log_datefmt_logfile**

Default: %Y-%m-%d %H:%M:%S

The date and time format used in log file messages. Allowed date/time formatting can be seen on `time.strftime`.

log_datefmt_logfile: '%Y-%m-%d %H:%M:%S'

**log_fmt_console**

Default: [%levelname]-8s %message

The format of the console logging messages. All standard python logging `LogRecord` attributes can be used. Salt also provides these custom LogRecord attributes to colorize console log output:

- '%(colorlevel)s'  # log level name colorized by level
- '%(colormsg)s'    # log message colorized by level
- '%(colorname)s'   # colorized module name
- '%(colorprocess)s' # colorized process number

606 Chapter 31. Reference
Note: The %(colorlevel)s, %(colormname)s, and %(colorprocess)s LogRecord attributes also include padding and enclosing brackets, [ and ] to match the default values of their collateral non-colorized LogRecord attributes.

log_fmt_console: '[(levelname)-8s] %(message)s'

log_fmt_logfile

Default: %(asctime)s,%(msecs)03.0f [%(name)-17s][%(levelname)-8s] %(message)s

The format of the log file logging messages. All standard python logging LogRecord attributes can be used. Salt also provides these custom LogRecord attributes that include padding and enclosing brackets [ and ]:

%(bracketlevel)s  # equivalent to [%s(levelname)-8s]
%(bracketname)s   # equivalent to [%s(name)-17s]
%(bracketprocess)s # equivalent to [%s(process)5s]

log_fmt_logfile: '[(asctime)s,%(msecs)03.0f [%(name)-17s][%(levelname)-8s] %(message)s'

log_granular_levels

Default: {}

This can be used to control logging levels more specifically. The example sets the main salt library at the 'warning' level, but sets salt.modules to log at the debug level:

log_granular_levels:
'盐': 'warning'
'salt.modules': 'debug'

External Logging Handlers

Besides the internal logging handlers used by salt, there are some external which can be used, see the external logging handlers document.

31.12 External Logging Handlers

<table>
<thead>
<tr>
<th>logstash_mod</th>
<th>Logstash Logging Handler</th>
</tr>
</thead>
<tbody>
<tr>
<td>sentry_mod</td>
<td>Sentry Logging Handler</td>
</tr>
</tbody>
</table>

31.12.1 Logstash Logging Handler

New in version 0.17.0.

This module provides some Logstash logging handlers.
UDP Logging Handler

For versions of Logstash before 1.2.0:

In the salt configuration file:

```yaml
logstash_udp_handler:
  host: 127.0.0.1
  port: 9999
  version: 0
```

In the Logstash configuration file:

```yaml
input {
  udp {
    type => "udp-type"
    format => "json_event"
  }
}
```

For version 1.2.0 of Logstash and newer:

In the salt configuration file:

```yaml
logstash_udp_handler:
  host: 127.0.0.1
  port: 9999
  version: 1
```

In the Logstash configuration file:

```yaml
input {
  udp {
    port => 9999
    codec => json
  }
}
```

Please read the UDP input configuration page for additional information.

ZeroMQ Logging Handler

For versions of Logstash before 1.2.0:

In the salt configuration file:

```yaml
logstash_zmq_handler:
  address: tcp://127.0.0.1:2021
  version: 0
```

In the Logstash configuration file:

```yaml
input {
  zeromq {
    type => "zeromq-type"
    mode => "server"
    topology => "pubsub"
    address => "tcp://0.0.0.0:2021"
    charset => "UTF-8"
    format => "json_event"
  }
}
```
For version 1.2.0 of Logstash and newer:

In the salt configuration file:

```yaml
logstash_zmq_handler:
  address: tcp://127.0.0.1:2021
  version: 1
```

In the Logstash configuration file:

```yaml
input {
  zeromq {
    topology => "pubsub"
    address => "tcp://0.0.0.0:2021"
    codec => json
  }
}
```

Please read the ZeroMQ input configuration page for additional information.

### Important Logstash Setting

One of the most important settings that you should not forget on your Logstash configuration file regarding these logging handlers is **format**. Both the UDP and ZeroMQ inputs need to have **format** as **json_event** which is what we send over the wire.

### Log Level

Both the `logstash_udp_handler` and the `logstash_zmq_handler` configuration sections accept an additional setting **log_level**. If not set, the logging level used will be the one defined for **log_level** in the global configuration file section.

### HWM

The **high water mark** for the ZMQ socket setting. Only applicable for the `logstash_zmq_handler`.

### Inspiration

This work was inspired in pylogstash, python-logstash, canary and the PyZMQ logging handler.

### 31.12.2 Sentry Logging Handler

New in version 0.17.0.

This module provides a Sentry logging handler.

### Note

The Raven library needs to be installed on the system for this logging handler to be available.
Configuring the python Sentry client, Raven, should be done under the `sentry_handler` configuration key. Additional context may be provided for corresponding grain item(s). At the bare minimum, you need to define the DSN. As an example:

```python
sentry_handler:
    dsn: https://pub-key:secret-key@app.getsentry.com/app-id
```

More complex configurations can be achieved, for example:

```python
sentry_handler:
    servers:
        - https://sentry.example.com
        - http://192.168.1.1
    project: app-id
    public_key: deadbeefdeadbeefdeadbeefdeadbeef
    secret_key: beefdeadbeefdeadbeefdeadbeefdead
    context:
        - os
        - master
        - saltversion
        - cpuarch
        - ec2.tags.environment
```

All the client configuration keys are supported, please see the Raven client documentation.

The default logging level for the sentry handler is ERROR. If you wish to define a different one, define `log_level` under the `sentry_handler` configuration key:

```python
sentry_handler:
    dsn: https://pub-key:secret-key@app.getsentry.com/app-id
    log_level: warning
```

The available log levels are those also available for the salt cli tools and configuration; `salt --help` should give you the required information.

### Threaded Transports

Raven's documents rightly suggest using its threaded transport for critical applications. However, don't forget that if you start having troubles with Salt after enabling the threaded transport, please try switching to a non-threaded transport to see if that fixes your problem.

#### 31.13 Salt File Server

Salt comes with a simple file server suitable for distributing files to the Salt minions. The file server is a stateless ZeroMQ server that is built into the Salt master.

The main intent of the Salt file server is to present files for use in the Salt state system. With this said, the Salt file server can be used for any general file transfer from the master to the minions.

##### 31.13.1 File Server Backends

In Salt 0.12.0, the modular filesaver was introduced. This feature added the ability for the Salt Master to integrate different file server backends. File server backends allow the Salt file server to act as a transparent bridge to external resources. A good example of this is the git backend, which allows Salt to serve files sourced from one or more git repositories, but there are several others as well. Click here for a full list of Salt's fileserver backends.
Enabling a Fileserver Backend

Fileserver backends can be enabled with the `fileserver_backend` option.

```yaml
fileserver_backend:
  - git
```

See the documentation for each backend to find the correct value to add to `fileserver_backend` in order to enable them.

Using Multiple Backends

If `fileserver_backend` is not defined in the Master config file, Salt will use the `roots` backend, but the `fileserver_backend` option supports multiple backends. When more than one backend is in use, the files from the enabled backends are merged into a single virtual filesystem. When a file is requested, the backends will be searched in order for that file, and the first backend to match will be the one which returns the file.

```yaml
fileserver_backend:
  - roots
  - git
```

With this configuration, the environments and files defined in the `file_roots` parameter will be searched first, and if the file is not found then the git repositories defined in `gitfs_remotes` will be searched.

Environments

Just as the order of the values in `fileserver_backend` matters, so too does the order in which different sources are defined within a fileserver environment. For example, given the below `file_roots` configuration, if both `/srv/salt/dev/foo.txt` and `/srv/salt/prod/foo.txt` exist on the Master, then `salt://foo.txt` would point to `/srv/salt/dev/foo.txt` in the `dev` environment, but it would point to `/srv/salt/prod/foo.txt` in the `base` environment.

```yaml
file_roots:
  base:
    - /srv/salt/prod
  qa:
    - /srv/salt/qa
    - /srv/salt/prod
  dev:
    - /srv/salt/dev
    - /srv/salt/qa
    - /srv/salt/prod
```

Similarly, when using the `git` backend, if both repositories defined below have a `hotfix23` branch/tag, and both of them also contain the file `bar.txt` in the root of the repository at that branch/tag, then `salt://bar.txt` in the `hotfix23` environment would be served from the first repository.

```yaml
gitfs_remotes:
  - https://mydomain.tld/repos/first.git
  - https://mydomain.tld/repos/second.git
```

Note: Environments map differently based on the fileserver backend. For instance, the mappings are explicitly defined in `roots` backend, while in the VCS backends (`git, hg, svn`) the environments are created from branches/tags/bookmarks/etc. For the `minion` backend, the files are all in a single environment, which is specified by the `minionfs_env` option.
See the documentation for each backend for a more detailed explanation of how environments are mapped.

### 31.13.2 Dynamic Module Distribution

New in version 0.9.5.

Salt Python modules can be distributed automatically via the Salt file server. Under the root of any environment defined via the `file_roots` option on the master server directories corresponding to the type of module can be used.

The directories are prepended with an underscore:

1. `_modules`
2. `_grains`
3. `_renderers`
4. `_returners`
5. `_states`

The contents of these directories need to be synced over to the minions after Python modules have been created in them. There are a number of ways to sync the modules.

**Sync Via States**

The minion configuration contains an option `autoload_dynamic_modules` which defaults to True. This option makes the state system refresh all dynamic modules when states are run. To disable this behavior set `autoload_dynamic_modules` to False in the minion config.

When dynamic modules are autoloaded via states, modules only pertinent to the environments matched in the master's top file are downloaded.

This is important to remember, because modules can be manually loaded from any specific environment that environment specific modules will be loaded when a state run is executed.

**Sync Via the saltutil Module**

The saltutil module has a number of functions that can be used to sync all or specific dynamic modules. The saltutil module function `saltutil.sync_all` will sync all module types over to a minion. For more information see: `salt.modules.saltutil`

### 31.13.3 File Server Configuration

The Salt file server is a high performance file server written in ZeroMQ. It manages large files quickly and with little overhead, and has been optimized to handle small files in an extremely efficient manner.

The Salt file server is an environment aware file server. This means that files can be allocated within many root directories and accessed by specifying both the file path and the environment to search. The individual environments can span across multiple directory roots to create overlays and to allow for files to be organized in many flexible ways.
Environments

The Salt file server defaults to the mandatory base environment. This environment **MUST** be defined and is used to download files when no environment is specified.

Environments allow for files and sls data to be logically separated, but environments are not isolated from each other. This allows for logical isolation of environments by the engineer using Salt, but also allows for information to be used in multiple environments.

Directory Overlay

The environment setting is a list of directories to publish files from. These directories are searched in order to find the specified file and the first file found is returned.

This means that directory data is prioritized based on the order in which they are listed. In the case of this file_roots configuration:

```yaml
file_roots:
  base:
    - /srv/salt/base
    - /srv/salt/failover
```

If a file's URI is salt://httpd/httpd.conf, it will first search for the file at /srv/salt/base/httpd/httpd.conf. If the file is found there it will be returned. If the file is not found there, then /srv/salt/failover/httpd/httpd.conf will be used for the source.

This allows for directories to be overlaid and prioritized based on the order they are defined in the configuration.

It is also possible to have file_roots which supports multiple environments:

```yaml
file_roots:
  base:
    - /srv/salt/base
  dev:
    - /srv/salt/dev
    - /srv/salt/base
  prod:
    - /srv/salt/prod
    - /srv/salt/base
```

This example ensures that each environment will check the associated environment directory for files first. If a file is not found in the appropriate directory, the system will default to using the base directory.

Local File Server

New in version 0.9.8.

The file server can be rerouted to run from the minion. This is primarily to enable running Salt states without a Salt master. To use the local file server interface, copy the file server data to the minion and set the file_roots option on the minion to point to the directories copied from the master. Once the minion file_roots option has been set, change the file_client option to local to make sure that the local file server interface is used.

31.13.4 The cp Module

The cp module is the home of minion side file server operations. The cp module is used by the Salt state system, salt-cp, and can be used to distribute files presented by the Salt file server.
Escaping Special Characters

The `salt://` url format can potentially contain a query string, for example `salt://dir/file.txt?saltenv=base`. You can prevent the fileclient/fileserver from interpreting ? as the initial token of a query string by referencing the file with `salt://|` rather than `salt:///`.

```
/etc/marathon/conf/?checkpoint:
file.managed:
  - source: salt://|hw/config/?checkpoint
  - makedirs: True
```

Environments

Since the file server is made to work with the Salt state system, it supports environments. The environments are defined in the master config file and when referencing an environment the file specified will be based on the root directory of the environment.

get_file

The `cp.get_file` function can be used on the minion to download a file from the master, the syntax looks like this:

```bash
# salt '*' cp.get_file salt://vimrc /etc/vimrc
```

This will instruct all Salt minions to download the vimrc file and copy it to `/etc/vimrc`

Template rendering can be enabled on both the source and destination file names like so:

```bash
# salt '*' cp.get_file "salt://{{grains.os}}/vimrc" /etc/vimrc template=jinja
```

This example would instruct all Salt minions to download the vimrc from a directory with the same name as their OS grain and copy it to `/etc/vimrc`

For larger files, the `cp.get_file` module also supports gzip compression. Because gzip is CPU-intensive, this should only be used in scenarios where the compression ratio is very high (e.g. pretty-printed JSON or YAML files).

To use compression, use the `gzip` named argument. Valid values are integers from 1 to 9, where 1 is the lightest compression and 9 the heaviest. In other words, 1 uses the least CPU on the master (and minion), while 9 uses the most.

```bash
# salt '*' cp.get_file salt://vimrc /etc/vimrc gzip=5
```

Finally, note that by default `cp.get_file` does *not* create new destination directories if they do not exist. To change this, use the `makedirs` argument:

```bash
# salt '*' cp.get_file salt://vimrc /etc/vim/vimrc makedirs=True
```

In this example, `/etc/vim/` would be created if it didn’t already exist.

get_dir

The `cp.get_dir` function can be used on the minion to download an entire directory from the master. The syntax is very similar to `get_file`:

```bash
# salt '*' cp.get_dir salt://etc/apache2 /etc
```

cp.get_dir supports template rendering and gzip compression arguments just like get_file:
File Server Client API

A client API is available which allows for modules and applications to be written which make use of the Salt file server.

The file server uses the same authentication and encryption used by the rest of the Salt system for network communication.

FileClient Class

The FileClient class is used to set up the communication from the minion to the master. When creating a FileClient object the minion configuration needs to be passed in. When using the FileClient from within a minion module the built in __opts__ data can be passed:

```python
import salt.minion

def get_file(path, dest, env='base'):
    '''
    Used to get a single file from the Salt master
    CLI Example:
salt '*' cp.get_file salt://vimrc /etc/vimrc
    '''
    # Create the FileClient object
    client = salt.minion.FileClient(__opts__)
    # Call get_file
    return client.get_file(path, dest, False, env)
```

Using the FileClient class outside of a minion module where the __opts__ data is not available, it needs to be generated:

```python
import salt.minion
import salt.config

def get_file(path, dest, env='base'):
    '''
    Used to get a single file from the Salt master
    '''
    # Get the configuration data
    opts = salt.config.minion_config('/etc/salt/minion')
    # Create the FileClient object
    client = salt.minion.FileClient(opts)
    # Call get_file
    return client.get_file(path, dest, False, env)
```

31.14.1 salt.fileserver.azurefs

The backend for serving files from the Azure blob storage service.

To enable, add `azurefs` to the `fileserver_backend` option in the Master config file.

```python
fileserver_backend:
  - azurefs
```

Each environment is configured as a storage container. The name of the container must match the name of the environment. The `storage_account` is the name of the storage account inside Azure where the container lives, and the `storage_key` is the access key used for that storage account:

```python
azurefs_envs:
  base:
    storage_account: my_storage
    storage_key: frehgfsw34fwGegG07fwsfw343tGFDSDGDFGD==
```

With this configuration, multiple storage accounts can be used with a single salt infrastructure.

- `salt.fileserver.azurefs.dir_list(load)`
  Return a list of all directories on the master
- `salt.fileserver.azurefs.envs()`
  Treat each container as an environment
- `salt.fileserver.azurefs.file_hash(load, find)`
  Return a file hash, the hash type is set in the master config file
- `salt.fileserver.azurefs.file_list(load)`
  Return a list of all files on the file server in a specified environment
- `salt.fileserver.azurefs.find_file(path, saltenv='base', env=None, **kwargs)`
  Search the environment for the relative path
- `salt.fileserver.azurefs.serve_file(load, find)`
  Return a chunk from a file based on the data received
- `salt.fileserver.azurefs.update()`
  When we are asked to update (regular interval) lets reap the cache

31.14.2 salt.fileserver.gitfs

Git Fileserver Backend

With this backend, branches and tags in a remote git repository are exposed to salt as different environments.

To enable, add `git` to the `fileserver_backend` option in the Master config file.

```python
fileserver_backend:
  - git
```
As of Salt 2014.7.0, the Git fileserver backend supports `GitPython`, `pygit2`, and `dulwich` to provide the Python interface to git. If more than one of these are present, the order of preference for which one will be chosen is the same as the order in which they were listed: `pygit2`, `GitPython`, `dulwich` (keep in mind, this order is subject to change).

An optional master config parameter (`gitfs_provider`) can be used to specify which provider should be used. More detailed information on how to use `gitfs` can be found in the `Gitfs Walkthrough`.

**Note:** Minimum requirements
To use `GitPython` for `gitfs` requires a minimum `GitPython` version of 0.3.0, as well as the `git` CLI utility. Instructions for installing `GitPython` can be found [here](#).

To use `pygit2` for `gitfs` requires a minimum `pygit2` version of 0.20.3. `pygit2` 0.20.3 requires `libgit2` 0.20.0. `pygit2` and `libgit2` are developed alongside one another, so it is recommended to keep them both at the same major release to avoid unexpected behavior. For example, `pygit2` 0.21.x requires `libgit2` 0.21.x, `pygit2` 0.22.x will require `libgit2` 0.22.x, etc.

To find stale refs, `pygit2` additionally requires the `git` CLI utility to be installed.

```python
salt.fileserver.gitfs.clear_cache()
    Completely clear gitfs cache

clear_lock = lambda remote=None: salt.fileserver.gitfs.clear_lock(remote=remote)
    Clear update.lk

clear_cache = lambda load: salt.fileserver.gitfs.clear_cache(load=load)
    Return a list of all directories on the master

dir_list = lambda load: salt.fileserver.gitfs.dir_list(load=load)
    Return a list of refs that can be used as environments

file_hash = lambda load, fnd: salt.fileserver.gitfs.file_hash(load, fnd)
    Return a file hash, the hash type is set in the master config file

file_list = lambda load: salt.fileserver.gitfs.file_list(load=load)
    Return a list of all files on the file server in a specified environment (specified as a key within the load dict).

file_list_emptydirs = lambda load: salt.fileserver.gitfs.file_list_emptydirs(load)
    Return a list of all empty directories on the master

find_file = lambda path, tgt_env='base', **kwargs: salt.fileserver.gitfs.find_file(path, tgt_env=tgt_env, **kwargs)
    Find the first file to match the path and ref, read the file out of git and send the path to the newly cached file

init = lambda: salt.fileserver.gitfs.init()
    Initialize remotes. This is only used by the master’s pre-flight checks, and is not invoked by GitFS.

lock = lambda remote=None: salt.fileserver.gitfs.lock(remote=remote)
    Place an update.lk

    remote can either be a dictionary containing repo configuration information, or a pattern. If the latter, then remotes for which the URL matches the pattern will be locked.

serve_file = lambda load, fnd: salt.fileserver.gitfs.serve_file(load, fnd)
    Return a chunk from a file based on the data received

symlink_list = lambda load: salt.fileserver.gitfs.symlink_list(load)
    Return a dict of all symlinks based on a given path in the repo

update = lambda: salt.fileserver.gitfs.update()
    Execute a git fetch on all of the repos
```
31.14.3 salt.fileserver.hgfs

Mercurial Fileserver Backend

To enable, add hg to the `fileserver_backend` option in the Master config file.

```yaml
cfg.fileserver_backend:
    - hg
```

After enabling this backend, branches, bookmarks, and tags in a remote mercurial repository are exposed to salt as different environments. This feature is managed by the `fileserver_backend` option in the salt master config file.

This fileserver has an additional option `hgfs_branch_method` that will set the desired branch method. Possible values are: branches, bookmarks, or mixed. If using branches or mixed, the default branch will be mapped to base.

Changed in version 2014.1.0: The `hgfs_base` master config parameter was added, allowing for a branch other than default to be used for the base environment, and allowing for a base environment to be specified when using an `hgfs_branch_method` of bookmarks.

```plaintext
depends
  - mercurial
  - python bindings for mercurial (python-hglib)
```

salt.fileserver.hgfs.clear_cache()
Complete clear hgfs cache

salt.fileserver.hgfs.clear_lock(remote=None)
Clear update.lk

remote can either be a dictionary containing repo configuration information, or a pattern. If the latter, then remotes for which the URL matches the pattern will be locked.

salt.fileserver.hgfs.dir_list(load)
Return a list of all directories on the master

salt.fileserver.hgfs.envs(ignore_cache=False)
Return a list of refs that can be used as environments

salt.fileserver.hgfs.file_hash(load, find)
Return a file hash, the hash type is set in the master config file

salt.fileserver.hgfs.file_list(load)
Return a list of all files on the file server in a specified environment

salt.fileserver.hgfs.file_list_emptydirs(load)
Return a list of all empty directories on the master

salt.fileserver.hgfs.find_file(path, tgt_env='base', **kwargs)
Find the first file to match the path and ref, read the file out of hg and send the path to the newly cached file

salt.fileserver.hgfs.init()
Return a list of hglib objects for the various hgfs remotes

salt.fileserver.hgfs.lock(remote=None)
Place an update.lk

remote can either be a dictionary containing repo configuration information, or a pattern. If the latter, then remotes for which the URL matches the pattern will be locked.
salt.fileserver.hgfs.\texttt{serve\_file}(load,fnd)
\hspace{1em}Return a chunk from a file based on the data received

salt.fileserver.hgfs.\texttt{update}()
\hspace{1em}Execute an hg pull on all of the repos

### 31.14.4 salt.fileserver.minionfs

Fileserver backend which serves files pushed to the Master

The \texttt{cp.push} function allows Minions to push files up to the Master. Using this backend, these pushed files are exposed to other Minions via the Salt fileserver.

To enable minionfs, \texttt{file_recv} needs to be set to \texttt{True} in the master config file (otherwise \texttt{cp.push} will not be allowed to push files to the Master), and \texttt{minion} must be added to the \texttt{fileservers_backends} list.

```python
fileserver_backend:
   - minion
```

Other minionfs settings include: \texttt{minionfs_whitelist}, \texttt{minionfs_blacklist}, \texttt{minionfs_mountpoint}, and \texttt{minionfs_env}.

See also:

\textit{MinionFS Backend Walkthrough}

salt.fileserver.minionfs.\texttt{dir\_list}(load)
\hspace{1em}Return a list of all directories on the master

\textit{CLI Example:}

```bash
$ salt 'source-minion' cp.push /absolute/path/file  # Push the file to the master
$ salt 'destination-minion' cp.list_master_dirs
destination-minion:
  - source-minion/absolute
  - source-minion/absolute/path
```

salt.fileserver.minionfs.\texttt{envs}()
\hspace{1em}Returns the one environment specified for minionfs in the master configuration.

salt.fileserver.minionfs.\texttt{file\_hash}(load,fnd)
\hspace{1em}Return a file hash, the hash type is set in the master config file

salt.fileserver.minionfs.\texttt{file\_list}(load)
\hspace{1em}Return a list of all files on the file server in a specified environment

salt.fileserver.minionfs.\texttt{find\_file}(path,tgt_env='base',**kwargs)
\hspace{1em}Search the environment for the relative path

salt.fileserver.minionfs.\texttt{serve\_file}(load,fnd)
\hspace{1em}Return a chunk from a file based on the data received

\textit{CLI Example:}

```bash
# Push the file to the master
$ salt 'source-minion' cp.push /path/to/the/file
$ salt 'destination-minion' cp.get_file salt://source-minion/path/to/the/file /destination/file
```

salt.fileserver.minionfs.\texttt{update}()
\hspace{1em}When we are asked to update (regular interval) let's reap the cache

#### 31.14. Full list of builtin fileserver modules

---

619
31.14.5 salt.fileserver.roots

The default file server backend

This fileserver backend serves files from the Master's local filesystem. If `fileserver_backend` is not defined in the Master config file, then this backend is enabled by default. If it is defined then `roots` must be in the `fileserver_backend` list to enable this backend.

```yaml
fileserver_backend:
  - roots
```

Fileserver environments are defined using the `file_roots` configuration option.

```python
salt.fileserver.roots.dir_list(load)
Return a list of all directories on the master

salt.fileserver.roots.envs()
Return the file server environments

salt.fileserver.roots.file_hash(load, fnd)
Return a file hash, the hash type is set in the master config file

salt.fileserver.roots.file_list(load)
Return a list of all files on the file server in a specified environment

salt.fileserver.roots.file_list_emptydirs(load)
Return a list of all empty directories on the master

salt.fileserver.roots.find_file(path, saltenv='base', env=None, **kwargs)
Search the environment for the relative path

salt.fileserver.roots.serve_file(load, fnd)
Return a chunk from a file based on the data received

salt.fileserver.roots.symlink_list(load)
Return a dict of all symlinks based on a given path on the Master

salt.fileserver.roots.update()
When we are asked to update (regular interval) lets reap the cache
```

31.14.6 salt.fileserver.s3fs

Amazon S3 Fileserver Backend

This backend exposes directories in S3 buckets as Salt environments. To enable this backend, add `s3fs` to the `fileserver_backend` option in the Master config file.

```yaml
fileserver_backend:
  - s3fs
```

S3 credentials must also be set in the master config file:

```yaml
s3.keyid: GKTADJGHEIQSXMKKRBJ08H
s3.key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
```

Alternatively, if on EC2 these credentials can be automatically loaded from instance metadata.

This fileserver supports two modes of operation for the buckets:

1. A single bucket per environment
s3.buckets:
    production:
    - bucket1
    - bucket2
    staging:
    - bucket3
    - bucket4

2. Multiple environments per bucket

s3.buckets:
  - bucket1
  - bucket2
  - bucket3
  - bucket4

Note that bucket names must be all lowercase both in the AWS console and in Salt, otherwise you may encounter SignatureDoesNotMatch errors.

A multiple-environment bucket must adhere to the following root directory structure:

```
s3://<bucket name>/<environment>/<files>
```

Note: This files server back-end requires the use of the MD5 hashing algorithm. MD5 may not be compliant with all security policies.

```
salt.fileserver.s3fs.dir_list(load)
    Return a list of all directories on the master
salt.fileserver.s3fs.envs()
    Return a list of directories within the bucket that can be used as environments.

salt.fileserver.s3fs.file_hash(load, fnd)
    Return an MD5 file hash

salt.fileserver.s3fs.file_list(load)
    Return a list of all files on the file server in a specified environment

salt.fileserver.s3fs.file_list_emptydirs(load)
    Return a list of all empty directories on the master

salt.fileserver.s3fs.find_file(path, saltenv='base', env=None, **kwargs)
    Look through the buckets cache file for a match. If the field is found, it is retrieved from S3 only if its cached version is missing, or if the MD5 does not match.

salt.fileserver.s3fs.serve_file(load, fnd)
    Return a chunk from a file based on the data received

salt.fileserver.s3fs.update()
    Update the cache file for the bucket.

31.14.7 salt.fileserver.svnfs

Subversion Files server Backend

After enabling this backend, branches, and tags in a remote subversion repository are exposed to salt as different environments. To enable this backend, add svn to the fileserver_backend option in the Master config file.
This backend assumes a standard svn layout with directories for branches, tags, and trunk, at the repository root.

**depends**
- subversion
- pysvn

Changed in version 2014.7.0: The paths to the trunk, branches, and tags have been made configurable, via the config options `svnfs_trunk`, `svnfs_branches`, and `svnfs_tags`. `svnfs_mountpoint` was also added. Finally, support for per-remote configuration parameters was added. See the documentation for more information.

```python
salt.fileserver.svnfs.clear_cache()
```  
Completely clear svnfs cache

```python
salt.fileserver.svnfs.clear_lock(remote=None)
```  
Clear update.lk

remote can either be a dictionary containing repo configuration information, or a pattern. If the latter, then remotes for which the URL matches the pattern will be locked.

```python
salt.fileserver.svnfs.dir_list(load)
```  
Return a list of all directories on the master

```python
salt.fileserver.svnfs.envs(ignore_cache=False)
```  
Return a list of refs that can be used as environments

```python
salt.fileserver.svnfs.file_hash(load, find)
```  
Return a file hash, the hash type is set in the master config file

```python
salt.fileserver.svnfs.file_list(load)
```  
Return a list of all files on the file server in a specified environment

```python
salt.fileserver.svnfs.file_list_emptydirs(load)
```  
Return a list of all empty directories on the master

```python
salt.fileserver.svnfs.find_file(path, tgt_env='base', **kwargs)
```  
Find the first file to match the path and ref. This operates similarly to the roots file server but with assumptions of the directory structure based on svn standard practices.

```python
salt.fileserver.svnfs.init()
```  
Return the list of svn remotes and their configuration information

```python
salt.fileserver.svnfs.lock(remote=None)
```  
Place an update.lk

remote can either be a dictionary containing repo configuration information, or a pattern. If the latter, then remotes for which the URL matches the pattern will be locked.

```python
salt.fileserver.svnfs.serve_file(load, find)
```  
Return a chunk from a file based on the data received

```python
salt.fileserver.svnfs.update()
```  
Execute an svn update on all of the repos
31.15 Salt code and internals

Reference documentation on Salt’s internal code.

31.15.1 Contents

salt.aggregation

salt.utils.aggregation

This library makes it possible to introspect dataset and aggregate nodes when it is instructed.

---

**Note:** The following examples with be expressed in YAML for convenience’s sake:

- `!aggr-scalar` will refer to Scalar python function
- `!aggr-map` will refer to Map python object
- `!aggr-seq` will refer for Sequence python object

---

### How to instructs merging

This yaml document has duplicate keys:

```yaml
foo: !aggr-scalar first
foo: !aggr-scalar second
bar: !aggr-map {first: foo}
bar: !aggr-map {second: bar}
baz: !aggr-scalar 42
```

but tagged values instruct Salt that overlapping values they can be merged together:

```yaml
foo: !aggr-seq [first, second]
bar: !aggr-map {first: foo, second: bar}
baz: !aggr-seq [42]
```

### Default merge strategy is keep untouched

For example, this yaml document still has duplicate keys, but does not instruct aggregation:

```yaml
foo: first
foo: second
bar: {first: foo}
bar: {second: bar}
baz: 42
```

So the late found values prevail:

```yaml
foo: second
bar: {second: bar}
baz: 42
```

### Limitations

Aggregation is permitted between tagged objects that share the same type. If not, the default merge strategy prevails.

For example, these examples:
foo: {first: value}
foo: !aggr-map {second: value}

bar: !aggr-map {first: value}
bar: 42

baz: !aggr-seq [42]
baz: [fail]

qux: 42
qux: !aggr-scalar fail

are interpreted like this:

foo: !aggr-map {second: value}
bar: 42
baz: [fail]
qux: !aggr-seq [fail]

Introspection  TODO: write this part

salt.utils.aggregation.aggregate(obj_a, obj_b, level=False, map_class=<class 'salt.utils.aggregation.Map'>, sequence_class=<class 'salt.utils.aggregation.Sequence'>)

Merge obj_b into obj_a.

>>> aggregate('first', 'second', True) == ['first', 'second']
True

class salt.utils.aggregation.Aggregate
Aggregation base.

class salt.utils.aggregation.Map(*args, **kws)
Map aggregation.

salt.utils.aggregation.Scalar(obj)
Shortcut for Sequence creation

>>> Scalar('foo') == Sequence(['foo'])
True

class salt.utils.aggregation.Sequence
Sequence aggregation.

Exceptions

Salt-specific exceptions should be thrown as often as possible so the various interfaces to Salt (CLI, API, etc) can handle those errors appropriately and display error messages appropriately.
salt.exceptions

This module is a central location for all salt exceptions

*exception salt.exceptions.AuthenticationError*(message='')
  If sha256 signature fails during decryption

*exception salt.exceptions.AuthorizationError*(message='')
  Thrown when runner or wheel execution fails due to permissions

*exception salt.exceptions.CommandExecutionError*(message='')
  Used when a module runs a command which returns an error and wants to show the user the output gracefully instead of dying

*exception salt.exceptions.CommandNotFoundError*(message='')
  Used in modules or grains when a required binary is not available

*exception salt.exceptions.EauthAuthenticationError*(message='')
  Thrown when eauth authentication fails

*exception salt.exceptions.FileserverConfigError*(message='')
  Used when invalid fileserver settings are detected

*exception salt.exceptions.LoadError*(message='')
  Problems loading the right renderer

*exception salt.exceptions.MasterExit*
  Rise when the master exits

*exception salt.exceptions.MinionError*(message='')
  Minion problems reading uris such as salt:// or http://

*exception salt.exceptions.NotImplemented*(message='')
  Used when a module runs a command which returns an error and wants to show the user the output gracefully instead of dying

*exception salt.exceptions.PkgParseError*(message='')
  Used when of the pkg modules cannot correctly parse the output from the CLI tool (pacman, yum, apt, aptitude, etc)

*exception salt.exceptions.PublishError*(message='')
  Problems encountered when trying to publish a command

*exception salt.exceptions.SaltCacheError*(message='')
  Thrown when a problem was encountered trying to read or write from the salt cache

*exception salt.exceptions.SaltClientError*(message='')
  Problem reading the master root key

*exception salt.exceptions.SaltClientTimeout*(msg, jid=None, *args, **kwargs)*
  Thrown when a job sent through one of the Client interfaces times out
  Takes the jid as a parameter

*exception salt.exceptions.SaltCloudConfigError*(message='')
  Raised when a configuration setting is not found and should exist.

*exception salt.exceptions.SaltCloudException*(message='')
  Generic Salt Cloud Exception

*exception salt.exceptions.SaltCloudExecutionFailure*(message='')
  Raised when too much failures have occurred while querying/waiting for data.
exception salt.exceptions.SaltCloudExecutionTimeout(message='')
    Raised when too much time has passed while querying/waiting for data.

exception salt.exceptions.SaltCloudNotFound(message='')
    Raised when some cloud provider function cannot find what's being searched.

exception salt.exceptions.SaltCloudPasswordError(message='')
    Raise when virtual terminal password input failed

exception salt.exceptions.SaltCloudSystemExit(message, exit_code=1)
    This exception is raised when the execution should be stopped.

exception salt.exceptions.SaltDaemonNotRunning(message='')
    Throw when a running master/minion/syndic is not running but is needed to perform the requested operation
    (e.g., eauth).

exception salt.exceptions.SaltException(message='')
    Base exception class; all Salt-specific exceptions should subclass this

    pack()
    Pack this exception into a serializable dictionary that is safe for transport via msgpack

exception salt.exceptions.SaltInvocationError(message='')
    Used when the wrong number of arguments are sent to modules or invalid arguments are specified on the
    command line

exception salt.exceptions.SaltMasterError(message='')
    Problem reading the master root key

exception salt.exceptions.SaltNoMinionsFound(message='')
    An attempt to retrieve a list of minions failed

exception salt.exceptions.SaltRenderError(message, line_num=None, buf='', marker='^=*=*=*=*=*=*=*=*=*=*=^=', trace=None)
    Used when a renderer needs to raise an explicit error. If a line number and buffer string are passed, get_context
    will be invoked to get the location of the error.

exception salt.exceptions.SaltReqTimeoutError(message='')
    Thrown when a salt master request call fails to return within the timeout

exception salt.exceptions.SaltRunnerError(message='')
    Problem in runner

exception salt.exceptions.SaltSyndicMasterError(message='')
    Problem while proxying a request in the syndication master

exception salt.exceptions.SaltSystemExit(code=0, msg=None)
    This exception is raised when an unsolvable problem is found. There's nothing else to do, salt should just exit.

exception salt.exceptions.SaltWheelError(message='')
    Problem in wheel

exception salt.exceptions.TimedProcTimeoutError(message='')
    Thrown when a timed subprocess does not terminate within the timeout, or if the specified timeout is not an
    int or a float

exception salt.exceptions.TokenAuthenticationError(message='')
    Thrown when token authentication fails

Salt opts dictionary

It is very common in the Salt codebase to see opts referred to in a number of contexts.
For example, it can be seen as __opts__ in certain cases, or simply as opts as an argument to a function in others.

Simply put, this data structure is a dictionary of Salt's runtime configuration information that's passed around in order for functions to know how Salt is configured.

When writing Python code to use specific parts of Salt, it may become necessary to initialize a copy of opts from scratch in order to have it available for a given function.

To do so, use the utility functions available in salt.config.

As an example, here is how one might generate and print an options dictionary for a minion instance:

```python
import salt.config
opts = salt.config.minion_config('/etc/salt/minion')
print(opts)
```

To generate and display opts for a master, the process is similar:

```python
import salt.config
opts = salt.config.master_config('/etc/salt/master')
print(opts)
```

salt.exceptions

This module is a central location for all salt exceptions

exception salt.exceptions.AuthenticationError(message=''
    If sha256 signature fails during decryption
exception salt.exceptions.AuthorizationError(message=''
    Thrown when runner or wheel execution fails due to permissions
exception salt.exceptions.CommandExecutionError(message=''
    Used when a module runs a command which returns an error and wants to show the user the output gracefully instead of dying
exception salt.exceptions.CommandNotFoundError(message=''
    Used in modules or grains when a required binary is not available
exception salt.exceptions.EauthAuthenticationError(message=''
    Thrown when eauth authentication fails
exception salt.exceptions.FileserverConfigError(message=''
    Used when invalid fileserver settings are detected
exception salt.exceptions.LoaderError(message=''
    Problems loading the right renderer
exception salt.exceptions.MasterExit
    Rise when the master exits
exception salt.exceptions.MinionError(message=''
    Minion problems reading uris such as salt:// or http://
exception salt.exceptions.NotImplemented(message=''
    Used when a module runs a command which returns an error and wants to show the user the output gracefully instead of dying
exception salt.exceptions.PkgParseError(message=''
    Used when of the pkg modules cannot correctly parse the output from the CLI tool (pacman, yum, apt, aptitude, etc)
exception salt.exceptions.PublishError(message='')
    Problems encountered when trying to publish a command

exception salt.exceptions.SaltCacheError(message='')
    Thrown when a problem was encountered trying to read or write from the salt cache

exception salt.exceptions.SaltClientError(message='')
    Problem reading the master root key

exception salt.exceptions.SaltClientTimeout(msg, jid=None, *args, **kwargs)
    Thrown when a job sent through one of the Client interfaces times out
    Takes the jid as a parameter

exception salt.exceptions.SaltCloudConfigError(message='')
    Raised when a configuration setting is not found and should exist.

exception salt.exceptions.SaltCloudException(message='')
    Generic Salt Cloud Exception

exception salt.exceptions.SaltCloudExecutionFailure(message='')
    Raised when too much failures have occurred while querying/waiting for data.

exception salt.exceptions.SaltCloudExecutionTimeout(message='')
    Raised when too much time has passed while querying/waiting for data.

exception salt.exceptions.SaltCloudNotFound(message='')
    Raised when some cloud provider function cannot find what's being searched.

exception salt.exceptions.SaltCloudPasswordError(message='')
    Raise when virtual terminal password input failed

exception salt.exceptions.SaltCloudSystemExit(message, exit_code=1)
    This exception is raised when the execution should be stopped.

exception salt.exceptions.SaltDaemonNotRunning(message='')
    Throw when a running master/minion/syndic is not running but is needed to perform the requested operation
    (e.g., eauth).

exception salt.exceptions.SaltException(message='')
    Base exception class; all Salt-specific exceptions should subclass this

pack()
    Pack this exception into a serializable dictionary that is safe for transport via msgpack

exception salt.exceptions.SaltInvocationError(message='')
    Used when the wrong number of arguments are sent to modules or invalid arguments are specified on the
    command line

exception salt.exceptions.SaltMasterError(message='')
    Problem reading the master root key

exception salt.exceptions.SaltNoMinionsFound(message='')
    An attempt to retrieve a list of minions failed

exception salt.exceptions.SaltRenderError(message, line_num=None, buf='', marker='<----------------------', trace=None)
    Used when a renderer needs to raise an explicit error. If a line number and buffer string are passed, get_context
    will be invoked to get the location of the error.

exception salt.exceptions.SaltReqTimeoutError(message='')
    Thrown when a salt master request call fails to return within the timeout
```python
definitions:
- SaltDocumentation:
  - Release:
    - 2015.8.0

exceptions:
- SaltRunnerError
  - salt.exceptions
  - Problem in runner
- SaltSyndicMasterError
  - salt.exceptions
  - Problem while proxying a request in the syndication master
- SaltSystemExit
  - salt.exceptions
  - This exception is raised when an unsolvable problem is found. There’s nothing else to do, salt should just exit.
- SaltWheelError
  - salt.exceptions
  - Problem in wheel
- TimedProcTimeoutError
  - salt.exceptions
  - Thrown when a timed subprocess does not terminate within the timeout, or if the specified timeout is not an int or a float
- TokenAuthenticationError
  - salt.exceptions
  - Thrown when token authentication fails

31.16 Full list of builtin execution modules

Virtual modules

31.16.1 salt.modules.pkg

pkg is a virtual module that is fulfilled by one of the following modules:
- salt.modules.aptpkg
- salt.modules.brew
- salt.modules.ebuild
- salt.modules.freebsdpkg
- salt.modules.openbsdpkg
- salt.modules.pacman
- salt.modules.pkgin
- salt.modules.pkgng
- salt.modules.pkgutil
- salt.modules.solarispkg
- salt.modules.win_pkg
- salt.modules.yumpkg
- salt.modules.zypper
```

<tr>
<td>composer</td>
<td>Use composer to install PHP dependencies for a directory</td>
</tr>
<tr>
<td>config</td>
<td>Return config information</td>
</tr>
<tr>
<td>consul</td>
<td>Interact with Consul</td>
</tr>
<tr>
<td>container_resource</td>
<td>Common resources for LXC and systemd-nspawn containers</td>
</tr>
<tr>
<td>cp</td>
<td>Minion side functions for salt-cp</td>
</tr>
<tr>
<td>cpan</td>
<td>Manage Perl modules using CPAN</td>
</tr>
<tr>
<td>cron</td>
<td>Work with cron</td>
</tr>
<tr>
<td>cyg</td>
<td>Manage cygwin packages.</td>
</tr>
<tr>
<td>daemontools</td>
<td>daemontools service module. This module will create daemontools type</td>
</tr>
<tr>
<td>darwin_pkgrutil</td>
<td>Installer support for OS X.</td>
</tr>
<tr>
<td>darwin_sysctl</td>
<td>Module for viewing and modifying sysctl parameters</td>
</tr>
<tr>
<td>data</td>
<td>Manage a local persistent data structure that can hold any arbitrary data</td>
</tr>
<tr>
<td>ddns</td>
<td>Support for RFC 2136 dynamic DNS updates.</td>
</tr>

<td>The service module for FreeBSD</td>
</tr>
<tr>
<td><strong>gem</strong></td>
<td>Manage ruby gems.</td>
</tr>
<tr>
<td><strong>genesis</strong></td>
<td>Module for managing container and VM images</td>
</tr>
<tr>
<td><strong>gentoo_service</strong></td>
<td>Top level package command wrapper, used to translate the os detected by grains</td>
</tr>
<tr>
<td><strong>gentoolkitmod</strong></td>
<td>Support for Gentoolkit</td>
</tr>
<tr>
<td><strong>git</strong></td>
<td>Support for the Git SCM</td>
</tr>
<tr>
<td><strong>glance</strong></td>
<td>Module for handling openstack glance calls</td>
</tr>
<tr>
<td><strong>glusterfs</strong></td>
<td>Manage a glusterfs pool</td>
</tr>
<tr>
<td><strong>gnomedesktop</strong></td>
<td>GNOME implementations</td>
</tr>
<tr>
<td><strong>gpg</strong></td>
<td>Manage a GPG keychains, add keys, create keys, retrieve keys from keyservers.</td>
</tr>
<tr>
<td><strong>grains</strong></td>
<td>Return/control aspects of the grains data</td>
</tr>
<tr>
<td><strong>groupadd</strong></td>
<td>Manage groups on Linux, OpenBSD and NetBSD</td>
</tr>
<tr>
<td><strong>grub_legacy</strong></td>
<td>Support for GRUB Legacy</td>
</tr>
<tr>
<td><strong>guestfs</strong></td>
<td>Interact with virtual machine images via libguestfs</td>
</tr>
<tr>
<td><strong>hadoop</strong></td>
<td>Support for hadoop</td>
</tr>
<tr>
<td><strong>haproxyconn</strong></td>
<td>Support for haproxy</td>
</tr>
<tr>
<td><strong>hashutil</strong></td>
<td>A collection of hashing and encoding functions</td>
</tr>
<tr>
<td><strong>hg</strong></td>
<td>Support for the Mercurial SCM</td>
</tr>
<tr>
<td>Module</td>
<td>Description</td>
</tr>
<tr>
<td>----------</td>
<td>-------------</td>
</tr>
<tr>
<td>hipchat</td>
<td>Module for sending messages to hipchat.</td>
</tr>
<tr>
<td>hosts</td>
<td>Manage the information in the hosts file.</td>
</tr>
<tr>
<td>htpasswd</td>
<td>Support for htpasswd command.</td>
</tr>
<tr>
<td>http</td>
<td>Module for making various web calls.</td>
</tr>
<tr>
<td>ifttt</td>
<td>Support for IFTTT.</td>
</tr>
<tr>
<td>ilo</td>
<td>Manage HP ILO.</td>
</tr>
<tr>
<td>img</td>
<td>Virtual machine image management tools.</td>
</tr>
<tr>
<td>incron</td>
<td>Work with incron.</td>
</tr>
<tr>
<td>influx</td>
<td>InfluxDB - A distributed time series database.</td>
</tr>
<tr>
<td>ini_manage</td>
<td>Edit ini files.</td>
</tr>
<tr>
<td>introspect</td>
<td>Functions to perform introspection on a minion, and return data in a format.</td>
</tr>
<tr>
<td>ipmi</td>
<td>Support IPMI commands over LAN.</td>
</tr>
<tr>
<td>ipset</td>
<td>Support for ipset.</td>
</tr>
<tr>
<td>iptables</td>
<td>Support for iptables.</td>
</tr>
<tr>
<td>jboss7</td>
<td>Module for managing JBoss AS 7 through the CLI interface.</td>
</tr>
<tr>
<td>jboss7_cli</td>
<td>Module for low-level interaction with JBossAS7 through CLI.</td>
</tr>
<tr>
<td>junos</td>
<td>Module for interfacing to Junos devices.</td>
</tr>
<tr>
<td>kerberos</td>
<td>Manage Kerberos KDC.</td>
</tr>
<tr>
<td>key</td>
<td>Functions to view the minion's public key information.</td>
</tr>
<tr>
<td>keyboard</td>
<td>Module for managing keyboards on supported POSIX-like systems using systemd, or such as Redhat, Debian, and Gentoo.</td>
</tr>
<tr>
<td>keystone</td>
<td>Module for handling openstack keystone calls.</td>
</tr>
<tr>
<td>kmod</td>
<td>Module to manage Linux kernel modules.</td>
</tr>
<tr>
<td>launchctl</td>
<td>Module for the management of MacOS systems that use launchd/launchctl.</td>
</tr>
<tr>
<td>layman</td>
<td>Support for Layman.</td>
</tr>
<tr>
<td>ldapmod</td>
<td>Salt interface to LDAP commands.</td>
</tr>
<tr>
<td>linux_acl</td>
<td>Support for Linux File Access Control Lists.</td>
</tr>
<tr>
<td>linux_lvm</td>
<td>Support for Linux LVM2.</td>
</tr>
<tr>
<td>linux_sysctl</td>
<td>Module for viewing and modifying sysctl parameters.</td>
</tr>
<tr>
<td>localemod</td>
<td>Module for managing locales on POSIX-like systems.</td>
</tr>
<tr>
<td>locate</td>
<td>Module for using the locate utilities.</td>
</tr>
<tr>
<td>logadm</td>
<td>Module for managing Solaris logadm based log rotations.</td>
</tr>
<tr>
<td>logrotate</td>
<td>Module for managing logrotate.</td>
</tr>
<tr>
<td>lvs</td>
<td>Support for LVS (Linux Virtual Server).</td>
</tr>
<tr>
<td>lxc</td>
<td>Control Linux Containers via Salt.</td>
</tr>
<tr>
<td>mac_group</td>
<td>Manage groups on Mac OS 10.7+.</td>
</tr>
<tr>
<td>mac_user</td>
<td>Manage users on Mac OS 10.7+.</td>
</tr>
<tr>
<td>macports</td>
<td>Support for MacPorts under Mac OSX.</td>
</tr>
<tr>
<td>makeconf</td>
<td>Support for modifying make.conf under Gentoo.</td>
</tr>
<tr>
<td>match</td>
<td>The match module allows for match routines to be run and determine target specs.</td>
</tr>
<tr>
<td>mdadm</td>
<td>Salt module to manage RAID arrays with mdadm.</td>
</tr>
<tr>
<td>memcached</td>
<td>Module for Management of Memcached Keys.</td>
</tr>
<tr>
<td>mine</td>
<td>The function cache system allows for data to be stored on the master so it can be easily read by other minions.</td>
</tr>
<tr>
<td>mod_random</td>
<td>New in version 2014.7.0.</td>
</tr>
<tr>
<td>modjk</td>
<td>Control Modjk via the Apache Tomcat `&quot;Status&quot; worker.</td>
</tr>
<tr>
<td>mongodb</td>
<td>Module to provide MongoDB functionality to Salt.</td>
</tr>
<tr>
<td>monit</td>
<td>Monit service module.</td>
</tr>
<tr>
<td>moosefs</td>
<td>Module for gathering and managing information about MooseFS.</td>
</tr>
<tr>
<td>mount</td>
<td>Salt module to manage unix mounts and the fstab file.</td>
</tr>
<tr>
<td>mssql</td>
<td>Module to provide MS SQL Server compatibility to salt.</td>
</tr>
<tr>
<td>munin</td>
<td>Run munin plugins/checks from salt and format the output as data.</td>
</tr>
</tbody>
</table>

<tr>
<td>svn</td>
<td>Subversion SCM</td>
</tr>
<tr>
<td>swift</td>
<td>Module for handling OpenStack Swift calls</td>
</tr>
<tr>
<td>sysbench</td>
<td>The <code>sysbench</code> module is used to analyze the performance of the minions, right from the master! It measures various system parameters such as CPU, Memory, File I/O, Threads, and Mutex.</td>
</tr>
<tr>
<td>syslog_ng</td>
<td>Module for getting information about syslog-ng</td>
</tr>
<tr>
<td>sysmod</td>
<td>The sys module provides information about the available functions on the minion</td>
</tr>
<tr>
<td>sysrc</td>
<td>sysrc module for FreeBSD</td>
</tr>
<tr>
<td>system</td>
<td>Support for reboot, shutdown, etc</td>
</tr>
<tr>
<td>system_profiler</td>
<td>System Profiler Module</td>
</tr>
<tr>
<td>systemd</td>
<td>Provide the service module for systemd</td>
</tr>
<tr>
<td>temp</td>
<td>Simple module for creating temporary directories and files</td>
</tr>
<tr>
<td>test</td>
<td>Module for running arbitrary tests</td>
</tr>
<tr>
<td>test_virtual</td>
<td>Module for running arbitrary tests with a <strong>virtual</strong> function</td>
</tr>
<tr>
<td>timezone</td>
<td>Module for managing timezone on POSIX-like systems.</td>
</tr>
<tr>
<td>tls</td>
<td>A salt module for SSL/TLS</td>
</tr>
<tr>
<td>tomcat</td>
<td>Support for Tomcat</td>
</tr>
<tr>
<td>trafficserver</td>
<td>Apache Traffic Server execution module.</td>
</tr>
<tr>
<td>tuned</td>
<td>Interface to Red Hat tuned-adm module</td>
</tr>
<tr>
<td>twilio_notify</td>
<td>Module for notifications via Twilio</td>
</tr>
<tr>
<td>udev</td>
<td>Manage and query udev info</td>
</tr>
<tr>
<td>upstart</td>
<td>Module for the management of upstart systems</td>
</tr>
<tr>
<td>uptime</td>
<td>Wrapper around uptime API</td>
</tr>
<tr>
<td>useradd</td>
<td>Manage users with the useradd command</td>
</tr>
<tr>
<td>varnish</td>
<td>Support for Varnish</td>
</tr>
<tr>
<td>vbox_guest</td>
<td>VirtualBox Guest Additions installer</td>
</tr>
<tr>
<td>victorops</td>
<td>Support for VictorOps</td>
</tr>
<tr>
<td>virt</td>
<td>Work with virtual machines managed by libvirt</td>
</tr>
<tr>
<td>virtualenv_mod</td>
<td>Create virtualenv environments</td>
</tr>
<tr>
<td>win_autoruns</td>
<td>Module for listing programs that automatically run on startup</td>
</tr>
<tr>
<td>win_dacl</td>
<td>Manage DACLs on Windows</td>
</tr>
<tr>
<td>win_disk</td>
<td>Module for gathering disk information on Windows</td>
</tr>

<tr>
<td>zypper</td>
<td>Package support for openSUSE via the zypper package manager</td>
</tr>
</tbody>
</table>

#### 31.16.2 salt.modules.aliases

Manage the information in the aliases file

**salt.modules.aliases.get_target(alias)**
Return the target associated with an alias

CLI Example:
```
salt '*' aliases.get_target alias
```

**salt.modules.aliases.has_target(alias, target)**
Return true if the alias/target is set

CLI Example:
```
salt '*' aliases.has_target alias target
```

**salt.modules.aliases.list_aliases()**
Return the aliases found in the aliases file in this format:

```json
{'alias': 'target'}
```

CLI Example:
```
salt '*' aliases.list_aliases
```

**salt.modules.aliases.rm_alias(alias)**
Remove an entry from the aliases file

CLI Example:
```
salt '*' aliases.rm_alias alias
```

**salt.modules.aliases.set_target(alias, target)**
Set the entry in the aliases file for the given alias, this will overwrite any previous entry for the given alias or create a new one if it does not exist.
31.16.3 salt.modules.alternatives

Support for Alternatives system

codeauthor Radek Rada <radek.rada@gmail.com>

salt.modules.alternatives.auto(name)
Trigger alternatives to set the path for <name> as specified by priority.

CLI Example:

    salt '*' alternatives.auto name

salt.modules.alternatives.check_installed(name, path)
Check if the current highest-priority match for a given alternatives link is set to the desired path

CLI Example:

    salt '*' alternatives.check_installed name path

salt.modules.alternatives.display(name)
Display alternatives settings for defined command name

CLI Example:

    salt '*' alternatives.display editor

salt.modules.alternatives.install(name, link, path, priority)
Install symbolic links determining default commands

CLI Example:

    salt '*' alternatives.install editor /usr/bin/editor /usr/bin/emacs23 50

salt.modules.alternatives.remove(name, path)
Remove symbolic links determining the default commands.

CLI Example:

    salt '*' alternatives.remove name path

salt.modules.alternatives.set(name, path)
Manually set the alternative <path> for <name>.

CLI Example:

    salt '*' alternatives.set name path

salt.modules.alternatives.show_current(name)
Display the current highest-priority alternative for a given alternatives link

CLI Example:

    salt '*' alternatives.show_current editor
31.16.4 salt.modules.apache

Support for Apache

Note: The functions in here are generic functions designed to work with all implementations of Apache. Debian-specific functions have been moved into deb_apache.py, but will still load under the apache namespace when a Debian-based system is detected.

salt.modules.apache.config(name, config, edit=True)
Create VirtualHost configuration files

- name: File for the virtual host
- config: VirtualHost configurations

Note: This function is not meant to be used from the command line. Config is meant to be an ordered dict of all of the apache configs.

CLI Example:

```
salt '*' apache.config /etc/httpd/conf.d/ports.conf config="[{'Listen': '22'}]"
```

salt.modules.apache.directives()
Return list of directives together with expected arguments and places where the directive is valid (apachectl -L)

CLI Example:

```
salt '*' apache.directives
```

salt.modules.apache.fullversion()
Return server version (apachectl -V)

CLI Example:

```
salt '*' apache.fullversion
```

salt.modules.apache.modules()
Return list of static and shared modules (apachectl -M)

CLI Example:

```
salt '*' apache.modules
```

salt.modules.apache.server_status(profile='default')
Get Information from the Apache server-status handler

Note: The server-status handler is disabled by default. In order for this function to work it needs to be enabled. See [http://httpd.apache.org/docs/2.2/mod/mod_status.html](http://httpd.apache.org/docs/2.2/mod/mod_status.html)

The following configuration needs to exists in pillar/grains. Each entry nested in apache.server-status is a profile of a vhost/server. This would give support for multiple apache servers/vhosts.

```
apache.server-status:
    default:
        url: http://localhost/server-status
        user: someuser
        pass: password
```
realm: 'authentication realm for digest passwords'
        timeout: 5

CLI Examples:
salt '*' apache.server_status
salt '*' apache.server_status other-profile

salt.modules.apache.servermods()
        Return list of modules compiled into the server (apachectl -l)
        CLI Example:
salt '*' apache.servermods

salt.modules.apache.signal(signal=None)
        Signals httpd to start, restart, or stop.
        CLI Example:
salt '*' apache.signal restart

salt.modules.apache.useradd(pwfile, user, password, opts='')
        Add HTTP user using the htpasswd command. If the htpasswd file does not exist, it will be created. Valid options that can be passed are:
        n  Don't update file; display results on stdout.
        m  Force MD5 encryption of the password (default).
        d  Force CRYPT encryption of the password.
        p  Do not encrypt the password (plaintext).
        s  Force SHA encryption of the password.
        CLI Examples:
salt '*' apache.useradd /etc/httpd/htpasswd larry badpassword
salt '*' apache.useradd /etc/httpd/htpasswd larry badpass opts=ns

salt.modules.apache.userdel(pwfile, user)
        Delete HTTP user from the specified htpasswd file.
        CLI Example:
salt '*' apache.userdel /etc/httpd/htpasswd larry

salt.modules.apache.version()
        Return server version (apachectl -v)
        CLI Example:
salt '*' apache.version

salt.modules.apache.vhosts()
        Show the settings as parsed from the config file (currently only shows the virtualhost settings) (apachectl -S). Because each additional virtual host adds to the execution time, this command may require a long timeout be specified by using -t 10.
        CLI Example:
salt -t 10 '*' apache.vhosts
31.16.5 salt.modules.aptpkg

Support for APT (Advanced Packaging Tool)

Note: For virtual package support, either the python-apt or dctrl-tools package must be installed. For repository management, the python-apt package must be installed.

salt.modules.aptpkg.autoremove(list_only=False, purge=False)

New in version 2015.5.0.

Remove packages not required by another package using apt-get autoremove.

list_only [False] Only retrieve the list of packages to be auto-removed, do not actually perform the auto-removal.

purge [False] Also remove package config data when autoremoving packages.

New in version 2015.8.0.

CLI Example:

```
salt '*' pkg.autoremove
salt '*' pkg.autoremove list_only=True
salt '*' pkg.autoremove purge=True
```

salt.modules.aptpkg.del_repo(repo, **kwargs)

Delete a repo from the sources.list / sources.list.d

If the .list file is in the sources.list.d directory and the file that the repo exists in does not contain any other repo configuration, the file itself will be deleted.

The repo passed in must be a fully formed repository definition string.

CLI Examples:

```
salt '*' pkg.del_repo "myrepo definition"
```

salt.modules.aptpkg.del_repo_key(name=None, **kwargs)

New in version 2015.8.0.

Remove a repo key using apt-key del

name Repo from which to remove the key. Unnecessary if keyid is passed.

keyid The KeyID of the GPG key to remove

keyid_ppa [False] If set to True, the repo's GPG key ID will be looked up from ppa.launchpad.net and removed.

Note: Setting this option to True requires that the name param also be passed.

CLI Examples:

```
salt '*' pkg.del_repo_key keyid=0123ABCD
salt '*' pkg.del_repo_key name='ppa:foo/bar' keyid_ppa=True
```

salt.modules.aptpkg.expand_repo_def(repokwargs)

Take a repository definition and expand it to the full pkg repository dict that can be used for comparison. This is a helper function to make the Debian/Ubuntu apt sources sane for comparison in the pkgrepo states.

There is no use to calling this function via the CLI.
salt.modules.aptpkg.file_dict("packages")
List the files that belong to a package, grouped by package. Not specifying any packages will return a list of _every_ file on the system's package database (not generally recommended).

CLI Examples:

```
salt '*' pkg.file_list httpd
salt '*' pkg.file_list httpd postfix
salt '*' pkg.file_list
```

salt.modules.aptpkg.file_list("packages")
List the files that belong to a package. Not specifying any packages will return a list of _every_ file on the system's package database (not generally recommended).

CLI Examples:

```
salt '*' pkg.file_list httpd
salt '*' pkg.file_list httpd postfix
salt '*' pkg.file_list
```

salt.modules.aptpkg.get_repo(repo, **kwargs)
Display a repo from the sources.list / sources.list.d

The repo passed in needs to be a complete repo entry.

CLI Examples:

```
salt '*' pkg.get_repo "myrepo definition"
```

salt.modules.aptpkg.get_selections(pattern=None, state=None)
View package state from the dpkg database.

Returns a dict of dicts containing the state, and package names:

```
{'<host>': {'<state>': ['pkg1', ...
   ],
   ...}
```

CLI Example:

```
salt '*' pkg.get_selections
salt '*' pkg.get_selections 'python-*'
salt '*' pkg.get_selections state=hold
salt '*' pkg.get_selections 'openssh*' state=hold
```

salt.modules.aptpkg.hold(name=None, pkgs=None, sources=None, **kwargs)
New in version 2014.7.0.

Set package in `hold` state, meaning it will not be upgraded.

name  The name of the package, e.g., `tmux`

CLI Example:

```
salt '*' pkg.hold <package name>
```

pkgs  A list of packages to hold. Must be passed as a python list.

CLI Example:
salt '*' pkg.hold pkgs='["foo", "bar"]'

```
salt.modules.aptpkg.info_installed('names')
```

Return the information of the named package(s), installed on the system.

CLI example:
```
salt '*' pkg.info_installed <package1>
salt '*' pkg.info_installed <package1> <package2> <package3> ...
```

```
salt.modules.aptpkg.install(name=None, refresh=False, fromrepo=None, skip_verify=False, debconf=None, pkgs=None, sources=None, reinstall=False, **kwargs)
```

Install the passed package, add refresh=True to update the dpkg database.

- **name**: The name of the package to be installed. Note that this parameter is ignored if either ``pkgs`` or ``sources`` is passed. Additionally, please note that this option can only be used to install packages from a software repository. To install a package file manually, use the ``sources`` option.

  32-bit packages can be installed on 64-bit systems by appending the architecture designation (i386, etc.) to the end of the package name.

  CLI Example:
```
salt '*' pkg.install <package name>
```

- **refresh**: Whether or not to refresh the package database before installing.

- **fromrepo**: Specify a package repository to install from (e.g., apt-get -t unstable install somepackage)

- **skip_verify**: Skip the GPG verification check (e.g., --allow-unauthenticated, or --force-bad-verify for install from package file).

- **debconf**: Provide the path to a debconf answers file, processed before installation.

- **version**: Install a specific version of the package, e.g. 1.2.3-0ubuntu0. Ignored if ``pkgs`` or ``sources`` is passed.

- **reinstall** [False] Specifying reinstall=True will use apt-get install --reinstall rather than simply apt-get install for requested packages that are already installed.

  If a version is specified with the requested package, then apt-get install --reinstall will only be used if the installed version matches the requested version.

  New in version 2015.8.0.

Multiple Package Installation Options:

- **pkgs**: A list of packages to install from a software repository. Must be passed as a python list.

  CLI Example:
```
salt '*' pkg.install pkgs='["foo", "bar"]'
salt '*' pkg.install pkgs='["foo", {"bar": "1.2.3-0ubuntu0"}]'
```

- **sources**: A list of DEB packages to install. Must be passed as a list of dicts, with the keys being package names, and the values being the source URI or local path to the package. Dependencies are automatically resolved and marked as auto-installed.
Salt Documentation, Release 2015.8.0

32-bit packages can be installed on 64-bit systems by appending the architecture designation
(:i386, etc.) to the end of the package name.
Changed in version 2014.7.0.
CLI Example:
salt '*' pkg.install sources='[{"foo": "salt://foo.deb"},{"bar": "salt://bar.deb"}]'

force_yes Passes --force-yes to the apt-get command. Don't use this unless you know what
you're doing.
New in version 0.17.4.
install_recommends Whether to install the packages marked as recommended. Default is True.
New in version 2015.5.0.
only_upgrade Only upgrade the packages, if they are already installed. Default is False.
New in version 2015.5.0.
force_conf_new
Always install the new version of any configuration files.
New in version 2015.8.0.
Returns a dict containing the new package names and versions:
{'<package>': {'old': '<old-version>',
'new': '<new-version>'}}

salt.modules.aptpkg.latest_version(*names, **kwargs)
Return the latest version of the named package available for upgrade or installation. If more than one package
name is specified, a dict of name/version pairs is returned.
If the latest version of a given package is already installed, an empty string will be returned for that package.
A specific repo can be requested using the fromrepo keyword argument.
CLI Example:
salt '*' pkg.latest_version <package name>
salt '*' pkg.latest_version <package name> fromrepo=unstable
salt '*' pkg.latest_version <package1> <package2> <package3> ...

salt.modules.aptpkg.list_pkgs(versions_as_list=False,
**kwargs)
List the packages currently installed in a dict:

removed=False,

purge_desired=False,

{'<package_name>': '<version>'}

removed If True, then only packages which have been removed (but not purged) will be returned.
purge_desired If True, then only packages which have been marked to be purged, but can't be purged due
to their status as dependencies for other installed packages, will be returned. Note that these packages
will appear in installed
Changed in version 2014.1.1: Packages in this state now correctly show up in the output of this function.

31.16. Full list of builtin execution modules

643


Note: External dependencies

Virtual package resolution requires the `dctrl-tools` package to be installed. Virtual packages will show a version of 1.

CLI Example:
```python
salt '*' pkg.list_pkgs
salt '*' pkg.list_pkgs versions_as_list=True
```

```
salt.modules.aptpkg.list_repos()

Lists all repos in the sources.list (and sources.lists.d) files

CLI Example:
```python
salt '*' pkg.list_repos
salt '*' pkg.list_repos disabled=True
```

```
salt.modules.aptpkg.list_upgrades(refresh=True, dist_upgrade=True)

List all available package upgrades.

- `refresh` Whether to refresh the package database before listing upgrades. Default: True.
- `dist_upgrade` Whether to list the upgrades using dist-upgrade vs upgrade. Default is to use dist-upgrade.

CLI Example:
```python
salt '*' pkg.list_upgrades
```

```
salt.modules.aptpkg.mod_repo(repo, saltenv='base', **kwargs)

Modify one or more values for a repo. If the repo does not exist, it will be created, so long as the definition is well formed. For Ubuntu the `ppa:<project>/repo` format is acceptable. `ppa:` format can only be used to create a new repository.

The following options are available to modify a repo definition:

- `comps` (a comma separated list of components for the repo, e.g. "main")
- `file` (a file name to be used)
- `keyserver` (keyserver to get gpg key from)
- `keyid` (key id to load with the keyserver argument)
- `key_url` (URL to a gpg key to add to the apt gpg keyring)
- `consolidate` (if true, will attempt to de-dup and consolidate sources)

* Note: Due to the way keys are stored for apt, there is a known issue where the key wont be updated unless another change is made at the same time. Keys should be properly added on initial configuration.

CLI Examples:
```python
salt '*' pkg.mod_repo 'myrepo definition' uri=http://new/uri
salt '*' pkg.mod_repo 'myrepo definition' comps=main,universe
```

```
salt.modules.aptpkg.owner('paths')

New in version 2014.7.0.

Return the name of the package that owns the file. Multiple file paths can be passed. Like `pkg.version`, if a single path is passed, a string will be returned, and if multiple paths are passed, a dictionary of file/package name pairs will be returned.
If the file is not owned by a package, or is not present on the minion, then an empty string will be returned for that path.

CLI Example:

```
salt '*' pkg.owner /usr/bin/apachectl
salt '*' pkg.owner /usr/bin/apachectl /usr/bin/basename
```

**salt.modules.aptpkg.purge**(name=``None``, pkgs=``None``, **kwargs)

Remove packages via `apt-get purge` along with all configuration files.

- **name**: The name of the package to be deleted.
- **pkgs**: A list of packages to delete. Must be passed as a python list. The name parameter will be ignored if this option is passed.

New in version 0.16.0.

Returns a dict containing the changes.

CLI Example:

```
salt '*' pkg.purge <package name>
salt '*' pkg.purge <package1>,<package2>,<package3>
salt '*' pkg.purge pkgs=['"foo", "bar"]'
```

**salt.modules.aptpkg.refresh_db()**

Updates the APT database to latest packages based upon repositories

Returns a dict, with the keys being package databases and the values being the result of the update attempt. Values can be one of the following:

- **True**: Database updated successfully
- **False**: Problem updating database
- **None**: Database already up-to-date

CLI Example:

```
salt '*' pkg.refresh_db
```

**salt.modules.aptpkg.remove**(name=``None``, pkgs=``None``, **kwargs)

Remove packages using `apt-get remove`.

- **name**: The name of the package to be deleted.
- **pkgs**: A list of packages to delete. Must be passed as a python list. The name parameter will be ignored if this option is passed.

New in version 0.16.0.

Returns a dict containing the changes.

CLI Example:

```
salt '*' pkg.remove <package name>
salt '*' pkg.remove <package1>,<package2>,<package3>
salt '*' pkg.remove pkgs=['"foo", "bar"]'
```
salt.modules.aptpkg.set_selections(path=None, selection=None, clear=False, saltenv='base')
Change package state in the dpkg database.

The state can be any one of, documented in `dpkg(1):

- install
- hold
- deinstall
- purge

This command is commonly used to mark specific packages to be held from being upgraded, that is, to be kept at a certain version. When a state is changed to anything but being held, then it is typically followed by `apt-get -u dselect-upgrade`.

Note: Be careful with the clear argument, since it will start with setting all packages to deinstall state.

Returns a dict of dicts containing the package names, and the new and old versions:

```python
{'<host>':
 {'<package>': {'new': '<new-state>',
                'old': '<old-state>'}}
}
```

CLI Example:

```bash
salt '*' pkg.set_selections selection="{"install": ["netcat"]}"  
salt '*' pkg.set_selections selection="{"hold": ["openssh-server", "openssh-client"]}"  
salt '*' pkg.set_selections salt://path/to/file  
salt '*' pkg.set_selections salt://path/to/file clear=True
```

salt.modules.aptpkg.unhold(name=None, pkgs=None, sources=None, **kwargs)
New in version 2014.7.0.

Set package current in `hold` state to install state, meaning it will be upgraded.

- name   The name of the package, e.g., `tmux`

CLI Example:

```bash
salt '*' pkg.unhold <package name>
```

- pkgs   A list of packages to hold. Must be passed as a python list.

CLI Example:

```bash
salt '*' pkg.unhold pkgs='["foo", "bar"]'
```

salt.modules.aptpkg.upgrade(refresh=True, dist_upgrade=False, **kwargs)

Upgrades all packages via `apt-get dist-upgrade`

Returns a dict containing the changes.

```python
{`<package>`: {`old`: `<old-version>`, `new`: `<new-version>`}}
```

- dist_upgrade   Whether to perform the upgrade using dist-upgrade vs upgrade. Default is to use upgrade.

New in version 2014.7.0.
force_conf_new

Always install the new version of any configuration files.
New in version 2015.8.0.

CLI Example:

```
salt '*' pkg.upgrade
```

salt.modules.aptpkg.upgrade_available(name)

Check whether or not an upgrade is available for a given package

CLI Example:

```
salt '*' pkg.upgrade_available <package name>
```

salt.modules.aptpkg.version('names', **kwargs)

Returns a string representing the package version or an empty string if not installed. If more than one package name is specified, a dict of name/version pairs is returned.

CLI Example:

```
salt '*' pkg.version <package name>
salt '*' pkg.version <package1> <package2> <package3> ...
```

salt.modules.aptpkg.version_cmp(pkg1, pkg2)

Do a cmp-style comparison on two packages. Return -1 if pkg1 < pkg2, 0 if pkg1 == pkg2, and 1 if pkg1 > pkg2. Return None if there was a problem making the comparison.

CLI Example:

```
salt '*' pkg.version_cmp '0.2.4-@ubuntu1' '0.2.4.1-@ubuntu1'
```

31.16.6 salt.modules.archive

A module to wrap (non-Windows) archive calls

New in version 2014.1.0.

salt.modules.archive.cmd_unzip(zip_file, dest, excludes=None, template=None, options=None, runas=None)

New in version 2015.5.0: In versions 2014.7.x and earlier, this function was known as archive.unzip.

Uses the unzip command to unpack zip files. This command is part of the Info-ZIP suite of tools, and is typically packaged as simply unzip.

zip_file  Path of zip file to be unpacked
dest  The destination directory into which the file should be unpacked
excludes  [None] Comma-separated list of files not to unpack. Can also be passed in a Python list.
template  [None] Can be set to `jinja` or another supported template engine to render the command arguments before execution:
```
salt '*' archive.cmd_unzip template=jinja /tmp/zipfile.zip /tmp/{{grains.id}}/ excludes=file
```
options  [None] Additional command-line options to pass to the unzip binary.

Changed in version 2015.8.0: The mandatory -prefixing has been removed. An options string beginning with a `--long-option`, would have uncharacteristically needed its first - removed under the former scheme.
runas [None] Unpack the zip file as the specified user. Defaults to the user under which the minion is running.

New in version 2015.5.0.

CLI Example:
```bash
salt '*' archive.cmd_unzip /tmp/zipfile.zip /home/strongbad/ excludes=file_1,file_2
```

salt.modules.archive.cmd_zip(zip_file, sources, template=None, cwd=None, runas=None)
New in version 2015.5.0: In versions 2014.7.x and earlier, this function was known as archive.zip.

Uses the zip command to create zip files. This command is part of the Info-ZIP suite of tools, and is typically packaged as simply zip.

**zip_file** Path of zip file to be created

**sources** Comma-separated list of sources to include in the zip file. Sources can also be passed in a Python list.

**template** [None] Can be set to `jinja` or another supported template engine to render the command arguments before execution:
```bash
salt '*' archive.cmd_zip template=jinja /tmp/zipfile.zip /tmp/sourcefile1,/tmp/{{grains.id}}.txt
```

**cwd** [None] Use this argument along with relative paths in sources to create zip files which do not contain the leading directories. If not specified, the zip file will be created as if the cwd was ``, and creating a zip file of `/foo/bar/baz.txt` will contain the parent directories foo and bar. To create a zip file containing just `baz.txt`, the following command would be used:
```bash
salt '*' archive.cmd_zip /tmp/zipfile.zip baz.txt cwd=/foo/bar
```

New in version 2014.7.1.

**runas** [None] Create the zip file as the specified user. Defaults to the user under which the minion is running.

New in version 2015.5.0.

CLI Example:
```bash
salt '*' archive.cmd_zip /tmp/sourcefile1,/tmp/sourcefile2
```

salt.modules.archive.gunzip(gzipfile, template=None, runas=None)
Uses the gunzip command to unpack gzip files

**template** [None] Can be set to `jinja` or another supported template engine to render the command arguments before execution:
```bash
salt '*' archive.gunzip template=jinja /tmp/{{grains.id}}.txt.gz
```

CLI Example:
```bash
# Create /tmp/sourcefile.txt
salt '*' archive.gunzip /tmp/sourcefile.txt.gz
```

salt.modules.archive.gzip(sourcefile, template=None, runas=None)
Uses the gzip command to create gzip files

**template** [None] Can be set to `jinja` or another supported template engine to render the command arguments before execution:
```bash
salt '*' archive.gzip template=jinja /tmp/{{grains.id}}.txt
```

CLI Example:
# Create /tmp/sourcefile.txt.gz
salt '*' archive.gzip /tmp/sourcefile.txt

salt.modules.archive.rar(rarfile, sources, template=None, cwd=None, runas=None)
Uses `rar` for Linux to create rar files

- **rarfile**  Path of rar file to be created
- **sources**  Comma-separated list of sources to include in the rar file. Sources can also be passed in a Python list.
- **cwd**  [None] Run the `rar` command from the specified directory. Use this argument along with relative file paths to create rar files which do not contain the leading directories. If not specified, this will default to the home directory of the user under which the salt minion process is running.

  New in version 2014.7.1.
- **template**  [None] Can be set to `jinja` or another supported template engine to render the command arguments before execution:

```bash
salt '*' archive.rar template=jinja /tmp/rarfile.rar /tmp/sourcefile1,/tmp/sourcefile2
```

CLI Example:

```bash
salt '*' archive.rar /tmp/rarfile.rar /tmp/sourcefile1,/tmp/sourcefile2
```

salt.modules.archive.tar(options, tarfile, sources=None, dest=None, cwd=None, template=None, runas=None)

**Note:** This function has changed for version 0.17.0. In prior versions, the `cwd` and `template` arguments must be specified, with the source directories/files coming as a space-separated list at the end of the command. Beginning with 0.17.0, `sources` must be a comma-separated list, and the `cwd` and `template` arguments are optional.

Uses the tar command to pack, unpack, etc. tar files

- **options**  Options to pass to the tar command

  Changed in version 2015.8.0: The mandatory `-prefixing has been removed. An options string beginning with a `--long-option`, would have uncharacteristically needed its first `- removed under the former scheme. Also, tar will parse its options differently if short options are used with or without a preceding `-`, so it is better to not confuse the user into thinking they’re using the non-- format, when really they are using the with-- format.

- **tarfile**  The filename of the tar archive to pack/unpack
- **sources**  Comma delimited list of files to **pack** into the tarfile. Can also be passed as a Python list.
- **dest**  The destination directory into which to **unpack** the tarfile
- **cwd**  [None] The directory in which the tar command should be executed. If not specified, will default to the home directory of the user under which the salt minion process is running.
- **template**  [None] Can be set to `jinja` or another supported template engine to render the command arguments before execution:

```bash
salt '*' archive.tar -cjvf /tmp/salt.tar.bz2 {{grains.saltpath}} template=jinja
```

CLI Examples:
# Create a tarfile
salt '*' archive.tar -cjvf /tmp/tarfile.tar.bz2 /tmp/file_1,/tmp/file_2

# Unpack a tarfile
salt '*' archive.tar xf foo.tar dest=/target/directory

salt.modules.archive.unrar (rarfile, dest, excludes=None, template=None, runas=None)

Uses `rar` for Linux to unpack rar files

- **rarfile** Name of rar file to be unpacked
- **dest** The destination directory into which to unpack the rar file
- **template** [None] Can be set to `jinja` or another supported template engine to render the command arguments before execution:

```
salt '*' archive.unrar template=jinja /tmp/rarfile.rar /tmp/{{grains.id}}/ excludes=file_1,file_2
```

CLI Example:

```
salt '*' archive.unrar /tmp/rarfile.rar /home/strongbad/ excludes=file_1,file_2
```

salt.modules.archive.unzip (zip_file, dest, excludes=None, template=None, runas=None)

Uses the `zipfile` Python module to unpack zip files

Changed in version 2015.5.0: This function was rewritten to use Python's native zip file support. The old functionality has been preserved in the new function `archive.cmd_unzip`. For versions 2014.7.x and earlier, see the `archive.cmd_zip` documentation.

- **zip_file** Path of zip file to be unpacked
- **dest** The destination directory into which the file should be unpacked
- **excludes** [None] Comma-separated list of files not to unpack. Can also be passed in a Python list.
- **template** [None] Can be set to `jinja` or another supported template engine to render the command arguments before execution:

```
salt '*' archive.unzip template=jinja /tmp/zipfile.zip /tmp/{{grains.id}}/ excludes=file_1,file_2
```

CLI Example:

```
salt '*' archive.unzip /tmp/zipfile.zip /home/strongbad/ excludes=file_1,file_2
```

salt.modules.archive.zip (zip_file, sources, template=None, cwd=None, runas=None)

Uses the `zipfile` Python module to create zip files

Changed in version 2015.5.0: This function was rewritten to use Python's native zip file support. The old functionality has been preserved in the new function `archive.cmd_zip`. For versions 2014.7.x and earlier, see the `archive.cmd_zip` documentation.

- **zip_file** Path of zip file to be created
- **sources** Comma-separated list of sources to include in the zip file. Sources can also be passed in a Python list.
- **template** [None] Can be set to `jinja` or another supported template engine to render the command arguments before execution:

```
salt '*' archive.zip template=jinja /tmp/zipfile.zip /tmp/sourcefile1,/tmp/{{grains.id}}.txt
```

CLI Example:

```
**cwd** [None] Use this argument along with relative paths in sources to create zip files which do not contain the leading directories. If not specified, the zip file will be created as if the cwd was /, and creating a zip file of /foo/bar/baz.txt will contain the parent directories foo and bar. To create a zip file containing just baz.txt, the following command would be used:

```bash
salt '*' archive.zip /tmp/baz.zip baz.txt cwd=/foo/bar
```

**runas** [None] Create the zip file as the specified user. Defaults to the user under which the minion is running.

CLI Example:

```bash
salt '*' archive.zip /tmp/zipfile.zip /tmp/sourcefile1,/tmp/sourcefile2
```

### 31.16.7 `salt.modules.artifactory`

Module for fetching artifacts from Artifactory

**exception** `salt.modules.artifactory.ArtifactError(value)`

```python
salt.modules.artifactory.get_latest_snapshot(artifact_url, repository, group_id, artifact_id, packaging, target_dir='/tmp', target_file=None, classifier=None, username=None, password=None)
```

Gets latest snapshot of the given artifact

- **artifact_url** URL of artifactory instance
- **repository** Snapshot repository in artifactory to retrieve artifact from, for example: libs-snapshots
- **group_id** Group Id of the artifact
- **artifact_id** Artifact Id of the artifact
- **packaging** Packaging type (jar,war,ear,etc)
- **target_dir** Target directory to download artifact to (default: /tmp)
- **target_file** Target file to download artifact to (by default it is target_dir/artifact_id-snapshot_version.packaging)
- **classifier** Artifact classifier name (ex: sources,javadoc,etc). Optional parameter.
- **username** Artifactory username. Optional parameter.
- **password** Artifactory password. Optional parameter.

```python
salt.modules.artifactory.get_release(artifact_url, repository, group_id, artifact_id, packaging, version, target_dir='/tmp', target_file=None, classifier=None, username=None, password=None)
```

Gets the specified release of the artifact

- **artifact_url** URL of artifactory instance
- **repository** Release repository in artifactory to retrieve artifact from, for example: libs-releases
- **group_id** Group Id of the artifact
- **artifact_id** Artifact Id of the artifact
- **packaging** Packaging type (jar,war,ear,etc)
- **version** Version of the artifact
- **target_dir** Target directory to download artifact to (default: /tmp)
target_file  Target file to download artifact to (by default it is target_dir/artifact_id-version.packaging)
classifier   Artifact classifier name (ex: sources,javadoc,etc). Optional parameter.
username     Artifactory username. Optional parameter.
password     Artifactory password. Optional parameter.

```
salt.modules.artifactory.get_snapshot(artifactory_url, repository, group_id, artifact_id, packaging, version, snapshot_version=None, target_dir='/tmp', target_file=None, classifier=None, username=None, password=None)
```

Gets snapshot of the desired version of the artifact

artifactory_url  URL of artifactory instance
repository   Snapshot repository in artifactory to retrieve artifact from, for example: libs-snapshots
group_id     Group Id of the artifact
artifact_id  Artifact Id of the artifact
packaging    Packaging type (jar,war,ear,etc)
version     Version of the artifact
target_dir  Target directory to download artifact to (default: /tmp)
target_file Target file to download artifact to (by default it is target_dir/artifact_id-
snapshot_version.packaging)

classifier   Artifact classifier name (ex: sources,javadoc,etc). Optional parameter.
username     Artifactory username. Optional parameter.
password     Artifactory password. Optional parameter.

31.16.8  salt.modules.at

Wrapper module for at(1)

Also, a `tag' feature has been added to more easily tag jobs.

```
salt.modules.at.at(*args, **kwargs)
```

Add a job to the queue.

The `timespec' follows the format documented in the at(1) manpage.

CLI Example:

```
salt '*' at.at <timespec> <cmd> [tag=<tag>] [runas=<user>]
salt '*' at.at 12:05am '/sbin/reboot' tag=reboot
salt '*' at.at '3:05am +3 days' 'bin/myscript' tag=nightly runas=jim
```

```
salt.modules.at.atc(jobid)
```

Print the at(1) script that will run for the passed job id. This is mostly for debugging so the output will just be text.

CLI Example:

```
salt '*' at.atc <jobid>
```
salt.modules.at.atq(tag=None)
    List all queued and running jobs or only those with an optional `tag`.
    
    CLI Example:
    
    ```
    salt '*' at.atq
    salt '*' at.atq [tag]
    salt '*' at.atq [job number]
    ```

salt.modules.at.atrm(*args)
    Remove jobs from the queue.
    
    CLI Example:
    
    ```
    salt '*' at.atrm <jobid> <jobid> .. <jobid>
    salt '*' at.atrm all
    salt '*' at.atrm all [tag]
    ```

salt.modules.at.jobcheck(**kwargs)
    Check the job from queue. The kwargs dict include `hour minute day month year tag runas`. Other parameters will be ignored.
    
    CLI Example:
    
    ```
    salt '*' at.jobcheck runas=jam day=13
    salt '*' at.jobcheck day=13 month=12 year=13 tag=rose
    ```

### 31.16.9 salt.modules.augeas_cfg

Manages configuration files via augeas

This module requires the augeas Python module.

**Warning**: Minimal installations of Debian and Ubuntu have been seen to have packaging bugs with python-augeas, causing the augeas module to fail to import. If the minion has the augeas module installed, but the functions in this execution module fail to run due to being unavailable, first restart the salt-minion service. If the problem persists past that, the following command can be run from the master to determine what is causing the import to fail:

```
salt minion-id cmd.run 'python -c "from augeas import Augeas"'
```

For affected Debian/Ubuntu hosts, installing libpython2.7 has been known to resolve the issue.

salt.modules.augeas_cfg.execute(context=None, lens=None, commands=())
    Execute Augeas commands
    
    New in version 2014.7.0.
    
    CLI Example:
    
    ```
    salt '*' augeas.execute /files/etc/redis/redis.conf commands='["set bind 0.0.0.0", "set maxmemory 1G"]'
    ```

salt.modules.augeas_cfg.get(path, value='')
    Get a value for a specific augeas path
    
    CLI Example:
    
    ```
    salt '*' augeas.get /files/etc/hosts/1/ ipaddr
    ```
salt.modules.augeas_cfg.ls(path)
List the direct children of a node

CLI Example:
salt '*' augeas.ls /files/etc/passwd

salt.modules.augeas_cfg.match(path, value='``

Get matches for path expression

CLI Example:
salt '*' augeas.match /files/etc/services/service-name ssh

salt.modules.augeas_cfg.remove(path)
Get matches for path expression

CLI Example:
salt '*' augeas.remove /files/etc/sysctl.conf/net.ipv4.conf.all.log_martians

salt.modules.augeas_cfg.setvalue('args)
Set a value for a specific augeas path

CLI Example:
salt '*' augeas.setvalue /files/etc/hosts/1/canonical localhost

This will set the first entry in /etc/hosts to localhost

CLI Example:
salt '*' augeas.setvalue /files/etc/hosts/01/ipaddr 192.168.1.1 \\
/files/etc/hosts/01/canonical test

Adds a new host to /etc/hosts the ip address 192.168.1.1 and hostname test

CLI Example:
salt '*' augeas.setvalue prefix=/files/etc/sudoers/ \\
    "spec[user = '%wheel']/user" "%wheel" \\
    "spec[user = '%wheel']/host_group/host" 'ALL' \\
    "spec[user = '%wheel']/host_group/command[1]" 'ALL' \\
    "spec[user = '%wheel']/host_group/command[1]/tag" 'PASSWD' \\
    "spec[user = '%wheel']/host_group/command[2]" '/usr/bin/apt-get' \\
    "spec[user = '%wheel']/host_group/command[2]/tag" NOPASSWD

Ensures that the following line is present in /etc/sudoers:

%wheel ALL = PASSWD : ALL , NOPASSWD : /usr/bin/apt-get , /usr/bin/aptitude

salt.modules.augeas_cfg.tree(path)
Returns recursively the complete tree of a node

CLI Example:
salt '*' augeas.tree /files/etc/

31.16.10 salt.modules.aws_sqs
Support for the Amazon Simple Queue Service.
salt.modules.aws_sqs.create_queue(name, region, opts=None, user=None)

Creates a queue with the correct name.

- **name**: Name of the SQS queue to create
- **region**: Region to create the SQS queue in
- **opts**: [None] Any additional options to add to the command line
- **user**: [None] Run hg as a user other than what the minion runs as

salt.modules.aws_sqs.delete_message(queue, region, receipthandle, opts=None, user=None)

Delete one or more messages from a queue in a region

- **queue**: The name of the queue to delete messages from
- **region**: Region where SQS queues exists
- **receipthandle**: The ReceiptHandle of the message to delete. The ReceiptHandle is obtained in the return from `receive_message`
- **opts**: [None] Any additional options to add to the command line
- **user**: [None] Run as a user other than what the minion runs as

CLI Example:
```
salt '*' aws_sqs.delete_message <sqs queue> <region> receipthandle='<sqs ReceiptHandle>'
```

New in version 2014.7.0.

salt.modules.aws_sqs.delete_queue(name, region, opts=None, user=None)

Deletes a queue in the region.

- **name**: Name of the SQS queue to deletes
- **region**: Name of the region to delete the queue from
- **opts**: [None] Any additional options to add to the command line
- **user**: [None] Run hg as a user other than what the minion runs as

salt.modules.aws_sqs.list_queues(region, opts=None, user=None)

List the queues in the selected region.

- **region**: Region to list SQS queues for
- **opts**: [None] Any additional options to add to the command line
- **user**: [None] Run hg as a user other than what the minion runs as

salt.modules.aws_sqs.queue_exists(name, region, opts=None, user=None)

Returns True or False on whether the queue exists in the region

- **name**: Name of the SQS queue to search for
- **region**: Name of the region to search for the queue in
- **opts**: [None] Any additional options to add to the command line
- **user**: [None] Run hg as a user other than what the minion runs as

salt.modules.aws_sqs.receive_message(queue, region, num=1, opts=None, user=None)

Receive one or more messages from a queue in a region

- **queue**: The name of the queue to receive messages from
- **region**: Region where SQS queues exists
num [1] The max number of messages to receive

opts [None] Any additional options to add to the command line

user [None] Run as a user other than what the minion runs as

CLI Example:

```
salt '*' aws_sqs.receive_message <sqs queue> <region>
salt '*' aws_sqs.receive_message <sqs queue> <region> num=10
```

New in version 2014.7.0.

### 31.16.11 salt.modules.bamboohr

Support for BambooHR

New in version 2015.8.0.

Requires a subdomain and an apikey in /etc/salt/minion:

salt.modules.bamboohr.list_employees(order_by='id')

Show all employees for this company.

CLI Example:

```
salt myminion bamboohr.list_employees
```

By default, the return data will be keyed by ID. However, it can be ordered by any other field. Keep in mind that if the field that is chosen contains duplicate values (i.e., location is used, for a company which only has one location), then each duplicate value will be overwritten by the previous. Therefore, it is advisable to only sort by fields that are guaranteed to be unique.

CLI Examples:

```
salt myminion bamboohr.list_employees order_by=id salt myminion bamboohr.list_employees order_by=displayName
```

salt.modules.bamboohr.list_meta_fields()

Show all meta data fields for this company.

CLI Example:

```
salt myminion bamboohr.list_meta_fields
```

salt.modules.bamboohr.list_users(order_by='id')

Show all users for this company.

CLI Example:

```
salt myminion bamboohr.list_users
```

By default, the return data will be keyed by ID. However, it can be ordered by any other field. Keep in mind that if the field that is chosen contains duplicate values (i.e., location is used, for a company which only has one location), then each duplicate value will be overwritten by the previous. Therefore, it is advisable to only sort by fields that are guaranteed to be unique.

CLI Examples:

```
salt myminion bamboohr.list_users order_by=id salt myminion bamboohr.list_users order_by=email
```
salt.modules.bamboohr.show_employee(emp_id, fields=None)

Show all employees for this company.

CLI Example:
    salt myminion bamboohr.show_employee 1138

By default, the fields normally returned from bamboohr.list_employees are returned. These fields are:

- canUploadPhoto
- department
- displayName
- firstName
- id
- jobTitle
- lastName
- location
- mobilePhone
- nickname
- photoUploaded
- photoUrl
- workEmail
- workPhone
- workPhoneExtension

If needed, a different set of fields may be specified, separated by commas:

CLI Example:
    salt myminion bamboohr.show_employee 1138 displayName, dateOfBirth

A list of available fields can be found at http://www.bamboohr.com/api/documentation/employees.php

salt.modules.bamboohr.update_employee(emp_id, key=None, value=None, items=None)

Update one or more items for this employee. Specifying an empty value will clear it for that employee.

CLI Examples:
    salt myminion bamboohr.update_employee 1138 nickname Curly
    salt myminion bamboohr.update_employee 1138 nickname
    salt myminion bamboohr.update_employee 1138 items={"nickname": "Curly"}
    salt myminion bamboohr.update_employee 1138 items={"nickname": ""}

31.16.12 salt.modules.beacons

Module for managing the Salt beacons on a minion

New in version 2015.8.0.

salt.modules.beacons.add(name, beacon_data, **kwargs)

Add a beacon on the minion

Parameters
• **name** -- Name of the beacon to configure

• **beacon_data** -- Dictionary or list containing configuration for beacon.

Returns Boolean and status message on success or failure of add.

CLI Example:

```bash
salt '*' beacons.add ps "{'salt-master': 'stopped', 'apache2': 'stopped'}"
```

Function: salt.modules.beacons.delete

Delete a beacon item

Parameters

- **name** -- Name of the beacon to delete

Returns Boolean and status message on success or failure of delete.

CLI Example:

```bash
salt '*' beacons.delete ps
salt '*' beacons.delete load
```

Function: salt.modules.beacons.disable

Disable all beacons job on the minion

Returns Boolean and status message on success or failure of disable.

CLI Example:

```bash
salt '*' beacons.disable
```

Function: salt.modules.beacons.disable_beacon

Disable beacon on the minion

- **Name** Name of the beacon to enable.

Returns Boolean and status message on success or failure of disable.

CLI Example:

```bash
salt '*' beacons.disable_beacon ps
```

Function: salt.modules.beacons.enable

Enable all beacons on the minion

Returns Boolean and status message on success or failure of enable.

CLI Example:

```bash
salt '*' beacons.enable
```

Function: salt.modules.beacons.enable_beacon

Enable beacon on the minion

- **Name** Name of the beacon to enable.

Returns Boolean and status message on success or failure of enable.

CLI Example:

```bash
salt '*' beacons.enable_beacon ps
```

Function: salt.modules.beacons.list

List the beacons currently configured on the minion
Parameters `return_yaml` -- Whether to return YAML formatted output, default True

Returns List of currently configured Beacons.

CLI Example:
```
salt '*' beacons.list
```

```
salt.modules.beacons.modify(name, beacon_data, **kwargs)
Modify an existing beacon

Parameters

- `name` -- Name of the beacon to configure
- `beacon_data` -- Dictionary or list containing updated configuration for beacon.

Returns Boolean and status message on success or failure of modify.

CLI Example:
```
salt '*' beacon.modify ps "{'salt-master': 'stopped', 'apache2': 'stopped'}"
```

```
salt.modules.beacons.save()
Save all beacons on the minion

Returns Boolean and status message on success or failure of save.

CLI Example:
```
salt '*' beacons.save
```

### 31.16.13 salt.modules.bigip

An execution module which can manipulate an f5 bigip via iControl REST

```
maturity  develop
platform  f5_bigip_11.6
```

```
salt.modules.bigip.add_pool_member(hostname, username, password, name, member)
A function to connect to a bigip device and add a new member to an existing pool.

- `hostname` The host/address of the bigip device
- `username` The iControl REST username
- `password` The iControl REST password
- `name` The name of the pool to modify
- `member` The name of the member to add i.e. 10.1.1.2:80

CLI Example:
```
salt '*' bigip.add_pool_members bigip admin admin my-pool 10.2.2.1:80
```

```
salt.modules.bigip.commit_transaction(hostname, username, password, label)
A function to connect to a bigip device and commit an existing transaction.

Parameters:
- `hostname`: The host/address of the bigip device
- `username`: The iControl REST username
- `password`: The iControl REST password
- `label`: the label of this transaction stored within the grain: bigip_f5_trans:<label>

CLI Example:
```
```
salt`*'bigip.commit_transaction bigip admin admin my_transaction

salt.modules.bigip.create_monitor(hostname, username, password, monitor_type, name, **kwargs)

A function to connect to a bigip device and create a monitor.

**Parameters:**
- hostname: The host/address of the bigip device
- username: The iControl REST username
- password: The iControl REST password
- monitor_type: The type of monitor to create
- name: The name of the monitor to create

**Keyword Args:** [arg=val]...
Consult F5 BIGIP user guide for specific options for each monitor type. Typically, tmsh arg names are used.

**CLI Example:**
salt`*'bigip.create_monitor bigip admin admin http my-http-monitor timeout=10 interval=5

salt.modules.bigip.create_node(hostname, username, password, name, address, trans_label=None)

A function to connect to a bigip device and create a node.

**Parameters:**
- hostname: The host/address of the bigip device
- username: The iControl REST username
- password: The iControl REST password
- name: The name of the node
- address: The address of the node
- trans_label: The label of the transaction stored within the grain: bigip_f5_trans:<label>

**CLI Example:**
salt `*' bigip.create_node bigip admin admin 10.1.1.2

salt.modules.bigip.create_pool(hostname, username, password, name, members=None, allow_nat=None, allow_snat=None, description=None, gateway_failsafe_device=None, ignore_persisted_weight=None, ip_tos_to_client=None, ip_tos_to_server=None, link_qos_to_client=None, link_qos_to_server=None, load_balancing_mode=None, min_active_members=None, min_up_members=None, min_up_members_action=None, min_up_members_checking=None, monitor=None, profiles=None, queue_depth_limit=None, queue_on_connection_limit=None, queue_time_limit=None, reselect_tries=None, service_down_action=None, slow_ramp_time=None)

A function to connect to a bigip device and create a pool.

**Parameters:**
- hostname: The host/address of the bigip device
- username: The iControl REST username
- password: The iControl REST password
- name: The name of the pool to create.
- members: List of comma delimited pool members to add to the pool.

i.e. 10.1.1.1:80,10.1.1.2:80,10.1.1.3:80

- allow_nat: [yes | no]
- allow_snat: [yes | no]
- description: [string]
- gateway_failsafe_device: [string]
- ignore_persisted_weight: [enabled | disabled]
- ip_tos_to_client: [pass-through | [integer]]
- ip_tos_to_server: [pass-through | [integer]]
- link_qos_to_client: [pass-through | [integer]]
- link_qos_to_server: [pass-through | [integer]]
- load_balancing_mode: [dynamic-ratio-member | dynamic-ratio-node | fast-end-app-response | fast-end-node | least-connections-members | least-connections-node | least-sessions | observed-member | observed-node | predictive-member | predictive-node | ratio-least-connections-member | ratio-least-connections-node | ratio-member | ratio-node | ratio-session | round-robin | weighted-least-connections-member | weighted-least-connections-node]

- min_active_members: [integer]
- min_up_members: [integer]
- min_up_members_action: [failover | reboot | restart-all]
- min_up_members_checking: [enabled | disabled]
- monitor: [name]
- profiles: [none | profile_name]
- queue_depth_limit: [integer]
- queue_on_connection_limit: [enabled | disabled]
queue_time_limit: [integer] reselect_tries: [integer] service_down_action: [drop | none | reselect | reset]
slow_ramp_time: [integer]

CLI Example:
salt '*' bigip.create_pool bigip admin admin my-pool 10.1.1.1:80,10.1.1.2:80,10.1.1.3:80 monitor=http

salt.modules.bigip.create_profile(hostname, username, password, profile_type, name, **kwargs)
A function to connect to a bigip device and create a profile.

Parameters:
hostname: The host/address of the bigip device username: The iControl REST username password: The iControl REST password profile_type: The type of profile to create name: The name of the profile to create

Keyword Args: [arg=val] ... [arg=key1=val1,key2=val2] ... Consult F5 BIGIP user guide for specific options for each monitor type. Typically, tmsh arg names are used.

Creating Complex Args: Profiles can get pretty complicated in terms of the amount of possible config options. Use the following shorthand to create complex arguments such as lists, dictionaries, and lists of dictionaries. An option is also provided to pass raw json as well.

lists [i,i,i]: param='item1,item2,item3'
Dictionary [k:v,k,v,k,v]: param='key-1:val-1,key-2:val2,key-3:val-3'
List of Dictionaries [k:v,k,v,k,v]: param='key-1:val-1,key-2:val-2|key-1:val-1,key-2:val-2|key-1:val-1,key-2:val-2'
JSON: '[j ... ]j': cert-key-chain='j{``default'': {``cert'': ``default.crt'',``chain'': ``default.crt'',``key'': ``default.key''}}j'

Escaping Delimiters: Use , or : or | to escape characters which shouldn't be treated as delimiters i.e. ciphers='DEFAULT:!SSLv3'

CLI Examples:
salt '*' bigip.create_profile bigip admin admin http my-http-profile defaultsFrom='/Common/http' salt '*' bigip.create_profile bigip admin admin http my-http-profile defaultsFrom='/Common/http' n enforcement=maxHeaderCount:3200,maxRequests:10

salt.modules.bigip.create_virtual(hostname, username, password, name, destination, pool=None, address_status=None, auto_lasthop=None, bwc_policy=None, cmp_enabled=None, connection_limit=None, dhcp_relay=None, description=None, fallback_persistence=None, flow_eviction_policy=None, gtm_score=None, ip_forward=None, ip_protocol=None, internal=None, twelve_forward=None, last_hop_pool=None, mask=None, mirror=None, nat64=None, persist=None, profiles=None, policies=None, rate_class=None, rate_limit=None, rate_limit_mode=None, rate_limit_dst=None, rate_limit_src=None, rules=None, related_rules=None, reject=None, source=None, source_address_translation=None, source_port=None, state=None, traffic_classes=None, translate_address=None, translate_port=None, vlans=None)
A function to connect to a bigip device and create a virtual server.

Parameters:
hostname: The host/address of the bigip device username: The iControl REST username password: The iControl REST password name: The name of the virtual to create destination: [ [virtual_address_name:port] | [ipv4:port] | [ipv6:port] ]
pool: [ [pool_name] | none] address_status: [yes | no] auto_lasthop: [default | enabled | disabled ]
flow_eviction_policy: [none | [eviction policy name] ] gtm_score: [integer] ip_forward: [yes | no]
policies: [none | default | policy1,policy2,policy3 ... ] rate_class: [name] rate_limit: [integer] rate_limit-mode: [destination | object | object-destination | source | source-destination]
translate_address: [enabled | disabled] translate_port: [enabled | disabled] vlans: [none | default | [enabled|disabled]:vlan1,vlan2,vlan3 ... ]

CLI Examples:
salt '*' bigip.create_virtual bigip admin admin my-virtual-3 26.2.2.5:80 n pool=my-http-pool-http
 profiles=http,tc n
salt '*' bigip.create_virtual bigip admin admin my-virtual-3 43.2.2.5:80 n pool=test-http-pool-
http_profiles=http,websecurity persist=cookie,hash n policies=asm_auto_l7_policy_http
virtual n rules=sys_APM_ExchangeSupport_helper.Sys_HTTP_redirect n related_rules=sys_APM_acts
ivesyncnc Sys_APM_ExchangeSupport_helper n source_address_translation=snat:my-snat-pool n translate_address=enabled translate_port=enabled n traffic_classes=my-class,other-class n vlans=enabled:external,internal

salt.modules.bigip.delete_monitor( hostname, username, password, monitor_type, name )
A function to connect to a bigip device and delete an existing monitor.

Parameters: hostname: The host/address of the bigip device username: The iControl REST username password: The iControl REST password monitor_type: The type of monitor to delete name: The name of the monitor to delete

CLI Example:
salt '*' bigip.delete_monitor bigip admin admin http my-http-monitor

salt.modules.bigip.delete_node( hostname, username, password, name, trans_label=None )
A function to connect to a bigip device and delete a specific node.

Parameters: hostname: The host/address of the bigip device username: The iControl REST username password: The iControl REST password name: The name of the node which will be deleted.
trans_label: The label of the transaction stored within the grain: bigip_5_trans:<label>

CLI Example:
salt '*' bigip.delete_node bigip admin admin my-node

salt.modules.bigip.delete_pool( hostname, username, password, name )
A function to connect to a bigip device and delete a specific pool.

Parameters: hostname: The host/address of the bigip device username: The iControl REST username password: The iControl REST password name: The name of the pool which will be deleted

CLI Example:
salt '*' bigip.delete_pool bigip admin admin my-pool

662 Chapter 31. Reference
salt.modules.bigip.delete_pool_member(hostname, username, password, name, member)
A function to connect to a bigip device and delete a specific pool.

Parameters:
- hostname: The host/address of the bigip device
- username: The iControl REST username
- password: The iControl REST password
- name: The name of the pool to modify
- member: The name of the pool member to delete

CLI Example:
salt '*' bigip.delete_node bigip admin admin my-pool 10.2.2.2:80

salt.modules.bigip.delete_profile(hostname, username, password, profile_type, name)
A function to connect to a bigip device and delete an existing profile.

Parameters:
- hostname: The host/address of the bigip device
- username: The iControl REST username
- password: The iControl REST password
- profile_type: The type of profile to delete
- name: The name of the profile to delete

CLI Example:
salt '*' bigip.delete_profile bigip admin admin http my-http-profile

salt.modules.bigip.delete_transaction(hostname, username, password, label)
A function to connect to a bigip device and delete an existing transaction.

Parameters:
- hostname: The host/address of the bigip device
- username: The iControl REST username
- password: The iControl REST password
- label: The label of this transaction stored within the grain: bigip_f5_trans:<label>

CLI Example:
salt '*' bigip.delete_transaction bigip admin admin my_transaction

salt.modules.bigip.delete_virtual(hostname, username, password, name)
A function to connect to a bigip device and delete a specific virtual.

Parameters:
- hostname: The host/address of the bigip device
- username: The iControl REST username
- password: The iControl REST password
- name: The name of the virtual to delete

CLI Example:
salt '*' bigip.delete_virtual bigip admin admin my-virtual

salt.modules.bigip.list_monitor(hostname, username, password, monitor_type, name=None)
A function to connect to a bigip device and list an existing monitor. If no name is provided then all monitors of the specified type will be listed.

Parameters:
- hostname: The host/address of the bigip device
- username: The iControl REST username
- password: The iControl REST password
- monitor_type: The type of monitor(s) to list
- name: The name of the monitor to list

CLI Example:
salt '*' bigip.list_monitor bigip admin admin http my-http-monitor

salt.modules.bigip.list_node(hostname, username, password, name=None, trans_label=None)
A function to connect to a bigip device and list all nodes or a specific node.

Parameters:
- hostname: The host/address of the bigip device
- username: The iControl REST username
- password: The iControl REST password
- name: The name of the node to list. If no name is specified then all nodes will be listed.
- trans_label: The label of the transaction stored within the grain: bigip_f5_trans:<label>
CLI Example:

salt '*' bigip.list_node bigip admin admin my-node

salt.modules.bigip.list_pool(hostname, username, password, name=None)
A function to connect to a bigip device and list all pools or a specific pool.

Parameters:
hostname: The host/address of the bigip device
username: The iControl REST username
password: The iControl REST password
name: The name of the pool to list. If no name is specified then all pools will be listed.

CLI Example:

salt '*' bigip.list_pool bigip admin admin my-pool

salt.modules.bigip.list_profile(hostname, username, password, profile_type, name=None)
A function to connect to a bigip device and list an existing profile. If no name is provided than all profiles of the specified type will be listed.

Parameters:
hostname: The host/address of the bigip device
username: The iControl REST username
password: The iControl REST password
profile_type: The type of profile(s) to list
name: The name of the profile to list

CLI Example:

salt '*' bigip.list_profile bigip admin admin http my-http-profile

salt.modules.bigip.list_transaction(hostname, username, password, label)
A function to connect to a bigip device and list an existing transaction.

Parameters:
hostname: The host/address of the bigip device
username: The iControl REST username
password: The iControl REST password
label: the label of this transaction stored within the grain: bigip_f5_trans:<label>

CLI Example:

salt '*' bigip.list_transaction bigip admin admin my_transaction

salt.modules.bigip.list_virtual(hostname, username, password, name=None)
A function to connect to a bigip device and list all virtuals or a specific virtual.

Parameters:
hostname: The host/address of the bigip device
username: The iControl REST username
password: The iControl REST password
name: The name of the virtual to list. If no name is specified then all virtuals will be listed.

CLI Example:

salt '*' bigip.list_virtual bigip admin admin my-virtual

salt.modules.bigip.modify_monitor(hostname, username, password, monitor_type, name, **kwargs)
A function to connect to a bigip device and modify an existing monitor.

Parameters:
hostname: The host/address of the bigip device
username: The iControl REST username
password: The iControl REST password
monitor_type: The type of monitor to modify
name: The name of the monitor to modify

Keyword Args: [ arg=val ] ... Consult F5 BIGIP user guide for specific options for each monitor type. Typically, tmsh arg names are used.

CLI Example:
A function to connect to a bigip device and modify an existing node.

**Parameters:**
- **hostname:** The host/address of the bigip device
- **username:** The iControl REST username
- **password:** The iControl REST password
- **name:** The name of the node to modify
- **connection_limit:** [integer]
- **description:** [string]
- **dynamic_ratio:** [integer]
- **logging:** [enabled | disabled]
- **monitor:** [[name] | none | default]
- **rate_limit:** [integer]
- **ratio:** [integer]
- **session:** [user-enabled | user-disabled]
- **state:** [user-down | user-up]
- **trans_label:** The label of the transaction stored within the grain:

```
bigip_f5_trans:<label>
```

**CLI Example:**

```
salt '*' bigip.modify_node bigip admin admin http my-http-monitor timeout=16 interval=6
```

```python
salt.modules.bigip.modify_node(
    hostname, username, password, name, connection_limit=None,
    description=None, dynamic_ratio=None, logging=None,
    monitor=None, rate_limit=None, ratio=None, session=None,
    state=None, trans_label=None)
```

A function to connect to a bigip device and modify an existing pool.

**Parameters:**
- **hostname:** The host/address of the bigip device
- **username:** The iControl REST username
- **password:** The iControl REST password
- **name:** The name of the pool to modify
- **allow_nat:** [yes | no]
- **allow_snat:** [yes | no]
- **description:** [string]
- **gateway_failsafe_device:** [string]
- **ignore_persisted_weight:** [yes | no]
- **ip_tos_to_client:** [pass-through | [integer]]
- **ip_tos_to_server:** [pass-through | [integer]]
- **link_qos_to_client:** [pass-through | [integer]]
- **link_qos_to_server:** [pass-through | [integer]]
- **load_balancing_mode:** [dynamic-ratio-member | dynamic-ratio-node]
- **fastest-app-response:**
- **fastest-node:**
- **least-connections-members:**
- **least-connections-node:**
- **least-sessions:**
- **observed-member:**
- **observed-node:**
- **predictive-member:**
- **predictive-node:**
- **ratio-least-connections-member:**
- **ratio-least-connections-node:**
- **ratio-member:**
- **ratio-node:**
- **ratio-session:**
- **round-robin:**
- **weighted-least-connections-member:**
- **weighted-least-connections-node:**
- **min_active_members:** [integer]
- **min_up_members:** [integer]
- **min_up_members_action:** [failover | reboot | restart-all]
- **min_up_members_checking:** [enabled | disabled]
- **monitor:** [name]
- **profiles:** [none | profile_name]
- **queue_on_connection_limit:** [enabled | disabled]
- **queue_depth_limit:** [integer]
- **queue_time_limit:** [integer]
- **reselect_tries:** [integer]
- **service_down_action:** [drop | none | reselect | reset]
- **slow_ramp_time:** [integer]

**CLI Example:**

```
salt '*' bigip.modify_pool bigip admin admin my-pool 10.1.1.1:80,10.1.1.2:80,10.1.1.3:80 min_active_members=1
```

31.16. Full list of builtin execution modules 665
salt.modules.bigip.modify_pool_member(hostname, username, password, name, member, connection_limit=None, description=None, dynamic_ratio=None, inherit_profile=None, logging=None, monitor=None, priority_group=None, profiles=None, rate_limit=None, ratio=None, session=None, state=None)

A function to connect to a bigip device and modify an existing member of a pool.

Parameters:
hostname: The host/address of the bigip device
username: The iControl REST username
password: The iControl REST password
name: The name of the pool to modify
member: The name of the member to modify
i.e. 10.1.1.2:80

collection_limit: [integer]
description: [string]
dynamic_ratio: [integer]
inherit_profile: [enabled | disabled]
logging: [enabled | disabled]
monitor: [name]
priority_group: [integer]
profiles: [none | profile_name]
ratio: [integer]
state: [user-up | user-down]

CLI Example: salt '*' bigip.modify_pool_member bigip admin admin my-pool 10.2.2.1:80 state=use-down
session=user-disabled

salt.modules.bigip.modify_profile(hostname, username, password, profile_type, name, **kwargs)

A function to connect to a bigip device and create a profile.

Parameters:
hostname: The host/address of the bigip device
username: The iControl REST username
password: The iControl REST password
profile_type: The type of profile to modify
name: The name of the profile to modify

Keyword Args: [arg=val] ... [arg-key1:val1,key2:val2] ... Consult F5 BIGIP user guide for specific options for each monitor type. Typically, tmsh arg names are used.

Creating Complex Args: Profiles can get pretty complicated in terms of the amount of possible config options. Use the following shorthand to create complex arguments such as lists, dictionaries, and lists of dictionaries. An option is also provided to pass raw json as well.

lists [i,i,i]: param='item1,item2,item3'
Dictionary [k,v,k,v,k,v]: param='key-1:val-1,key-2:val2,key-3:val3'
List of Dictionaries [k,v,k,v,k,v,k,v]: param='key-1:val-1,key-2:val2,key-3:val3'
JSON: '[j[...]]j': cert-key-chain='[j[``default'': {``cert'': ``default.crt'',``chain'': ``default.crt'',``key'': ``default.key''}]j'

Escaping Delimiters: Use , or : or | to escape characters which shouldn't be treated as delimiters i.e. ciphers='DEFAULT:!SSLv3'

CLI Examples:
salt '*' bigip.modify_profile bigip admin http my-http-profile defaultsFrom='/Common/http' salt '*' bigip.modify_profile bigip admin http my-http-profile defaultsFrom='/Common/http' n enforement=maxHeaderCount:3200,maxRequests:10
salt '*' bigip.modify_profile bigip admin client-ssl my-client-ssl-1 retainCertificate=false n ciphers='DEFAULT:!SSLv3' cert_key_chain='[j[``default'': {``cert'': ``default.crt'',``chain'': ``default.crt'',``key'': ``default.key''}]j]'
**salt.modules.bigip.modify_virtual** *(hostname, username, password, name, destination=None, pool=None, address_status=None, auto_lasthop=None, bwc_policy=None, cmp_enabled=None, connection_limit=None, dhcp_relay=None, description=None, fallback_persistence=None, flow_eviction_policy=None, gtm_score=None, ip_forward=None, ip_protocol=None, internal=None, twelve_forward=None, last_hop_pool=None, mask=None, mirror=None, nat64=None, persist=None, profiles=None, policies=None, rate_class=None, rate_limit=None, rate_limit_mode=None, rate_limit_dst=None, rate_limit_src=None, rules=None, related_rules=None, reject=None, source=None, source_address_translation=None, source_port=None, state=None, traffic_classes=None, translate_address=None, translate_port=None, vlans=None)*

A function to connect to a bigip device and modify an existing virtual server.

**Parameters:**
hostname: The host/address of the bigip device
username: The iControl REST username
password: The iControl REST password
name: The name of the virtual to modify

destination: [ [virtual_address_name:port] | [ipv4:port] | [ipv6:port] ]
pool: [ [pool_name] | none ]
address_status: [ yes | no ]
auto_lasthop: [ default | enabled | disabled ]
bwc_policy: [ none | string ]
cmp_enabled: [ yes | no ]
dhcp_relay: [ yes | no ]
connection_limit: [ integer ]
description: [ string ]
state: [ disabled | enabled ]
fallback_persistence: [ none | [ profile name ] ]
flow_eviction_policy: [ none | [ eviction policy name ] ]
gtm_score: [ integer ]
ip_forward: [ yes | no ]
ip_protocol: [ any | protocol ]
internal: [ yes | no ]
twelve_forward: [12-forward]: [ yes | no ]
last_hop_pool: [ [pool_name] | none ]
mask: [ [ipv4] | [ipv6] ]
mirror: [ [ disabled | enabled | none ] ]
nat64: [ enabled | disabled ]
persist: [ none | [ profile1,profile2,profile3 ... ] ]
profiles: [ none | default | profile1,profile2,profile3 ... ]
policies: [ none | default | policy1,policy2,policy3 ... ]
rate_class: [ name ]
rate_limit: [ integer ]
rate_limit_mode: [ destination | object | object-destination | object-source | object-source-destination | source | source-destination ]
rate_limit_dst: [ integer ]
rate_limit_src: [ integer ]
rules: [ none | [ rule_one,rule_two ... ] ]
related_rules: [ none | [ rule_one,rule_two ... ] ]
reject: [ yes | no ]
source: [ [ipv4[/prefixlen]] | [ipv6[/prefixlen]] ]
source_address_translation: [ [snat:pool_name] | lsn | automap ]
source_port: [ change | preserve | preserve-strict ]
state: [ enabled | disable ]
traffic_classes: [ none | default | class_one,class_two ... ]
translate_address: [ enabled | disabled ]
translate_port: [ enabled | disabled ]
vlans: [ none | default | [ enabled | disabled ]:vlan1,vlan2,vlan3 ... ]

**CLI Example:**
salt '*' bigip.modify_virtual bigip admin admin my-virtual source_address_translation=none salt '*' bigip.modify_virtual bigip admin admin my-virtual_rules=my-rule,my-other-rule

**salt.modules.bigip.replace_pool_members** *(hostname, username, password, name, members)*

A function to connect to a bigip device and replace members of an existing pool with new members.

**Parameters:**
hostname: The host/address of the bigip device
username: The iControl REST username
password: The iControl REST password
name: The name of the pool to modify members: List of comma delimited pool members to replace existing members with.

e.g. 10.2.2.1:80,10.2.2.2:80,10.2.2.3:80

**CLI Example:**
salt '*' bigip.replace_pool_members bigip admin admin my-pool 10.2.2.1:80,10.2.2.2:80,10.2.2.3:80

**salt.modules.bigip.start_transaction** *(hostname, username, password, label)*

A function to connect to a bigip device and start a new transaction.

**Parameters:**
hostname: The host/address of the bigip device
username: The iControl REST username
password: The iControl REST password
label: The name / alias for this transaction

The actual transaction
id will be stored within a grain called bigip_f5_trans:

CLI Example:

```
salt '*' bigip.start_transaction bigip admin admin my_transaction
```

### 31.16.14 `salt.modules.blockdev`

Module for managing block devices

New in version 2014.7.0.

- `salt.modules.blockdev.dump(device, args=None)`
  - Return all contents of dumpt2fs for a specified device
    - CLI Example: `salt '*' extfs.dump /dev/sda1`

- `salt.modules.blockdev.resize2fs(device)`
  - Resizes the filesystem.
    - CLI Example: `salt '*' blockdev.resize2fs /dev/sda1`

- `salt.modules.blockdev.tune(device, **kwargs)`
  - Set attributes for the specified device
    - CLI Example:
      ```
salt '*' blockdev.tune /dev/sda1 read-ahead=1024 read-write=True
      ```
  
  Valid options are: read-ahead, filesystem-read-ahead, read-only, read-write.

  See the blockdev(8) manpage for a more complete description of these options.

- `salt.modules.blockdev.wipe(device)`
  - Remove the filesystem information
    - CLI Example:
      ```
salt '*' blockdev.wipe /dev/sda1
      ```

### 31.16.15 `salt.modules.bluez`

Support for Bluetooth (using BlueZ in Linux).

The following packages are required packages for this module:

- bluez >= 5.7 bluez-libs >= 5.7 bluez-libs-libs >= 5.7 pybluez >= 0.18

- `salt.modules.bluez.address()`
  - Get the many addresses of the Bluetooth adapter
    - CLI Example:
      ```
salt '*' bluetooth.address
      ```

- `salt.modules.bluez.block(bdaddr)`
  - Block a specific bluetooth device by BD Address
    - CLI Example:

salt.modules.bluez.discoverable(dev)
   Enable this bluetooth device to be discoverable.
   CLI Example:
   salt '*' bluetooth.discoverable hci0

salt.modules.bluez.noscan(dev)
   Turn off scanning modes on this device.
   CLI Example:
   salt '*' bluetooth.noscan hci0

salt.modules.bluez.pair(address, key)
   Pair the bluetooth adapter with a device
   CLI Example:
   salt '*' bluetooth.pair DE:AD:BE:EF:CA:FE 1234

Where DE:AD:BE:EF:CA:FE is the address of the device to pair with, and 1234 is the passphrase.

TODO: This function is currently broken, as the bluez-simple-agent program no longer ships with BlueZ >= 5.0. It needs to be refactored.

salt.modules.bluez.power(dev, mode)
   Power a bluetooth device on or off
   CLI Examples:
   salt '*' bluetooth.power hci0 on
   salt '*' bluetooth.power hci0 off

salt.modules.bluez.scan()
   Scan for bluetooth devices in the area
   CLI Example:
   salt '*' bluetooth.scan

salt.modules.bluez.start()
   Start the bluetooth service.
   CLI Example:
   salt '*' bluetooth.start

salt.modules.bluez.stop()
   Stop the bluetooth service.
   CLI Example:
   salt '*' bluetooth.stop

salt.modules.bluez.unblock(bdaddr)
   Unblock a specific bluetooth device by BD Address
   CLI Example:
salt '*

salt.modules.bluez.unpair(address)
Unpair the bluetooth adapter from a device
CLI Example:
salt '*

Where DE:AD:BE:EF:CA:FE is the address of the device to unpair.
TODO: This function is currently broken, as the bluez-simple-agent program no longer ships with BlueZ >=
5.0. It needs to be refactored.

salt.modules.bluez.version()
Return Bluez version from bluetoothd -v
CLI Example:
salt '*
bluetoothd.version

31.16.16 salt.modules.boto_asg
Connection module for Amazon Autoscale Groups
New in version 2014.7.0.

configuration This module accepts explicit autoscale credentials but can also utilize IAM roles assigned
to the instance trough Instance Profiles. Dynamic credentials are then automatically obtained from
AWS API and no further configuration is necessary. More Information available at:

If IAM roles are not used you need to specify them either in a pillar or in the minion's config file:

asg.keyid: GKTADJGHEIQSXMKKRBJ08H
asg.key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs

A region may also be specified in the configuration:
asg.region: us-east-1

If a region is not specified, the default is us-east-1.
It's also possible to specify key, keyid and region via a profile, either as a passed in dict, or as a
string to pull from pillars or minion config:

myprofile:
  keyid: GKTADJGHEIQSXMKKRBJ08H
  key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
  region: us-east-1

depends boto
salt.modules.boto_asg.create(name, launch_config_name, availability_zones, min_size, max_size, desired_capacity=None, load_balancers=None, default_cooldown=None, health_check_type=None, health_check_period=None, placement_group=None, vpc_zone_identifier=None, tags=None, termination_policies=None, suspended_processes=None, scaling_policies=None, region=None, notification_arn=None, notification_types=None, key=None, keyid=None, profile=None)

Create an autoscale group.

CLI example:
```
salt myminion boto_asg.create myasg mylc ['"us-east-1a", "us-east-1e"'] 1 10 load_balancers='["myelb", "myelb2"]'
```

salt.modules.boto_asg.create_launch_configuration(name, image_id, key_name=None, security_groups=None, user_data=None, instance_type='m1.small', kernel_id=None, ramdisk_id=None, block_device_mappings=None, instance_monitoring=False, spot_price=None, instance_profile_name=None, ebs_optimized=False, associate_public_ip_address=None, volume_type=None, delete_on_termination=True, iops=None, use_block_device_types=False, region=None, key=None, keyid=None, profile=None)

Create a launch configuration.

CLI example:
```
salt myminion boto_asg.create_launch_configuration mylc image_id=ami-0b9c9f62 key_name='mykey' security_groups='["mygroup"]' instance_type='c3.2xlarge'
```

salt.modules.boto_asg.delete(name, force=False, region=None, key=None, keyid=None, profile=None)

Delete an autoscale group.

CLI example:
```
salt myminion boto_asg.delete myasg region=us-east-1
```

salt.modules.boto_asg.delete_launch_configuration(name, region=None, key=None, keyid=None, profile=None)

Delete a launch configuration.

CLI example:
```
salt myminion boto_asg.delete_launch_configuration mylc
```

salt.modules.boto_asg.exists(name, region=None, key=None, keyid=None, profile=None)

Check to see if an autoscale group exists.

CLI example:
salt myminion boto_asg.exists myasg region=us-east-1

salt.modules.boto_asg.get_cloud_init_mime(cloud_init)
Get a mime multipart encoded string from a cloud-init dict. Currently supports scripts and cloud-config.
CLI Example:
salt myminion boto.get_cloud_init_mime <cloud init>

salt.modules.boto_asg.get_config(name, region=None, key=None, keyid=None, profile=None)
Get the configuration for an autoscale group.
CLI example:
salt myminion boto_asg.get_config myasg region=us-east-1

salt.modules.boto_asg.get_instances(name, lifecycle_state='InService', health_status='Healthy', attribute='private_ip_address', region=None, key=None, keyid=None, profile=None)
return attribute of all instances in the named autoscale group.
CLI example:
salt-call boto_asg.get_instances my_autoscale_group_name

salt.modules.boto_asg.get_scaling_policy_arn(as_group, scaling_policy_name, region=None, key=None, keyid=None, profile=None)
Return the arn for a scaling policy in a specific autoscale group or None if not found. Mainly used as a helper method for boto_cloudwatch_alarm, for linking alarms to scaling policies.
CLI Example:
salt '*' boto_asg.get_scaling_policy_arn mygroup mypolicy

salt.modules.boto_asg.launch_configuration_exists(name, region=None, key=None, keyid=None, profile=None)
Check for a launch configuration's existence.
CLI example:
salt myminion boto_asg.launch_configuration_exists mylc

salt.modules.boto_asg.update(name, launch_config_name, availability_zones, min_size, max_size, desired_capacity=None, load_balancers=None, default_cooldown=None, health_check_type=None, health_check_period=None, placement_group=None, vpc_zone_identifier=None, tags=None, termination_policies=None, suspended_processes=None, scaling_policies=None, notification_arn=None, notification_types=None, region=None, key=None, keyid=None, profile=None)
Update an autoscale group.
CLI example:
salt myminion boto_asg.update myasg mylc '["us-east-1a", "us-east-1e"]' 1 10 load_balancers='["myelb", "myelb2"]'
31.16.17 salt.modules.boto_cfn

Connection module for Amazon Cloud Formation

New in version 2015.5.0.

configuration This module accepts explicit AWS credentials but can also utilize IAM roles assigned to the instance through Instance Profiles. Dynamic credentials are then automatically obtained from AWS API and no further configuration is necessary. More Information available at:

If IAM roles are not used you need to specify them either in a pillar or in the minion's config file:

| cfn.keyid: GKTADJGHEIQSXMKKRBJ08H |
| cfn.key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs |

A region may also be specified in the configuration:

| cfn.region: us-east-1 |

depends boto

salt.modules.boto_cfn.create(name, template_body=None, template_url=None, parameters=None, notification_arns=None, disable_rollback=None, timeout_in_minutes=None, capabilities=None, tags=None, on_failure=None, stack_policy_body=None, stack_policy_url=None, region=None, key=None, keyid=None, profile=None)

Create a CFN stack.

CLI example to create a stack:

salt myminion boto_cfn.create mystack template_url='https://s3.amazonaws.com/bucket/template.cft' region=us-east-1

salt.modules.boto_cfn.delete(name, region=None, key=None, keyid=None, profile=None)

Delete a CFN stack.

CLI example to delete a stack:

salt myminion boto_cfn.delete mystack region=us-east-1

salt.modules.boto_cfn.describe(name, region=None, key=None, keyid=None, profile=None)

Describe a stack.

New in version 2015.8.0.

CLI example:

salt myminion boto_cfn.describe mystack region=us-east-1

salt.modules.boto_cfn.exists(name, region=None, key=None, keyid=None, profile=None)

Check to see if a stack exists.

CLI example:

salt myminion boto_cfn.exists mystack region=us-east-1

salt.modules.boto_cfn.get_template(name, region=None, key=None, keyid=None, profile=None)

Check to see if attributes are set on a CFN stack.

CLI example:
salt myminion boto_cfn.get_template mystack

salt.modules.boto_cfn.update_stack(name, template_body=None, template_url=None, parameters=None, notification_arns=None, disable_rollback=False, timeout_in_minutes=None, capabilities=None, tags=None, use_previous_template=None, stack_policy_during_update_body=None, stack_policy_during_update_url=None, stack_policy_body=None, stack_policy_url=None, region=None, key=None, keyid=None, profile=None)

Update a CFN stack.
New in version 2015.8.0.
CLI example to update a stack:
salt myminion boto_cfn.update_stack mystack template_url='https://s3.amazonaws.com/bucket/template.cft' region=us-east-1

salt.modules.boto_cfn.validate_template(template_body=None, template_url=None, region=None, key=None, keyid=None, profile=None)

Validate cloudformation template
New in version 2015.8.0.
CLI example:
salt myminion boto_cfn.validate_template mystack-template

31.16.18 salt.modules.boto_cloudwatch

Connection module for Amazon CloudWatch
New in version 2014.7.0.
configuration This module accepts explicit credentials but can also utilize IAM roles assigned to the instance trough Instance Profiles. Dynamic credentials are then automatically obtained from AWS API and no further configuration is necessary. More Information available at:

If IAM roles are not used you need to specify them either in a pillar or in the minion's config file:
cloudwatch.keyid: GKTADJGHEIQSXMKKRBJ08H
cloudwatch.key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs

A region may also be specified in the configuration:
cloudwatch.region: us-east-1

If a region is not specified, the default is us-east-1.
It's also possible to specify key, keyid and region via a profile, either as a passed in dict, or as a string to pull from pillars or minion config:

myprofile:
    keyid: GKTADJGHEIQSXMKKRBJ08H
    key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
    region: us-east-1
depends boto

```
salt.modules.boto_cloudwatch.convert_to_arn(arns, region=None, key=None, keyid=None, profile=None)
```

Convert a list of strings into actual arns. Converts convenience names such as `scaling_policy:`...

CLI Example:
```
salt '*' convert_to_arn 'scaling_policy:'
```

```
salt.modules.boto_cloudwatch.create_or_update_alarm(connection=None, name=None, metric=None, namespace=None, statistic=None, comparison=None, threshold=None, period=None, evaluation_periods=None, unit=None, description='`, dimensions=None, alarm_actions=None, insufficient_data_actions=None, ok_actions=None, region=None, key=None, keyid=None, profile=None)
```

Create or update a cloudwatch alarm.

Dimensions must be a dict. If the value of Dimensions is a string, it will be json decoded to produce a dict. `alarm_actions`, `insufficient_data_actions`, and `ok_actions` must be lists of string. If the passed-in value is a string, it will be split on “,” to produce a list. The strings themselves for `alarm_actions`, `insufficient_data_actions`, and `ok_actions` must be Amazon resource names (ARN's); however, this method also supports an arn lookup notation, as follows:

```
arn:aws:.... ARN as per [http://docs.aws.amazon.com/general/latest/gr/aws-arns-and-namespaces.html](http://docs.aws.amazon.com/general/latest/gr/aws-arns-and-namespaces.html) scaling_policy::<as_name>:<scaling_policy_name> The named autoscale group scaling policy, for the named group (e.g. scaling_policy:my-asg:ScaleDown)
```

This is convenient for setting up autoscaling as follows. First specify a `boto_asg.present` state for an ASG with scaling_policies, and then set up `boto_cloudwatch_alarm.present` states which have `alarm_actions` that reference the `scaling_policy`.

CLI example:
```
salt myminion boto_cloudwatch.create_alarm name=myalarm ... region=us-east-1
```

```
salt.modules.boto_cloudwatch.delete_alarm(name, region=None, key=None, keyid=None, profile=None)
```

Delete a cloudwatch alarm

CLI example to delete a queue:
```
salt myminion boto_cloudwatch.delete_alarm myalarm region=us-east-1
```

```
salt.modules.boto_cloudwatch.get_alarm(name, region=None, key=None, keyid=None, profile=None)
```

Get alarm details. Also can be used to check to see if an alarm exists.

CLI example:
```
salt myminion boto_cloudwatch.get_alarm myalarm region=us-east-1
```
salt.modules.boto_cloudwatch.get_all_alarms(region=None, prefix=None, key=None, keyid=None, profile=None)

Get all alarm details. Produces results that can be used to create an sls file.

If prefix parameter is given, alarm names in the output will be prepended with the prefix; alarms that have the prefix will be skipped. This can be used to convert existing alarms to be managed by salt, as follows:

1. Make a "backup" of all existing alarms
   $ salt-call boto_cloudwatch.get_all_alarms --out=txt | sed "s/local: //" > legacy_alarms.sls

2. Get all alarms with new prefixed names
   $ salt-call boto_cloudwatch.get_all_alarms `prefix="**MANAGED BY SALT**"` --out=txt | sed "s/local: //" > managed_alarms.sls

3. Insert the managed alarms into cloudwatch
   $ salt-call state.template managed_alarms.sls

4. Manually verify that the new alarms look right

5. Delete the original alarms
   $ sed s/present/absent/ legacy_alarms.sls > remove_legacy_alarms.sls
   $ salt-call state.template remove_legacy_alarms.sls

6. Get all alarms again, verify no changes
   $ salt-call boto_cloudwatch.get_all_alarms --out=txt | sed "s/local: //" > final_alarms.sls
   $ diff final_alarms.sls managed_alarms.sls

CLI example:

```
salt myminion boto_cloudwatch.get_all_alarms region=us-east-1 --out=txt
```

31.16.19 salt.modules.boto_dynamodb

Connection module for Amazon DynamoDB

New in version 2015.5.0.

configuration

This module accepts explicit DynamoDB credentials but can also utilize IAM roles assigned to the instance through Instance Profiles. Dynamic credentials are then automatically obtained from AWS API and no further configuration is necessary. More Information available at:

If IAM roles are not used you need to specify them either in a pillar or in the minion's config file:

```
keyid: GKTADJGHEIQXSXMKRRBJJ08H
key: askdjghsdfjkghWupUjasdflkSdkflgjjsdfjajkgghs
```

A region may also be specified in the configuration:

```
region: us-east-1
```

If a region is not specified, the default is us-east-1.

It's also possible to specify key, keyid and region via a profile, either as a passed in dict, or as a string to pull from pillars or minion config:

```
.. code-block:: yaml

  myprofile: keyid: GKTADJGHEIQXSXMKRRBJJ08H key: askdjghsdfjkghWupUjasdflkSdkflgjjsdfjajkgghs region: us-east-1
```

depends boto
salt.modules.boto_dynamodb.create_table(table_name, region=None, key=None, keyid=None, profile=None, read_capacity_units=None, write_capacity_units=None, hash_key=None, hash_key_data_type=None, range_key=None, range_key_data_type=None, local_indexes=None, global_indexes=None)

Creates a DynamoDB table.

CLI Example:

```
salt myminion boto_dynamodb.create_table table_name / region=us-east-1 / hash_key=id / hash_key_data_type=N / range_key=created_at / range_key_data_type=N / read_capacity_units=1 / write_capacity_units=1
```

salt.modules.boto_dynamodb.delete(table_name, region=None, key=None, keyid=None, profile=None)

Delete a DynamoDB table.

CLI Example:

```
salt myminion boto_dynamodb.delete table_name region=us-east-1
```

salt.modules.boto_dynamodb.exists(table_name, region=None, key=None, keyid=None, profile=None)

Check to see if a table exists.

CLI Example:

```
salt myminion boto_dynamodb.exists table_name region=us-east-1
```

**31.16.20 salt.modules.boto_ec2**

Connection module for Amazon EC2

New in version 2015.8.0.

**configuration** This module accepts explicit EC2 credentials but can also utilize IAM roles assigned to the instance through Instance Profiles. Dynamic credentials are then automatically obtained from AWS API and no further configuration is necessary. More Information available at:

If IAM roles are not used you need to specify them either in a pillar or in the minion's config file:

```
ec2.keyid: GKTADJGHEIQSXMKKRBJ08H
e2.key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
```

A region may also be specified in the configuration:

```
ec2.region: us-east-1
```

If a region is not specified, the default is us-east-1.

It's also possible to specify key, keyid and region via a profile, either as a passed in dict, or as a string to pull from pillars or minion config:
Salt Documentation, Release 2015.8.0

```python
myprofile:
keyid: GKTADJGHEIQSXMKKRBJ08H
key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
region: us-east-1
```

```python
depends boto

salt.modules.boto_ec2.create_key(key_name, save_path, region=None, key=None, keyid=None, profile=None)

Creates a key and saves it to a given path. Returns the private key.

CLI Example:

```
salt myminion boto_ec2.create_key /root/
```

salt.modules.boto_ec2.delete_key(key_name, region=None, key=None, keyid=None, profile=None)

Deletes a key. Always returns True

CLI Example:

```
salt myminion boto_ec2.delete_key mykey
```

salt.modules.boto_ec2.exists(instance_id=None, name=None, tags=None, region=None, key=None, keyid=None, profile=None)

Given a instance id, check to see if the given instance id exists.

Returns True if the given an instance with the given id, name, or tags exists; otherwise, False is returned.

CLI Example:

```
salt myminion boto_ec2.exists myinstance
```

salt.modules.boto_ec2.find_instances(instance_id=None, name=None, tags=None, region=None, key=None, keyid=None, profile=None, return_objs=False)

Given instance properties, find and return matching instance ids

CLI Examples:

```
salt myminion boto_ec2.find_instances # Lists all instances
salt myminion boto_ec2.find_instances name=myinstance
salt myminion boto_ec2.find_instances tags='{"mytag": "value"}'
```

salt.modules.boto_ec2.get_attribute(attribute, instance_name=None, instance_id=None, region=None, key=None, keyid=None, profile=None)

Get an EC2 instance attribute.

CLI Example:

```
salt myminion boto_ec2.get_attribute name=my_instance attribute=sourceDestCheck
```

Available attributes:

- instanceType
- kernel
- ramdisk
- userData
- disableApiTermination
```
- `instanceInitiatedShutdownBehavior`
- `rootDeviceName`
- `blockDeviceMapping`
- `productCodes`
- `sourceDestCheck`
- `groupSet`
- `ebsOptimized`
- `sriovNetSupport`

```python
salt.modules.boto_ec2.get_id(name=None, tags=None, region=None, key=None, keyid=None, profile=None)
```

Given instance properties, return the instance id if it exists.

CLI Example:
```
salt myminion boto_ec2.get_id myinstance
```

```python
salt.modules.boto_ec2.get_key(key_name, region=None, key=None, keyid=None, profile=None)
```

Check to see if a key exists. Returns fingerprint and name if it does and False if it doesn't

CLI Example:
```
salt myminion boto_ec2.get_key mykey
```

```python
salt.modules.boto_ec2.get_keys(keynames=None, filters=None, region=None, key=None, keyid=None, profile=None)
```

Gets all keys or filters them by name and returns a list. `keynames` (list):: A list of the names of keypairs to retrieve. If not provided, all key pairs will be returned. `filters` (dict):: Optional filters that can be used to limit the results returned. Filters are provided in the form of a dictionary consisting of filter names as the key and filter values as the value. The set of allowable filter names/values is dependent on the request being performed. Check the EC2 API guide for details.

CLI Example:
```
salt myminion boto_ec2.get_keys
```

```python
salt.modules.boto_ec2.get_zones(region=None, key=None, keyid=None, profile=None)
```

Get a list of AZs for the configured region.

CLI Example:
```
salt myminion boto_ec2.get_zones
```

```python
salt.modules.boto_ec2.import_key(key_name, public_key_material, region=None, key=None, keyid=None, profile=None)
```

Imports the public key from an RSA key pair that you created with a third-party tool. Supported formats:
- OpenSSH public key format (e.g., the format in ~/.ssh/authorized_keys)
- Base64 encoded DER format
- SSH publickey file format as specified in RFC4716

DSA keys are not supported. Make sure your key generator is set up to create RSA keys. Supported lengths: 1024, 2048, and 4096.

CLI Example:
```
salt myminion boto_ec2.import mykey publickey
```

```python
salt.modules.boto_ec2.run(image_id, name=None, tags=None, instance_type='m1.small',
key_name=None, security_groups=None, user_data=None, placement=None, region=None, key=None, keyid=None, profile=None)
```

Create and start an EC2 instance.
Returns True if the instance was created; otherwise False.

CLI Example:

```bash
salt myminion boto_ec2.run ami-b80c2b87 name=myinstance
```

```python
salt.modules.boto_ec2.set_attribute(attribute, attribute_value, instance_name=None, instance_id=None, region=None, key=None, keyid=None, profile=None)
```

Set an EC2 instance attribute. Returns whether the operation succeeded or not.

CLI Example:

```bash
salt myminion boto_ec2.set_attribute instance_name=my_instance attribute=sourceDestCheck attribute_value=False
```

Available attributes:

- instanceType
- kernel
- ramdisk
- userData
- disableApiTermination
- instanceInitiatedShutdownBehavior
- rootDeviceName
- blockDeviceMapping
- productCodes
- sourceDestCheck
- groupSet
- ebsOptimized
- srivNetSupport

```python
salt.modules.boto_ec2.terminate(instance_id=None, name=None, region=None, key=None, keyid=None, profile=None)
```

Terminate the instance described by instance_id or name.

CLI Example:

```bash
salt myminion boto_ec2.terminate name=myinstance
salt myminion boto_ec2.terminate instance_id=i-a46b9f
```

### 31.16.21 salt.modules.boto_elasticache

Connection module for Amazon Elasticache

New in version 2014.7.0.

**configuration** This module accepts explicit elasticache credentials but can also utilize IAM roles assigned to the instance through Instance Profiles. Dynamic credentials are then automatically obtained from AWS API and no further configuration is necessary. More Information available at:
If IAM roles are not used you need to specify them either in a pillar or the minion's config file:

```yaml
elasticache.keyid: GKTADJGHEIQSXMKKRBJ08H
elasticache.key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
```

A region may also be specified in the configuration:

```yaml
elasticache.region: us-east-1
```

If a region is not specified, the default is us-east-1.

It's also possible to specify key, keyid and region via a profile, either as a passed in dict, or as a string to pull from pillars or minion config:

```yaml
myprofile:
  keyid: GKTADJGHEIQSXMKKRBJ08H
  key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
  region: us-east-1
```

depends boto

```
salt.modules.boto_elasticache.authorize_cache_security_group_ingress(name, ec2_security_group_name, ec2_security_group_owner_id, region=None, key=None, keyid=None, profile=None)

Authorize network ingress from an ec2 security group to a cache security group.

CLI example:

```bash
salt myminion boto_elasticache.authorize_cache_security_group_ingress myelasticachesg myec2sg 879879
```
```
salt.modules.boto_elasticache.create(name, num_cache_nodes=None, engine=None, cache_node_type=None, replication_group_id=None, engine_version=None, cache_parameter_group_name=None, cache_subnet_group_name=None, cache_security_group_names=None, security_group_ids=None, snapshot_arns=None, preferred_availability_zone=None, preferred_maintenance_window=None, port=None, notification_topic_arn=None, auto_minor_version_upgrade=None, wait=None, region=None, key=None, keyid=None, profile=None)

Create a cache cluster.

CLI example:

```bash
salt myminion boto_elasticache.create myelasticache 1 redis cache.t1.micro cache_security_group_names='["myelasticachesg"]'
```
salt.modules.boto_elasticache.create_cache_security_group(name, description, region=None, key=None, keyid=None, profile=None)

Create a cache security group.
CLI example:
salt myminion boto_elasticache.create_cache_security_group myelasticachesg 'My Cache Security Group'

salt.modules.boto_elasticache.create_replication_group(name, primary_cluster_id, replication_group_description, wait=None, region=None, key=None, keyid=None, profile=None)

Create replication group.
CLI example:
salt myminion boto_elasticache.create_replication_group myelasticache myprimarycluster description

salt.modules.boto_elasticache.create_subnet_group(name, description, subnet_ids, tags=None, region=None, key=None, keyid=None, profile=None)

Create an ElastiCache subnet group
CLI example to create an ElastiCache subnet group:
salt myminion boto_elasticache.create_subnet_group my-subnet-group "group description" ['subnet-12345678', 'subnet-87654321'] region=us-east-1

salt.modules.boto_elasticache.delete(name, wait=False, region=None, key=None, keyid=None, profile=None)

Delete a cache cluster.
CLI example:
salt myminion boto_elasticache.delete myelasticache

salt.modules.boto_elasticache.delete_cache_security_group(name, region=None, key=None, keyid=None, profile=None)

Delete a cache security group.
CLI example:
salt myminion boto_elasticache.delete_cache_security_group myelasticachesg 'My Cache Security Group'

salt.modules.boto_elasticache.delete_subnet_group(name, region=None, key=None, keyid=None, profile=None)

Delete an ElastiCache subnet group.
CLI example:
salt myminion boto_elasticache.delete_subnet_group my-subnet-group region=us-east-1

salt.modules.boto_elasticache.describe_replication_group(name, region=None, key=None, keyid=None, profile=None, parameter=None)

Get replication group information.
CLI example:

```python
salt myminion boto_elasticache.describe_replication_group mygroup
```

```python
salt.modules.boto_elasticache.exists(name, region=None, key=None, keyid=None, profile=None)
```

Check to see if a cache cluster exists.

CLI example:

```python
salt myminion boto_elasticache.exists myelasticache
```

```python
salt.modules.boto_elasticache.get_cache_subnet_group(name, region=None, key=None, keyid=None, profile=None)
```

Get information about a cache subnet group.

CLI example:

```python
salt myminion boto_elasticache.get_cache_subnet_group mycache_subnet_group
```

```python
salt.modules.boto_elasticache.get_config(name, region=None, key=None, keyid=None, profile=None)
```

Get the configuration for a cache cluster.

CLI example:

```python
salt myminion boto_elasticache.get_config myelasticache
```

```python
salt.modules.boto_elasticache.get_group_host(name, region=None, key=None, keyid=None, profile=None)
```

Get hostname from replication cache group

CLI example:

```python
salt myminion boto_elasticache.get_group_host myelasticachegroup
```

```python
salt.modules.boto_elasticache.get_node_host(name, region=None, key=None, keyid=None, profile=None)
```

Get hostname from cache node

CLI example:

```python
salt myminion boto_elasticache.get_node_host myelasticache
```

```python
salt.modules.boto_elasticache.group_exists(name, region=None, key=None, keyid=None, profile=None)
```

Check to see if a replication group exists.

CLI example:

```python
salt myminion boto_elasticache.group_exists myelasticache
```

```python
salt.modules.boto_elasticache.revoke_cache_security_group_ingress(name, 
ec2_security_group_name, 
ec2_security_group_owner_id, 
region=None, 
key=None, 
keyid=None, 
profile=None)
```

Revoke network ingress from an ec2 security group to a cache security group.
### 31.16.22 salt.modules.boto_elb

Connection module for Amazon ELB

New in version 2014.7.0.

**configuration** This module accepts explicit elb credentials but can also utilize IAM roles assigned to the instance through Instance Profiles. Dynamic credentials are then automatically obtained from AWS API and no further configuration is necessary. More Information available at:

If IAM roles are not used you need to specify them either in a pillar or in the minion's config file:

```
elb.keyid: GKTADJGHEIQSXMKKRBJ08H
elb.key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
```

A region may also be specified in the configuration:

```
elb.region: us-east-1
```

If a region is not specified, the default is us-east-1.

It's also possible to specify key, keyid and region via a profile, either as a passed in dict, or as a string to pull from pillars or minion config:

```
myprofile:
  keyid: GKTADJGHEIQSXMKKRBJ08H
  key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
  region: us-east-1
```

**depends** boto >= 2.33.0

salt.modules.boto_elb.**apply_security_groups**(name, security_groups, region=None, key=None, keyid=None, profile=None)

Apply security groups to ELB.

CLI example:

```
salt myminion boto_elb.apply_security_groups myelb '"["mysecgroup1"]' 
```

salt.modules.boto_elb.**attach_subnets**(name, subnets, region=None, key=None, keyid=None, profile=None)

Attach ELB to subnets.

CLI example:
salt.myminion.boto_elb.attach_subnets(myelb, "["mysubnet"]")

salt.modules.boto_elb.create(name, availability_zones=None, subnets=None, security_groups=None, scheme='internet-facing', region=None, key=None, keyid=None, profile=None)

Create an ELB

CLI example to create an ELB:

salt.myminion.boto_elb.create(myelb, "["us-east-1a", "us-east-1e"]", listeners='[[443, 80, "HTTPS", "HTTP", "arn:aws:iam::1111111:server-certificate/mycert"]]", region=us-east-1)

salt.modules.boto_elb.create_listeners(name, listeners=None, region=None, key=None, keyid=None, profile=None)

Create listeners on an ELB.

CLI example:

salt.myminion.boto_elb.create_listeners(myelb, listeners=["HTTPS", "HTTP", 443, 80, "arn:aws:iam::1111111:server-certificate/mycert"], region=us-east-1)

salt.modules.boto_elb.delete(name, region=None, key=None, keyid=None, profile=None)

Delete an ELB.

CLI example to delete an ELB:

salt.myminion.boto_elb.delete(myelb, region=us-east-1)

salt.modules.boto_elb.delete_listeners(name, ports, region=None, key=None, keyid=None, profile=None)

Delete listeners on an ELB.

CLI example:

salt.myminion.boto_elb.delete_listeners(myelb, [80, 443], region=us-east-1)

salt.modules.boto_elb.deregister_instances(name, instances, region=None, key=None, keyid=None, profile=None)

Deregister instances with an ELB. Instances is either a string instance id or a list of string instance id's.

Returns:

• True: instance(s) deregistered successfully
• False: instance(s) failed to be deregistered
• None: instance(s) not valid or not registered, no action taken

CLI example:

salt.myminion.boto_elb.deregister_instances(myelb, "[instance_id, instance_id]", region=us-east-1)

salt.modules.boto_elb.detach_subnets(name, subnets, region=None, key=None, keyid=None, profile=None)

Detach ELB from subnets.

CLI example:

salt.myminion.boto_elb.detach_subnets(myelb, "["mysubnet"]")

salt.modules.boto_elb.disable_availability_zones(name, availability_zones, region=None, key=None, keyid=None, profile=None)

Disable availability zones for ELB.
salt.modules.boto_elb.enable_availability_zones(name, availability_zones, region=None, key=None, keyid=None, profile=None)
Enable availability zones for ELB.
CLI example:
   salt myminion boto_elb.enable_availability_zones myelb ['"us-east-1a"']

salt.modules.boto_elb.exists(name, region=None, key=None, keyid=None, profile=None)
Check to see if an ELB exists.
CLI example:
   salt myminion boto_elb.exists myelb region=us-east-1

salt.modules.boto_elb.get_attributes(name, region=None, key=None, keyid=None, profile=None)
Check to see if attributes are set on an ELB.
CLI example:
   salt myminion boto_elb.get_attributes myelb

salt.modules.boto_elb.get_elb_config(name, region=None, key=None, keyid=None, profile=None)
Check to see if an ELB exists.
CLI example:
   salt myminion boto_elb.exists myelb region=us-east-1

salt.modules.boto_elb.get_health_check(name, region=None, key=None, keyid=None, profile=None)
Get the health check configured for this ELB.
CLI example:
   salt myminion boto_elb.get_health_check myelb

salt.modules.boto_elb.get_instance_health(name, region=None, key=None, keyid=None, profile=None, instances=None)
Get a list of instances and their health state
CLI example:
   salt myminion boto_elb.get_instance_health myelb
   salt myminion boto_elb.get_instance_health myelb region=us-east-1 instances="[instance_id,instance_id]"

salt.modules.boto_elb.register_instances(name, instances, region=None, key=None, keyid=None, profile=None)
Register instances with an ELB. Instances is either a string instance id or a list of string instance id's.
Returns:
   True: instance(s) registered successfully
   False: instance(s) failed to be registered
CLI example:
salt.myminion boto_elb.register_instances myelb instance_id
salt.myminion boto_elb.register_instances myelb "[instance_id,instance_id]"

salt.modules.boto_elb.set_attributes(name, attributes, region=None, key=None, keyid=None, profile=None)

Set attributes on an ELB.
CLI example to set attributes on an ELB:

salt.myminion boto_elb.set_attributes myelb '{"access_log": {"enabled": "true", "s3_bucket_name": "mylogs"}}'

salt.modules.boto_elb.set_health_check(name, health_check, region=None, key=None, keyid=None, profile=None)

Set attributes on an ELB.
CLI example to set attributes on an ELB:

salt.myminion boto_elb.set_health_check myelb '{"target": "HTTP:80/"}''

31.16.23 salt.modules.boto_iam

Connection module for Amazon IAM

New in version 2014.7.0.

classification This module accepts explicit iam credentials but can also utilize IAM roles assigned to
the instance through Instance Profiles. Dynamic credentials are then automatically obtained from
AWS API and no further configuration is necessary. More Information available at:

If IAM roles are not used you need to specify them either in a pillar or in the minion's config file:

iam.keyid: GKTADJGHEIQSXMKKRBJ08H
iam.key: askdjghsdfjkgHwupUjasdflkdfklgjjsdfjakjghs
iam.region: us-east-1

It's also possible to specify key, keyid and region via a profile, either as a passed in dict, or as a
string to pull from pillars or minion config:

myprofile:
  keyid: GKTADJGHEIQSXMKKRBJ08H
  key: askdjghsdfjkgHwupUjasdflkdfklgjjsdfjakjghs
  region: us-east-1

depends boto

salt.modules.boto_iam.add_user_to_group(user_name, group_name, region=None, key=None, keyid=None, profile=None)

Add user to group.
New in version 2015.8.0.
CLI Example:
salt.myminion boto_iam.add_user_to_group myuser mygroup

salt.modules.boto_iam.associate_profile_to_role(profile_name, role_name, region=None, key=None, keyid=None, profile=None)

Associate an instance profile with an IAM role.
Salt Documentation, Release 2015.8.0

CLI Example:

```python
salt myminion boto_iams.associate_profile_to_role myirole myiprofile
```

`salt.modules.boto_iams.build_policy(region=None, key=None, keyid=None, profile=None)`
Build a default assume role policy.
New in version 2015.8.0.
CLI Example:

```python
salt myminion boto_iams.build_policy
```

`salt.modules.boto_iams.create_access_key(user_name, region=None, key=None, keyid=None, profile=None)`
Create access key id for a user.
New in version 2015.8.0.
CLI Example:

```python
salt myminion boto_iams.create_access_key myuser
```

`salt.modules.boto_iams.create_group(group_name, path=None, region=None, key=None, keyid=None, profile=None)`
Create a group.
New in version 2015.8.0.
CLI Example:

```python
salt myminion boto_iams.create_group group
```

`salt.modules.boto_iams.create_instance_profile(name, region=None, key=None, keyid=None, profile=None)`
Create an instance profile.
CLI Example:

```python
salt myminion boto_iams.create_instance_profile myiprofile
```

`salt.modules.boto_iams.create_login_profile(user_name, password, region=None, key=None, keyid=None, profile=None)`
Creates a login profile for the specified user, give the user the ability to access AWS services and the AWS Management Console.
New in version 2015.8.0.
CLI Example:

```python
salt myminion boto_iams.create_login_profile user_name password
```

`salt.modules.boto_iams.create_role(name, policy_document=None, path=None, region=None, key=None, keyid=None, profile=None)`
Create an instance role.
CLI Example:

```python
salt myminion boto_iams.create_role myrole
```

`salt.modules.boto_iams.create_role_policy(role_name, policy_name, policy, region=None, key=None, keyid=None, profile=None)`
Create or modify a role policy.
CLI Example:
```
salt myminion boto_iam.create_role_policy myrole mypolicy
```}

```
salt.modules.boto_iam.create_user(
    user_name,
    path=None,
    region=None,
    key=None,
    keyid=None,
    profile=None)
```
Create a user.
New in version 2015.8.0.
CLI Example:
```
salt myminion boto_iam.create_user myuser
```

```
salt.modules.boto_iam.delete_access_key(
    access_key_id,
    user_name=None,
    region=None,
    key=None,
    keyid=None,
    profile=None)
```
Delete access key id from a user.
New in version 2015.8.0.
CLI Example:
```
salt myminion boto_iam.delete_access_key myuser
```

```
salt.modules.boto_iam.delete_group_policy(
    group_name,
    policy_name,
    region=None,
    key=None,
    keyid=None,
    profile=None)
```
Delete a group policy.
CLI Example:
```
.. code-block:: bash
    salt myminion boto_iam.delete_group_policy mygroup mypolicy
```

```
salt.modules.boto_iam.delete_instance_profile(
    name,
    region=None,
    key=None,
    keyid=None,
    profile=None)
```
Delete an instance profile.
CLI Example:
```
salt myminion boto_iam.delete_instance_profile myiprofile
```

```
salt.modules.boto_iam.delete_role(
    name,
    region=None,
    key=None,
    keyid=None,
    profile=None)
```
Delete an IAM role.
CLI Example:
```
salt myminion boto_iam.delete_role myirole
```

```
salt.modules.boto_iam.delete_role_policy(
    role_name,
    policy_name,
    region=None,
    key=None,
    keyid=None,
    profile=None)
```
Delete a role policy.
CLI Example:
```
salt myminion boto_iam.delete_role_policy myirole mypolicy
```

```
salt.modules.boto_iam.delete_server_cert(
    cert_name,
    region=None,
    key=None,
    keyid=None,
    profile=None)
```
Deletes a certificate from Amazon.
New in version 2015.8.0.

31.16. Full list of builtin execution modules
**CLI Example:**
```
salt myminion boto_iam.delete_server_cert mycert_name
```

salt.modules.boto_iam.delete_user(user_name, region=None, key=None, keyid=None, profile=None)
Delete a user.
New in version 2015.8.0.
**CLI Example:**
```
salt myminion boto_iam.delete_user myuser
```

salt.modules.boto_iam.delete_user_policy(user_name, policy_name, region=None, key=None, keyid=None, profile=None)
Delete a user policy.
**CLI Example:**
```
salt myminion boto_iam.delete_user_policy myuser mypolicy
```

salt.modules.boto_iam.describe_role(name, region=None, key=None, keyid=None, profile=None)
Get information for a role.
**CLI Example:**
```
salt myminion boto_iam.describe_role myirole
```

salt.modules.boto_iam.disassociate_profile_from_role(profile_name, role_name, region=None, key=None, keyid=None, profile=None)
Disassociate an instance profile from an IAM role.
**CLI Example:**
```
salt myminion boto_iam.disassociate_profile_from_role myirole myiprofile
```

salt.modules.boto_iam.get_account_id(region=None, key=None, keyid=None, profile=None)
Get the AWS account id associated with the used credentials.
**CLI Example:**
```
salt myminion boto_iam.get_account_id
```

salt.modules.boto_iam.get_account_policy(region=None, key=None, keyid=None, profile=None)
Get account policy for the AWS account.
New in version 2015.8.0.
**CLI Example:**
```
salt myminion boto_iam.get_account_policy
```

salt.modules.boto_iam.get_all_access_keys(user_name, marker=None, max_items=None, region=None, key=None, keyid=None, profile=None)
Get all access keys from a user.
New in version 2015.8.0.
CLI Example:
```bash
salt myminion boto_iam.get_all_access_keys myuser
```

`salt.modules.boto_iam.get_all_group_policies(group_name, region=None, key=None, keyid=None, profile=None)`
Get a list of policy names from a group.

CLI Example:
```bash
salt myminion boto_iam.get_all_group_policies mygroup
```

`salt.modules.boto_iam.get_all_user_policies(user_name, marker=None, max_items=None, region=None, key=None, keyid=None, profile=None)`
Get all user policies.
New in version 2015.8.0.

CLI Example:
```bash
salt myminion boto_iam.get_group mygroup
```

`salt.modules.boto_iam.get_group(group_name, marker=None, max_items=None, region=None, key=None, keyid=None, profile=None)`
Get group information.
New in version 2015.8.0.

CLI Example:
```bash
salt myminion boto_iam.get_group mygroup
```

`salt.modules.boto_iam.get_group_policy(group_name, policy_name, region=None, key=None, keyid=None, profile=None)`
Retrieves the specified policy document for the specified group.
New in version 2015.8.0.

CLI Example:
```bash
salt myminion boto_iam.get_group_policy mygroup policymapname
```

`salt.modules.boto_iam.get_role_policy(role_name, policy_name, region=None, key=None, keyid=None, profile=None)`
Get a role policy.

CLI Example:
```bash
salt myminion boto_iam.get_role_policy myirole mypolicy
```

`salt.modules.boto_iam.get_server_certificate(cert_name, region=None, key=None, keyid=None, profile=None)`
Returns certificate information from Amazon
New in version 2015.8.0.

CLI Example:
```bash
salt myminion boto_iam.get_server_certificate mycert_name
```

`salt.modules.boto_iam.get_user(user_name=None, region=None, key=None, keyid=None, profile=None)`
Get user information.

31.16. Full list of builtin execution modules
New in version 2015.8.0.

CLI Example:

```shell
salt myminion boto_iam.get_user myuser
```

salt.modules.boto_iam.get_user_policy

```python
(user_name, policy_name, region=None, key=None,
 keyid=None, profile=None)
```

Retrieves the specified policy document for the specified user.

New in version 2015.8.0.

CLI Example:

```shell
salt myminion boto_iam.get_user_policy myuser mypolicynname
```

salt.modules.boto_iam.instance_profile_exists

```python
(name, region=None, key=None,
 keyid=None, profile=None)
```

Check to see if an instance profile exists.

CLI Example:

```shell
salt myminion boto_iam.instance_profile_exists myiprofile
```

salt.modules.boto_iam.list_role_policies

```python
(role_name, region=None, key=None,
 keyid=None, profile=None)
```

Get a list of policy names from a role.

CLI Example:

```shell
salt myminion boto_iam.list_role_policies myirole
```

salt.modules.boto_iam.profile_associated

```python
(role_name, profile_name, region, key, keyid, pro-
 file)
```

Check to see if an instance profile is associated with an IAM role.

CLI Example:

```shell
salt myminion boto_iam.profile_associated myirole myiprofile
```

salt.modules.boto_iam.put_group_policy

```python
(group_name, policy_name, policy_json, region=None,
 key=None, keyid=None, profile=None)
```

Adds or updates the specified policy document for the specified group.

New in version 2015.8.0.

CLI Example:

```shell
salt myminion boto_iam.put_group_policy mygroup policymcname policyrules
```

salt.modules.boto_iam.put_user_policy

```python
(user_name, policy_name, policy_json, region=None,
 key=None, keyid=None, profile=None)
```

Adds or updates the specified policy document for the specified user.

New in version 2015.8.0.

CLI Example:

```shell
salt myminion boto_iam.put_user_policy myuser policymcname policyrules
```

salt.modules.boto_iam.remove_user_from_group

```python
(group_name, user_name, region=None,
 key=None, keyid=None, profile=None)
```

Remove user from group.
New in version 2015.8.0.

CLI Example:

```
salt myminion boto_iam.remove_user_from_group mygroup myuser
```

```
salt.modules.boto_iam.role_exists(name, region=None, key=None, keyid=None, profile=None)
Check to see if an IAM role exists.
```

CLI Example:

```
salt myminion boto_iam.role_exists myirole
```

```
salt.modules.boto_iam.update_account_password_policy(allow_users_to_change_password=None,
hard_expiry=None,
max_password_age=None, minimum_password_length=None,
password_reuse_prevention=None,
require_lowercase_characters=None,
require_numbers=None,
require_symbols=None, require_uppercase_characters=None,
region=None, key=None, keyid=None, profile=None)
Update the password policy for the AWS account.
New in version 2015.8.0.
```

CLI Example:

```
salt myminion boto_iam.update_account_password_policy True
```

```
salt.modules.boto_iam.update_assume_role_policy(role_name, policy_document, region=None, key=None, keyid=None, profile=None)
Update an assume role policy for a role.
New in version 2015.8.0.
```

CLI Example:

```
salt myminion boto_iam.update_assume_role_policy myrole '{"Statement":...}"
```

```
salt.modules.boto_iam.upload_server_cert(cert_name, cert_body, private_key, cert_chain=None, path=None, region=None, key=None, keyid=None, profile=None)
Upload a certificate to Amazon.
New in version 2015.8.0.
```

CLI Example:

```
salt myminion boto_iam.upload_server_cert mycert_name crt priv_key
```

Parameters

- **cert_name** -- The name for the server certificate. Do not include the path in this value.
- **cert_body** -- The contents of the public key certificate in PEM-encoded format.
- **private_key** -- The contents of the private key in PEM-encoded format.
- **cert_chain** -- The contents of the certificate chain. This is typically a concatenation of the PEM-encoded public key certificates of the chain.
- **path** -- The path for the server certificate.
- **region** -- The name of the region to connect to.
- **key** -- The key to be used in order to connect
- **keyid** -- The keyid to be used in order to connect
- **profile** -- The profile that contains a dict of region, key, keyid

**Returns** True / False

```python
salt.modules.boto_iam.user_exists_in_group(user_name, group_name, region=None, key=None, keyid=None, profile=None)
```

Check if user exists in group.

New in version 2015.8.0.

CLI Example:
```
salt myminion boto_iam.user_exists_in_group myuser mygroup
```

### 31.16.24 salt.modules.boto_kms

Connection module for Amazon KMS

New in version 2015.8.0.

**configuration** This module accepts explicit kms credentials but can also utilize IAM roles assigned to the instance through Instance Profiles. Dynamic credentials are then automatically obtained from AWS API and no further configuration is necessary. More Information available at:

If IAM roles are not used you need to specify them either in a pillar or in the minion's config file:

```python
kms.keyid: GKTADJGHEIQSXMKKRBJ08H
kms.key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
```

A region may also be specified in the configuration:

```python
kms.region: us-east-1
```

If a region is not specified, the default is us-east-1.

It's also possible to specify key, keyid and region via a profile, either as a passed in dict, or as a string to pull from pillars or minion config:

```python
myprofile: keyid: GKTADJGHEIQXSXMKKRBJ08H key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs region: us-east-1
```

**depends** boto

```python
salt.modules.boto_kms.create_alias(alias_name, target_key_id, region=None, key=None, keyid=None, profile=None)
```

Create a display name for a key.

CLI example:
```
salt myminion boto_kms.create_alias 'alias/mykey' key_id
```

```
salt.modules.boto_kms.create_grant(key_id, grantee_principal, retiring_principal=None, operations=None, constraints=None, grant_tokens=None, region=None, key=None, keyid=None, profile=None)
```

Adds a grant to a key to specify who can access the key and under what conditions.

CLI example:
```
salt myminion boto_kms.create_grant 'alias/mykey' 'arn:aws:iam::111111111111:role/myrole' operations=['Encrypt','Decrypt']
```

```
salt.modules.boto_kms.create_key(policy=None, description=None, key_usage=None, region=None, key=None, keyid=None, profile=None)
```

Creates a master key.

CLI example:
```
salt myminion boto_kms.create_key '{"Statement":...}' "My master key"
```

```
salt.modules.boto_kms.decrypt(ciphertext_blob, encryption_context=None, grant_tokens=None, region=None, key=None, keyid=None, profile=None)
```

Decrypt ciphertext.

CLI example:
```
salt myminion boto_kms.decrypt encrypted_ciphertext
```

```
salt.modules.boto_kms.describe_key(key_id, region=None, key=None, keyid=None, profile=None)
```

Get detailed information about a key.

CLI example:
```
salt myminion boto_kms.describe_key 'alias/mykey'
```

```
salt.modules.boto_kms.disable_key(key_id, region=None, key=None, keyid=None, profile=None)
```

Mark key as disabled.

CLI example:
```
salt myminion boto_kms.disable_key 'alias/mykey'
```

```
salt.modules.boto_kms.disable_key_rotation(key_id, region=None, key=None, keyid=None, profile=None)
```

Disable key rotation for specified key.

CLI example:
```
salt myminion boto_kms.disable_key_rotation 'alias/mykey'
```

```
salt.modules.boto_kms.enable_key(key_id, region=None, key=None, keyid=None, profile=None)
```

Mark key as enabled.

CLI example:
```
salt myminion boto_kms.enable_key 'alias/mykey'
```

```
salt.modules.boto_kms.enable_key_rotation(key_id, region=None, key=None, keyid=None, profile=None)
```

Disable key rotation for specified key.

CLI example:
salt.myminion.boto_kms.enable_key_rotation('alias/mykey')

salt.modules.boto_kms.encrypt(key_id, plaintext, encryption_context=None, grant_tokens=None, region=None, key=None, keyid=None, profile=None)

Encrypt plaintext into cipher text using specified key.

CLI example:

```bash
salt myminion boto_kms.encrypt 'alias/mykey' 'myplaindata' '{"aws:username":"myuser"}'
```

salt.modules.boto_kms.generate_data_key(key_id, encryption_context=None, number_of_bytes=None, key_spec=None, grant_tokens=None, region=None, key=None, keyid=None, profile=None)

Generate a secure data key.

CLI example:

```bash
salt myminion boto_kms.generate_data_key 'alias/mykey' number_of_bytes=1024 key_spec=AES_128
```

salt.modules.boto_kms.generate_data_key_without_plaintext(key_id, encryption_context=None, number_of_bytes=None, key_spec=None, grant_tokens=None, region=None, key=None, keyid=None, profile=None)

Generate a secure data key without a plaintext copy of the key.

CLI example:

```bash
salt myminion boto_kms.generate_data_key_without_plaintext 'alias/mykey' number_of_bytes=1024 key_spec=AES_128
```

salt.modules.boto_kms.generate_random(number_of_bytes=None, region=None, key=None, keyid=None, profile=None)

Generate a random string.

CLI example:

```bash
salt myminion boto_kms.generate_random number_of_bytes=1024
```

salt.modules.boto_kms.get_key_policy(key_id, policy_name, region=None, key=None, keyid=None, profile=None)

Get the policy for the specified key.

CLI example:

```bash
salt myminion boto_kms.get_key_policy 'alias/mykey' mypolicy
```

salt.modules.boto_kms.get_key_rotation_status(key_id, region=None, key=None, keyid=None, profile=None)

Get status of whether or not key rotation is enabled for a key.

CLI example:

```bash
salt myminion boto_kms.get_key_rotation_status 'alias/mykey'
```

salt.modules.boto_kms.key_exists(key_id, region=None, key=None, keyid=None, profile=None)

Check for the existence of a key.
CLI example:
```
salt myminion boto_kms.key_exists 'alias/mykey'
```

```python
salt.modules.boto_kms.list_grants(key_id, limit=None, marker=None, region=None, key=None, keyid=None, profile=None)
```
List grants for the specified key.

CLI example:
```
salt myminion boto_kms.list_grants 'alias/mykey'
```

```python
salt.modules.boto_kms.list_key_policies(key_id, limit=None, marker=None, region=None, key=None, keyid=None, profile=None)
```
List key policies for the specified key.

CLI example:
```
salt myminion boto_kms.list_key_policies 'alias/mykey'
```

```python
salt.modules.boto_kms.put_key_policy(key_id, policy_name, policy, region=None, key=None, keyid=None, profile=None)
```
Attach a key policy to the specified key.

CLI example:
```
salt myminion boto_kms.put_key_policy 'alias/mykey' default '{"Statement":...}'
```

```python
salt.modules.boto_kms.re_encrypt(ciphertext_blob, destination_key_id, source_encryption_context=None, destination_encryption_context=None, grant_tokens=None, region=None, key=None, keyid=None, profile=None)
```
Reencrypt encrypted data with a new master key.

CLI example:
```
salt myminion boto_kms.re_encrypt 'encrypted_data' 'alias/mynewkey' default '{"Statement":...}'
```

```python
salt.modules.boto_kms.revoke_grant(key_id, grant_id, region=None, key=None, keyid=None, profile=None)
```
Revoke a grant from a key.

CLI example:
```
salt myminion boto_kms.revoke_grant 'alias/mykey' 8u89hf-j09j...
```

```python
salt.modules.boto_kms.update_key_description(key_id, description, region=None, key=None, keyid=None, profile=None)
```
Update a key's description.

CLI example:
```
salt myminion boto_kms.update_key_description 'alias/mykey' 'My key'
```

### 31.16.25 salt.modules.boto_rds

Connection module for Amazon RDS

New in version 2015.8.0.
**configuration** This module accepts explicit rds credentials but can also utilize IAM roles assigned to the instance through Instance Profiles. Dynamic credentials are then automatically obtained from AWS API and no further configuration is necessary. More Information available at:

If IAM roles are not used you need to specify them either in a pillar or in the minion's config file:

```python
rds.keyid: GKTADJGHEIQSXMKKRBJ08H
rds.key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
```

A region may also be specified in the configuration:

```python
rds.region: us-east-1
```

If a region is not specified, the default is us-east-1.

It's also possible to specify key, keyid and region via a profile, either as a passed in dict, or as a string to pull from pillars or minion config:

```python
myprofile:
    keyid: GKTADJGHEIQSXMKKRBJ08H
    key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
    region: us-east-1
```

**depends** boto

salt.modules.boto_rds.create(name, allocated_storage, storage_type, db_instance_class, engine, master_username, master_user_password, db_name=None, db_security_groups=None, vpc_security_group_ids=None, availability_zone=None, db_subnet_group_name=None, preferred_maintenance_window=None, db_parameter_group_name=None, backup_retention_period=None, preferred_backup_window=None, port=None, multi_az=None, engine_version=None, auto_minor_version_upgrade=None, license_model=None, iops=None, option_group_name=None, character_set_name=None, publicly_accessible=None, wait_status=None, tags=None, region=None, key=None, keyid=None, profile=None)

Create an RDS

CLI example to create an RDS:

```bash
salt myminion boto_rds.create myrds 10 db.t2.micro MySQL sqlusr sqlpass
```

salt.modules.boto_rds.create_option_group(name, engine_name, major_engine_version, option_group_description, tags=None, region=None, key=None, keyid=None, profile=None)

Create an RDS option group

CLI example to create an RDS option group:

```bash
salt myminion boto_rds.create_option_group my-opt-group mysql 5.6
```

salt.modules.boto_rds.create_parameter_group(name, db_parameter_group_family, description, tags=None, region=None, key=None, keyid=None, profile=None)

Create an RDS parameter group

CLI example to create an RDS parameter group:
salt.myminion boto_rds.create_parameter_group my-param-group mysql5.6

salt.modules.boto_rds.create_read_replica(name, source_name, db_instance_class=None, availability_zone=None, port=None, auto_minor_version_upgrade=None, iops=None, option_group_name=None, publicly_accessible=None, tags=None, region=None, key=None, keyid=None, profile=None)

Create an RDS read replica

CLI example to create an RDS read replica:

```
salt myminion boto_rds.create_read_replica replicaname source_name
```

salt.modules.boto_rds.create_subnet_group(name, description, subnet_ids, tags=None, region=None, key=None, keyid=None, profile=None)

Create an RDS subnet group

CLI example to create an RDS subnet group:

```
salt myminion boto_rds.create_subnet_group my-subnet-group "group description" '[subnet-12345678, subnet-87654321]' region=us-east-1
```

salt.modules.boto_rds.delete(name, skip_final_snapshot=None, final_db_snapshot_identifier=None, region=None, key=None, keyid=None, profile=None)

Delete an RDS instance.

CLI example:

```
salt myminion boto_rds.delete myrds skip_final_snapshot=True region=us-east-1
```

salt.modules.boto_rds.delete_option_group(name, region=None, key=None, keyid=None, profile=None)

Delete an RDS option group.

CLI example:

```
salt myminion boto_rds.delete_option_group my-opt-group region=us-east-1
```

salt.modules.boto_rds.delete_parameter_group(name, region=None, key=None, keyid=None, profile=None)

Delete an RDS parameter group.

CLI example:

```
salt myminion boto_rds.delete_parameter_group my-param-group region=us-east-1
```

salt.modules.boto_rds.delete_subnet_group(name, region=None, key=None, keyid=None, profile=None)

Delete an RDS subnet group.

CLI example:

```
salt myminion boto_rds.delete_subnet_group my-subnet-group region=us-east-1
```

salt.modules.boto_rds.describe(name, tags=None, region=None, key=None, keyid=None, profile=None)

Return RDS instance details.

CLI example:
salt myminion boto_rds.describe myrds

salt.modules.boto_rds.exists(name, tags=None, region=None, key=None, keyid=None, profile=None)
Check to see if an RDS exists.
CLI example:
    salt myminion boto_rds.exists myrds region=us-east-1

salt.modules.boto_rds.get_endpoint(name, tags=None, region=None, key=None, keyid=None, profile=None)
Return the endpoint of an RDS instance.
CLI example:
    salt myminion boto_rds.get_endpoint myrds

salt.modules.boto_rds.option_group_exists(name, tags=None, region=None, key=None, keyid=None, profile=None)
Check to see if an RDS option group exists.
CLI example:
    salt myminion boto_rds.option_group_exists myoptiongr region=us-east-1

salt.modules.boto_rds.parameter_group_exists(name, tags=None, region=None, key=None, keyid=None, profile=None)
Check to see if an RDS parameter group exists.
CLI example:
    salt myminion boto_rds.parameter_group_exists myparametergroup region=us-east-1

salt.modules.boto_rds.subnet_group_exists(name, tags=None, region=None, key=None, keyid=None, profile=None)
Check to see if an RDS subnet group exists.
CLI example:
    salt myminion boto_rds.subnet_group_exists my-param-group region=us-east-1

salt.modules.boto_rds.update_parameter_group(name, parameters, apply_method='pending-reboot', tags=None, region=None, key=None, keyid=None, profile=None)
Update an RDS parameter group.
CLI example:
    salt myminion boto_rds.update_parameter_group my-param-group parameters='{"back_'

31.16.26 salt.modules.boto_route53

Connection module for Amazon Route53

New in version 2014.7.0.

configuration This module accepts explicit route53 credentials but can also utilize IAM roles assigned to the instance through Instance Profiles. Dynamic credentials are then automatically obtained from AWS API and no further configuration is necessary. More Information available at:
If IAM roles are not used you need to specify them either in a pillar or in the minion's config file:

```python
route53.keyid: GKTADJGHEIQSXMKKRBJ08H
route53.key: askdjghsdfjkgWupUjasdflkdfklgjsdfjajkghs
```

A region may also be specified in the configuration:

```python
route53.region: us-east-1
```

If a region is not specified, the default is us-east-1.

It's also possible to specify key, keyid and region via a profile, either as a passed in dict, or as a string to pull from pillars or minion config:

```python
myprofile:
    keyid: GKTADJGHEIQSXMKKRBJ08H
    key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
    region: us-east-1
```

depends boto

`salt.modules.boto_route53.add_record(name, value, zone, record_type, identifier=None, ttl=None, region=None, key=None, keyid=None, profile=None, wait_for_sync=True, split_dns=False, private_zone=False)`

Add a record to a zone.

CLI example:

```
salt myminion boto_route53.add_record test.example.org 1.1.1.1 example.org A
```

`salt.modules.boto_route53.create_zone(zone, private=False, vpc_id=None, vpc_region=None, region=None, key=None, keyid=None, profile=None)`

Create a Route53 hosted zone.

New in version 2015.8.0.

CLI Example:

```
salt myminion boto_route53.create_zone example.org
```

`salt.modules.boto_route53.delete_record(name, zone, record_type, identifier=None, all_records=False, region=None, key=None, keyid=None, profile=None, wait_for_sync=True, split_dns=False, private_zone=False)`

Modify a record in a zone.

CLI example:

```
salt myminion boto_route53.delete_record test.example.org example.org A
```

`salt.modules.boto_route53.delete_zone(zone, region=None, key=None, keyid=None, profile=None)`

Delete a Route53 hosted zone.

New in version 2015.8.0.

CLI Example:
salt.myminion boto_route53.delete_zone example.org

salt.modules.boto_route53.get_record(name, zone, record_type, fetch_all=False, region=None, key=None, keyid=None, profile=None, split_dns=False, private_zone=False)

Get a record from a zone.
CLI example:

    salt myminion boto_route53.get_record test.example.org example.org A

salt.modules.boto_route53.update_record(name, value, zone, record_type, identifier=None, ttl=None, region=None, key=None, keyid=None, profile=None, wait_for_sync=True, split_dns=False, private_zone=False)

Modify a record in a zone.
CLI example:

    salt myminion boto_route53.modify_record test.example.org 1.1.1.1 example.org A

salt.modules.boto_route53.zone_exists(zone, region=None, key=None, keyid=None, profile=None)

Check for the existence of a Route53 hosted zone.
New in version 2015.8.0.
CLI Example:

    salt myminion boto_route53.zone_exists example.org

31.16.27 salt.modules.boto_secgroup

Connection module for Amazon Security Groups
New in version 2014.7.0.

configuration This module accepts explicit ec2 credentials but can also utilize IAM roles assigned to the instance through instance Profiles. Dynamic credentials are then automatically obtained from AWS API and no further configuration is necessary. More Information available at:

If IAM roles are not used you need to specify them either in a pillar or in the minion's config file:

    segroup.keyid: GKTADJGHEIQSXMKKRBJ08H
    segroup.key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs

A region may also be specified in the configuration:

    segroup.region: us-east-1

If a region is not specified, the default is us-east-1.
It's also possible to specify key, keyid and region via a profile, either as a passed in dict, or as a string to pull from pillars or minion config:
myprofile:
  keyid: GKTADJGHEIQSXMKKRBJ08H
  key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
  region: us-east-1

depends boto

salt.modules.boto_secgroup.authorize(name=None, source_group_name=None, source_group_owner_id=None, ip_protocol=None, from_port=None, to_port=None, cidr_ip=None, group_id=None, source_group_group_id=None, region=None, key=None, keyid=None, profile=None, vpc_id=None, egress=False)

Add a new rule to an existing security group.

CLI example:
```
salt myminion boto_secgroup.authorize mysecgroup ip_protocol=tcp from_port=80 to_port=80 cidr_ip=\['10.0.0.0/8', '192.168.0.0/24'\]
```

salt.modules.boto_secgroup.convert_to_group_ids(groups, vpc_id, region=None, key=None, keyid=None, profile=None)

Given a list of security groups and a vpc_id, convert_to_group_ids will convert all list items in the given list to security group ids.

CLI example:
```
salt myminion boto_secgroup.convert_to_group_ids mysecgroup vpc-89yhh7h
```

salt.modules.boto_secgroup.create(name, description, vpc_id=None, region=None, key=None, keyid=None, profile=None)

Create a security group.

CLI example:
```
salt myminion boto_secgroup.create mysecgroup 'My Security Group'
```

salt.modules.boto_secgroup.delete(name=None, group_id=None, region=None, key=None, keyid=None, profile=None, vpc_id=None)

Delete a security group.

CLI example:
```
salt myminion boto_secgroup.delete mysecgroup
```

salt.modules.boto_secgroup.exists(name=None, region=None, key=None, keyid=None, profile=None, vpc_id=None, group_id=None)

Check to see if an security group exists.

CLI example:
```
salt myminion boto_secgroup.exists mysecgroup
```

salt.modules.boto_secgroup.get_config(name=None, group_id=None, region=None, key=None, keyid=None, profile=None, vpc_id=None)

Get the configuration for a security group.

CLI example:
```
salt myminion boto_secgroup.get_config mysecgroup
```

31.16. Full list of builtin execution modules
salt.modules.boto_secgroup.get_group_id(name, vpc_id=None, region=None, key=None, keyid=None, profile=None)

Get a Group ID given a Group Name or Group Name and VPC ID

CLI example:
```
salt myminion boto_secgroup.get_group_id mysecgroup
```

salt.modules.boto_secgroup.revoke(name=None, source_group_name=None, source_group_owner_id=None, ip_protocol=None, from_port=None, to_port=None, cidr_ip=None, group_id=None, source_group_group_id=None, region=None, key=None, keyid=None, profile=None, vpc_id=None, egress=False)

Remove a rule from an existing security group.

CLI example:
```
salt myminion boto_secgroup.revoke mysecgroup ip_protocol=tcp from_port=80 to_port=80 cidr_ip='10.0.0.0/8'
```

### 31.16.28 salt.modules.boto_sns

Connection module for Amazon SNS

**configuration** This module accepts explicit sns credentials but can also utilize IAM roles assigned to the instance through Instance Profiles. Dynamic credentials are then automatically obtained from AWS API and no further configuration is necessary. More Information available at:

If IAM roles are not used you need to specify them either in a pillar or in the minion’s config file:

```
sns.keyid: GKTADJGHEIQSXMKKRBJ08H
sns.key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
```

A region may also be specified in the configuration:

```
sns.region: us-east-1
```

If a region is not specified, the default is us-east-1.

It's also possible to specify key, keyid and region via a profile, either as a passed in dict, or as a string to pull from pillars or minion config:

```
myprofile:
  keyid: GKTADJGHEIQSXMKKRBJ08H
  key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
  region: us-east-1
```

**depends** boto

salt.modules.boto_sns.create(name, region=None, key=None, keyid=None, profile=None)

Create an SNS topic.

CLI example to create a topic:
```
salt myminion boto_sns.create mytopic region=us-east-1
```
**salt.modules.boto_sns.delete** *(name, region=None, key=None, keyid=None, profile=None)*

Delete an SNS topic.

CLI example to delete a topic:

```bash
salt myminion boto_sns.delete mytopic region=us-east-1
```

**salt.modules.boto_sns.exists** *(name, region=None, key=None, keyid=None, profile=None)*

Check to see if an SNS topic exists.

CLI example:

```bash
salt myminion boto_sns.exists mytopic region=us-east-1
```

**salt.modules.boto_sns.get_all_subscriptions_by_topic** *(name, region=None, key=None, keyid=None, profile=None)*

Get list of all subscriptions to a specific topic.

CLI example to delete a topic:

```bash
salt myminion boto_sns.get_all_subscriptions_by_topic mytopic region=us-east-1
```

**salt.modules.boto_sns.get_all_topics** *(region=None, key=None, keyid=None, profile=None)*

Returns a list of the all topics.

CLI example:

```bash
salt myminion boto_sns.get_all_topics
```

**salt.modules.boto_sns.get_arn** *(name, region=None, key=None, keyid=None, profile=None)*

Returns the full ARN for a given topic name.

CLI example:

```bash
salt myminion boto_sns.get_arn mytopic
```

**salt.modules.boto_sns.subscribe** *(topic, protocol, endpoint, region=None, key=None, keyid=None, profile=None)*

Subscribe to a Topic.

CLI example to delete a topic:

```bash
salt myminion boto_sns.subscribe mytopic https https://www.example.com/sns-endpoint region=us-east-1
```

31.16.29 **salt.modules.boto_sqs**

Connection module for Amazon SQS

New in version 2014.7.0.

**configuration** This module accepts explicit sqs credentials but can also utilize IAM roles assigned to the instance through Instance Profiles. Dynamic credentials are then automatically obtained from AWS API and no further configuration is necessary. More Information available at:

If IAM roles are not used you need to specify them either in a pillar or in the minion's config file:

```bash
sqs.keyid: GKTADJGHEIQSXMKKRBJ08H
sqs.key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
```
A region may also be specified in the configuration:

```python
sqs.region: us-east-1
```

If a region is not specified, the default is us-east-1.

It's also possible to specify key, keyid and region via a profile, either as a passed in dict, or as a string to pull from pillars or minion config:

```python
myprofile:
  keyid: GKTADJGHEIQSXMKKRBJ08H
  key: askdjghsdfjkgHupUjasdflkdfklgjsdfjajkghs
  region: us-east-1
```

**depends** boto

```python
salt.modules.boto_sqs.create(name, region=None, key=None, keyid=None, profile=None)
```

Create an SQS queue.

CLI example to create a queue:

```bash
salt myminion boto_sqs.create myqueue region=us-east-1
```

```python
salt.modules.boto_sqs.delete(name, region=None, key=None, keyid=None, profile=None)
```

Delete an SQS queue.

CLI example to delete a queue:

```bash
salt myminion boto_sqs.delete myqueue region=us-east-1
```

```python
salt.modules.boto_sqs.exists(name, region=None, key=None, keyid=None, profile=None)
```

Check to see if a queue exists.

CLI example:

```bash
salt myminion boto_sqs.exists myqueue region=us-east-1
```

```python
salt.modules.boto_sqs.get_attributes(name, region=None, key=None, keyid=None, profile=None)
```

Check to see if attributes are set on an SQS queue.

CLI example:

```bash
salt myminion boto_sqs.get_attributes myqueue
```

```python
salt.modules.boto_sqs.set_attributes(name, attributes, region=None, key=None, keyid=None, profile=None)
```

Set attributes on an SQS queue.

CLI example to set attributes on a queue:

```bash
salt myminion boto_sqs.set_attributes myqueue '{ReceiveMessageWaitTimeSeconds: 20}' region=us-east-1
```

### 31.16.30 salt.modules.boto_vpc

Connection module for Amazon VPC

New in version 2014.7.0.
**configuration**  This module accepts explicit VPC credentials but can also utilize IAM roles assigned to the instance through Instance Profiles. Dynamic credentials are then automatically obtained from AWS API and no further configuration is necessary. More Information available at:

If IAM roles are not used you need to specify them either in a pillar or in the minion's config file:

```yaml
vpc.keyid: GKTADJGHEIQSXMKKRBJ08H
vpc.key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
```

A region may also be specified in the configuration:

```yaml
vpc.region: us-east-1
```

If a region is not specified, the default is us-east-1.

It's also possible to specify key, keyid and region via a profile, either as a passed in dict, or as a string to pull from pillars or minion config:

```yaml
myprofile:
  keyid: GKTADJGHEIQSXMKKRBJ08H
  key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
  region: us-east-1
```

Changed in version 2015.8.0: All methods now return a dictionary. Create and delete methods return:

```yaml
created: true
```

or

```yaml
created: false
error:
  message: error message
```

Request methods (e.g., `describe_vpc`) return:

```yaml
vpcs:
- {...}
- {...}
```

or

```yaml
error:
  message: error message
```

**depends** boto

```python
salt.modules.boto_vpc.associate_dhcp_options_to_vpc(dhcp_options_id, vpc_id=None, vpc_name=None, region=None, key=None, keyid=None, profile=None)
```

Given valid DHCP options id and a valid VPC id, associate the DHCP options record with the VPC.

Returns True if the DHCP options record were associated and returns False if the DHCP options record was not associated.

CLI Example:

```bash
salt myminion boto_vpc.associate_dhcp_options_to_vpc 'dhcp-a0bl34pp' 'vpc-6b1fe402'
```
salt.modules.boto_vpc.associate_network_acl_to_subnet(network_acl_id=None, subnet_id=None, network_acl_name=None, subnet_name=None, region=None, key=None, keyid=None, profile=None)

Given a network acl and subnet ids or names, associate a network acl to a subnet.

CLI Example:

```bash
salt myminion boto_vpc.associate_network_acl_to_subnet
  network_acl_id='acl-5fb85d36' subnet_id='subnet-6a1fe403'
```

```bash
salt myminion boto_vpc.associate_network_acl_to_subnet
  network_acl_id='myacl' subnet_id='mysubnet'
```

salt.modules.boto_vpc.associate_new_dhcp_options_to_vpc(vpc_id, domain_name=None, domain_name_servers=None, ntp_servers=None, netbios_name_servers=None, netbios_node_type=None, region=None, key=None, keyid=None, profile=None)

.. deprecated:: Boron
   This function has been deprecated in favor of boto_vpc.create_dhcp_options, which now takes vpc_id or vpc_name as kwargs.

   This function will be removed in the Salt Boron release.

   Given valid DHCP options and a valid VPC id, create and associate the DHCP options record with the VPC.

   CLI Example:

   ```bash
   salt myminion boto_vpc.associate_new_dhcp_options_to_vpc 'vpc-6b1fe402' domain_name='example.com'
   ```

salt.modules.boto_vpc.associate_new_network_acl_to_subnet(vpc_id, subnet_id, network_acl_name=None, tags=None, region=None, key=None, keyid=None, profile=None)

.. deprecated:: Boron
   This function has been deprecated in favor of boto_vpc.create_network_acl, which now takes subnet_id or subnet_name as kwargs.

   This function will be removed in the Salt Boron release.

   Given a vpc ID and a subnet ID, associates a new network act to a subnet.

   Returns a dictionary containing the network acl id and the new association id if successful. If unsuccessful, returns False.

   CLI Example:

   ```bash
   salt myminion boto_vpc.associate_new_network_acl_to_subnet 'vpc-6b1fe402' 'subnet-6a1fe403'
   ```

salt.modules.boto_vpc.associate_route_table(route_table_id=None, subnet_id=None, route_table_name=None, subnet_name=None, region=None, key=None, keyid=None, profile=None)
Given a route table and subnet name or id, associates the route table with the subnet.

CLI Example:

```bash
salt myminion boto_vpc.associate_route_table 'rtb-1f382e7d' 'subnet-6a1fe403'
```

```bash
salt myminion boto_vpc.associate_route_table route_table_name='myrtb' \ subnet_name='mysubnet'
```

```bash
salt.modules.boto_vpc.create(cidr_block, instance_tenancy=None, vpc_name=None, enable_dns_support=None, enable_dns_hostnames=None, tags=None, region=None, key=None, keyid=None, profile=None)
```

Given a valid CIDR block, create a VPC.

An optional instance_tenancy argument can be provided. If provided, the valid values are 'default' or 'dedicated'

An optional vpc_name argument can be provided.

Returns {created: true} if the VPC was created and returns {created: False} if the VPC was not created.

CLI Example:

```bash
salt myminion boto_vpc.create '10.0.0.0/24'
```

```bash
salt.modules.boto_vpc.create_customer_gateway(vpn_connection_type, ip_address, bgp_asn, customer_gateway_name=None, tags=None, region=None, key=None, keyid=None, profile=None)
```

Given a valid VPN connection type, a static IP address and a customer gateway’s Border Gateway Protocol (BGP) Autonomous System Number, create a customer gateway.

Returns the customer gateway id if the customer gateway was created and returns False if the customer gateway was not created.

CLI Example:

```bash
salt myminion boto_vpc.create_customer_gateway 'ipsec.1', '12.1.2.3', 65534
```

```bash
salt.modules.boto_vpc.create_dhcp_options(domain_name=None, domain_name_servers=None, ntp_servers=None, netbios_name_servers=None, netbios_node_type=None, dhcp_options_name=None, tags=None, vpc_id=None, vpc_name=None, region=None, key=None, keyid=None, profile=None)
```

Given valid DHCP options, create a DHCP options record, optionally associating it with an existing VPC.

Returns True if the DHCP options record was created and returns False if the DHCP options record was not deleted.

Changed in version 2015.8.0: Added vpc_name and vpc_id arguments

CLI Example:

```bash
salt myminion boto_vpc.create_dhcp_options domain_name='example.com' \ domain_name_servers='[1.2.3.4]' ntp_servers='[5.6.7.8]' \ netbios_name_servers='[10.0.0.1]' netbios_node_type=1 \ vpc_name='myvpc'
```
salt.modules.boto_vpc.create_internet_gateway(internet_gateway_name=None, vpc_id=None, vpc_name=None, tags=None, region=None, key=None, keyid=None, profile=None)

Create an Internet Gateway, optionally attaching it to an existing VPC.

Returns the internet gateway id if the internet gateway was created and returns False if the internet gateways was not created.

New in version 2015.8.0.

CLI Example:

```
salt myminion boto_vpc.create_internet_gateway internet_gateway_name=myigw vpc_name=myvpc
```

salt.modules.boto_vpc.create_network_acl(vpc_id=None, vpc_name=None, network_acl_name=None, subnet_id=None, subnet_name=None, tags=None, region=None, key=None, keyid=None, profile=None)

Given a vpc_id, creates a network acl.

Returns the network acl id if successful, otherwise returns False.

Changed in version 2015.8.0: Added vpc_name, subnet_id, and subnet_name arguments

CLI Example:

```
salt myminion boto_vpc.create_network_acl 'vpc-6b1fe402'
```

salt.modules.boto_vpc.create_network_acl_entry(network_acl_id=None, rule_number=None, protocol=None, rule_action=None, cidr_block=None, egress=None, network_acl_name=None, icmp_code=None, icmp_type=None, port_range_from=None, port_range_to=None, region=None, key=None, keyid=None, profile=None)

Creates a network acl entry.

CLI Example:

```
salt myminion boto_vpc.create_network_acl_entry 'acl-5fb85d36' '32767' 'all' 'deny' '0.0.0.0/0' egress=true
```

salt.modules.boto_vpc.create_route(route_table_id=None, destination_cidr_block=None, route_table_name=None, gateway_id=None, internet_gateway_name=None, instance_id=None, interface_id=None, region=None, key=None, keyid=None, profile=None)

Creates a route.

CLI Example:

```
salt myminion boto_vpc.create_route 'rtb-1f382e7d' '10.0.0.0/16' gateway_id='vgw-a1b2c3'
```

salt.modules.boto_vpc.create_route_table(vpc_id=None, vpc_name=None, route_table_name=None, tags=None, region=None, key=None, keyid=None, profile=None)

Creates a route table.
Changed in version 2015.8.0: Added vpc_name argument

CLI Examples:

```salt
salt myminion boto_vpc.create_route_table vpc_id='vpc-6b1fe402' route_table_name='myroutetable'
salt myminion boto_vpc.create_route_table vpc_name='myvpc' route_table_name='myroutetable'
```

```python
salt.modules.boto_vpc.create_subnet(vpc_id=None, cidr_block=None, vpc_name=None, availability_zone=None, subnet_name=None, tags=None, region=None, key=None, keyid=None, profile=None)
```

Given a valid VPC ID or Name and a CIDR block, create a subnet for the VPC.

An optional availability zone argument can be provided.

Returns True if the VPC subnet was created and returns False if the VPC subnet was not created.

Changed in version 2015.8.0: Added vpc_name argument

CLI Examples:

```salt
salt myminion boto_vpc.create_subnet vpc_id='vpc-6b1fe402' subnet_name='mysubnet' cidr_block='10.0.0.0/25'
salt myminion boto_vpc.create_subnet vpc_name='myvpc' subnet_name='mysubnet', cidr_block='10.0.0.0/25'
```

```python
salt.modules.boto_vpc.customer_gateway_exists(customer_gateway_id=None, customer_gateway_name=None, region=None, key=None, keyid=None, profile=None)
```

Given a customer gateway ID, check if the customer gateway ID exists.

Returns True if the customer gateway ID exists; Returns False otherwise.

CLI Example:

```salt
salt myminion boto_vpc.customer_gateway_exists cgw-b6a247df
salt myminion boto_vpc.customer_gateway_exists customer_gateway_name=mycgw
```

```python
salt.modules.boto_vpc.delete(vpc_id=None, name=None, vpc_name=None, tags=None, region=None, key=None, keyid=None, profile=None)
```

Given a VPC ID or VPC name, delete the VPC.

Returns [deleted: true] if the VPC was deleted and returns [deleted: false] if the VPC was not deleted.

CLI Example:

```salt
salt myminion boto_vpc.delete vpc_id='vpc-6b1fe402'
salt myminion boto_vpc.delete name='myvpc'
```

```python
salt.modules.boto_vpc.delete_customer_gateway(customer_gateway_id=None, customer_gateway_name=None, region=None, key=None, keyid=None, profile=None)
```

Given a customer gateway ID or name, delete the customer gateway.

Returns True if the customer gateway was deleted and returns False if the customer gateway was not deleted.

Changed in version 2015.8.0: Added customer_gateway_name argument

CLI Example:
salt myminion boto_vpc.delete_customer_gateway 'cgw-b6a247df'

salt.modules.boto_vpc.delete_dhcp_options(dhcp_options_id=None, dhcp_options_name=None, region=None, key=None, keyid=None, profile=None)

Delete dhcp options by id or name.
New in version 2015.8.0.
CLI Example:

salt myminion boto_vpc.delete_dhcp_options 'dopt-b6a247df'

salt.modules.boto_vpc.delete_internet_gateway(internet_gateway_id=None, internet_gateway_name=None, detach=False, region=None, key=None, keyid=None, profile=None)

Delete an internet gateway (by name or id).
Returns True if the internet gateway was deleted and otherwise False.
New in version 2015.8.0.
CLI Examples:

salt myminion boto_vpc.delete_internet_gateway internet_gateway_id=igw-1a2b3c
salt myminion boto_vpc.delete_internet_gateway internet_gateway_name=myigw

salt.modules.boto_vpc.delete_network_acl(network_acl_id=None, network_acl_name=None, disassociate=False, region=None, key=None, keyid=None, profile=None)

Delete a network acl based on the network_acl_id or network_acl_name provided.

CLI Examples:

salt myminion boto_vpc.delete_network_acl network_acl_id='acl-5fb85d36' \ disassociate=false
salt myminion boto_vpc.delete_network_acl network_acl_name='myacl' \ disassociate=true

salt.modules.boto_vpc.delete_network_acl_entry(network_acl_id=None, rule_number=None, egress=None, network_acl_name=None, region=None, key=None, keyid=None, profile=None)

Deletes a network acl entry.

CLI Example:

salt myminion boto_vpc.delete_network_acl_entry 'acl-5fb85d36' '32767'

salt.modules.boto_vpc.delete_route(route_table_id=None, destination_cidr_block=None, route_table_name=None, region=None, key=None, keyid=None, profile=None)

Deletes a route.

CLI Example:

salt myminion boto_vpc.delete_route 'rtb-1f382e7d' '10.0.0.0/16'
salt.modules.boto_vpc.delete_route_table(route_table_id=None, route_table_name=None, region=None, key=None, keyid=None, profile=None)

Deletes a route table.

CLI Examples:

salt myminion boto_vpc.delete_route_table route_table_id='rtb-1f382e7d'
salt myminion boto_vpc.delete_route_table route_table_name='myroutetable'

salt.modules.boto_vpc.delete_subnet(subnet_id=None, subnet_name=None, region=None, key=None, keyid=None, profile=None)

Given a subnet ID or name, delete the subnet.
Returns True if the subnet was deleted and returns False if the subnet was not deleted.
Changed in version 2015.8.0: Added subnet_name argument

CLI Example:

salt myminion boto_vpc.delete_subnet 'subnet-6a1fe403'

salt.modules.boto_vpc.describe(vpc_id=None, vpc_name=None, region=None, key=None, keyid=None, profile=None)

Given a VPC ID describe its properties.
Returns a dictionary of interesting properties.
Changed in version 2015.8.0: Added vpc_name argument

CLI Example:

salt myminion boto_vpc.describe vpc_id=vpc-123456
salt myminion boto_vpc.describe vpc_name=myvpc

salt.modules.boto_vpc.describe_route_table(route_table_id=None, route_table_name=None, tags=None, region=None, key=None, keyid=None, profile=None)

Given route table properties, return route table details if matching table(s) exist.
New in version 2015.8.0.

CLI Example:

salt myminion boto_vpc.describe_route_table route_table_id='rtb-1f382e7d'

salt.modules.boto_vpc.describe_subnet(subnet_id=None, subnet_name=None, region=None, key=None, keyid=None, profile=None)

Given a subnet id or name, describe its properties.
Returns a dictionary of interesting properties.
New in version 2015.8.0.

CLI Examples:

salt myminion boto_vpc.describe_subnet subnet_id=subnet-123456
salt myminion boto_vpc.describe_subnet subnet_name=mysubnet

salt.modules.boto_vpc.describe_subnets(subnet_ids=None, subnet_names=None, vpc_id=None, cidr=None, region=None, key=None, keyid=None, profile=None)

Given a VPC ID or subnet CIDR, returns a list of associated subnets and their details. Return all subnets if VPC ID or CIDR are not provided. If a subnet id or CIDR is provided, only its associated subnet details will be returned.
New in version 2015.8.0.

CLI Examples:

```bash
salt myminion boto_vpc.describe_subnets
```

```bash
salt myminion boto_vpc.describe_subnets subnet_ids=['subnet-ba1987ab', 'subnet-ba1987cd']
```

```bash
salt myminion boto_vpc.describe_subnets vpc_id=vpc-123456
```

```bash
salt myminion boto_vpc.describe_subnets cidr=10.0.0.0/21
```

```bash
salt.modules.boto_vpc.describe_vpcs(vpc_id=None, name=None, cidr=None, region=None, key=None, keyid=None, profile=None)
```

Describe all VPCs, matching the filter criteria if provided.

Returns a a list of dictionaries with interesting properties.

New in version 2015.8.0.

CLI Example:

```bash
salt myminion boto_vpc.describe_vpcs
```

```bash
salt.modules.boto_vpc.dhcp_options_exists(dhcp_options_id=None, name=None, dhcp_options_name=None, region=None, key=None, keyid=None, profile=None)
```

Check if a dhcp option exists.

Returns True if the dhcp option exists; Returns False otherwise.

CLI Example:

```bash
salt myminion boto_vpc.dhcp_options_exists dhcp_options_id='dhcp-a0bl34pp'
```

```bash
salt.modules.boto_vpc.disassociate_network_acl(subnet_id=None, vpc_id=None, subnet_name=None, vpc_name=None, region=None, key=None, keyid=None, profile=None)
```

Given a subnet ID, disassociates a network acl.

CLI Example:

```bash
salt myminion boto_vpc.disassociate_network_acl 'subnet-6a1fe403'
```

```bash
salt.modules.boto_vpc.disassociate_route_table(association_id, region=None, key=None, keyid=None, profile=None)
```

Disasssociates a route table.

association_id The Route Table Association ID to disassociate

CLI Example:

```bash
salt myminion boto_vpc.disassociate_route_table 'rtbassoc-d8ccddba'
```

```bash
salt.modules.boto_vpc.exists(vpc_id=None, name=None, cidr=None, tags=None, region=None, key=None, keyid=None, profile=None)
```

Given a VPC ID, check to see if the given VPC ID exists.

Returns True if the given VPC ID exists and returns False if the given VPC ID does not exist.

CLI Example:
Given VPC properties, return the VPC id if a match is found.

CLI Example:

```bash
salt myminion boto_vpc.get_id myvpc
```

Get an AWS id for a VPC resource by type and name.

New in version 2015.8.0.

CLI Example:

```bash
salt myminion boto_vpc.get_resource_id internet_gateway myigw
```

Given a subnet (aka: a vpc zone identifier) or list of subnets, returns vpc association.

Returns a VPC ID if the given subnets are associated with the same VPC ID. Returns False on an error or if the given subnets are associated with different VPC IDs.

CLI Examples:

```bash
salt myminion boto_vpc.get_subnet_association subnet-61b47516
salt myminion boto_vpc.get_subnet_association [subnet-61b47516, subnet-2cb9785b]
```

Checks if a network acl exists.

Returns True if the network acl exists or returns False if it doesn’t exist.

CLI Example:

```bash
salt myminion boto_vpc.network_acl_exists network_acl_id='acl-5fb85d36'
```

Replaces a network acl entry.

CLI Example:

```bash
salt myminion boto_vpc.replace_network_acl_entry 'acl-5fb85d36' '32767' 'all' 'deny' '0.0.0.0/0' egress=true
```
salt.modules.boto_vpc.replace_route(route_table_id=None, destination_cidr_block=None, route_table_name=None, gateway_id=None, instance_id=None, interface_id=None, region=None, key=None, keyid=None, profile=None)

Replaces a route.

CLI Example:
```
salt myminion boto_vpc.replace_route 'rtb-1f382e7d' '10.0.0.0/16' gateway_id='vgw-a1b2c3'
```

salt.modules.boto_vpc.replace_route_table_association(association_id, route_table_id, region=None, key=None, keyid=None, profile=None)

Replaces a route table association.

CLI Example:
```
salt myminion boto_vpc.replace_route_table_association 'rtbassoc-d8ccddba' 'rtb-1f382e7d'
```

salt.modules.boto_vpc.resource_exists(resource, name=None, resource_id=None, tags=None, region=None, key=None, keyid=None, profile=None)

Given a resource type and name, return {exists: true} if it exists, {exists: false} if it does not exist, or {error: {message: error text}} on error.

New in version 2015.8.0.

CLI Example:
```
salt myminion boto_vpc.resource_exists internet_gateway myigw
```

salt.modules.boto_vpc.route_exists(destination_cidr_block, route_table_name=None, route_table_id=None, gateway_id=None, instance_id=None, interface_id=None, tags=None, region=None, key=None, keyid=None, profile=None)

Checks if a route exists.

New in version 2015.8.0.

CLI Example:
```
salt myminion boto_vpc.route_exists destination_cidr_block='10.0.0.0/20' gateway_id='local' route_table_name='test'
```

salt.modules.boto_vpc.route_table_exists(route_table_id=None, name=None, route_table_name=None, tags=None, region=None, key=None, keyid=None, profile=None)

Checks if a route table exists.

CLI Example:
```
salt myminion boto_vpc.route_table_exists route_table_id='rtb-1f382e7d'
```

salt.modules.boto_vpc.subnet_exists(subnet_id=None, name=None, subnet_name=None, cidr=None, tags=None, zones=None, region=None, key=None, keyid=None, profile=None)

Check if a subnet exists.

Returns True if the subnet exists, otherwise returns False.

Changed in version 2015.8.0: Added subnet_name argument Deprecated name argument

CLI Example:
31.16.31 salt.modules.bower

Manage and query Bower packages

This module manages the installed packages using Bower. Note that npm, git and bower must be installed for this module to be available.

salt.modules.bower.install(pkg, dir, pkgs=None, runas=None, env=None)

Install a Bower package.

If no package is specified, the dependencies (from bower.json) of the package in the given directory will be installed.

- **pkg** A package name in any format accepted by Bower, including a version identifier
- **dir** The target directory in which to install the package
- **pkgs** A list of package names in the same format as the **pkg** parameter
- **runas** The user to run Bower with
- **env** Environment variables to set when invoking Bower. Uses the same **env** format as the ```cmd.run``` execution function.

CLI Example:

```bash
salt '*' bower.install underscore /path/to/project
salt '*' bower.install jquery#2.0 /path/to/project
```

salt.modules.bower.list(dir, runas=None, env=None)

List installed Bower packages.

- **dir** The directory whose packages will be listed
- **runas** The user to run Bower with
- **env** Environment variables to set when invoking Bower. Uses the same **env** format as the ```cmd.run``` execution function.

CLI Example:

```bash
salt '*' bower.list /path/to/project
```

salt.modules.bower.uninstall(pkg, dir, runas=None, env=None)

Uninstall a Bower package.

- **pkg** A package name in any format accepted by Bower
- **dir** The target directory from which to uninstall the package
- **runas** The user to run Bower with
- **env** Environment variables to set when invoking Bower. Uses the same **env** format as the ```cmd.run``` execution function.

CLI Example:

```bash
salt '*' bower.uninstall underscore /path/to/project
```
31.16.32 salt.modules.brew

Homebrew for Mac OS X

salt.modules.brew.install(name=None, pkgs=None, taps=None, options=None, **kwargs)

Install the passed package(s) with brew install

name The name of the formula to be installed. Note that this parameter is ignored if `"pkgs"` is passed.

CLI Example:

```
salt '*' pkg.install <package name>
```

taps Unofficial GitHub repos to use when updating and installing formulas.

CLI Example:

```
salt '*' pkg.install <package name> tap='<tap>'
salt '*' pkg.install zlib taps='homebrew/dupes'
salt '*' pkg.install php54 taps='["josegonzalez/php", "homebrew/dupes"]'
```

options Options to pass to brew. Only applies to initial install. Due to how brew works, modifying chosen options requires a full uninstall followed by a fresh install. Note that if `"pkgs"` is used, all options will be passed to all packages. Unrecognized options for a package will be silently ignored by brew.

CLI Example:

```
salt '*' pkg.install <package name> tap='<tap>'
salt '*' pkg.install php54 taps='["josegonzalez/php", "homebrew/dupes"]' options='["--with-fpm"]'
```

Multiple Package Installation Options:

pkgs A list of formulas to install. Must be passed as a python list.

CLI Example:

```
salt '*' pkg.install pkgs='["foo","bar"]'
```

Returns a dict containing the new package names and versions:

```
{'<package>': {'old': '<old-version>', 'new': '<new-version>'}}
```

CLI Example:

```
salt '*' pkg.install 'package package package'
```

salt.modules.brew.latest_version(*names, **kwargs)

Return the latest version of the named package available for upgrade or installation

Note that this currently not fully implemented but needs to return something to avoid a traceback when calling pkg.latest.

CLI Example:

```
salt '*' pkg.latest_version <package name>
salt '*' pkg.latest_version <package1> <package2> <package3>
```

salt.modules.brew.list_pkgs(versions_as_list=False, **kwargs)

List the packages currently installed in a dict:
{'<package_name>': '<version>'}

CLI Example:
salt '*' pkg.list_pkgs

salt.modules.brew.list_upgrades(refresh=True)
Check whether or not an upgrade is available for all packages

CLI Example:
salt '*' pkg.list_upgrades

salt.modules.brew.refresh_db()
Update the homebrew package repository.

CLI Example:
salt '*' pkg.refresh_db

salt.modules.brew.remove(name=None, pkgs=None, **kwargs)
Removes packages with brew uninstall.

name The name of the package to be deleted.

Multiple Package Options:

pkgs A list of packages to delete. Must be passed as a python list. The name parameter will be ignored if this option is passed.

New in version 0.16.0.

Returns a dict containing the changes.

CLI Example:
salt '*' pkg.remove <package name>
salt '*' pkg.remove <package1>,<package2>,<package3>
salt '*' pkg.remove pkgs='["foo", "bar"]'

salt.modules.brew.upgrade(refresh=True)
Upgrade outdated, unpinned brews.

refresh Fetch the newest version of Homebrew and all formulae from GitHub before installing.

Return a dict containing the new package names and versions:

{'<package>': {'old': '<old-version>',
              'new': '<new-version>'}}

CLI Example:
salt '*' pkg.upgrade

salt.modules.brew.upgrade_available(pkg)
Check whether or not an upgrade is available for a given package

CLI Example:
salt '*' pkg.upgrade_available <package name>
salt.modules.brew.version(*names, **kwargs)
    Returns a string representing the package version or an empty string if not installed. If more than one package
    name is specified, a dict of name/version pairs is returned.

    CLI Example:
    salt '*' pkg.version <package name>
salt '*' pkg.version <package1> <package2> <package3>

31.16.33 salt.modules.bridge

Module for gathering and managing bridging information
salt.modules.bridge.add(br=None)
    Creates a bridge
    CLI Example:
salt '*' bridge.add br0

salt.modules.bridge.addif(br=None, iface=None)
    Adds an interface to a bridge
    CLI Example:
salt '*' bridge.addif br0 eth0

salt.modules.bridge.delete(br=None)
    Deletes a bridge
    CLI Example:
salt '*' bridge.delete br0

salt.modules.bridge.delif(br=None, iface=None)
    Removes an interface from a bridge
    CLI Example:
salt '*' bridge.delif br0 eth0

salt.modules.bridge.find_interfaces(*args)
    Returns the bridge to which the interfaces are bond to
    CLI Example:
salt '*' bridge.find_interfaces eth0 [eth1...]

salt.modules.bridge.interfaces(br=None)
    Returns interfaces attached to a bridge
    CLI Example:
salt '*' bridge.interfaces br0

salt.modules.bridge.list()
    Returns the machine's bridges list
    CLI Example:
salt 'x' bridge.list

salt.modules.bridge.show(br=None)
Returns bridges interfaces along with enslaved physical interfaces. If no interface is given, all bridges are shown, else only the specified bridge values are returned.

CLI Example:
salt 'x' bridge.show
salt 'x' bridge.show br0

salt.modules.bridge.stp(br=None, state='disable', iface=None)
Sets Spanning Tree Protocol state for a bridge

CLI Example:
salt 'x' bridge.stp br0 enable
salt 'x' bridge.stp br0 disable

For BSD-like operating systems, it is required to add the interface on which to enable the STP.

CLI Example:
salt 'x' bridge.stp bridge0 enable fxp0
salt 'x' bridge.stp bridge0 disable fxp0

31.16.34 salt.modules.bsd_shadow

Manage the password database on BSD systems

salt.modules.bsd_shadow.default_hash()
Returns the default hash used for unset passwords

CLI Example:
salt 'x' shadow.default_hash

salt.modules.bsd_shadow.info(name)
Return information for the specified user

CLI Example:
salt 'x' shadow.info someuser

salt.modules.bsd_shadow.set_change(name, change)
Sets the time at which the password expires (in seconds since the EPOCH). See man usermod on NetBSD and OpenBSD or man pw on FreeBSD. ``0'' means the password never expires.

CLI Example:
salt 'x' shadow.set_change username 1419980400

salt.modules.bsd_shadow.set_expire(name, expire)
Sets the time at which the account expires (in seconds since the EPOCH). See man usermod on NetBSD and OpenBSD or man pw on FreeBSD. ``0'' means the account never expires.

CLI Example:
salt 'x' shadow.set_expire username 1419980400

31.16. Full list of builtin execution modules
salt.modules.bsd_shadow.set_password(name, password)
Set the password for a named user. The password must be a properly defined hash. The password hash can be
generated with this command:

```
python -c "import crypt; print crypt.crypt('password', ciphersalt)"
```

NOTE: When constructing the ciphersalt string, you must escape any dollar signs, to avoid them being
interpolated by the shell.

'password' is, of course, the password for which you want to generate a hash.

ciphersalt is a combination of a cipher identifier, an optional number of rounds, and the cryptographic
salt. The arrangement and format of these fields depends on the cipher and which flavor of BSD you are using.
For more information on this, see the manpage for crypt(3). On NetBSD, additional information is available
in passwd.conf(5).

It is important to make sure that a supported cipher is used.

CLI Example:
```
salt '*' shadow.set_password someuser '$1$UYCIxa628.9qXjpQCjM4a..'
```

31.16.35 salt.modules.btrfs

Module for managing BTRFS file systems.

salt.modules.btrfs.add(mountpoint, *devices, **kwargs)
Add a devices to a BTRFS filesystem.

General options:

- **nodiscard**: Do not perform whole device TRIM
- **force**: Force overwrite existing filesystem on the disk

CLI Example:
```
salt '*' btrfs.add /mountpoint /dev/sda1 /dev/sda2
```

salt.modules.btrfs.convert(device, permanent=False, keeplf=False)
Convert ext2/3/4 to BTRFS. Device should be mounted.

Filesystem can be converted temporarily so the further processing and rollback is possible, or permanently,
where previous extended filesystem image gets deleted. Please note, permanent conversion takes a while as
BTRFS filesystem needs to be properly rebalanced afterwards.

General options:

- **permanent**: Specify if the migration should be permanent (false by default)
- **keeplf**: Keep lost+found of the partition (removed by default, but still in the image, if not perma-
nent migration)

CLI Example:
```
salt '*' btrfs.convert /dev/sda1
salt '*' btrfs.convert /dev/sda1 permanent=True
```

salt.modules.btrfs.defragment(path)
Defragment mounted BTRFS filesystem. In order to defragment a filesystem, device should be properly
mounted and writable.
If passed a device name, then defragmented whole filesystem, mounted on in. If passed a mount point of the filesystem, then only this mount point is defragmented.

CLI Example:

```
salt '*' btrfs.defragment /dev/sda1
salt '*' btrfs.defragment /path/on/filesystem
```

salt.modules.btrfs.delete(mountpoint, *devices, **kwargs)
Remove devices from a BTRFS filesystem.

CLI Example:

```
salt '*' btrfs.delete /mountpoint /dev/sda1 /dev/sda2
```

salt.modules.btrfs.devices()
Get known BTRFS formatted devices on the system.

CLI Example:

```
salt '*' btrfs.devices
```

caller.modules.btrfs.features()
List currently available BTRFS features.

CLI Example:

```
salt '*' btrfs.mkfs_features
```

caller.modules.btrfs.info(device)
Get BTRFS filesystem information.

CLI Example:

```
salt '*' btrfs.info /dev/sda1
```

caller.modules.btrfs.mkfs(*devices, **kwargs)
Create a filesystem on the specified device. By default wipes out with force.

General options:

- **allocsize**: Specify the BTRFS offset from the start of the device.
- **bytecount**: Specify the size of the resultant filesystem.
- **nodesize**: Node size.
- **leafsize**: Specify the nodesize, the tree block size in which btrfs stores data.
- **noforce**: Prevent force overwrite when an existing filesystem is detected on the device.
- **sectorsize**: Specify the sector size, the minimum data block allocation unit.
- **nodiscard**: Do not perform whole device TRIM operation by default.
- **uuid**: Pass UUID or pass True to generate one.

Options:

- **dto**: (raid0|raid1|raid5|raid6|raid10|single|dup) Specify how the data must be spanned across the devices specified.
- **mto**: (raid0|raid1|raid5|raid6|raid10|single|dup) Specify how metadata must be spanned across the devices specified.
- **fts**: Features (call salt <host> btrfs.features for full list of available features)
See the `mkfs.btrfs(8)` manpage for a more complete description of corresponding options description.

CLI Example:
```
salt '*' btrfs.mkfs /dev/sdal
salt '*' btrfs.mkfs /dev/sdal noforce=True
```

```
salt.modules.btrfs.properties(obj, type=None, set=None)
 List properties for given btrfs object. The object can be path of BTRFS device, mount point, or any directories/files inside the BTRFS filesystem.

General options:
• type: Possible types are s[ubvol], f[ilesystem], i[node] and d[evice].
• force: Force overwrite existing filesystem on the disk
• set: <key=value,key1=value1…> Options for a filesystem properties.

CLI Example:
```
salt '*' btrfs.properties /mountpoint
salt '*' btrfs.properties /dev/sdal type=subvol set='ro=false,label="My Storage"'
```

```
salt.modules.btrfs.resize(mountpoint, size)
 Resize filesystem.

General options:
• mountpoint: Specify the BTRFS mountpoint to resize.
• size: ([+/-]<newsize>[kKmMgGtTpPeE]|max) Specify the new size of the target.

CLI Example:
```
salt '*' btrfs.resize /mountpoint size=+1g
salt '*' btrfs.resize /dev/sdal size=max
```

```
salt.modules.btrfs.usage(path)
 Show in which disk the chunks are allocated.

CLI Example:
```
salt '*' btrfs.usage /your/mountpoint
```

```
salt.modules.btrfs.version()
 Return BTRFS version.

CLI Example:
```
salt '*' btrfs.version
```

31.16.36 salt.modules.cabal

Manage and query Cabal packages

New in version 2015.8.0.

```
salt.modules.cabal.install(pkg=None, pkgs=None, user=None, install_global=False, env=None)
 Install a cabal package.
```

pkg A package name in format accepted by cabal-install. See: https://wiki.haskell.org/Cabal-Install
**pkgs** A list of packages names in same format as `pkg`

**user** The user to run cabal install with

**install_global** Install package globally instead of locally

**env** Environment variables to set when invoking cabal. Uses the same `env` format as the `cmd.run` execution function

**CLI Example:**

```bash
salt '*/' cabal.install shellcheck
salt '*/' cabal.install shellcheck-0.3.5
```

salt.modules.cabal.list(**pkg=None, user=None, installed=False, env=None**)  
List packages matching a search string.

**pkg** Search string for matching package names

**user** The user to run cabal list with

**installed** If True, only return installed packages.

**env** Environment variables to set when invoking cabal. Uses the same `env` format as the `cmd.run` execution function

**CLI Example:**

```bash
salt '*' cabal.list
salt '*' cabal.list ShellCheck
```

salt.modules.cabal.uninstall(**pkg, user=None, env=None**)  
Uninstall a cabal package.

**pkg** The package to uninstall

**user** The user to run ghc-pkg unregister with

**env** Environment variables to set when invoking cabal. Uses the same `env` format as the `cmd.run` execution function

salt.modules.cabal.update(**user=None, env=None**)  
Updates list of known packages.

### 31.16.37 salt.modules.cassandra

Cassandra NoSQL Database Module

**depends**

- pycassa Cassandra Python adapter

**configuration** The location of the `nodetool` command, host, and thrift port needs to be specified via pillar:

```yaml
    cassandra.nodetool: /usr/local/bin/nodetool
cassandra.host: localhost
cassandra.thrift_port: 9160
```

salt.modules.cassandra.column_families(**keyspace=None**)  
Return existing column families for all keyspaces or just the provided one.

**CLI Example:**

```bash
```
salt '*' cassandra.column_families
salt '*' cassandra.column_families <keyspace>

salt.modules.cassandra.column_family_definition(keyspace, column_family)
Return a dictionary of column family definitions for the given keyspace/column_family

CLI Example:
salt '*' cassandra.column_family_definition <keyspace> <column_family>

salt.modules.cassandra.compactionstats()
Return compactionstats info

CLI Example:
salt '*' cassandra.compactionstats

salt.modules.cassandra.info()
Return cassandra node info

CLI Example:
salt '*' cassandra.info

salt.modules.cassandra.keyspaces()
Return existing keyspaces

CLI Example:
salt '*' cassandra.keyspaces

salt.modules.cassandra.netstats()
Return netstats info

CLI Example:
salt '*' cassandra.netstats

salt.modules.cassandra.ring()
Return cassandra ring info

CLI Example:
salt '*' cassandra.ring

salt.modules.cassandra.tpstats()
Return tpstats info

CLI Example:
salt '*' cassandra.tpstats

salt.modules.cassandra.version()
Return the cassandra version

CLI Example:
salt '*' cassandra.version
31.16.38  salt.modules.cassandra_cql

Cassandra Database Module
New in version 2015.5.0.

depends  DataStax Python Driver for Apache Cassandra  https://github.com/datastax/python-driver  pip install cassandra-driver

referenced by  Salt's cassandra_cql returner

configuration  The Cassandra cluster members and connection port can either be specified in the master or minion config, the minion's pillar or be passed to the module.

Example configuration in the config for a single node:

```
cassandra:
  cluster: 192.168.50.10
  port: 9000
```

Example configuration in the config for a cluster:

```
cassandra:
  cluster:
    - 192.168.50.10
    - 192.168.50.11
    - 192.168.50.12
  port: 9000
  username: cas_admin
```

salt.modules.cassandra_cql.cql_query(query, contact_points=None, port=None, cql_user=None, cql_pass=None)

Run a query on a Cassandra cluster and return a dictionary.

Parameters

- `query (str)` -- The query to execute.
- `contact_points (str / list[str])` -- The Cassandra cluster addresses, can either be a string or a list of IPs.
- `cql_user (str)` -- The Cassandra user if authentication is turned on.
- `cql_pass (str)` -- The Cassandra user password if authentication is turned on.
- `port (int)` -- The Cassandra cluster port, defaults to None.
- `params (str)` -- The parameters for the query, optional.

Returns  A dictionary from the return values of the query

Return type  list[dict]

salt.modules.cassandra_cql.create_keyspace(keyspace, replication_strategy='SimpleStrategy', replication_factor=1, replication_datacenters=None, contact_points=None, port=None, cql_user=None, cql_pass=None)

Create a new keyspace in Cassandra.

Parameters

- `keyspace (str)` -- The keyspace name
- `replication_strategy (str)` -- either SimpleStrategy or NetworkTopologyStrategy
• `replication_factor` *(int)* -- number of replicas of data on multiple nodes. Not used if using NetworkTopologyStrategy.

• `replication_datacenters` *(str | dict[str, int]*) -- string or dict of datacenter names to replication factors, required if using NetworkTopologyStrategy (will be a dict if coming from state file).

• `contact_points` *(str | list[str]*) -- The Cassandra cluster addresses, can either be a string or a list of IPs.

• `cql_user` *(str)* -- The Cassandra user if authentication is turned on.

• `cql_pass` *(str)* -- The Cassandra user password if authentication is turned on.

• `port` *(int)* -- The Cassandra cluster port, defaults to None.

Returns
The info for the keyspace or False if it does not exist.

Return type
`dict`

```python
salt 'minion1' cassandra_cql.create_keyspace keyspace=newkeyspace
salt 'minion1' cassandra_cql.create_keyspace keyspace=newkeyspace replication_strategy=NetworkTopologyStrategy
```

salt.modules.cassandra_cql.create_user *(username, password, superuser=False, contact_points=None, port=None, cql_user=None, cql_pass=None)*

Create a new cassandra user with credentials and superuser status.

Parameters

• `username` *(str)* -- The name of the new user.

• `password` *(str)* -- The password of the new user.

• `superuser` *(bool)* -- Is the new user going to be a superuser? default: False

• `contact_points` *(str | list[str]*) -- The Cassandra cluster addresses, can either be a string or a list of IPs.

• `cql_user` *(str)* -- The Cassandra user if authentication is turned on.

• `cql_pass` *(str)* -- The Cassandra user password if authentication is turned on.

• `port` *(int)* -- The Cassandra cluster port, defaults to None.

Returns

Return type
`dict`

```python
salt 'minion1' cassandra_cql.create_user username=joe password=secret
salt 'minion1' cassandra_cql.create_user username=joe password=secret superuser=True
salt 'minion1' cassandra_cql.create_user username=joe password=secret superuser=True contact_points=Minion1
```

salt.modules.cassandra_cql.drop_keyspace *(keyspace, contact_points=None, port=None, cql_user=None, cql_pass=None)*

Drop a keyspace if it exists in a Cassandra cluster.

Parameters

• `keyspace` *(str)* -- The keyspace to drop.

• `contact_points` *(str | list[str]*) -- The Cassandra cluster addresses, can either be a string or a list of IPs.
• **cql_user** *(str)* -- The Cassandra user if authentication is turned on.
• **cql_pass** *(str)* -- The Cassandra user password if authentication is turned on.
• **port** *(int)* -- The Cassandra cluster port, defaults to None.

Returns

The info for the keyspace or False if it does not exist.

Return type  
dict

CLI Example:

```bash
salt 'minion1' cassandra_cql.drop_keyspace keyspace=test
salt 'minion1' cassandra_cql.drop_keyspace keyspace=test contact_points=minion1
```

```python
salt.modules.cassandra_cql.grant_permission(username, resource=None, resource_type='keyspace', permission=None, contact_points=None, port=None, cql_user=None, cql_pass=None)
```

Grant permissions to a user.

Parameters

• **username** *(str)* -- The name of the user to grant permissions to.
• **resource** *(str)* -- The resource (keyspace or table), if None, permissions for all resources are granted.
• **resource_type** *(str)* -- The resource_type (keyspace or table), defaults to `keyspace`.
• **permission** *(str)* -- A permission name (e.g. select), if None, all permissions are granted.
• **contact_points** *(str|list[str])* -- The Cassandra cluster addresses, can either be a string or a list of IPs.
• **cql_user** *(str)* -- The Cassandra user if authentication is turned on.
• **cql_pass** *(str)* -- The Cassandra user password if authentication is turned on.
• **port** *(int)* -- The Cassandra cluster port, defaults to None.

Returns

Return type

```bash
salt 'minion1' cassandra_cql.grant_permission
salt 'minion1' cassandra_cql.grant_permission username=joe resource=test_keyspace permission=select contact_points=None
salt 'minion1' cassandra_cql.grant_permission username=joe resource=test_table resource_type=table permission=select contact_points=None
```

```python
salt.modules.cassandra_cql.info(contact_points=None, port=None, cql_user=None, cql_pass=None)
```

Show the Cassandra information for this cluster.

Parameters

• **contact_points** *(str|list[str])* -- The Cassandra cluster addresses, can either be a string or a list of IPs.
• **cql_user** *(str)* -- The Cassandra user if authentication is turned on.
• **cql_pass** *(str)* -- The Cassandra user password if authentication is turned on.
• **port** *(int)* -- The Cassandra cluster port, defaults to None.
Returns  The information for this Cassandra cluster.

Return type  dict

CLI Example:
salt 'minion1' cassandra_cql.info
salt 'minion1' cassandra_cql.info  contact_points=minion1

salt.modules.cassandra_cql.keyspace_exists(
    keyspace,  contact_points=None,  port=None,
cql_user=None,  cql_pass=None)

Check if a keyspace exists in a Cassandra cluster.

:returns: bool

CLI Example:
salt 'minion1' cassandra_cql.keyspace_exists  keyspace=system
salt 'minion1' cassandra_cql.list_keyspaces  keyspace=system  contact_points=minion1

salt.modules.cassandra_cql.list_column_families(
    keyspace=None,  contact_points=None,  port=None,
cql_user=None,  cql_pass=None)

List column families in a Cassandra cluster for all keyspaces or just the provided one.

Parameters

  - keyspace (str) -- The keyspace to provide the column families for, optional.
  - contact_points (str | list[str]) -- The Cassandra cluster addresses, can either be a string or a list of IPs.
  - cql_user (str) -- The Cassandra user if authentication is turned on.
  - cql_pass (str) -- The Cassandra user password if authentication is turned on.
  - port (int) -- The Cassandra cluster port, defaults to None.

Returns  The column families in this Cassandra cluster.

Return type  list[dict]

CLI Example:
salt 'minion1' cassandra_cql.list_column_families
salt 'minion1' cassandra_cql.list_column_families  contact_points=minion1
salt 'minion1' cassandra_cql.list_column_families  keyspace=system

salt.modules.cassandra_cql.list_keyspaces(
    contact_points=None,  port=None,
cql_user=None,  cql_pass=None)

List keyspaces in a Cassandra cluster.

Parameters

  - contact_points (str | list[str]) -- The Cassandra cluster addresses, can either be a string or a list of IPs.
- **cql_user** *(str)* -- The Cassandra user if authentication is turned on.
- **cql_pass** *(str)* -- The Cassandra user password if authentication is turned on.
- **port** *(int)* -- The Cassandra cluster port, defaults to None.

**Returns**  The keyspaces in this Cassandra cluster.

**Return type**  list[dict]

**CLI Example:**

```bash
salt 'minion1' cassandra_cql.list_keyspaces
salt 'minion1' cassandra_cql.list_keyspaces contact_points=minion1 port=9000
```

```
salt.modules.cassandra_cql.list_permissions(username=None, resource=None, resource_type='keyspace', permission=None, contact_points=None, port=None, cql_user=None, cql_pass=None)
```

List permissions.

**Parameters**

- **username** *(str)* -- The name of the user to list permissions for.
- **resource** *(str)* -- The resource (keyspace or table), if None, permissions for all resources are listed.
- **resource_type** *(str)* -- The resource_type (keyspace or table), defaults to `keyspace`.
- **permission** *(str)* -- A permission name (e.g. select), if None, all permissions are listed.
- **contact_points** *(str|list[str]*) -- The Cassandra cluster addresses, can either be a string or a list of IPs.
- **cql_user** *(str)* -- The Cassandra user if authentication is turned on.
- **cql_pass** *(str)* -- The Cassandra user password if authentication is turned on.
- **port** *(int)* -- The Cassandra cluster port, defaults to None.

**Returns**  Dictionary of permissions.

**Return type**  dict

```bash
salt 'minion1' cassandra_cql.list_permissions
salt 'minion1' cassandra_cql.list_permissions username=joe resource=test_keyspace permission=select
salt 'minion1' cassandra_cql.list_permissions username=joe resource=test_table resource_type=table
```

```
salt.modules.cassandra_cql.list_users(contact_points=None, port=None, cql_user=None, cql_pass=None)
```

List existing users in this Cassandra cluster.

**Parameters**

- **contact_points** *(str|list[str]*) -- The Cassandra cluster addresses, can either be a string or a list of IPs.
- **port** *(int)* -- The Cassandra cluster port, defaults to None.
- **cql_user** *(str)* -- The Cassandra user if authentication is turned on.
- **cql_pass** *(str)* -- The Cassandra user password if authentication is turned on.

31.16. Full list of builtin execution modules

731
Returns  The list of existing users.

Return type  dict

.. code-block:: salt

    salt 'minion1' cassandra_cql.list_users
    salt 'minion1' cassandra_cql.list_users contact_points=minion1

salt.modules.cassandra_cql.version(contact_points=None, port=None, cql_user=None, cql_pass=None)

Show the Cassandra version.

Parameters

- **contact_points** (*str / list[**str**]*) -- The Cassandra cluster addresses, can either be a string or a list of IPs.
- **cql_user** (*str*) -- The Cassandra user if authentication is turned on.
- **cql_pass** (*str*) -- The Cassandra user password if authentication is turned on.
- **port** (*int*) -- The Cassandra cluster port, defaults to None.

Returns  The version for this Cassandra cluster.

Return type  str

CLI Example:

.. code-block:: salt

    salt 'minion1' cassandra_cql.version
    salt 'minion1' cassandra_cql.version contact_points=minion1

31.16.39  salt.modules.chef

Execute chef in server or solo mode

salt.modules.chef.client(whyrun=False, localmode=False, logfile=None, **kwargs)

Execute a chef client run and return a dict with the stderr, stdout, return code, and pid.

CLI Example:

.. code-block:: salt

    salt '*' chef.client server=https://localhost

server  The chef server URL

client_key  Set the client key file location

config  The configuration file to use

config-file-jail  Directory under which config files are allowed to be loaded (no client.rb or knife.rb outside this path will be loaded).

environment  Set the Chef Environment on the node

group  Group to set privilege to

json-attributes  Load attributes from a JSON file or URL

localmode  Point chef-client at local repository if True

log_level  Set the log level (debug, info, warn, error, fatal)

logfile  Set the log file location
node-name  The node name for this client

override-runlist  Replace current run list with specified items for a single run

pid  Set the PID file location, defaults to /tmp/chef-client.pid

run-lock-timeout  Set maximum duration to wait for another client run to finish, default is indefinitely.

runlist  Permanently replace current run list with specified items

user  User to set privilege to

validation_key  Set the validation key file location, used for registering new clients

whyrun  Enable whyrun mode when set to True

```
salt.modules.chef.solo(whyrun=False, logfile=None, **kwargs)
```
Execute a chef solo run and return a dict with the stderr, stdout, return code, and pid.

CLI Example:

```
salt '*' chef.solo override-runlist=test
```

config  The configuration file to use

environment  Set the Chef Environment on the node

group  Group to set privilege to

json-attributes  Load attributes from a JSON file or URL

log_level  Set the log level (debug, info, warn, error, fatal)

logfile  Set the log file location

node-name  The node name for this client

override-runlist  Replace current run list with specified items for a single run

recipe-url  Pull down a remote gzipped tarball of recipes and untar it to the cookbook cache

run-lock-timeout  Set maximum duration to wait for another client run to finish, default is indefinitely.

task-runner  Start a task runner.

user  User to set privilege to

whyrun  Enable whyrun mode when set to True

31.16.40  salt.modules.chocolatey

A dead simple module wrapping calls to the Chocolatey package manager (http://chocolatey.org)

New in version 2014.1.0.

```
salt.modules.chocolatey.bootstrap(force=False)
```
 Download and install the latest version of the Chocolatey package manager via the official bootstrap.

Chocolatey requires Windows PowerShell and the .NET v4.0 runtime. Depending on the host’s version of Windows, chocolatey.bootstrap will attempt to ensure these prerequisites are met by downloading and executing the appropriate installers from Microsoft.

Note that if PowerShell is installed, you may have to restart the host machine for Chocolatey to work.

force  Run the bootstrap process even if Chocolatey is found in the path.

CLI Example:
salt '*' chocolatey.bootstrap
salt '*' chocolatey.bootstrap force=True

salt.modules.chocolatey.chocolatey_version()

New in version 2014.7.0.

Returns the version of Chocolatey installed on the minion.

CLI Example:
salt '*' chocolatey.chocolatey_version

salt.modules.chocolatey.install(name, version=None, source=None, force=False, install_args=None, override_args=False, force_x86=False)

Instructs Chocolatey to install a package.

name The name of the package to be installed. Only accepts a single argument.

version Install a specific version of the package. Defaults to latest version.

source Chocolatey repository (directory, share or remote URL feed) the package comes from. Defaults to the official Chocolatey feed.

force Reinstall the current version of an existing package.

install_args A list of install arguments you want to pass to the installation process i.e product key or feature list

override_args

Set to true if you want to override the original install arguments (for the native installer) in the package and use your own. When this is set to False install_args will be appended to the end of the default arguments

force_x86 Force x86 (32bit) installation on 64 bit systems. Defaults to false.

CLI Example:
salt '*' chocolatey.install <package name>
salt '*' chocolatey.install <package name> version=<package version>
salt '*' chocolatey.install <package name> install_args=<args> override_args=True

salt.modules.chocolatey.install_cygwin(name, install_args=None, override_args=False)

Instructs Chocolatey to install a package via Cygwin.

name The name of the package to be installed. Only accepts a single argument.

install_args A list of install arguments you want to pass to the installation process i.e product key or feature list

override_args

Set to true if you want to override the original install arguments (for the native installer) in the package and use your own. When this is set to False install_args will be appended to the end of the default arguments

CLI Example:
salt '*' chocolatey.install_cygwin <package name>
salt '*' chocolatey.install_cygwin <package name> install_args=<args> override_args=True

salt.modules.chocolatey.install_gem(name, version=None, install_args=None, override_args=False)

Instructs Chocolatey to install a package via Ruby’s Gems.
name  The name of the package to be installed. Only accepts a single argument.

version Install a specific version of the package. Defaults to latest version available.

install_args A list of install arguments you want to pass to the installation process i.e product key or feature list

override_args

Set to true if you want to override the original install arguments (for the native installer) in the package and use your own. When this is set to False install_args will be appended to the end of the default arguments

CLI Example:
	salt '*' chocolatey.install_gem <package name>
	salt '*' chocolatey.install_gem <package name> version=<package version>
	salt '*' chocolatey.install_gem <package name> install_args=<args> override_args=True

salt.modules.chocolatey.install_missing(name, version=None, source=None)
Instructs Chocolatey to install a package if it doesn't already exist.

Changed in version 2014.7.0: If the minion has Chocolatey >= 0.9.8.24 installed, this function calls chocolatey.install instead, as installmissing is deprecated as of that version and will be removed in Chocolatey 1.0.

name  The name of the package to be installed. Only accepts a single argument.

version Install a specific version of the package. Defaults to latest version available.

source Chocolatey repository (directory, share or remote URL feed) the package comes from. Defaults to the official Chocolatey feed.

CLI Example:
	salt '*' chocolatey.install_missing <package name>
	salt '*' chocolatey.install_missing <package name> version=<package version>

salt.modules.chocolatey.install_python(name, version=None, install_args=None, override_args=False)
Instructs Chocolatey to install a package via Python's easy_install.

name  The name of the package to be installed. Only accepts a single argument.

version Install a specific version of the package. Defaults to latest version available.

install_args A list of install arguments you want to pass to the installation process i.e product key or feature list

override_args

Set to true if you want to override the original install arguments (for the native installer) in the package and use your own. When this is set to False install_args will be appended to the end of the default arguments

CLI Example:
	salt '*' chocolatey.install_python <package name>
	salt '*' chocolatey.install_python <package name> version=<package version>
	salt '*' chocolatey.install_python <package name> install_args=<args> override_args=True

salt.modules.chocolatey.install_webpi(name, install_args=None, override_args=False)
Instructs Chocolatey to install a package via the Microsoft Web PI service.
**name**  The name of the package to be installed. Only accepts a single argument.

**install_args**  A list of install arguments you want to pass to the installation process i.e product key or feature list

**override_args**

*Set to true if you want to override the original install arguments (for the native installer) in the package and use your own. When this is set to False install_args will be appended to the end of the default arguments*

CLI Example:

```python
salt '*' chocolatey.install_webpi <package name>
salt '*' chocolatey.install_webpi <package name> install_args=<args> override_args=True
```

salt.modules.chocolatey.install_windowsfeatures(name)

Instructs Chocolatey to install a Windows Feature via the Deployment Image Servicing and Management tool.

**name**  The name of the feature to be installed. Only accepts a single argument.

CLI Example:

```python
salt '*' chocolatey.install_windowsfeatures <package name>
```

salt.modules.chocolatey.list(narrow=None, all_versions=False, pre_versions=False, source=None, local_only=False)

Instructs Chocolatey to pull a vague package list from the repository.

**narrow**  Term used to narrow down results. Searches against name/description/tag.

**all_versions**  Display all available package versions in results. Defaults to False.

**pre_versions**  Display pre-release packages in results. Defaults to False.

**source**  Chocolatey repository (directory, share or remote URL feed) the package comes from. Defaults to the official Chocolatey feed.

**local_only**  Display packages only installed locally

CLI Example:

```python
salt '*' chocolatey.list <narrow>
salt '*' chocolatey.list <narrow> all_versions=True
```

salt.modules.chocolatey.list_webpi()

Instructs Chocolatey to pull a full package list from the Microsoft Web PI repository.

CLI Example:

```python
salt '*' chocolatey.list_webpi
```

salt.modules.chocolatey.list_windowsfeatures()

Instructs Chocolatey to pull a full package list from the Windows Features list, via the Deployment Image Servicing and Management tool.

CLI Example:

```python
salt '*' chocolatey.list_windowsfeatures
```

salt.modules.chocolatey.uninstall(name, version=None, uninstall_args=None, override_args=False)

Instructs Chocolatey to uninstall a package.
name  The name of the package to be uninstalled. Only accepts a single argument.

version  Uninstalls a specific version of the package. Defaults to latest version installed.

uninstall_args  A list of uninstall arguments you want to pass to the uninstallation process i.e product key or feature list

override_args

Set to true if you want to override the original uninstall arguments (for the native uninstaller) in the package and use your own. When this is set to False uninstall_args will be appended to the end of the default arguments

CLI Example:

salt '*' chocolatey.uninstall <package name>
salt '*' chocolatey.uninstall <package name> version=<package version>
salt '*' chocolatey.uninstall <package name> version=<package version> uninstall_args=args override_args=True

salt.modules.chocolatey.update(name, source=None, pre_versions=False)

Instructs Chocolatey to update packages on the system.

name  The name of the package to update, or `all` to update everything installed on the system.

source  Chocolatey repository (directory, share or remote URL feed) the package comes from. Defaults to the official Chocolatey feed.

pre_versions  Include pre-release packages in comparison. Defaults to False.

CLI Example:

salt "*" chocolatey.update all
salt "*" chocolatey.update <package name> pre_versions=True

salt.modules.chocolatey.version(name, check_remote=False, source=None, pre_versions=False)

Instructs Chocolatey to check an installed package version, and optionally compare it to one available from a remote feed.

name  The name of the package to check.

check_remote  Get the version number of the latest package from the remote feed. Defaults to False.

source  Chocolatey repository (directory, share or remote URL feed) the package comes from. Defaults to the official Chocolatey feed.

pre_versions  Include pre-release packages in comparison. Defaults to False.

CLI Example:

salt "*" chocolatey.version <package name>
salt "*" chocolatey.version <package name> check_remote=True

31.16.41  salt.modules.cloud

Salt-specific interface for calling Salt Cloud directly

salt.modules.cloud.action(fun=None, cloudmap=None, names=None, provider=None, instance=None, **kwargs)

Execute a single action on the given provider/instance

CLI Example:
```python
salt '*' cloud.action start instance=myinstance
salt '*' cloud.action stop instance=myinstance
salt '*' cloud.action show_image provider=my-ec2-config image=ami-1624987f

salt.modules.cloud.create(provider, names, **kwargs)
    Create an instance using Salt Cloud
    CLI Example:
    salt minionname cloud.create my-ec2-config myinstance image=ami-1624987f size='t1.micro' ssh_user=ec2-user

salt.modules.cloud.destroy(names)
    Destroy the named VM(s)
    CLI Example:
    salt '*' cloud.destroy myinstance

salt.modules.cloud.full_query(query_type='list_nodes_full')
    List all available cloud provider data
    CLI Example:
    salt '*' cloud.full_query

salt.modules.cloud.get_instance(name, provider=None)
    Return details on an instance.
    Similar to the cloud action show_instance but returns only the instance details.
    CLI Example:
    salt '*' cloud.get_instance myinstance
    SLS Example:
    {{ salt['cloud.get_instance']('myinstance')['mac_address'] }}

salt.modules.cloud.has_instance(name, provider=None)
    Return true if the instance is found on a provider
    CLI Example:
    salt '*' cloud.has_instance myinstance

salt.modules.cloud.list_images(provider='all')
    List cloud provider images for the given providers
    CLI Example:
    salt '*' cloud.list_images my-gce-config

salt.modules.cloud.list_locations(provider='all')
    List cloud provider locations for the given providers
    CLI Example:
    salt '*' cloud.list_locations my-gce-config

salt.modules.cloud.list_sizes(provider='all')
    List cloud provider sizes for the given providers
```
CLI Example:
```
salt '*' cloud.list_sizes my-gce-config
```

```
salt.modules.cloud.network_create(provider, names, **kwargs)
    Create private network
CLI Example:
salt minionname cloud.network_create my-nova names=['salt'] cidr='192.168.100.0/24'
```

```
salt.modules.cloud.network_list(provider)
    List private networks
CLI Example:
salt minionname cloud.network_list my-nova
```

```
salt.modules.cloud.profile(profile, names, vm_overrides=None, **kwargs)
    Spin up an instance using Salt Cloud
CLI Example:
salt '*' cloud.profile my-gce-config myinstance
```

```
salt.modules.cloud.query(query_type='list_nodes')
    List cloud provider data for all providers
CLI Examples:
salt '*' cloud.query
salt '*' cloud.query list_nodes_full
salt '*' cloud.query list_nodes_select
```

```
salt.modules.cloud.select_query(query_type='list_nodes_select')
    List selected nodes
CLI Example:
salt '*' cloud.select_query
```

```
salt.modules.cloud.virtual_interface_create(provider, names, **kwargs)
    Attach private interfaces to a server
CLI Example:
salt minionname cloud.virtual_interface_create my-nova names=['salt-master'] net_name='salt'
```

```
salt.modules.cloud.virtual_interface_list(provider, names, **kwargs)
    List virtual interfaces on a server
CLI Example:
salt minionname cloud.virtual_interface_list my-nova names=['salt-master']
```

```
salt.modules.cloud.volume_attach(provider, names, **kwargs)
    Attach volume to a server
CLI Example:
salt minionname cloud.volume_attach my-nova myblock server_name=myserver device='/dev/xvdf'
```

31.16. Full list of built-in execution modules
salt.modules.cloud.volume_create(provider, names, **kwargs)
Create volume

CLI Example:
```
salt minionname cloud.volume_create my-nova myblock size=100 voltype=SSD
```

salt.modules.cloud.volume_delete(provider, names, **kwargs)
Delete volume

CLI Example:
```
salt minionname cloud.volume_delete my-nova myblock
```

salt.modules.cloud.volume_detach(provider, names, **kwargs)
Detach volume from a server

CLI Example:
```
salt minionname cloud.volume_detach my-nova myblock server_name=myserver
```

salt.modules.cloud.volume_list(provider)
List block storage volumes

CLI Example:
```
salt minionname cloud.volume_list my-nova
```

31.16.42 salt.modules.cmdmod

A module for shelling out.

Keep in mind that this module is insecure, in that it can give whomever has access to the master root execution access to all salt minions.

salt.modules.cmdmod.exec_code(lang, code, cwd=None)
Pass in two strings, the first naming the executable language, aka - python2, python3, ruby, perl, lua, etc. the second string containing the code you wish to execute. The stdout will be returned.

CLI Example:
```
salt '*' cmd.exec_code ruby 'puts "cheese"'
```

salt.modules.cmdmod.exec_code_all(lang, code, cwd=None)
Pass in two strings, the first naming the executable language, aka - python2, python3, ruby, perl, lua, etc. the second string containing the code you wish to execute. All cmd artifacts (stdout, stderr, retcode, pid) will be returned.

CLI Example:
```
salt '*' cmd.exec_code_all ruby 'puts "cheese"'
```

salt.modules.cmdmod.has_exec(cmd)
Returns true if the executable is available on the minion, false otherwise

CLI Example:
```
salt '*' cmd.has_exec cat
```
salt.modules.cmdmod.retcodex(cmd, cwd=None, stdin=None, runas=None, shell='/bin/bash',
   python_shell=None, env=None, clean_env=False, template=None, umask=None, output_loglevel='debug', log_callback=None, timeout=None, reset_system_locale=True, ignore_retcode=False, saltenv='base', use_vt=False, **kwargs)

Execute a shell command and return the command’s return code.

cmd: The command to run. ex: `ls -lart /home`
cwd  The current working directory to execute the command in, defaults to /root
stdin  A string of standard input can be specified for the command to be run using the stdin parameter. This can be useful in cases where sensitive information must be read from standard input.: runas  User to run script as.
sHELL  Shell to execute under. Defaults to the system default shell.
python_shell  If True, let python handle the positional arguments. Set to False to use shell features, such as pipes or redirection
ev

   A list of environment variables to be set prior to execution. Example:

   ```
salt://scripts/foo.sh:
cmd.script:
   - env:
      - BATCH: 'yes'
   ```

**Warning:** The above illustrates a common PyYAML pitfall, that yes, no, on, off, true, and false are all loaded as boolean True and False values, and must be enclosed in quotes to be used as strings. More info on this (and other) PyYAML idiosyncrasies can be found [here](#).

Variables as values are not evaluated. So $PATH in the following example is a literal `$PATH`:

```
salt://scripts/bar.sh:
cmd.script:
   - env: "PATH=/some/path:$PATH"
```

One can still use the existing $PATH by using a bit of Jinja:

```
{% set current_path = salt['environ.get']('PATH', '/bin:/usr/bin') %}

mycommand:
   cmd.run:
      - name: ls -l /
      - env:
         - PATH: {{ [current_path, '/my/special/bin']|join('::') }}
```

clean_env: Attempt to clean out all other shell environment variables and set only those provided in the `env` argument to this function.

template  If this setting is applied then the named templating engine will be used to render the downloaded file. Currently jinja, mako, and wempy are supported
rstrip  Strip all whitespace off the end of output before it is returned.

31.16. Full list of builtin execution modules  741
**output_loglevel**  Control the loglevel at which the output from the command is logged. Note that the command being run will still be logged (loglevel: DEBUG) regardless, unless quiet is used for this value.

**timeout**  A timeout in seconds for the executed process to return.

**use_vt**  Use VT utils (saltstack) to stream the command output more interactively to the console and the logs. This is experimental.

Note that env represents the environment variables for the command, and should be formatted as a dict, or a YAML string which resolves to a dict.

- **Return type** int
- **Return type** None
- **Returns**  Return Code as an int or None if there was an exception.

**CLI Example:**

```
salt '*' cmd.retcode "file /bin/bash"
```

The template arg can be set to 'jinja' or another supported template engine to render the command arguments before execution. For example:

```
salt '*' cmd.retcode template=jinja "file {{grains.pythonpath[0]}}/python"
```

A string of standard input can be specified for the command to be run using the stdin parameter. This can be useful in cases where sensitive information must be read from standard input:

```
salt '*' cmd.retcode "grep f" stdin='one
two
three
four
five
'
```

```
salt.modules.cmdmod.run(cmd, cwd=None, stdin=None, runas=None, shell='/bin/bash', python_shell=None, env=None, clean_env=False, template=None, rstrip=True, umask=None, output_loglevel='debug', log_callback=None, timeout=None, reset_system_locale=True, ignore_retcode=False, saltenv='base', use_vt=False, **kwargs)
```

Execute the passed command and return the output as a string

Note that env represents the environment variables for the command, and should be formatted as a dict, or a YAML string which resolves to a dict.

- **cmd**  The command to run. ex: `ls -lart /home`
- **cwd**  The current working directory to execute the command in, defaults to /root
- **stdin**  A string of standard input can be specified for the command to be run using the stdin parameter. This can be useful in cases where sensitive information must be read from standard input.: 
- **runas**  User to run script as.
- **shell**  Shell to execute under. Defaults to the system default shell.
- **python_shell**  If True, let python handle the positional arguments. Set to False to use shell features, such as pipes or redirection
- **env**  A list of environment variables to be set prior to execution. Example:

```
salt://scripts/foo.sh:
  cmd.script:
    - env:
        - BATCH: 'yes'
```
Variables as values are not evaluated. So $PATH in the following example is a literal `$PATH`:

```
salt://scripts/bar.sh:
  cmd.script:
    - env: "PATH=/some/path:$PATH"
```

One can still use the existing $PATH by using a bit of Jinja:

```
{% set current_path = salt['environ.get']('PATH', '/bin:/usr/bin') %}
mycommand:
  cmd.run:
    - name: ls -l /
    - env:
      PATH: {{ [current_path, '/my/special/bin']|join(':') }}
```

### clean_env

Attempt to clean out all other shell environment variables and set only those provided in the `env` argument to this function.

### template

If this setting is applied then the named templating engine will be used to render the downloaded file. Currently jinja, mako, and wempy are supported.

### rstrip

Strip all whitespace off the end of output before it is returned.

### umask

The umask (in octal) to use when running the command.

### output_loglevel

Control the loglevel at which the output from the command is logged. Note that the command being run will still be logged (loglevel: DEBUG) regardless, unless quiet is used for this value.

### timeout

A timeout in seconds for the executed process to return.

### use_vt

Use VT utils (saltstack) to stream the command output more interactively to the console and the logs. This is experimental.

**Warning:** This function does not process commands through a shell unless the python_shell flag is set to True. This means that any shell-specific functionality such as `echo` or the use of pipes, redirection or `&&`, should either be migrated to cmd.shell or have the python_shell=True flag set here.

The use of python_shell=True means that the shell will accept _any_ input including potentially malicious commands such as `good_command;rm -rf /`. Be absolutely certain that you have sanitized your input prior to using python_shell=True

**CLI Example:**

```
salt '*' cmd.run "ls -l | awk '/foo/{print \$2}"
```

The template arg can be set to `jinja` or another supported template engine to render the command arguments before execution. For example:

```
salt '*' cmd.run template=jinja "ls -l /tmp/{{grains.id}} | awk '/foo/{print \$2}"
```

Specify an alternate shell with the shell parameter:
A string of standard input can be specified for the command to be run using the `stdin` parameter. This can be useful in cases where sensitive information must be read from standard input:

```shell
salt '*' cmd.run "grep f" stdin='one

two

three

four

five\n'
```

If an equal sign (=) appears in an argument to a Salt command it is interpreted as a keyword argument in the format key=val. That processing can be bypassed in order to pass an equal sign through to the remote shell command by manually specifying the kwarg:

```shell
salt '*' cmd.run cmd='sed -e s/=/:/g'
```

```
salt.modules.cmdmod.run_all(cmd, cwd=None, stdin=None, runas=None, shell='/bin/bash', python_shell=None, env=None, clean_env=False, template=None, rstrip=True, umask=None, output_loglevel='debug', ignore_retcode=False, saltenv='base', use_vt=False, **kwargs)
```

Execute the passed command and return a dict of return data

- **cmd**: The command to run. ex: `ls -lart /home`
- **cwd**: The current working directory to execute the command in, defaults to /root
- **stdin**: A string of standard input can be specified for the command to be run using the `stdin` parameter. This can be useful in cases where sensitive information must be read from standard input.
- **runas**: User to run script as.
- **shell**: Shell to execute under. Defaults to the system default shell.
- **python_shell**: If True, let python handle the positional arguments. Set to False to use shell features, such as pipes or redirection
- **env**: A list of environment variables to be set prior to execution. Example:

```
salt://scripts/foo.sh:
  cmd.script:
    - env:
    - BATCH: 'yes'
```

**Warning**: The above illustrates a common PyYAML pitfall, that `yes`, `no`, `on`, `off`, `true`, and `false` are all loaded as boolean `True` and `False` values, and must be enclosed in quotes to be used as strings. More info on this (and other) PyYAML idiosyncrasies can be found [here](#).

Variables as values are not evaluated. So `$PATH` in the following example is a literal `'$PATH'`:

```
salt://scripts/bar.sh:
  cmd.script:
    - env: "PATH=/some/path:$PATH"
```

One can still use the existing `$PATH` by using a bit of Jinja:

```
{% set current_path = salt['environ.get']('PATH', '/bin:/usr/bin') %}
mycommand:
```
cmd.run:
- name: ls -l /
- env:
  - PATH: {{ [current_path, '/my/special/bin']|join(':') }}

clean_env: Attempt to clean out all other shell environment variables and set only those provided in the 'env' argument to this function.

template If this setting is applied then the named templating engine will be used to render the downloaded file. Currently jinja, mako, and wempy are supported

rstrip Strip all whitespace off the end of output before it is returned.

umask The umask (in octal) to use when running the command.

output_loglevel Control the loglevel at which the output from the command is logged. Note that the command being run will still be logged (loglevel: DEBUG) regardless, unless quiet is used for this value.

timeout A timeout in seconds for the executed process to return.

use_vt Use VT utils (saltstack) to stream the command output more interactively to the console and the logs.
This is experimental.

Note that env represents the environment variables for the command, and should be formatted as a dict, or a YAML string which resolves to a dict.

CLI Example:

salt '*' cmd.run_all "ls -l | awk '/foo/{print \$2}'"

The template arg can be set to 'jinja' or another supported template engine to render the command arguments before execution. For example:

salt '*' cmd.run_all template=jinja "ls -l /tmp/{{grains.id}} | awk '/foo/{print \$2}'"

A string of standard input can be specified for the command to be run using the stdin parameter. This can be useful in cases where sensitive information must be read from standard input:

salt '*' cmd.run_all "grep f" stdin='one
two
three
four
five'

salt.modules.cmdmod.run_chroot(root, cmd, cwd=None, stdin=None, runas=None, shell='/bin/bash', python_shell=True, env=None, clean_env=False, template=None, rstrip=True, umask=None, output_loglevel='quiet', log_callback=None, quiet=False, timeout=None, reset_system_locale=True, ignore_retcode=False, saltenv='base', use_vt=False, **kwargs)

New in version 2014.7.0.
This function runs cmd.run_all wrapped within a chroot, with dev and proc mounted in the chroot

root: Path to the root of the jail to use.

cmd: The command to run. ex: `ls -lart /home`

cwd The current working directory to execute the command in, defaults to /root

stdin A string of standard input can be specified for the command to be run using the stdin parameter. This can be useful in cases where sensitive information must be read from standard input:

runas User to run script as.

shell Shell to execute under. Defaults to the system default shell.
**python_shell**  If True, let python handle the positional arguments. Set to False to use shell features, such as pipes or redirection

**env**

A list of environment variables to be set prior to execution. Example:

```yaml
salt://scripts/foo.sh:
  cmd.script:
    - env:
      - BATCH: 'yes'
```

**Warning:** The above illustrates a common PyYAML pitfall, that **yes**, **no**, **on**, **off**, **true**, and **false** are all loaded as boolean **True** and **False** values, and must be enclosed in quotes to be used as strings. More info on this (and other) PyYAML idiosyncrasies can be found [here](#).

Variables as values are not evaluated. So **PATH** in the following example is a literal `$PATH`:

```yaml
salt://scripts/bar.sh:
  cmd.script:
    - env: "PATH=/some/path:$PATH"
```

One can still use the existing **PATH** by using a bit of Jinja:

```yaml
{% set current_path = salt['environ.get']('PATH', '/bin:/usr/bin') %}

mycommand:
  cmd.run:
    - name: ls -l /
    - env:
      - PATH: {{ [current_path, '/my/special/bin']|join(':') }}
```

**clean_env**: Attempt to clean out all other shell environment variables and set only those provided in the `env` argument to this function.

**template**  If this setting is applied then the named templating engine will be used to render the downloaded file. Currently jinja, mako, and wempy are supported

**rstrip** Strip all whitespace off the end of output before it is returned.

**umask**  The umask (in octal) to use when running the command.

**output_loglevel** Control the loglevel at which the output from the command is logged. Note that the command being run will still be logged (loglevel: DEBUG) regardless, unless **quiet** is used for this value.

**timeout** A timeout in seconds for the executed process to return.

**use_vt** Use VT utils (saltstack) to stream the command output more interactively to the console and the logs.

This is experimental.

CLI Example:

```
salt '*' cmd.run_chroot /var/lib/lxc/container_name/rootfs 'sh /tmp/bootstrap.sh'
```
Execute a command and only return the standard error

**cmd**: The command to run. ex: `ls -l /home`

**cwd**: The current working directory to execute the command in, defaults to `/root`

**stdin**: A string of standard input can be specified for the command to be run using the `stdin` parameter. This can be useful in cases where sensitive information must be read from standard input:

**runas**: User to run script as.

**shell**: Shell to execute under. Defaults to the system default shell.

**python_shell**: If True, let python handle the positional arguments. Set to False to use shell features, such as pipes or redirection

**env**: A list of environment variables to be set prior to execution. Example:

```yaml
salt://scripts/foo.sh:
  cmd.script:
    - env:
      - BATCH: 'yes'
```

**Warning**: The above illustrates a common PyYAML pitfall, that `yes`, `no`, `on`, `off`, `true`, and `false` are all loaded as boolean `True` and `False` values, and must be enclosed in quotes to be used as strings. More info on this (and other) PyYAML idiosyncrasies can be found [here](#).

Variables as values are not evaluated. So `PATH` in the following example is a literal `$PATH`:

```yaml
salt://scripts/bar.sh:
  cmd.script:
    - env: "$PATH=/some/path:$PATH"
```

One can still use the existing `PATH` by using a bit of Jinja:

```yaml
{% set current_path = salt['environ.get']('PATH', '/bin:/usr/bin') %}

mycommand:
  cmd.run:
    - name: ls -l /
    - env:
      - PATH: {{ [current_path, '/my/special/bin']|join(':') }}
```

**clean_env**: Attempt to clean out all other shell environment variables and set only those provided in the `env` argument to this function.

**template**: If this setting is applied then the named templating engine will be used to render the downloaded file. Currently jinja, mako, and wempy are supported

**rstrip**: Strip all whitespace off the end of output before it is returned.

**umask**: The umask (in octal) to use when running the command.
output_loglevel  Control the loglevel at which the output from the command is logged. Note that the command being run will still be logged (loglevel: DEBUG) regardless, unless quiet is used for this value.

timeout  A timeout in seconds for the executed process to return.

use_vt  Use VT utils (saltstack) to stream the command output more interactively to the console and the logs. This is experimental.

Note that env represents the environment variables for the command, and should be formatted as a dict, or a YAML string which resolves to a dict.

CLI Example:

```
salt '*' cmd.run_stderr "ls -l | awk '/foo/{print $2}'"
```

The template arg can be set to 'jinja' or another supported template engine to render the command arguments before execution. For example:

```
salt '*' cmd.run_stderr template=jinja "ls -l /tmp/{{grains.id}} | awk '/foo/{print $2}'"
```

A string of standard input can be specified for the command to be run using the stdin parameter. This can be useful in cases where sensitive information must be read from standard input:

```
salt '*' cmd.run_stderr "grep f" stdin='one
two
three
four
five\n'
```

salt.modules.cmdmod.run_stdout(cmd, cwd=None, stdin=None, runas=None, shell='/bin/bash', python_shell=None, env=None, clean_env=False, template=None, log_callback=None, timeout=None, reset_system_locale=True, ignore_retcode=False, saltenv='base', use_vt=False, **kwargs)

Execute a command, and only return the standard out

- **cmd**: The command to run. ex: `ls -lart /home`
- **cwd**: The current working directory to execute the command in, defaults to /root
- **stdin**: A string of standard input can be specified for the command to be run using the stdin parameter. This can be useful in cases where sensitive information must be read from standard input.
- **runas**: User to run script as.
- **shell**: Shell to execute under. Defaults to the system default shell.
- **python_shell**: If True, let python handle the positional arguments. Set to False to use shell features, such as pipes or redirection
- **env**: A list of environment variables to be set prior to execution. Example:

```
salt://scripts/foo.sh:
  cmd.script:
    - env:
      - BATCH: 'yes'
```

**Warning**: The above illustrates a common PyYAML pitfall, that yes, no, on, off, true, and false are all loaded as boolean True and False values, and must be enclosed in quotes to be used as strings. More info on this (and other) PyYAML idiosyncrasies can be found [here](#).

Variables as values are not evaluated. So $PATH in the following example is a literal `$PATH`:
salt://scripts/bar.sh:
    cmd.script:
        - env: "PATH=/some/path:$PATH"

One can still use the existing $PATH by using a bit of Jinja:

```
{% set current_path = salt['environ.get']('PATH', '/bin:/usr/bin') %}

mycommand:
    cmd.run:
        - name: ls -l /
        - env:
            - PATH: {{ [current_path, '/my/special/bin']|join(':') }}
```

### clean_env

Attempt to clean out all other shell environment variables and set only those provided in the `env` argument to this function.

### template

If this setting is applied then the named templating engine will be used to render the downloaded file. Currently jinja, mako, and wempy are supported.

### rstrip

Strip all whitespace off the end of output before it is returned.

### umask

The umask (in octal) to use when running the command.

### output_loglevel

Control the loglevel at which the output from the command is logged. Note that the command being run will still be logged (loglevel: DEBUG) regardless, unless quiet is used for this value.

### timeout

A timeout in seconds for the executed process to return.

### use_vt

Use VT utils (saltstack) to stream the command output more interactively to the console and the logs. This is experimental.

Note that env represents the environment variables for the command, and should be formatted as a dict, or a YAML string which resolves to a dict.

### CLI Example:

```
salt '*' cmd.run_stdout "ls -l | awk '/foo/ {print $2}'"
```

The template arg can be set to `jinja` or another supported template engine to render the command arguments before execution. For example:

```
salt '*' cmd.run_stdout template=jinja "ls -l /tmp/{{grains.id}} | awk '/foo/ {print $2}'"
```

A string of standard input can be specified for the command to be run using the stdin parameter. This can be useful in cases where sensitive information must be read from standard input:

```
salt '*' cmd.run_stdout "grep f stdin='one\ntwo\nthree\nfour\nfive\n'
```

salt.modules.cmdmod.script(source, args=None, cwd=None, stdin=None, runas=None, shell="/bin/bash", python_shell=None, env=None, template=None, umask=None, output_loglevel='debug', log_callback=None, quiet=False, timeout=None, reset_system_locale=True, __env__=None, saltenv='base', use_vt=False, **kwargs)

Download a script from a remote location and execute the script locally. The script can be located on the salt master file server or on an HTTP/FTP server.

The script will be executed directly, so it can be written in any available programming language.
source  The location of the script to download. If the file is located on the master in the directory named spam, and is called eggs, the source string is salt://spam/eggs

args  String of command line args to pass to the script. Only used if no args are specified as part of the name argument. To pass a string containing spaces in YAML, you will need to doubly-quote it: `arg1 'arg two' arg3`

cwd  The current working directory to execute the command in, defaults to /root

stdin  A string of standard input can be specified for the command to be run using the stdin parameter. This can be useful in cases where sensitive information must be read from standard input.

runas  User to run script as.

shell  Shell to execute under. Defaults to the system default shell.

python_shell  If True, let python handle the positional arguments. Set to False to use shell features, such as pipes or redirection

eenv  A list of environment variables to be set prior to execution. Example:

```
salt://scripts/foo.sh:
  cmd.script:
    - env:
      - BATCH: 'yes'
```

**Warning:** The above illustrates a common PyYAML pitfall, that yes, no, on, off, true, and false are all loaded as boolean True and False values, and must be enclosed in quotes to be used as strings. More info on this (and other) PyYAML idiosyncrasies can be found [here](#).

Variables as values are not evaluated. So $PATH in the following example is a literal `$PATH`:

```
salt://scripts/bar.sh:
  cmd.script:
    - env: "PATH=/some/path:$PATH"
```

One can still use the existing $PATH by using a bit of Jinja:

```
{% set current_path = salt['environ.get']('PATH', '/bin:/usr/bin') %}

mycommand:
  cmd.run:
    - name: ls -l /
    - env:
        - PATH: {{ [current_path, '/my/special/bin']|join(':') }}
```

template  If this setting is applied then the named templating engine will be used to render the downloaded file. Currently jinja, mako, and wempy are supported

umask  The umask (in octal) to use when running the command.

output_loglevel  Control the loglevel at which the output from the command is logged. Note that the command being run will still be logged (loglevel: DEBUG) regardless, unless quiet is used for this value.

quiet  The command will be executed quietly, meaning no log entries of the actual command or its return data. This is deprecated as of the 2014.1.0 release, and is being replaced with output_loglevel: quiet.

timeout  If the command has not terminated after timeout seconds, send the subprocess sigterm, and if sigterm is ignored, follow up with sigkill

use_vt  Use VT utils (saltstack) to stream the command output more interactively to the console and the logs. This is experimental.
CLI Example:

```bash
salt '*' cmd.script salt://scripts/runme.sh
salt '*' cmd.script salt://scripts/runme.sh 'arg1 arg2 "arg 3"'
salt '*' cmd.script salt://scripts/windows_task.ps1 args=' -Input c:\tmp\infile.txt'
```

```bash
salt '*' cmd.script salt://scripts/runme.sh stdin='one
two
three
four
five'
```

```bash
salt.modules.cmdmod.script_retcode(source, args=None, cwd=None, stdin=None, runas=None, shell='/bin/bash', python_shell=None, env=None, template='jinja', umask=None, timeout=None, reset_system_locale=True, __env__=None, saltenv='base', output_loglevel='debug', log_callback=None, use_vt=False, **kwargs)
```

Download a script from a remote location and execute the script locally. The script can be located on the salt master file server or on an HTTP/FTP server.

The script will be executed directly, so it can be written in any available programming language.

The script can also be formatted as a template, the default is jinja.

Only evaluate the script return code and do not block for terminal output

**source** The location of the script to download. If the file is located on the master in the directory named spam, and is called eggs, the source string is salt://spam/eggs

**args** String of command line args to pass to the script. Only used if no args are specified as part of the name argument. To pass a string containing spaces in YAML, you will need to doubly-quote it: ``arg1 'arg two' arg3``

**cwd** The current working directory to execute the command in, defaults to /root

**stdin** A string of standard input can be specified for the command to be run using the stdin parameter. This can be useful in cases where sensitive information must be read from standard input.

**runas** User to run script as.

**shell** Shell to execute under. Defaults to the system default shell.

**python_shell** If True, let python handle the positional arguments. Set to False to use shell features, such as pipes or redirection

**env** A list of environment variables to be set prior to execution. Example:

```bash
salt://scripts/foo.sh:
cmd.script:
  - env:
    - BATCH: 'yes'
```

**Warning:** The above illustrates a common PyYAML pitfall, that yes, no, on, off, true, and false are all loaded as boolean True and False values, and must be enclosed in quotes to be used as strings. More info on this (and other) PyYAML idiosyncrasies can be found here.

Variables as values are not evaluated. So $PATH in the following example is a literal `$PATH`:

```bash
salt://scripts/bar.sh:
cmd.script:
  - env: "PATH=/some/path:$PATH"
```

One can still use the existing $PATH by using a bit of Jinja:
```yaml
{% set current_path = salt['environ.get']('PATH', '/bin:/usr/bin') %}

mycommand:
  cmd.run:
    - name: ls -l /
    - env:
      - PATH: {{ [current_path, '/my/special/bin']|join(':') }}
```

template  If this setting is applied then the named templating engine will be used to render the downloaded file. Currently jinja, mako, and wempy are supported

umask  The umask (in octal) to use when running the command.

output_loglevel  Control the loglevel at which the output from the command is logged. Note that the command being run will still be logged (loglevel: DEBUG) regardless, unless quiet is used for this value.

quiet  The command will be executed quietly, meaning no log entries of the actual command or its return data. This is deprecated as of the 2014.1.0 release, and is being replaced with output_loglevel: quiet.

timeout  If the command has not terminated after timeout seconds, send the subprocess sigterm, and if sigterm is ignored, follow up with sigkill

use_vt  Use VT utils (saltstack) to stream the command output more interactively to the console and the logs. This is experimental.

CLI Example:

```bash
salt '*' cmd.script_retcode salt://scripts/runme.sh
salt '*' cmd.script_retcode salt://scripts/runme.sh 'arg1 arg2 "arg 3"'
salt '*' cmd.script_retcode salt://scripts/windows_task.ps1 args=' -Input c:\tmp\infile.txt' shell='powershell'
```

A string of standard input can be specified for the command to be run using the stdin parameter. This can be useful in cases where sensitive information must be read from standard input.:

```bash
salt '*' cmd.script_retcode salt://scripts/runme.sh stdin='one
two
three
four
five
'
salt.modules.cmdmod.shell(cmd, cwd=None, stdin=None, runas=None, shell='/bin/bash', env=None, clean_env=False, template=None, rstrip=True, umask=None, output_loglevel='debug', log_callback=None, quiet=False, timeout=None, reset_system_locale=True, ignore_retcode=False, saltenv='base', use_vt=False, **kwargs)
```

Execute the passed command and return the output as a string.

New in version 2015.5.0.

cmd: The command to run. ex: `ls -lart /home`

cwd: The current working directory to execute the command in, defaults to /root

stdin: A string of standard input can be specified for the command to be run using the stdin parameter. This can be useful in cases where sensitive information must be read from standard input:

runas: User to run script as.

shell: Shell to execute under. Defaults to the system default shell.

env: A list of environment variables to be set prior to execution. Example:
- env:
  - BATCH: 'yes'

**Warning:** The above illustrates a common PyYAML pitfall, that yes, no, on, off, true, and false are all loaded as boolean True and False values, and must be enclosed in quotes to be used as strings. More info on this (and other) PyYAML idiosyncrasies can be found [here](#).

Variables as values are not evaluated. So $PATH in the following example is a literal `$PATH`:

```
salt://scripts/bar.sh:
  cmd.script:
    - env: "PATH=/some/path:$PATH"
```

One can still use the existing $PATH by using a bit of Jinja:

```
{% set current_path = salt['environ.get']('PATH', '/bin:/usr/bin') %}

mycommand:
  cmd.run:
    - name: ls -l /
    - env:
      - PATH: {{ current_path, '/my/special/bin'|join(':') }}
```

**clean_env:** Attempt to clean out all other shell environment variables and set only those provided in the `env` argument to this function.

**template** If this setting is applied then the named templating engine will be used to render the downloaded file. Currently jinja, mako, and wempy are supported

**rstrip** Strip all whitespace off the end of output before it is returned.

**umask** The umask (in octal) to use when running the command.

**output_loglevel** Control the loglevel at which the output from the command is logged. Note that the command being run will still be logged (loglevel: DEBUG) regardless, unless quiet is used for this value.

**timeout** A timeout in seconds for the executed process to return.

**use_vt** Use VT utils (saltstack) to stream the command output more interactively to the console and the logs. This is experimental.

**Warning:** This passes the cmd argument directly to the shell without any further processing! Be absolutely sure that you have properly sanitized the command passed to this function and do not use untrusted inputs.

Note that env represents the environment variables for the command, and should be formatted as a dict, or a YAML string which resolves to a dict.

**CLI Example:**

```
salt '*' cmd.shell "ls -l | awk '/foo/{print \$2}'"
```

The template arg can be set to 'jinja' or another supported template engine to render the command arguments before execution. For example:

```
salt '*' cmd.shell template=jinja "ls -l /tmp/{{grains.id}} | awk '/foo/{print \$2}'"
```

Specify an alternate shell with the shell parameter:
A string of standard input can be specified for the command to be run using the `stdin` parameter. This can be useful in cases where sensitive information must be read from standard input:

```
salt '*' cmd.shell "grep f stdin='one\ntag\ntwone\nthree\nfour\nfive\n'
```

If an equal sign (=) appears in an argument to a Salt command it is interpreted as a keyword argument in the format `key=val`. That processing can be bypassed in order to pass an equal sign through to the remote shell command by manually specifying the kwarg:

```
salt '*' cmd.shell cmd='sed -e s/=/:/g'
```

### salt.modules.cmdmod.shells()

List the valid shells on this system via the `/etc/shells` file

New in version 2015.5.0.

CLI Example:
```
salt '*' cmd.shells
```

### salt.modules.cmdmod.tty

Echo a string to a specific tty

CLI Example:
```
salt '*' cmd.tty tty0 'This is a test'
salt '*' cmd.tty pts3 'This is a test'
```

### salt.modules.cmdmod.which(cmd)

Returns the path of an executable available on the minion, `None` otherwise

CLI Example:
```
salt '*' cmd.which cat
```

### salt.modules.cmdmod.which_bin(cmds)

Returns the first command found in a list of commands

CLI Example:
```
salt '*' cmd.which_bin 'pip2, pip, pip-python'
```

## 31.16.43 salt.modules.composer

Use composer to install PHP dependencies for a directory

### salt.modules.composer.did_composer_install(dir)

Test to see if the vendor directory exists in this directory

**dir** Directory location of the composer.json file

CLI Example:
```
salt '*' composer.did_composer_install /var/www/application
```

### salt.modules.composer.install(dir, composer=None, php=None, runas=None, prefer_source=None, prefer_dist=None, no_scripts=None, no_plugins=None, optimize=None, no_dev=None, quiet=False, composer_home='/root')

Install composer dependencies for a directory.
If composer has not been installed globally making it available in the system PATH & making it executable, the composer and php parameters will need to be set to the location of the executables.

**dir** Directory location of the composer.json file.

**composer** Location of the composer.phar file. If not set composer will just execute `"composer"` as if it is installed globally. (i.e. /path/to/composer.phar)

**php** Location of the php executable to use with composer. (i.e. /usr/bin/php)

**runas** Which system user to run composer as.

**prefer_source** --prefer-source option of composer.

**prefer_dist** --prefer-dist option of composer.

**no_scripts** --no-scripts option of composer.

**no_plugins** --no-plugins option of composer.

**optimize** --optimize-autoloader option of composer. Recommended for production.

**no_dev** --no-dev option for composer. Recommended for production.

**quiet** --quiet option for composer. Whether or not to return output from composer.

**composer_home** $COMPOSER_HOME environment variable

CLI Example:

```
salt '*' composer.install /var/www/application
```

salt.modules.composer.selfupdate((composer=None, php=None, runas=None, quiet=False, composer_home='/root'))

Update composer itself.

If composer has not been installed globally making it available in the system PATH & making it executable, the composer and php parameters will need to be set to the location of the executables.

**composer** Location of the composer.phar file. If not set composer will just execute `"composer"` as if it is installed globally. (i.e. /path/to/composer.phar)

**php** Location of the php executable to use with composer. (i.e. /usr/bin/php)

**runas** Which system user to run composer as.

**quiet** --quiet option for composer. Whether or not to return output from composer.

**composer_home** $COMPOSER_HOME environment variable

CLI Example:

```
salt '*' composer.selfupdate
```

salt.modules.composer.update((dir=None, composer=None, php=None, runas=None, prefer_source=None, prefer_dist=None, no_scripts=None, no_plugins=None, optimize=None, no_dev=None, quiet=False, composer_home='/root'))

Update composer dependencies for a directory.

If composer install has not yet been run, this runs composer install instead.

If composer has not been installed globally making it available in the system PATH & making it executable, the composer and php parameters will need to be set to the location of the executables.

**dir** Directory location of the composer.json file.
**composer** Location of the composer.phar file. If not set composer will just execute "composer" as if it is installed globally. (i.e. /path/to/composer.phar)

**php** Location of the php executable to use with composer. (i.e. /usr/bin/php)

**runas** Which system user to run composer as.

**prefer_source** --prefer-source option of composer.

**prefer_dist** --prefer-dist option of composer.

**no_scripts** --no-scripts option of composer.

**no_plugins** --no-plugins option of composer.

**optimize** --optimize-autoloader option of composer. Recommended for production.

**no_dev** --no-dev option for composer. Recommended for production.

**quiet** --quiet option for composer. Whether or not to return output from composer.

**composer_home** $COMPOSER_HOME environment variable

CLI Example:

```
salt '*' composer.update /var/www/application

salt '*' composer.update /var/www/application no_dev=True optimize=True
```

### 31.16.44 salt.modules.config

Return config information

**salt.modules.config.backup_mode**(*backup='*')

Return the backup mode

CLI Example:

```
salt '*' config.backup_mode
```

**salt.modules.config.dot_vals**(*value*)

Pass in a configuration value that should be preceded by the module name and a dot, this will return a list of all read key/value pairs

CLI Example:

```
salt '*' config.dot_vals host
```

**salt.modules.config.gather_bootstrap_script**(*bootstrap=None*)

Download the salt-bootstrap script, and return its location

**bootstrap** URL of alternate bootstrap script

CLI Example:

```
salt '*' config.gather_bootstrap_script
```

**salt.modules.config.get**(*key, default='*', delimiter=':', merge=None*)

Attempt to retrieve the named value from the minion config file, pillar, grains or the master config. If the named value is not available, return the value specified by default. If not specified, the default is an empty string.

Values can also be retrieved from nested dictionaries. Assume the below data structure:
To retrieve the value associated with the `apache` key, in the sub-dictionary corresponding to the `pkg` key, the following command can be used:

```bash
salt myminion config.get pkg:apache
```

The `:` (colon) is used to represent a nested dictionary level.

Changed in version 2015.5.0: The `delimiter` argument was added, to allow delimiters other than `:` to be used.

This function traverses these data stores in this order, returning the first match found:

- Minion config file
- Minion’s grains
- Minion’s pillar data
- Master config file

This means that if there is a value that is going to be the same for the majority of minions, it can be configured in the Master config file, and then overridden using the grains, pillar, or Minion config file.

### Arguments

- **delimiter** New in version 2015.5.0.

  Override the delimiter used to separate nested levels of a data structure.

- **merge** New in version 2015.5.0.

  If passed, this parameter will change the behavior of the function so that, instead of traversing each data store above in order and returning the first match, the data stores are first merged together and then searched. The pillar data is merged into the master config data, then the grains are merged, followed by the Minion config data. The resulting data structure is then searched for a match. This allows for configurations to be more flexible.

**Note:** The merging described above does not mean that grain data will end up in the Minion’s pillar data, or pillar data will end up in the master config data, etc. The data is just combined for the purposes of searching an amalgam of the different data stores.

The supported merge strategies are as follows:

- **recurse** - If a key exists in both dictionaries, and the new value is not a dictionary, it is replaced. Otherwise, the sub-dictionaries are merged together into a single dictionary, recursively on down, following the same criteria. For example:

```python
>>> dict1 = {'foo': {'bar': 1, 'qux': True},
            'hosts': ['a', 'b', 'c'],
            'only_x': None}
>>> dict2 = {'foo': {'baz': 2, 'qux': False},
            'hosts': ['d', 'e', 'f'],
            'only_y': None}
>>> merged
{'foo': {'bar': 1, 'baz': 2, 'qux': False},
 'hosts': ['d', 'e', 'f'],
 'only_dict1': None,
 'only_dict2': None}
```
• **overwrite** - If a key exists in the top level of both dictionaries, the new value completely overwrites the old. For example:

```python
dict1 = {'foo': {'bar': 1, 'qux': True},
         'hosts': ['a', 'b', 'c'],
         'only_x': None}
dict2 = {'foo': {'baz': 2, 'qux': False},
         'hosts': ['d', 'e', 'f'],
         'only_y': None}
```

```python
>>> merged = {'foo': {'baz': 2, 'qux': False},
            'hosts': ['d', 'e', 'f'],
            'only_dict1': None,
            'only_dict2': None}
```

**CLI Example:**

```
salt '*' config.get pkg:apache
salt '*' config.get lxc.container_profile:centos merge=recurse
```

salt.modules.config.manage_mode(mode)

Return a mode value, normalized to a string.

**CLI Example:**

```
salt '*' config.manage_mode
```

salt.modules.config.merge(value, default='`, omit_opts=False, omit_master=False, omit_pillar=False)

Retrieves an option based on key, merging all matches.

Same as `option()` except that it merges all matches, rather than taking the first match.

**CLI Example:**

```
salt '*' config.merge schedule
```

salt.modules.config.option(value, default='`, omit_opts=False, omit_master=False, omit_pillar=False)

Pass in a generic option and receive the value that will be assigned.

**CLI Example:**

```
salt '*' config.option redis.host
```

salt.modules.config.valid_fileproto(uri)

Returns a boolean value based on whether or not the URI passed has a valid remote file protocol designation.

**CLI Example:**

```
salt '*' config.valid_fileproto salt://path/to/file
```

### 31.16.45 **salt.modules.consul**

Interact with Consul

https://www.consul.io

salt.modules.consul.acl_clone(consul_url=None, **kwargs)

Information about an ACL token.
Parameters

- **consul_url** -- The Consul server URL.
- **id** -- Unique identifier for the ACL to update.

Returns Boolean, message of success or failure, and new ID of cloned ACL.

CLI Example:
```
salt '*' consul.acl_info id='c1c4d223-91cb-3d1f-1ee8-f2af9e7b6716'
```

salt.modules.consul.acl_create(**kwargs)
Create a new ACL token.

Parameters

- **consul_url** -- The Consul server URL.
- **name** -- Meaningful indicator of the ACL’s purpose.
- **type** -- Type is either client or management. A management token is comparable to a root user and has the ability to perform any action including creating, modifying, and deleting ACLs.
- **rules** -- The Consul server URL.

Returns Boolean & message of success or failure.

CLI Example:
```
salt '*' consul.acl_create
```

salt.modules.consul.acl_delete(**kwargs)
Delete an ACL token.

Parameters

- **consul_url** -- The Consul server URL.
- **id** -- Unique identifier for the ACL to update.

Returns Boolean & message of success or failure.

CLI Example:
```
salt '*' consul.acl_delete id='c1c4d223-91cb-3d1f-1ee8-f2af9e7b6716'
```

salt.modules.consul.acl_info(**kwargs)
Information about an ACL token.

Parameters

- **consul_url** -- The Consul server URL.
- **id** -- Unique identifier for the ACL to update.

Returns Information about the ACL requested.

CLI Example:
```
salt '*' consul.acl_info id='c1c4d223-91cb-3d1f-1ee8-f2af9e7b6716'
```

salt.modules.consul.acl_list(**kwargs)
List the ACL tokens.

Parameters **consul_url** -- The Consul server URL.
Returns  List of ACLs

CLI Example:

```bash
salt '*' consul.acl_list
```

```
salt.modules.consul.acl_update(consul_url=None, **kwargs)
```

Update an ACL token.

Parameters

- **consul_url** -- The Consul server URL.
- **name** -- Meaningful indicator of the ACL’s purpose.
- **id** -- Unique identifier for the ACL to update.
- **type** -- Type is either client or management. A management token is comparable to a root user and has the ability to perform any action including creating, modifying, and deleting ACLs.
- **rules** -- The Consul server URL.

Returns  Boolean & message of success or failure.

CLI Example:

```bash
salt '*' consul.acl_update
```

```
salt.modules.consul.agent_check_deregister(consul_url=None, checkid=None)
```

The agent will take care of deregistering the check from the Catalog.

Parameters

- **consul_url** -- The Consul server URL.
- **checkid** -- The ID of the check to deregister from Consul.

Returns  Boolean and message indicating success or failure.

CLI Example:

```bash
salt '*' consul.agent_check_deregister checkid='Memory Utilization'
```

```
salt.modules.consul.agent_check_fail(consul_url=None, checkid=None, **kwargs)
```

This endpoint is used with a check that is of the TTL type. When this is called, the status of the check is set to critical and the TTL clock is reset.

Parameters

- **consul_url** -- The Consul server URL.
- **checkid** -- The ID of the check to deregister from Consul.
- **note** -- A human-readable message with the status of the check.

Returns  Boolean and message indicating success or failure.

CLI Example:

```bash
salt '*' consul.agent_check_fail checkid='redis_check1' 
    note='Forcing check into critical state.'
```

```
salt.modules.consul.agent_check_pass(consul_url=None, checkid=None, **kwargs)
```

This endpoint is used with a check that is of the TTL type. When this is called, the status of the check is set to passing and the TTL clock is reset.
Parameters

- **consul_url** -- The Consul server URL.
- **checkid** -- The ID of the check to mark as passing.
- **note** -- A human-readable message with the status of the check.

Returns Boolean and message indicating success or failure.

CLI Example:

```bash
salt '*' consul.agent_check_pass checkid='redis_check1'
  note='Forcing check into passing state.'
```

salt.modules.consul.agent_check_register(consul_url=None, **kwargs)
The register endpoint is used to add a new check to the local agent.

Parameters

- **consul_url** -- The Consul server URL.
- **name** -- The description of what the check is for.
- **id** -- The unique name to use for the check, if not provided `name` is used.
- **notes** -- Human readable description of the check.
- **script** -- If script is provided, the check type is a script, and Consul will evaluate that script based on the interval parameter.
- **http** -- Check will perform an HTTP GET request against the value of HTTP (expected to be a URL) based on the interval parameter.
- **ttl** -- If a TTL type is used, then the TTL update endpoint must be used periodically to update the state of the check.
- **interval** -- Interval at which the check should run.

Returns Boolean and message indicating success or failure.

CLI Example:

```bash
salt '*' consul.agent_check_register name='Memory Utilization'
  script='/usr/local/bin/check_mem.py'
  interval='15s'
```

salt.modules.consul.agent_check_warn(consul_url=None, checkid=None, **kwargs)
This endpoint is used with a check that is of the TTL type. When this is called, the status of the check is set to warning and the TTL clock is reset.

Parameters

- **consul_url** -- The Consul server URL.
- **checkid** -- The ID of the check to deregister from Consul.
- **note** -- A human-readable message with the status of the check.

Returns Boolean and message indicating success or failure.

CLI Example:

```bash
salt '*' consul.agent_check_warn checkid='redis_check1'
  note='Forcing check into warning state.'
```

salt.modules.consul.agent_checks(consul_url=None)
Returns the checks the local agent is managing.
Parameters **consul_url** -- The Consul server URL.

Returns Returns the checks the local agent is managing

CLI Example:

```bash
salt '*' consul.agent_checks
```

salt.modules.consul.agent_join(*consul_url=*, **address=*, **kwargs*)

Triggers the local agent to join a node

Parameters

- **consul_url** -- The Consul server URL.
- **address** -- The address for the agent to connect to.
- **wan** -- Causes the agent to attempt to join using the WAN pool.

Returns Boolean and message indicating success or failure.

CLI Example:

```bash
salt '*' consul.agent_join address='192.168.1.1'
```

salt.modules.consul.agent_leave(*consul_url=*, **node=*)

Used to instruct the agent to force a node into the left state.

Parameters

- **consul_url** -- The Consul server URL.
- **node** -- The node the agent will force into left state

Returns Boolean and message indicating success or failure.

CLI Example:

```bash
salt '*' consul.agent_leave node='web1.example.com'
```

salt.modules.consul.agent_maintenance(*consul_url=*, **kwargs*)

Manages node maintenance mode

Parameters

- **consul_url** -- The Consul server URL.
- **enable** -- The enable flag is required. Acceptable values are either true (to enter maintenance mode) or false (to resume normal operation).
- **reason** -- If provided, its value should be a text string explaining the reason for placing the node into maintenance mode.

Returns Boolean and message indicating success or failure.

CLI Example:

```bash
salt '*' consul.agent_maintenance enable='False' reason='Upgrade in progress'
```

salt.modules.consul.agent_members(*consul_url=*, **kwargs*)

Returns the members as seen by the local serf agent

Parameters **consul_url** -- The Consul server URL.

Returns Returns the members as seen by the local serf agent

CLI Example:
salt '*' consul.agent_members

```python
salt.modules.consul.agent_self(consul_url=None)
```

Returns the local node configuration

Parameters:
- **consul_url** -- The Consul server URL.

Returns: Returns the local node configuration

CLI Example:
```bash
salt '*' consul.agent_self
```

salt.modules.consul.agent_service_deregister(consul_url=None, serviceid=None)

Used to remove a service.

Parameters:
- **consul_url** -- The Consul server URL.
- **serviceid** -- A name describing the service.

Returns: Boolean and message indicating success or failure.

CLI Example:
```bash
salt '*' consul.agent_service_deregister serviceid='redis'
```

salt.modules.consul.agent_service_maintenance(consul_url=None, serviceid=None, **kwargs)

Used to place a service into maintenance mode.

Parameters:
- **consul_url** -- The Consul server URL.
- **serviceid** -- A name of the service.
- **enable** -- Whether the service should be enabled or disabled.
- **reason** -- A human readable message of why the service was enabled or disabled.

Returns: Boolean and message indicating success or failure.

CLI Example:
```bash
salt '*' consul.agent_service_deregister serviceid='redis'
enable='True' reason='Down for upgrade'
```

salt.modules.consul.agent_service_register(consul_url=None, **kwargs)

The used to add a new service, with an optional health check, to the local agent.

Parameters:
- **consul_url** -- The Consul server URL.
- **name** -- A name describing the service.
- **address** -- The address used by the service, defaults to the address of the agent.
- **port** -- The port used by the service.
- **id** -- Unique ID to identify the service, if not provided the value of the name parameter is used.
- **tags** -- Identifying tags for service, string or list.
• **script** -- If script is provided, the check type is a script, and Consul will evaluate that script based on the interval parameter.

• **http** -- Check will perform an HTTP GET request against the value of HTTP (expected to be a URL) based on the interval parameter.

• **check_ttl** -- If a TTL type is used, then the TTL update endpoint must be used periodically to update the state of the check.

• **check_interval** -- Interval at which the check should run.

**Returns** Boolean and message indicating success or failure.

CLI Example:
```bash
salt '*' consul.agent_service_register name='redis' tags='["master", "v1"]' address="127.0.0.1" port="8080" check_script="/usr/local/bin/check_redis.py" interval="10s"
```

salt.modules.consul.agent_services(consul_url=None)
Returns the services the local agent is managing

**Parameters**
- **consul_url** -- The Consul server URL.

**Returns**
Returns the services the local agent is managing

CLI Example:
```bash
salt '*' consul.agent_services
```

salt.modules.consul.catalog_datacenters(consul_url=None)
Return list of available datacenters from catalog.

**Parameters**
- **consul_url** -- The Consul server URL.

**Returns**
The list of available datacenters.

CLI Example:
```bash
salt '*' consul.catalog_datacenters
```

salt.modules.consul.catalog_deregister(consul_url=None, **kwargs)
Deregisters a node, service, or check

**Parameters**
- **consul_url** -- The Consul server URL.
- **node** -- The node to deregister.
- **datacenter** -- By default, the datacenter of the agent is queried; however, the dc can be provided using the `dc` parameter.
- **checkid** -- The ID of the health check to deregister.
- **serviceid** -- The ID of the service to deregister.

**Returns**
Boolean & message of success or failure.

CLI Example:
```bash
salt '*' consul.catalog_register node='node1' serviceid='redis_server1' checkid='redis_check1'
```

salt.modules.consul.catalog_node(consul_url=None, node=None, **kwargs)
Information about the registered node.
Parameters

- **consul_url** -- The Consul server URL.
- **node** -- The node to request information about.
- **dc** -- By default, the datacenter of the agent is queried; however, the dc can be provided using the `"dc"` parameter.

Returns Information about the requested node.

CLI Example:
```
salt '*' consul.catalog_service service='redis'
```

```
salt.modules.consul.catalog_nodes(consul_url=None, **kwargs)

Return list of available nodes from catalog.

Parameters

- **consul_url** -- The Consul server URL.
- **dc** -- By default, the datacenter of the agent is queried; however, the dc can be provided using the `"dc"` parameter.

Returns The list of available nodes.

CLI Example:
```
salt '*' consul.catalog_nodes
```

salt.modules.consul.catalog_register(consul_url=None, **kwargs)

Registers a new node, service, or check

Parameters

- **consul_url** -- The Consul server URL.
- **dc** -- By default, the datacenter of the agent is queried; however, the dc can be provided using the `"dc"` parameter.
- **node** -- The node to register.
- **address** -- The address of the node.
- **service** -- The service that will be registered.
- **service_address** -- The address that the service listens on.
- **service_port** -- The port for the service.
- **service_id** -- A unique identifier for the service, if this is not provided `"name"` will be used.
- **service_tags** -- Any tags associated with the service.
- **check** -- The name of the health check to register
- **check_status** -- The initial status of the check, must be one of unknown, passing, warning, or critical.
- **check_service** -- The service that the check is performed against.
- **check_id** -- Unique identifier for the service.
- **check_notes** -- An opaque field that is meant to hold human-readable text.

Returns Boolean & message of success or failure.
CLI Example:

```bash
salt '*' consul.catalog_register node='node1' address='192.168.1.1'
    service='redis' service_address='127.0.0.1' service_port='8080'
    service_id='redis_server1'
```

salt.modules.consul.catalog_service(consul_url=None, service=None, **kwargs)

Information about the registered service.

Parameters

- **consul_url** -- The Consul server URL.
- **dc** -- By default, the datacenter of the agent is queried; however, the dc can be provided using the `"dc"` parameter.
- **tag** -- Filter returned services with tag parameter.

Returns Information about the requested service.

CLI Example:

```bash
salt '*' consul.catalog_service service='redis'
```

salt.modules.consul.catalog_services(consul_url=None, **kwargs)

Return list of available services from catalog.

Parameters

- **consul_url** -- The Consul server URL.
- **dc** -- By default, the datacenter of the agent is queried; however, the dc can be provided using the `"dc"` parameter.

Returns The list of available services.

CLI Example:

```bash
salt '*' consul.catalog_services
```

salt.modules.consul.delete(consul_url=None, key=None, **kwargs)

Delete values from Consul

Parameters

- **consul_url** -- The Consul server URL.
- **key** -- The key to use as the starting point for the list.
- **recurse** -- Delete values recursively beginning at the value of key.
- **cas** -- This flag is used to turn the DELETE into a Check-And-Set operation.

Returns Boolean & message of success or failure.

CLI Example:

```bash
salt '*' consul.delete key='web'

salt '*' consul.delete key='web' recurse='True'
```

salt.modules.consul.event_fire(consul_url=None, name=None, **kwargs)

List the ACL tokens.

Parameters
Salt Documentation, Release 2015.8.0

- **consul_url** -- The Consul server URL.
- **name** -- The name of the event to fire.
- **dc** -- By default, the datacenter of the agent is queried; however, the dc can be provided using the `"dc"` parameter.
- **node** -- Filter by node name.
- **service** -- Filter by service name.
- **tag** -- Filter by tag name.

**Returns** List of ACLs

**CLI Example:**

```
salt '*' consul.event_fire name='deploy'
```

**salt.modules.consul.event_list(consul_url=None, **kwargs)**

List the recent events.

**Parameters**

- **consul_url** -- The Consul server URL.
- **name** -- The name of the event to fire.

**Returns** List of ACLs

**CLI Example:**

```
salt '*' consul.event_list
```

**salt.modules.consul.get(consul_url=None, key=None, recurse=False, decode=False, raw=False)**

Get key from Consul

**Parameters**

- **consul_url** -- The Consul server URL.
- **key** -- The key to use as the starting point for the list.
- **recurse** -- Return values recursively beginning at the value of key.
- **decode** -- By default values are stored as Base64 encoded values, decode will return the whole key with the value decoded.
- **raw** -- Simply return the decoded value of the key.

**Returns** The keys in Consul.

**CLI Example:**

```
salt '*' consul.get key='web/key1'
salt '*' consul.list key='web' recurse='True'
salt '*' consul.list key='web' recurse='True' decode='True'
```

By default values stored in Consul are base64 encoded, passing the decode option will show them as the decoded values.

```
salt '*' consul.list key='web' recurse='True' decode='True' raw='True'
```
By default Consult will return other information about the key, the raw option will return only the raw value.

salt.modules.consul.health_checks(consul_url=None, service=None, **kwargs)
Health information about the registered service.

Parameters

• consul_url -- The Consul server URL.
• service -- The service to request health information about.
• dc -- By default, the datacenter of the agent is queried; however, the dc can be provided using the `dc` parameter.

Returns Health information about the requested node.

CLI Example:
salt '*' consul.health_checks service='redis1'

salt.modules.consul.health_node(consul_url=None, node=None, **kwargs)
Health information about the registered node.

Parameters

• consul_url -- The Consul server URL.
• node -- The node to request health information about.
• dc -- By default, the datacenter of the agent is queried; however, the dc can be provided using the `dc` parameter.

Returns Health information about the requested node.

CLI Example:
salt '*' consul.health_node node='node1'

salt.modules.consul.health_service(consul_url=None, service=None, **kwargs)
Health information about the registered service.

Parameters

• consul_url -- The Consul server URL.
• service -- The service to request health information about.
• dc -- By default, the datacenter of the agent is queried; however, the dc can be provided using the `dc` parameter.
• tag -- Filter returned services with tag parameter.
• passing -- Filter results to only nodes with all checks in the passing state.

Returns Health information about the requested node.

CLI Example:
salt '*' consul.health_service service='redis1'
salt '*' consul.health_service service='redis1' passing='True'

salt.modules.consul.health_state(consul_url=None, state=None, **kwargs)
Returns the checks in the state provided on the path.
Parameters

- **consul_url** -- The Consul server URL.
- **state** -- The state to show checks for. The supported states are any, unknown, passing, warning, or critical. The any state is a wildcard that can be used to return all checks.
- **dc** -- By default, the datacenter of the agent is queried; however, the dc can be provided using the "dc" parameter.

**Returns** The checks in the provided state.

```bash
salt '*' consul.health_state state='redis1'
salt '*' consul.health_state service='redis1' passing='True'
```

```python
salt.modules.consul.list(consul_url=None, key=None, **kwargs)
List keys in Consul

Parameters

- **consul_url** -- The Consul server URL.
- **key** -- The key to use as the starting point for the list.

**Returns** The list of keys.

```bash
salt '*' consul.list
salt '*' consul.list key='web'
```

```python
salt.modules.consul.put(consul_url=None, key=None, value=None, **kwargs)
Put values into Consul

Parameters

- **consul_url** -- The Consul server URL.
- **key** -- The key to use as the starting point for the list.
- **value** -- The value to set the key to.
- **flags** -- This can be used to specify an unsigned value between 0 and 2^64-1. Clients can choose to use this however makes sense for their application.
- **cas** -- This flag is used to turn the PUT into a Check-And-Set operation.
- **acquire** -- This flag is used to turn the PUT into a lock acquisition operation.
- **release** -- This flag is used to turn the PUT into a lock release operation.

**Returns** Boolean & message of success or failure.

```bash
salt '*' consul.put key='web/key1' value="Hello there"
salt '*' consul.put key='web/key1' value="Hello there"
   acquire='d5d371f4-c380-5280-12fd-8810be175592'
salt '*' consul.put key='web/key1' value="Hello there"
   release='d5d371f4-c380-5280-12fd-8810be175592'
```
salt.modules.consul.session_create(consul_url=None, **kwargs)

Used to create a session.

Parameters

- **consul_url** -- The Consul server URL.
- **lockdelay** -- Duration string using a `s` suffix for seconds. The default is 15s.
- **node** -- Must refer to a node that is already registered, if specified. By default, the agent's own node name is used.
- **name** -- A human-readable name for the session
- **checks** -- A list of associated health checks. It is highly recommended that, if you override this list, you include the default `serfHealth`.
- **behavior** -- Can be set to either release or delete. This controls the behavior when a session is invalidated. By default, this is release, causing any locks that are held to be released. Changing this to delete causes any locks that are held to be deleted. delete is useful for creating ephemeral key/value entries.
- **ttl** -- Session is invalidated if it is not renewed before the TTL expires

Returns

Boolean and message indicating success or failure.

CLI Example:

```
salt '*' consul.session_create node='node1' name='my-session'
    behavior='delete' ttl='3600s'
```

salt.modules.consul.session_destroy(consul_url=None, session=None, **kwargs)

Destroy session

Parameters

- **consul_url** -- The Consul server URL.
- **session** -- The ID of the session to destroy.
- **dc** -- By default, the datacenter of the agent is queried; however, the dc can be provided using the `dc` parameter.

Returns

Boolean & message of success or failure.

CLI Example:

```
salt '*' consul.session_destroy session='c1c4d223-91cb-3d1f-1ee8-f2af9e7b6716'
```

salt.modules.consul.session_info(consul_url=None, session=None, **kwargs)

Information about a session

Parameters

- **consul_url** -- The Consul server URL.
- **session** -- The ID of the session to return information about.
- **dc** -- By default, the datacenter of the agent is queried; however, the dc can be provided using the `dc` parameter.

Returns

Boolean & message of success or failure.

CLI Example:
salt '*_' consul.session_info session='c1c4d223-91cb-3d1f-1ee8-f2af9e7b6716'

salt.modules.consul.session_list(consul_url=None, return_list=False, **kwargs)

Used to list sessions.

Parameters

- **consul_url** -- The Consul server URL.
- **dc** -- By default, the datacenter of the agent is queried; however, the dc can be provided using the "`dc" parameter.
- **return_list** -- By default, all information about the sessions is returned, using the return_list parameter will return a list of session IDs.

Returns A list of all available sessions.

CLI Example:

```
salt '*_' consul.session_list
```

salt.modules.consul.status_leader(consul_url=None)

Returns the current Raft leader

Parameters **consul_url** -- The Consul server URL.

Returns The address of the Raft leader.

CLI Example:

```
salt '*_' consul.status_leader
```

salt.modules.consul.status_peers(consul_url)

Returns the current Raft peer set

Parameters **consul_url** -- The Consul server URL.

Returns Retrieves the Raft peers for the datacenter in which the the agent is running.

CLI Example:

```
salt '*_' consul.status_peers
```

### 31.16.46 salt.modules.container_resource

Common resources for LXC and systemd-nspawn containers

New in version 2015.8.0.

These functions are not designed to be called directly, but instead from the `lxc`, `nspawn`, and `dockerng` execution modules. They provide for common logic to be re-used for common actions.

salt.modules.container_resource.cache_file(source)

Wrapper for `cp.cache_file` which raises an error if the file was unable to be cached.

CLI Example:

```
salt myminion container_resource.cache_file salt://foo/bar/baz.txt
```

salt.modules.container_resource.copy_to(*args, **kwargs)

Common logic for copying files to containers

- **path** path to the container parent (for LXC only) default: `/var/lib/lxc` (system default)
CLI Example:
```
salt myminion container_resource.copy_to mycontainer /local/file/path /container/file/path
docker
nsenter
salt.modules.container_resource.run(*args, **kwargs)
Common logic for running shell commands in containers
```
```
path: path to the container parent (for LXC only) default: /var/lib/lxc (system default)
```
```
CLI Example:
salt myminion container_resource.run mycontainer 'ps aux' container_type=docker exec_driver=nsenter
```

31.16.47 salt.modules.cp

Minion side functions for salt-cp

salt.modules.cp.cache_dir(path, saltenv='base', include_empty=False, include_pat=None, exclude_pat=None, env=None)

Download and cache everything under a directory from the master

include_pat [None] Glob or regex to narrow down the files cached from the given path. If matching with a regex, the regex must be prefixed with E@, otherwise the expression will be interpreted as a glob.

New in version 2014.7.0.

exclude_pat [None] Glob or regex to exclude certain files from being cached from the given path. If matching with a regex, the regex must be prefixed with E@, otherwise the expression will be interpreted as a glob.

Note: If used with include_pat, files matching this pattern will be excluded from the subset of files defined by include_pat.

New in version 2014.7.0.

CLI Examples:
```
salt '*' cp.cache_dir salt://path/to/dir
salt '*' cp.cache_dir salt://path/to/dir include_pat='E@*.py$'
```

salt.modules.cp.cache_file(path, saltenv='base', env=None)

Used to cache a single file on the salt-minion Returns the location of the new cached file on the minion

CLI Example:
```
salt '*' cp.cache_file salt://path/to/file
```

salt.modules.cp.cache_files(paths, saltenv='base', env=None)

Used to gather many files from the master, the gathered files will be saved in the minion cachedir reflective to the paths retrieved from the master.

CLI Example:
```
salt '*' cp.cache_files salt://path/to/file1,salt://path/to/file1
```

salt.modules.cp.cache_local_file(path)

Cache a local file on the minion in the localfiles cache

CLI Example:
salt 'salt-master' cp.cache_local_file /etc/hosts

salt.modules.cp.cache_master(saltenv='base', env=None)
Retrieve all of the files on the master and cache them locally

CLI Example:
salt '*' cp.cache_master

salt.modules.cp.get_dir(path, dest, saltenv='base', template=None, gzip=None, env=None, **kwargs)
Used to recursively copy a directory from the salt master

CLI Example:
salt '*' cp.get_dir salt://path/to/dir/ /minion/dest

get_dir supports the same template and gzip arguments as get_file.

salt.modules.cp.get_file(path, dest, saltenv='base', makedirs=False, template=None, gzip=None, env=None, **kwargs)
Used to get a single file from the salt master

CLI Example:
salt '*' cp.get_file salt://path/to/file /minion/dest

Template rendering can be enabled on both the source and destination file names like so:
salt '*' cp.get_file "salt://{{grains.os}}/vimrc" /etc/vimrc template=jinja

This example would instruct all Salt minions to download the vimrc from a directory with the same name as their os grain and copy it to /etc/vimrc

For larger files, the cp.get_file module also supports gzip compression. Because gzip is CPU-intensive, this should only be used in scenarios where the compression ratio is very high (e.g. pretty-printed JSON or YAML files).

Use the gzip named argument to enable it. Valid values are 1..9, where 1 is the lightest compression and 9 the heaviest. 1 uses the least CPU on the master (and minion), 9 uses the most.

salt.modules.cp.get_file_str(path, saltenv='base', env=None)
Return the contents of a file from a URL

CLI Example:
salt '*' cp.get_file_str salt://my/file

salt.modules.cp.get_template(path, dest, template='jinja', saltenv='base', env=None, makedirs=False, **kwargs)
Render a file as a template before setting it down. Warning, order is not the same as in fileclient.cp for non breaking old API.

CLI Example:
salt '*' cp.get_template salt://path/to/template /minion/dest

salt.modules.cp.get_url(path, dest, saltenv='base', env=None)
Used to get a single file from a URL.

The default behaviour is to write the fetched file to the given destination path. To simply return the text contents instead, set destination to None.
CLI Example:
```
salt '*' cp.get_url salt://my/file /tmp/mine
salt '*' cp.get_url http://www.slashdot.org /tmp/index.html
```

```
salt.modules.cp.hash_file(path, saltenv='base', env=None)
Return the hash of a file, to get the hash of a file on the salt master file server prepend the path with salt://<file
on server> otherwise, prepend the file with / for a local file.

CLI Example:
salt '*' cp.hash_file salt://path/to/file
```

```
salt.modules.cp.is_cached(path, saltenv='base', env=None)
Return a boolean if the given path on the master has been cached on the minion

CLI Example:
salt '*' cp.is_cached salt://path/to/file
```

```
salt.modules.cp.list_master(saltenv='base', prefix='`, env=None)
List all of the files stored on the master

CLI Example:
salt '*' cp.list_master
```

```
salt.modules.cp.list_master_dirs(saltenv='base', prefix='`, env=None)
List all of the directories stored on the master

CLI Example:
salt '*' cp.list_master_dirs
```

```
salt.modules.cp.list_master_symlinks(saltenv='base', prefix='`, env=None)
List all of the symlinks stored on the master

CLI Example:
salt '*' cp.list_master_symlinks
```

```
salt.modules.cp.list_minion(saltenv='base', env=None)
List all of the files cached on the minion

CLI Example:
salt '*' cp.list_minion
```

```
salt.modules.cp.list_states(saltenv='base', env=None)
List all of the available state modules in an environment

CLI Example:
salt '*' cp.list_states
```

```
salt.modules.cp.push(path, keep_symlinks=False, upload_path=None)
Push a file from the minion up to the master, the file will be saved to the salt master in the master's minion
files cachedir (defaults to /var/cache/salt/master/minions/minion-id/files)
Since this feature allows a minion to push a file up to the master server it is disabled by default for security
purposes. To enable, set file_recv to True in the master configuration file, and restart the master.

keep_symlinks Keep the path value without resolving its canonical form
upload_path  Provide a different path inside the master's minion files cachedir

CLI Example:

```bash
salt '*' cp.push /etc/fstab
salt '*' cp.push /etc/system-release keep_symlinks=True
salt '*' cp.push /etc/fstab upload_path='/new/path/fstab'
```

salt.modules.cp.push_dir(path, glob=None, upload_path=None)

Push a directory from the minion up to the master, the files will be saved to the salt master in the master's minion files cachedir (defaults to /var/cache/salt/master/minions/minion-id/files). It also has a glob for matching specific files using globbing.

New in version 2014.7.0.

Since this feature allows a minion to push files up to the master server it is disabled by default for security purposes. To enable, set file_recv to True in the master configuration file, and restart the master.

upload_path  Provide a different path and directory name inside the master's minion files cachedir

CLI Example:

```bash
salt '*' cp.push /usr/lib/mysql
salt '*' cp.push /usr/lib/mysql upload_path='/newmysql/path'
salt '*' cp.push_dir /etc/modprobe.d/ glob='*.conf'
```

salt.modules.cp.recv(files, dest)

Used with salt-cp, pass the files dict, and the destination.

This function receives small fast copy files from the master via salt-cp. It does not work via the CLI.

31.16.48  salt.modules.cpan

Manage Perl modules using CPAN

New in version 2015.5.0.

salt.modules.cpan.install(module)

Install a Perl module from CPAN

CLI Example:

```bash
salt '*' cpan.install Template::Alloy
```

salt.modules.cpan.list()

List installed Perl modules, and the version installed

CLI Example:

```bash
salt '*' cpan.list
```

salt.modules.cpan.remove(module, details=False)

Attempt to remove a Perl module that was installed from CPAN. Because the cpan command doesn't actually support `uninstall`-like functionality, this function will attempt to do what it can, with what it has from CPAN.

Until this function is declared stable, USE AT YOUR OWN RISK!

CLI Example:

```bash
salt '*' cpan.remove Old::Package
```
salt.modules.cpan.show(module)
    Show information about a specific Perl module
    CLI Example:
    ```
salt '*' cpan.show Template::Alloy
    ```

salt.modules.cpan.show_config()
    Return a dict of CPAN configuration values
    CLI Example:
    ```
salt '*' cpan.show_config
    ```

31.16.49 salt.modules.cron

Work with cron
salt.modules.cron.list_tab(user)
    Return the contents of the specified user's crontab
    CLI Example:
    ```
salt '*' cron.list_tab root
    ```

salt.modules.cron.ls(user)
    Return the contents of the specified user's crontab
    CLI Example:
    ```
salt '*' cron.list_tab root
    ```

salt.modules.cron.raw_cron(user)
    Return the contents of the user's crontab
    CLI Example:
    ```
salt '*' cron.raw_cron root
    ```

salt.modules.cron.rm(user, cmd, minute=None, hour=None, daymonth=None, month=None, dayweek=None, identifier=None)
    Remove a cron job for a specified user. If any of the day/time params are specified, the job will only be removed if the specified params match.
    CLI Example:
    ```
salt '*' cron.rm_job root /usr/local/weekly
salt '*' cron.rm_job root /usr/bin/foo dayweek=1
    ```

salt.modules.cron.rm_env(user, name)
    Remove cron environment variable for a specified user.
    CLI Example:
    ```
salt '*' cron.rm_env root MAILTO
    ```

salt.modules.cron.rm_job(user, cmd, minute=None, hour=None, daymonth=None, month=None, dayweek=None, identifier=None)
    Remove a cron job for a specified user. If any of the day/time params are specified, the job will only be removed if the specified params match.
CLI Example:

```
salt '*' cron.rm_job root /usr/local/weekly
salt '*' cron.rm_job root /usr/bin/foo dayweek=1
```

```python
salt.modules.cron.set_env(user, name, value=None)
```
Set up an environment variable in the crontab.

CLI Example:

```
salt '*' cron.set_env root MAILTO user@example.com
```

```python
salt.modules.cron.set_job(user, minute, hour, daymonth, month, dayweek, cmd, comment=None, identifier=None)
```
Sets a cron job up for a specified user.

CLI Example:

```
salt '*' cron.set_job root '*' '*' '*' '*' 1 /usr/local/weekly
```

```python
salt.modules.cron.set_special(user, special, cmd)
```
Set up a special command in the crontab.

CLI Example:

```
salt '*' cron.set_special root @hourly 'echo foobar'
```

```python
salt.modules.cron.write_cron_file(user, path)
```
Writes the contents of a file to a user's crontab

CLI Example:

```
salt '*' cron.write_cron_file root /tmp/new_cron
```

```python
salt.modules.cron.write_cron_file_verbose(user, path)
```
Writes the contents of a file to a user's crontab and return error message on error

CLI Example:

```
salt '*' cron.write_cron_file_verbose root /tmp/new_cron
```

31.16.50 salt.modules.cyg

Manage cygwin packages.
Module file to accompany the cyg state.

```python
salt.modules.cyg.check_valid_package(package, cyg_arch='x86_64', mirrors=None)
```
Check if the package is valid on the given mirrors.

```python
salt.modules.cyg.install(packages=None, cyg_arch='x86_64', mirrors=None)
```
Install one or several packages.

```
packages [None] The packages to install
cyg_arch [x86_64] Specify the architecture to install the package under Current options are x86 and x86_64
```

CLI Example:

```
salt '*' cyg.install dos2unix
salt '*' cyg.install dos2unix mirrors=[{"http://mirror': 'http://url/to/public/key}]
```
salt.modules.cyg.list(`package='`', `cyg_arch='x86_64'`)  
List locally installed packages.

    package ['`'] package name to check. else all  
    cyg_arch : Cygwin architecture to use Options are x86 and x86_64  

CLI Example:

    salt '*' cyg.list

salt.modules.cyg.uninstall(`packages, `cyg_arch='x86_64', `mirrors=None`)  
Uninstall one or several packages.

    packages The packages to uninstall.  
    cyg_arch [x86_64] Specify the architecture to remove the package from Current options are x86 and x86_64  

CLI Example:

    salt '*' cyg.uninstall dos2unix  
    salt '*' cyg.uninstall dos2unix mirrors=['http://mirror': 'http://url/to/public/key']

salt.modules.cyg.update(`cyg_arch='x86_64', `mirrors=None)  
Update all packages.

    cyg_arch [x86_64] Specify the cygwin architecture update Current options are x86 and x86_64  

CLI Example:

    salt '*' cyg.update  
    salt '*' cyg.update dos2unix mirrors=['http://mirror': 'http://url/to/public/key']

31.16.51 salt.modules.daemontools

Daemontools service module. This module will create daemontools type service watcher.

This module is compatible with the service states, so it can be used to maintain services using the provider argument:

    myservice:  
        service.running:  
            - provider: daemontools

salt.modules.daemontools.available(`name`)  
Returns True if the specified service is available, otherwise returns False.

CLI Example:

    salt '*' daemontools.available foo

salt.modules.daemontools.full_restart(`name`)  
Calls daemontools.restart() function

CLI Example:

    salt '*' daemontools.full_restart <service name>

salt.modules.daemontools.get_all()  
Return a list of all available services

CLI Example:
salt '∗' daemontools.get_all

salt.modules.daemontools.missing(name)
The inverse of daemontools.available. Returns True if the specified service is not available, otherwise returns False.

CLI Example:
salt '∗' daemontools.missing foo

salt.modules.daemontools.reload(name)
Wrapper for term()

CLI Example:
salt '∗' daemontools.reload <service name>

salt.modules.daemontools.restart(name)
Restart service via daemontools. This will stop/start service

CLI Example:
salt '∗' daemontools.restart <service name>

salt.modules.daemontools.start(name)
Starts service via daemontools

CLI Example:
salt '∗' daemontools.start <service name>

salt.modules.daemontools.status(name, sig=None)
Return the status for a service via daemontools, return pid if running

CLI Example:
salt '∗' daemontools.status <service name>

salt.modules.daemontools.stop(name)
Stops service via daemontools

CLI Example:
salt '∗' daemontools.stop <service name>

salt.modules.daemontools.term(name)
Send a TERM to service via daemontools

CLI Example:
salt '∗' daemontools.term <service name>

31.16.52 salt.modules.darwin_pkgutil

Installer support for OS X.

Installer is the native .pkg/mpkg package manager for OS X.

salt.modules.darwin_pkgutil.install(source, package_id=None)
Install a .pkg from an URI or an absolute path.

CLI Example:
salt modules.darwin_pkgutil.is_installed(package_id)
Returns whether a given package id is installed.

CLI Example:
salt '*' darwin_pkgutil.is_installed com.apple.pkg.gcc4.2Leo

salt.modules.darwin_pkgutil.list()
List the installed packages.

CLI Example:
salt '*' darwin_pkgutil.list

31.16.53 salt.modules.darwin_sysctl
Module for viewing and modifying sysctl parameters

salt.modules.darwin_sysctl.assign(name, value)
Assign a single sysctl parameter for this minion

name  The name of the sysctl value to edit.
value  The sysctl value to apply.

CLI Example:
salt '*' sysctl.assign net.inet.icmp.icmplim 50

salt.modules.darwin_sysctl.get(name)
Return a single sysctl parameter for this minion

name  The name of the sysctl value to display.

CLI Example:
salt '*' sysctl.get hw.physmem

salt.modules.darwin_sysctl.persist(name, value, config='/etc/sysctl.conf', apply_change=False)
Assign and persist a simple sysctl parameter for this minion

name  The name of the sysctl value to edit.
value  The sysctl value to apply.
config  The location of the sysctl configuration file.
apply_change  Default is False; Default behavior only creates or edits the sysctl.conf file. If apply is set to True, the changes are applied to the system.

CLI Example:
salt '*' sysctl.persist net.inet.icmp.icmplim 50
salt '*' sysctl.persist coretemp_load NO config=/etc/sysctl.conf

salt.modules.darwin_sysctl.show(config_file=False)
Return a list of sysctl parameters for this minion

CLI Example:
**31.16.54 salt.modules.data**

Manage a local persistent data structure that can hold any arbitrary data specific to the minion

```python
salt.modules.data.cas(key, value, old_value)
```
Check and set a value in the minion datastore

CLI Example:
```
salt '*' data.cas <key> <value> <old_value>
```

```python
salt.modules.data.clear()
```
Clear out all of the data in the minion datastore, this function is destructive!

CLI Example:
```
salt '*' data.clear
```

```python
salt.modules.data.dump(new_data)
```
Replace the entire datastore with a passed data structure

CLI Example:
```
salt '*' data.dump '{'eggs': 'spam'}'
```

```python
salt.modules.data.get(key, default=None)
```
Get a (list of) value(s) from the minion datastore

New in version 2015.8.0.

CLI Example:
```
salt '*' data.get <key(s)>
```

```python
salt.modules.data.getval(key)
```
Get a value from the minion datastore

Deprecated since version Boron: Use get instead

CLI Example:
```
salt '*' data.getval <key>
```

```python
salt.modules.data.getvals(*keylist)
```
Get values from the minion datastore

Deprecated since version Boron: Use get instead

CLI Example:
```
salt '*' data.getvals <key> [<key> ...]
```

```python
salt.modules.data.has_key(key)
```
Check if key is in the minion datastore

New in version 2015.8.0.

CLI Example:
salt 'data has_key <mykey>

salt.modules.data.items()

Get items from the minion datastore

New in version 2015.8.0.

CLI Example:
	salt '*' data.items

salt.modules.data.keys()

Get all keys from the minion datastore

New in version 2015.8.0.

CLI Example:
	salt '*' data.keys

salt.modules.data.load()

Return all of the data in the minion datastore

CLI Example:
	salt '*' data.load

salt.modules.data.pop(key, default=None)

Pop (return & delete) a value from the minion datastore

New in version 2015.5.2.

CLI Example:
	salt '*' data.pop <key> "there was no val"

salt.modules.data.update(key, value)

Update a key with a value in the minion datastore

CLI Example:
	salt '*' data.update <key> <value>

salt.modules.data.values()

Get values from the minion datastore

New in version 2015.8.0.

CLI Example:
	salt '*' data.values

31.16.55 salt.modules.ddns

Support for RFC 2136 dynamic DNS updates.

depends

- dnspython Python module
configuration If you want to use TSIG authentication for the server, there are a couple of optional configuration parameters made available to support this (the keyname is only needed if the keyring contains more than one key):

- keyring: keyring file (default=None)
- keyname: key name in file (default=None)

The keyring file needs to be in json format and the key name needs to end with an extra period in the file, similar to this:

```
{"keyname." : "keycontent"}
```

salt.modules.ddns.add_host(zone, name, ttl, ip, nameserver='127.0.0.1', replace=True, **kwargs)
Add, replace, or update the A and PTR (reverse) records for a host.

CLI Example:

```bash
salt ns1 ddns.add_host example.com host1 60 10.1.1.1
```

salt.modules.ddns.delete(zone, name, rdtype=None, data=None, nameserver='127.0.0.1', **kwargs)
Delete a DNS record.

CLI Example:

```bash
salt ns1 ddns.delete example.com host1 A
```

salt.modules.ddns.delete_host(zone, name, nameserver='127.0.0.1', **kwargs)
Delete the forward and reverse records for a host.

Returns true if any records are deleted.

CLI Example:

```bash
salt ns1 ddns.delete_host example.com host1
```

salt.modules.ddns.update(zone, name, ttl, rdtype, data, nameserver='127.0.0.1', replace=False, **kwargs)
Add, replace, or update a DNS record. nameserver must be an IP address and the minion running this module must have update privileges on that server. If replace is true, first deletes all records for this name and type.

CLI Example:

```bash
salt ns1 ddns.update example.com host1 60 A 10.0.0.1
```

31.16.56 salt.modules.deb_apache

Support for Apache

Please note: The functions in here are Debian-specific. Placing them in this separate file will allow them to load only on Debian-based systems, while still loading under the apache namespace.

salt.modules.deb_apache.a2dismod(mod)
Runs a2dismod for the given mod.

This will only be functional on Debian-based operating systems (Ubuntu, Mint, etc).

CLI Examples:

```bash
salt '*' apache.a2dismod vhost_alias
```
salt.modules.deb_apache.a2dissite(site)
    Runs a2dissite for the given site.
    This will only be functional on Debian-based operating systems (Ubuntu, Mint, etc).
    CLI Examples:
    ```
salt '*' apache.a2dissite example.com
    ```

salt.modules.deb_apache.a2enmod(mod)
    Runs a2enmod for the given mod.
    This will only be functional on Debian-based operating systems (Ubuntu, Mint, etc).
    CLI Examples:
    ```
salt '*' apache.a2enmod vhost_alias
    ```

salt.modules.deb_apache.a2ensite(site)
    Runs a2ensite for the given site.
    This will only be functional on Debian-based operating systems (Ubuntu, Mint, etc).
    CLI Examples:
    ```
salt '*' apache.a2ensite example.com
    ```

salt.modules.deb_apache.check_mod_enabled(mod)
    Checks to see if the specific mod symlink is in /etc/apache2/mods-enabled.
    This will only be functional on Debian-based operating systems (Ubuntu, Mint, etc).
    CLI Examples:
    ```
salt '*' apache.check_mod_enabled status.conf
salt '*' apache.check_mod_enabled status.load
    ```

salt.modules.deb_apache.check_site_enabled(site)
    Checks to see if the specific Site symlink is in /etc/apache2/sites-enabled.
    This will only be functional on Debian-based operating systems (Ubuntu, Mint, etc).
    CLI Examples:
    ```
salt '*' apache.check_site_enabled example.com
    ```

31.16.57 salt.modules.deb_postgres

Module to provide Postgres compatibility to salt for debian family specific tools.

salt.modules.deb_postgres.cluster_create(version, name='main', port=None, locale=None, encoding=None, datadir=None)
    Adds a cluster to the Postgres server.
    CLI Example:
    ```
salt '*' postgres.cluster_create '9.3'
salt '*' postgres.cluster_create '9.3' 'main'
salt '*' postgres.cluster_create '9.3' locale='fr_FR'
```
salt.modules.deb_postgres.cluster_exists(version, name='main')
Checks if a given version and name of a cluster exists.

CLI Example:

```
salt '*' postgres.cluster_exists '9.3'
salt '*' postgres.cluster_exists '9.3' 'main'
```

salt.modules.deb_postgres.cluster_list(verbos=False)
Return a list of cluster of Postgress server (tuples of version and name).

CLI Example:

```
salt '*' postgres.cluster_list
salt '*' postgres.cluster_list verbose=True
```

salt.modules.deb_postgres.cluster_remove(version, name='main', stop=False)
Remove a cluster on a Postgress server. By default it doesn't try to stop the cluster.

CLI Example:

```
salt '*' postgres.cluster_remove '9.3'
salt '*' postgres.cluster_remove '9.3' 'main'
salt '*' postgres.cluster_remove '9.3' 'main' stop=True
```

31.16.58 salt.modules.debconfmod

Support for Debcconf

salt.modules.debconfmod.get_selections(fetchempty=True)
Answers to debconf questions for all packages in the following format:

```
{'package': [[{'question', 'type', 'value'}, ...]]}
```

CLI Example:

```
salt '*' debconf.get_selections
```

salt.modules.debconfmod.set(package, question, type, value, *extra)
Set answers to debconf questions for a package.

CLI Example:

```
salt '*' debconf.set <package> <question> <type> <value> [...] [...]
```

salt.modules.debconfmod.set_file(path, saltenv='base', **kwargs)
Set answers to debconf questions from a file.

CLI Example:

```
salt '*' debconf.set_file salt://path/to/pkg.selections
```

salt.modules.debconfmod.set_template(path, template, context, defaults, saltenv='base', **kwargs)
Set answers to debconf questions from a template.
path  location of the file containing the package selections

template  template format

context  variables to add to the template environment

default  default values for the template environment

CLI Example:
```
salt '*' debconf.set_template salt://path/to/pkg.selections.jinja jinja None None
```

salt.modules.debconfmod.show(name)
Answers to debconf questions for a package in the following format:
```
[{'question': 'question', 'type': 'type', 'value': 'value'}, ...]
```
If debconf doesn't know about a package, we return None.

CLI Example:
```
salt '*' debconf.show <package name>
```

### 31.16.59 salt.modules.debian_ip

The networking module for Debian based distros

References:

salt.modules.debian_ip.apply_network_settings(**settings)
Apply global network configuration.

CLI Example:
```
salt '*' ip.apply_network_settings
```

salt.modules.debian_ip.build_bond(iface, **settings)
Create a bond script in /etc/modprobe.d with the passed settings and load the bonding kernel module.

CLI Example:
```
salt '*' ip.build_bond bond0 mode=balance-alb
```

salt.modules.debian_ip.build_interface(iface, iface_type, enabled, **settings)
Build an interface script for a network interface.

CLI Example:
```
salt '*' ip.build_interface eth0 eth <settings>
```

salt.modules.debian_ip.build_network_settings(**settings)
Build the global network script.

CLI Example:
```
salt '*' ip.build_network_settings <settings>
```

salt.modules.debian_ip.build_routes(iface, **settings)
Add route scripts for a network interface using up commands.

CLI Example:
salt '*' ip.build_routes eth0 <settings>

salt.modules.debian_ip.down(iface, iface_type)
    Shutdown a network interface
    CLI Example:
    
    `salt '*' ip.down eth0 eth`

salt.modules.debian_ip.get_bond(iface)
    Return the content of a bond script
    CLI Example:
    
    `salt '*' ip.get_bond bond0`

salt.modules.debian_ip.get_interface(iface)
    Return the contents of an interface script
    CLI Example:
    
    `salt '*' ip.get_interface eth0`

salt.modules.debian_ip.get_network_settings()
    Return the contents of the global network script.
    CLI Example:
    
    `salt '*' ip.get_network_settings`

salt.modules.debian_ip.get_routes(iface)
    Return the routes for the interface
    CLI Example:
    
    `salt '*' ip.get_routes eth0`

salt.modules.debian_ip.up(iface, iface_type)
    Start up a network interface
    CLI Example:
    
    `salt '*' ip.up eth0 eth`

31.16.60 salt.modules.debian_service

Service support for Debian systems (uses update-rc.d and /sbin/service)

salt.modules.debian_service.available(name)
    Returns True if the specified service is available, otherwise returns False.
    CLI Example:
    
    `salt '*' service.available sshd`

salt.modules.debian_service.disable(name, **kwargs)
    Disable the named service to start at boot
    CLI Example:
salt '*' service.disable <service name>

```
salt.modules.debian_service.disabled(name)
    Return True if the named service is enabled, false otherwise
    CLI Example:
    salt '*' service.disabled <service name>
```

salt.modules.debian_service.enable(name, **kwargs)
    Enable the named service to start at boot
    CLI Example:
    salt '*' service.enable <service name>

salt.modules.debian_service.enabled(name, **kwargs)
    Return True if the named service is enabled, false otherwise
    CLI Example:
    salt '*' service.enabled <service name>

salt.modules.debian_service.force_reload(name)
    Force-reload the named service
    CLI Example:
    salt '*' service.force_reload <service name>

salt.modules.debian_service.get_all()
    Return all available boot services
    CLI Example:
    salt '*' service.get_all

salt.modules.debian_service.get_disabled()
    Return a set of services that are installed but disabled
    CLI Example:
    salt '*' service.get_disabled

salt.modules.debian_service.get_enabled()
    Return a list of service that are enabled on boot
    CLI Example:
    salt '*' service.get_enabled

salt.modules.debian_service.missing(name)
    The inverse of service.available. Returns True if the specified service is not available, otherwise returns False.
    CLI Example:
    salt '*' service.missing sshd

salt.modules.debian_service.reload(name)
    Reload the named service
    CLI Example:
salt 'service name' service.reload

salt.modules.debian_service.restart(name)
    Restart the named service
    CLI Example:
    salt 'service name' service.restart

salt.modules.debian_service.start(name)
    Start the specified service
    CLI Example:
    salt 'service name' service.start

salt.modules.debian_service.status(name, sig=None)
    Return the status for a service, pass a signature to use to find the service via ps
    CLI Example:
    salt 'service name' service.status

salt.modules.debian_service.stop(name)
    Stop the specified service
    CLI Example:
    salt 'service name' service.stop

31.16.61 salt.modules.defaults

salt.modules.defaults.get(key, default=None)
    defaults.get is used much like pillar.get except that it will read a default value for a pillar from defaults.json or defaults.yaml files that are stored in the root of a salt formula.
    When called from the CLI it works exactly like pillar.get.
    CLI Example:
    salt 'core:users:root'

    When called from an SLS file, it works by first reading a defaults.json and second a defaults.yaml file. If the key exists in these files and does not exist in a pillar named after the formula, the value from the defaults file is used.

    Example core/defaults.json file for the `core` formula:

    ```json
    {
        "users": {
            "root": 0
        }
    }
    ```

    With this, from a state file you can use salt['defaults.get']('users:root') to read the `0` value from defaults.json if a core:users:root pillar key is not defined.
31.16.62  salt.modules.devmap

Device-Mapper module

salt.modules.devmap.multipath_flush(device)

Device-Mapper Multipath flush

CLI Example:

```
salt '*' devmap.multipath_flush mpath1
```

salt.modules.devmap.multipath_list()

Device-Mapper Multipath list

CLI Example:

```
salt '*' devmap.multipath_list
```

31.16.63  salt.modules.dig

Compendium of generic DNS utilities. The `dig' command line tool must be installed in order to use this module.

salt.modules.dig.A(host, nameserver=None)

Return the A record for host.

Always returns a list.

CLI Example:

```
salt ns1 dig.A www.google.com
```

salt.modules.dig.AAAA(host, nameserver=None)

Return the AAAA record for host.

Always returns a list.

CLI Example:

```
salt ns1 dig.AAAA www.google.com
```

salt.modules.dig.MX(domain, resolve=False, nameserver=None)

Return a list of lists for the MX of domain.

If the resolve argument is True, resolve IPs for the servers.

It's limited to one IP, because although in practice it's very rarely a round robin, it is an acceptable configuration and pulling just one IP lets the data be similar to the non-resolved version. If you think an MX has multiple IPs, don't use the resolver here, resolve them in a separate step.

CLI Example:

```
salt ns1 dig.MX google.com
```

salt.modules.dig.NS(domain, resolve=True, nameserver=None)

Return a list of IPs of the nameservers for domain.

If resolve is False, don't resolve names.

CLI Example:

```
salt ns1 dig.NS google.com
```
### `salt.modules.dig.SPF` *(domain, record='SPF', nameserver=None)*

Return the allowed IPv4 ranges in the SPF record for `domain`.

- If record is SPF and the SPF record is empty, the TXT record will be searched automatically. If you know the domain uses TXT and not SPF, specifying that will save a lookup.

CLI Example:
```
salt ns1 dig.SPF google.com
```

### `salt.modules.dig.TXT` *(host, nameserver=None)*

Return the TXT record for `host`.

- Always returns a list.

CLI Example:
```
salt ns1 dig.TXT google.com
```

### `salt.modules.dig.check_ip` *(addr)*

Check if address is a valid IP. Returns True if valid, otherwise False.

CLI Example:
```
salt ns1 dig.check_ip 127.0.0.1
```

### 31.16.64 `salt.modules.disk`

Module for gathering disk information

#### `salt.modules.disk.blkid` *(device=None)*

Return block device attributes: UUID, LABEL, etc. This function only works on systems where blkid is available.

CLI Example:
```
salt '*' disk.blkid
salt '*' disk.blkid /dev/sda
```

#### `salt.modules.disk_inodeusage` *(args=None)*

Return inode usage information for volumes mounted on this minion

CLI Example:
```
salt '*' disk_inodeusage
```

#### `salt.modules.disk.percent` *(args=None)*

Return partition information for volumes mounted on this minion

CLI Example:
```
salt '*' disk.percent /var
```

#### `salt.modules.disk.usage` *(args=None)*

Return usage information for volumes mounted on this minion

CLI Example:
```
salt '*' disk.usage
```
31.16.65 salt.modules.djangomod

Manage Django sites

```python
salt.modules.djangomod.collectstatic(settings_module, bin_env=None, no_post_process=False,
ignore=None, dry_run=False, clear=False, link=False,
no_default_ignore=False, pythonpath=None, env=None)
```

Collect static files from each of your applications into a single location that can easily be served in production.

CLI Example:
```
salt '*' django.collectstatic <settings_module>
```

```python
salt.modules.djangomod.command(settings_module, command, bin_env=None, pythonpath=None,
env=None, *args, **kwargs)
```

Run arbitrary django management command

CLI Example:
```
salt '*' django.command <settings_module> <command>
```

```python
salt.modules.djangomod.createsuperuser(settings_module, username, email, bin_env=None,
database=None, pythonpath=None, env=None)
```

Create a super user for the database. This function defaults to use the --noinput flag which prevents the creation of a password for the superuser.

CLI Example:
```
salt '*' django.createsuperuser <settings_module> user user@example.com
```

```python
salt.modules.djangomod.loaddata(settings_module, fixtures, bin_env=None, database=None,
pythonpath=None, env=None)
```

Load fixture data

**Fixtures**: comma separated list of fixtures to load

CLI Example:
```
salt '*' django.loaddata <settings_module> <comma delimited list of fixtures>
```

```python
salt.modules.djangomod.syncdb(settings_module, bin_env=None, migrate=False, database=None,
pythonpath=None, env=None, noinput=True)
```

Run syncdb

Execute the Django-Admin syncdb command, if South is available on the minion the migrate option can be passed as True calling the migrations to run after the syncdb completes

CLI Example:
```
salt '*' django.syncdb <settings_module>
```

31.16.66 salt.modules.dnsmasq

Module for managing dnsmasq

```python
salt.modules.dnsmasq.fullversion()
```

Shows installed version of dnsmasq and compile options.

CLI Example:
```
```
salt ' '*' dnsmasq.version

salt.modules.dnsmasq.get_config(config_file='/etc/dnsmasq.conf')
Dumps all options from the config file.

CLI Examples:

    salt '*' dnsmasq.get_config
    salt '*' dnsmasq.get_config file=/etc/dnsmasq.conf

salt.modules.dnsmasq.set_config(config_file='/etc/dnsmasq.conf', follow=True, **kwargs)
Sets a value or a set of values in the specified file. By default, if conf-dir is configured in this file, salt will
attempt to set the option in any file inside the conf-dir where it has already been enabled. If it does not find it
inside any files, it will append it to the main config file. Setting follow to False will turn off this behavior.

If a config option currently appears multiple times (such as dhcp-host, which is specified at least once per
host), the new option will be added to the end of the main config file (and not to any includes). If you need an
option added to a specific include file, specify it as the config_file.

CLI Examples:

    salt '*' dnsmasq.set_config domain=mydomain.com
    salt '*' dnsmasq.set_config follow=False domain=mydomain.com
    salt '*' dnsmasq.set_config file=/etc/dnsmasq.conf domain=mydomain.com

salt.modules.dnsmasq.version()
Shows installed version of dnsmasq.

CLI Example:

    salt '*' dnsmasq.version

31.16.67 salt.modules.dnsutil

Compendium of generic DNS utilities

salt.modules.dnsutil.A(host, nameserver=None)
Return the A record(s) for host.
Always returns a list.

CLI Example:

    salt ns1 dnsutil.A www.google.com

salt.modules.dnsutil.AAAA(host, nameserver=None)
Return the AAAA record(s) for host.
Always returns a list.
New in version 2014.7.5.

CLI Example:

    salt ns1 dnsutil.AAAA www.google.com

salt.modules.dnsutil.MX(domain, resolve=False, nameserver=None)
Return a list of lists for the MX of domain.

If the `resolve` argument is True, resolve IPs for the servers.
It's limited to one IP, because although in practice it's very rarely a round robin, it is an acceptable configuration and pulling just one IP lets the data be similar to the non-resolved version. If you think an MX has multiple IPs, don't use the resolver here, resolve them in a separate step.

CLI Example:

```bash
salt ns1 dig.MX google.com
```

**salt.modules.dnsutil.NS** *(domain, resolve=True, nameserver=None)*

Return a list of IPs of the nameservers for domain.

If `resolve` is False, don't resolve names.

CLI Example:

```bash
salt ns1 dig.NS google.com
```

**salt.modules.dnsutil.SPF** *(domain, record='SPF', nameserver=None)*

Return the allowed IPv4 ranges in the SPF record for domain.

If record is SPF and the SPF record is empty, the TXT record will be searched automatically. If you know the domain uses TXT and not SPF, specifying that will save a lookup.

CLI Example:

```bash
salt ns1 dig.SPF google.com
```

**salt.modules.dnsutil.check_ip** *(ip_addr)*

Check that string `ip_addr` is a valid IP.

CLI Example:

```bash
salt ns1 dig.check_ip 127.0.0.1
```

**salt.modules.dnsutil.hosts_append** *(hostsfile='/etc/hosts', ip_addr=None, entries=None)*

Append a single line to the `/etc/hosts` file.

CLI Example:

```bash
salt '*' dnsutil.hosts_append /etc/hosts 127.0.0.1 ad1.yuk.co,ad2.yuk.co
```

**salt.modules.dnsutil.hosts_remove** *(hostsfile='/etc/hosts', entries=None)*

Remove a host from the `/etc/hosts` file. If doing so will leave a line containing only an IP address, then the line will be deleted. This function will leave comments and blank lines intact.

CLI Examples:

```bash
salt '*' dnsutil.hosts_remove /etc/hosts ad1.yuk.co
salt '*' dnsutil.hosts_remove /etc/hosts ad2.yuk.co,ad1.yuk.co
```

**salt.modules.dnsutil.parse_hosts** *(hostsfile='/etc/hosts', hosts=None)*

Parse `/etc/hosts` file.

CLI Example:

```bash
salt '*' dnsutil.parse_hosts
```

**salt.modules.dnsutil.parse_zone** *(zonefile=None, zone=None)*

Parses a zone file. Can be passed raw zone data on the API level.

CLI Example:
salt.modules.dnsutil.parse_zone /var/lib/named/example.com.zone

salt.modules.dnsutil.serial(zone='`, update=False)

Return, store and update a dns serial for your zone files.
zone: a keyword for a specific zone
update: store an updated version of the serial in a grain
If update is False, the function will retrieve an existing serial or return the current date if no serial is stored. Nothing will be stored
If update is True, the function will set the serial to the current date if none exist or if the existing serial is for a previous date. If a serial for greater than the current date is already stored, the function will increment it.
This module stores the serial in a grain, you can explicitly set the stored value as a grain named dnsserial_<zone_name>.

CLI Example:
salt ns1 dnsutil.serial example.com

31.16.68 salt.modules.dockerio

Management of Docker Containers
New in version 2014.1.0.
Deprecated since version 2015.8.0: Future feature development will be done only in docker-ng. See the documentation for this module for information on the deprecation path.

Note: The DockerIO integration is still in beta; the API is subject to change

General Notes
As we use states, we don’t want to be continuously popping dockers, so we will map each container id (or image) with a grain whenever it is relevant.
As a corollary, we will resolve a container id either directly by the id or try to find a container id matching something stocked in grain.

Installation Prerequisites

- You will need the docker-py python package in your python installation path that is running salt. Its version should support Docker Remote API v1.12.
Currently, docker-py 0.5.0 is known to support Docker Remote API v1.12

    pip install docker-py==0.5.0

Prerequisite Pillar Configuration for Authentication

- To push or pull you will need to be authenticated as the docker-py bindings require it
- For this to happen, you will need to configure a mapping in the pillar representing your per URL authentication bits:

```yaml
docker-registries:
  registry_url:
    email: foo@foo.com
    password: s3cr3t
    username: foo
```

- You need at least an entry to the default docker index:

```yaml
docker-registries:
  https://index.docker.io/v1/:
    email: foo@foo.com
    password: s3cr3t
    username: foo
```

- You can define multiple registry blocks for them to be aggregated. The only thing to keep in mind is that their ID must finish with `-docker-registries`:

```yaml
ac-docker-registries:
  https://index.bar.io/v1/:
    email: foo@foo.com
    password: s3cr3t
    username: foo

ab-docker-registries:
  https://index.foo.io/v1/:
    email: foo@foo.com
    password: s3cr3t
    username: foo
```

This could be also written as:

```yaml
docker-registries:
  https://index.bar.io/v1/:
    email: foo@foo.com
    password: s3cr3t
    username: foo
  https://index.foo.io/v1/:
    email: foo@foo.com
    password: s3cr3t
    username: foo
```

**Methods**

- Registry Dialog
  - login
  - push
  - pull

- Docker Management
  - version
  - info

- Image Management
- search
- inspect_image
- get_images
- remove_image
- import_image
- build
- tag
- save
- load

- Container Management
- start
- stop
- restart
- kill
- wait
- get_containers
- inspect_container
- remove_container
- is_running
- top
- port
- logs
- diff
- commit
- create_container
- export
- get_container_root

Runtime Execution within a specific, already existing/running container

Idea is to use lxc-attach to execute inside the container context. We do not want to use docker run but want to execute something inside a running container.

These are the available methods:

- retcode
- run
- run_all
- run_stderr
- `run_stdout`
- `script`
- `script_retcode`

salt.modules.dockerio.build(path=None, tag=None, quiet=False, fileobj=None, nocache=False, rm=True, timeout=None)

Build a docker image from a dockerfile or an URL

- **path** url/branch/docker_dir or path on the filesystem to the dockerfile
- **tag** tag of the image
- **quiet** quiet mode, Default is False
- **nocache** do not use docker image cache, Default is False
- **rm** remove intermediate commits, Default is True
- **timeout** timeout value before aborting (in seconds)

CLI Example:

```
salt '*' docker.build vieux/apache
salt '*' docker.build github.com/creack/docker-firefox
```

salt.modules.dockerio.commit(container, repository=None, tag=None, message=None, author=None, conf=None)

Commit a container (promotes it to an image)

- **container** container id
- **repository** repository/image to commit to
- **tag** tag of the image (Optional)
- **message** commit message (Optional)
- **author** author name (Optional)
- **conf** conf (Optional)

CLI Example:

```
salt '*' docker.commit <container id>
```

salt.modules.dockerio.create_container(image, command=None, hostname=None, user=None, detach=True, stdin_open=False, tty=False, mem_limit=0, ports=None, environment=None, dns=None, volumes=None, volumes_from=None, name=None, cpu_shares=None, cpuset=None, binds=None)

Create a new container

- **image** image to create the container from
- **command** command to execute while starting
- **hostname** hostname of the container
- **user** user to run docker as
- **detach** daemon mode, Default is True
- **environment** environment variable mapping ({{'foo':'BAR'}})
- **ports** port redirections ({{'222': {}}})
volumes  list of volume mappings in either local volume, bound volume, or read-only bound volume form:

     (['/var/lib/mysql/', '/usr/local/etc:/etc/ssl', '/etc/passwd:/etc/passwd:ro'])

binds  complete dictionary of bound volume mappings:

     { '/usr/local/etc/ssl/certs/internal.crt': {'bind': '/etc/ssl/certs/com.example.internal.crt', 'ro': True}, '/var/lib/mysql': { 'bind': '/var/lib/mysql/', 'ro': False} }

This dictionary is suitable for feeding directly into the Docker API, and all keys are required. (see http://docker-py.readthedocs.org/en/latest/volumes/)

tty  attach ttys, Default is False
stdin_open  let stdin open, Default is False
name  name given to container

CPU shares (relative weight)
cpuset  CPUs in which to allow execution ('0-3' or '0,1')

CLI Example:

salt '*' docker.create_container o/ubuntu volumes=['/s','/m:/f']

31.16. Full list of builtin execution modules 799
salt.modules.dockerio.get_container_root(container)

Get the container rootfs path

container container id or grain

CLI Example:

    salt '*' docker.get_container_root <container id>

salt.modules.dockerio.get_containers(all=True, trunc=False, since=None, before=None, limit=1, host=False, inspect=False)

Get a list of mappings representing all containers

all return all containers, Default is True

trunc set it to True to have the short ID, Default is False

host include the Docker host's ipv4 and ipv6 address in return, Default is False

inspect Get more granular information about each container by running a docker inspect

CLI Example:

    salt '*' docker.get_containers
    salt '*' docker.get_containers host=True
    salt '*' docker.get_containers host=True inspect=True

salt.modules.dockerio.get_images(name=None, quiet=False, all=True)

List docker images

name repository name

quiet only show image id, Default is False

all show all images, Default is True

CLI Example:

    salt '*' docker.get_images <name> [quiet=True|False] [all=True|False]

salt.modules.dockerio.import_image(src, repo, tag=None)

Import content from a local tarball or a URL to a docker image

src content to import (URL or absolute path to a tarball)

repo repository to import to

tag set tag of the image (Optional)

CLI Example:

    salt '*' docker.import_image <src> <repo> [tag]

salt.modules.dockerio.info()

Get the version information about docker. This is similar to docker info command

CLI Example:

    salt '*' docker.info

salt.modules.dockerio.inspect_container(container)

Get container information. This is similar to docker inspect command but only for containers

container container id
CLI Example:

```bash
clear
salt '*' docker.inspect_container <container id>
```

**salt.modules.dockerio.inspect_image**(*image*)

Inspect the status of an image and return relative data. This is similar to docker inspect command but only for images

*image* name of the image

CLI Example:

```bash
clear
salt '*' docker.inspect_image <image>
```

**salt.modules.dockerio.is_running**(*container*)

Check if the specified container is running

*container* container id

Returns True if container is running otherwise returns False

CLI Example:

```bash
clear
salt '*' docker.is_running <container id>
```

**salt.modules.dockerio.kill**(*container, signal=None*)

Kill a running container

*container* container id

*signal* signal to send

New in version 2015.8.0.

CLI Example:

```bash
clear
salt '*' docker.kill <container id>
```

**salt.modules.dockerio.load**(*imagepath*)

Load the specified file at imagepath into docker that was generated from a docker save command e.g. docker load < imagepath

*imagepath* imagepath to docker tar file

CLI Example:

```bash
clear
salt '*' docker.load /path/to/image
```

**salt.modules.dockerio.login**(*url=None, username=None, password=None, email=None*)

Wrapper to the docker.py login method (does not do much yet)

*url* registry url to authenticate to

*username* username to authenticate

*password* password to authenticate

*email* email to authenticate

CLI Example:

```bash
clear
salt '*' docker.login <url> <username> <password> <email>
```

**salt.modules.dockerio.logs**(*container*)

Return logs for a specified container
container  container id

CLI Example:
```
salt '*' docker.logs <container id>
```

```
salt.modules.dockerio.port(container, private_port)
```

Private port mapping allocation information. This method is broken on docker-py side. Just use the result of inspect to mangle port allocation

container  container id

private_port  private port on the container to query for

CLI Example:
```
salt '*' docker.port <container id> <private port>
```

```
salt.modules.dockerio.pull(repo, tag=None, insecure_registry=False)
```

Pulls an image from any registry. See documentation at top of this page to configure authenticated access

repo  name of repository

tag  specific tag to pull (Optional)

insecure_registry  set as True to use insecure (non HTTPS) registry. Default is False (only available if using docker-py >= 0.5.0)

CLI Example:
```
salt '*' docker.pull <repository> [tag]
```

```
salt.modules.dockerio.push(repo, tag=None, quiet=False, insecure_registry=False)
```

Pushes an image to any registry. See documentation at top of this page to configure authenticated access

repo  name of repository

tag  specific tag to push (Optional)

quiet  set as True to quiet output, Default is False

insecure_registry  set as True to use insecure (non HTTPS) registry. Default is False (only available if using docker-py >= 0.5.0)

CLI Example:
```
salt '*' docker.push <repository> [tag] [quiet=True|False]
```

```
salt.modules.dockerio.remove_container(container, force=False, v=False)
```

Remove a container from a docker installation

container  container id

force  remove a running container, Default is False

v  remove the volumes associated to the container, Default is False

CLI Example:
```
salt '*' docker.remove_container <container id> [force=True|False] [v=True|False]
```

```
salt.modules.dockerio.remove_image(image)
```

Remove an image from a system.

image  name of image
CLI Example:
```bash
salt '*' docker.remove_image <image>
```

salt.modules.dockerio.restart(containter, timeout=10)

- Restart a running container
  - `container` container id
  - `timeout` timeout for container to exit gracefully before killing it, Default is 10 seconds

CLI Example:
```bash
salt '*' docker.restart <container id> [timeout=20]
```

salt.modules.dockerio.retcode(containter, cmd)

- Wrapper for cmdmod.retcode inside a container context
  - `container` container id (or grain)
  - `cmd` command to execute

**Note:** The return is a bit different as we use the docker struct. Output of the command is in `out` and result is `False` if command failed to execute.

**Warning:** Be advised that this function allows for raw shell access to the named container! If allowing users to execute this directly it may allow more rights than intended!

CLI Example:
```bash
salt '*' docker.retcode <container id> 'ls -l /etc'
```

salt.modules.dockerio.run(containter, cmd)

- Wrapper for cmdmod.run inside a container context
  - `container` container id (or grain)
  - `cmd` command to execute

**Note:** The return is a bit different as we use the docker struct. Output of the command is in `out` and result is `True`.

**Warning:** Be advised that this function allows for raw shell access to the named container! If allowing users to execute this directly it may allow more rights than intended!

CLI Example:
```bash
salt '*' docker.run <container id> 'ls -l /etc'
```

salt.modules.dockerio.run_all(containter, cmd)

- Wrapper for cmdmod.run_all inside a container context
  - `container` container id (or grain)
  - `cmd` command to execute

**Note:** The return is a bit different as we use the docker struct. Output of the command is in `out` and result is `False` if command failed to execute.
Warning: Be advised that this function allows for raw shell access to the named container! If allowing users to execute this directly it may allow more rights than intended!

CLI Example:
```
salt '*' docker.run_all <container id> 'ls -l /etc'
```

```
salt.modules.dockerio.run_stderr(container, cmd)
    Wrapper for cmdmod.run_stderr inside a container context
    container  container id (or grain)
    cmd        command to execute

    Note: The return is a bit different as we use the docker struct. Output of the command is in `out` and result is always True.
```

Warning: Be advised that this function allows for raw shell access to the named container! If allowing users to execute this directly it may allow more rights than intended!

CLI Example:
```
salt '*' docker.run_stderr <container id> 'ls -l /etc'
```

```
salt.modules.dockerio.run_stdout(container, cmd)
    Wrapper for cmdmod.run_stdout inside a container context
    container  container id (or grain)
    cmd        command to execute

    Note: The return is a bit different as we use the docker struct. Output of the command is in `out` and result is always True.
```

Warning: Be advised that this function allows for raw shell access to the named container! If allowing users to execute this directly it may allow more rights than intended!

CLI Example:
```
salt '*' docker.run_stdout <container id> 'ls -l /etc'
```

```
salt.modules.dockerio.save(image, filename)
    New in version 2015.5.0.
    Save the specified image to filename from docker e.g. docker save image > filename
    image  name of image
    filename  The filename of the saved docker image

    CLI Example:
```
salt '*' docker.save arch_image /path/to/save/image
```

```
salt.modules.dockerio.script(container, source, args=None, cwd=None, stdin=None, runas=None, shell='/bin/bash', env=None, template='jinja', umask=None, timeout=None, reset_system_locale=True, no_clean=False, saltenv='base')
```
Wrapper for `cmdmod.script` inside a container context

**container** container id (or grain)

**additional parameters** See `cmd.script`

**Warning:** Be advised that this function allows for raw shell access to the named container! If allowing users to execute this directly it may allow more rights than intended!

Download a script from a remote location and execute the script in the container. The script can be located on the salt master file server or on an HTTP/FTP server.

The script will be executed directly, so it can be written in any available programming language.

The script can also be formatted as a template, the default is jinja. Arguments for the script can be specified as well.

**CLI Example:**

```
salt '*' docker.script <container id> salt://docker_script.py
salt '*' docker.script <container id> salt://scripts/runme.sh 'arg1 arg2 "arg 3"'
salt '*' docker.script <container id> salt://scripts/windows_task.ps1 args=' -Input c:\tmp\infile.txt'
```

A string of standard input can be specified for the command to be run using the stdin parameter. This can be useful in cases where sensitive information must be read from standard input:

**CLI Example:**

```
salt '*' docker.script <container id> salt://scripts/runme.sh stdin='one	two
three
four
five'
```

salt.modules.dockerio.script_retcode(`container`, `source`, `cwd=None`, `runas=None`,
`shell='/bin/bash', env=None, `template='jinja'
`umask=None, `timeout=None`, `reset_system_locale=True`,
`no_clean=False`, `saltenv='base'`)  

Wrapper for `cmdmod.script_retcode` inside a container context

**container** container id (or grain)

**additional parameters** See `cmd.script_retcode`

**Warning:** Be advised that this function allows for raw shell access to the named container! If allowing users to execute this directly it may allow more rights than intended!

**CLI Example:**

```
salt '*' docker.script_retcode <container id> salt://docker_script.py
```

salt.modules.dockerio.search(`term`)  
Search for an image on the registry

**term** search keyword

**CLI Example:**

```
salt '*' docker.search <term>
```

salt.modules.dockerio.start(`container`, `binds=None`, `port_bindings=None`,
`lxc_conf=None, publish_all_ports=None`, `links=None`, privileged=False, `dns=None`,
`volumes_from=None`, `network_mode=None`, `restart_policy=None`,
`cap_add=None`, `cap_drop=None`)  
Start the specified container
```python
container  container id

CLI Example:
salt '*' docker.start <container id>

salt.modules.dockerio.stop(container, timeout=10)
Stop a running container

container  container id
timeout  timeout for container to exit gracefully before killing it, Default is 10 seconds

CLI Example:
salt '*' docker.stop <container id> [timeout=20]

salt.modules.dockerio.tag(image, repository, tag=None, force=False)
Tag an image into a repository

image  name of image
repository  name of repository
tag  tag to apply (Optional)
force  force apply tag. Default is False

CLI Example:
salt '*' docker.tag <image> <repository> [tag] [force=True|False]

salt.modules.dockerio.top(container)
Run the docker top command on a specific container

container  container id

CLI Example:
salt '*' docker.top <container id>

salt.modules.dockerio.version()
Get docker version

CLI Example:
salt '*' docker.version

salt.modules.dockerio.wait(container)
Wait for a container to exit gracefully

container  container id

CLI Example:
salt '*' docker.wait <container id>
```

### 31.16.69 salt.modules.dockerng

Management of Docker Containers

New in version 2015.8.0.
Why Make a Second Docker Module?

We have received a lot of feedback on our Docker support. In the process of implementing recommended improvements, it became obvious that major changes needed to be made to the functions and return data. In the end, a complete rewrite was done.

The changes being too significant, it was decided that making a separate execution module and state module (called dockerng) would be the best option. This will give users a couple release cycles to modify their scripts, SLS files, etc. to use the new functionality, rather than forcing users to change everything immediately.

In the Carbon release of Salt (due early 2016), this execution module will take the place of the default Docker execution module, and backwards-compatible naming will be maintained for a couple releases after that to allow users time to replace references to dockerng with docker.

Installation Prerequisites

This execution module requires at least version 1.0.0 of both docker-py and Docker. docker-py can easily be installed using pip.install:

```
salt myminion pip.install docker-py
```

Authentication

To push or pull images, credentials must be configured. Because a password must be used, it is recommended to place this configuration in Pillar data. The configuration schema is as follows:

```python
docker-registries:
    <registry_url>:
        email: <email_address>
        password: <password>
        username: <username>
```

For example:

```python
docker-registries:
    https://index.docker.io/v1/:
        email: foo@foo.com
        password: s3cr3t
        username: foo
```

Multiple registries can be configured. This can be done in one of two ways. The first way is to configure each registry under the docker-registries pillar key.

```python
docker-registries:
    https://index.foo.io/v1/:
        email: foo@foo.com
        password: s3cr3t
        username: foo
    https://index.bar.io/v1/:
        email: foo@foo.com
        password: s3cr3t
        username: foo
```

The second way is to use separate pillar variables ending in -docker-registries:
foo-docker-registries:
  https://index.foo.io/v1/:
  email: foo@foo.com
  password: s3cr3t
  username: foo

bar-docker-registries:
  https://index.bar.io/v1/:
  email: foo@foo.com
  password: s3cr3t
  username: foo

Both methods can be combined; any registry configured under docker-registries or *-docker-registries will be detected.

Configuration Options

The following options can be set in the minion config:

- `docker.url`: URL to the docker service (default: local socket).
- `docker.version`: API version to use (default: currently 1.4 API).
- `docker.exec_driver`: Execution driver to use, one of the following:
  - nsenter
  - lxc-attach
  - docker-exec

See *Executing Commands Within a Running Container*.

Functions

- Information Gathering
  - `dockerng.depends`
  - `dockerng.diff`
  - `dockerng.exists`
  - `dockerng.history`
  - `dockerng.images`
  - `dockerng.info`
  - `dockerng.inspect`
  - `dockerng.inspect_container`
  - `dockerng.inspect_image`
  - `dockerng.list_containers`
  - `dockerng.list_tags`
  - `dockerng.logs`
  - `dockerng.pid`
  - `dockerng.port`
- dockerng.ps
- dockerng.state
- dockerng.search
- dockerng.top
- dockerng.version

• **Container Management**
  - dockerng.create
  - dockerng.copy_from
  - dockerng.copy_to
  - dockerng.export
  - dockerng.rm

• **Management of Container State**
  - dockerng.kill
  - dockerng.pause
  - dockerng.restart
  - dockerng.start
  - dockerng.stop
  - dockerng.unpause
  - dockerng.wait

• **Image Management**
  - dockerng.build
  - dockerng.commit
  - dockerng.dangling
  - dockerng.import
  - dockerng.load
  - dockerng.pull
  - dockerng.push
  - dockerng.rmi
  - dockerng.save
  - dockerng.tag

**Executing Commands Within a Running Container**

Multiple methods exist for executing commands within Docker containers:

- **lxc-attach**: Default for older versions of docker
- **nsenter**: Enters container namespace to run command
- **docker-exec**: Native support for executing commands in Docker containers (added in Docker 1.3)
Adding a configuration option (see `config.get`) called `docker.exec_driver` will tell Salt which execution driver to use:

```
docker.exec_driver: docker-exec
```

If this configuration option is not found, Salt will use the appropriate interface (either `nsenter` or `lxc-attach`) based on the `Execution Driver` value returned from `docker info`. `docker-exec` will not be used by default, as it is presently (as of version 1.6.2) only able to execute commands as the effective user of the container. Thus, if a `USER` directive was used to run as a non-privileged user, `docker-exec` would be unable to perform the action as root. Salt can still use `docker-exec` as an execution driver, but must be explicitly configured (as in the example above) to do so at this time.

If possible, try to manually specify the execution driver, as it will save Salt a little work.

This execution module provides functions that shadow those from the `cmd` module. They are as follows:

- `dockerng.retcode`
- `dockerng.run`
- `dockerng.run_all`
- `dockerng.run_stderr`
- `dockerng.run_stdout`
- `dockerng.script`
- `dockerng.script_retcode`

**Detailed Function Documentation**

### `salt.modules.dockerng.build`(`path=None, image=None, cache=True, rm=True, api_response=False, fileobj=None`) Build a docker image from a Dockerfile or a URL

- **path** Path to directory on the Minion containing a Dockerfile
- **image** Image to be built, in `repo:tag` notation. If just the repository name is passed, a tag name of `latest` will be assumed. If building from a URL, this parameter can be omitted.
- **cache** [True] Set to `False` to force the build process not to use the Docker image cache, and pull all required intermediate image layers
- **rm** [True] Remove intermediate containers created during build
- **api_response** [False] If `True`: an `API_Response` key will be present in the return data, containing the raw output from the Docker API.
- **fileobj** Allows for a file-like object containing the contents of the Dockerfile to be passed in place of a file `path` argument. This argument should not be used from the CLI, only from other Salt code.

**RETURN DATA**

A dictionary containing one or more of the following keys:

- **Id** - ID of the newly-built image
- **Time_Elapsed** - Time in seconds taken to perform the build
- **Intermediate_Containers** - IDs of containers created during the course of the build process
  
  *(Only present if `rm=False`)*
- **Images** - A dictionary containing one or more of the following keys:
– Already_Pulled - Layers that were already present on the Minion
– Pulled - Layers that were pulled
(Only present if the image specified by the "image" argument was not present on the Minion, or if cache=False)

• Status - A string containing a summary of the pull action (usually a message saying that an image was downloaded, or that it was up to date).
(Only present if the image specified by the "image" argument was not present on the Minion, or if cache=False)

CLI Example:
salt myminion dockerng.build /path/to/docker/build/dir image=myimage:dev
salt myminion dockerng.build https://github.com/myuser/myrepo.git image=myimage:latest

salt.modules.dockerng.commit(name, image, message=None, author=None)
Commits a container, thereby promoting it to an image. Equivalent to running the docker commit Docker CLI command.

name Container name or ID to commit
image Image to be committed, in repo:tag notation. If just the repository name is passed, a tag name of latest will be assumed.
message Commit message (Optional)
author Author name (Optional)

RETURN DATA
A dictionary containing the following keys:

• Id - ID of the newly-created image
• Image - Name of the newly-created image
• Time_Elapsed - Time in seconds taken to perform the commit

CLI Example:
salt myminion dockerng.commit mycontainer myuser/myimage
salt myminion dockerng.commit mycontainer myuser/myimage:mytag

salt.modules.dockerng.copy_from(name, *args, **kwargs)
Copy a file from inside a container to the Minion

name Container name
source Path of the file on the container's filesystem
dest Destination on the Minion. Must be an absolute path. If the destination is a directory, the file will be copied into that directory.
overwrite [False] Unless this option is set to True, then if a file exists at the location specified by the dest argument, an error will be raised.
makedirs [False] Create the parent directory on the container if it does not already exist.

RETURN DATA
A boolean (True if successful, otherwise False)

CLI Example:
salt myminion docker-ng.copy_from mycontainer /var/log/nginx/access.log /home/myuser

salt.modules.docker-ng.copy_to(name, *args, **kwargs)
Copy a file from the host into a container

name  Container name

source  File to be copied to the container. Can be a local path on the Minion or a remote file from the Salt fileserver.

dest  Destination on the container. Must be an absolute path. If the destination is a directory, the file will be copied into that directory.

exec_driver  [None] If not passed, the execution driver will be detected as described above.

overwrite  [False] Unless this option is set to True, then if a file exists at the location specified by the dest argument, an error will be raised.

makedirs  [False] Create the parent directory on the container if it does not already exist.

RETURN DATA
A boolean (True if successful, otherwise False)

CLI Example:
salt myminion docker-ng.copy_to mycontainer /tmp/foo /root/foo

salt.modules.docker-ng.create(*args, **kwargs)
Create a new container

name  Name for the new container. If not provided, Docker will randomly generate one for you.

image  Image from which to create the container

command  Command to run in the container

Example: command=bash

hostname  Hostname of the container. If not provided, and if a name has been provided, the hostname will default to the name that was passed.

Example: hostname=web1

Warning: If the container is started with network_mode=host, the hostname will be overridden by the hostname of the Minion.

domainname  Domain name of the container

Example: domainname=domain.tld

interactive  [False] Leave stdin open

Example: interactive=True

tty  [False] Attach TTYs

Example: tty=True

detach  [True] If True, run command in the background (daemon mode)

Example: detach=False

user  User under which to run docker

Example: user=foo
memory  [0] Memory limit. Can be specified in bytes or using single-letter units (i.e. 512M, 2G, etc.). A value of 0 (the default) means no memory limit.
Example: memory=512M, memory=1073741824

memory_swap  [-1] Total memory limit (memory plus swap). Set to -1 to disable swap. A value of 0 means no swap limit.
Example: memory_swap=1G, memory_swap=2147483648

mac_address  MAC address to use for the container. If not specified, a random MAC address will be used.
Example: mac_address=01:23:45:67:89:0a

network_disabled  [False] If True, networking will be disabled within the container.
Example: network_disabled=True

working_dir  Working directory inside the container
Example: working_dir=/var/log/nginx

entrypoint  Entrypoint for the container. Either a string (e.g. "mycmd --arg1 --arg2") or a Python list (e.g. "['mycmd', '--arg1', '--arg2']")
Example: entrypoint="cat access.log"

environment  Either a dictionary of environment variable names and their values, or a Python list of strings in the format VARNAME=value.
Example: "{'VAR1': 'value', 'VAR2': 'value'}", "['VAR1=value', 'VAR2=value']"

ports  A list of ports to expose on the container. Can be passed as comma-separated list or a Python list. If the protocol is omitted, the port will be assumed to be a TCP port.
Example: 1111,2222/udp, "['1111/tcp', '2222/udp']"

volumes  [None] List of directories to expose as volumes. Can be passed as a comma-separated list or a Python list.
Example: volumes=/mnt/vol1,/mnt/vol2, volumes="[/mnt/vol1, /mnt/vol2]"

cpu_shares  CPU shares (relative weight)
Example: cpu_shares=0.5, cpu_shares=1

cpuset  CPUs on which which to allow execution, specified as a string containing a range (e.g. 0-3) or a comma-separated list of CPUs (e.g. 0,1).
Example: cpuset="0-3", cpuset="0,1"

client_timeout  Timeout in seconds for the Docker client. This is not a timeout for this function, but for receiving a response from the API.

Note: This is only used if Salt needs to pull the requested image.

RETURN DATA
A dictionary containing the following keys:
•Id - ID of the newly-created container
•Name - Name of the newly-created container

CLI Example:
# Create a data-only container
```
salt myminion dockerng.create myuser/mycontainer volumes="/mnt/vol1,/mnt/vol2"
```

# Create a CentOS 7 container that will stay running once started
```
salt myminion dockerng.create centos:7 name=mycent7 interactive=True tty=True command=bash
```

salt.modules.dockerng.dangling(prune=False, force=False)

Return top-level images (those on which no other images depend) which do not have a tag assigned to them. These include:

- Images which were once tagged but were later untagged, such as those which were superseded by committing a new copy of an existing tagged image.
- Images which were loaded using `docker.load` (or the `docker load` Docker CLI command), but not tagged.

**prune** [False] Remove these images

**force** [False] If True, and if prune=True, then forcibly remove these images.

**RETURN DATA**

If prune=False, the return data will be a list of dangling image IDs.

If prune=True, the return data will be a dictionary with each key being the ID of the dangling image, and the following information for each image:

- **Comment** - Any error encountered when trying to prune a dangling image
  
  *(Only present if prune failed)*

- **Removed** - A boolean (True if prune was successful, False if not)

**CLI Example:**
```
salt myminion dockerng.dangling
salt myminion dockerng.dangling prune=True
```

salt.modules.dockerng.depends(name)

Returns the containers and images, if any, which depend on the given image

**name** Name or ID of image

**RETURN DATA**

A dictionary containing the following keys:

- **Containers** - A list of containers which depend on the specified image

- **Images** - A list of IDs of images which depend on the specified image

**CLI Example:**
```
salt myminion dockerng.depends myimage
salt myminion dockerng.depends 0123456789ab
```

salt.modules.dockerng.diff(name, *args, **kwargs)

Get information on changes made to container’s filesystem since it was created. Equivalent to running the `docker diff` Docker CLI command.

**name** Container name or ID

**RETURN DATA**

A dictionary containing any of the following keys:
- **Added** - A list of paths that were added.
- **Changed** - A list of paths that were changed.
- **Deleted** - A list of paths that were deleted.

These keys will only be present if there were changes, so if the container has no differences the return dict will be empty.

CLI Example:

```bash
salt myminion dockerng.diff mycontainer
```

**salt.modules.dockerng.exists(name)**

Check if a given container exists

**RETURN DATA**

A boolean (True if the container exists, otherwise False)

CLI Example:

```bash
salt myminion dockerng.exists mycontainer
```

**salt.modules.dockerng.export(name, *args, **kwargs)**

Exports a container to a tar archive. It can also optionally compress that tar archive, and push it up to the Master.

- **name** Container name or ID
- **path** Absolute path on the Minion where the container will be exported
- **overwrite** [False] Unless this option is set to True, then if a file exists at the location specified by the path argument, an error will be raised.
- **makedirs** [False] If True, then if the parent directory of the file specified by the path argument does not exist, Salt will attempt to create it.
- **compression** [None] Can be set to any of the following:
  - gzip or gz for gzip compression
  - bzip2 or bz2 for bzip2 compression
  - xz or lzma for XZ compression (requires xz-utils, as well as the lzma module from Python 3.3, available in Python 2 and Python 3.0-3.2 as backports.lzma)

This parameter can be omitted and Salt will attempt to determine the compression type by examining the filename passed in the path parameter.

- **push** [False] If True, the container will be pushed to the master using cp.push.

Note: This requires file_recv to be set to True on the Master.

**RETURN DATA**

A dictionary will containing the following keys:

- **Path** - Path of the file that was exported
- **Push** - Reports whether or not the file was successfully pushed to the Master

(Only present if push=True)
- **Size** - Size of the file, in bytes
- **Size_Human** - Size of the file, in human-readable units
- **Time_Elapsed** - Time in seconds taken to perform the export

**CLI Examples:**

```bash
salt myminion dockerng.export mycontainer /tmp/mycontainer.tar
salt myminion dockerng.export mycontainer /tmp/mycontainer.tar.xz push=True
```

### `salt.modules.dockerng.history(name, quiet=False)`

Return the history for an image. Equivalent to running the `docker history` Docker CLI command.

**name** Container name or ID

**quiet** [False] If True, the return data will simply be a list of the commands run to build the container.

```bash
$ salt myminion dockerng.history nginx:latest quiet=True
myminion:
- FROM scratch
- ADD file:e063ed80ae9579362871b9f23b2c0781ef7cd4e6ac822052cf6c9c5a12b1e2 in /
- CMD [/bin/bash]
- MAINTAINER NGINX Docker Maintainers "docker-maint@nginx.com"
- apt-key adv --keyserver pgp.mit.edu --recv-keys 573BFD6B3D8FBC641079A6ABABF5BD8727BD9FB
- echo "deb http://nginx.org/packages/mainline/debian/ wheezy nginx" >> /etc/apt/sources.list
- ENV NGINX_VERSION=1.7.10-1-wheezy
- apt-get update && apt-get install -y ca-certificates nginx=${NGINX_VERSION} &&
- ln -sf /dev/stdout /var/log/nginx/access.log
- ln -sf /dev/stderr /var/log/nginx/error.log
- VOLUME [var/cache/nginx]
- EXPOSE map[80/tcp:{}] 443/tcp:{}]
- CMD [nginx -g daemon off;]

https://github.com/saltstack/salt/pull/22421
```

**RETURN DATA**

If `quiet=False`, the return value will be a list of dictionaries containing information about each step taken to build the image. The keys in each step include the following:

- **Command** - The command executed in this build step
- **Id** - Layer ID
- **Size** - Cumulative image size, in bytes
- **Size_Human** - Cumulative image size, in human-readable units
- **Tags** - Tag(s) assigned to this layer
- **Time_Created_Epoch** - Time this build step was completed (Epoch time)
- **Time_Created_Local** - Time this build step was completed (Minion's local timezone)

**CLI Example:**

```bash
salt myminion dockerng.exists mycontainer
```

### `salt.modules.dockerng.images(verbos=False, **kwargs)`

Returns information about the Docker images on the Minion. Equivalent to running the `docker images` Docker CLI command.

**all** [False] If True, untagged images will also be returned

**verbose** [False] If True, a `docker inspect` will be run on each image returned.
**RETURN DATA**

A dictionary with each key being an image ID, and each value some general info about that image (time created, size, tags associated with the image, etc.)

CLI Example:

```python
salt myminion dockerng.images
salt myminion dockerng.images all=True
```

`salt.modules.dockerng.import(source, image, api_response=False)`

Imports content from a local tarball or a URL as a new docker image

- **source** Content to import (URL or absolute path to a tarball). URL can be a file on the Salt fileserver (i.e. `salt://path/to/rootfs/tarball.tar.xz`). To import a file from a saltenv other than base (e.g. `dev`), pass it at the end of the URL (ex. `salt://path/to/rootfs/tarball.tar.xz?saltenv=dev`).

- **image** Image to be created by the import, in `repo:tag` notation. If just the repository name is passed, a tag name of `latest` will be assumed.

- **api_response** [False] If True an `api_response` key will be present in the return data, containing the raw output from the Docker API.

**RETURN DATA**

A dictionary containing the following keys:

- **Id** - ID of the newly-created image
- **Image** - Name of the newly-created image
- **Time_Elapsed** - Time in seconds taken to perform the commit

CLI Example:

```python
salt myminion dockerng.import /tmp/cent7-minimal.tar.xz myuser/centos
salt myminion dockerng.import /tmp/cent7-minimal.tar.xz myuser/centos:7
salt myminion dockerng.import salt://dockerimages/cent7-minimal.tar.xz myuser/centos:7
```

`salt.modules.dockerng.info(*args, **kwargs)`

Returns a dictionary of system-wide information. Equivalent to running the `docker info` Docker CLI command.

CLI Example:

```python
salt myminion dockerng.info
```

`salt.modules.dockerng.inspect(name)`

This is a generic container/image inspecton function. It will first attempt to get container information for the passed name/ID using `docker.inspect_container`, and then will try to get image information for the passed name/ID using `docker.inspect_image`. If it is already known that the name/ID is an image, it is slightly more efficient to use `docker.inspect_image`.

- **name** Container/image name or ID

**RETURN DATA**

A dictionary of container/image information

CLI Example:

```python
salt myminion dockerng.inspect mycontainer
salt myminion dockerng.inspect busybox
```
salt.modules.dockerng.inspect_container(name, *args, **kwargs)
Retrieves container information. Equivalent to running the docker inspect Docker CLI command, but
will only look for container information.

**name** Container name or ID

**RETURN DATA**
A dictionary of container information

**CLI Example:**
salt myminion dockerng.inspect_container mycontainer
salt myminion dockerng.inspect_container 0123456789ab

salt.modules.dockerng.inspect_image(name)
Retrieves image information. Equivalent to running the docker inspect Docker CLI command, but will
only look for image information.

**name** Image name or ID

**RETURN DATA**
A dictionary of image information

**CLI Examples:**
salt myminion dockerng.inspect_image busybox
salt myminion dockerng.inspect_image centos:6
salt myminion dockerng.inspect_image 0123456789ab

salt.modules.dockerng.kill(*args, **kwargs)
Kill all processes in a running container instead of performing a graceful shutdown

**name** Container name or ID

**RETURN DATA**
A dictionary will be returned, containing the following keys:

- **status** - A dictionary showing the prior state of the container as well as the new state
- **result** - A boolean noting whether or not the action was successful
- **comment** - Only present if the container cannot be killed

**CLI Example:**
salt myminion dockerng.kill mycontainer

salt.modules.dockerng.layers(name)
Returns a list of the IDs of layers belonging to the specified image, with the top-most layer (the one corresp-onding to the passed name) appearing last.

**name** Image name or ID

**CLI Example:**
salt myminion dockerng.layers centos:7

salt.modules.dockerng.list_containers(**kwargs)
Returns a list of containers by name. This is different from dockerng.ps in that dockerng.ps returns its results organized by container ID.

**all** [False] If True, stopped containers will be included in return data
CLI Example:

```python
salt myminion dockerng.inspect_image <image>
```

`salt.modules.dockerng.list_tags()`  
Returns a list of tagged images  
CLI Example:  
```python
salt myminion dockerng.list_tags
```

`salt.modules.dockerng.load(path, image=None)`  
Load a tar archive that was created using `dockerng.save` (or via the Docker CLI using `docker save`).  
**path** Path to docker tar archive. Path can be a file on the Minion, or the URL of a file on the Salt files server (i.e. `salt://path/to/docker/saved/image.tar`). To load a file from a saltenv other than base (e.g. dev), pass it at the end of the URL (ex. `salt://path/to/rootfs/tarball.tar.xz?saltenv=dev`).  
**image** [None] If specified, the topmost layer of the newly-loaded image will be tagged with the specified repo and tag using `dockerng.tag`. The image name should be specified in `repo:tag` notation. If just the repository name is passed, a tag name of `latest` will be assumed.  

**RETURN DATA**  
A dictionary will be returned, containing the following keys:  
- **Path** - Path of the file that was saved  
- **Layers** - A list containing the IDs of the layers which were loaded. Any layers in the file that was loaded, which were already present on the Minion, will not be included.  
- **Image** - Name of tag applied to topmost layer  
  *(Only present if tag was specified and tagging was successful)*  
- **Time_Elapsed** - Time in seconds taken to load the file  
- **Warning** - Message describing any problems encountered in attempt to tag the topmost layer  
  *(Only present if tag was specified and tagging failed)*  

CLI Example:  
```python
salt myminion dockerng.load /path/to/image.tar  
salt myminion dockerng.load salt://path/to/docker/saved/image.tar image=myuser/myimage:mytag
```

`salt.modules.dockerng.logs(name)`  
Returns the logs for the container. Equivalent to running the `docker logs` Docker CLI command.  
**name** Container name or ID  
CLI Example:  
```python
salt myminion dockerng.logs mycontainer
```

`salt.modules.dockerng.pause(*args, **kwargs)`  
Pauses a container  
**name** Container name or ID  

**RETURN DATA**  
A dictionary will be returned, containing the following keys:
• **status** - A dictionary showing the prior state of the container as well as the new state
• **result** - A boolean noting whether or not the action was successful
• **comment** - Only present if the container cannot be paused

CLI Example:

```bash
salt myminion dockerng.pause mycontainer
```

salt.modules.dockerng.pid(name, *args, **kwargs)

Returns the PID of a container

- **name** Container name or ID

CLI Example:

```bash
salt myminion dockerng.pid mycontainer
salt myminion dockerng.pid 0123456789ab
```

salt.modules.dockerng.port(name, *args, **kwargs)

Returns port mapping information for a given container. Equivalent to running the `docker port` Docker CLI command.

- **name** Container name or ID

- **private_port** [None] If specified, get information for that specific port. Can be specified either as a port number (i.e. 5000), or as a port number plus the protocol (i.e. 5000/udp).

  If this argument is omitted, all port mappings will be returned.

**RETURN DATA**

A dictionary of port mappings, with the keys being the port and the values being the mapping(s) for that port.

CLI Examples:

```bash
salt myminion dockerng.port mycontainer
salt myminion dockerng.port mycontainer 5000
salt myminion dockerng.port mycontainer 5000/udp
```

salt.modules.dockerng.ps(**kwargs)

Returns information about the Docker containers on the Minion. Equivalent to running the `docker ps` Docker CLI command.

- **all** [False] If True, stopped containers will also be returned

- **host** False If True, local host's network topology will be included

- **verbose** [False] If True, a `docker inspect` will be run on each container returned.

**RETURN DATA**

A dictionary with each key being an container ID, and each value some general info about that container (time created, name, command, etc.)

CLI Example:

```bash
salt myminion dockerng.ps
salt myminion dockerng.ps all=True
```

salt.modules.dockerng.pull(image, insecure_registry=False, api_response=False, client_timeout=60)

Pulls an image from a Docker registry. See the documentation at the top of this page to configure authenticated access.
image  Image to be pulled, in repo:tag notation. If just the repository name is passed, a tag name of latest will be assumed.

insecure_registry  [False] If True, the Docker client will permit the use of insecure (non-HTTPS) registries.

api_response  [False] If True, an API_Response key will be present in the return data, containing the raw output from the Docker API.

Note: This may result in a lot of additional return data, especially for larger images.

client_timeout  Timeout in seconds for the Docker client. This is not a timeout for this function, but for receiving a response from the API.

RETURN DATA
A dictionary will be returned, containing the following keys:

- **Layers** - A dictionary containing one or more of the following keys:
  - Already_Pulled - Layers that that were already present on the Minion
  - Pulled - Layers that that were pulled
- **Status** - A string containing a summary of the pull action (usually a message saying that an image was downloaded, or that it was up to date).
- **Time_Elapsed** - Time in seconds taken to perform the pull

CLI Example:

```bash
cat
```

```bash
salt myminion dockerng.push centos
salt myminion dockerng.push centos:6
```

salt.modules.dockerng.push(image, insecure_registry=False, api_response=False, client_timeout=60)

Pushes an image to a Docker registry. See the documentation at top of this page to configure authenticated access.

image  Image to be pushed, in repo:tag notation. If just the repository name is passed, a tag name of latest will be assumed.

insecure_registry  [False] If True, the Docker client will permit the use of insecure (non-HTTPS) registries.

api_response  [False] If True, an API_Response key will be present in the return data, containing the raw output from the Docker API.

client_timeout  Timeout in seconds for the Docker client. This is not a timeout for this function, but for receiving a response from the API.

RETURN DATA
A dictionary will be returned, containing the following keys:

- **Id** - ID of the image that was pushed
- **Image** - Name of the image that was pushed
- **Layers** - A dictionary containing one or more of the following keys:
  - Already_Pushed - Layers that that were already present on the Minion
  - Pushed - Layers that that were pushed
- **Time_Elapsed** - Time in seconds taken to perform the push

CLI Example:
salt modules.dockerng.restart(name, *args, **kwargs)

Restarts a container

name Container name or ID

timeout [10] Timeout in seconds after which the container will be killed (if it has not yet gracefully shut down)

RETURN DATA

A dictionary will be returned, containing the following keys:

- status - A dictionary showing the prior state of the container as well as the new state
- result - A boolean noting whether or not the action was successful
- restarted - If restart was successful, this key will be present and will be set to True.

CLI Examples:

salt myminion dockerng.restart mycontainer
salt myminion dockerng.restart mycontainer timeout=20

salt modules.dockerng.retcode(name, cmd, exec_driver=None, stdin=None, python_shell=True, output_loglevel='debug', use_vt=False, ignore_retcode=False, keep_env=None)

Run cmd.retcode within a container

name Container name or ID in which to run the command

cmd Command to run

exec_driver [None] If not passed, the execution driver will be detected as described above.

stdin [None] Standard input to be used for the command

output_loglevel [debug] Level at which to log the output from the command. Set to quiet to suppress logging.

use_vt [False] Use SaltStack's utils.vt to stream output to console.

keep_env [None] If not passed, only a sane default PATH environment variable will be set. If True, all environment variables from the container's host will be kept. Otherwise, a comma-separated list (or Python list) of environment variable names can be passed, and those environment variables will be kept.

CLI Example:

salt myminion dockerng.retcode 'ls -l /etc'

salt modules.dockerng.rm(*args, **kwargs)

Removes a container

name Container name or ID

force [False] If True, the container will be killed first before removal, as the Docker API will not permit a running container to be removed. This option is set to False by default to prevent accidental removal of a running container.

volumes [False] Also remove volumes associated with container
RETURN DATA

A list of the IDs of containers which were removed

CLI Example:

```bash
salt myminion docker. rm mycontainer
salt myminion docker. rm mycontainer force=True
```

```python
salt.modules.dockerng.rmi(*names, **kwargs)
```

Removes an image

- **name** Name (in repo:tag notation) or ID of image.
- **force** [False] If True, the image will be removed even if the Minion has containers created from that image
- **prune** [True] If True, untagged parent image layers will be removed as well, set this to False to keep them.

RETURN DATA

A dictionary will be returned, containing the following two keys:

- **Layers** - A list of the IDs of image layers that were removed
- **Tags** - A list of the tags that were removed
- **Errors** - A list of any errors that were encountered

CLI Examples:

```bash
salt myminion docker. rmi busybox
salt myminion docker. rmi busybox force=True
salt myminion docker. rmi foo bar baz
```

```python
salt.modules.dockerng.run(name, cmd, exec_driver=None, stdin=None, python_shell=True,
                          output_loglevel='debug', use_vt=False, ignore_retcode=False,
                          keep_env=None)
```

Run cmd.run within a container

- **name** Container name or ID in which to run the command
- **cmd** Command to run
- **exec_driver** [None] If not passed, the execution driver will be detected as described above.
- **stdin** [None] Standard input to be used for the command
- **output_loglevel** [debug] Level at which to log the output from the command. Set to quiet to suppress logging.
- **use_vt** [False] Use SaltStack’s utils.vt to stream output to console.
- **keep_env** [None] If not passed, only a sane default PATH environment variable will be set. If True, all environment variables from the container’s host will be kept. Otherwise, a comma-separated list (or Python list) of environment variable names can be passed, and those environment variables will be kept.

CLI Example:

```bash
salt myminion docker. run mycontainer 'ls l /etc'
```

```python
salt.modules.dockerng.run_all(name, cmd, exec_driver=None, stdin=None, python_shell=True,
                               output_loglevel='debug', use_vt=False, ignore_retcode=False,
                               keep_env=None)
```

Run cmd.run_all within a container
Note: While the command is run within the container, it is initiated from the host. Therefore, the PID in the return dict is from the host, not from the container.

name  Container name or ID in which to run the command

**cmd** Command to run

**exec_driver** [None] If not passed, the execution driver will be detected as described above.

stdin [None] Standard input to be used for the command

**output_loglevel** [debug] Level at which to log the output from the command. Set to quiet to suppress logging.

use_vt [False] Use SaltStack's utils.vt to stream output to console.

keep_env [None] If not passed, only a sane default PATH environment variable will be set. If True, all environment variables from the container's host will be kept. Otherwise, a comma-separated list (or Python list) of environment variable names can be passed, and those environment variables will be kept.

CLI Example:

```
salt myminion dockerng.run_all mycontainer 'ls -l /etc'
```

```
salt.modules.dockerng.run_stderr(name, cmd, exec_driver=None, stdin=None, python_shell=True, output_loglevel='debug', use_vt=False, ignore_retcode=False, keep_env=None)
```

Run cmd.run_stderr within a container

name  Container name or ID in which to run the command

**cmd** Command to run

**exec_driver** [None] If not passed, the execution driver will be detected as described above.

stdin [None] Standard input to be used for the command

**output_loglevel** [debug] Level at which to log the output from the command. Set to quiet to suppress logging.

use_vt [False] Use SaltStack's utils.vt to stream output to console.

keep_env [None] If not passed, only a sane default PATH environment variable will be set. If True, all environment variables from the container's host will be kept. Otherwise, a comma-separated list (or Python list) of environment variable names can be passed, and those environment variables will be kept.

CLI Example:

```
salt myminion dockerng.run_stderr mycontainer 'ls -l /etc'
```

```
salt.modules.dockerng.run_stdout(name, cmd, exec_driver=None, stdin=None, python_shell=True, output_loglevel='debug', use_vt=False, ignore_retcode=False, keep_env=None)
```

Run cmd.run_stdout within a container

name  Container name or ID in which to run the command

**cmd** Command to run

**exec_driver** [None] If not passed, the execution driver will be detected as described above.

stdin [None] Standard input to be used for the command
output_loglevel [debug] Level at which to log the output from the command. Set to quiet to suppress logging.

use_vt [False] Use SaltStack's utils.vt to stream output to console.

keep_env [None] If not passed, only a sane default PATH environment variable will be set. If True, all environment variables from the container's host will be kept. Otherwise, a comma-separated list (or Python list) of environment variable names can be passed, and those environment variables will be kept.

CLI Example:

```
salt myminion dockerng.run_stdout mycontainer 'ls -l /etc'
```

```
salt.modules.dockerng.save(name, path, overwrite=False, makedirs=False, compression=None, **kwargs)
```

Saves an image and to a file on the minion. Equivalent to running the docker save Docker CLI command, but unlike docker save this will also work on named images instead of just images IDs.

name Name or ID of image. Specify a specific tag by using the repo:tag notation.

path Absolute path on the Minion where the image will be exported

overwrite [False] Unless this option is set to True, then if the destination file exists an error will be raised.

makedirs [False] If True, then if the parent directory of the file specified by the path argument does not exist, Salt will attempt to create it.

compression [None] Can be set to any of the following:

- gzip or gz for gzip compression
- bzip2 or bz2 for bzip2 compression
- xz or lzma for XZ compression (requires xz-utils, as well as the lzma module from Python 3.3, available in Python 2 and Python 3.0-3.2 as backports.lzma)

This parameter can be omitted and Salt will attempt to determine the compression type by examining the filename passed in the path parameter.

Note: Since the Docker API does not support docker save, compression will be a bit slower with this function than with docker.export since the image(s) will first be saved and then the compression done afterwards.

push [False] If True, the container will be pushed to the master using cp.push.

Note: This requires file_recv to be set to True on the Master.

**RETURN DATA**

A dictionary will be returned, containing the following keys:

- **Path** - Path of the file that was saved
- **Push** - Reports whether or not the file was successfully pushed to the Master
  
  *(Only present if push=True)*
- **Size** - Size of the file, in bytes
- **Size_Human** - Size of the file, in human-readable units
- **Time_Elapsed** - Time in seconds taken to perform the save

CLI Examples:
```
salt myminion dockerng.save centos:7 /tmp/cent7.tar
salt myminion dockerng.save 0123456789ab cdef01234567 /tmp/saved.tar
```

salt.modules.dockerng.script(``
name, source, saltenv='base', args=None, template=None, 
exec_driver=None, stdin=None, python_shell=True, output_loglevel='debug', ignore_retcode=False, use_vt=False, 
keep_env=None)
```

Run `cmd.script` within a container

**Note:** While the command is run within the container, it is initiated from the host. Therefore, the PID in the return dict is from the host, not from the container.

**name**  Container name or ID

**source**  Path to the script. Can be a local path on the Minion or a remote file from the Salt fileserver.

**args**  A string containing additional command-line options to pass to the script.

**template**  [None] Templating engine to use on the script before running.

**exec_driver**  [None] If not passed, the execution driver will be detected as described above.

**stdin**  [None] Standard input to be used for the script

**output_loglevel**  [debug] Level at which to log the output from the script. Set to quiet to suppress logging.

**use_vt**  [False] Use SaltStack's `utils.vt` to stream output to console.

**keep_env**  [None] If not passed, only a sane default PATH environment variable will be set. If True, all environment variables from the container's host will be kept. Otherwise, a comma-separated list (or Python list) of environment variable names can be passed, and those environment variables will be kept.

**CLI Example:**
```
salt myminion dockerng.script mycontainer salt://docker_script.py
salt myminion dockerng.script mycontainer salt://scripts/runme.sh  'arg1 arg2 "arg 3"'
```

salt.modules.dockerng.script_retcode(``
name, source, saltenv='base', args=None, template=None, 
exec_driver=None, stdin=None, python_shell=True, output_loglevel='debug', ignore_retcode=False, use_vt=False, keep_env=None)
```

Run `cmd.script_retcode` within a container

**name**  Container name or ID

**source**  Path to the script. Can be a local path on the Minion or a remote file from the Salt fileserver.

**args**  A string containing additional command-line options to pass to the script.

**template**  [None] Templating engine to use on the script before running.

**exec_driver**  [None] If not passed, the execution driver will be detected as described above.

**stdin**  [None] Standard input to be used for the script

**output_loglevel**  [debug] Level at which to log the output from the script. Set to quiet to suppress logging.

**use_vt**  [False] Use SaltStack's `utils.vt` to stream output to console.

**keep_env**  [None] If not passed, only a sane default PATH environment variable will be set. If True, all environment variables from the container's host will be kept. Otherwise, a comma-separated list (or Python list) of environment variable names can be passed, and those environment variables will be kept.
CLI Example:

```bash
salt myminion dockerng.script_retcode mycontainer salt://docker_script.py
salt myminion dockerng.script_retcode mycontainer salt://scripts/runme.sh 'arg1 arg2 "arg 3"'
salt myminion dockerng.script_retcode mycontainer salt://scripts/runme.sh stdin='one	two
three
four
five
'
```

```
salt.modules.dockerng.search(name, official=False, trusted=False)

Searches the registry for an image

name  Search keyword
official  [False] Limit results to official builds
trusted  [False] Limit results to trusted builds

RETURN DATA

A dictionary with each key being the name of an image, and the following information for each image:

- **Description** - Image description
- **Official** - A boolean (True if an official build, False if not)
- **Stars** - Number of stars the image has on the registry
- **Trusted** - A boolean (True if a trusted build, False if not)

CLI Example:

```bash
salt myminion dockerng.search centos
salt myminion dockerng.search centos official=True
```

```
salt.modules.dockerng.signal(*args, **kwargs)

Send a signal to a container. Signals can be either strings or numbers, and are defined in the Standard Signals section of the signal(7) manpage. Run `man 7 signal` on a Linux host to browse this manpage.

name  Container name or ID
signal  Signal to send to container

RETURN DATA

If the signal was successfully sent, True will be returned. Otherwise, an error will be raised.

CLI Example:

```bash
salt myminion dockerng.signal mycontainer SIGHUP
```

```
salt.modules.dockerng.start(*args, **kwargs)

Start a container

name  Container name or ID

validate_ip_addrs  [True] For parameters which accept IP addresses as input, IP address validation will be performed. To disable, set this to False

binds  Files/directories to bind mount. Each bind mount should be passed in the format `<host_path>:`<container_path>`:<read_only>`, where `<read_only>` is one of `rw` (for read-write access) or `ro` (for read-only access). Optionally, the read-only information can be left off the end and the bind mount will be assumed to be read-write. Examples 2 and 3 below are equivalent.

Example 1: `binds=/srv/www:/var/www:ro`
Example 2: `binds=/srv/www:/var/www:rw`
Example 3: `binds=/srv/www:/var/www`
```
**port_bindings** Bind exposed ports which were exposed using the `ports` argument to `dockerng.create`. These should be passed in the same way as the `--publish` argument to the `docker run` CLI command:

- `ip:hostPort:containerPort` - Bind a specific IP and port on the host to a specific port within the container.
- `ip::containerPort` - Bind a specific IP and an ephemeral port to a specific port within the container.
- `hostPort:containerPort` - Bind a specific port on all of the host's interfaces to a specific port within the container.
- `containerPort` - Bind an ephemeral port on all of the host's interfaces to a specific port within the container.

Multiple bindings can be separated by commas, or passed as a Python list. The below two examples are equivalent:

Example 1: `port_bindings="5000:5000,2123:2123/udp,8080"`
Example 2: `port_bindings="[5000:5000, '2123:2123/udp', '8080']"`

**Note:** When configuring bindings for UDP ports, the protocol must be passed in the `containerPort` value, as seen in the examples above.

**lxc_conf** Additional LXC configuration parameters to set before starting the container.

Example: `lxc_conf={"lxc.utsname": "docker"}`

**Note:** These LXC configuration parameters will only have the desired effect if the container is using the LXC execution driver, which has not been the default for some time.

**publish_all_ports** [False] Allocates a random host port for each port exposed using the `ports` argument to `dockerng.create`.

Example: `publish_all_ports=True`

**links** Link this container to another. Links should be specified in the format `<container_name_or_id>:<link_alias>`. Multiple links can be passed, either as a comma-separated list or a Python list.

Example 1: `links=mycontainer:myalias,links=web1:link1,web2:link2`
Example 2: `links=['mycontainer:myalias'] links=['web1:link1', 'web2:link2']`

**dns** List of DNS nameservers. Can be passed as a comma-separated list or a Python list.

Example: `dns=8.8.8.8,8.8.4.4 or dns="[8.8.8.8, 8.8.4.4]"`

**Note:** To skip IP address validation, use `validate_ip_addrs=False`

**dns_search** List of DNS search domains. Can be passed as a comma-separated list or a Python list.

Example: `dns_search=foo1.domain.tld,foo2.domain.tld` or `dns_search="[foo1.domain.tld, foo2.domain.tld]"

**volumes_from** Container names or IDs from which the container will get volumes. Can be passed as a comma-separated list or a Python list.

Example: `volumes_from=foo, volumes_from=foo,bar, volumes_from="[foo, bar]"`
**network_mode**  [bridge] One of the following:

- **bridge** - Creates a new network stack for the container on the docker bridge
- **null** - No networking (equivalent of the Docker CLI argument --net=none)
- **container:<name_or_id>** - Reuses another container's network stack
- **host** - Use the host's network stack inside the container

**Warning:** Using host mode gives the container full access to the host's system's services (such as D-bus), and is therefore considered insecure.

Example: `network_mode=null, network_mode=container:web1`

**restart_policy** Set a restart policy for the container. Must be passed as a string in the format policy[:retry_count] where policy is one of always or on-failure, and retry_count is an optional limit to the number of retries. The retry count is ignored when using the always restart policy.

Example 1: `restart_policy=on-failure:5`
Example 2: `restart_policy=always`

**cap_add** List of capabilities to add within the container. Can be passed as a comma-separated list or a Python list. Requires Docker 1.2.0 or newer.

Example: `cap_add=SYS_ADMIN, MKNOD, cap_add="[SYS_ADMIN, MKNOD]"`

**cap_drop** List of capabilities to drop within the container. Can be passed as a comma-separated string or a Python list. Requires Docker 1.2.0 or newer.

Example: `cap_drop=SYS_ADMIN, MKNOD, cap_drop="[SYS_ADMIN, MKNOD]"`

**extra_hosts** Additional hosts to add to the container's /etc/hosts file. Can be passed as a comma-separated list or a Python list. Requires Docker 1.3.0 or newer.

Example: `extra_hosts=web1:10.9.8.7, web2:10.9.8.8`

**Note:** To skip IP address validation, use `validate_ip_addrs=False`

**pid_mode** Set to host to use the host container's PID namespace within the container. Requires Docker 1.5.0 or newer.

Example: `pid_mode=host`

**RETURN DATA**

A dictionary will be returned, containing the following keys:

- **status** - A dictionary showing the prior state of the container as well as the new state
- **result** - A boolean noting whether or not the action was successful
- **comment** - Only present if the container cannot be started

CLI Example:

```
salt myminion dockerng.start mycontainer
```

```
salt.modules.dockerng.state(name, *args, **kwargs)
```

Returns the state of the container

- **name** Container name or ID
RETURN DATA
A string representing the current state of the container (either running, paused, or stopped)
CLI Example:
salt myminion dockerng.state mycontainer

salt.modules.dockerng.stop(*args, **kwargs)
Stops a running container
name Container name or ID
unpause [False] If True and the container is paused, it will be unpaused before attempting to stop the container.
timeout [10] Timeout in seconds after which the container will be killed (if it has not yet gracefully shut down)

RETURN DATA
A dictionary will be returned, containing the following keys:
• status - A dictionary showing the prior state of the container as well as the new state
• result - A boolean noting whether or not the action was successful
• comment - Only present if the container can not be stopped

CLI Examples:
salt myminion dockerng.stop mycontainer
salt myminion dockerng.stop mycontainer unpause=True
salt myminion dockerng.stop mycontainer timeout=20

salt.modules.dockerng.tag(name, image, force=False)
Tag an image into a repository and return True. If the tag was unsuccessful, an error will be raised.
name ID of image
image Tag to apply to the image, in repo:tag notation. If just the repository name is passed, a tag name of latest will be assumed.
force [False] Force apply tag

CLI Example:
salt myminion dockerng.tag 0123456789ab myrepo/mycontainer
salt myminion dockerng.tag 0123456789ab myrepo/mycontainer:mytag

salt.modules.dockerng.top(name, *args, **kwargs)
Runs the docker top command on a specific container
name Container name or ID

CLI Example:
RETURN DATA
A list of dictionaries containing information about each process

salt myminion dockerng.top mycontainer
salt myminion dockerng.top 0123456789ab

salt.modules.dockerng.unpause(*args, **kwargs)
Unpauses a container
name  Container name or ID

RETURN DATA
A dictionary will be returned, containing the following keys:

- **status** - A dictionary showing the prior state of the container as well as the new state
- **result** - A boolean noting whether or not the action was successful
- **comment** - Only present if the container cannot be unpaused

CLI Example:
```bash
salt myminion dockerng.pause mycontainer
```

**salt.modules.dockerng.version()**
Returns a dictionary of Docker version information. Equivalent to running the `docker version` Docker CLI command.

CLI Example:
```bash
salt myminion dockerng.version
```

**salt.modules.dockerng.wait(name)**
Wait for the container to exit gracefully, and return its exit code

**Note:** This function will block until the container is stopped.

name  Container name or ID

RETURN DATA
A dictionary will be returned, containing the following keys:

- **status** - A dictionary showing the prior state of the container as well as the new state
- **result** - A boolean noting whether or not the action was successful
- **exit_status** - Exit status for the container
- **comment** - Only present if the container is already stopped

CLI Example:
```bash
salt myminion dockerng.wait mycontainer
```

### 31.16.70 salt.modules.dpkg

Support for DEB packages

**salt.modules.dpkg.bin_pkg_info(path, saltenv='base')**

New in version 2015.8.0.

Parses RPM metadata and returns a dictionary of information about the package (name, version, etc.).

**path**  Path to the file. Can either be an absolute path to a file on the minion, or a salt fileserver URL (e.g. `salt://path/to/file.rpm`). If a salt fileserver URL is passed, the file will be cached to the minion so that it can be examined.

**saltenv**  [base] Salt fileserver environment from which to retrieve the package. Ignored if path is a local file path on the minion.
CLI Example:

```bash
salt '*' lowpkg.bin_pkg_info /root/foo-1.2.3-1ubuntu1_all.deb
salt '*' lowpkg.bin_pkg_info salt://foo-1.2.3-1ubuntu1_all.deb
```

```
salt.modules.dpkg.file_dict('packages')
List the files that belong to a package, grouped by package. Not specifying any packages will return a list of _every_ file on the system's package database (not generally recommended).

CLI Examples:

```bash
salt '*' lowpkg.file_list httpd
salt '*' lowpkg.file_list httpd postfix
salt '*' lowpkg.file_list
```

```
salt.modules.dpkg.file_list('packages')
List the files that belong to a package. Not specifying any packages will return a list of _every_ file on the system's package database (not generally recommended).

CLI Examples:

```bash
salt '*' lowpkg.file_list httpd
salt '*' lowpkg.file_list httpd postfix
salt '*' lowpkg.file_list
```

```
salt.modules.dpkg.info('packages')
Return a detailed package(s) summary information. If no packages specified, all packages will be returned.

Parameters packages --

Returns

CLI example:

```bash
salt '*' lowpkg.info apache2 bash
```

```
salt.modules.dpkg.list_pkgs('packages')
List the packages currently installed in a dict:

`{'<package_name>': '<version>'}`

External dependencies:

Virtual package resolution requires aptitude. Because this function uses dpkg, virtual packages will be reported as not installed.

CLI Example:

```bash
salt '*' lowpkg.list_pkgs
salt '*' lowpkg.list_pkgs httpd
```

```
salt.modules.dpkg.unpurge('packages')
Change package selection for each package specified to `install`

CLI Example:

```bash
salt '*' lowpkg.unpurge curl
```

### 31.16.71 salt.modules.drac

Manage Dell DRAC
salt.modules.drac.change_password(username, password, uid=None)
    Change users password
    CLI Example:
    salt dell drac.change_password [USERNAME] [PASSWORD] [UID - optional]
salt dell drac.change_password diana secret

salt.modules.drac.create_user(username, password, permissions, users=None)
    Create user accounts
    CLI Example:
    salt dell drac.create_user [USERNAME] [PASSWORD] [PRIVELEGES]
salt dell drac.create_user diana secret login,test_alerts,clear_logs

    DRAC Privileges
    • login : Login to iDRAC
    • drac : Configure iDRAC
    • user_management : Configure Users
    • clear_logs : Clear Logs
    • server_control_commands : Execute Server Control Commands
    • console_redirection : Access Console Redirection
    • virtual_media : Access Virtual Media
    • test_alerts : Test Alerts
    • debug_commands : Execute Debug Commands

salt.modules.drac.delete_user(username, uid=None)
    Delete a user
    CLI Example:
    salt dell drac.delete_user [USERNAME] [UID - optional]
salt dell drac.delete_user diana 4

salt.modules.drac.email_alerts(action)
    Enable/Disable email alerts
    CLI Example:
    salt dell drac.email_alerts True
    salt dell drac.email_alerts False

salt.modules.drac.list_users()
    List all DRAC users
    CLI Example:
    salt dell drac.list_users

salt.modules.drac.nameservers(*ns)
    Configure the nameservers on the DRAC
    CLI Example:
salt dell drac.nameservers [NAMESERVERS]
salt dell drac.nameservers ns1.example.com ns2.example.com

salt.modules.drac.network_info()
Return Network Configuration
CLI Example:
salt dell drac.network_info

salt.modules.drac.server_hardreset()
Performs a reset (reboot) operation on the managed server.
CLI Example:
salt dell drac.server_hardreset

salt.modules.drac.server_poweroff()
Powers down the managed server.
CLI Example:
salt dell drac.server_poweroff

salt.modules.drac.server_poweron()
Powers up the managed server.
CLI Example:
salt dell drac.server_poweron

salt.modules.drac.server_pxe()
Configure server to PXE perform a one off PXE boot
CLI Example:
salt dell drac.server_pxe

salt.modules.drac.server_reboot()
Issues a power-cycle operation on the managed server. This action is similar to pressing the power button on the system's front panel to power down and then power up the system.
CLI Example:
salt dell drac.server_reboot

salt.modules.drac.set_network(ip, netmask, gateway)
Configure Network
CLI Example:
salt dell drac.set_network [DRAC IP] [NETMASK] [GATEWAY]
salt dell drac.set_network 192.168.0.2 255.255.255.0 192.168.0.1

salt.modules.drac.set_permissions(username, permissions, uid=None)
Configure users permissions
CLI Example:
salt dell drac.set_permissions [USERNAME] [PRIVELEGES] [USER INDEX - optional]
salt dell drac.set_permissions diana login,test_alerts,clear_logs 4
**DRAC Privileges**

- login: Login to iDRAC
- drac: Configure iDRAC
- user_management: Configure Users
- clear_logs: Clear Logs
- server_control_commands: Execute Server Control Commands
- console_redirection: Access Console Redirection
- virtual_media: Access Virtual Media
- test_alerts: Test Alerts
- debug_commands: Execute Debug Commands

```
salt.modules.drac.set_snmp(community)
Configure SNMP community string

CLI Example:
salt dell drac.set_snmp [COMMUNITY]
salt dell drac.set_snmp public
```

```
salt.modules.drac.syslog(server, enable=True)
Configure syslog remote logging, by default syslog will automatically be enabled if a server is specified. However, if you want to disable syslog you will need to specify a server followed by False

CLI Example:
salt dell drac.syslog [SYSLOG IP] [ENABLE/DISABLE]
salt dell drac.syslog 0.0.0.0 False
```

```
salt.modules.drac.system_info()
Return System information

CLI Example:
salt dell drac.system_info
```

### 31.16.72 salt.modules.drbd

DRBD administration module

```
salt.modules.drbd.overview()
Show status of the DRBD devices

CLI Example:
salt '*' drbd.overview
```

### 31.16.73 salt.modules.ebuild

Support for Portage

```python
optdepends
  * portage Python adapter
```
For now all package names **MUST** include the package category, i.e. 'vim' will not work, 'app-editors/vim' will.

**salt.modules.ebuild.check_db(names, **kwargs)**

New in version 0.17.0.

Returns a dict containing the following information for each specified package:

1. A key `found`, which will be a boolean value denoting if a match was found in the package database.
2. If `found` is `False`, then a second key called `suggestions` will be present, which will contain a list of possible matches. This list will be empty if the package name was specified in `category/pkgname` format, since the suggestions are only intended to disambiguate ambiguous package names (ones submitted without a category).

CLI Examples:

```bash
salt '*' pkg.check_db <package1> <package2> <package3>
```

**salt.modules.ebuild.check_extra_requirements(pkgname, pkgver)**

Check if the installed package already has the given requirements.

CLI Example:

```bash
salt '*' pkg.check_extra_requirements 'sys-devel/gcc' '~>4.1.2:4.1::gentoo[nls,fortran]'
```

**salt.modules.ebuild.depclean(name=None, slot=None, fromrepo=None, pkgs=None)**

Portage has a function to remove unused dependencies. If a package is provided, it will only removed the package if no other package depends on it.

- **name**  The name of the package to be cleaned.
- **slot**  Restrict the remove to a specific slot. Ignored if `name` is `None`.
- **fromrepo**  Restrict the remove to a specific slot. Ignored if `name` is `None`.
- **pkgs**  Clean multiple packages. `slot` and `fromrepo` arguments are ignored if this argument is present. Must be passed as a python list.

Return a list containing the removed packages:

CLI Example:

```bash
salt '*' pkg.depclean <package name>
```

**salt.modules.ebuild.ex_mod_init(low)**

If the config option `ebuild.enforce_nice_config` is set to True, this module will enforce a nice tree structure for `/etc/portage/package.*` configuration files.

New in version 0.17.0: Initial automatic enforcement added when pkg is used on a Gentoo system.

Changed in version 2014.1.0-Hydrogen: Configure option added to make this behaviour optional, defaulting to off.

See also:

- `ebuild.ex_mod_init` is called automatically when a state invokes a pkg state on a Gentoo system.
- `salt.states.pkg.mod_init()`
- `ebuild.ex_mod_init` uses `portage_config.enforce_nice_config` to do the lifting.
- `salt.modules.portage_config.enforce_nice_config()`

CLI Example:
**salt**

`salt '*' pkg.ex_mod_init`

salt.modules.ebuild.

**install**

`install(name=None, refresh=False, pkgs=None, sources=None, slot=None, fromrepo=None, uses=None, binhost=None, **kwargs)`

Install the passed package(s), add refresh=True to sync the portage tree before package is installed.

**name**
The name of the package to be installed. Note that this parameter is ignored if either `pkgs` or `sources` is passed. Additionally, please note that this option can only be used to emerge a package from the portage tree. To install a tar.bz2 package manually, use the `sources` option described below.

CLI Example:

```
salt '*' pkg.install <package name>
```

**refresh**
Whether or not to sync the portage tree before installing.

**version**
Install a specific version of the package, e.g. 1.0.9-r1. Ignored if `pkgs` or `sources` is passed.

**slot**
Similar to version, but specifies a valid slot to be installed. It will install the latest available version in the specified slot. Ignored if `pkgs` or `sources` or `version` is passed.

CLI Example:

```
salt '*' pkg.install sys-devel/gcc slot='4.4'
```

**fromrepo**
Similar to slot, but specifies the repository from the package will be installed. It will install the latest available version in the specified repository. Ignored if `pkgs` or `sources` or `version` is passed.

CLI Example:

```
salt '*' pkg.install salt fromrepo='gentoo'
```

**uses**
Similar to slot, but specifies a list of use flag. Ignored if `pkgs` or `sources` or `version` is passed.

CLI Example:

```
salt '*' pkg.install sys-devel/gcc uses=['nptl','-nossp']
```

Multiple Package Installation Options:

**pkgs**
A list of packages to install from the portage tree. Must be passed as a python list.

CLI Example:

```
salt '*' pkg.install pkgs=['"foo","bar","-category/package:slot::repository[use]"']
```

**sources**
A list of tar.bz2 packages to install. Must be passed as a list of dicts, with the keys being package names, and the values being the source URI or local path to the package.

CLI Example:

```
salt '*' pkg.install sources='["foo": "salt://foo.tbz2"],["bar": "salt://bar.tbz2"]'
```

**binhost**
has two options try and force. try - tells emerge to try and install the package from a configured binhost. force - forces emerge to install the package from a binhost otherwise it fails out.

Returns a dict containing the new package names and versions:

```
{'<package>': {'old': '<old-version>',
              'new': '<new-version>'}}
```
salt.modules.ebuild.latest_version(*names, **kwargs)
Return the latest version of the named package available for upgrade or installation. If more than one package name is specified, a dict of name/version pairs is returned.

CLI Example:
```python
salt '*' pkg.latest_version <package name>
salt '*' pkg.latest_version <package1> <package2> <package3> ...
```

salt.modules.ebuild.list_pkgs(versions_as_list=False, **kwargs)
List the packages currently installed in a dict:
```python
{'<package_name>': '<version>'}
```

CLI Example:
```python
salt '*' pkg.list_pkgs
```

salt.modules.ebuild.list_upgrades(refresh=True, backtrack=3)
List all available package upgrades.
- **refresh** Whether or not to sync the portage tree before checking for upgrades.
- **backtrack** Specifies an integer number of times to backtrack if dependency calculation fails due to a conflict or an unsatisfied dependency (default: `3`).

CLI Example:
```python
salt '*' pkg.list_upgrades
```

salt.modules.ebuild.porttree_matches(name)
Returns a list containing the matches for a given package name from the portage tree. Note that the specific version of the package will not be provided for packages that have several versions in the portage tree, but rather the name of the package (i.e. ``dev-python/paramiko``).

salt.modules.ebuild.purge(name=None, slot=None, fromrepo=None, pkgs=None, **kwargs)
Portage does not have a purge, this function calls remove followed by depclean to emulate a purge process
- **name** The name of the package to be deleted.
- **slot** Restrict the remove to a specific slot. Ignored if name is None.
- **fromrepo** Restrict the remove to a specific slot. Ignored if name is None.

Multiple Package Options:
- **pkgs** Uninstall multiple packages. slot and fromrepo arguments are ignored if this argument is present. Must be passed as a python list.

New in version 0.16.0.

Returns a dict containing the changes.

CLI Example:
```python
salt '*' pkg.purge <package name>
salt '*' pkg.purge <package name> slot=4.4
salt '*' pkg.purge <package1>,<package2>,<package3>
salt '*' pkg.purge pkgs=('["foo", "bar"]')
```

salt.modules.ebuild.refresh_db()
Updates the portage tree (emerge --sync). Uses eix-sync if available.

CLI Example:
salt '★' pkg.refresh_db

salt.modules.ebuild.remove(name=None, slot=None, fromrepo=None, pkgs=None, **kwargs)
Remove packages via emerge --unmerge.

name  The name of the package to be deleted.
slot  Restrict the remove to a specific slot. Ignored if name is None.
fromrepo  Restrict the remove to a specific slot. Ignored if name is None.

Multiple Package Options:

pkgs  Uninstall multiple packages. slot and fromrepo arguments are ignored if this argument is present.

Must be passed as a python list.

New in version 0.16.0.

Returns a dict containing the changes.

CLI Example:

salt '★' pkg.remove <package name>
salt '★' pkg.remove <package name> slot=4.4 fromrepo=gentoo
salt '★' pkg.remove <package1>,<package2>,<package3>
salt '★' pkg.remove pkgs='["foo", "bar"]'

salt.modules.ebuild.update(pkgs, slot=None, fromrepo=None, refresh=False, binhost=None)
Updates the passed package (emerge --update package)

slot  Restrict the update to a particular slot. It will update to the latest version within the slot.
fromrepo  Restrict the update to a particular repository. It will update to the latest version within the repository.

binhost  has two options try and force. try - tells emerge to try and install the package from a configured binhost. force - forces emerge to install the package from a binhost otherwise it fails out.

Return a dict containing the new package names and versions:

{<package>: {'old': <old-version>,
             'new': <new-version>}}

CLI Example:

salt '★' pkg.update <package name>

salt.modules.ebuild.upgrade(refresh=True, binhost=None, backtrack=3)
Run a full system upgrade (emerge -uDN @world)

binhost  has two options try and force. try - tells emerge to try and install the package from a configured
binhost. force - forces emerge to install the package from a binhost otherwise it fails out.

backtrack  Specifies an integer number of times to backtrack if dependency calculation fails due to a conflict
or an unsatisfied dependency (default: 3).

Return a dict containing the new package names and versions:

{<package>: {'old': <old-version>,
             'new': <new-version>}}

CLI Example:
salt '*' pkg.upgrade

salt.modules.ebuild.upgrade_available(name)
    Check whether or not an upgrade is available for a given package
    CLI Example:
    salt '*' pkg.upgrade_available <package name>

salt.modules.ebuild.version('names', **kwargs)
    Returns a string representing the package version or an empty string if not installed. If more than one package
    name is specified, a dict of name/version pairs is returned.
    CLI Example:
    salt '*' pkg.version <package name>
    salt '*' pkg.version <package1> <package2> <package3> ...

salt.modules.ebuild.version_clean(version)
    Clean the version string removing extra data.
    CLI Example:
    salt '*' pkg.version_clean <version_string>

salt.modules.ebuild.version_cmp(pkg1, pkg2)
    Do a cmp-style comparison on two packages. Return -1 if pkg1 < pkg2, 0 if pkg1 == pkg2, and 1 if pkg1 >
    pkg2. Return None if there was a problem making the comparison.
    CLI Example:
    salt '*' pkg.version_cmp '0.2.4-0' '0.2.4.1-0'

31.16.74 salt.modules.eix

Support for Eix
salt.modules.eix.sync()
    Sync portage/overlay trees and update the eix database
    CLI Example:
    salt '*' eix.sync

salt.modules.eix.update()
    Update the eix database
    CLI Example:
    salt '*' eix.update

31.16.75 salt.modules.elasticsearch

Elasticsearch - A distributed RESTful search and analytics server
Module to provide Elasticsearch compatibility to Salt (compatible with Elasticsearch version 1.5.2+)
New in version 2015.8.0.
**depends**  elasticsearch-py

**configuration**  This module accepts connection configuration details either as parameters or as configuration settings in /etc/salt/minion on the relevant minions:

```yaml
elasticsearch:
  host: '10.10.10.100:9200'

elasticsearch:
  hosts:
    - '10.10.10.100:9200'
    - '10.10.10.101:9200'
    - '10.10.10.102:9200'

elasticsearch:
  hosts:
    - '10.10.10.100:9200'
  number_of_shards: 1
  number_of_replicas: 0
  functions_blacklist:
    - 'saltutil.find_job'
    - 'pillar.items'
    - 'grains.items'
```

This data can also be passed into pillar. Options passed into opts will overwrite options passed into pillar.

```python
salt.modules.elasticsearch.alias_create(indices, alias, hosts=None, body=None, profile=None)
```

Create an alias for a specific index/indices

CLI example:

```bash
salt myminion elasticsearch.alias_create testindex_v1 testindex
```

```python
salt.modules.elasticsearch.alias_delete(indices, aliases, hosts=None, body=None, profile=None)
```

Delete an alias of an index

CLI example:

```bash
salt myminion elasticsearch.alias_delete testindex_v1 testindex
```

```python
salt.modules.elasticsearch.alias_exists(aliases, indices=None, hosts=None, profile=None)
```

Return a boolean indicating whether given alias exists

CLI example:

```bash
salt myminion elasticsearch.alias_exists testindex
```

```python
salt.modules.elasticsearch.alias_get(indices=None, aliases=None, hosts=None, profile=None)
```

Check for the existence of an alias and if it exists, return it

CLI example:

```bash
salt myminion elasticsearch.alias_get testindex
```

```python
salt.modules.elasticsearch.document_create(index, doc_type, body=None, id=None, hosts=None, profile=None)
```

Create a document in a specified index

CLI example:
salt module documentation

salt.modules.elasticsearch.document_create(index, body=None, hosts=None, profile=None)

Create a new index.

CLI example:

salt myminion elasticsearch.document_create testindex doctype1 '{}'

salt.modules.elasticsearch.document_delete(index, doc_type, id, hosts=None, profile=None)

Delete a document from an index.

CLI example:

salt myminion elasticsearch.document_delete testindex doctype1 AUx-384m0Bug_8U80wQZ

salt.modules.elasticsearch.document_exists(index, id, doc_type='_all', hosts=None, profile=None)

Check for the existence of a document and if it exists, return it.

CLI example:

salt myminion elasticsearch.document_exists testindex AUx-384m0Bug_8U80wQZ

salt.modules.elasticsearch.document_get(index, id, doc_type='_all', hosts=None, profile=None)

Check for the existence of a document and if it exists, return it.

CLI example:

salt myminion elasticsearch.document_get testindex AUx-384m0Bug_8U80wQZ

salt.modules.elasticsearch.index_create(index, body=None, hosts=None, profile=None)

Create a new index.

CLI example:

salt myminion elasticsearch.index_create testindex

salt.modules.elasticsearch.index_delete(index, hosts=None, profile=None)

Delete a new index.

CLI example:

salt myminion elasticsearch.index_delete testindex

salt.modules.elasticsearch.index_exists(index, hosts=None, profile=None)

Check for the existence of an index and if it exists, return it.

CLI example:

salt myminion elasticsearch.index_exists testindex

salt.modules.elasticsearch.index_get(index, hosts=None, profile=None)

Check for the existence of an index and if it exists, return it.

CLI example:

salt myminion elasticsearch.index_get testindex

salt.modules.elasticsearch.index_template_create(name, body, hosts=None, profile=None)

Create an index template.

CLI example:

salt myminion elasticsearch.index_template_create testindextempl '{ "template": "logstash-*", "settings": { "number_of_replicas": 1 } }'
salt.modules.elasticsearch.index_template_delete(name, hosts=None, profile=None)
Delete an index template (type) along with its data

CLI example:
    salt myminion elasticsearch.index_template_delete testindex_templ user

salt.modules.elasticsearch.index_template_exists(name, hosts=None, profile=None)
Return a boolean indicating whether given index template exists

CLI example:
    salt myminion elasticsearch.index_template_exists testindex_templ

salt.modules.elasticsearch.index_template_get(name, hosts=None, profile=None)
Retrieves template definition of index or index/type

CLI example:
    salt myminion elasticsearch.index_template_get testindex_templ user

salt.modules.elasticsearch.mapping_create(index, doc_type, body, hosts=None, profile=None)
Create a mapping in a given index

CLI example:
    salt myminion elasticsearch.mapping_create testindex user '{ "user" : { "properties" : { "message" : {"type" : "string", "store" : true } } } }

salt.modules.elasticsearch.mapping_delete(index, doc_type, hosts=None, profile=None)
Delete a mapping (type) along with its data

CLI example:
    salt myminion elasticsearch.mapping_delete testindex user

salt.modules.elasticsearch.mapping_get(index, doc_type, hosts=None, profile=None)
Retrieves mapping definition of index or index/type

CLI example:
    salt myminion elasticsearch.mapping_get testindex user

31.16.76 salt.modules.environ

Support for getting and setting the environment variables of the current salt process.

salt.modules.environ.get(key, default='')
Get a single salt process environment variable.

key String used as the key for environment lookup.

default If the key is not found in the environment, return this value. Default: ''

CLI Example:
    salt '*' environ.get foo
    salt '*' environ.get baz default=False

salt.modules.environ.has_value(key, value=None)
Determine whether the key exists in the current salt process environment dictionary. Optionally compare the current value of the environment against the supplied value string.

31.16. Full list of builtin execution modules
key: Must be a string. Used as key for environment lookup.

value: Optional. If key exists in the environment, compare the current value with this value. Return True if they are equal.

CLI Example:

```
salt '*' environ.has_value foo
```

salt.modules.environ.item(keys, default='')
Get one or more salt process environment variables. Returns a dict.

keys: Either a string or a list of strings that will be used as the keys for environment lookup.

default: If the key is not found in the environment, return this value. Default: ''

CLI Example:

```
salt '*' environ.item foo
salt '*' environ.item ['foo', 'baz'] default=None
```

salt.modules.environ.items()
Return a dict of the entire environment set for the salt process

CLI Example:

```
salt '*' environ.items
```

salt.modules.environ.setenv(environ, false_unsets=False, clear_all=False, update_minion=False)
Set multiple salt process environment variables from a dict. Returns a dict.

environ: Must be a dict. The top-level keys of the dict are the names of the environment variables to set. Each key's value must be a string or False. Refer to the 'false_unsets' parameter for behavior when a value set to False.

false_unsets: If a key's value is False and false_unsets is True, then the key will be removed from the salt processes environment dict entirely. If a key's value is False and false_unsets is not True, then the key's value will be set to an empty string. Default: False.

clear_all: USE WITH CAUTION! This option can unset environment variables needed for salt to function properly. If clear_all is True, then any environment variables not defined in the environ dict will be deleted. Default: False.

update_minion: If True, apply these environ changes to the main salt-minion process. If False, the environ changes will only affect the current salt subprocess. Default: False.

CLI Example:

```
salt '*' environ.setenv '{"foo": "bar", "baz": "quux"}'
salt '*' environ.setenv '{"a": "b", "c": False}' false_unsets=True
```

salt.modules.environ.setval(key, val, false_unsets=False)
Set a single salt process environment variable. Returns True on success.

key: The environment key to set. Must be a string.

val: The value to set. Must be a string or False. Refer to the 'false_unsets' parameter for behavior when set to False.

false_unsets: If val is False and false_unsets is True, then the key will be removed from the salt processes environment dict entirely. If val is False and false_unsets is not True, then the key's value will be set to an empty string. Default: False.
CLI Example:

```python
salt '*' environ.setval foo bar
salt '*' environ.setval baz val=False false_unsets=True
```

## 31.16.77 `salt.modules.eselect`

Support for eeselect, Gentoo's configuration and management tool.

```python
salt.modules.eselect.exec_action(module, action, module_parameter=None, action_parameter=None, state_only=False)
```

Execute an arbitrary action on a module.

- **module**: name of the module to be executed
- **action**: name of the module's action to be run
- **module_parameter**: additional params passed to the defined module
- **action_parameter**: additional params passed to the defined action
- **state_only**: don't return any output but only the success/failure of the operation

CLI Example (updating the php implementation used for apache2):

```bash
salt '*' eeselect.exec_action php update action_parameter='apache2'
```

```python
salt.modules.eselect.get_current_target(module, module_parameter=None, action_parameter=None)
```

Get the currently selected target for the given module.

- **module**: name of the module to be queried for its current target
- **module_parameter**: additional params passed to the defined module
- **action_parameter**: additional params passed to the 'show' action

CLI Example (current target of system-wide java-vm):

```bash
salt '*' eeselect.get_current_target java-vm action_parameter='system'
```

CLI Example (current target of kernel symlink):

```bash
salt '*' eeselect.get_current_target kernel
```

```python
salt.modules.eselect.get_modules()
```

List available eeselect modules.

CLI Example:

```bash
salt '*' eeselect.get_modules
```

```python
salt.modules.eselect.get_target_list(module)
```

List available targets for the given module.

- **module**: name of the module to be queried for its targets

CLI Example:

```bash
salt '*' eeselect.get_target_list kernel
```
salt.modules.eselect.set_target(module, target, module_parameter=None, action_parameter=None)

Set the target for the given module. Target can be specified by index or name.

module name of the module for which a target should be set
target name of the target to be set for this module
module_parameter additional params passed to the defined module
action_parameter additional params passed to the defined action

CLI Example (setting target of system-wide java-vm):

```
salt '*' eselect.set_target java-vm icedtea-bin-7 action_parameter='system'
```

CLI Example (setting target of kernel symlink):

```
salt '*' eselect.set_target kernel linux-3.17.5-gentoo
```

### 31.16.78 salt.modules.etcd_mod

Execution module to work with etcd

depends

- python-etcd

In order to use an etcd server, a profile should be created in the master configuration file:

```
my_etd_config:
  etcd.host: 127.0.0.1
  etcd.port: 4001
```

It is technically possible to configure etcd without using a profile, but this is not considered to be a best practice, especially when multiple etcd servers or clusters are available.

```
etcd.host: 127.0.0.1
etcd.port: 4001
```

salt.modules.etcd_mod.get(key, recurse=False, profile=None)

New in version 2014.7.0.

Get a value from etcd, by direct path

CLI Examples:

```
salt myminion etcd.get /path/to/key
salt myminion etcd.get /path/to/key profile=my_etcd_config
salt myminion etcd.get /path/to/key recurse=True profile=my_etcd_config
```

salt.modules.etcd_mod.ls(path='/', profile=None)

New in version 2014.7.0.

Return all keys and dirs inside a specific path

CLI Example:

```
salt myminion etcd.ls /path/to/dir/
salt myminion etcd.ls /path/to/dir/ profile=my_etcd_config
```
salt.modules.etcd_mod.rm(key, recurse=False, profile=None)

Delete a key from etcd

CLI Example:

```bash
salt myminion etcd.rm /path/to/key
salt myminion etcd.rm /path/to/key recurse=True profile=my_etcd_config
```

salt.modules.etcd_mod.set(key, value, profile=None)

Set a value in etcd, by direct path

CLI Example:

```bash
salt myminion etcd.set /path/to/key value
salt myminion etcd.set /path/to/key value profile=my_etcd_config
```

salt.modules.etcd_mod.tree(path='/', profile=None)

Recurse through etcd and return all values

CLI Example:

```bash
salt myminion etcd.tree
salt myminion etcd.tree profile=my_etcd_config
salt myminion etcd.tree /path/to/keys profile=my_etcd_config
```

31.16.79 salt.modules.event

Use the Salt Event System to fire events from the master to the minion and vice-versa.

salt.modules.event.fire(data, tag)

Fire an event on the local minion event bus. Data must be formed as a dict.

CLI Example:

```bash
salt '*' event.fire '{"data":"my event data"}' 'tag'
```

salt.modules.event.fire_master(data, tag, preload=None)

Fire an event off up to the master server

CLI Example:

```bash
salt '*' event.fire_master '{"data":"my event data"}' 'tag'
```

salt.modules.event.send(tag, data=None, preload=None, with_env=False, with_grains=False, with_pillar=False, **kwargs)

Send an event to the Salt Master

New in version 2014.7.0.

Parameters

- **tag** -- A tag to give the event. Use slashes to create a namespace for related events. E.g., myco/build/buildserver1/start, myco/build/buildserver1/success, myco/build/buildserver1/failure.
- **data** -- A dictionary of data to send in the event. This is free-form. Send any data points that are needed for whoever is consuming the event. Arguments on the CLI are interpreted as YAML so complex data structures are possible.

- **with_env** (Specify `True` to include all environment variables, or specify a list of strings of variable names to include.) -- Include environment variables from the current shell environment in the event data as `envir...on`. This is a short-hand for working with systems that seed the environment with relevant data such as Jenkins.

- **with_grains** (Specify `True` to include all grains, or specify a list of strings of grain names to include.) -- Include grains from the current minion in the event data as `grains`.

- **with_pillar** (Specify `True` to include all Pillar values, or specify a list of strings of Pillar keys to include.) -- Include Pillar values from the current minion in the event data as `pillar`. Remember Pillar data is often sensitive data so be careful. This is useful for passing ephemeral Pillar values through an event. Such as passing the `pillar={} kwarg in state.sls` from the Master, through an event on the Minion, then back to the Master.

- **kwargs** -- Any additional keyword arguments passed to this function will be interpreted as key-value pairs and included in the event data. This provides a convenient alternative to YAML for simple values.

  **CLI Example:**

  ```
  salt-call event.send myco/mytag foo=Foo bar=Bar
  salt-call event.send 'myco/mytag' '{foo: Foo, bar: Bar}'
  ```

  A convenient way to allow Jenkins to execute `salt-call` is via sudo. The following rule in sudoers will allow the `jenkins` user to run only the following command.

  `/etc/sudoers (allow preserving the environment):
  
  jenkins ALL=(ALL) NOPASSWD:SETENV: /usr/bin/salt-call event.send*`

  Call Jenkins via sudo (preserve the environment):

  ```
  sudo -E salt-call event.send myco/jenkins/build/success with_env=[BUILD_ID, BUILD_URL, GIT_BRANCH, ...]
  ```

31.16.80 salt.modules.extfs

Module for managing ext2/3/4 file systems

**salt.modules.extfs.attributes** *(device, args=None)*

Return attributes from dumpe2fs for a specified device

**CLI Example:**

```
salt '*' extfs.attributes /dev/sda1
```

**salt.modules.extfs.blocks** *(device, args=None)*

Return block and inode info from dumpe2fs for a specified device

**CLI Example:**

```
salt '*' extfs.blocks /dev/sda1
```

**salt.modules.extfs.dump** *(device, args=None)*

Return all contents of dumpe2fs for a specified device
CLI Example:

```bash
salt '*' extfs.dump /dev/sda1
```

```python
salt.modules.extfs.mkfs(device=fs_type,**kwargs)
Create a file system on the specified device
```

CLI Example:

```bash
salt '*' extfs.mkfs /dev/sda1 fs_type=ext4 opts='acl,noexec'
```

Valid options are:

- `block_size`: 1024, 2048 or 4096
- `check`: check for bad blocks
- `direct`: use direct IO
- `ext_opt`: extended file system options (comma-separated)
- `fragment_size`: size of fragments
- `force`: setting force to True will cause mke2fs to specify the -F option twice (it is already set once); this is truly dangerous
- `blocks_per_group`: number of blocks in a block group
- `number_of_groups`: ext4 option for a virtual block group
- `bytes_per_inode`: set the bytes/inode ratio
- `inode_size`: size of the inode
- `journal`: set to True to create a journal (default on ext3/4)
- `journal_opt`: options for the fs journal (comma separated)
- `blocks_file`: read bad blocks from file
- `label`: label to apply to the file system
- `reserved`: percentage of blocks reserved for super-user
- `last_dir`: last mounted directory
- `test`: set to True to not actually create the file system (mke2fs -n)
- `number_of_inodes`: override default number of inodes
- `creator_os`: override `creator operating system` field
- `opts`: mount options (comma separated)
- `revision`: set the filesystem revision (default 1)
- `super`: write superblock and group descriptors only
- `fs_type`: set the filesystem type (REQUIRED)
- `usage_type`: how the filesystem is going to be used
- `uuid`: set the UUID for the file system

See the `mke2fs(8)` manpage for a more complete description of these options.
salt.modules.extfs.tune(device, **kwargs)
    Set attributes for the specified device (using tune2fs)

    CLI Example:
    ```
    salt '*' extfs.tune /dev/sda1 force=True label=wildstallyns opts='acl,noexec'
    ```

    Valid options are:

    - **max**: max mount count
    - **count**: mount count
    - **error**: error behavior
    - **extended_opts**: extended options (comma separated)
    - **force**: force, even if there are errors (set to True)
    - **group**: group name or gid that can use the reserved blocks
    - **interval**: interval between checks
    - **journal**: set to True to create a journal (default on ext3/4)
    - **journal_opts**: options for the fs journal (comma separated)
    - **label**: label to apply to the file system
    - **reserved**: percentage of blocks reserved for super-user
    - **last_dir**: last mounted directory
    - **opts**: mount options (comma separated)
    - **feature**: set or clear a feature (comma separated)
    - **mmp_check**: mmp check interval
    - **reserved**: reserved blocks count
    - **quota_opts**: quota options (comma separated)
    - **time**: time last checked
    - **user**: user or uid who can use the reserved blocks
    - **uuid**: set the UUID for the file system

    See the mke2fs(8) manpage for a more complete description of these options.

31.16.81 salt.modules.file

Manage information about regular files, directories, and special files on the minion, set/read user, group, mode, and data

salt.modules.file.access(path, mode)
    New in version 2014.1.0.

    Test whether the Salt process has the specified access to the file. One of the following modes must be specified:

    CLI Example:
    ```
    salt '*' file.access /path/to/file f
    salt '*' file.access /path/to/file x
    ```
salt.modules.file.append(path, *args, **kwargs)
   New in version 0.9.5.
   Append text to the end of a file

   path  path to file
   *args  strings to append to file

   CLI Example:
   
   salt '*' file.append /etc/motd
       "With all thine offerings thou shalt offer salt."
       "Salt is what makes things taste bad when it isn't in them."

   **Attention**
   
   If you need to pass a string to append and that string contains an equal sign, you must include the argument name, args. For example:

   salt '*' file.append /etc/motd args='cheese=spam'
   salt '*' file.append /etc/motd args="['cheese=spam', 'spam=cheese']"

salt.modules.file.basename(path)
   Returns the final component of a pathname

   New in version 2015.5.0.
   This can be useful at the CLI but is frequently useful when scripting.

   {%- set filename = salt['file.basename'](source_file) %}

   CLI Example:
   
   salt '*' file.basename 'test/test.config'

salt.modules.file.blockreplace(path, marker_start='-- start managed zone --', marker_end='-- end managed zone --', content='', append_if_not_found=False, prepend_if_not_found=False, backup='.bak', dry_run=False, show_changes=True)
   New in version 2014.1.0.
   Replace content of a text block in a file, delimited by line markers

   A block of content delimited by comments can help you manage several lines entries without worrying about old entries removal.

   **Note:** This function will store two copies of the file in-memory (the original version and the edited version) in order to detect changes and only edit the targeted file if necessary.

   path  Filesystem path to the file to be edited
   marker_start  The line content identifying a line as the start of the content block. Note that the whole line containing this marker will be considered, so whitespace or extra content before or after the marker is included in final output
   marker_end  The line content identifying a line as the end of the content block. Note that the whole line containing this marker will be considered, so whitespace or extra content before or after the marker is included in final output
content  The content to be used between the two lines identified by marker_start and marker_stop.

append_if_not_found  [False] If markers are not found and set to True then, the markers and content will be appended to the file.

prepend_if_not_found  [False] If markers are not found and set to True then, the markers and content will be prepended to the file.

backup  The file extension to use for a backup of the file if any edit is made. Set to False to skip making a backup.

dry_run  Don’t make any edits to the file.

show_changes  Output a unified diff of the old file and the new file. If False, return a boolean if any changes were made.

CLI Example:

```
salt '*' file.blockreplace /etc/hosts '#-- start managed zone foobar : DO NOT EDIT
#-- end managed zone foobar --' localhost/10.0.1.1 foo.foobar\n10.0.1.2 bar.foobar' True
```

salt.modules.file.check_file_meta(name, sfn, source, source_sum, user, group, mode, saltenv, contents=None)

Check for the changes in the file metadata.

CLI Example:

```
salt '*' file.check_file_meta /etc/httpd/conf.d/httpd.conf salt://httpd/conf.d httpd.conf {hash_type: 'md5', hsum: <md5sum>}
```

Note: Supported hash types include sha512, sha384, sha256, sha224, sha1, and md5.

name  Path to file destination

sfn  Template-processed source file contents

source  URL to file source

source_sum  File checksum information as a dictionary

    {hash_type: md5, hsum: <md5sum>}

user  Destination file user owner

group  Destination file group owner

mode  Destination file permissions mode

saltenv  Salt environment used to resolve source files

contents  File contents

salt.modules.file.check_hash(path, file_hash)

Check if a file matches the given hash string

Returns true if the hash matched, otherwise false. Raises ValueError if the hash was not formatted correctly.

path  A file path

hash  A string in the form <hash_type>:<hash_value>. For example: md5:e138491e9d5b97023cea823fe17bac22

CLI Example:
salt '.*' file.check_hash /etc/fstab md5:<md5sum>

```
salt.modules.file.check_managed(name, source, source_hash, user, group, mode, template, context, defaults, saltenv, contents=None, **kwargs)
```

Check to see what changes need to be made for a file

CLI Example:

```
salt '.*' file.check_managed /etc/httpd/conf.d/httpd.conf salt://http/httpd.conf '{hash_type: 'md5', 'hsum': <md5sum>}' root, root, '755' jinja True None None base
```

```
salt.modules.file.check_managed_changes(name, source, source_hash, user, group, mode, template, context, defaults, saltenv, contents=None, **kwargs)
```

Return a dictionary of what changes need to be made for a file

CLI Example:

```
salt '.*' file.check_managed_changes /etc/httpd/conf.d/httpd.conf salt://http/httpd.conf '{hash_type: 'md5', 'hsum': <md5sum>}' root, root, '755' jinja True None None base
```

```
salt.modules.file.check_perms(name, ret, user, group, mode, follow_symlinks=False)
```

Check the permissions on files and chown if needed

CLI Example:

```
salt '.*' file.check_perms /etc/sudoers '{}' root root 400
```

```
salt.modules.file.chgrp(path, group)
```

Change the group of a file

```
path  path to the file or directory

group group owner
```

CLI Example:

```
salt '.*' file.chgrp /etc/passwd root
```

```
salt.modules.file.chown(path, user, group)
```

Chown a file, pass the file the desired user and group

```
path  path to the file or directory

user  user owner

group group owner
```

CLI Example:

```
salt '.*' file.chown /etc/passwd root root
```

```
salt.modules.file.comment(path, regex, char='#', backup='.bak')
```

Deprecated since version 0.17.0: Use replace() instead.

Comment out specified lines in a file

```
path  The full path to the file to be edited

regex  A regular expression used to find the lines that are to be commented; this pattern will be wrapped in parenthesis and will move any preceding/trailing ^ or $ characters outside the parenthesis (e.g., the pattern ^foo$ will be rewritten as ^(foo)$)

char  [#] The character to be inserted at the beginning of a line in order to comment it out
```

31.16. Full list of builtin execution modules
backup [.bak] The file will be backed up before edit with this file extension

**Warning:** This backup will be overwritten each time `sed / comment / uncomment` is called. Meaning the backup will only be useful after the first invocation.

**CLI Example:**
```
salt '*' file.comment /etc/modules pcspkr
```

salt.modules.file.comment_line(path, regex, char='#', cmnt=True, backup='.bak')
Comment or Uncomment a line in a text file.

**Parameters**

- **path** -- string The full path to the text file.
- **regex** -- string A regex expression that begins with ^ that will find the line you wish to comment. Can be as simple as `^color =`
- **char** -- string The character used to comment a line in the type of file you're referencing. Default is #
- **cmnt** -- boolean True to comment the line. False to uncomment the line. Default is True.
- **backup** -- string The file extension to give the backup file. Default is .bak

**Returns** boolean Returns True if successful, False if not

**CLI Example:**
The following example will comment out the pcspkr line in the /etc/modules file using the default # character and create a backup file named modules.bak
```
salt '*' file.comment_line '/etc/modules' '^pcspkr'
```

**CLI Example:**
The following example will uncomment the log_level setting in minion config file if it is set to either warning, info, or debug using the # character and create a backup file named minion.bk
```
salt '*' file.comment_line 'C:\salt\conf\minion' '^log_level: (warning|info|debug)' '#' False '.bk'
```

salt.modules.file.contains(path, text)
Deprecated since version 0.17.0: Use `search()` instead.

Returns True if the file at path contains text

**CLI Example:**
```
salt '*' file.contains /etc/crontab 'mymaintenance.sh'
```

salt.modules.file.contains_glob(path, glob_expr)
Deprecated since version 0.17.0: Use `search()` instead.

Returns True if the given glob matches a string in the named file

**CLI Example:**
```
salt '*' file.contains_glob /etc/foobar '*cheese*' 
```

salt.modules.file.contains_regex(path, regex, lchar='`)
Deprecated since version 0.17.0: Use `search()` instead.

Returns True if the given regular expression matches on any line in the text of a given file.
If the leading char argument (leading char) is specified, it will strip leading char from the left side of each line before trying to match.

**CLI Example:**
```
salt '*' file.contains_regex /etc/crontab
```

### `salt.modules.file.contains_regex_multiline(path, regex)`

* Deprecated since version 0.17.0: Use `search()` instead.*

Return `True` if the given regular expression matches anything in the text of a given file. Traverses multiple lines at a time, via the salt BufferedReader (reads in chunks).

**CLI Example:**
```
salt '*' file.contains_regex_multiline /etc/crontab '^maint'
```

### `salt.modules.file.copy(src, dst, recurse=False, remove_existing=False)`

Copy a file or directory from source to destination.

In order to copy a directory, the recurse flag is required, and will by default overwrite files in the destination with the same path, and retain all other existing files. (similar to cp -r on unix)

`remove_existing` will remove all files in the target directory, and then copy files from the source.

**CLI Example:**
```
salt '*' file.copy /path/to/src /path/to/dst
salt '*' file.copy /path/to/src_dir /path/to/dst_dir recurse=True
salt '*' file.copy /path/to/src_dir /path/to/dst_dir recurse=True remove_existing=True
```

### `salt.modules.file.delete_backup(path, backup_id)`

* New in version 0.17.0.*

Delete a previous version of a file that was backed up using Salt’s file state backup system.

`path` The path on the minion to check for backups

`backup_id` The numeric id for the backup you wish to delete, as found using `file.list_backups`

**CLI Example:**
```
salt '*' file.restore_backup /foo/bar/baz.txt 0
```

### `salt.modules.file.directory_exists(path)`

Tests to see if path is a valid directory. Returns True/False.

**CLI Example:**
```
salt '*' file.directory_exists /etc
```

### `salt.modules.file.dirname(path)`

Returns the directory component of a path name.

* New in version 2015.5.0.*

This can be useful at the CLI but is frequently useful when scripting.

```
{% from salt['file.dirname'](tpldir) + '/vars.jinja' import parent_vars %}
```

**CLI Example:**
```
```
salt '*t' file.dirname 'test/path/filename.config'

salt.modules.file.diskusage(path)
Recursively calculate disk usage of path and return it in bytes
CLI Example:
salt '*t' file.diskusage /path/to/check

salt.modules.file.extract_hash(hash_fn, hash_type='sha256', file_name='')
This routine is called from the file.managed state to pull a hash from a remote file. Regular expressions are used line by line on the source_hash file, to find a potential candidate of the indicated hash type. This avoids many problems of arbitrary file layout rules. It specifically permits pulling hash codes from debian *.dsc files.
For example:

```
openerp_7.0_latest-1.tar.gz:
  file.managed:
    - name: /tmp/openerp_7.0-20121227-075624-1_all.deb
    - source: http://nightly.openerp.com/7.0/nightly/deb/openerp_7.0-20121227-075624-1.tar.gz
    - source_hash: http://nightly.openerp.com/7.0/nightly/deb/openerp_7.0-20121227-075624-1.dsc
```

CLI Example:
salt '*t' file.extract_hash /etc/foo sha512 /path/to/hash/file

salt.modules.file.file_exists(path)
Tests to see if path is a valid file. Returns True/False.
CLI Example:
salt 't' file.file_exists /etc/passwd

salt.modules.file.find(path, *args, **kwargs)
Approximate the Unix find(1) command and return a list of paths that meet the specified criteria.
The options include match criteria:

```
name      = path-glob       # case sensitive
iname     = path-glob       # case insensitive
regex     = path-regex      # case sensitive
iregex    = path-regex      # case insensitive
type      = file-types      # match any listed type
user       = users          # match any listed user
group     = groups         # match any listed group
size       = [+][-]number[size-unit] # default unit = byte
mtime      = interval       # modified since date
grep       = regex         # search file contents
```

and/or actions:
```
delete    [= file-types]  # default type = 'f'
exec       = command [arg ...] # where {} is replaced by pathname
print      [= print-opts]
```

and/or depth criteria:
```
maxdepth = maximum depth to transverse in path
mindepth = minimum depth to transverse before checking files or directories
```
The default action is `print=path`

**path-glob:**

* = match zero or more chars  
? = match any char  
[abc] = match a, b, or c  
[^abc] = match anything except a, b, and c  
[x-y] = match chars x through y  
[^x-y] = match anything except chars x through y  
{a,b,c} = match a or b or c

**path-regex:** a Python Regex (regular expression) pattern to match pathnames

**file-types:** a string of one or more of the following:

- a: all file types  
- b: block device  
- c: character device  
- d: directory  
- p: FIFO (named pipe)  
- f: plain file  
- l: symlink  
- s: socket

**users:** a space and/or comma separated list of user names and/or uids

**groups:** a space and/or comma separated list of group names and/or gids

**size-unit:**

- b: bytes  
- k: kilobytes  
- m: megabytes  
- g: gigabytes  
- t: terabytes

**interval:**

`[<num>w] [<num>d] [<num>h] [<num>m] [<num>s]`

where:

- w: week  
- d: day  
- h: hour  
- m: minute  
- s: second

**print-opts:** a comma and/or space separated list of one or more of the following:

- group: group name  
- md5: MD5 digest of file contents  
- mode: file permissions (as integer)  
- mtime: last modification time (as time_t)  
- name: file basename  
- path: file absolute path  
- size: file size in bytes  
- type: file type  
- user: user name

CLI Examples:
```
salt '*' file.find / type=f name='*.bak' size='+10m
salt '*' file.find /var mtime='+30d' size='+10m' print=path,size,mtime
salt '*' file.find /var/log name='*.[0-9]' mtime='+30d' size='+10m' delete
```

**salt.modules.file.get_devmm(name)**

Get major/minor info from a device

CLI Example:
```
salt '*' file.get_devmm /dev/chr
```

**salt.modules.file.get_diff(minionfile, masterfile, env=None, saltenv='base')**

Return unified diff of file compared to file on master

CLI Example:
```
salt '*' file.get_diff /home/fred/.vimrc salt://users/fred/.vimrc
```

**salt.modules.file.get_gid(path, follow_symlinks=True)**

Return the id of the group that owns a given file

- **path** file or directory of which to get the gid
- **follow_symlinks** indicated if symlinks should be followed

CLI Example:
```
salt '*' file.get_gid /etc/passwd
```

Changed in version 0.16.4: follow_symlinks option added

**salt.modules.file.get_group(path, follow_symlinks=True)**

Return the group that owns a given file

- **path** file or directory of which to get the group
- **follow_symlinks** indicated if symlinks should be followed

CLI Example:
```
salt '*' file.get_group /etc/passwd
```

Changed in version 0.16.4: follow_symlinks option added

**salt.modules.file.get_hash(path, form='sha256', chunk_size=65536)**

Get the hash sum of a file

This is better than **get_sum** for the following reasons:

- It does not read the entire file into memory.
- It does not return a string on error. The returned value of **get_sum** cannot really be trusted since it is vulnerable to collisions: get_sum(..., 'xyz') == 'Hash xyz not supported'

- **path** path to the file or directory
- **form** desired sum format
- **chunk_size** amount to sum at once

CLI Example:
salt '*' file.get_hash /etc/shadow

salt.modules.file.get_managed(name, template, source, source_hash, user, group, mode, saltenv, context, defaults, **kwargs)

Return the managed file data for file.managed

name  location where the file lives on the server
template  template format
source  managed source file
source_hash  hash of the source file
user  user owner
group  group owner
mode  file mode
context  variables to add to the environment
default  default values of for context_dict

CLI Example:

```
```

salt.modules.file.get_mode(path, follow_symlinks=True)

Return the mode of a file

path  file or directory of which to get the mode
follow_symlinks  indicated if symlinks should be followed

CLI Example:

```
salt '*' file.get_mode /etc/passwd
```

Changed in version 2014.1.0: follow_symlinks option added

salt.modules.file.get_selinux_context(path)

Get an SELinux context from a given path

CLI Example:

```
salt '*' file.get_selinux_context /etc/hosts
```

salt.modules.file.get_sum(path, form='sha256')

Return the checksum for the given file. The following checksum algorithms are supported:

- md5
- sha1
- sha224
- sha256 (default)
- sha384
- sha512

path  path to the file or directory
form  desired sum format
**CLI Example:**

```bash
cd /etc/audit
salt '*' file.get_sum /etc/passwd sha512
```

`salt.modules.file.get_uid(path, follow_symlinks=True)`

Return the id of the user that owns a given file

- `path` : file or directory of which to get the uid
- `follow_symlinks` : indicated if symlinks should be followed

**CLI Example:**

```bash
cd /etc/audit
salt '*' file.get_uid /etc/passwd
```

Changed in version 0.16.4: `follow_symlinks` option added

`salt.modules.file.get_user(path, follow_symlinks=True)`

Return the user that owns a given file

- `path` : file or directory of which to get the user
- `follow_symlinks` : indicated if symlinks should be followed

**CLI Example:**

```bash
cd /etc/audit
salt '*' file.get_user /etc/passwd
```

Changed in version 0.16.4: `follow_symlinks` option added

`salt.modules.file.gid_to_group(gid)`

Convert the group id to the group name on this system

- `gid` : gid to convert to a group name

**CLI Example:**

```bash
cd /etc/audit
salt '*' file.gid_to_group 0
```

`salt.modules.file.grep(path, pattern, *args)`

Grep for a string in the specified file

**Note:** This function’s return value is slated for refinement in future versions of Salt

- `path` : A file path
- `pattern` : A string. For example: `test a[0-5]`
- `args` : grep options. For example: " -v" " -i -B2"

**CLI Example:**

```bash
cd /etc/audit
salt '*' file.grep /etc/passwd nobody
salt '*' file.grep /etc/sysconfig/network-scripts/ifcfg-eth0 ipaddr " -i"
salt '*' file.grep /etc/sysconfig/network-scripts/ifcfg-eth0 ipaddr " -i -B2"
salt '*' file.grep "/etc/sysconfig/network-scripts/*" ipaddr " -i -l"
```

`salt.modules.file.group_to_gid(group)`

Convert the group to the gid on this system

- `group` : group to convert to its gid

**CLI Example:**

```bash
cd /etc/audit
```
salt '.transition' file.group_to_gid root

salt.modules.file.is_blkdev(name)
Check if a file exists and is a block device.

CLI Example:

    salt '*' file.is_blkdev /dev/blk

salt.modules.file.is_chrdev(name)
Check if a file exists and is a character device.

CLI Example:

    salt '*' file.is_chrdev /dev/chr

salt.modules.file.is_fifo(name)
Check if a file exists and is a FIFO.

CLI Example:

    salt '*' file.is_fifo /dev/fifo

salt.modules.file.is_link(path)
Check if the path is a symlink

CLI Example:

    salt '*' file.is_link /path/to/link

salt.modules.file.join(*args)
Return a normalized file system path for the underlying OS

New in version 2014.7.0.

This can be useful at the CLI but is frequently useful when scripting combining path variables:

    {% set www_root = '/var' %}
    {% set app_dir = 'myapp' %}

    myapp_config:
        file:
            - managed
            - name: {{ salt['file.join'](www_root, app_dir, 'config.yaml') }}

    CLI Example:

    salt '*' file.join '/usr/local/bin'

salt.modules.file.lchown(path, user, group)
Chown a file, pass the file the desired user and group without following symlinks.

    path  path to the file or directory
    user  user owner
    group group owner

CLI Example:

    salt '*' file.lchown /etc/passwd root root
salt.modules.file.line(path, content, match=None, mode=None, location=None, before=None, after=None, show_changes=True, backup=False, quiet=False, indent=True)

New in version 2015.8.0.

Edit a line in the configuration file.

Parameters

- **path** -- Filesystem path to the file to be edited.
- **content** -- Content of the line.
- **match** -- Match the target line for an action by a fragment of a string or regular expression.
- **mode** --
  
  Ensure If line does not exist, it will be added.
  Replace If line already exist, it will be replaced.
  Delete Delete the line, once found.
  Insert Insert a line.
- **location** --
  
  start Place the content at the beginning of the file.
  end Place the content at the end of the file.
- **before** -- Regular expression or an exact case-sensitive fragment of the string.
- **after** -- Regular expression or an exact case-sensitive fragment of the string.

**:param show_changes** Output a unified diff of the old file and the new file. If False return a boolean if any changes were made. Default is True

**Note:** Using this option will store two copies of the file in-memory (the original version and the edited version) in order to generate the diff.

**:param backup** Create a backup of the original file with the extension: ``Year-Month-Day-Hour-Minutes-Seconds``.

**:param quiet** Do not raise any exceptions. E.g. ignore the fact that the file that is tried to be edited does not exist and nothing really happened.

**:param indent** Keep indentation with the previous line.

CLI Examples:

```
salt '*' file.line /etc/nsswitch.conf "networks: files dns", after="hosts:.:*", mode='ensure'
```

salt.modules.file.link(src, path)

New in version 2014.1.0.

Create a hard link to a file

CLI Example:

```
salt '*' file.link /path/to/file /path/to/link
```

salt.modules.file.list_backups(path, limit=None)

New in version 0.17.0.

Lists the previous versions of a file backed up using Salt’s file state backup system.
path  The path on the minion to check for backups
limit  Limit the number of results to the most recent N backups

CLI Example:
salt '*' file.list_backups /foo/bar/baz.txt

salt.modules.file.list_backups_dir(path, limit=None)
Lists the previous versions of a directory backed up using Salt's file state backup system.
path  The directory on the minion to check for backups
limit  Limit the number of results to the most recent N backups

CLI Example:
salt '*' file.list_backups_dir /foo/bar/baz/

salt.modules.file.lstat(path)
New in version 2014.1.0.
Returns the lstat attributes for the given file or dir. Does not support symbolic links.

CLI Example:
salt '*' file.lstat /path/to/file

salt.modules.file.makedirs(path, user=None, group=None, mode=None)
Ensure that the directory containing this path is available.

Note: The path must end with a trailing slash otherwise the directory/directories will be created up to the parent directory. For example if path is /opt/code, then it would be treated as /opt/ but if the path ends with a trailing slash like /opt/code/, then it would be treated as /opt/code/.

CLI Example:
salt '*' file.makedirs /opt/code/

salt.modules.file.makedirs_perms(name, user=None, group=None, mode='0755')
Taken and modified from os.makedirs to set user, group and mode for each directory created.

CLI Example:
salt '*' file.makedirs_perms /opt/code

salt.modules.file.manage_file(name, sfn, ret, source, source_sum, user, group, mode, saltenv, backup, makedirs=False, template=None, show_diff=True, contents=None, dir_mode=None, follow_symlinks=True)
Checks the destination against what was retrieved with get_managed and makes the appropriate modifications (if necessary).

name  location to place the file
sfn  location of cached file on the minion

This is the path to the file stored on the minion. This file is placed on the minion using cp.cache_file. If the hash sum of that file matches the source_sum, we do not transfer the file to the minion again.

This file is then grabbed and if it has template set, it renders the file to be placed into the correct place on the system using salt.files.utils.copyfile()

ret  The initial state return data structure. Pass in None to use the default structure.
source  file reference on the master
source_hash  sum hash for source
user  user owner
group  group owner
backup  backup_mode
makedirs  make directories if they do not exist
template  format of templating
show_diff  Include diff in state return
contents:  contents to be placed in the file
dir_mode  mode for directories created with makedirs

CLI Example:

```bash
salt '*' file.manage_file /etc/httpd/conf.d/httpd.conf '{hash_type: md5, hsum: '5259b1b3525'} salt://httpd/httpd.conf {hash_type: md5, hsum: '<md5sum>}'
```

Changed in version 2014.7.0: follow_symlinks option added

```bash
salt.modules.file.mkdir(dir_path, user=None, group=None, mode=None)
```

Ensure that a directory is available.

CLI Example:

```bash
salt '*' file.mkdir /opt/jetty/context
```

```bash
salt.modules.file.mknod(name, ntype, major=0, minor=0, user=None, group=None, mode='0600')
```

New in version 0.17.0.
Create a block device, character device, or fifo pipe. Identical to the gnu mknod.

CLI Examples:

```bash
salt '*' file.mknod /dev/chr c 180 31
salt '*' file.mknod /dev/blk b 8 999
salt '*' file.mknod /dev/fifo p
```

```bash
salt.modules.file.mknod_blkdev(name, major, minor, user=None, group=None, mode='0660')
```

New in version 0.17.0.
Create a block device.

CLI Example:

```bash
salt '*' file.mknod_blkdev /dev/blk 8 999
```

```bash
salt.modules.file.mknod_chrdev(name, major, minor, user=None, group=None, mode='0660')
```

New in version 0.17.0.
Create a character device.

CLI Example:

```bash
salt '*' file.mknod_chrdev /dev/chr 180 31
```

```bash
salt.modules.file.mknod_fifo(name, user=None, group=None, mode='0660')
```

New in version 0.17.0.
Create a FIFO pipe.
CLI Example:
```
salt '*' file.mknod_fifo /dev/fifo
```

salt.modules.file.move(src, dst)
Move a file or directory

CLI Example:
```
salt '*' file.move /path/to/src /path/to/dst
```

salt.modules.file.normpath(path)
Returns Normalize path, eliminating double slashes, etc.

New in version 2015.5.0.
This can be useful at the CLI but is frequently useful when scripting.

```
{% from salt['file.normpath'](tpldir + '/../vars.jinja') import parent_vars %}
```

CLI Example:
```
salt '*' file.normpath 'a/b/c/..
```

salt.modules.file.open_files(by_pid=False)
Return a list of all physical open files on the system.

CLI Examples:
```
salt '*' file.open_files
salt '*' file.open_files by_pid=True
```

salt.modules.file.pardir()
Return the relative parent directory path symbol for underlying OS

New in version 2014.7.0.
This can be useful when constructing Salt Formulas.

```
{% set pardir = salt['file.pardir']() %}
{% set final_path = salt['file.join']('subdir', pardir, 'confdir') %}
```

CLI Example:
```
salt '*' file.pardir
```

salt.modules.file.patch(originalfile, patchfile, options='~', dry_run=False)
Apply a patch to a file

Equivalent to:

```
patch <options> <originalfile> <patchfile>
```

originalfile The full path to the file or directory to be patched

patchfile A patch file to apply to originalfile

options Options to pass to patch.

CLI Example:
salt '/*' file.patch /opt/file.txt /tmp/file.txt.patch

salt.modules.file.path_exists_glob(path)
Tests to see if path after expansion is a valid path (file or directory). Expansion allows usage of ? * and character ranges []. Tilde expansion is not supported. Returns True/False.
New in version Helium.
CLI Example:

```
salt '/*' file.path_exists_glob /etc/pam*/pass*
```

salt.modules.file.prepend(path, *args, **kwargs)
New in version 2014.7.0.
Prepend text to the beginning of a file

**path** path to file

**args** strings to prepend to the file

CLI Example:

```
salt '/*' file.prepend /etc/motd
  "With all thine offerings thou shalt offer salt."
  "Salt is what makes things taste bad when it isn't in them."
```

Attention
If you need to pass a string to append and that string contains an equal sign, you must include the argument name, args. For example:

```
salt '/*' file.prepend /etc/motd args='cheese=spam'
salt '/*' file.prepend /etc/motd args="[\'cheese=spam\',\'spam=cheese\']"
```

salt.modules.file.psed(path, before, after, limit='', backup='.bak', flags='gMS', escape_all=False, multi=False)
Deprecated since version 0.17.0: Use replace() instead.
Make a simple edit to a file (pure Python version)
Equivalent to:

```
sed <backup> <options> "/<limit>/ s/<before>/<after>/<flags> <file>"
```

**path** The full path to the file to be edited
**before** A pattern to find in order to replace with after
**after** Text that will replace before
**limit** ['',] An initial pattern to search for before searching for before
**backup** ['.bak] The file will be backed up before edit with this file extension; WARNING: each time sed/comment/uncomment is called will overwrite this backup
**flags** [gMS]
Flags to modify the search. Valid values are:
- g: Replace all occurrences of the pattern, not just the first.
I: Ignore case.
L: Make \w, \W, \b, \B, \s and \S dependent on the locale.
M: Treat multiple lines as a single line.
S: Make . match all characters, including newlines.
U: Make \w, \W, \b, \B, \d, \D, \s and \S dependent on Unicode.
X: Verbose (whitespace is ignored).

multi: False If True, treat the entire file as a single line

Forward slashes and single quotes will be escaped automatically in the before and after patterns.

CLI Example:
```
salt '*' file.sed /etc/httpd/httpd.conf 'LogLevel warn' 'LogLevel info'
```

salt.modules.file.readdir(path)
New in version 2014.1.0.
Return a list containing the contents of a directory

CLI Example:
```
salt '*' file.readdir /path/to/dir/
```

salt.modules.file.readlink(path, canonicalize=False)
New in version 2014.1.0.
Return the path that a symlink points to If canonicalize is set to True, then it return the final target

CLI Example:
```
salt '*' file.readlink /path/to/link
```

salt.modules.file.remove(path)
Remove the named file

CLI Example:
```
salt '*' file.remove /tmp/foo
```

salt.modules.file.rename(src, dst)
Rename a file or directory

CLI Example:
```
salt '*' file.rename /path/to/src /path/to/dst
```

salt.modules.file.replace(path, pattern, repl, count=0, flags=0, bufsize=1, append_if_not_found=False, prepend_if_not_found=False, not_found_content=None, backup='.bak', dry_run=False, search_only=False, show_changes=True, ignore_if_missing=False, preserve_inode=True)
New in version 0.17.0.
Replace occurrences of a pattern in a file
This is a pure Python implementation that wraps Python's sub().

path  Filesystem path to the file to be edited
pattern  Python's regular expression search [https://docs.python.org/2/library/re.html](https://docs.python.org/2/library/re.html)

repl  The replacement text

count  Maximum number of pattern occurrences to be replaced

flags (list or int)  A list of flags defined in the re module documentation. Each list item should be a string that will correlate to the human-friendly flag name. E.g., ['IGNORECASE', 'MULTILINE']. Note: multiline searches must specify file as the bufsize argument below.

bufsize (int or str)  How much of the file to buffer into memory at once. The default value 1 processes one line at a time. The special value file may be specified which will read the entire file into memory before processing. Note: multiline searches must specify file buffering.

append_if_not_found  New in version 2014.7.0.

If pattern is not found and set to True then, the content will be appended to the file. Default is False

prepend_if_not_found  New in version 2014.7.0.

If pattern is not found and set to True then, the content will be appended to the file. Default is False

not_found_content  New in version 2014.7.0.

Content to use for append/prepend if not found. If None (default), uses repl. Useful when repl uses references to group in pattern.

backup  The file extension to use for a backup of the file before editing. Set to False to skip making a backup. Default is .bak

dry_run  Don't make any edits to the file, Default is False

search_only  Just search for the pattern; ignore the replacement; stop on the first match. Default is False

show_changes  Output a unified diff of the old file and the new file. If False return a boolean if any changes were made. Default is True

Note: Using this option will store two copies of the file in-memory (the original version and the edited version) in order to generate the diff.

ignore_if_missing  New in version 2015.8.0.

When this parameter is True, file.replace will return False if the file doesn't exist. When this parameter is False, file.replace will throw an error if the file doesn't exist. Default is False (to maintain compatibility with prior behaviour).

preserve_inode  New in version 2015.8.0.

Preserve the inode of the file, so that any hard links continue to share the inode with the original filename. This works by copying the file, reading from the copy, and writing to the file at the original inode. If False, the file will be moved rather than copied, and a new file will be written to a new inode, but using the original filename. Hard links will then share an inode with the backup, instead (if using backup to create a backup copy). Default is True.

If an equal sign (=) appears in an argument to a Salt command it is interpreted as a keyword argument in the format key=val. That processing can be bypassed in order to pass an equal sign through to the remote shell command by manually specifying the kwarg:

```
salt '*' file.replace /path/to/file pattern='=' repl=':'
salt '*' file.replace /path/to/file pattern="bind-address\$s*=" repl='bind-address: '
```

CLI Examples:
salt.modules.file.restore_backup(path, backup_id)
    New in version 0.17.0.
    Restore a previous version of a file that was backed up using Salt’s file state backup system.
    
    path  The path on the minion to check for backups
    backup_id  The numeric id for the backup you wish to restore, as found using file.list_backups
    
    CLI Example:
    ```
salt '*' file.restore_backup /foo/bar/baz.txt 0
    ```

salt.modules.file.restorecon(path, recursive=False)
    Reset the SELinux context on a given path
    
    CLI Example:
    ```
salt '*' file.restorecon /home/user/.ssh/authorized_keys
    ```

salt.modules.file.rmdir(path)
    New in version 2014.1.0.
    Remove the specified directory. Fails if a directory is not empty.
    
    CLI Example:
    ```
salt '*' file.rmdir /tmp/foo/
    ```

salt.modules.file.search(path, pattern, flags=0, bufsize=1, ignore_if_missing=False, multiline=False)
    New in version 0.17.0.
    Search for occurrences of a pattern in a file
    Except for multiline, params are identical to replace().
    
    multiline  If true, inserts `MULTILINE' into flags and sets bufsize to `file'.
                New in version 2015.8.0.
    
    CLI Example:
    ```
salt '*' file.search /etc/crontab 'mymaintenance.sh'
    ```

salt.modules.file.sed(path, before, after, limit='', backup='.bak', options='-r -e', flags='g', escape_all=False, negate_match=False)
    Deprecated since version 0.17.0: Use replace() instead.
    Make a simple edit to a file
    Equivalent to:
    ```
sed <backup> <options> "/<limit>/ s/<before>/<after>/<flags> <file>"
    ```
    
    path  The full path to the file to be edited
    before  A pattern to find in order to replace with after
    after  Text that will replace before
    limit  [''] An initial pattern to search for before searching for before
backup [.bak] The file will be backed up before edit with this file extension; WARNING: each time sed/comment/uncomment is called will overwrite this backup

options [-r -e] Options to pass to sed
flags [g] Flags to modify the sed search; e.g., i for case-insensitive pattern matching
negate_match [False] Negate the search command (!)

New in version 0.17.0.

Forward slashes and single quotes will be escaped automatically in the before and after patterns.

CLI Example:
```
salt '*' file.sed /etc/httpd/httpd.conf 'LogLevel warn' 'LogLevel info'
```

salt.modules.file.sed_contains(path, text, limit='', flags='g')

Deprecated since version 0.17.0: Use search() instead.

Return True if the file at path contains text. Utilizes sed to perform the search (line-wise search).

Note: the p flag will be added to any flags you pass in.

CLI Example:
```
salt '*' file.contains /etc/crontab 'mymaintenance.sh'
```

salt.modules.file.seek_read(path, size, offset)

New in version 2014.1.0.

Seek to a position on a file and read it

path path to file
seek amount to read at once
offset offset to start into the file

CLI Example:
```
salt '*' file.seek_read /path/to/file 4096 0
```

salt.modules.file.seek_write(path, data, offset)

New in version 2014.1.0.

Seek to a position on a file and write to it

path path to file
data data to write to file
offset position in file to start writing

CLI Example:
```
salt '*' file.seek_write /path/to/file 'some data' 4096
```

salt.modules.file.set_mode(path, mode)

Set the mode of a file

path file or directory of which to set the mode
mode mode to set the path to

CLI Example:
**Salt Documentation, Release 2015.8.0**

---

```
salt '*' file.set_mode /etc/passwd 0644
```

salt.modules.file.set_selinux_context(path, user=None, role=None, type=None, range=None)

Set a specific SELinux label on a given path

CLI Example:

```
salt '*' file.set_selinux_context path <role> <type> <range>
```

salt.modules.file.source_list(source, source_hash, saltenv)

Check the source list and return the source to use

CLI Example:

```
salt '*' file.source_list salt://http/httpd.conf '{hash_type: 'md5', 'hsum': <md5sum>}' base
```

salt.modules.file.stats(path, hash_type=None, follow_symlinks=True)

Return a dict containing the stats for a given file

CLI Example:

```
salt '*' file.stats /etc/passwd
```

salt.modules.file.statvfs(path)

New in version 2014.1.0.

Perform a statvfs call against the filesystem that the file resides on

CLI Example:

```
salt '*' file.statvfs /path/to/file
```

salt.modules.file.symlink(src, path)

Create a symbolic link to a file

CLI Example:

```
salt '*' file.symlink /path/to/file /path/to/link
```

salt.modules.file.touch(name, atime=None, mtime=None)

New in version 0.9.5.

Just like the touch command, create a file if it doesn’t exist or simply update the atime and mtime if it already does.

- **atime**: Access time in Unix epoch time
- **mtime**: Last modification in Unix epoch time

CLI Example:

```
salt '*' file.touch /var/log/emptyfile
```

salt.modules.file.truncate(path, length)

New in version 2014.1.0.

Seek to a position on a file and delete everything after that point

- **path**: path to file
- **length**: offset into file to truncate

CLI Example:

```
salt '*' file.truncate /path/to/file
```
salt '*' file.truncate /path/to/file 512

salt.modules.file.uid_to_user(uid)
   Convert a uid to a user name
   uid  uid to convert to a username
   CLI Example:
   salt '*' file.uid_to_user 0

salt.modules.file.uncomment(path, regex='^', char='#', backup='.bak')
   Deprecated since version 0.17.0: Use replace() instead.
   Uncomment specified commented lines in a file
   path  The full path to the file to be edited
   regex A regular expression used to find the lines that are to be uncommented. This regex should not include the comment character. A leading ^ character will be stripped for convenience (for easily switching between comment() and uncomment()).
   char  [#] The character to remove in order to uncomment a line
   backup [.bak] The file will be backed up before edit with this file extension; WARNING: each time sed/comment/uncomment is called will overwrite this backup
   CLI Example:
   salt '*' file.uncomment /etc/hosts.deny 'ALL: PARANOID'

salt.modules.file.user_to_uid(user)
   Convert username to a uid
   user  user name to convert to its uid
   CLI Example:
   salt '*' file.user_to_uid root

salt.modules.file.write(path, *args, **kwargs)
   New in version 2014.7.0.
   Write text to a file, overwriting any existing contents.
   path  path to file
   *args strings to write to the file
   CLI Example:
   salt '*' file.write /etc/motd "With all thine offerings thou shalt offer salt."

Attention
   If you need to pass a string to append and that string contains an equal sign, you must include the argument name, args. For example:
   salt '*' file.write /etc/motd args='cheese=spam'
   salt '*' file.write /etc/motd args="['cheese=spam','spam=cheese']"
31.16.82  salt.modules.firewalld

Support for firewalld.

New in version 2015.2.0.

```
salt.modules.firewalld.add_masquerade(zone)
```
Enable masquerade on a zone.

New in version 2015.8.0.

CLI Example:

```
salt '*' firewalld.add_masquerade
```

```
salt.modules.firewalld.add_port(zone, port)
```
Allow specific ports in a zone.

New in version 2015.8.0.

CLI Example:

```
salt '*' firewalld.add_port internal 443/tcp
```

```
salt.modules.firewalld.add_port_fwd(zone, src, dest, proto='tcp', dstaddr='')
```
Add port forwarding.

New in version 2015.8.0.

CLI Example:

```
salt '*' firewalld.add_port_fwd public 80 443 tcp
```

```
salt.modules.firewalld.add_service(name, zone=None, permanent=True)
```
Add a service for zone. If zone is omitted, default zone will be used.

CLI Example:

```
salt '*' firewalld.add_service ssh
```

To assign a service to a specific zone:

```
salt '*' firewalld.add_service ssh my_zone
```

```
salt.modules.firewalld.allow_icmp(zone, icmp)
```
Allow a specific ICMP type on a zone

New in version 2015.8.0.

CLI Example:

```
salt '*' firewalld.allow_icmp zone echo-reply
```

```
salt.modules.firewalld.block_icmp(zone, icmp)
```
Block a specific ICMP type on a zone

New in version 2015.8.0.

CLI Example:

```
salt '*' firewalld.block_icmp zone echo-reply
```
salt.modules.firewalld.default_zone()  
Print default zone for connections and interfaces  
CLI Example:
```
salt '*' firewalld.default_zone
```

salt.modules.firewalld.delete_service(name, restart=True)  
Delete an existing service  
CLI Example:
```
salt '*' firewalld.delete_service my_service
```
By default firewalld will be reloaded. However, to avoid reloading you need to specify the restart as False
```
salt '*' firewalld.delete_service my_service False
```

salt.modules.firewalld.delete_zone(zone, restart=True)  
Delete an existing zone  
CLI Example:
```
salt '*' firewalld.delete_zone my_zone
```
By default firewalld will be reloaded. However, to avoid reloading you need to specify the restart as False
```
salt '*' firewalld.delete_zone my_zone False
```

salt.modules.firewalld.get_icmp_types()  
Print predefined icmp types  
CLI Example:
```
salt '*' firewalld.get_icmp_types
```

salt.modules.firewalld.get_masquerade(zone)  
Show if masquerading is enabled on a zone  
CLI Example:
```
salt '*' firewalld.get_masquerade zone
```

salt.modules.firewalld.get_services()  
Print predefined services  
CLI Example:
```
salt '*' firewalld.get_services
```

salt.modules.firewalld.get_zones()  
Print predefined zones  
CLI Example:
```
salt '*' firewalld.get_zones
```

salt.modules.firewalld.list_all(zone=None)  
List everything added for or enabled in a zone  
CLI Example:
salt ' numerous firewalld.list_all

List a specific zone
salt ' numerous firewalld.list_all my_zone

salt.modules.firewalld.list_all

salt.modules.firewalld.list_all

salt.modules.firewalld.list_icmp_block(zone)
List ICMP blocks on a zone
New in version 2015.8.0.
CLI Example:
salt ' numerous firewalld.list_icmp_block zone

salt.modules.firewalld.list_port_fwd(zone)
List port forwarding
New in version 2015.8.0.
CLI Example:
salt ' numerous firewalld.list_port_fwd public

salt.modules.firewalld.list_ports(zone)
List all ports in a zone.
New in version 2015.8.0.
CLI Example:
salt ' numerous firewalld.list_ports

salt.modules.firewalld.list_services(zone=None)
List services added for zone as a space separated list. If zone is omitted, default zone will be used.
CLI Example:
salt ' numerous firewalld.list_services

List a specific zone
salt ' numerous firewalld.list_services my_zone

salt.modules.firewalld.list_zones()
List everything added for or enabled in all zones
CLI Example:
salt ' numerous firewalld.list_zones

salt.modules.firewalld.new_service(name, restart=True)
Add a new service
CLI Example:
salt ' numerous firewalld.new_service my_service

By default firewalld will be reloaded. However, to avoid reloading you need to specify the restart as False
salt ' numerous firewalld.new_service my_service False
salt.modules.firewalld.new_zone(zone, restart=True)

Add a new zone

CLI Example:

```
salt '*' firewalld.new_zone my_zone
```

By default firewalld will be reloaded. However, to avoid reloading you need to specify the restart as False

```
salt '*' firewalld.new_zone my_zone False
```

salt.modules.firewalld.remove_masquerade(zone)

Remove masquerade on a zone.

New in version 2015.8.0.

CLI Example:

```
salt '*' firewalld.remove_masquerade
```

salt.modules.firewalld.remove_port(zone, port)

Remove a specific port from a zone.

New in version 2015.8.0.

CLI Example:

```
salt '*' firewalld.remove_port internal 443/tcp
```

salt.modules.firewalld.remove_port_fwd(zone, src, dest, proto='tcp')

Remove Port Forwarding.

New in version 2015.8.0.

CLI Example:

```
salt '*' firewalld.remove_port_fwd public 80 443 tcp
```

salt.modules.firewalld.remove_service(name, zone=None, permanent=True)

Remove a service from zone. This option can be specified multiple times. If zone is omitted, default zone will be used.

CLI Example:

```
salt '*' firewalld.remove_service ssh
```

To remove a service from a specific zone

```
salt '*' firewalld.remove_service ssh dmz
```

salt.modules.firewalld.set_default_zone(zone)

Set default zone

CLI Example:

```
salt '*' firewalld.set_default_zone damian
```

salt.modules.firewalld.version()

Return version from firewall-cmd

CLI Example:
31.16.83 salt.modules.freebsd_sysctl

Module for viewing and modifying sysctl parameters

```
salt.modules.freebsd_sysctl.assign(name, value)
    Assign a single sysctl parameter for this minion
    CLI Example:
    salt '*' sysctl.assign net.inet.icmp.icmplim 50
```

```
salt.modules.freebsd_sysctl.get(name)
    Return a single sysctl parameter for this minion
    CLI Example:
    salt '*' sysctl.get hw.physmem
```

```
salt.modules.freebsd_sysctl.persist(name, value, config='/etc/sysctl.conf')
    Assign and persist a simple sysctl parameter for this minion
    CLI Example:
    salt '*' sysctl.persist net.inet.icmp.icmplim 50
    salt '*' sysctl.persist coretemp_load NO config=/boot/loader.conf
```

```
salt.modules.freebsd_sysctl.show(config_file=False)
    Return a list of sysctl parameters for this minion
    CLI Example:
    salt '*' sysctl.show
```

31.16.84 salt.modules.freebsdjail

The jail module for FreeBSD

```
salt.modules.freebsdjail.fstab(jail)
    Display contents of a fstab(5) file defined in specified jail's configuration. If no file is defined, return False.
    CLI Example:
    salt '*' jail.fstab <jail name>
```

```
salt.modules.freebsdjail.get_enabled()
    Return which jails are set to be run
    CLI Example:
    salt '*' jail.get_enabled
```

```
salt.modules.freebsdjail.is_enabled()
    See if jail service is actually enabled on boot
    CLI Example:
```
salt '.*' jail.is_enabled <jail name>

salt.modules.freebsdjail.restart('jail-')
    Restart the specified jail or all, if none specified
    CLI Example:
    salt '.*' jail.restart [<jail name>]

salt.modules.freebsdjail.show_config(jail)
    Display specified jail's configuration
    CLI Example:
    salt '.*' jail.show_config <jail name>

salt.modules.freebsdjail.start('jail-')
    Start the specified jail or all, if none specified
    CLI Example:
    salt '.*' jail.start [<jail name>]

salt.modules.freebsdjail.status(jail)
    See if specified jail is currently running
    CLI Example:
    salt '.*' jail.status <jail name>

salt.modules.freebsdjail.stop('jail-')
    Stop the specified jail or all, if none specified
    CLI Example:
    salt '.*' jail.stop [<jail name>]

salt.modules.freebsdjail.sysctl()
    Dump all jail related kernel states (sysctl)
    CLI Example:
    salt '.*' jail.sysctl

31.16.85 salt.modules.freebsdkmod

Module to manage FreeBSD kernel modules

salt.modules.freebsdkmod.available()
    Return a list of all available kernel modules
    CLI Example:
    salt '.*' kmod.available

salt.modules.freebsdkmod.check_available(mod)
    Check to see if the specified kernel module is available
    CLI Example:
**salt.modules.freebsdkmod**

- **is_loaded**(mod)**
  
  Check to see if the specified kernel module is loaded

  CLI Example:

  `salt '*' kmod.is_loaded vmm`

- **load**(mod, persist=False)**
  
  Load the specified kernel module

  **mod** Name of the module to add

  **persist** Write the module to sysrc kld_modules to make it load on system reboot

  CLI Example:

  `salt '*' kmod.load bhyve`

- **lsmod()**
  
  Return a dict containing information about currently loaded modules

  CLI Example:

  `salt '*' kmod.lsmod`

- **mod_list**(only_persist=False)**
  
  Return a list of the loaded module names

  CLI Example:

  `salt '*' kmod.mod_list`

- **remove**(mod, persist=False)**
  
  Remove the specified kernel module

  CLI Example:

  `salt '*' kmod.remove vmm`

### 31.16.86 salt.modules.freebsdpkg

Remote package support using pkg_add(1)

**Warning:** This module has been completely rewritten. Up to and including version 0.17.0, it supported pkg_add(1), but checked for the existence of a pkgng local database and, if found, would provide some of pkgng's functionality. The rewrite of this module has removed all pkgng support, and moved it to the pkgng execution module. For versions <= 0.17.0, the documentation here should not be considered accurate. If your Minion is running one of these versions, then the documentation for this module can be viewed using the sys.doc function:

```
salt bsdminion sys.doc pkg
```

This module acts as the default package provider for FreeBSD 9 and older. If you need to use pkgng on a FreeBSD 9 system, you will need to override the pkg provider by setting the providers parameter in your Minion config file, in order to use pkgng.
providers:
    pkg: pkgng

More information on pkgng support can be found in the documentation for the **pkgng** module.

This module will respect the **PACKAGEROOT** and **PACKAGESITE** environment variables, if set, but these values can also be overridden in several ways:

1. **Salt configuration parameters.** The configuration parameters freebsdpkg.PACKAGEROOT and freebsdpkg.PACKAGESITE are recognized. These config parameters are looked up using `config.get` and can thus be specified in the Master config file, Grains, Pillar, or in the Minion config file. Example:

   ```
   ```

2. **CLI arguments.** Both the packageroot (used interchangeably with fromrepo for API compatibility) and packagesite CLI arguments are recognized, and override their config counterparts from section 1 above.

   ```
   salt -G 'os:FreeBSD' pkg.install zsh fromrepo=ftp://ftp2.freebsd.org/
   salt -G 'os:FreeBSD' pkg.install zsh packageroot=ftp://ftp2.freebsd.org/
   salt -G 'os:FreeBSD' pkg.install zsh packagesite=ftp://ftp2.freebsd.org/pub/FreeBSD/ports/ia64/packages-9-stable/Latest/
   ```

   .. note::
   These arguments can also be passed through in states:

   ```
   .. code-block:: yaml
   
   zsh:
       pkg.installed:
   ```

.. code-block:: python

   salt.modules.freebsdpkg.file_dict(*packages*)
   List the files that belong to a package, grouped by package. Not specifying any packages will return a list of _every_ file on the system’s package database (not generally recommended).
   
   CLI Examples:

   ```
   salt '*' pkg.file_list httpd
   salt '*' pkg.file_list httpd postfix
   salt '*' pkg.file_list
   ```

.. code-block:: python

   salt.modules.freebsdpkg.file_list(*packages*)
   List the files that belong to a package. Not specifying any packages will return a list of _every_ file on the system’s package database (not generally recommended).
   
   CLI Examples:

   ```
   salt '*' pkg.file_list httpd
   salt '*' pkg.file_list httpd postfix
   salt '*' pkg.file_list
   ```

.. code-block:: python

   salt.modules.freebsdpkg.install(name=None, refresh=False, fromrepo=None, pkgs=None, 
                                   sources=None, **kwargs)
   Install package(s) using pkg_add(1)
   
   name  The name of the package to be installed.
   
   refresh  Whether or not to refresh the package database before installing.
fromrepo or packageroot  Specify a package repository from which to install. Overrides the system default, as well as the PACKAGEROOT environment variable.

package site  Specify the exact directory from which to install the remote package. Overrides the PACKAGE-SITE environment variable, if present.

Multiple Package Installation Options:

pkgs  A list of packages to install from a software repository. Must be passed as a python list.

   CLI Example:
   ```
salt '*' pkg.install pkgs='["foo", "bar"]'
   ```

sources  A list of packages to install. Must be passed as a list of dicts, with the keys being package names, and the values being the source URI or local path to the package.

   CLI Example:
   ```
salt '*' pkg.install sources='[{"foo": "salt://foo.deb"}, {"bar": "salt://bar.deb"}]'
   ```

Return a dict containing the new package names and versions:

   ```
   {'<package>': {"old": '<old-version>',
                   'new': '<new-version>'}}
   ```

   CLI Example:
   ```
salt '*' pkg.install <package name>
   ```

   ```
salt.modules.freebsdpkg.latest_version('names', **kwargs)
   ```

    pkg_add(1) is not capable of querying for remote packages, so this function will always return results as if there is no package available for install or upgrade.

   CLI Example:
   ```
salt '*' pkg.latest_version <package name>
   ```

   ```
salt '*' pkg.latest_version <package1> <package2> <package3> ...
   ```

   ```
salt.modules.freebsdpkg.list_pkgs(versions_as_list=False, with_origin=False, **kwargs)
   ```

   List the packages currently installed as a dict:

   ```
   {'<package_name>': '<version>'}
   ```

   with_origin  [False] Return a nested dictionary containing both the origin name and version for each installed package.

   New in version 2014.1.0.

   CLI Example:
   ```
salt '*' pkg.list_pkgs
   ```

   ```
salt.modules.freebsdpkg.refresh_db()
   ```

    pkg_add(1) does not use a local database of available packages, so this function simply returns True. It exists merely for API compatibility.

   CLI Example:
   ```
salt '*' pkg.refresh_db
   ```
salt.modules.freebsdpkg.remove(name=None, pkgs=None, **kwargs)

Remove packages using pkg_delete(1)

**name** The name of the package to be deleted.

***Multiple Package Options:***

**pkgs** A list of packages to delete. Must be passed as a python list. The name parameter will be ignored if this option is passed.

New in version 0.16.0.

Returns a dict containing the changes.

CLI Example:

```
salt '*' pkg.remove <package name>
salt '*' pkg.remove <package1>,<package2>,<package3>
salt '*' pkg.remove pkgs='["foo", "bar"]'
```

salt.modules.freebsdpkg.upgrade()

Upgrades are not supported with pkg_add(1). This function is included for API compatibility only and always returns an empty dict.

CLI Example:

```
salt '*' pkg.upgrade
```

salt.modules.freebsdpkg.version(*names, **kwargs)

Returns a string representing the package version or an empty string if not installed. If more than one package name is specified, a dict of name/version pairs is returned.

**with_origin** [False] Return a nested dictionary containing both the origin name and version for each specified package.

New in version 2014.1.0.

CLI Example:

```
salt '*' pkg.version <package name>
salt '*' pkg.version <package1> <package2> <package3> ...
```

31.16.87 salt.modules.freebsdports

Install software from the FreeBSD ports(7) system

New in version 2014.1.0.

This module allows you to install ports using BATCH=yes to bypass configuration prompts. It is recommended to use the ports state to install ports, but it also possible to use this module exclusively from the command line.

```
salt minion-id ports.config security/nmap IPV6=off
salt minion-id ports.install security/nmap
```

salt.modules.freebsdports.config(name, reset=False, **kwargs)

Modify configuration options for a given port. Multiple options can be specified. To see the available options for a port, use ports.showconfig.

**name** The port name, in category/name format

**reset** [False] If True, runs a make rmconfig for the port, clearing its configuration before setting the desired options
CLI Examples:

```bash
salt '*' ports.config security/nmap IPV6=off
```

```
salt.modules.freebsdports.deinstall(name)
De-install a port.
CLI Example:

```
salt '/*' ports.deinstall security/nmap
```

```
salt.modules.freebsdports.install(name, clean=True)
Install a port from the ports tree. Installs using BATCH=yes for non-interactive building. To set config options for a given port, use ports.config.

```clean [True] If True, cleans after installation. Equivalent to running make install clean BATCH=yes.
```

**Note:** It may be helpful to run this function using the `-t` option to set a higher timeout, since compiling a port may cause the Salt command to exceed the default timeout.

CLI Example:

```bash
salt -t 1200 '/*' ports.install security/nmap
```

```
salt.modules.freebsdports.list_all()
Lists all ports available.
CLI Example:

```
salt '/*' ports.list_all
```

**Warning:** Takes a while to run, and returns a LOT of output

```
salt.modules.freebsdports.rmconfig(name)
Clear the cached options for the specified port; run a make rmconfig
name The name of the port to clear
CLI Example:

```
salt '/*' ports.rmconfig security/nmap
```

```
salt.modules.freebsdports.search(name)
Search for matches in the ports tree. Globs are supported, and the category is optional
CLI Examples:

```
salt '/*' ports.search 'security/*'
salt '/*' ports.search 'security/n*' 
salt '/*' ports.search nmap
```

**Warning:** Takes a while to run

```
salt.modules.freebsdports.showconfig(name, default=False, dict_return=False)
Show the configuration options for a given port.
default [False] Show the default options for a port (not necessarily the same as the current configuration)
dict_return [False] Instead of returning the output of make showconfig, return the data in an dictionary

31.16. Full list of builtin execution modules
CLI Example:
```
salt '*' ports.showconfig security/nmap
salt '*' ports.showconfig security/nmap default=True
```

```python
salt.modules.freebsdports.update(extract=False)
```
Update the ports tree

extract [False] If True, runs a portsnap extract after fetching, should be used for first-time installation of the ports tree.

CLI Example:
```
salt '*' ports.update
```

### 31.16.88 salt.modules.freebsdservice

The service module for FreeBSD

```python
salt.modules.freebsdservice.available(name)
```
Check that the given service is available.

CLI Example:
```
salt '*' service.available sshd
```

```python
salt.modules.freebsdservice.disable(name, **kwargs)
```
Disable the named service to start at boot

Arguments the same as for enable()

CLI Example:
```
salt '*' service.disable <service name>
```

```python
salt.modules.freebsdservice.disabled(name)
```
Return True if the named service is disabled, false otherwise

CLI Example:
```
salt '*' service.disabled <service name>
```

```python
salt.modules.freebsdservice.enable(name, **kwargs)
```
Enable the named service to start at boot

```python
name service name
```

```python
config [/etc/rc.conf] Config file for managing service. If config value is empty string, then /etc/rc.conf.d/<service> used. See man rc.conf(5) for details.
```

Also service.config variable can be used to change default.

CLI Example:
```
salt '*' service.enable <service name>
```

```python
salt.modules.freebsdservice.enabled(name, **kwargs)
```
Return True if the named service is enabled, false otherwise

```
name Service name
```

CLI Example:
salt 'service name'

salt.modules.freebsdservice.get_all()
Return a list of all available services

CLI Example:
salt 'service name'

salt.modules.freebsdservice.get_disabled()
Return what services are available but not enabled to start at boot

CLI Example:
salt 'service name'

salt.modules.freebsdservice.get_enabled()
Return what services are set to run on boot

CLI Example:
salt 'service name'

salt.modules.freebsdservice.missing(name)
The inverse of service.available. Returns True if the specified service is not available, otherwise returns False.

CLI Example:
salt 'service missing sshd'

salt.modules.freebsdservice.reload(name)
Restart the named service

CLI Example:
salt 'service reload <service name>'

salt.modules.freebsdservice.restart(name)
Restart the named service

CLI Example:
salt 'service restart <service name>'

salt.modules.freebsdservice.start(name)
Start the specified service

CLI Example:
salt 'service start <service name>'

salt.modules.freebsdservice.status(name, sig=None)
Return the status for a service (True or False).

name Name of service

CLI Example:
salt 'service status <service name>'
salt.modules.freebsdservice.stop(name)
Stop the specified service

CLI Example:
```
salt '*' service.stop <service name>
```

31.16.89 salt.modules.gem

Manage ruby gems.
salt.modules.gem.install(gems, ruby=None, gem_bin=None, runas=None, version=None, rdoc=False, ri=False, pre_releases=False, proxy=None)
Installs one or several gems.

Parameters
- **gems** -- string The gems to install
- **gem_bin** -- string: None Full path to gem binary to use.
- **ruby** -- string: None If RVM or rbenv are installed, the ruby version and gemset to use. Ignored if gem_bin is specified.
- **runas** -- string: None The user to run gem as.
- **version** -- string: None Specify the version to install for the gem. Doesn't play nice with multiple gems at once
- **rdoc** -- boolean: False Generate RDoc documentation for the gem(s).
- **ri** -- boolean: False Generate RI documentation for the gem(s).
- **pre_releases** -- boolean: False Include pre-releases in the available versions
- **proxy** -- string: None Use the specified HTTP proxy server for all outgoing traffic. Format: http://hostname[port]

CLI Example:
```
salt '*' gem.install vagrant
```
```
salt '*' gem.install redphone gem_bin=/opt/sensu/embedded/bin/gem
```

salt.modules.gem.list(prefix='', ruby=None, runas=None, gem_bin=None)
List locally installed gems.

Parameters
- **prefix** -- string: Only list gems when the name matches this prefix.
- **gem_bin** -- string: None Full path to gem binary to use.
- **ruby** -- string: None If RVM or rbenv are installed, the ruby version and gemset to use. Ignored if gem_bin is specified.
- **runas** -- string: None The user to run gem as.

CLI Example:
```
salt '*' gem.list
```
salt.modules.gem.list_upgrades(ruby=None, runas=None, gem_bin=None)
New in version 2015.8.0.
Check if an upgrade is available for installed gems

gem_bin [None] Full path to gem binary to use.
ruby [None] If RVM or rbenv are installed, the ruby version and gemset to use. Ignored if gem_bin is specified.
runas [None] The user to run gem as.

CLI Example:
salt '*' gem.list_upgrades

salt.modules.gem.sources_add(source_uri, ruby=None, runas=None, gem_bin=None)
Add a gem source.
Parameters

- source_uri -- string The source URI to add.
- gem_bin -- string : None Full path to gem binary to use.
- ruby -- string : None If RVM or rbenv are installed, the ruby version and gemset to use. Ignored if gem_bin is specified.
- runas -- string : None The user to run gem as.

CLI Example:
salt '*' gem.sources_add http://rubygems.org/

salt.modules.gem.sources_list(ruby=None, runas=None, gem_bin=None)
List the configured gem sources.
Parameters

- gem_bin -- string : None Full path to gem binary to use.
- ruby -- string : None If RVM or rbenv are installed, the ruby version and gemset to use. Ignored if gem_bin is specified.
- runas -- string : None The user to run gem as.

CLI Example:
salt '*' gem.sources_list

salt.modules.gem.sources_remove(source_uri, ruby=None, runas=None, gem_bin=None)
Remove a gem source.
Parameters

- source_uri -- string The source URI to remove.
- gem_bin -- string : None Full path to gem binary to use.
- ruby -- string : None If RVM or rbenv are installed, the ruby version and gemset to use. Ignored if gem_bin is specified.
- runas -- string : None The user to run gem as.

CLI Example:
salt '...' gem.sources_remove http://rubygems.org/

salt.modules.gem.uninstall(gems, ruby=None, runas=None, gem_bin=None)
Uninstall one or several gems.

Parameters
- **gems** -- string The gems to uninstall.
- **gem_bin** -- string : None Full path to gem binary to use.
- **ruby** -- string : None If RVM or rbenv are installed, the ruby version and gemset to use. Ignored if gem_bin is specified.
- **runas** -- string : None The user to run gem as.

CLI Example:
salt '...' gem.uninstall vagrant

salt.modules.gem.update(gems, ruby=None, runas=None, gem_bin=None)
Update one or several gems.

Parameters
- **gems** -- string The gems to update.
- **gem_bin** -- string : None Full path to gem binary to use.
- **ruby** -- string : None If RVM or rbenv are installed, the ruby version and gemset to use. Ignored if gem_bin is specified.
- **runas** -- string : None The user to run gem as.

CLI Example:
salt '...' gem.update vagrant

salt.modules.gem.update_system(version='*', ruby=None, runas=None, gem_bin=None)
Update rubygems.

Parameters
- **version** -- string : (newest) The version of rubygems to install.
- **gem_bin** -- string : None Full path to gem binary to use.
- **ruby** -- string : None If RVM or rbenv are installed, the ruby version and gemset to use. Ignored if gem_bin is specified.
- **runas** -- string : None The user to run gem as.

CLI Example:
salt '...' gem.update_system

31.16.90   salt.modules.genesis

Module for managing container and VM images
New in version 2014.7.0.
salt.modules.genesis.avail_platforms()
   Return which platforms are available
   CLI Example:
   ```bash
   salt myminion genesis.avail_platforms
   ```

salt.modules.genesis.bootstrap(platform, root, img_format='dir', fs_format='ext2', arch=None, flavor=None, repo_url=None, static_qemu=None)
   Create an image for a specific platform.
   Please note that this function MUST be run as root, as images that are created make files belonging to root.
   platform Which platform to use to create the image. Currently supported platforms are rpm, deb and pacman.
   root Local path to create the root of the image filesystem.
   img_format Which format to create the image in. By default, just copies files into a directory on the local filesystem (dir). Future support will exist for sparse.
   fs_format When using a non-dir img_format, which filesystem to format the image to. By default, ext2.
   arch Architecture to install packages for, if supported by the underlying bootstrap tool. Currently only used for deb.
   flavor Which flavor of operating system to install. This correlates to a specific directory on the distribution repositories. For instance, wheezy on Debian.
   repo_url Mainly important for Debian-based repos. Base URL for the mirror to install from. (e.x.: http://ftp.debian.org/debian/)
   static_qemu Local path to the static qemu binary required for this arch. (e.x.: /usr/bin/qemu-amd64-static)
   pkg_confs The location of the conf files to copy into the image, to point the installer to the right repos and configuration.
   CLI Examples:
   ```bash
   salt myminion genesis.bootstrap pacman /root/arch
   salt myminion genesis.bootstrap rpm /root/redhat
   salt myminion genesis.bootstrap deb /root/wheezy arch=amd64 flavor=wheezy static_qemu=/usr/bin/qemu-amd64-static
   ```

salt.modules.genesis.pack(name, root, path=None, pack_format='tar', compress='bzip2')
   Pack up a directory structure, into a specific format
   CLI Examples:
   ```bash
   salt myminion genesis.pack centos /root/centos
   salt myminion genesis.pack centos /root/centos pack_format='tar'
   ```

salt.modules.genesis.unpack(name, dest=None, path=None, pack_format='tar', compress='bz2')
   Unpack an image into a directory structure
   CLI Example:
   ```bash
   salt myminion genesis.unpack centos /root/centos
   ```

31.16.91 salt.modules.gentoo_service

Top level package command wrapper, used to translate the os detected by grains to the correct service manager
salt.modules.gentoo_service.available(name)
 Returns True if the specified service is available, otherwise returns False.

CLI Example:
```
salt '*' service.available sshd
```

salt.modules.gentoo_service.disable(name, **kwargs)
 Disable the named service to start at boot

CLI Example:
```
salt '*' service.disable <service name>
```

salt.modules.gentoo_service.disabled(name)
 Return True if the named service is enabled, false otherwise

CLI Example:
```
salt '*' service.disabled <service name>
```

salt.modules.gentoo_service.enable(name, **kwargs)
 Enable the named service to start at boot

CLI Example:
```
salt '*' service.enable <service name>
```

salt.modules.gentoo_service.enabled(name, **kwargs)
 Return True if the named service is enabled, false otherwise

CLI Example:
```
salt '*' service.enabled <service name>
```

salt.modules.gentoo_service.get_all()
 Return all available boot services

CLI Example:
```
salt '*' service.get_all
```

salt.modules.gentoo_service.get_disabled()
 Return a set of services that are installed but disabled

CLI Example:
```
salt '*' service.get_disabled
```

salt.modules.gentoo_service.get_enabled()
 Return a list of service that are enabled on boot

CLI Example:
```
salt '*' service.get_enabled
```

salt.modules.gentoo_service.missing(name)
 The inverse of service.available. Returns True if the specified service is not available, otherwise returns False.

CLI Example:
salt 's' service.missing sshd

salt.modules.gentoo_service.restart(name)
    Restart the named service
    CLI Example:
    
    salt '*' service.restart <service name>

salt.modules.gentoo_service.start(name)
    Start the specified service
    CLI Example:
    
    salt '*' service.start <service name>

salt.modules.gentoo_service.status(name, sig=None)
    Return the status for a service, returns the PID or an empty string if the service is running or not, pass a signature to use to find the service via ps
    CLI Example:
    
    salt '*' service.status <service name> [service signature]

salt.modules.gentoo_service.stop(name)
    Stop the specified service
    CLI Example:
    
    salt '*' service.stop <service name>

31.16.92 salt.modules.gentoolkitmod

Support for Gentoolkit

salt.modules.gentoolkitmod.eclean_dist( destructive=False, package_names=False, size_limit=0, time_limit=0, fetch_restricted=False, exclude_file='/etc/eclean/distfiles.exclude')

Clean obsolete portage sources

destructive  Only keep minimum for reinstallation

package_names  Protect all versions of installed packages. Only meaningful if used with destructive=True

size_limit <size>  Don’t delete distfiles bigger than <size>. <size> is a size specification: ''10M'' is ''ten megabytes'', ''200K'' is ''two hundreds kilobytes'', etc. Units are: G, M, K and B.

time_limit <time>  Don’t delete distfiles files modified since <time> <time> is an amount of time: ''1y'' is ''one year'', ''2w'' is ''two weeks'', etc. Units are: y (years), m (months), w (weeks), d (days) and h (hours).

fetch_restricted  Protect fetch-restricted files. Only meaningful if used with destructive=True

exclude_file  Path to exclusion file. Default is '/etc/eclean/distfiles.exclude' This is the same default eclean-dist uses. Use None if this file exists and you want to ignore.

Returns a dict containing the cleaned, saved, and deprecated dists:

{'cleaned': {<dist file>: <size>},
 'deprecated': {<package>: <dist file>},
}
CLI Example:

```
salt '*' gentoolkit.eclean_dist destructive=True
```

```
salt.modules.gentoolkitmod.eclean_pkg(destructive=False, package_names=False, time_limit=0, exclude_file='/etc/eclean/packages.exclude')
```

Clean obsolete binary packages

- **destructive** Only keep minimum for reinstallation
- **package_names** Protect all versions of installed packages. Only meaningful if used with destructive=True
- **time_limit** `<time>` Don’t delete distfiles files modified since `<time>` is an amount of time: `''y''` is `''one year''`, `''2w''` is `''two weeks''`, etc. Units are: `y` (years), `m` (months), `w` (weeks), `d` (days) and `h` (hours).
- **exclude_file** Path to exclusion file. Default is `/etc/eclean/packages.exclude` This is the same default `eclean-pkg` uses. Use None if this file exists and you want to ignore.

Returns a dict containing the cleaned binary packages:

```
{'cleaned': {'<dist file>': '<size>'},
'total_cleaned': '<size>'
```

CLI Example:

```
salt '*' gentoolkit.eclean_pkg destructive=True
```

```
salt.modules.gentoolkitmod.glsa_check_list(glsa_list)
```

List the status of Gentoo Linux Security Advisories

- **glsa_list** can contain an arbitrary number of GLSA ids, filenames containing GLSAs or the special identifiers `''all''` and `''affected''`

Returns a dict containing glsa ids with a description, status, and CVEs:

```
{'<glsa_id>': {'description': '<glsa_description>', 'status': '<glsa_status>', 'CVEs': ['<list of CVEs>']}}
```

CLI Example:

```
salt '*' gentoolkit.glsa_check_list 'affected'
```

```
salt.modules.gentoolkitmod.revdep_rebuild(lib=None)
```

Fix up broken reverse dependencies

- **lib** Search for reverse dependencies for a particular library rather than every library on the system. It can be a full path to a library or basic regular expression.

CLI Example:

```
salt '*' gentoolkit.revdep_rebuild
```

## 31.16.93 salt.modules.git

Support for the Git SCM
salt.modules.git.add(cwd, filename, opts='--', user=None, ignore_retcode=False)

Changed in version 2015.8.0: The --verbose command line argument is now implied

**Interface to** git-add(1)

- **cwd** The path to the git checkout
- **filename** The location of the file/directory to add, relative to **cwd**
- **opts** Any additional options to add to the command line, in a single string

**Note:** On the Salt CLI, if the opts are preceded with a dash, it is necessary to precede them with opts=(as in the CLI examples below) to avoid causing errors with Salt’s own argument parsing.

- **user** User under which to run the git command. By default, the command is run by the user under which the minion is running.
- **ignore_retcode** [False] If True, do not log an error to the minion log if the git command returns a nonzero exit status.

New in version 2015.8.0.

CLI Examples:

```bash
salt myminion git.add /path/to/repo foo/bar.py
salt myminion git.add /path/to/repo foo/bar.py opts='--dry-run'
```

salt.modules.git.archive(cwd, output, rev='HEAD', fmt=None, prefix=None, user=None, ignore_retcode=False, **kwargs)

Changed in version 2015.8.0: Returns True if successful, raises an error if not.

**Interface to** git-archive(1), exports a tarball/zip file of the repository

- **cwd** The path to be archived

**Note:** git archive permits a partial archive to be created. Thus, this path does not need to be the root of the git repository. Only the files within the directory specified by cwd (and its subdirectories) will be in the resulting archive. For example, if there is a git checkout at /tmp/foo, then passing /tmp/foo/bar as the cwd will result in just the files underneath /tmp/foo/bar to be exported as an archive.

- **output** The path of the archive to be created
- **overwrite** [False] Unless set to True, Salt will over overwrite an existing archive at the path specified by the output argument.

New in version 2015.8.0.

- **rev** [HEAD] The revision from which to create the archive
- **format** Manually specify the file format of the resulting archive. This argument can be omitted, and git archive will attempt to guess the archive type (and compression) from the filename. zip, tar, tar.gz, and tgz are extensions that are recognized automatically, and git can be configured to support other archive types with the addition of git configuration keys.

See the git-archive(1) manpage explanation of the --format argument (as well as the CONFIGURATION section of the manpage) for further information.

New in version 2015.8.0.

- **fmt** Replaced by format in version 2015.8.0

Deprecated since version 2015.8.0.
prefix  Prepend `<prefix>` to every filename in the archive. If unspecified, the name of the directory at the
top level of the repository will be used as the prefix (e.g. if `cwd` is set to `/foo/bar/baz`, the prefix
will be `baz`, and the resulting archive will contain a top-level directory by that name).

**Note:** The default behavior if the `--prefix` option for `git archive` is not specified is to not prepend
a prefix, so Salt's behavior differs slightly from `git archive` in this respect. Use `prefix=''` to create
an archive with no prefix.

Changed in version 2015.8.0: The behavior of this argument has been changed slightly. As of this version,
it is necessary to include the trailing slash when specifying a prefix, if the prefix is intended to create a
top-level directory.

user  User under which to run the git command. By default, the command is run by the user under which the
minion is running.

ignore_reetcode  [False] If `True`, do not log an error to the minion log if the git command returns a nonzero
exit status.

New in version 2015.8.0.

CLI Example:

```
salt myminion git.archive /path/to/repo /path/to/archive.tar
```

**salt.modules.git.branch** *(cwd, name=None, opts=' ', user=None, ignore_reetcode=False)*

Interface to `git-branch(1)`

**cwd**  The path to the git checkout

**name**  Name of the branch on which to operate. If not specified, the current branch will be assumed.

**opts**  Any additional options to add to the command line, in a single string

**Note:** To create a branch based on something other than HEAD, pass the name of the revision as `opts`. If
the revision is in the format `remotename/branch`, then this will also set the remote tracking branch.
Additionally, on the Salt CLI, if the opts are preceded with a dash, it is necessary to precede them with
`opts=` (as in the CLI examples below) to avoid causing errors with Salt's own argument parsing.

user  User under which to run the git command. By default, the command is run by the user under which the
minion is running.

ignore_reetcode  [False] If `True`, do not log an error to the minion log if the git command returns a nonzero
exit status.

New in version 2015.8.0.

CLI Examples:

```
# Set remote tracking branch
salt myminion git.branch /path/to/repo mybranch opts='--set-upstream-to origin/mybranch'
# Create new branch
salt myminion git.branch /path/to/repo mybranch upstream/somebranch
# Delete branch
salt myminion git.branch /path/to/repo mybranch opts='--d'
# Rename branch (2015.8.0 and later)
salt myminion git.branch /path/to/repo newbranch opts='--m oldbranch'
```

**salt.modules.git.checkout** *(cwd, rev=None, force=False, opts=' ', user=None, ignore_reetcode=False)*

Interface to `git-checkout(1)`

894 Chapter 31. Reference
**cwd**  The path to the git checkout

**opts**  Any additional options to add to the command line, in a single string

*Note:* On the Salt CLI, if the opts are preceded with a dash, it is necessary to precede them with `opts=` (as in the CLI examples below) to avoid causing errors with Salt’s own argument parsing.

**rev**  The remote branch or revision to checkout.

  Changed in version 2015.8.0: Optional when using `-b` or `-B` in `opts`.

**force**  [False] Force a checkout even if there might be overwritten changes

**user**  User under which to run the git command. By default, the command is run by the user under which the minion is running.

**ignore_retcode**  [False] If True, do not log an error to the minion log if the git command returns a nonzero exit status.

  New in version 2015.8.0.

CLI Examples:

```
# Checking out local local revisions
salt myminion git.checkout /path/to/repo somebranch user=jeff
salt myminion git.checkout /path/to/repo opts='testbranch -- conf/file1 file2'
salt myminion git.checkout /path/to/repo rev=origin/mybranch opts='--track'

# Checking out remote revision into new branch
salt myminion git.checkout /path/to/repo upstream/master opts='-b newbranch'

# Checking out current revision into new branch (2015.8.0 and later)
salt myminion git.checkout /path/to/repo rev=origin/mybranch opts='--track'
```

**salt.modules.git.clone**(cwd,  url=None,  name=None,  opts='`,  user=None,  identity=None,  https_user=None,  https_pass=None,  ignore_retcode=False,  repository=None)

Interface to `git-clone(1)`

**cwd**  Location of git clone

  Changed in version 2015.8.0: If `name` is passed, then the clone will be made within this directory.

**url**  The URL of the repository to be cloned

  Changed in version 2015.8.0: Argument renamed from `repository` to `url`

**name**  Optional alternate name for the top-level directory to be created by the clone

  New in version 2015.8.0.

**opts**  Any additional options to add to the command line, in a single string

**user**  User under which to run the git command. By default, the command is run by the user under which the minion is running.

  Run git as a user other than what the minion runs as

**identity**  Path to a private key to use for ssh URLs

*Warning:* Key must be passphraseless to allow for non-interactive login. For greater security with passphraseless private keys, see the `sshd(8)` manpage for information on securing the keypair from the remote side in the `authorized_keys` file.

**https_user**  Set HTTP Basic Auth username. Only accepted for HTTPS URLs.

  New in version 2015.5.0.
**https_pass**  Set HTTP Basic Auth password. Only accepted for HTTPS URLs.

New in version 2015.5.0.

**ignore_recode**  [False] If True, do not log an error to the minion log if the git command returns a nonzero exit status.

New in version 2015.8.0.

CLI Example:

```python
salt myminion git.clone /path/to/repo_parent_dir git://github.com/saltstack/salt.git
```

salt.modules.git.commit(cwd, message, opts=`, user=None, filename=None, ignore_recode=False)

Interface to `git-commit(1)`

cwd  The path to the git checkout

message  Commit message

opts  Any additional options to add to the command line, in a single string

**Note:** On the Salt CLI, if the opts are preceded with a dash, it is necessary to precede them with `opts=` (as in the CLI examples below) to avoid causing errors with Salt's own argument parsing.

The `-m` option should not be passed here, as the commit message will be defined by the message argument.

user  User under which to run the git command. By default, the command is run by the user under which the minion is running.

filename  The location of the file/directory to commit, relative to `cwd`. This argument is optional, and can be used to commit a file without first staging it.

**Note:** This argument only works on files which are already tracked by the git repository.

New in version 2015.8.0.

ignore_recode  [False] If True, do not log an error to the minion log if the git command returns a nonzero exit status.

New in version 2015.8.0.

CLI Examples:

```python
salt myminion git.commit /path/to/repo 'The commit message'
salt myminion git.commit /path/to/repo 'The commit message' filename=foo/bar.py
```

salt.modules.git.config_get(key, cwd=None, user=None, ignore_recode=False, **kwargs)

Get the value of a key in the git configuration file

key  The name of the configuration key to get

Changed in version 2015.8.0: Argument renamed from setting_name to key

cwd  The path to the git checkout

Changed in version 2015.8.0: Now optional if global is set to True

global  [False] If True, query the global git configuration. Otherwise, only the local git configuration will be queried.

New in version 2015.8.0.
all  [False] If True, return a list of all values set for key. If the key does not exist, None will be returned.

    New in version 2015.8.0.
user  User under which to run the git command. By default, the command is run by the user under which the
    minion is running.
ignore_retcode  [False] If True, do not log an error to the minion log if the git command returns a nonzero
    exit status.

    New in version 2015.8.0.

CLI Examples:

    salt myminion git.config_get user.name cwd=/path/to/repo
    salt myminion git.config_get user.email  user.name
    salt myminion git.config_get core.gitproxy cwd=/path/to/repo all=True

salt.modules.git.config_get-regexp(key, value_regex=None, cwd=None, user=None, ignore_retcode=False, **kwargs)

    New in version 2015.8.0.

Get the value of a key or keys in the git configuration file using regexes for more flexible matching. The return
    data is a dictionary mapping keys to lists of values matching the value_regex. If no values match, an empty
dictionary will be returned.

key  Regex on which key names will be matched
value_regex  If specified, return all values matching this regex. The return data will be a dictionary mapping
    keys to lists of values matching the regex.

    Important: Only values matching the value_regex will be part of the return data. So, if key matches
    a multivar, then it is possible that not all of the values will be returned. To get all values set for a multivar,
simply omit the value_regex argument.
cwd  The path to the git checkout
global  [False] If True, query the global git configuration. Otherwise, only the local git configuration will be
    queried.
user  User under which to run the git command. By default, the command is run by the user under which the
    minion is running.
ignore_retcode  [False] If True, do not log an error to the minion log if the git command returns a nonzero
    exit status.

CLI Examples:

    # Matches any values for key 'foo.bar'
    salt myminion git.config_get-regexp /path/to/repo foo.bar
    # Matches any value starting with 'baz' set for key 'foo.bar'
    salt myminion git.config_get-regexp /path/to/repo foo.bar 'baz.*'
    # Matches any key starting with 'user.'
    salt myminion git.config_get-regexp '^user\.' global=True

salt.modules.git.config_set(key, value=None, add=False, multivar=None, cwd=None, user=None, ignore_retcode=False, **kwargs)

    Changed in version 2015.8.0: Return the value(s) of the key being set

Set a key in the git configuration file

cwd  The path to the git checkout. Must be an absolute path, or the word global to indicate that a global
    key should be set.

31.16. Full list of builtin execution modules 897
Changed in version 2014.7.0: Made cwd argument optional if is_global=True

key  The name of the configuration key to set
    Changed in version 2015.8.0: Argument renamed from setting_name to key
value  The value to set for the specified key. Incompatible with the multivar argument.
    Changed in version 2015.8.0: Argument renamed from setting_value to value
add  [False] Add a value to a key, creating/updating a multivar
    New in version 2015.8.0.

multivar  Set a multivar all at once. Values can be comma-separated or passed as a Python list. Incompatible with the value argument.
    New in version 2015.8.0.
user  User under which to run the git command. By default, the command is run by the user under which the minion is running.
ignore_retcode  [False] If True, do not log an error to the minion log if the git command returns a nonzero exit status.
    New in version 2015.8.0.
global  [False] If True, set a global variable
    Deprecated since version 2015.8.0: Use global instead

CLI Example:

```
salt myminion git.config_set user.email me@example.com cwd=/path/to/repo
salt myminion git.config_set user.email foo@bar.com global=True
```

salt.modules.git.config_unset(key, value_regex=None, cwd=None, user=None, ignore_retcode=False, **kwargs)

New in version 2015.8.0.

Unset a key in the git configuration file

cwd  The path to the git checkout. Must be an absolute path, or the word global to indicate that a global key should be unset.
key  The name of the configuration key to unset
value_regex  Regular expression that matches exactly one key, used to delete a single value from a multivar.
    Ignored if all is set to True.
all  [False] If True unset all values for a multivar. If False, and key is a multivar, an error will be raised.
global  [False] If True, unset set a global variable. Otherwise, a local variable will be unset.
user  User under which to run the git command. By default, the command is run by the user under which the minion is running.
ignore_retcode  [False] If True, do not log an error to the minion log if the git command returns a nonzero exit status.

CLI Example:

```
salt myminion git.config_unset /path/to/repo foo.bar
salt myminion git.config_unset /path/to/repo foo.bar all=True
```
salt.modules.git.current_branch(cwd, user=None, ignore_retcode=False)

Returns the current branch name of a local checkout. If HEAD is detached, return the SHA1 of the revision which is currently checked out.

cwd  The path to the git checkout

user  User under which to run the git command. By default, the command is run by the user under which the minion is running.

ignore_retcode [False] If True, do not log an error to the minion log if the git command returns a nonzero exit status.

New in version 2015.8.0.

CLI Example:

```
salt myminion git.current_branch /path/to/repo
```

salt.modules.git.describe(cwd, rev='HEAD', user=None, ignore_retcode=False)

Returns the git-describe(1) string (or the SHA1 hash if there are no tags) for the given revision.

cwd  The path to the git checkout

rev  [HEAD] The revision to describe

user  User under which to run the git command. By default, the command is run by the user under which the minion is running.

ignore_retcode [False] If True, do not log an error to the minion log if the git command returns a nonzero exit status.

New in version 2015.8.0.

CLI Examples:

```
salt myminion git.describe /path/to/repo
salt myminion git.describe /path/to/repo develop
```

salt.modules.git.fetch(cwd, remote=None, force=False, refspecs=None, opts='', user=None, identity=None, ignore_retcode=False)

Interface to git-fetch(1)

cwd  The path to the git checkout

remote  Optional remote name to fetch. If not passed, then git will use its default behavior (as detailed in git-fetch(1)).

New in version 2015.8.0.

force  Force the fetch even when it is not a fast-forward.

New in version 2015.8.0.

refspecs  Override the refspec(s) configured for the remote with this argument. Multiple refspecs can be passed, comma-separated.

New in version 2015.8.0.

opts  Any additional options to add to the command line, in a single string

Note: On the Salt CLI, if the opts are preceded with a dash, it is necessary to precede them with opts=- (as in the CLI examples below) to avoid causing errors with Salt's own argument parsing.

user  User under which to run the git command. By default, the command is run by the user under which the minion is running.
**identity**  Path to a private key to use for ssh URLs

**Warning:** Key must be passphraseless to allow for non-interactive login. For greater security with passphraseless private keys, see the `sshd(8)` manpage for information on securing the keypair from the remote side in the `authorized_keys` file.

**ignore_retcode**  [False] If True, do not log an error to the minion log if the git command returns a nonzero exit status.

New in version 2015.8.0.

CLI Example:

```python
salt myminion git.fetch /path/to/repo upstream
salt myminion git.fetch /path/to/repo identity=/root/.ssh/id_rsa
```

**salt.modules.git.init**

```python
salt.modules.git.init(cwd, bare=False, template=None, separate_git_dir=None, shared=None, opts='--',
                   user=None, ignore_retcode=False)
```

Interface to `git-init(1)`

- **cwd**  The path to the directory to be initialized
- **bare**  [False] If True, init a bare repository

New in version 2015.8.0.

- **template**  Set this argument to specify an alternate template directory

New in version 2015.8.0.

- **separate_git_dir**  Set this argument to specify an alternate $GIT_DIR

New in version 2015.8.0.

- **shared**  Set sharing permissions on git repo. See `git-init(1)` for more details.

New in version 2015.8.0.

- **opts**  Any additional options to add to the command line, in a single string

  **Note:** On the Salt CLI, if the opts are preceded with a dash, it is necessary to precede them with `opts=` (as in the CLI examples below) to avoid causing errors with Salt’s own argument parsing.

- **user**  User under which to run the git command. By default, the command is run by the user under which the minion is running.

- **ignore_retcode**  [False] If True, do not log an error to the minion log if the git command returns a nonzero exit status.

New in version 2015.8.0.

CLI Examples:

```python
salt myminion git.init /path/to/repo
# Init a bare repo (before 2015.8.0)
salt myminion git.init /path/to/bare/repo.git opts='--bare'
# Init a bare repo (2015.8.0 and later)
salt myminion git.init /path/to/bare/repo.git bare=True
```

**salt.modules.git.is_worktree**

```python
salt.modules.git.is_worktree(cwd, user=None)
```

New in version 2015.8.0.
This function will attempt to determine if \texttt{cwd} is part of a worktree by checking its \texttt{.git} to see if it is a file containing a reference to another gitdir.

\texttt{cwd} path to the worktree to be removed

\texttt{user} User under which to run the git command. By default, the command is run by the user under which the minion is running.

CLI Example:

```
salt myminion git.is_worktree /path/to/repo
```

\texttt{salt.modules.git.list_branches}(\texttt{cwd}, \texttt{remote=False}, \texttt{user=None}, \texttt{ignore_retcode=False})

New in version 2015.8.0.

Return a list of branches

\texttt{cwd} The path to the git checkout

\texttt{remote} [False] If \texttt{True}, list remote branches. Otherwise, local branches will be listed.

\texttt{Warning:} This option will only return remote branches of which the local checkout is aware, use \texttt{git.fetch} to update remotes.

\texttt{user} User under which to run the git command. By default, the command is run by the user under which the minion is running.

\texttt{ignore_retcode} [False] If \texttt{True}, do not log an error to the minion log if the git command returns a nonzero exit status.

New in version 2015.8.0.

CLI Examples:

```
salt myminion git.list_branches /path/to/repo
salt myminion git.list_branches /path/to/repo remote=True
```

\texttt{salt.modules.git.list_tags}(\texttt{cwd}, \texttt{user=None}, \texttt{ignore_retcode=False})

New in version 2015.8.0.

Return a list of tags

\texttt{cwd} The path to the git checkout

\texttt{user} User under which to run the git command. By default, the command is run by the user under which the minion is running.

\texttt{ignore_retcode} [False] If \texttt{True}, do not log an error to the minion log if the git command returns a nonzero exit status.

New in version 2015.8.0.

CLI Examples:

```
salt myminion git.list_tags /path/to/repo
```

\texttt{salt.modules.git.list_worktrees}(\texttt{cwd}, \texttt{stale=False}, \texttt{user=None}, **\texttt{kwargs})

New in version 2015.8.0.

Return a dictionary mapping worktrees to their locations.

\texttt{Note:} This information is compiled by analyzing the administrative data in \texttt{$GIT_DIR/worktrees}. By default,
only worktrees for which the gitdir is still present are returned, but this can be changed using the all and stale arguments (described below).

cwd  The path to the git checkout

user  User under which to run the git command. By default, the command is run by the user under which the minion is running.

all  [False] If True, then return all worktrees, including ones whose gitdir is no longer present.

stale  [False] If True, return only worktrees whose gitdir is no longer present.

CLI Examples:

```
salt myminion git.list_worktrees /path/to/repo
salt myminion git.list_worktrees /path/to/repo all=True
salt myminion git.list_worktrees /path/to/repo stale=True
```

salt.modules.git.ls_remote(cwd=None, remote='origin', ref='master', opts='', user=None, identity=None, https_user=None, https_pass=None, ignore_retcode=False)

Interface to git-ls-remote(1). Returns the upstream hash for a remote reference.

cwd  The path to the git checkout. Optional (and ignored if present) when remote is set to a URL instead of a remote name.

remote  [origin] The name of the remote to query. Can be the name of a git remote (which exists in the git checkout defined by the cwd parameter), or the URL of a remote repository.

Changed in version 2015.8.0: Argument renamed from repository to remote

ref  [master] The name of the ref to query. Can be a branch or tag name, or the full name of the reference (for example, to get the hash for a Github pull request number 1234, ref can be set to refs/pull/1234/head

Changed in version 2015.8.0: Argument renamed from branch to ref

opts  Any additional options to add to the command line, in a single string

New in version 2015.8.0.

user  User under which to run the git command. By default, the command is run by the user under which the minion is running.

identity  Path to a private key to use for ssh URLs

**Warning:** Key must be passphraseless to allow for non-interactive login. For greater security with passphraseless private keys, see the sshd(8) manpage for information on securing the keypair from the remote side in the authorized_keys file.

https_user  Set HTTP Basic Auth username. Only accepted for HTTPS URLs.

New in version 2015.5.0.

https_pass  Set HTTP Basic Auth password. Only accepted for HTTPS URLs.

New in version 2015.5.0.

ignore_retcode  [False] If True, do not log an error to the minion log if the git command returns a nonzero exit status.

New in version 2015.8.0.
salt.modules.git.merge(cwd, rev=None, opts='`, user=None, branch=None, ignore_retcode=False)

Interface to git-merge(1)

cwd  The path to the git checkout

rev  Revision to merge into the current branch. If not specified, the remote tracking branch will be merged.

New in version 2015.8.0.

branch  The remote branch or revision to merge into the current branch Revision to merge into the current

branch

Deprecated since version 2015.8.0: Use rev instead.

opts  Any additional options to add to the command line, in a single string

Note: On the Salt CLI, if the opts are preceded with a dash, it is necessary to precede them with opts=
(as in the CLI examples below) to avoid causing errors with Salt's own argument parsing.

user  User under which to run the git command. By default, the command is run by the user under which the

minion is running.

ignore_retcode  [False] If True, do not log an error to the minion log if the git command returns a nonzero

exit status.

New in version 2015.8.0.

CLI Example:

# Fetch first...
salt myminion git.fetch /path/to/repo
# ... then merge the remote tracking branch
salt myminion git.merge /path/to/repo
# ... or merge another rev
salt myminion git.merge /path/to/repo rev=upstream/foo

salt.modules.git.merge_base(cwd, refs=None, octopus=False, is_ancestor=False, independent=False, fork_point=None, opts='`, user=None, ignore_retcode=False, **kwargs)

New in version 2015.8.0.

Interface to git-merge-base(1).

cwd  The path to the git checkout

refs  Any refs/commits to check for a merge base. Can be passed as a comma-separated list or a Python list.

all  [False] Return a list of all matching merge bases. Not compatible with any of the below options except for

octopus.

octopus  [False] If True, then this function will determine the best common ancestors of all specified commits,
in preparation for an n-way merge. See here for a description of how these bases are determined.

Set all to True with this option to return all computed merge bases, otherwise only the `"best" will be

returned.

is_ancestor  [False] If True, then instead of returning the merge base, return a boolean telling whether or

not the first commit is an ancestor of the second commit.
Note: This option requires two commits to be passed.

**independent** [False] If True, this function will return the IDs of the refs/commits passed which cannot be reached by another commit.

**fork_point** If passed, then this function will return the commit where the commit diverged from the ref specified by *fork_point*. If no fork point is found, None is returned.

Note: At most one commit is permitted to be passed if a *fork_point* is specified. If no commits are passed, then HEAD is assumed.

**opts** Any additional options to add to the command line, in a single string

Note: On the Salt CLI, if the opts are preceded with a dash, it is necessary to precede them with **opts=** (as in the CLI examples below) to avoid causing errors with Salt's own argument parsing.

This option should not be necessary unless new CLI arguments are added to git-merge-base(1) and are not yet supported in Salt.

**user** User under which to run the git command. By default, the command is run by the user under which the minion is running.

**ignore_retcode** [False] if True, do not log an error to the minion log if the git command returns a nonzero exit status.

CLI Examples:

```plaintext
salt myminion git.merge_base /path/to/repo HEAD upstream/mybranch
salt myminion git.merge_base /path/to/repo 8f2e542,4ad8cab,cdc9886 octopus=True
salt myminion git.merge_base /path/to/repo refs=8f2e542,4ad8cab,cdc9886 independent=True
salt myminion git.merge_base /path/to/repo refs=8f2e542,4ad8cab is_ancestor=True
salt myminion git.merge_base /path/to/repo fork_point=upstream/master
salt myminion git.merge_base /path/to/repo refs=mybranch fork_point=upstream/master
```

**salt.modules.git.merge_tree**(*cwd*, *ref1*, *ref2*, *base=None*, *user=None*, *ignore_retcode=False*)

New in version 2015.8.0.

Interface to git-merge-tree(1), shows the merge results and conflicts from a 3-way merge without touching the index.

**cwd** The path to the git checkout

**ref1** First ref/commit to compare

**ref2** Second ref/commit to compare

**base** The base tree to use for the 3-way-merge. If not provided, then **git.merge_base** will be invoked on *ref1* and *ref2* to determine the merge base to use.

**user** User under which to run the git command. By default, the command is run by the user under which the minion is running.

**ignore_retcode** [False] if True, do not log an error to the minion log if the git command returns a nonzero exit status.

CLI Examples:

```plaintext
salt myminion git.merge_tree /path/to/repo HEAD upstream/dev
salt myminion git.merge_tree /path/to/repo HEAD upstream/dev base=aaf3c3d
```
**salt.modules.git.pull**

```python
salt.modules.git.pull(cwd, opts='--rebase origin master', user=None, identity=None, ignore_retcode=False)
```

Interfaceto **git-pull(1)**

**cwd** The path to the git checkout

**opts** Any additional options to add to the command line, in a single string

**Note:** On the Salt CLI, if the opts are preceded with a dash, it is necessary to precede them with `opts=` (as in the CLI examples below) to avoid causing errors with Salt's own argument parsing.

**user** User under which to run the git command. By default, the command is run by the user under which the minion is running.

**identity** Path to a private key to use for ssh URLs

**Warning:** Key must be passphraseless to allow for non-interactive login. For greater security with passphraseless private keys, see the `sshd(8)` manpage for information on securing the keypair from the remote side in the `authorized_keys` file.

**ignore_retcode** [False] If True, do not log an error to the minion log if the git command returns a nonzero exit status.

New in version 2015.8.0.

**CLI Example:**

```
salt myminion git.pull /path/to/repo opts='--rebase origin master'
```

**salt.modules.git.push**

```python
salt.modules.git.push(cwd, remote=None, ref=None, opts='--rebase origin master', user=None, identity=None, ignore_retcode=False, branch=None)
```

Interfaceto **git-push(1)**

**cwd** The path to the git checkout

**remote** Name of the remote to which the ref should being pushed

New in version 2015.8.0.

**ref** [master] Name of the ref to push

**Note:** Being a `refspec`, this argument can include a colon to define local and remote ref names.

**branch** Name of the ref to push

Deprecated since version 2015.8.0: Use `ref` instead

**opts** Any additional options to add to the command line, in a single string

**Note:** On the Salt CLI, if the opts are preceded with a dash, it is necessary to precede them with `opts=` (as in the CLI examples below) to avoid causing errors with Salt's own argument parsing.

**user** User under which to run the git command. By default, the command is run by the user under which the minion is running.

**identity** Path to a private key to use for ssh URLs

**Warning:** Key must be passphraseless to allow for non-interactive login. For greater security with passphraseless private keys, see the `sshd(8)` manpage for information on securing the keypair from the remote side in the `authorized_keys` file.
**ignore_retcode**  [False] If **True**, do not log an error to the minion log if the git command returns a nonzero exit status.

New in version 2015.8.0.

CLI Example:

```bash
# Push master as origin/master
salt myminion git.push /path/to/repo origin master
# Push issue21 as upstream/develop
salt myminion git.push /path/to/repo upstream issue21:develop
# Delete remote branch 'upstream/temp'
salt myminion git.push /path/to/repo upstream :temp
```

salt.modules.git.rebase(cwd, rev='master', opts='-', user=None, ignore_retcode=False)

Interface to `git-rebase(1)`

- **cwd** The path to the git checkout
- **rev** [master] The revision to rebase onto the current branch
- **opts** Any additional options to add to the command line, in a single string

**Note:** On the Salt CLI, if the opts are preceded with a dash, it is necessary to precede them with **opts=** (as in the CLI examples below) to avoid causing errors with Salt’s own argument parsing.

- **user** User under which to run the git command. By default, the command is run by the user under which the minion is running.
- **ignore_retcode** [False] If **True**, do not log an error to the minion log if the git command returns a nonzero exit status.

New in version 2015.8.0.

CLI Example:

```bash
salt myminion git.rebase /path/to/repo master
salt myminion git.rebase /path/to/repo 'origin master'
salt myminion git.rebase /path/to/repo origin/master opts='--onto newbranch'
```

salt.modules.git.remote_get(cwd, remote='origin', user=None, redact_auth=True, ignore_retcode=False)

Get the fetch and push URL for a specific remote

- **cwd** The path to the git checkout
- **remote** [origin] Name of the remote to query
- **user** User under which to run the git command. By default, the command is run by the user under which the minion is running.
- **redact_auth** [True] Set to **False** to include the username/password if the remote uses HTTPS Basic Auth. Otherwise, this information will be redacted.

**Warning:** Setting this to **False** will not only reveal any HTTPS Basic Auth that is configured, but the return data will also be written to the job cache. When possible, it is recommended to use SSH for authentication.

New in version 2015.5.6.

- **ignore_retcode** [False] If **True**, do not log an error to the minion log if the git command returns a nonzero exit status.
New in version 2015.8.0.

CLI Examples:

```
salt myminion git.remote_get /path/to/repo
salt myminion git.remote_get /path/to/repo upstream
```

```
salt.modules.git.remote.refs(url, heads=False, tags=False, user=None, identity=None, https_user=None, https_pass=None, ignore_retcode=False)
```

New in version 2015.8.0.

Return the remote refs for the specified URL.

- **url**: URL of the remote repository.
- **heads**: [False] Restrict output to heads. Can be combined with `tags`.
- **tags**: [False] Restrict output to tags. Can be combined with `heads`.
- **user**: User under which to run the git command. By default, the command is run by the user under which the minion is running.
- **identity**: Path to a private key to use for ssh URLs.

**Warning**: Key must be passphraseless to allow for non-interactive login. For greater security with passphraseless private keys, see the `sshd(8)` manpage for information on securing the keypair from the remote side in the `authorized_keys` file.

- **https_user**: Set HTTP Basic Auth username. Only accepted for HTTPS URLs.
- **https_pass**: Set HTTP Basic Auth password. Only accepted for HTTPS URLs.
- **ignore_retcode**: [False] If True, do not log an error to the minion log if the git command returns a nonzero exit status.

CLI Example:

```
salt myminion git.remote.refs https://github.com/saltstack/salt.git
```

```
salt.modules.git.remote.set(cwd, url, remote='origin', user=None, https_user=None, https_pass=None, push_url=None, push_https_user=None, push_https_pass=None, ignore_retcode=False)
```

- **cwd**: The path to the git checkout.
- **url**: Remote URL to set.
- **remote**: [origin] Name of the remote to set.
- **push_url**: If unset, the push URL will be identical to the fetch URL.
  
  New in version 2015.8.0.
- **user**: User under which to run the git command. By default, the command is run by the user under which the minion is running.
- **https_user**: Set HTTP Basic Auth username. Only accepted for HTTPS URLs.
  
  New in version 2015.5.0.
- **https_pass**: Set HTTP Basic Auth password. Only accepted for HTTPS URLs.
  
  New in version 2015.5.0.
**push_https_user** Set HTTP Basic Auth user for `push_url`. Ignored if `push_url` is unset. Only accepted for HTTPS URLs.

New in version 2015.8.0.

**push_https_pass** Set HTTP Basic Auth password for `push_url`. Ignored if `push_url` is unset. Only accepted for HTTPS URLs.

New in version 2015.8.0.

**ignore_recode** [False] If True, do not log an error to the minion log if the git command returns a nonzero exit status.

New in version 2015.8.0.

**CLI Examples:**

```bash
salt myminion git.remote_set /path/to/repo git@github.com:user/repo.git
salt myminion git.remote_set /path/to/repo git@github.com:user/repo.git
```

**salt.modules.git.remotes**( `cwd`, `user=None`, `redact_auth=True`, `ignore_recode=False` )

Get fetch and push URLs for each remote in a git checkout

- **cwd** The path to the git checkout
- **user** User under which to run the git command. By default, the command is run by the user under which the minion is running.
- **redact_auth** [True] Set to False to include the username/password for authenticated remotes in the return data. Otherwise, this information will be redacted.

**Warning:** Setting this to False will not only reveal any HTTPS Basic Auth that is configured, but the return data will also be written to the job cache. When possible, it is recommended to use SSH for authentication.

New in version 2015.5.6.

**ignore_recode** [False] If True, do not log an error to the minion log if the git command returns a nonzero exit status.

New in version 2015.8.0.

**CLI Example:**

```bash
salt myminion git.remotes /path/to/repo
```

**salt.modules.git.reset**( `cwd`, `opts='`, `user=None`, `ignore_recode=False` )

Interface to `git-reset(1)`, returns the stdout from the git command

- **cwd** The path to the git checkout
- **opts** Any additional options to add to the command line, in a single string

**Note:** On the Salt CLI, if the opts are preceded with a dash, it is necessary to precede them with `opts=` (as in the CLI examples below) to avoid causing errors with Salt's own argument parsing.

- **user** User under which to run the git command. By default, the command is run by the user under which the minion is running.
- **ignore_recode** [False] If True, do not log an error to the minion log if the git command returns a nonzero exit status.
New in version 2015.8.0.

CLI Examples:

```
# Soft reset to a specific commit ID
salt myminion git.reset /path/to/repo ac3ee5c

# Hard reset
salt myminion git.reset /path/to/repo opts='--hard origin/master'
```

```
salt.modules.git.rev_parse(cwd, rev='HEAD', opts='', user=None, ignore_retcode=False)
```

New in version 2015.8.0.

Interface to `git-rev-parse(1)`

- **cwd** The path to the git checkout
- **rev** Revision to parse. See the SPECIFYING REVISIONS section of the `git-rev-parse(1)` manpage for details on how to format this argument.
  
  This argument is optional when using the options in the Options for Files section of the `git-rev-parse(1)` manpage.
- **opts** Any additional options to add to the command line, in a single string
- **user** User under which to run the git command. By default, the command is run by the user under which the minion is running.
- **ignore_retcode** [False] If True, do not log an error to the minion log if the git command returns a nonzero exit status.

CLI Examples:

```
# Get the full SHA1 for HEAD
salt myminion git.rev_parse /path/to/repo HEAD

# Get the short SHA1 for HEAD
salt myminion git.rev_parse /path/to/repo HEAD opts='--short'

# Get the develop branch's upstream tracking branch
salt myminion git.rev_parse /path/to/repo 'develop@{upstream}' opts='--abbrev-ref'

# Get the SHA1 for the commit corresponding to tag v1.2.3
salt myminion git.rev_parse /path/to/repo 'v1.2.3^commit'

# Find out whether or not the repo at /path/to/repo is a bare repository
salt myminion git.rev_parse /path/to/repo opts='--is-bare-repository'
```

```
salt.modules.git.revision(cwd, rev='HEAD', short=False, user=None, ignore_retcode=False)
```

Returns the SHA1 hash of a given identifier (hash, branch, tag, HEAD, etc.)

- **cwd** The path to the git checkout
- **rev** [HEAD] The revision
- **short** [False] If True, return an abbreviated SHA1 git hash
- **user** User under which to run the git command. By default, the command is run by the user under which the minion is running.
- **ignore_retcode** [False] If True, do not log an error to the minion log if the git command returns a nonzero exit status.

CLI Example:

```
salt myminion git.revision /path/to/repo mybranch
```
salt.modules.git.rm(cwd, filename, opts='', user=None, ignore_retcode=False)

Interface to git-rm(1)

cwd  The path to the git checkout
filename  The location of the file/directory to remove, relative to cwd

| Note: To remove a directory, -r must be part of the opts parameter. |

| opts  Any additional options to add to the command line, in a single string |
| Note: On the Salt CLI, if the opts are preceded with a dash, it is necessary to precede them with opts= (as in the CLI examples below) to avoid causing errors with Salt’s own argument parsing. |

user  User under which to run the git command. By default, the command is run by the user under which the minion is running.

ignore_retcode  [False] If True, do not log an error to the minion log if the git command returns a nonzero exit status.

New in version 2015.8.0.

CLI Examples:

<table>
<thead>
<tr>
<th>command</th>
</tr>
</thead>
<tbody>
<tr>
<td>salt myminion git.rm /path/to/repo foo/bar.py options='--dry-run'</td>
</tr>
<tr>
<td>salt myminion git.rm /path/to/repo foo/bar.py options='-r'</td>
</tr>
</tbody>
</table>

salt.modules.git.stash(cwd, action='save', opts='', user=None, ignore_retcode=False)

Interface to git-stash(1), returns the stdout from the git command

cwd  The path to the git checkout

| opts  Any additional options to add to the command line, in a single string. Use this to complete the git stash command by adding the remaining arguments (i.e. 'save <stash comment>', 'apply stash@{2}', 'show', etc.). Omitting this argument will simply run git stash. |

user  User under which to run the git command. By default, the command is run by the user under which the minion is running.

ignore_retcode  [False] If True, do not log an error to the minion log if the git command returns a nonzero exit status.

New in version 2015.8.0.

CLI Examples:

<table>
<thead>
<tr>
<th>command</th>
</tr>
</thead>
<tbody>
<tr>
<td>salt myminion git.stash /path/to/repo save options='work in progress'</td>
</tr>
<tr>
<td>salt myminion git.stash /path/to/repo apply options='stash@{1}'</td>
</tr>
<tr>
<td>salt myminion git.stash /path/to/repo drop options='stash@{1}'</td>
</tr>
<tr>
<td>salt myminion git.stash /path/to/repo list</td>
</tr>
</tbody>
</table>

salt.modules.git.status(cwd, user=None, ignore_retcode=False)

Changed in version 2015.8.0: Return data has changed from a list of lists to a dictionary

Returns the changes to the repository

cwd  The path to the git checkout

user  User under which to run the git command. By default, the command is run by the user under which the minion is running.
**ignore_retcode**  [False] If True, do not log an error to the minion log if the git command returns a nonzero exit status.

New in version 2015.8.0.

CLI Example:

```
salt myminion git.status /path/to/repo
```

**salt.modules.git.submodule** (cwd, command, opts='', user=None, identity=None, init=False, ignore_retcode=False)

Changed in version 2015.8.0: Added the command argument to allow for operations other than update to be run on submodules, and deprecated the init argument. To do a submodule update with init=True moving forward, use command=update opts='--init'

Interface to git-submodule(1)

cwd  The path to the submodule

command  Submodule command to run, see git-submodule(1) <git submodule> for more information. Any additional arguments after the command (such as the URL when adding a submodule) must be passed in the opts parameter.

New in version 2015.8.0.

opts  Any additional options to add to the command line, in a single string

**Note:** On the Salt CLI, if the opts are preceded with a dash, it is necessary to precede them with opts= (as in the CLI examples below) to avoid causing errors with Salt’s own argument parsing.

**init**  [False] If True, ensures that new submodules are initialized

Deprecated since version 2015.8.0: Pass init as the command parameter, or include --init in the opts param with command set to update.

user  User under which to run the git command. By default, the command is run by the user under which the minion is running.

identity  Path to a private key to use for ssh URLs

**Warning:** Key must be passphraseless to allow for non-interactive login. For greater security with passphraseless private keys, see the sshd(8) manpage for information on securing the keypair from the remote side in the authorized_keys file.

**ignore_retcode**  [False] If True, do not log an error to the minion log if the git command returns a nonzero exit status.

New in version 2015.8.0.

CLI Example:

```
# Update submodule and ensure it is initialized (before 2015.8.0)
salt myminion git.submodule /path/to/repo/sub/repo init=True

# Update submodule and ensure it is initialized (2015.8.0 and later)
salt myminion git.submodule /path/to/repo/sub/repo update opts='--init'

# Rebase submodule (2015.8.0 and later)
salt myminion git.submodule /path/to/repo/sub/repo update opts='--rebase'

# Add submodule (2015.8.0 and later)
salt myminion git.submodule /path/to/repo/sub/repo add opts='https://mydomain.tld/repo.git'
```
# Unregister submodule (2015.8.0 and later)
salt myminion git.submodule /path/to/repo/sub/repo deinit

```
salt.modules.git.symbolic_ref(cwd, ref, value=None, opts='`, user=None, ignore_retcode=False)
```

New in version 2015.8.0.

**Interface to** `git-symbolic-ref(1)`

- **cwd** The path to the git checkout
- **ref** Symbolic ref to read/modify
- **value** If passed, then the symbolic ref will be set to this value and an empty string will be returned.
  
  If not passed, then the ref to which `ref` points will be returned, unless `--delete` is included in `opts` (in which case the symbolic ref will be deleted).
- **opts** Any additional options to add to the command line, in a single string
- **user** User under which to run the git command. By default, the command is run by the user under which the minion is running.

**ignore_retcode** [False] If `True`, do not log an error to the minion log if the git command returns a nonzero exit status.

New in version 2015.8.0.

**CLI Examples:**

```
# Get ref to which HEAD is pointing
salt myminion git.symbolic_ref /path/to/repo HEAD

# Set/overwrite symbolic ref 'FOO' to local branch 'foo'
salt myminion git.symbolic_ref /path/to/repo FOO refs/heads/foo

# Delete symbolic ref 'FOO'
salt myminion git.symbolic_ref /path/to/repo FOO opts='--delete'
```

```
salt.modules.git.version(versioninfo=False)
```

New in version 2015.8.0.

Returns the version of Git installed on the minion

**versioninfo** [False] If `True`, return the version in a versioninfo list (e.g. `[2, 5, 0]`)

**CLI Example:**

```
salt myminion git.version
```

```
salt.modules.git.worktree_add(cwd, worktree_path, branch=None, ref=None, reset_branch=None, force=None, detach=False, opts='`, user=None, ignore_retcode=False)
```

New in version 2015.8.0.

**Interface to** `git-worktree(1)`, adds a worktree

- **cwd** The path to the git checkout
- **worktree_path** Path to the new worktree. Can be either absolute, or relative to `cwd`.
- **branch** Name of new branch to create. If omitted, will be set to the basename of the `worktree_path`. For example, if the `worktree_path` is `/foo/bar/baz`, then `branch` will be `baz`.
- **ref** Name of the ref on which to base the new worktree. If omitted, then HEAD is use, and a new branch will be created, named for the basename of the `worktree_path`. For example, if the `worktree_path` is `/foo/bar/baz` then a new branch `baz` will be created, and pointed at HEAD.
reset_branch  [False] If False, then git-worktree(1) will fail to create the worktree if the targeted branch already exists. Set this argument to True to reset the targeted branch to point at ref, and checkout the newly-reset branch into the new worktree.

force  [False] By default, git-worktree(1) will not permit the same branch to be checked out in more than one worktree. Set this argument to True to override this.

opts  Any additional options to add to the command line, in a single string

Note: On the Salt CLI, if the opts are preceded with a dash, it is necessary to precede them with opts= to avoid causing errors with Salt's own argument parsing.

All CLI options for adding worktrees as of Git 2.5.0 are already supported by this function as of Salt 2015.8.0, so using this argument is unnecessary unless new CLI arguments are added to git-worktree(1) and are not yet supported in Salt.

user  User under which to run the git command. By default, the command is run by the user under which the minion is running.

ignore_retcode  [False] If True, do not log an error to the minion log if the git command returns a nonzero exit status.

New in version 2015.8.0.

CLI Examples:

```bash
salt myminion git.worktree_add /path/to/repo/main ../hotfix
ref=origin/master
```

```bash
salt myminion git.worktree_add /path/to/repo/main ../hotfix
branch=hotfix21 ref=v2.1.9.3
```

salt.modules.git.worktree_prune(cwd, dry_run=False, verbose=True, expire=None, opts='', user=None, ignore_retcode=False)

New in version 2015.8.0.

Interface to git-worktree(1), prunes stale worktree administrative data from the gitdir

cwd  The path to the main git checkout or a linked worktree

dry_run  [False] If True, then this function will report what would have been pruned, but no changes will be made.

verbose  [True] Report all changes made. Set to False to suppress this output.

expire  Only prune unused worktree data older than a specific period of time. The date format for this parameter is described in the documentation for the gc.pruneWorktreesExpire config param in the git-config(1) manpage.

opts  Any additional options to add to the command line, in a single string

Note: On the Salt CLI, if the opts are preceded with a dash, it is necessary to precede them with opts= to avoid causing errors with Salt's own argument parsing.

All CLI options for pruning worktrees as of Git 2.5.0 are already supported by this function as of Salt 2015.8.0, so using this argument is unnecessary unless new CLI arguments are added to git-worktree(1) and are not yet supported in Salt.

user  User under which to run the git command. By default, the command is run by the user under which the minion is running.

ignore_retcode  [False] If True, do not log an error to the minion log if the git command returns a nonzero exit status.

New in version 2015.8.0.
CLI Examples:

```
salt myminion git.worktree_prune /path/to/repo
salt myminion git.worktree_prune /path/to/repo dry_run=True
salt myminion git.worktree_prune /path/to/repo expire=1.day.ago
```

salt.modules.git.worktree_rm(cwd, user=None)

New in version 2015.8.0.

Recursively removes the worktree located at cwd, returning True if successful. This function will attempt to determine if cwd is actually a worktree by invoking git.is_worktree. If the path does not correspond to a worktree, then an error will be raised and no action will be taken.

**Warning:** There is no undoing this action. Be VERY careful before running this function.

- **cwd** Path to the worktree to be removed
- **user** User under which to run the git command. By default, the command is run by the user under which the minion is running.

CLI Examples:

```
salt myminion git.worktree_rm /path/to/worktree
```

31.16.94 salt.modules.glance

Module for handling openstack glance calls.

**optdepends**

- glanceclient Python adapter

**configuration** This module is not usable until the following are specified either in a pillar or in the minion's config file:

```
keystone.user: admin
keystone.password: verybadpass
keystone.tenant: admin
keystone.insecure: False  #(optional)
keystone.auth_url: 'http://127.0.0.1:5000/v2.0/
```

If configuration for multiple openstack accounts is required, they can be set up as different configuration profiles: For example:

```
openstack1:
    keystone.user: admin
    keystone.password: verybadpass
    keystone.tenant: admin
    keystone.auth_url: 'http://127.0.0.1:5000/v2.0/

openstack2:
    keystone.user: admin
    keystone.password: verybadpass
    keystone.tenant: admin
    keystone.auth_url: 'http://127.0.0.2:5000/v2.0/
```

With this configuration in place, any of the glance functions can make use of a configuration profile by declaring it explicitly. For example:
salt '*' glance.image_list profile=openstack1

```
salt.modules.glance.image_create(name, location=None, profile=None, visibility=None, container_format='bare', disk_format='raw', protected=None, copy_from=None, is_public=None)
```

Create an image (glance image-create)

CLI Example, old format:
```
salt '*' glance.image_create name=f16-jeos is_public=true disk_format=qcow2 container_format=ovf copy_from=http://berrange.fedorapeople.org/ images/2012-02-29/f16-x86_64-openstack-sda.qcow2
```

CLI Example, new format resembling Glance API v2:
```
salt '*' glance.image_create name=f16-jeos visibility=public disk_format=qcow2 container_format=ovf copy_from=http://berrange.fedorapeople.org/ images/2012-02-29/f16-x86_64-openstack-sda.qcow2
```

The parameter `visibility' defaults to `public' if neither `visibility' nor `is_public' is specified.

```
salt.modules.glance.image_delete(id=None, name=None, profile=None)
```

Delete an image (glance image-delete)

CLI Examples:
```
salt '*' glance.image_delete c2eb2eb0-53e1-4a80-b990-8ec887eae7df
salt '*' glance.image_delete id=c2eb2eb0-53e1-4a80-b990-8ec887eae7df
salt '*' glance.image_delete name=f16-jeos
```

```
salt.modules.glance.image_list(id=None, profile=None, name=None)
```

Return a list of available images (glance image-list)

CLI Example:
```
salt '*' glance.image_list
```

```
salt.modules.glance.image_schema(profile=None)
```

Returns names and descriptions of the schema `image`'s properties for this profile's instance of glance

```
salt.modules.glance.image_show(id=None, name=None, profile=None)
```

Return details about a specific image (glance image-show)

CLI Example:
```
salt '*' glance.image_show
```

```
salt.modules.glance.image_update(id=None, name=None, profile=None, **kwargs)
```

Update properties of given image. Known to work for: - min_ram (in MB) - protected (bool) - visibility (`public' or `private')

```
salt.modules.glance.schema_get(name, profile=None)
```

Known valid names of schemas are:
- image
- images
- member
- members
31.16.95  salt.modules.glusterfs

Manage a glusterfs pool

salt.modules.glusterfs.add_volume_bricks(name, bricks)
Add brick(s) to an existing volume
  name  Volume name
  bricks  List of bricks to add to the volume

salt.modules.glusterfs.create(name, bricks, stripe=False, replica=False, device_vg=False, transport='tcp', start=False, force=False)
Create a glusterfs volume.
  name  Name of the gluster volume
  bricks  Bricks to create volume from, in <peer>:<brick path> format. For multiple bricks use list format: `[
               "<peer1>:<brick1>,`",`<peer2>:<brick2>"'
           ]`
  stripe  Stripe count, the number of bricks should be a multiple of the stripe count for a distributed striped volume
  replica  Replica count, the number of bricks should be a multiple of the replica count for a distributed replicated volume
  device_vg  If true, specifies volume should use block backend instead of regular posix backend. Block device backend volume does not support multiple bricks
  transport  Transport protocol to use, can be `tcp`, `rdma` or `tcp,rdma`
  start  Start the volume after creation
  force  Force volume creation, this works even if creating in root FS

CLI Example:
  salt host1 glusterfs.create newvolume host1:/brick
  salt gluster1 glusterfs.create vol2 '[
          gluster1:/export/vol2/brick,
          gluster2:/export/vol2/brick'

salt.modules.glusterfs.delete(target, stop=True)
Deletes a gluster volume
  target  Volume to delete
  stop  Stop volume before delete if it is started, True by default

salt.modules.glusterfs.list_peers()
Return a list of gluster peers

CLI Example:
  salt '*' glusterfs.list_peers

GLUSTER direct CLI example (to show what salt is sending to gluster):
  $ gluster peer status

GLUSTER CLI 3.4.4 return example (so we know what we are parsing):
  Number of Peers: 2
  Hostname: ftp2 Port: 24007 Uuid: cbcb256b-e66e-4ec7-a718-21082d396c24 State: Peer in Cluster (Connected)
salt.modules.glusterfs.list_volumes()
List configured volumes

CLI Example:

```
salt '*' glusterfs.list_volumes
```

salt.modules.glusterfs.peer(name)
Add another node into the peer list.

name The remote host to probe.

CLI Example:

```
salt 'one.gluster.*' glusterfs.peer two
```

GLUSTER direct CLI example (to show what salt is sending to gluster):

```
$ gluster peer probe ftp2
```

GLUSTER CLI 3.4.4 return example (so we know what we are parsing):

```
# if the `peer` is the local host:
peer probe: success: on localhost not needed

# if the peer was just added: peer probe: success

# if the peer was already part of the cluster: peer probe: success: host ftp2 port 24007 already in peer list
```

salt.modules.glusterfs.start_volume(name)
Start a gluster volume.

name Volume name

CLI Example:

```
salt '*' glusterfs.start mycluster
```

salt.modules.glusterfs.status(name)
Check the status of a gluster volume.

name Volume name

CLI Example:

```
salt '*' glusterfs.status myvolume
```

salt.modules.glusterfs.stop_volume(name)
Stop a gluster volume.

name Volume name

CLI Example:

```
salt '*' glusterfs.stop_volume mycluster
```

31.16.96 salt.modules.gnomedesktop

GNOME implementations

31.16. Full list of builtin execution modules
salt.modules.gnomedesktop.get(schema=None, key=None, user=None, **kwargs)
Get key in a particular GNOME schema

CLI Example:
```
salt '*' gnome.get user=<username> schema=org.gnome.desktop.screensaver key=idle-activation-enabled
```

salt.modules.gnomedesktop.getClockFormat(**kwargs)
Return the current clock format, either 12h or 24h format.

CLI Example:
```
salt '*' gnome.getClockFormat user=<username>
```

salt.modules.gnomedesktop.getClockShowDate(**kwargs)
Return the current setting, if the date is shown in the clock

CLI Example:
```
salt '*' gnome.getClockShowDate user=<username>
```

salt.modules.gnomedesktop.getIdleActivation(**kwargs)
Get whether the idle activation is enabled

CLI Example:
```
salt '*' gnome.getIdleActivation user=<username>
```

salt.modules.gnomedesktop.getIdleDelay(**kwargs)
Return the current idle delay setting in seconds

CLI Example:
```
salt '*' gnome.getIdleDelay user=<username>
```

salt.modules.gnomedesktop.ping(**kwargs)
A test to ensure the GNOME module is loaded

CLI Example:
```
salt '*' gnome.ping user=<username>
```

salt.modules.gnomedesktop.setClockFormat(clockFormat, **kwargs)
Set the clock format, either 12h or 24h format.

CLI Example:
```
salt '*' gnome.setClockFormat <12h|24h> user=<username>
```

salt.modules.gnomedesktop.setClockShowDate(kvalue, **kwargs)
Set whether the date is visible in the clock

CLI Example:
```
salt '*' gnome.setClockShowDate <True|False> user=<username>
```

salt.modules.gnomedesktop.setIdleActivation(kvalue, **kwargs)
Set whether the idle activation is enabled

CLI Example:
salt '*' gnome.setIdleActivation <True|False> user=<username>

salt.modules.gnomedesktop.setIdleDelay(delaySeconds, **kwargs)
    Set the current idle delay setting in seconds
    CLI Example:
    
    salt '*' gnome.setIdleDelay <seconds> user=<username>

salt.modules.gnomedesktop.set(schema=None, key=None, user=None, value=None, **kwargs)
    Set key in a particular GNOME schema
    CLI Example:
    
    salt '*' gnome.set user=<username> schema=org.gnome.desktop.screensaver key=idle-activation-enabled value=False

31.16.97 salt.modules.gpg

Manage a GPG keychains, add keys, create keys, retrieve keys from keyservers. Sign, encrypt and sign & encrypt text and files.

New in version 2015.5.0.

Note: The python-gnupg library and gpg binary are required to be installed.

salt.modules.gpg.create_key(key_type='RSA', key_length=1024, name_real='Autogenerated Key', name_comment='Generated by SaltStack', name_email=None, subkey_type=None, subkey_length=None, expire_date=None, use_passphrase=False, user=None, gnupghome=None)

Create a key in the GPG keychain

Note: GPG key generation requires a lot of entropy and randomness. Difficult to do over a remote connection, consider having another process available which is generating randomness for the machine. Also especially difficult on virtual machines, consider the rng-tools package.

The create_key process takes awhile so increasing the timeout may be necessary, e.g. -t 15.

key_type  The type of the primary key to generate. It must be capable of signing. `RSA` or `DSA`.

key_length  The length of the primary key in bits.

name_real  The real name of the user identity which is represented by the key.

name_comment  A comment to attach to the user id.

name_email  An email address for the user.

subkey_type  The type of the secondary key to generate.

subkey_length  The length of the secondary key in bits.

expire_date  The expiration date for the primary and any secondary key. You can specify an ISO date, A number of days/weeks/months/years, an epoch value, or 0 for a non-expiring key.

use_passphrase  Whether to use a passphrase with the signing key. Passphrase is received from pillar.

user  Which user's keychain to access, defaults to user Salt is running as. Passing the user as `salt` will set the GPG home directory to /etc/salt/gpgkeys.

gnupghome  Specify the location where GPG related files are stored.
CLI Example:
```bash
salt -t 15 '*' gpg.create_key
```

```python
salt.modules.gpg.decrypt(user=None, text=None, filename=None, output=None, use_passphrase=False, gnupghome=None, bare=False)
```

Decrypt a message or file

- **user** Which user’s keychain to access, defaults to user Salt is running as. Passing the user as `salt` will set the GPG home directory to `/etc/salt/gpgkeys`.
- **text** The encrypted text to decrypt.
- **filename** The encrypted filename to decrypt.
- **output** The filename where the decrypted data will be written, default is standard out.
- **use_passphrase** Whether to use a passphrase with the signing key. Passphrase is received from pillar.
- **gnupghome** Specify the location where GPG related files are stored.
- **bare** If True, return the (armored) decrypted block as a string without the standard comment/res dict

CLI Example:
```bash
salt '*' gpg.decrypt filename="/path/to/important.file.gpg"
```

```bash
salt '*' gpg.decrypt filename="/path/to/important.file.gpg" use_passphrase=True
```

```python
salt.modules.gpg.delete_key(keyid=None, fingerprint=None, delete_secret=False, user=None, gnupghome=None)
```

Get a key from the GPG keychain

- **keyid** The keyid of the key to be deleted.
- **fingerprint** The fingerprint of the key to be deleted.
- **delete_secret** Whether to delete a corresponding secret key prior to deleting the public key. Secret keys must be deleted before deleting any corresponding public keys.
- **user** Which user’s keychain to access, defaults to user Salt is running as. Passing the user as `salt` will set the GPG home directory to `/etc/salt/gpgkeys`.
- **gnupghome** Specify the location where GPG related files are stored.

CLI Example:
```bash
salt '*' gpg.delete_key keyid=3FAD9F1E
salt '*' gpg.delete_key fingerprint=53C96788253E58416D20BCD352952C84C3252192
salt '*' gpg.delete_key keyid=3FAD9F1E user=username
salt '*' gpg.delete_key keyid=3FAD9F1E user=username delete_secret=True
```

```python
salt.modules.gpg.encrypt(user=None, recipients=None, text=None, filename=None, output=None, sign=None, use_passphrase=False, gnupghome=None, bare=False)
```

Encrypt a message or file

- **user** Which user’s keychain to access, defaults to user Salt is running as. Passing the user as `salt` will set the GPG home directory to `/etc/salt/gpgkeys`.
- **recipients** The fingerprints for those recipient whom the data is being encrypted for.
- **text** The text to encrypt.
filename  The filename to encrypt.

output  The filename where the signed file will be written, default is standard out.

sign  Whether to sign, in addition to encrypt, the data. True to use default key or fingerprint to specify a different key to sign with.

use_passphrase  Whether to use a passphrase with the signing key. Passphrase is received from pillar.

gnupghome  Specify the location where GPG related files are stored.

bare  If True, return the (armored) encrypted block as a string without the standard comment/res dict

CLI Example:

```
salt '*' gpg.encrypt text='Hello there. How are you?'
salt '*' gpg.encrypt filename='/path/to/important.file'
salt '*' gpg.encrypt filename='/path/to/important.file' use_passphrase=True
```

salt.modules.gpg.export_key(keyids=None, secret=False, user=None, gnupghome=None)

Export a key from the GPG keychain

keyids  The keyid(s) of the key(s) to be exported. Can be specified as a comma separated string or a list. Anything which GnuPG itself accepts to identify a key - for example, the keyid or the fingerprint could be used.

secret  Export the secret key identified by the keyid information passed.

user  Which user's keychain to access, defaults to user Salt is running as. Passing the user as `salt' will set the GPG home directory to /etc/salt/gpgkeys.

gnupghome  Specify the location where GPG related files are stored.

CLI Example:

```
salt '*' gpg.export_key keyids=3FAD9F1E
salt '*' gpg.export_key keyids=3FAD9F1E secret=True
salt '*' gpg.export_key keyid="[3FAD9F1E',3FBD8F1E']" user=username
```

salt.modules.gpg.get_key(keyid=None, fingerprint=None, user=None, gnupghome=None)

Get a key from the GPG keychain

keyid  The keyid of the key to be retrieved.

fingerprint  The fingerprint of the key to be retrieved.

user  Which user's keychain to access, defaults to user Salt is running as. Passing the user as `salt' will set the GPG home directory to /etc/salt/gpgkeys.

 gnupghome  Specify the location where GPG related files are stored.

CLI Example:

```
salt '*' gpg.get_key keyid=3FAD9F1E
salt '*' gpg.get_key fingerprint=53C96788253E58416D20BCD352952C84C3252192
salt '*' gpg.get_key keyid=3FAD9F1E user=username
```
salt.modules.gpg.get_secret_key(keyid=None, fingerprint=None, user=None, gnupghome=None)
Get a key from the GPG keychain

keyid  The keyid of the key to be retrieved.

fingerprint  The fingerprint of the key to be retrieved.

user  Which user's keychain to access, defaults to user Salt is running as. Passing the user as `salt' will set the GPG home directory to /etc/salt/gpgkeys.

gnupghome  Specify the location where GPG related files are stored.

CLI Example:

```
salt '*' gpg.get_secret_key keyid=3FAD9F1E
salt '*' gpg.get_secret_key fingerprint=53C96788253E58416D20BCD352952C84C3252192
salt '*' gpg.get_secret_key keyid=3FAD9F1E user=username
```

salt.modules.gpg.import_key(user=None, text=None, filename=None, gnupghome=None)
Import a key from text or file

user  Which user's keychain to access, defaults to user Salt is running as. Passing the user as `salt' will set the GPG home directory to /etc/salt/gpgkeys.

text  The text containing to import.

filename  The filename containing the key to import.

gnupghome  Specify the location where GPG related files are stored.

CLI Example:

```
salt '*' gpg.import_key text='-----BEGIN PGP PUBLIC KEY BLOCK-----
... -----END PGP PUBLIC KEY BLOCK-----'
salt '*' gpg.import_key filename='/path/to/public-key-file'
```

salt.modules.gpg.list_keys(user=None, gnupghome=None)
List keys in GPG keychain

user  Which user's keychain to access, defaults to user Salt is running as. Passing the user as `salt' will set the GPG home directory to /etc/salt/gpgkeys.

gnupghome  Specify the location where GPG related files are stored.

CLI Example:

```
salt '*' gpg.list_keys
```

salt.modules.gpg.list_secret_keys(user=None, gnupghome=None)
List secret keys in GPG keychain

user  Which user's keychain to access, defaults to user Salt is running as. Passing the user as `salt' will set the GPG home directory to /etc/salt/gpgkeys.

gnupghome  Specify the location where GPG related files are stored.

CLI Example:

```
salt '*' gpg.list_secret_keys
```

salt.modules.gpg.receive_keys(keyserver=None, keys=None, user=None, gnupghome=None)
Receive key(s) from keyservers and add them to keychain

keyserver  Keyserver to use for searching for GPG keys, defaults to pgp.mit.edu
keys  The keyID(s) to retrieve from the keyserver. Can be specified as a comma separated string or a list.

user  Which user's keychain to access, defaults to user Salt is running as. Passing the user as `salt' will set the GPG home directory to /etc/salt/gpgkeys.

CLI Example:

```
salt '*' gpg.receive_key keys='3FAD9F1E'
salt '*' gpg.receive_key keys='[3FAD9F1E,3FBD9F2E]'
salt '*' gpg.receive_key keys=3FAD9F1E user=username
```

salt.modules.gpg.search_keys(text, keyserver=None, user=None)

Search keys from keyserver

text  Text to search the keyserver for, e.g. email address, keyID or fingerprint.

keyserver  Keyserver to use for searching for GPG keys, defaults to pgp.mit.edu

user  Which user's keychain to access, defaults to user Salt is running as. Passing the user as `salt' will set the GPG home directory to /etc/salt/gpgkeys.

CLI Example:

```
salt '*' gpg.search_keys user@example.com
salt '*' gpg.search_keys user@example.com keyserver=keyserver.ubuntu.com
salt '*' gpg.search_keys user@example.com keyserver=keyserver.ubuntu.com user=username
```

salt.modules.gpg.sign(user=None, keyid=None, text=None, filename=None, output=None, use_passphrase=False, gnupghome=None)

Sign message or file

user  Which user's keychain to access, defaults to user Salt is running as. Passing the user as `salt' will set the GPG home directory to /etc/salt/gpgkeys.

keyid  The keyid of the key to set the trust level for, defaults to first key in the secret keyring.

text  The text to sign.

filename  The filename to sign.

output  The filename where the signed file will be written, default is standard out.

use_passphrase  Whether to use a passphrase with the signing key. Passphrase is received from pillar.

gnupghome  Specify the location where GPG related files are stored.

CLI Example:

```
salt '*' gpg.sign text='Hello there. How are you?'
salt '*' gpg.sign filename='/path/to/important.file'
salt '*' gpg.sign filename='/path/to/important.file' use_passphrase=True
```

salt.modules.gpg.trust_key(keyid=None, fingerprint=None, trust_level=None, user=None)

Set the trust level for a key in GPG keychain

keyid  The keyid of the key to set the trust level for.

fingerprint  The fingerprint of the key to set the trust level for.
trust_level  The trust level to set for the specified key, must be one of the following: expired, unknown, not_trusted, marginally, fully, ultimately

user  Which user's keychain to access, defaults to user Salt is running as. Passing the user as `salt' will set the GPG home directory to /etc/salt/gpgkeys.

CLI Example:

```
salt '*' gpg.trust_key keyid='3FAD9F1E' trust_level='marginally'
salt '*' gpg.trust_key fingerprint='53C96788253E58416D20BCD352952C84C3252192' trust_level='not_trusted'
salt '*' gpg.trust_key keys='3FAD9F1E' trust_level='ultimately' user='username'
```

```
salt.modules.gpg.verify(text=None, user=None, filename=None, gnupghome=None)
```
Verify a message or file

- **text**  The text to verify.
- **filename**  The filename to verify.
- **user**  Which user's keychain to access, defaults to user Salt is running as. Passing the user as `salt' will set the GPG home directory to /etc/salt/gpgkeys.
- **gnupghome**  Specify the location where GPG related files are stored.

CLI Example:

```
salt '*' gpg.verify text='Hello there. How are you?'
salt '*' gpg.verify filename='/path/to/important.file'
salt '*' gpg.verify filename='/path/to/important.file' use_pasphrase=True
```

31.16.98  salt.modules.grains

Return/control aspects of the grains data

```
salt.modules.grains.append(key, val, convert=False, delimiter=':')
```
New in version 0.17.0.

Append a value to a list in the grains config file. If the grain doesn't exist, the grain key is added and the value is appended to the new grain as a list item.

- **key**  The grain key to be appended to
- **val**  The value to append to the grain key

**Parameters**

- **convert**  -- If convert is True, convert non-list contents into a list. If convert is False and the grain contains non-list contents, an error is given. Defaults to False.

- **delimiter**  -- The key can be a nested dict key. Use this parameter to specify the delimiter you use. You can now append values to a list in nested dictionary grains. If the list doesn't exist at this level, it will be created. .. versionadded:: 2014.7.6

CLI Example:

```
salt '*' grains.append key val
```
salt.modules.grains.delval(key, destructive=False)
New in version 0.17.0.
Delete a grain from the grains config file

Parameters destructive -- Delete the key, too. Defaults to False.

CLI Example:
salt '!' grains.delval key

salt.modules.grains.filter_by(lookup_dict, grain='os_family', merge=None, default='default', base=None)
New in version 0.17.0.
Look up the given grain in a given dictionary for the current OS and return the result

Although this may occasionally be useful at the CLI, the primary intent of this function is for use in Jinja to
make short work of creating lookup tables for OS-specific data. For example:

{% set apache = salt['grains.filter_by']({
    'Debian': {'pkg': 'apache2', 'srv': 'apache2'},
    'RedHat': {'pkg': 'httpd', 'srv': 'httpd'},
}, default='Debian') %}

myapache:
    - name: {{ apache.pkg }}
service.running:
    - name: {{ apache.srv }}

Values in the lookup table may be overridden by values in Pillar. An example Pillar to override values in the
example above could be as follows:

apache:
    lookup:
        pkg: apache_13
        srv: apache

The call to filter_by() would be modified as follows to reference those Pillar values:

{% set apache = salt['grains.filter_by']({
    ...,
    }, merge=salt['pillar.get']('apache:lookup')) %}

Parameters

- **lookup_dict** -- A dictionary, keyed by a grain, containing a value or values relevant
to systems matching that grain. For example, a key could be the grain for an OS and the
value could the name of a package on that particular OS.

- **grain** -- The name of a grain to match with the current system's grains. For example, the
value of the `os_family` grain for the current system could be used to pull values from
the lookup_dict dictionary.

- **merge** -- A dictionary to merge with the results of the grain selection from
lookup_dict. This allows Pillar to override the values in the lookup_dict. This
could be useful, for example, to override the values for non-standard package names such
as when using a different Python version from the default Python version provided by the
OS (e.g., python26-mysql instead of python-mysql).
• **default** -- default lookup_dict's key used if the grain does not exists or if the grain value has no match on lookup_dict. If unspecified the value is ``default``.

New in version 2014.1.0.

• **base** -- A lookup_dict key to use for a base dictionary. The grain-selected lookup_dict is merged over this and then finally the merge dictionary is merged. This allows common values for each case to be collected in the base and overridden by the grain selection dictionary and the merge dictionary. Default is unset.

New in version 2015.5.0.

**CLI Example:**

```bash
salt '*' grains.filter_by '{Debian: Debheads rule, RedHat: I love my hat}'
# this one will render {D: {E: I, G: H}, J: K}
# next one renders {A: {B: G}, D: J}
salt '*' grains.filter_by '{default: {A: {B: C}, D: E}, F: {A: {B: G}}, H: {D: I}}' 'xxx' '{D: J}'
# next same as above when default='H' instead of 'F' renders {A: {B: C}, D: J}
```

**salt.modules.grains.get(key, default='`, delimiter=':')**

Attempt to retrieve the named value from grains, if the named value is not available return the passed default. The default return is an empty string.

The value can also represent a value in a nested dict using a ":" delimiter for the dict. This means that if a dict in grains looks like this:

```
{ 'pkg': { 'apache': 'httpd' } }
```

To retrieve the value associated with the apache key in the pkg dict this key can be passed:

```
pkg:apache
```

**delimiter** Specify an alternate delimiter to use when traversing a nested dict

New in version 2014.7.0.

**CLI Example:**

```bash
salt '*' grains.get pkg:apache
```

**salt.modules.grains.get_or_set_hash(name, length=8, chars='abcdefghijklmnopqrstuvwxyz0123456789!@#$%^&*(-_=+)')**

Perform a one-time generation of a hash and write it to the local grains. If that grain has already been set return the value instead.

This is useful for generating passwords or keys that are specific to a single minion that don't need to be stored somewhere centrally.

**State Example:**

```yaml
some_mysql_user:
  mysql_user:
    - present
    - host: localhost
    - password: {{ salt['grains.get_or_set_hash']('mysql:some_mysql_user') }}
```

**CLI Example:**
**salt** `'*' grains.get_or_set_hash 'django:SECRET_KEY' 50`

*Warning:* This function could return strings which may contain characters which are reserved as directives by the YAML parser, such as strings beginning with `%`. To avoid issues when using the output of this function in an SLS file containing YAML+Jinja, surround the call with single quotes.

---

**salt.modules.grains**.has_value(key)

Determine whether a named value exists in the grains dictionary.

Given a grains dictionary that contains the following structure:

```json
{ 'pkg': { 'apache': 'httpd' }}
```

One would determine if the `apache` key in the `pkg` dict exists by:

```python
pkg:apache
```

**CLI Example**

```bash
salt '*' grains.has_value pkg:apache
```

---

**salt.modules.grains**.item(*args, **kwargs)

Return one or more grains

**CLI Example**

```bash
salt '*' grains.item os
salt '*' grains.item os osrelease oscodename
```

Sanitized **CLI Example**:

```bash
salt '*' grains.item host sanitize=True
```

---

**salt.modules.grains**.items(sanitize=False)

Return all of the minion’s grains

**CLI Example**

```bash
salt '*' grains.items
```

Sanitized **CLI Example**:

```bash
salt '*' grains.items sanitize=True
```

---

**salt.modules.grains**.ls()

Return a list of all available grains

**CLI Example**

```bash
salt '*' grains.ls
```

---

**salt.modules.grains**.remove(key, val)

New in version 0.17.0.

Remove a value from a list in the grains config file

**CLI Example**

```bash
salt '*' grains.remove key val
```
salt.modules.grains.set(key, val='`, force=False, destructive=False, delimiter=':')

Set a key to an arbitrary value. It is used like setval but works with nested keys.

This function is conservative. It will only overwrite an entry if its value and the given one are not a list or a
dict. The force parameter is used to allow overwriting in all cases.

New in version 2015.8.0.

Parameters

- **force** -- Force writing over existing entry if given or existing values are list or dict. Defaultsto False.
- **destructive** -- If an operation results in a key being removed, delete the key, too. Defaultsto False.
- **delimiter** -- Specify an alternate delimiter to use when traversing a nested dict

CLI Example:

```
salt '*' grains.set 'apps:myApp:port' 2209
salt '*' grains.set 'apps:myApp' '{port: 2209}'
```

salt.modules.grains.setval(key, val, destructive=False)

Set a grains value in the grains config file

Parameters

- **Destructive** -- If an operation results in a key being removed, delete the key, too.
  Defaultsto False.

CLI Example:

```
salt '*' grains.setval key val
salt '*' grains.setval key "{'sub-key': 'val', 'sub-key2': 'val2'}"
```

salt.modules.grains.setvals(grains, destructive=False)

Set new grains values in the grains config file

Parameters

- **Destructive** -- If an operation results in a key being removed, delete the key, too.
  Defaultsto False.

CLI Example:

```
salt '*' grains.setvals "{'key1': 'val1', 'key2': 'val2'}"
```

31.16.99 salt.modules.groupadd

Manage groups on Linux, OpenBSD and NetBSD

salt.modules.groupadd.add(name, gid=None, system=False)

Add the specified group

CLI Example:

```
salt '*' group.add foo 3456
```

salt.modules.groupadd.adduser(name, username)

Add a user in the group.

CLI Example:

```
salt '*' group.adduser foo bar
```
Verifies if a valid username 'bar' as a member of an existing group 'foo', if not then adds it.

```
salt.modules.groupadd.chgid(name, gid)
    Change the gid for a named group
    
    CLI Example:
    
    salt '*' group.chgid foo 4376
```

```
salt.modules.groupadd.delete(name)
    Remove the named group
    
    CLI Example:
    
    salt '*' group.delete foo
```

```
salt.modules.groupadd.deluser(name, username)
    Remove a user from the group.
    
    CLI Example:
    
    salt '*' group.deluser foo bar
```

Removes a member user 'bar' from a group 'foo'. If group is not present then returns True.

```
salt.modules.groupadd.getent(refresh=False)
    Return info on all groups
    
    CLI Example:
    
    salt '*' group.getent
```

```
salt.modules.groupadd.info(name)
    Return information about a group
    
    CLI Example:
    
    salt '*' group.info foo
```

```
salt.modules.groupadd.members(name, members_list)
    Replaces members of the group with a provided list.
    
    CLI Example:
    
    salt '*' group.members foo 'user1,user2,user3,...'
```

Replaces a membership list for a local group 'foo'. foo:x:1234:user1,user2,user3,...

31.16.100 salt.modules.grub_legacy

Support for GRUB Legacy

```
salt.modules.grub_legacy.conf()
    Parse GRUB conf file
    
    CLI Example:
    
    salt '*' grub.conf
```

31.16. Full list of built-in execution modules
salt.modules.grub_legacy.version()
  Return server version from grub --version
  CLI Example:
  
  salt '*' grub.version

31.16.101 salt.modules.guestfs

Interact with virtual machine images via libguestfs

  depends
  
  • libguestfs

salt.modules.guestfs.mount(location, access='rw')
  Mount an image
  
  CLI Example:
  
  salt '*' guest.mount /srv/images/fedora.qcow

31.16.102 salt.modules.hadoop

Support for hadoop

  maintainer  Yann Jouanin <yann.jouanin@intelunix.fr>
  maturity   new
  depends
  
  platform   linux

salt.modules.hadoop.dfs(command=None, *args)
  Execute a command on DFS
  
  CLI Example:
  
  salt '*' hadoop.dfs ls /

salt.modules.hadoop.dfs_absent(path)
  Check if a file or directory is absent on the distributed FS.
  
  CLI Example:
  
  salt '*' hadoop.dfs_absent /some_random_file

    Returns True if the file is absent

salt.modules.hadoop.dfs_present(path)
  Check if a file or directory is present on the distributed FS.
  
  CLI Example:
  
  salt '*' hadoop.dfs_present /some_random_file

    Returns True if the file is present

salt.modules.hadoop.namenode_format(force=None)
  Format a name node
salt '*' hadoop.namenode_format force=True

salt.modules.hadoop.version()
    Return version from hadoop version
    CLI Example:
    salt '*' hadoop.version

31.16.103 salt.modules.haproxyconn

Support for haproxy
New in version 2014.7.0.

salt.modules.haproxyconn.disable_server(name, backend, socket='/var/run/haproxy.sock')
    Disable server in haproxy.
    name  Server to disable
    backend  haproxy backend
    socket  haproxy stats socket
    CLI Example:
    salt '*' haproxy.disable_server db1.example.com mysql

salt.modules.haproxyconn.enable_server(name, backend, socket='/var/run/haproxy.sock')
    Enable Server in haproxy
    name  Server to enable
    backend  haproxy backend
    socket  haproxy stats socket
    CLI Example:
    salt '*' haproxy.enable_server web1.example.com www

salt.modules.haproxyconn.get_weight(name, backend, socket='/var/run/haproxy.sock')
    Get server weight
    name  Server name
    backend  haproxy backend
    socket  haproxy stats socket
    CLI Example:
    salt '*' haproxy.get_weight web1.example.com www

salt.modules.haproxyconn.list_servers(backend, socket='/var/run/haproxy.sock', objec-
tify=False)
    List servers in haproxy backend.
    backend  haproxy backend
    socket  haproxy stats socket
    CLI Example:
Salt Documentation, Release 2015.8.0

* salt '*' haproxy.list_servers mysql

salt.modules.haproxyconn.set_weight(name, backend, weight=0, socket='/var/run/haproxy.sock')
Set server weight
- name Server name
- backend haproxy backend
- weight Server Weight
- socket haproxy stats socket

CLI Example:
* salt '*' haproxy.set_weight web1.example.com www 13

salt.modules.haproxyconn.show_backends(socket='/var/run/haproxy.sock')
Show HaProxy Backends
- socket haproxy stats socket

CLI Example:
* salt '*' haproxy.show_backends

salt.modules.haproxyconn.show_frontends(socket='/var/run/haproxy.sock')
Show HaProxy frontends
- socket haproxy stats socket

CLI Example:
* salt '*' haproxy.show_frontends

---

### 31.16.104 salt.modules.hashutil

A collection of hashing and encoding functions

salt.modules.hashutil.base64_decodestring(instr)
Decode a base64-encoded string

New in version 2014.7.0.

CLI Example:
* salt '*' hashutil.base64_decodestring 'Z2V0IHNhbHRlZA==\n'

salt.modules.hashutil.base64_encodestring(instr)
Encode a string as base64

New in version 2014.7.0.

CLI Example:
* salt '*' hashutil.base64_encodestring 'get salted'

salt.modules.hashutil.hmac_signature(string, shared_secret, challenge_hmac)
Verify a challenging hmac signature against a string / shared-secret

New in version 2014.7.0.
Returns a boolean if the verification succeeded or failed.

CLI Example:
```
salt '*' hashutil.hmac_signature 'get salted' 'shared secret' 'eBWf9bstXg+NiPSA0wpp85HMvZlYMpZEM'
```

```python
salt.modules.hashutil.md5_digest(instr)
```
Generate an MD5 hash of a given string
New in version 2014.7.0.

CLI Example:
```
salt '*' hashutil.md5_digest 'get salted'
```

```python
salt.modules.hashutil.sha256_digest(instr)
```
Generate a SHA256 hash of a given string
New in version 2014.7.0.

CLI Example:
```
salt '*' hashutil.sha256_digest 'get salted'
```

```python
salt.modules.hashutil.sha512_digest(instr)
```
Generate a SHA512 hash of a given string
New in version 2014.7.0.

CLI Example:
```
salt '*' hashutil.sha512_digest 'get salted'
```

### 31.16.105 salt.modules.hg

Support for the Mercurial SCM

```python
salt.modules.hg.archive(cwd, output, rev='tip', fmt=None, prefix=None, user=None)
```
Export a tarball from the repository

- **cwd** The path to the Mercurial repository
- **output** The path to the archive tarball
- **rev** The revision to create an archive from
- **fmt** None Format of the resulting archive. Mercurial supports: tar, tbz2, tgz, zip, uzip, and files formats.
- **prefix** [None] Prepend `<prefix>/` to every filename in the archive
- **user** [None] Run hg as a user other than what the minion runs as

If **prefix** is not specified it defaults to the basename of the repo directory.

CLI Example:
```
salt '*' hg.archive /path/to/repo output=/tmp/archive.tgz fmt=tgz
```

```python
salt.modules.hg.clone(cwd, repository, opts=None, user=None, identity=None)
```
Clone a new repository

- **cwd** The path to the Mercurial repository
- **repository** The hg URI of the repository
opts [None] Any additional options to add to the command line
user [None] Run hg as a user other than what the minion runs as
identity [None] Private SSH key on the minion server for authentication (ssh://)

New in version 2015.5.0.

CLI Example:

    salt '*' hg.clone /path/to/repo https://bitbucket.org/birkenfeld/sphinx

\texttt{salt.modules.hg.describe(cwd, rev='tip', user=None)}

Mimic \texttt{git describe} and return an identifier for the given revision

\begin{itemize}
  \item cwd The path to the Mercurial repository
  \item rev: tip The path to the archive tarball
  \item user [None] Run hg as a user other than what the minion runs as
\end{itemize}

CLI Example:

    salt '*' hg.describe /path/to/repo

\texttt{salt.modules.hg.pull(cwd, opts=None, user=None, identity=None, repository=None)}

Perform a pull on the given repository

\begin{itemize}
  \item cwd The path to the Mercurial repository
  \item repository [None] Perform pull from the repository different from \texttt{.hg/hgrc:[paths]:default}
  \item opts [None] Any additional options to add to the command line
  \item user [None] Run hg as a user other than what the minion runs as
  \item identity [None] Private SSH key on the minion server for authentication (ssh://)
\end{itemize}

New in version 2015.5.0.

CLI Example:

    salt '*' hg.pull /path/to/repo opts=-u

\texttt{salt.modules.hg.revision(cwd, rev='tip', short=False, user=None)}

Returns the long hash of a given identifier (hash, branch, tag, HEAD, etc)

\begin{itemize}
  \item cwd The path to the Mercurial repository
  \item rev: tip The revision
  \item short: False Return an abbreviated commit hash
  \item user [None] Run hg as a user other than what the minion runs as
\end{itemize}

CLI Example:

    salt '*' hg.revision /path/to/repo mybranch

\texttt{salt.modules.hg.update(cwd, rev, force=False, user=None)}

Update to a given revision

\begin{itemize}
  \item cwd The path to the Mercurial repository
  \item rev The revision to update to
  \item force [False] Force an update
\end{itemize}
**user** [None] Run hg as a user other than what the minion runs as

CLI Example:

```
salt devserver1 hg.update /path/to/repo somebranch
```

### 31.16.106 salt.modules.hipchat

Module for sending messages to hipchat.

New in version 2015.5.0.

**configuration** This module can be used by either passing an api key and version directly or by specifying both in a configuration profile in the salt master/minion config.

For example:

```
  hipchat:
  api_key: peWcBiMOS9HrZG15peWcBiMOS9HrZG15
  api_version: v1
```

**salt.modules.hipchat.find_room(name, api_key=None, api_version=None)**

Find a room by name and return it.  

: **param** name: The room name.  
: **param** api_key: The HipChat admin api key.  
: **param** api_version: The HipChat api version, if not specified in the configuration.  
: **return**: The room object.

CLI Example:

```
salt '*' hipchat.find_room name="Development Room"
```

```
salt '*' hipchat.find_room name="Development Room" api_key=peWcBiMOS9HrZG15peWcBiMOS9HrZG15 api_version=v1
```

**salt.modules.hipchat.find_user(name, api_key=None, api_version=None)**

Find a user by name and return it.  

: **param** name: The user name.  
: **param** api_key: The HipChat admin api key.  
: **param** api_version: The HipChat api version, if not specified in the configuration.  
: **return**: The user object.

CLI Example:

```
salt '*' hipchat.find_user name="Thomas Hatch"
```

```
salt '*' hipchat.find_user name="Thomas Hatch" api_key=peWcBiMOS9HrZG15peWcBiMOS9HrZG15 api_version=v1
```

**salt.modules.hipchat.list_rooms(api_key=None, api_version=None)**

List all HipChat rooms.

**Parameters**

- **api_key** -- The HipChat admin api key.
- **api_version** -- The HipChat api version, if not specified in the configuration.

**Returns** The room list.

CLI Example:

```
salt '*' hipchat.list_rooms
```

```
salt '*' hipchat.list_rooms api_key=peWcBiMOS9HrZG15peWcBiMOS9HrZG15 api_version=v1
```

31.16. Full list of builtin execution modules
salt.modules.hipchat.list_users(api_key=None, api_version=None)

List all HipChat users.  

:param api_key: The HipChat admin api key.  
:param api_version: The HipChat api version, if not specified in the configuration.  
:return: The user list.

CLI Example:

```
salt '*' hipchat.list_users
salt '*' hipchat.list_users api_key=peWcBiMOS9HrZG15peWcBiMOS9HrZG15 api_version=v1
```

salt.modules.hipchat.send_message(room_id, message, from_name, api_key=None, api_version=None, color='yellow', notify=False)

Send a message to a HipChat room.  

:param room_id: The room id or room name, either will work.  
:param message: The message to send to the HipChat room.  
:param from_name: Specify who the message is from.  
:param api_key: The HipChat api key, if not specified in the configuration.  
:param api_version: The HipChat api version, if not specified in the configuration.  
:param color: The color for the message, default: yellow.  
:param notify: Whether to notify the room, default: False.  
:return: Boolean if message was sent successfully.

CLI Example:

```
salt '*' hipchat.send_message room_id="Development Room" message="Build is done" from_name="Build Server"
salt '*' hipchat.send_message room_id="Development Room" message="Build failed" from_name="Build Server" color="red" notify=True
```

31.16.107 salt.modules.hosts

Manage the information in the hosts file

salt.modules.hosts.add_host(ip, alias)

Add a host to an existing entry, if the entry is not in place then create it with the given host

CLI Example:

```
salt '*' hosts.add_host <ip> <alias>
```

salt.modules.hosts.get_alias(ip)

Return the list of aliases associated with an ip

CLI Example:

```
salt '*' hosts.get_alias <ip addr>
```

salt.modules.hosts.get_ip(host)

Return the ip associated with the named host

CLI Example:

```
salt '*' hosts.get_ip <hostname>
```

salt.modules.hosts.has_pair(ip, alias)

Return true if the alias is set

CLI Example:

```
salt '*' hosts.has_pair <ip> <alias>
```

salt.modules.hosts.list_hosts()

Return the hosts found in the hosts file in this format:
{'<ip addr>': ['alias1', 'alias2', ...]}

CLI Example:
salt '*' hosts.list_hosts

salt.modules.hosts.rm_host(ip, alias)
Remove a host entry from the hosts file

CLI Example:
salt '*' hosts.rm_host <ip> <alias>

salt.modules.hosts.set_host(ip, alias)
Set the host entry in the hosts file for the given ip, this will overwrite any previous entry for the given ip

CLI Example:
salt '*' hosts.set_host <ip> <alias>

31.16.108 salt.modules.htpasswd

Support for htpasswd command
New in version 2014.1.0.

The functions here will load inside the webutil module. This allows other functions that don't use htpasswd to use
the webutil module name.

salt.modules.htpasswd.useradd(pwfile, user, password, opts='r', runas=None)
Add a user to htpasswd file using the htpasswd command. If the htpasswd file does not exist, it will be created.

pwfile  Path to htpasswd file
user  User name
password  User password
opts  Valid options that can be passed are:
  • n  Don't update file; display results on stdout.
  • m  Force MD5 encryption of the password (default).
  • d  Force CRYPT encryption of the password.
  • p  Do not encrypt the password (plaintext).
  • s  Force SHA encryption of the password.
runas  The system user to run htpasswd command with

CLI Examples:
salt '*' webutil.useradd /etc/httpd/htpasswd larry badpassword
salt '*' webutil.useradd /etc/httpd/htpasswd larry badpass opts=ns

salt.modules.htpasswd.useradd_all(pwfile, user, password, opts='r', runas=None)
Add a user to htpasswd file using the htpasswd command. If the htpasswd file does not exist, it will be created.

pwfile  Path to htpasswd file
user  User name
password  User password

opts  Valid options that can be passed are:
  •  n  Don’t update file; display results on stdout.
  •  m  Force MD5 encryption of the password (default).
  •  d  Force CRYPT encryption of the password.
  •  p  Do not encrypt the password (plaintext).
  •  s  Force SHA encryption of the password.

runas  The system user to run htpasswd command with

CLI Examples:

```shell
salt '*' webutil.useradd /etc/httpd/htpasswd larry badpassword
salt '*' webutil.useradd /etc/httpd/htpasswd larry badpass opts=ns
```

salt.modules.htpasswd.userdel(pwfile, user, runas=’None’)
Delete a user from the specified htpasswd file.

   pwfile  Path to htpasswd file
   user  User name
   runas  The system user to run htpasswd command with

CLI Examples:

```shell
salt '*' webutil.userdel /etc/httpd/htpasswd larry
```

31.16.109  salt.modules.http

Module for making various web calls. Primarily designed for webhooks and the like, but also useful for basic http testing.

New in version 2015.5.0.

salt.modules.http.query(url, **kwargs)
Query a resource, and decode the return data

New in version 2015.5.0.

CLI Example:

```shell
salt '*' http.query http://somelink.com/
salt '*' http.query http://somelink.com/ method=POST params='key1=val1&key2=val2'
salt '*' http.query http://somelink.com/ method=POST data='<xml>somecontent</xml>'
```

salt.modules.http.update_ca_bundle(target=’None’, source=’None’, merge_files=’None’)
Update the local CA bundle file from a URL.

New in version 2015.5.0.

CLI Example:

```shell
salt '*' http.update_ca_bundle
salt '*' http.update_ca_bundle target=/path/to/cacerts.pem
salt '*' http.update_ca_bundle source=https://example.com/cacerts.pem
```
If the target is not specified, it will be pulled from the \texttt{ca\_cert} configuration variable available to the minion. If it cannot be found there, it will be placed at \texttt{<<FILE\_ROOTS>>/cacerts.pem}.

If the source is not specified, it will be pulled from the \texttt{ca\_cert\_url} configuration variable available to the minion. If it cannot be found, it will be downloaded from the cURL website, using an http (not https) URL. USING THE DEFAULT URL SHOULD BE AVOIDED!

\texttt{merge\_files} may also be specified, which includes a string or list of strings representing a file or files to be appended to the end of the CA bundle, once it is downloaded.

CLI Example:

\begin{verbatim}
salt '*' http.update_ca_bundle merge_files=/path/to/mycert.pem
\end{verbatim}

### 31.16.110 salt.modules.ifttt

Support for IFTTT

New in version 2015.8.0.

Requires an \texttt{api\_key} in /etc/salt/minion:

\begin{verbatim}
salt.modules.ifttt.trigger_event(event=None, **kwargs)
\end{verbatim}

Trigger a configured event in IFTTT.

- **Parameters**
  - \texttt{event} -- The name of the event to trigger.

- **Returns**
  - A dictionary with status, text, and error if result was failure.

CLI Example:

### 31.16.111 salt.modules.ilo

Manage HP ILO

- \texttt{depends} hponecfg (SmartStart Scripting Toolkit Linux Edition)

\begin{verbatim}
salt.modules.ilo.change_password(username, password)
\end{verbatim}

Reset a users password

CLI Example:

\begin{verbatim}
salt '*' ilo.change_password damianMyerscough
\end{verbatim}

\begin{verbatim}
salt.modules.ilo.change_username(old_username, new_username)
\end{verbatim}

Change a username

CLI Example:

\begin{verbatim}
salt '*' ilo.change_username damian diana
\end{verbatim}

\begin{verbatim}
salt.modules.ilo.configure_network(ip, netmask, gateway)
\end{verbatim}

Configure Network Interface

CLI Example:

\begin{verbatim}
salt '*' ilo.configure_network [IP ADDRESS] [NETMASK] [GATEWAY]
\end{verbatim}
salt.modules.ilo.configure_snmp(community, snmp_port=161, snmp_trapport=161)
Configure SNMP

CLI Example:
```
salt '*' ilo.configure_snmp [COMMUNITY STRING] [SNMP PORT] [SNMP TRAP PORT]
```

salt.modules.ilo.create_user(name, password, *privileges)
Create user

CLI Example:
```
salt '*' ilo.create_user damian secretagent VIRTUAL_MEDIA_PRIV
```

If no permissions are specify the user will only have a read-only account.

Supported privileges:
- ADMIN_PRIV Enables the user to administer user accounts.
- REMOTE_CONS_PRIV Enables the user to access the Remote Console functionality.
- RESET_SERVER_PRIV Enables the user to remotely manipulate the server power setting.
- VIRTUAL_MEDIA_PRIV Enables the user permission to access the virtual media functionality.
- CONFIG_ILO_PRIV Enables the user to configure iLO settings.

salt.modules.ilo.delete_ssh_key(username)
Delete a users SSH key from the ILO

CLI Example:
```
salt '*' ilo.delete_user_sshkey damian
```

salt.modules.ilo.delete_user(username)
Delete a user

CLI Example:
```
salt '*' ilo.delete_user damian
```

salt.modules.ilo.disable_dhcp()
Disable DHCP

CLI Example:
```
salt '*' ilo.disable_dhcp
```

salt.modules.ilo.disable_ssh()
Disable the SSH daemon

CLI Example:
```
salt '*' ilo.disable_ssh
```

salt.modules.ilo.enable_dhcp()
Enable DHCP

CLI Example:
```
salt '*' ilo.enable_dhcp
```
salt.modules.ilo.enable_ssh()
    Enable the SSH daemon

    CLI Example:
    salt '*' ilo.enable_ssh

salt.modules.ilo.get_user(username)
    Returns local user information, excluding the password

    CLI Example:
    salt '*' ilo.get_user damian

salt.modules.ilo.global_settings()
    Show global settings

    CLI Example:
    salt '*' ilo.global_settings

salt.modules.ilo.list_users()
    List all users

    CLI Example:
    salt '*' ilo.list_users

salt.modules.ilo.list_users_info()
    List all users in detail

    CLI Example:
    salt '*' ilo.list_users_info

salt.modules.ilo.network()
    Grab the current network settings

    CLI Example:
    salt '*' ilo.network

salt.modules.ilo.set_http_port(port=80)
    Configure the port HTTP should listen on

    CLI Example:
    salt '*' ilo.set_http_port 8080

salt.modules.ilo.set_https_port(port=443)
    Configure the port HTTPS should listen on

    CLI Example:
    salt '*' ilo.set_https_port 4334

salt.modules.ilo.set_ssh_key(public_key)
    Configure SSH public keys for specific users

    CLI Example:
    salt '*' ilo.set_ssh_key "ssh-dss AAAAB3NzaC1kc3MAAACBA... damian"
The SSH public key needs to be DSA and the last argument in the key needs to be the username (case-sensitive) of the ILO username.

```python
salt.modules.ilo.set_ssh_port(port=22)
```
Enable SSH on a user defined port

CLI Example:

```bash
salt '*' ilo.set_ssh_port 2222
```

### 31.16.112 salt.modules.img

Virtual machine image management tools

```python
salt.modules.img.bootstrap(location, size, fmt)
```
HIGHLY EXPERIMENTAL Bootstrap a virtual machine image

- **location**: The location to create the image
- **size**: The size of the image to create in megabytes
- **fmt**: The image format, raw or qcow2

CLI Example:

```bash
salt '*' img.bootstrap /srv/salt-images/host.qcow 4096 qcow2
```

```python
salt.modules.img.mount_image(location)
```
Mount the named image and return the mount point

```bash
salt '*' img.mount_image /tmp/foo
```

```python
salt.modules.img.umount_image(mnt)
```
Unmount an image mountpoint

```bash
salt '*' img.umount_image /mnt/foo
```

### 31.16.113 salt.modules.incron

Work with incron

```python
salt.modules.incron.list_tab(user)
```
Return the contents of the specified user’s incrontab

```bash
salt '*' incron.list_tab root
```

```python
salt.modules.incron.ls(user)
```
Return the contents of the specified user’s incrontab

```bash
salt '*' incron.list_tab root
```
<table>

</tr>
</tbody>
</table>

### 31.16.114 salt.modules.influx

InfluxDB - A distributed time series database

Module to provide InfluxDB compatibility to Salt (compatible with InfluxDB version 0.5+)

New in version 2014.7.0.

**depends**
- influxdb Python module

31.16. Full list of built-in execution modules 943
configuration  This module accepts connection configuration details either as parameters or as configuration settings in /etc/salt/minion on the relevant minions:

```yaml
influxdb.host: 'localhost'
influxdb.port: 8086
influxdb.user: 'root'
influxdb.password: 'root'
```

This data can also be passed into pillar. Options passed into opts will overwrite options passed into pillar.

**salt.modules.influx.db_create**(name, user=None, password=None, host=None, port=None)
Create a database

- **name**  Database name to create
- **user**  The user to connect as
- **password**  The password of the user
- **host**  The host to connect to
- **port**  The port to connect to

CLI Example:

```
salt '*' influxdb.db_create <name>
salt '*' influxdb.db_create <name> <user> <password> <host> <port>
```

**salt.modules.influx.db_exists**(name, user=None, password=None, host=None, port=None)
Checks if a database exists in InfluxDB

- **name**  Database name to create
- **user**  The user to connect as
- **password**  The password of the user
- **host**  The host to connect to
- **port**  The port to connect to

CLI Example:

```
salt '*' influxdb.db_exists <name>
salt '*' influxdb.db_exists <name> <user> <password> <host> <port>
```

**salt.modules.influx.db_list**(user=None, password=None, host=None, port=None)
List all InfluxDB databases

- **user**  The user to connect as
- **password**  The password of the user
- **host**  The host to connect to
- **port**  The port to connect to

CLI Example:

```
salt '*' influxdb.db_list
salt '*' influxdb.db_list <user> <password> <host> <port>
```

**salt.modules.influx.db_remove**(name, user=None, password=None, host=None, port=None)
Remove a database
name  Database name to remove
user  The user to connect as
password  The password of the user
host  The host to connect to
port  The port to connect to

CLI Example:

```
salt '*' influxdb.db_remove <name>
salt '*' influxdb.db_remove <name> <user> <password> <host> <port>
```

```python
salt.modules.influx.login_test(name, password, database=None, host=None, port=None)
```

Checks if a credential pair can log in at all.

If a database is specified: it will check for database user existence. If a database is not specified: it will check for cluster admin existence.

name  The user to connect as
password  The password of the user
database  The database to try to log in to
host  The host to connect to
port  The port to connect to

CLI Example:

```
salt '*' influxdb.login_test <name>
salt '*' influxdb.login_test <name> <database>
salt '*' influxdb.login_test <name> <database> <user> <password> <host> <port>
```

```python
salt.modules.influx.query(database, query, time_precision='s', chunked=False, user=None, password=None, host=None, port=None)
```

Querying data
database  The database to query
query  Query to be executed
time_precision  Time precision to use ("s", "m", or "u")
chunked  Whether is chunked or not
user  The user to connect as
password  The password of the user
host  The host to connect to
port  The port to connect to

CLI Example:

```
salt '*' influxdb.query <database> <query>
salt '*' influxdb.query <database> <query> <time_precision> <chunked> <user> <password> <host> <port>
```

```python
salt.modules.influx.user_chpass(name, passwd, database=None, user=None, password=None, host=None, port=None)
```

Change password for a cluster admin or a database user.
If a database is specified: it will update database user password. If a database is not specified: it will update cluster admin password.

**name** User name for whom to change the password

**passwd** New password

**database** The database on which to operate

**user** The user to connect as

**password** The password of the user

**host** The host to connect to

**port** The port to connect to

CLI Example:

```
salt '*' influxdb.user_chpass <name> <passwd>
salt '*' influxdb.user_chpass <name> <passwd> <database>
salt '*' influxdb.user_chpass <name> <passwd> <database> <user> <password> <host> <port>
```

**salt.modules.influx.user_create**(name, passwd, database=None, user=None, password=None, host=None, port=None)

Create a cluster admin or a database user.

If a database is specified: it will create database user. If a database is not specified: it will create a cluster admin.

**name** User name for the new user to create

**passwd** Password for the new user to create

**database** The database to create the user in

**user** The user to connect as

**password** The password of the user

**host** The host to connect to

**port** The port to connect to

CLI Example:

```
salt '*' influxdb.user_create <name> <passwd>
salt '*' influxdb.user_create <name> <passwd> <database>
salt '*' influxdb.user_create <name> <passwd> <database> <user> <password> <host> <port>
```

**salt.modules.influx.user_exists**(name, database=None, user=None, password=None, host=None, port=None)

Checks if a cluster admin or database user exists.

If a database is specified: it will check for database user existence. If a database is not specified: it will check for cluster admin existence.

**name** User name

**database** The database to check for the user to exist

**user** The user to connect as

**password** The password of the user

**host** The host to connect to

**port** The port to connect to
CLI Example:

```
salt '*' influxdb.user_exists <name>
salt '*' influxdb.user_exists <name> <database>
salt '*' influxdb.user_exists <name> <database> <user> <password> <host> <port>
```

```
salt.modules.influx.user_list(database=None, user=None, password=None, host=None, port=None)
```

List cluster admins or database users.

If a database is specified: it will return database users list. If a database is not specified: it will return cluster admins list.

- **database**: The database to list the users from
- **user**: The user to connect as
- **password**: The password of the user
- **host**: The host to connect to
- **port**: The port to connect to

CLI Example:

```
salt '*' influxdb.user_list
salt '*' influxdb.user_list <database>
salt '*' influxdb.user_list <database> <user> <password> <host> <port>
```

```
salt.modules.influx.user_remove(name, database=None, user=None, password=None, host=None, port=None)
```

Remove a cluster admin or a database user.

If a database is specified: it will remove the database user. If a database is not specified: it will remove the cluster admin.

- **name**: User name to remove
- **database**: The database to remove the user from
- **user**: User name for the new user to delete
- **user**: The user to connect as
- **password**: The password of the user
- **host**: The host to connect to
- **port**: The port to connect to

CLI Example:

```
salt '*' influxdb.user_remove <name>
salt '*' influxdb.user_remove <name> <database>
salt '*' influxdb.user_remove <name> <database> <user> <password> <host> <port>
```

**31.16.115 salt.modules.ini_manage**

Edit ini files

- **maintainer**: <akilesh1597@gmail.com>
- **maturity**: new
depends re
platform all

Use section as DEFAULT_IMPLICIT if your ini file does not have any section (for example /etc/sysctl.conf)

`salt.modules.ini_manage.get_option(file_name, section, option)`
Get value of a key from a section in an ini file. Returns None if no matching key was found.

API Example:
```
import salt
sc = salt.client.get_local_client()
sc.cmd('target', 'ini.get_option',
       [path_to_ini_file, section_name, option])
```

CLI Example:
```
salt '*' ini.get_option /path/to/ini section_name option_name
```

`salt.modules.ini_manage.get_section(file_name, section)`
Retrieve a section from an ini file. Returns the section as dictionary. If the section is not found, an empty
dictionary is returned.

API Example:
```
import salt
sc = salt.client.get_local_client()
sc.cmd('target', 'ini.get_section',
       [path_to_ini_file, section_name])
```

CLI Example:
```
salt '*' ini.get_section /path/to/ini section_name
```

`salt.modules.ini_manage.remove_option(file_name, section, option)`
Remove a key/value pair from a section in an ini file. Returns the value of the removed key, or None if nothing
was removed.

API Example:
```
import salt
sc = salt.client.get_local_client()
sc.cmd('target', 'ini.remove_option',
       [path_to_ini_file, section_name, option])
```

CLI Example:
```
salt '*' ini.remove_option /path/to/ini section_name option_name
```

`salt.modules.ini_manage.remove_section(file_name, section)`
Remove a section in an ini file. Returns the removed section as dictionary, or None if nothing was removed.

API Example:
```
import salt
sc = salt.client.get_local_client()
sc.cmd('target', 'ini.remove_section',
       [path_to_ini_file, section_name])
```

CLI Example:
salt '...' ini.remove_section /path/to/ini section_name

salt.modules.ini_manage.set_option(file_name, sections=None, summary=True)
Edit an ini file, replacing one or more sections. Returns a dictionary containing the changes made.

file_name  path of ini file
sections  [None] A dictionary representing the sections to be edited ini file
Set summary=False if return data need not have previous option value

API Example:

```python
import salt
sc = salt.client.get_local_client()
sc.cmd('target', 'ini.set_option',
       ['path_to_ini_file', '{"section_to_change": {"key": "value"}]}')
```

CLI Example:

```bash
salt '...' ini.set_option /path/to/ini '{section_foo: {key: value}}'
```

31.16.116 salt.modules.introspect

Functions to perform introspection on a minion, and return data in a format usable by Salt States

salt.modules.introspect.enabled_service_owners()
Return which packages own each of the services that are currently enabled.

CLI Example:

```bash
salt myminion introspect.enabled_service_owners
```

salt.modules.introspect.running_service_owners(exclude=(`/dev', `/home', `/media', `/proc', `/run', `/sys', `/tmp', `/var'))
Determine which packages own the currently running services. By default, excludes files whose full path starts with /dev, /home, /media, /proc, /run, /sys, /tmp and /var. This can be overridden by passing in a new list to exclude.

CLI Example:

```bash
salt myminion introspect.running_service_owners
```

salt.modules.introspect.service_highstate(requires=True)
Return running and enabled services in a highstate structure. By default also returns package dependencies for those services, which means that package definitions must be created outside this function. To drop the package dependencies, set requires to False.

CLI Example:

```bash
salt myminion introspect.service_highstate salt myminion introspect.service_highstate requires=False
```

31.16.117 salt.modules.ipmi

Support IPMI commands over LAN. This module does not talk to the local systems hardware through IPMI drivers. It uses a python module pyghmi.

depends Python module pyghmi. You can install pyghmi using pip:
pip install pyghmi

configuration

The following configuration defaults can be define (pillar or config files):

```python
ipmi.config:
    api_host: 127.0.0.1
    api_user: admin
    api_pass: apassword
    api_port: 623
    api_kg: None
```

Usage can override the config defaults:

```bash
salt-call ipmi.get_user api_host=myipmienabled.system
    api_user=admin api_pass=pass
    uid=1
```

```python
salt.modules.ipmi.create_user(uid, name, password, channel=14, callback=False, link_auth=True, ipmi_msg=True, privilege_level='administrator', **kwargs)
```

create/ensure a user is created with provided settings.

Parameters

- **privilege_level** -- User Privilege Limit. (Determines the maximum privilege level that the user is allowed to switch to on the specified channel)
- **callback**user
- **operator
- **administrator
- **proprietary
- **no_access

- **kwargs**

  - api_host=127.0.0.1
  - api_user=admin
  - api_pass=example
  - api_port=623
  - api_kg=None

CLI Examples:

```bash
salt-call ipmi.create_user uid=2 name=steverweber api_host=172.168.0.7 api_pass=nevertell
```

```python
salt.modules.ipmi.fast_connect_test(**kwargs)
```

Returns True if connection success. This uses an aggressive timeout value!

Parameters **kwargs --

- api_host=127.0.0.1
- api_user=admin
- api_pass=example
- api_port=623
- api_kg=None

CLI Examples:

```bash
salt-call ipmi.fast_connect_test api_host=172.168.0.9
```

```python
salt.modules.ipmi.get_bootdev(**kwargs)
```

Get current boot device override information.
Provides the current requested boot device. Be aware that not all IPMI devices support this. Even in BMCs that claim to, occasionally the BIOS or UEFI fail to honor it. This is usually only applicable to the next reboot.

**Parameters**

- **kwargs**
  - api_host=127.0.0.1
  - api_user=admin
  - api_pass=example
  - api_port=623
  - api_kg=None

**CLI Example:**

```
salt-call ipmi.get_bootdev api_host=127.0.0.1 api_user=admin api_pass=pass
```

```
salt.modules.ipmi.get_channel_access(channel=14, read_mode='non_volatile', **kwargs)
```

```
:param kwargs:api_host='127.0.0.1' api_user='admin' api_pass='example' api_port=623
```

**Parameters**

- **channel** -- number [1:7]
- **read_mode** --
  - non_volatile = get non-volatile Channel Access
  - volatile = get present volatile (active) setting of Channel Access
- **kwargs** --
  - api_host=127.0.0.1
  - api_user=admin
  - api_pass=example
  - api_port=623
  - api_kg=None

**return** A Python dict with the following keys/values:

```
{
    'alerting':
    'per_msg_auth':
    'user_level_auth':
    'access_mode': { (ONE OF)
        0: 'disabled',
        1: 'pre_boot',
        2: 'always',
        3: 'shared'
    }
    'privilege_level': { (ONE OF)
        1: 'callback',
        2: 'user',
        3: 'operator',
        4: 'operator',
        5: 'proprietary',
    }
}
```
CLI Examples:

```
salt-call ipmi.get_channel_access channel=1
```

```
salt.modules.ipmi.get_channel_info(channel=14, **kwargs)
Get channel info
```

Parameters

- **channel** -- number [1:7]
- **kwargs**
  - api_host=127.0.0.1
  - api_user=admin
  - api_pass=example
  - api_port=623
  - api_kg=None

**return** channel session supports:
- no_session: channel is session-less
- single: channel is single-session
- multi: channel is multi-session
- auto: channel is session-based (channel could alternate between single- and multi-session operation, as can occur with a serial/modem channel that supports connection mode auto-detect)

```
salt-call ipmi.get_channel_info
```

```
salt.modules.ipmi.get_channel_max_user_count(channel=14, **kwargs)
Get max users in channel
```

Parameters

- **channel** -- number [1:7]
- **kwargs**
  - api_host=127.0.0.1
  - api_user=admin
  - api_pass=example
  - api_port=623
  - api_kg=None

**Returns** int -- often 16

```
salt-call ipmi.get_channel_max_user_count
```

```
salt.modules.ipmi.get_health(**kwargs)
Get Summarize health
```
This provides a summary of the health of the managed system. It additionally provides an iterable list of reasons for warning, critical, or failed assessments.

good health: `{badreadings: [], `health': 0}

Parameters **kwargs --
  • api_host=127.0.0.1
  • api_user=admin
  • api_pass=example
  • api_port=623
  • api_kg=None

CLI Example:

```
salt-call ipmi.get_health api_host=127.0.0.1 api_user=admin api_pass=pass
```

salt.modules.ipmi.get_power(**kwargs)
Get current power state

The response, if successful, should contain `powerstate' key and either `on' or `off' to indicate current state.

Parameters **kwargs --
  • api_host=127.0.0.1
  • api_user=admin
  • api_pass=example
  • api_port=623
  • api_kg=None

CLI Example:

```
salt-call ipmi.get_power api_host=127.0.0.1 api_user=admin api_pass=pass
```

salt.modules.ipmi.get_sensor_data(**kwargs)
Get sensor readings

Iterates sensor reading objects

Parameters **kwargs --
  • api_host=127.0.0.1
  • api_user=admin
  • api_pass=example
  • api_port=623
  • api_kg=None

CLI Example:

```
salt-call ipmi.get_sensor_data api_host=127.0.0.1 api_user=admin api_pass=pass
```

salt.modules.ipmi.get_user(uid, channel=14, **kwargs)
Get user from uid and access on channel

Parameters
• **uid** -- user number [1:16]
• **channel** -- number [1:7]
• **kwargs** --
  - api_host=127.0.0.1
  - api_user=admin
  - api_pass=example
  - api_port=623
  - api_kg=None

```python
return
```
```python
name: (str)
uid: (int)
channel: (int)
access:
  - callback (bool)
  - link_auth (bool)
  - ipmi_msg (bool)
  - privilege_level: (str)[callback, user, operator administrator, proprietary, no_access]
```

**CLI Examples:**

```
salt-call ipmi.get_user uid=2
```

```python
salt.modules.ipmi.get_user_access(uid, channel=14, **kwargs)
```

Get user access

**Parameters**

• **uid** -- user number [1:16]
• **channel** -- number [1:7]
• **kwargs** --
  - api_host=127.0.0.1
  - api_user=admin
  - api_pass=example
  - api_port=623
  - api_kg=None

```python
return
```
```python
channel_info:
  - max_user_count = maximum number of user IDs on this channel
  - enabled_users = count of User ID slots presently in use
  - users_with_fixed_names = count of user IDs with fixed names
access:
  - callback
  - link_auth
  - ipmi_msg
  - privilege_level: [reserved, callback, user, operator administrator, proprietary, no_access]
```
**CLI Examples:**

```
salt-call ipmi.get_user_access uid=2
```

`salt.modules.ipmi.get_user_name(uid, return_none_on_error=True, **kwargs)`

Get user name

**Parameters**

- **uid** -- user number [1:16]
- **return_none_on_error** -- return None on error
- **kwargs**
  - api_host=127.0.0.1
  - api_user=admin
  - api_pass=example
  - api_port=623
  - api_kg=None

**CLI Examples:**

```
salt-call ipmi.get_user_name uid=2
```

`salt.modules.ipmi.get_users(channel=14, **kwargs)`

get list of users and access information

**Parameters**

- **channel** -- number [1:7]
- **kwargs**
  - api_host=127.0.0.1
  - api_user=admin
  - api_pass=example
  - api_port=623
  - api_kg=None

**Returns**

- name: (str)
- uid: (int)
- channel: (int)
- access:
  - callback (bool)
  - link_auth (bool)
  - ipmi_msg (bool)
  - privilege_level: (str)[callback, user, operator, administrator, proprietary, no_access]

**CLI Examples:**
salt-call ipmi.get_users api_host=172.168.0.7

salt.modules.ipmi.raw_command(netfn, command, bridge_request=None, data=(), retry=True, delay_xmit=None, **kwargs)

Send raw ipmi command
This allows arbitrary IPMI bytes to be issued. This is commonly used for certain vendor specific commands.

Parameters

- **netfn** -- Net function number
- **command** -- Command value
- **bridge_request** -- The target slave address and channel number for the bridge request.
- **data** -- Command data as a tuple or list
- **kwargs** --
  - api_host=127.0.0.1
  - api_user=admin
  - api_pass=example
  - api_port=623
  - api_kg=None

Returns dict -- The response from IPMI device

CLI Examples:

```
salt-call ipmi.raw_command netfn=0x06 command=0x46 data=[0x02]
# this will return the name of the user with id 2 in bytes
```

salt.modules.ipmi.set_bootdev(bootdev='default', persist=False, uefiboott=False, **kwargs)

Set boot device to use on next reboot

Parameters

- **bootdev** --
  - network: Request network boot
  - hd: Boot from hard drive
  - safe: Boot from hard drive, requesting `safe mode`
  - optical: boot from CD/DVD/BD drive
  - setup: Boot into setup utility
  - default: remove any IPMI directed boot device request
- **persist** -- If true, ask that system firmware use this device beyond next boot. Be aware many systems do not honor this
- **uefiboott** -- If true, request UEFI boot explicitly. Strictly speaking, the spec sugests that if not set, the system should BIOS boot and offers no `don't care` option. In practice, this flag not being set does not preclude UEFI boot on any system I've encountered.
- **kwargs** --
  - api_host=127.0.0.1
  - api_user=admin
- api_pass=example
- api_port=623
- api_kg=None

**Returns**  dict or True -- If callback is not provided, the response

**CLI Examples:**

```
salt-call ipmi.set_bootdev bootdev=network persist=True
```

```python
salt.modules.ipmi.set_channel_access(channel=14, access_update_mode='non_volatile',
                                      alerting=False, per_msg_auth=False,
                                      user_level_auth=False, access_mode='always',
                                      privilege_update_mode='non_volatile', privilege_level='administrator', **kwargs)
```

Set channel access

**Parameters**

- **channel** -- number [1:7]
- **access_update_mode** --
  - `dont_change` = don’t set or change Channel Access
  - `non_volatile` = set non-volatile Channel Access
  - `volatile` = set volatile (active) setting of Channel Access
- **alerting** -- PEF Alerting Enable/Disable - True = enable PEF Alerting - False = disable PEF Alerting on this channel
  (Alert Immediate command can still be used to generate alerts)
- **per_msg_auth** -- Per-message Authentication - True = enable - False = disable Per-message Authentication. [Authentication required to activate any session on this channel, but authentication not used on subsequent packets for the session.]
- **user_level_auth** -- User Level Authentication Enable/Disable. - True = enable User Level Authentication. All User Level commands are to be authenticated per the Authentication Type that was negotiated when the session was activated.
  - False = disable User Level Authentication. Allow User Level commands to be executed without being authenticated. If the option to disable User Level Command authentication is accepted, the BMC will accept packets with Authentication Type set to None if they contain user level commands. For outgoing packets, the BMC returns responses with the same Authentication Type that was used for the request.
- **access_mode** -- Access Mode for IPMI messaging (PEF Alerting is enabled/disabled separately from IPMI messaging) * disabled = disabled for IPMI messaging * pre_boot = pre-boot only channel only available when system is in a powered down state or in BIOS prior to start of boot.
  - always = channel always available regardless of system mode. BIOS typically dedicates the serial connection to the BMC.
- shared = same as always available, but BIOS typically leaves the serial port available for software use.

- **privilege_update_mode** -- Channel Privilege Level Limit. This value sets the maximum privilege level that can be accepted on the specified channel. * dont_change = don't set or change channel Privilege Level Limit * non_volatile = non-volatile Privilege Level Limit according * volatile = volatile setting of Privilege Level Limit

- **privilege_level** -- Channel Privilege Level Limit * reserved = unused * callback * user * operator * administrator * proprietary = used by OEM

- **kwargs**
  - api_host=127.0.0.1
  - api_user=admin
  - api_pass=example
  - api_port=623
  - api_kg=None

CLI Examples:

```
salt-call ipmi.set_channel_access privilege_level='administrator'
```
- reset -- reset (without waiting for OS)
- boot -- If system is off, then `on`, else `reset`

**ensure** -- If (bool True), do not return until system actually completes requested state change for 300 seconds. If a non-zero (int), adjust the wait time to the requested number of seconds

**kwargs** --
- api_host=127.0.0.1
- api_user=admin
- api_pass=example
- api_port=623
- api kg=None

**Returns**  
dict -- A dict describing the response retrieved

CLI Examples:

```
salt-call ipmi.set_power state=shutdown wait=True
```

```
salt.modules.ipmi.set_user_access(uid, channel=14, callback=True, link_auth=True, ipmi_msg=True, privilege_level='administrator', **kwargs)
```

Set user access

**Parameters**

- **uid** -- user number [1:16]
- **channel** -- number [1:7]

**Parm callback**  
User Restricted to Callback

**False** = User Privilege Limit is determined by the User Privilege Limit parameter, below, for both callback and non-callback connections.

**True** = User Privilege Limit is determined by the User Privilege Limit parameter for callback connections, but is restricted to Callback level for non-callback connections. Thus, a user can only initiate a Callback when they `call in` to the BMC, but once the callback connection has been made, the user could potentially establish a session as an Operator.

**Parameters**  
**link_auth** -- User Link authentication

enable/disable (used to enable whether this user's name and password information will be used for link authentication, e.g. PPP CHAP) for the given channel. Link authentication itself is a global setting for the channel and is enabled/disabled via the serial/modem configuration parameters.

**Parameters**  
**ipmi_msg** -- User IPMI Messaging:

(used to enable/disable whether this user's name and password information will be used for IPMI Messaging. In this case, `IPMI Messaging` refers to the ability to execute generic IPMI commands that are not associated with a particular payload type. For example, if IPMI Messaging is disabled for a user, but that user is enabled for activating the SOL payload type, then IPMI commands associated with SOL and session management, such as Get SOL Configuration Parameters and Close Session are available, but generic IPMI commands such as Get SEL Time are unavailable.)

**Parameters**  
**privilege_level** --
User Privilege Limit. (Determines the maximum privilege level that the user is allowed to switch to on the specified channel.)

- callback
- user
- operator
- administrator
- proprietary
- no_access

Parameters **kwargs --

- api_host=127.0.0.1
- api_user=admin
- api_pass=example
- api_port=623
- api_kg=None

CLI Examples:

```bash
salt-call ipmi.set_user_access uid=2 privilege_level='operator'
```

```
salt.modules.ipmi.set_user_name(uid, name, **kwargs)
```

Set user name

Parameters

- **uid** -- user number [1:16]
- **name** -- username (limit of 16bytes)
- **kwargs** --
  - api_host=127.0.0.1
  - api_user=admin
  - api_pass=example
  - api_port=623
  - api_kg=None

CLI Examples:

```bash
salt-call ipmi.set_user_name uid=2 name='steverweber'
```

```
salt.modules.ipmi.set_user_password(uid, mode='set_password', password=None, **kwargs)
```

Set user password and (modes)

Parameters

- **uid** -- id number of user. see: get_names_uid()['name']
- **mode** --
  - disable = disable user connections
  - enable = enable user connections
- set_password = set or ensure password
- test_password = test password is correct

- **password** -- max 16 char string (optional when mode is [disable or enable])
- **kwargs**
  - api_host=127.0.0.1
  - api_user=admin
  - api_pass=example
  - api_port=623
  - api_kg=None

Returns: True on success when mode = test_password, return False on bad password

CLI Example:

```
salt-call ipmi.set_user_password api_host=127.0.0.1 api_user=admin api_pass=pass uid=1 password=newPass
salt-call ipmi.set_user_password uid=1 mode=enable
```

salt.modules.ipmi..user_delete(uid, channel=14, **kwargs)

Delete user (helper)

Parameters

- **uid** -- user number [1:16]
- **channel** -- number [1:7]
- **kwargs**
  - api_host=127.0.0.1
  - api_user=admin
  - api_pass=example
  - api_port=623
  - api_kg=None

CLI Examples:

```
salt-call ipmi.user_delete uid=2
```

### 31.16.118 salt.modules.ipset

Support for ipset

salt.modules.ipset.add(set=None, entry=None, family='ipv4', **kwargs)

Append an entry to the specified set.

CLI Example:

```
salt '*' ipset.add setname 192.168.1.26
```
salt.modules.ipset.check(set=None, entry=None, family='ipv4')
Check that an entry exists in the specified set.

- **set** The ipset name
- **entry** An entry in the ipset. This parameter can be a single IP address, a range of IP addresses, or a subnet block. Example:
  192.168.0.1
  192.168.0.2-192.168.0.19
  192.168.0.0/25

- **family** IP protocol version: ipv4 or ipv6

CLI Example:
```
salt '*' ipset.check setname '192.168.0.1' comment "Hello"
```

salt.modules.ipset.check_set(set=None, family='ipv4')
Check that given ipset set exists.
New in version 2014.7.0.

CLI Example:
```
salt '*' ipset.check_set setname
```

salt.modules.ipset.delete(set=None, entry=None, family='ipv4', **kwargs)
Delete an entry from the specified set.

CLI Example:
```
```

salt.modules.ipset.delete_set(set=None, family='ipv4')
New in version 2014.7.0.
Delete ipset set.

CLI Example:
```
salt '*' ipset.delete_set custom_set
```

IPv6:
```
salt '*' ipset.delete_set custom_set family=ipv6
```

salt.modules.ipset.flush(set=None, family='ipv4')
Flush entries in the specified set, Flush all sets if set is not specified.

CLI Example:
```
salt '*' ipset.flush
salt '*' ipset.flush set
```

IPv6:
```
salt '*' ipset.flush
salt '*' ipset.flush set
```

salt.modules.ipset.list_sets(family='ipv4')
New in version 2014.7.0.
List all ipset sets.

CLI Example:

```bash
salt '*' ipset.list_sets
```

`salt.modules.ipset.new_set`(set=None, set_type=None, family='ipv4', comment=False, **kwargs)

New in version 2014.7.0.

Create new custom set

CLI Example:

```bash
custom_set
salt '*' ipset.new_set custom_set list:set
```

IPv6:

```bash
custom_set
salt '*' ipset.new_set custom_set list:set family=ipv6
```

`salt.modules.ipset.rename_set`(set=None, new_set=None, family='ipv4')

New in version 2014.7.0.

Delete ipset set.

CLI Example:

```bash
custom_set
salt '*' ipset.rename_set custom_set new_set=new_set_name
```

IPv6:

```bash
custom_set
salt '*' ipset.rename_set custom_set new_set=new_set_name family=ipv6
```

`salt.modules.ipset.test`(set=None, entry=None, family='ipv4', **kwargs)

Test if an entry is in the specified set.

CLI Example:

```bash
custom_set
salt '*' ipset.test setname 192.168.0.2
```

IPv6:

```bash
custom_set
salt '*' ipset.test setname fd81:fc56:9ac7::/48
```

`salt.modules.ipset.version()`

Return version from `ipset --version`

CLI Example:

```bash
custom_set
salt '*' ipset.version
```

## 31.16.119 salt.modules.iptables

Support for iptables

`salt.modules.iptables.append`(table='filter', chain=None, rule=None, family='ipv4')

Append a rule to the specified table/chain.

This function accepts a rule in a standard `iptables` command format, starting with the chain. Trying to force users to adapt to a new method of creating rules would be irritating at best, and we already have a parser that can handle it.

CLI Example:
salt '*' iptables.append filter INPUT \
    rule='-m state --state RELATED,ESTABLISHED -j ACCEPT'

IPv6:
salt '*' iptables.append filter INPUT \
    rule='-m state --state RELATED,ESTABLISHED -j ACCEPT' \ 
    family=ipv6

salt.modules.iptables.build_rule(table='filter', chain=None, command=None, position='', full=None, family='ipv4', **kwargs)

Build a well-formatted iptables rule based on kwargs. A table and chain are not required, unless full is True.

If full is True, then table, chain and command are required. command may be specified as either a short option (‘I’) or a long option (‘--insert’). This will return the iptables command, exactly as it would be used from the command line.

If a position is required (as with -I or -D), it may be specified as position. This will only be useful if full is True.

If connstate is passed in, it will automatically be changed to state.

To pass in jump options that doesn’t take arguments, pass in an empty string.

CLI Examples:

salt '*' iptables.build_rule match=state \ 
    connstate=RELATED,ESTABLISHED jump=ACCEPT

salt '*' iptables.build_rule filter INPUT command=I position=3 \ 
    full=True match=state state=RELATED,ESTABLISHED jump=ACCEPT

salt '*' iptables.build_rule filter INPUT command=A \ 
    full=True match=state state=RELATED,ESTABLISHED \ 
    source='127.0.0.1' jump=ACCEPT

.. Invert Rules
salt '*' iptables.build_rule filter INPUT command=A \ 
    full=True match=state state=RELATED,ESTABLISHED \ 
    source='! 127.0.0.1' jump=ACCEPT

salt '*' iptables.build_rule filter INPUT command=A \ 
    full=True match=state state=RELATED,ESTABLISHED \ 
    destination='not 127.0.0.1' jump=ACCEPT

IPv6:
salt '*' iptables.build_rule match=state \ 
    connstate=RELATED,ESTABLISHED jump=ACCEPT \ 
    family=ipv6
salt '*' iptables.build_rule filter INPUT command=I position=3 \ 
    full=True match=state state=RELATED,ESTABLISHED jump=ACCEPT \ 
    family=ipv6

salt.modules.iptables.check(table='filter', chain=None, rule=None, family='ipv4')

Check for the existence of a rule in the table and chain.

This function accepts a rule in a standard iptables command format, starting with the chain. Trying to force users to adapt to a new method of creating rules would be irritating at best, and we already have a parser that can handle it.

CLI Example:
salt '***' iptables.check filter INPUT
  rule='*m state --state RELATED,ESTABLISHED -j ACCEPT'

IPv6:
salt '***' iptables.check filter INPUT
  rule='*m state --state RELATED,ESTABLISHED -j ACCEPT'
  family=ipv6

salt.modules.iptables.check_chain(table='filter', chain=None, family='ipv4')
  New in version 2014.1.0.
  Check for the existence of a chain in the table
  CLI Example:

  salt '***' iptables.check_chain filter INPUT
  IPv6:
salt '***' iptables.check_chain filter INPUT family=ipv6

salt.modules.iptables.delete(table=chain=None, position=None, rule=None, family=ipv4)
  Delete a rule from the specified table/chain, specifying either the rule in its entirety, or the rule's position in the chain.
  This function accepts a rule in a standard iptables command format, starting with the chain. Trying to force users to adapt to a new method of creating rules would be irritating at best, and we already have a parser that can handle it.
  CLI Examples:

  salt '***' iptables.delete filter INPUT position=3
  salt '***' iptables.delete filter INPUT
  rule='*m state --state RELATED,ESTABLISHED -j ACCEPT'
  IPv6:
salt '***' iptables.delete filter INPUT position=3 family=ipv6
  salt '***' iptables.delete filter INPUT
  rule='*m state --state RELATED,ESTABLISHED -j ACCEPT'
  family=ipv6

salt.modules.iptables.delete_chain(table='filter', chain=None, family='ipv4')
  New in version 2014.1.0.
  Delete custom chain to the specified table.
  CLI Example:

  salt '***' iptables.delete_chain filter CUSTOM_CHAIN
  IPv6:
salt '***' iptables.delete_chain filter CUSTOM_CHAIN family=ipv6

salt.modules.iptables.flush(table='filter', chain='', family='ipv4')
  Flush the chain in the specified table, flush all chains in the specified table if not specified chain.
  CLI Example:

  salt '***' iptables.flush filter INPUT
### IPv6

```
salt '*' iptables.flush filter INPUT family=ipv6
```

#### `salt.modules.iptables.get_policy(table='filter', chain=None, family='ipv4')`

Return the current policy for the specified table/chain

CLI Example:

```
salt '*' iptables.get_policy filter INPUT
```

#### `salt.modules.iptables.get_saved_policy(table='filter', chain=None, conf_file=None, family='ipv4')`

Return the current policy for the specified table/chain

CLI Examples:

```
salt '*' iptables.get_saved_policy filter INPUT
salt '*' iptables.get_saved_policy filter INPUT /etc/iptables.saved
IPv6:
salt '*' iptables.get_saved_policy filter INPUT family=ipv6
salt '*' iptables.get_saved_policy filter INPUT /etc/iptables.saved family=ipv6
```

#### `salt.modules.iptables.get_rules(family='ipv4')`

Return a data structure of the current, in-memory rules

CLI Example:

```
salt '*' iptables.get_rules
```

IPv6:

```
salt '*' iptables.get_rules family=ipv6
```

#### `salt.modules.iptables.insert(table='filter', chain=None, position=None, rule=None, family='ipv4')`

Insert a rule into the specified table/chain, at the specified position.

This function accepts a rule in a standard `iptables` command format, starting with the chain. Trying to force users to adapt to a new method of creating rules would be irritating at best, and we already have a parser that can handle it.

If the position specified is a negative number, then the insert will be performed counting from the end of the list. For instance, a position of -1 will insert the rule as the second to last rule. To insert a rule in the last position, use the append function instead.

CLI Examples:
salt '.*' iptables.insert filter INPUT position=3  \
   rules='^-m state --state RELATED,ESTABLISHED -j ACCEPT'

IPv6:
salt '.*' iptables.insert filter INPUT position=3  \r
   rules='^-m state --state RELATED,ESTABLISHED -j ACCEPT'  \
   family=ipv6

salt.modules.iptables.new_chain(\table='filter', chain=None, family='ipv4')

Create new custom chain to the specified table.

CLI Example:

salt '.*' iptables.new_chain filter CUSTOM_CHAIN

IPv6:
salt '.*' iptables.new_chain filter CUSTOM_CHAIN family=ipv6

salt.modules.iptables.save(filename=None, family='ipv4')

Save the current in-memory rules to disk

CLI Example:

salt '.*' iptables.save /etc/sysconfig/iptables

IPv6:
salt '.*' iptables.save /etc/sysconfig/iptables family=ipv6

salt.modules.iptables.set_policy(\table='filter', chain=None, policy=None, family='ipv4')

Set the current policy for the specified table/chain

CLI Example:

salt '.*' iptables.set_policy filter INPUT ACCEPT

IPv6:
salt '.*' iptables.set_policy filter INPUT ACCEPT family=ipv6

salt.modules.iptables.version(family='ipv4')

Return version from iptables --version

CLI Example:

salt '.*' iptables.version

IPv6:
salt '.*' iptables.version family=ipv6

31.16.120 salt.modules.jboss7

Module for managing JBoss AS 7 through the CLI interface.

New in version 2015.5.0.

In order to run each function, jboss_config dictionary with the following properties must be passed:

- cli_path: the path to jboss-cli script, for example: `/opt/jboss/jboss-7.0/bin/jboss-cli.sh`
- controller: the ip address and port of controller, for example: 10.11.12.13:9999
- cli_user: username to connect to jboss administration console if necessary
- cli_password: password to connect to jboss administration console if necessary

Example:

```plaintext
jboss_config:
  cli_path: '/opt/jboss/jboss-7.0/bin/jboss-cli.sh'
  controller: 10.11.12.13:9999
  cli_user: 'jbossadm'
  cli_password: 'jbossadm'

salt.modules.jboss7.create_datasource(jboss_config, name, datasource_properties)
Create datasource in running jboss instance

jboss_config Configuration dictionary with properties specified above.
name Datasource name
datasource_properties
A dictionary of datasource properties to be created:
  - driver-name: mysql
  - connection-url: 'jdbc:mysql://localhost:3306/sampleDatabase'
  - jndi-name: 'java:jboss/datasources/sampleDS'
  - user-name: sampleuser
  - password: secret
  - min-pool-size: 3
  - use-java-context: True

CLI Example:

salt.modules.jboss7.create_simple_binding(jboss_config, binding_name, value)
Create a simple jndi binding in the running jboss instance

jboss_config Configuration dictionary with properties specified above.
binding_name Binding name to be created
value Binding value

CLI Example:
salt '*' jboss7.create_simple_binding \ 
  '{"cli_path": "integration.modules.sysmod.SysModuleTest.test_valid_docs", \ 
  "controller": "10.11.12.13:9999", "cli_user": "jbossadm", "cli_password": "jbossadm"}' \ 
  my_binding_name my_binding_value

salt.modules.jboss7.deploy(jboss_config, source_file)
Deploy the application on the jboss instance from the local file system where minion is running.

jboss_config Configuration dictionary with properties specified above.
source_file Source file to deploy from

CLI Example:
Salt Documentation, Release 2015.8.0

salt.modules.jboss7.list_deployments(jboss_config)
List all deployments on the jboss instance

jboss_config
Configuration dictionary with properties specified above.

CLI Example:

salt.modules.jboss7.read_datasource(jboss_config, name)
Read datasource properties in the running jboss instance.

jboss_config  Configuration dictionary with properties specified above.
name  Datasource name

CLI Example:
salt '*' jboss7.read_datasource '{"cli_path": "integration.modules.sysmod.SysModuleTest.test_valid_docs", "controller": "10.11.12.13:9999", "cli_user": "jbossadm", "cli_password": "jbossadm"}', my_binding_name

salt.modules.jboss7.read_simple_binding(jboss_config, binding_name)
Read jndi binding in the running jboss instance

jboss_config  Configuration dictionary with properties specified above.
binding_name  Binding name to be created

CLI Example:
salt '*' jboss7.read_simple_binding '{\"cli_path": \"integration.modules.sysmod.SysModuleTest.test_valid_docs\", \"controller": \"10.11.12.13:9999\", \"cli_user": \"jbossadm\", \"cli_password": \"jbossadm\"}', my_binding_name

salt.modules.jboss7.reload(jboss_config)
Reload running jboss instance

jboss_config  Configuration dictionary with properties specified above.

CLI Example:

salt.modules.jboss7.remove_datasource(jboss_config, name)
Remove an existing datasource from the running jboss instance.

jboss_config  Configuration dictionary with properties specified above.
name  Datasource name

CLI Example:
salt '*' jboss7.remove_datasource '{"cli_path": "integration.modules.sysmod.SysModuleTest.test_valid_docs", "controller": "10.11.12.13:9999", "cli_user": "jbossadm", "cli_password": "jbossadm"}', my_datasource_name

salt.modules.jboss7.status(jboss_config)
Get status of running jboss instance.

jboss_config  Configuration dictionary with properties specified above.

CLI Example:

salt.modules.jboss7.stop_server(jboss_config)
Stop running jboss instance

  jboss_config  Configuration dictionary with properties specified above.

  CLI Example:

salt.modules.jboss7.undeploy(jboss_config, deployment)
Undeploy the application from jboss instance

  jboss_config  Configuration dictionary with properties specified above.

  deployment  Deployment name to undeploy

  CLI Example:

salt.modules.jboss7.update_datasource(jboss_config, name, new_properties)
Update an existing datasource in running jboss instance. If the property doesn't exist if will be created, if it does, it will be updated with the new value

  jboss_config  Configuration dictionary with properties specified above.

  name  Datasource name

  new_properties

    A dictionary of datasource properties to be updated. For example:

    - driver-name: mysql
    - connection-url: 'jdbc:mysql://localhost:3306/sampleDatabase'
    - jndi-name: 'java:jboss/datasources/sampleDS'
    - user-name: sampleuser
    - password: secret
    - min-pool-size: 3
    - use-java-context: True

  CLI Example:

salt.modules.jboss7.update_simple_binding(jboss_config, binding_name, value)
Update the simple jndi binding in the running jboss instance

  jboss_config  Configuration dictionary with properties specified above.

  binding_name  Binding name to be updated

  value  New binding value

  CLI Example:
salt '*' jboss7.update_simple_binding '{"cli_path": "integration.modules.sysmod.SysModuleTest.test_valid_docs", "controller": "10.11.12.13:9999", "cli_user": "jbossadm", "cli_password": "jbossadm"}' 'my_binding_name my_binding_value'
31.16.121  salt.modules.jboss7_cli

Module for low-level interaction with JbossAS7 through CLI.
This module exposes two ways of interaction with the CLI, either through commands or operations.

Note: Following JBoss documentation (https://developer.jboss.org/wiki/CommandLineInterface): `Operations are considered a low level but comprehensive way to manage the AS controller, i.e. if it can't be done with operations it can't be done in any other way. Commands, on the other hand, are more user-friendly in syntax, although most of them still translate into operation requests and some of them even into a few composite operation requests, i.e. commands also simplify some management operations from the user's point of view.``

The difference between calling a command or operation is in handling the result. Commands return a zero return code if operation is successful or return non-zero return code and print an error to standard output in plain text, in case of an error.

Operations return a json-like structure, that contain more information about the result. In case of a failure, they also return a specific return code. This module parses the output from the operations and returns it as a dictionary so that an execution of an operation can then be verified against specific errors.

In order to run each function, jboss_config dictionary with the following properties must be passed:

- cli_path: the path to jboss-cli script, for example: `/opt/jboss/jboss-7.0/bin/jboss-cli.sh`
- controller: the ip address and port of controller, for example: 10.11.12.13:9999
- cli_user: username to connect to jboss administration console if necessary
- cli_password: password to connect to jboss administration console if necessary

Example:

```
jboss_config:
    cli_path: '/opt/jboss/jboss-7.0/bin/jboss-cli.sh'
    controller: 10.11.12.13:9999
    cli_user: 'jbossadm'
    cli_password: 'jbossadm'
```

salt.modules.jboss7_cli.run_command(jboss_config, command, fail_on_error=True)
Execute a command against jboss instance through the CLI interface.

- jboss_config Configuration dictionary with properties specified above.
- command Command to execute against jboss instance
- fail_on_error (default=True) Is true, raise CommandExecutionException exception if execution fails. If false, `success` property of the returned dictionary is set to False

CLI Example:
```
```

salt.modules.jboss7_cli.run_operation(jboss_config, operation, fail_on_error=True, retries=1)
Execute an operation against jboss instance through the CLI interface.

- jboss_config Configuration dictionary with properties specified above.
- operation An operation to execute against jboss instance
- fail_on_error (default=True) Is true, raise CommandExecutionException exception if execution fails. If false, `success` property of the returned dictionary is set to False
- retries: Number of retries in case of ```JBAS012144: Could not connect to remote``` error.
31.16.122  **salt.modules.junos**

Module for interfacing to Junos devices

ALPHA QUALITY code.

- `salt.modules.junos.call_rpc()`
- `salt.modules.junos.commit()`
- `salt.modules.junos.diff()`
- `salt.modules.junos.facts_refresh()`  
  Reload the facts dictionary from the device. Usually only needed if the device configuration is changed by some other actor.
- `salt.modules.junos.ping()`
- `salt.modules.junos.rollback()`
- `salt.modules.junos.set_hostname(hostname=None, commit_change=True)`

31.16.123  **salt.modules.kerberos**

Manage Kerberos KDC

**configuration** In order to manage your KDC you will need to generate a keytab that can authenticate without requiring a password.

```bash
# ktadd -k /root/secure.keytab kadmin/admin kadmin/changepw
```

On the KDC minion you will need to add the following to the minion configuration file so Salt knows what keytab to use and what principal to authenticate as.

- `auth_keytab: /root/auth.keytab`
- `auth_principal: kadmin/admin`

- `salt.modules.kerberos.create_keytab(name, keytab, enctypes=None)`  
  Create keytab
  
  CLI Example:

  ```
salt 'kdc.example.com' host/host1.example.com host1.example.com.keytab
  ```

- `salt.modules.kerberos.create_principal(name, enctypes=None)`  
  Create Principal
  
  CLI Example:

  ```
salt 'kdc.example.com' kerberos.create_principal host/example.com
  ```

- `salt.modules.kerberos.delete_principal(name)`  
  Delete Principal
  
  CLI Example:
salt.modules.kerberos.get_policy(name)
Get policy details

CLI Example:
salt 'kdc.example.com' kerberos.get_policy my_policy

salt.modules.kerberos.get_principal(name)
Get principal details

CLI Example:
salt 'kdc.example.com' kerberos.get_principal root/admin

salt.modules.kerberos.get_privs()
Current privileges

CLI Example:
salt 'kdc.example.com' kerberos.get_privs

salt.modules.kerberos.list_policies()
List policies

CLI Example:
salt 'kdc.example.com' kerberos.list_policies

salt.modules.kerberos.list_principals()
Get all principals

CLI Example:
salt 'kdc.example.com' kerberos.list_principals

31.16.124 salt.modules.key

Functions to view the minion’s public key information

salt.modules.key.finger()
Return the minion’s public key fingerprint

CLI Example:
salt '*' key.finger

salt.modules.key.finger_master()
Return the fingerprint of the master’s public key on the minion.

CLI Example:
salt '*' key.finger_master

31.16.125 salt.modules.keyboard

Module for managing keyboards on supported POSIX-like systems using systemd, or such as Redhat, Debian and Gentoo.
salt.modules.keyboard.get_sys()  
Get current system keyboard setting

CLI Example:
```
salt '*' keyboard.get_sys
```

salt.modules.keyboard.get_x()  
Get current X keyboard setting

CLI Example:
```
salt '*' keyboard.get_x
```

salt.modules.keyboard.set_sys(layout)  
Set current system keyboard setting

CLI Example:
```
salt '*' keyboard.set_sys dvorak
```

salt.modules.keyboard.set_x(layout)  
Set current X keyboard setting

CLI Example:
```
salt '*' keyboard.set_x dvorak
```

### 31.16.126 salt.modules.keystone

Module for handling openstack keystone calls.

**optdepends**

- keystoneclient Python adapter

**configuration** This module is not usable until the following are specified either in a pillar or in the minion's config file:

```
keystone.user: admin  
keystone.password: verybadpass  
keystone.tenant: admin  
keystone.tenant_id: f80919baedab48ec8931f200c65a50df  
keystone.auth_url: 'http://127.0.0.1:5000/v2.0/
```

OR (for token based authentication)

```
keystone.token: 'ADMIN'  
keystone.endpoint: 'http://127.0.0.1:35357/v2.0'
```

If configuration for multiple openstack accounts is required, they can be set up as different configuration profiles. For example:

```python
openstack1:  
    keystone.user: admin  
    keystone.password: verybadpass  
    keystone.tenant: admin  
    keystone.tenant_id: f80919baedab48ec8931f200c65a50df  
    keystone.auth_url: 'http://127.0.0.1:5000/v2.0/
```
openstack2:
  
  - `keystone.user`: admin
  - `keystone.password`: verybadpass
  - `keystone.tenant`: admin
  - `keystone.tenant_id`: f80919baedab48ec8931f200c65a50df
  - `keystone.auth_url`: 'http://127.0.0.2:5000/v2.0/

With this configuration in place, any of the `keystone` functions can make use of a configuration profile by declaring it explicitly. For example:

```
salt '*' keystone.tenant_list profile=openstack1
```

**salt.modules.keystone.auth**

```
salt.modules.keystone.auth(profile=None, **connection_args)
```

Set up `keystone` credentials. Only intended to be used within Keystone-enabled modules.

**CLI Example:**

```
salt '*' keystone.auth
```

**salt.modules.keystone.ec2_credentials_create**

```
salt.modules.keystone.ec2_credentials_create(user_id=None, name=None, tenant_id=None, tenant=None, profile=None, **connection_args)
```

Create `EC2`-compatible credentials for user per tenant

**CLI Examples:**

```
salt '*' keystone.ec2_credentials_create name=admin tenant=admin
salt '*' keystone.ec2_credentials_create user_id=c965f79c4f864eaa9c3b41904e67082 tenant_id=722787eb540b4915868370dc627ec5f
```

**salt.modules.keystone.ec2_credentials_delete**

```
salt.modules.keystone.ec2_credentials_delete(user_id=None, name=None, access_key=None, profile=None, **connection_args)
```

Delete `EC2`-compatible credentials

**CLI Examples:**

```
salt '*' keystone.ec2_credentials_delete 860f8c2c38ca4fab989f9bc56a061a64 access_key=5f66d2f24f6b8b9cd28886106f442
salt '*' keystone.ec2_credentials_delete name=admin access_key=5f66d2f24f6b8b9cd28886106f442
```

**salt.modules.keystone.ec2_credentials_get**

```
salt.modules.keystone.ec2_credentials_get(user_id=None, name=None, access=None, profile=None, **connection_args)
```

Return `ec2` credentials for a user (keystone ec2-credentials-get)

**CLI Examples:**

```
salt '*' keystone.ec2_credentials_get c965f79c4f864eaa9c3b41904e67082 access=722787eb540b4915868370dc627ec5f
salt '*' keystone.ec2_credentials_get user_id=c965f79c4f864eaa9c3b41904e67082 access=722787eb540b4915868370dc627ec5f
salt '*' keystone.ec2_credentials_get name=nova access=722787eb540b4915868370dc627ec5f
```

**salt.modules.keystone.ec2_credentials_list**

```
salt.modules.keystone.ec2_credentials_list(user_id=None, name=None, profile=None, **connection_args)
```

Return a list of `ec2` credentials for a specific user (keystone ec2-credentials-list)

**CLI Examples:**

```
salt '*' keystone.ec2_credentials_list 298ce377245c4ec9b70e1c639c89e654
salt '*' keystone.ec2_credentials_list user_id=298ce377245c4ec9b70e1c639c89e654
salt '*' keystone.ec2_credentials_list name=jack
```
salt.modules.keystone.endpoint_create(service, publicurl=None, internalurl=None, adminurl=None, region=None, profile=None, **connection_args)

Create an endpoint for an Openstack service

CLI Examples:

```
salt '*' keystone.endpoint_create nova 'http://public/url' 'http://internal/url' 'http://adminurl/url' region
```

salt.modules.keystone.endpoint_delete(service, profile=None, **connection_args)

Delete endpoints of an Openstack service

CLI Examples:

```
salt '*' keystone.endpoint_delete nova
```

salt.modules.keystone.endpoint_get(service, profile=None, **connection_args)

Return a specific endpoint (keystone endpoint-get)

CLI Example:

```
salt '*' keystone.endpoint_get nova
```

salt.modules.keystone.endpoint_list(profile=None, **connection_args)

Return a list of available endpoints (keystone endpoints-list)

CLI Example:

```
salt '*' keystone.endpoint_list
```

salt.modules.keystone.role_create(name, profile=None, **connection_args)

Create a named role.

CLI Example:

```
salt '*' keystone.role_create admin
```

salt.modules.keystone.role_delete(role_id=None, name=None, profile=None, **connection_args)

Delete a role (keystone role-delete)

CLI Examples:

```
salt '*' keystone.role_delete c965f79c4f864eaa9c3b41904e67082
salt '*' keystone.role_delete role_id=c965f79c4f864eaa9c3b41904e67082
salt '*' keystone.role_delete name=admin
```

salt.modules.keystone.role_get(role_id=None, name=None, profile=None, **connection_args)

Return a specific roles (keystone role-get)

CLI Examples:

```
salt '*' keystone.role_get c965f79c4f864eaa9c3b41904e67082
salt '*' keystone.role_get role_id=c965f79c4f864eaa9c3b41904e67082
salt '*' keystone.role_get name=admin
```

salt.modules.keystone.role_list(profile=None, **connection_args)

Return a list of available roles (keystone role-list)

CLI Example:
salt '*' keystone.role_list

salt.modules.keystone.service_create(name, service_type, description=None, profile=None, **connection_args)

Add service to Keystone service catalog

CLI Examples:

salt '*' keystone.service_create nova compute 'OpenStack Compute Service'

salt.modules.keystone.service_delete(service_id=None, name=None, profile=None, **connection_args)

Delete a service from Keystone service catalog

CLI Examples:

salt '*' keystone.service_delete c965f79c4f864eaa9c3b41904e67082
salt '*' keystone.service_delete name=nova

salt.modules.keystone.service_get(service_id=None, name=None, profile=None, **connection_args)

Return a specific services (keystone service-get)

CLI Examples:

salt '*' keystone.service_get c965f79c4f864eaa9c3b41904e67082
salt '*' keystone.service_get service_id=c965f79c4f864eaa9c3b41904e67082
salt '*' keystone.service_get name=nova

salt.modules.keystone.service_list(profile=None, **connection_args)

Return a list of available services (keystone services-list)

CLI Example:

salt '*' keystone.service_list

salt.modules.keystone.tenant_create(name, description=None, enabled=True, profile=None, **connection_args)

Create a keystone tenant

CLI Examples:

salt '*' keystone.tenant_create nova description='nova tenant'
salt '*' keystone.tenant_create test enabled=False

salt.modules.keystone.tenant_delete(tenant_id=None, name=None, profile=None, **connection_args)

Delete a tenant (keystone tenant-delete)

CLI Examples:

salt '*' keystone.tenant_delete c965f79c4f864eaa9c3b41904e67082
salt '*' keystone.tenant_delete tenant_id=c965f79c4f864eaa9c3b41904e67082
salt '*' keystone.tenant_delete name=demo

salt.modules.keystone.tenant_get(tenant_id=None, name=None, profile=None, **connection_args)

Return a specific tenants (keystone tenant-get)

CLI Examples:
salt '***' keystone.tenant_get c965f79c4f864eaaa9c3b41904e67082
salt '***' keystone.tenant_get tenant_id=c965f79c4f864eaaa9c3b41904e67082
salt '***' keystone.tenant_get name=nova

salt.modules.keystone.tenant_list(profile=None, **connection_args)
   Return a list of available tenants (keystone tenants-list)
   CLI Example:
   salt '***' keystone.tenant_list

salt.modules.keystone.tenant_update(tenant_id=None, name=None, description=None,
   enabled=None, profile=None, **connection_args)
   Update a tenant's information (keystone tenant-update) The following fields may be updated: name, email, enabled. Can only update name if targeting by ID
   CLI Examples:
   salt '***' keystone.tenant_update name=admin enabled=True
   salt '***' keystone.tenant_update c965f79c4f864eaaa9c3b41904e67082 name=admin email=admin@domain.com

salt.modules.keystone.token_get(profile=None, **connection_args)
   Return the configured tokens (keystone token-get)
   CLI Example:
   salt '***' keystone.token_get c965f79c4f864eaaa9c3b41904e67082

salt.modules.keystone.user_create(name, password, email, tenant_id=None,
   enabled=True, profile=None, **connection_args)
   Create a user (keystone user-create)
   CLI Examples:
   salt '***' keystone.user_create name=jack password=zero email=jack@halloweentown.org tenant_id=a28

salt.modules.keystone.user_delete(user_id=None, name=None, profile=None, **connection_args)
   Delete a user (keystone user-delete)
   CLI Examples:
   salt '***' keystone.user_delete c965f79c4f864eaaa9c3b41904e67082
   salt '***' keystone.user_delete user_id=c965f79c4f864eaaa9c3b41904e67082
   salt '***' keystone.user_delete name=nova

salt.modules.keystone.user_get(user_id=None, name=None, profile=None, **connection_args)
   Return a specific users (keystone user-get)
   CLI Examples:
   salt '***' keystone.user_get c965f79c4f864eaaa9c3b41904e67082
   salt '***' keystone.user_get user_id=c965f79c4f864eaaa9c3b41904e67082
   salt '***' keystone.user_get name=nova

salt.modules.keystone.user_list(profile=None, **connection_args)
   Return a list of available users (keystone user-list)
   CLI Example:
salt 'salt' user_list

```
salt.modules.keystone.user_password_update (user_id=None, name=None, password=None, profile=None, **connection_args)
Update a user's password (keystone user-password-update)
CLI Examples:
salt '*' keystone.user_password_update user_id=c965f79c4f864eaaa9c3b41904e67082 password=12345
salt '*' keystone.user_password_update name=nova password=12345
```

```
salt.modules.keystone.user_role_add (user_id=None, user=None, tenant_id=None, tenant=None, role_id=None, role=None, profile=None, **connection_args)
Add role for user in tenant (keystone user-role-add)
CLI Examples:
salt '*' keystone.user_role_add user_id=298ce377245c4ecb70e1c639c89e654 tenant_id=7167a092e8ce46b9 role_id=ce3772d45c4ecb70e1c639e8ca6e9cead4
salt '*' keystone.user_role_add user=admin tenant=admin role=admin
```

```
salt.modules.keystone.user_role_list (user_id=None, tenant_id=None, user_name=None, tenant_name=None, profile=None, **connection_args)
Return a list of available user_roles (keystone user-roles-list)
CLI Examples:
salt '*' keystone.user_role_list user_id=298ce377245c4ecb70e1c639c89e654 tenant_id=7167a092e8ce46b9
salt '*' keystone.user_role_list user_name=admin tenant_name=admin
```

```
salt.modules.keystone.user_role_remove (user_id=None, user=None, tenant_id=None, tenant=None, role_id=None, role=None, profile=None, **connection_args)
Remove role for user in tenant (keystone user-role-remove)
CLI Examples:
salt '*' keystone.user_role_remove user_id=298ce377245c4ecb70e1c639c89e654 tenant_id=7167a092e8ce46b9 role_id=ce3772d45c4ecb70e1c639e8ca6e9cead4
salt '*' keystone.user_role_remove user=admin tenant=admin role=admin
```

```
salt.modules.keystone.user_update (user_id=None, name=None, email=None, enabled=None, tenant=None, profile=None, **connection_args)
Update a user's information (keystone user-update) The following fields may be updated: name, email, enabled, tenant. Because the name is one of the fields, a valid user id is required.
CLI Examples:
salt '*' keystone.user_update user_id=c965f79c4f864eaaa9c3b41904e67082 name=newname
salt '*' keystone.user_update c965f79c4f864eaaa9c3b41904e67082 name=newname email=newemail@domain.com
```

```
salt.modules.keystone.user_verify_password (user_id=None, name=None, password=None, profile=None, **connection_args)
Verify a user's password
CLI Examples:
salt '*' keystone.user_verify_password name=test password=foobar
salt '*' keystone.user_verify_password user_id=c965f79c4f864eaaa9c3b41904e67082 password=foobar
```

31.16. Full list of builtin execution modules
31.16.127 salt.modules.kmod

Module to manage Linux kernel modules

salt.modules.kmod.available()
    Return a list of all available kernel modules
    CLI Example:
    salt '*' kmod.available

salt.modules.kmod.check_available(mod)
    Check to see if the specified kernel module is available
    CLI Example:
    salt '*' kmod.check_available kvm

salt.modules.kmod.is_loaded(mod)
    Check to see if the specified kernel module is loaded
    CLI Example:
    salt '*' kmod.is_loaded kvm

salt.modules.kmod.load(mod, persist=False)
    Load the specified kernel module
    mod  Name of module to add
    persist  Write module to /etc/modules to make it load on system reboot
    CLI Example:
    salt '*' kmod.load kvm

salt.modules.kmod.lsmod()
    Return a dict containing information about currently loaded modules
    CLI Example:
    salt '*' kmod.lsmod

salt.modules.kmod.mod_list(only_persist=False)
    Return a list of the loaded module names
    CLI Example:
    salt '*' kmod.mod_list

salt.modules.kmod.remove(mod, persist=False, comment=True)
    Remove the specified kernel module
    mod  Name of module to remove
    persist  Also remove module from /etc/modules
    comment  If persist is set don’t remove line from /etc/modules but only comment it
    CLI Example:
    salt '*' kmod.remove kvm
31.16.128 salt.modules.launchctl

Module for the management of MacOS systems that use launchd/launchctl

depends
- plistlib Python module

salt.modules.launchctl.available(job_label)
Check that the given service is available.

CLI Example:
```
salt '*' service.available com.openssh.sshd
```

salt.modules.launchctl.get_all()
Return all installed services

CLI Example:
```
salt '*' service.get_all
```

salt.modules.launchctl.missing(job_label)
The inverse of service.available Check that the given service is not available.

CLI Example:
```
salt '*' service.missing com.openssh.sshd
```

salt.modules.launchctl.restart(job_label, runas=None)
Restart the named service

CLI Example:
```
salt '*' service.restart <service label>
```

salt.modules.launchctl.start(job_label, runas=None)
Start the specified service

CLI Example:
```
salt '*' service.start <service label>
salt '*' service.start org.ntp.ntpd
salt '*' service.start /System/Library/LaunchDaemons/org.ntp.ntpd.plist
```

salt.modules.launchctl.status(job_label, runas=None)
Return the status for a service, returns a bool whether the service is running.

CLI Example:
```
salt '*' service.status <service label>
```

salt.modules.launchctl.stop(job_label, runas=None)
Stop the specified service

CLI Example:
```
salt '*' service.stop <service label>
salt '*' service.stop org.ntp.ntpd
salt '*' service.stop /System/Library/LaunchDaemons/org.ntp.ntpd.plist
```
31.16.129 salt.modules.layman

Support for Layman

salt.modules.layman.add(overlay)
Add the given overlay from the cached remote list to your locally installed overlays. Specify 'ALL' to add all overlays from the remote list.

Return a list of the new overlay(s) added:

CLI Example:

    salt '*' layman.add <overlay name>

salt.modules.layman.delete(overlay)
Remove the given overlay from your locally installed overlays. Specify 'ALL' to remove all overlays.

Return a list of the overlays(s) that were removed:

CLI Example:

    salt '*' layman.delete <overlay name>

salt.modules.layman.list_all()
List all overlays, including remote ones.

Return a list of available overlays:

CLI Example:

    salt '*' layman.list_all

salt.modules.layman.list_local()
List the locally installed overlays.

Return a list of installed overlays:

CLI Example:

    salt '*' layman.list_local

salt.modules.layman.sync(overlay='ALL')
Update the specified overlay. Use 'ALL' to synchronize all overlays. This is the default if no overlay is specified.

overlay Name of the overlay to sync. (Defaults to 'ALL')

CLI Example:

    salt '*' layman.sync

31.16.130 salt.modules.ldapmod

Salt interface to LDAP commands

depends

- ldap Python module

configuration In order to connect to LDAP, certain configuration is required in the minion config on the LDAP server. The minimum configuration items that must be set are:
ldap.basedn: dc=acme,dc=com (example values, adjust to suit)

If your LDAP server requires authentication then you must also set:

- ldap.anonymous: False
- ldap.binddn: admin
- ldap.bindpw: password

In addition, the following optional values may be set:

- ldap.server: localhost (default=localhost, see warning below)
- ldap.port: 389 (default=389, standard port)
- ldap.tls: False (default=False, no TLS)
- ldap.no_verify: False (default=False, verify TLS)
- ldap.anonymous: True (default=True, bind anonymous)
- ldap.scope: 2 (default=2, ldap.SCOPE_SUBTREE)
- ldap.attrs: [saltAttr] (default=None, return all attributes)

**Warning:** At the moment this module only recommends connection to LDAP services listening on localhost. This is deliberate to avoid the potentially dangerous situation of multiple minions sending identical update commands to the same LDAP server. It's easy enough to override this behavior, but badness may ensue - you have been warned.

```
salt.modules.ldapmod.search(filter, dn=None, scope=None, attrs=None, **kwargs)
```

Run an arbitrary LDAP query and return the results.

CLI Example:
```
salt 'ldaphost' ldap.search "filter=cn=myhost"
```

Return data:
```
{'myhost': {'count': 1,
            'results': [[[cn=myhost, ou=hosts, o=acme, c=gb],
                         {'saltKeyVal': ['ntpserver=ntp.acme.local',
                                         'foo=foo'],
                          'saltState': ['foo', 'bar']]),
            'time': {'human': '1.2ms', 'raw': '0.00123'}}}
```

Search and connection options can be overridden by specifying the relevant option as key=value pairs, for example:
```
salt 'ldaphost' ldap.search filter=cn=myhost dn=ou=hosts, o=acme, c=gb scope=1 attrs='' server='localhost' port='3793' tls=True bindpw='ssh'
```

31.16.131 salt.modules.linux_acl

Support for Linux File Access Control Lists

```
salt.modules.linux_acl.delfacl(acl_type, acl_name='', *args, **kwargs)
```

Remove specific FACL from the specified file(s)

CLI Examples:
```
salt '*' acl.delfacl user myuser /tmp/house/kitchen
salt '*' acl.delfacl default:group mygroup /tmp/house/kitchen
salt '*' acl.delfacl d:u myuser /tmp/house/kitchen
```
salt 'acl.delfacl g myuser /tmp/house/kitchen /tmp/house/livingroom
salt 'acl.delfacl user myuser /tmp/house/kitchen recursive=True

salt.modules.linux_acl.getfacl(*args, **kwargs)
    Return (extremely verbose) map of FACLS on specified file(s)

    CLI Examples:
    salt 'acl.getfacl /tmp/house/kitchen
    salt 'acl.getfacl /tmp/house/kitchen /tmp/house/livingroom
    salt 'acl.getfacl /tmp/house/kitchen /tmp/house/livingroom recursive=True

salt.modules.linux_acl.modfacl(acl_type, acl_name='`, perms='`, *args, **kwargs)
    Add or modify a FACL for the specified file(s)

    CLI Examples:
    salt 'acl.modfacl user myuser rwx /tmp/house/kitchen
    salt 'acl.modfacl default:group mygroup rx /tmp/house/kitchen
    salt 'acl.modfacl d:u myuser 7 /tmp/house/kitchen
    salt 'acl.modfacl g mygroup 0 /tmp/house/kitchen /tmp/house/livingroom
    salt 'acl.modfacl user myuser rwx /tmp/house/kitchen recursive=True

salt.modules.linux_acl.version()
    Return facl version from getfacl --version

    CLI Example:
    salt 'acl.version

salt.modules.linux_acl.wipefacls(*args, **kwargs)
    Remove all FACLS from the specified file(s)

    CLI Examples:
    salt 'acl.wipefacls /tmp/house/kitchen
    salt 'acl.wipefacls /tmp/house/kitchen /tmp/house/livingroom
    salt 'acl.wipefacls /tmp/house/kitchen /tmp/house/livingroom recursive=True

31.16.132 salt.modules.linux_lvm

Support for Linux LVM2

salt.modules.linux_lvm.fullversion()
    Return all version info from lvm version

    CLI Example:
    salt 'lvm.fullversion

salt.modules.linux_lvm.lvcreate(lvname, vgname, size=None, extents=None, snapshot=None, pv=None, **kwargs)
    Create a new logical volume, with option for which physical volume to be used

    CLI Examples:
    salt 'lvm.lvcreate new_volume_name vg_name size=10G
    salt 'lvm.lvcreate new_volume_name vg_name extents=100 pv=/dev/sdb
    salt 'lvm.lvcreate new_snapshot vg_name snapshot=volume_name size=36
salt.modules.linux_lvm.lvdisplay(lvname='')
    Return information about the logical volume(s)
    
    CLI Examples:
    
    salt '*' lvm.lvdisplay
    salt '*' lvm.lvdisplay /dev/vg_myserver/root

salt.modules.linux_lvm.lvremove(lvname, vgname)
    Remove a given existing logical volume from a named existing volume group
    
    CLI Example:
    
    salt '*' lvm.lvremove lvname vgname force=True

salt.modules.linux_lvm.lvresize(size, lvpath)
    Return information about the logical volume(s)
    
    CLI Examples:
    
    salt '*' lvm.lvresize +12M /dev/mapper/vg1-test

salt.modules.linux_lvm.pvcreate(devices, override=True, **kwargs)
    Set a physical device to be used as an LVM physical volume
    
    **override** Skip devices, if they are already an LVM physical volumes
    
    CLI Examples:
    
    salt mymachine lvm.pvcreate /dev/sdb1,/dev/sdb2
    salt mymachine lvm.pvcreate /dev/sdb1 dataalignmentoffset=7s

salt.modules.linux_lvm.pvdisplay(pvname='')
    Return information about the physical volume(s)
    
    CLI Examples:
    
    salt '*' lvm.pvdisplay
    salt '*' lvm.pvdisplay /dev/md0

salt.modules.linux_lvm.pvremove(devices, override=True)
    Remove a physical device being used as an LVM physical volume
    
    **override** Skip devices, if they are already not used as an LVM physical volumes
    
    CLI Examples:
    
    salt mymachine lvm.pvremove /dev/sdb1,/dev/sdb2

salt.modules.linux_lvm.version()
    Return LVM version from lvm version
    
    CLI Example:
    
    salt '*' lvm.version

salt.modules.linux_lvm.vgcreate(vgname, devices, **kwargs)
    Create an LVM volume group
    
    CLI Examples:
    
    salt mymachine lvm.vgcreate my_vg /dev/sdb1,/dev/sdb2
    salt mymachine lvm.vgcreate my_vg /dev/sdb1 clustered=y
salt.modules.linux_lvm.vgdisplay(vgname='')
    Return information about the volume group(s)

    CLI Examples:
    salt '*' lvm.vgdisplay
    salt '*' lvm.vgdisplay nova-volumes

salt.modules.linux_lvm.vgextend(vgname, devices)
    Add physical volumes to an LVM volume group

    CLI Examples:
    salt mymachine lvm.vgextend my_vg /dev/sdb1,/dev/sdb2
    salt mymachine lvm.vgextend my_vg /dev/sdb1

salt.modules.linux_lvm.vgremove(vgname)
    Remove an LVM volume group

    CLI Examples:
    salt mymachine lvm.vgremove vgname
    salt mymachine lvm.vgremove vgname force=True

31.16.133 salt.modules.linux_sysctl

Module for viewing and modifying sysctl parameters

salt.modules.linux_sysctl.assign(name, value)
    Assign a single sysctl parameter for this minion

    CLI Example:
    salt '*' sysctl.assign net.ipv4.ip_forward 1

salt.modules.linux_sysctl.default_config()
    Linux hosts using systemd 207 or later ignore /etc/sysctl.conf and only load from
    /etc/sysctl.d/*.conf. This function will do the proper checks and return a default config file which
    will be valid for the Minion. Hosts running systemd >= 207 will use /etc/sysctl.d/99-salt.conf.

    CLI Example:
    salt -G 'kernel:Linux' sysctl.default_config

salt.modules.linux_sysctl.get(name)
    Return a single sysctl parameter for this minion

    CLI Example:
    salt '*' sysctl.get net.ipv4.ip_forward

salt.modules.linux_sysctl.persist(name, value, config=None)
    Assign and persist a simple sysctl parameter for this minion. If config is not specified, a sensible default
    will be chosen using sysctl.default_config.

    CLI Example:
    salt '*' sysctl.persist net.ipv4.ip_forward 1
salt.modules.linux_sysctl.show(config_file=False)
   Return a list of sysctl parameters for this minion
   
   config: Pull the data from the system configuration file instead of the live data.
   
   CLI Example:
   
   ```
   salt '*' sysctl.show
   ```

31.16.134 salt.modules.localemod

Module for managing locales on POSIX-like systems.

salt.modules.localemod.avail(locale)
   Check if a locale is available.
   
   New in version 2014.7.0.
   
   CLI Example:
   
   ```
   salt '*' locale.avail 'en_US.UTF-8'
   ```

salt.modules.localemod.gen_locale(locale, **kwargs)
   Generate a locale. Options:
   
   New in version 2014.7.0.
   
   Parameters locale -- Any locale listed in /usr/share/i18n/locales or /usr/share/i18n/SUPPORTED for Debian and Gentoo based distributions, which require the charmap to be specified as part of the locale when generating it.

   verbose Show extra warnings about errors that are normally ignored.
   
   CLI Example:
   
   ```
   salt '*' locale.gen_locale en_US.UTF-8
   salt '*' locale.gen_locale 'en_IE.UTF-8 UTF-8' # Debian/Gentoo only
   ```

salt.modules.localemod.get_locale()
   Get the current system locale
   
   CLI Example:
   
   ```
   salt '*' locale.get_locale
   ```

salt.modules.localemod.list_avail()
   Lists available (compiled) locales
   
   CLI Example:
   
   ```
   salt '*' locale.list_avail
   ```

salt.modules.localemod.set_locale(locale)
   Sets the current system locale
   
   CLI Example:
   
   ```
   salt '*' locale.set_locale 'en_US.UTF-8'
   ```

31.16. Full list of builtin execution modules
31.16.135 salt.modules.locate

Module for using the locate utilities

salt.modules.locate.locate(pattern, database='`', limit=0, **kwargs)

Performs a file lookup. Valid options (and their defaults) are:

- basename=False
- count=False
- existing=False
- follow=True
- ignore=False
- nofollow=False
- wholename=True
- regex=False
- database=<locate's default database>
- limit=<integer, not set by default>

See the manpage for locate(1) for further explanation of these options.

CLI Example:

```
salt '*' locate.locate
```

salt.modules.locate.stats()

Returns statistics about the locate database

CLI Example:

```
salt '*' locate.stats
```

salt.modules.locate.updatedb()

Updates the locate database

CLI Example:

```
salt '*' locate.updatedb
```

salt.modules.locate.version()

Returns the version of locate

CLI Example:

```
salt '*' locate.version
```

31.16.136 salt.modules.logadm

Module for managing Solaris logadm based log rotations.

salt.modules.logadm.remove(name, conf_file='/etc/logadm.conf')

Remove log pattern from logadm

CLI Example:

```
salt '*' logadm.remove myapplog
```

salt.modules.logadm.rotate(name, pattern=False, count=False, age=False, size=False, copy=True, conf_file='/etc/logadm.conf')

Set up pattern for logging.

CLI Example:
Salt Modules

**logadm**

Logadm is used to rotate log files.

```python
salt '*' logadm.rotate myapplog pattern='*/var/log/myapp/*.log' count=7
```

**show_conf**

Show parsed configuration.

```python
salt.modules.logadm.show_conf(conf_file='/etc/logadm.conf')
```

**CLI Example:**

```bash
salt '*' logadm.show_conf
```

### 31.16.137 salt.modules.logrotate

Module for managing logrotate.

```python
salt.modules.logrotate.set(key, value, setting=None, conf_file='/etc/logrotate.conf')
```

Set a new value for a specific configuration line.

**CLI Example:**

```bash
salt '*' logrotate.set rotate 2
```

Can also be used to set a single value inside a multiline configuration block. For instance, to change rotate in the following block:

```ini
/var/log/wtmp {
    monthly
    create 0664 root root
    rotate 1
}
```

Use the following command:

```bash
salt '*' logrotate.set /var/log/wtmp rotate 2
```

This module also has the ability to scan files inside an include directory, and make changes in the appropriate file.

```python
salt.modules.logrotate.show_conf(conf_file='/etc/logrotate.conf')
```

**CLI Example:**

```bash
salt '*' logrotate.show_conf
```

### 31.16.138 salt.modules.lvs

Support for LVS (Linux Virtual Server)

```python
salt.modules.lvs.add_server(protocol=None, service_address=None, server_address=None, packet_forward_method='dr', weight=1, **kwargs)
```

Add a real server to a virtual service.

**protocol** The service protocol (only support tcp, udp and fwmark service).

**service_address** The LVS service address.

**server_address** The real server address.

**packet_forward_method** The LVS packet forwarding method (dr for direct routing, tunnel for tunneling, nat for network access translation).
weight  The capacity of a server relative to the others in the pool.

CLI Example:

```
salt '*' lvs.add_server tcp 1.1.1.1:80 192.168.0.11:8080 nat 1
```

```
salt.modules.lvs.add_service(protocol=None, service_address=None, scheduler='wlc')
```

Add a virtual service.

```
protocol  The service protocol (only support tcp, udp and fwmark service).
```

```
service_address  The LVS service address.
```

```
scheduler  Algorithm for allocating TCP connections and UDP datagrams to real servers.
```

CLI Example:

```
salt '*' lvs.add_service tcp 1.1.1.1:80 rr
```

```
salt.modules.lvs.check_server(protocol=None, service_address=None, server_address=None, **kwargs)
```

Check the real server exists in the specified service.

CLI Example:

```
salt '*' lvs.check_server tcp 1.1.1.1:80 192.168.0.11:8080
```

```
salt.modules.lvs.check_service(protocol=None, service_address=None, **kwargs)
```

Check the virtual service exists.

CLI Example:

```
salt '*' lvs.check_service tcp 1.1.1.1:80
```

```
salt.modules.lvs.clear()
```

Clear the virtual server table

CLI Example:

```
salt '*' lvs.clear
```

```
salt.modules.lvs.delete_server(protocol=None, service_address=None, server_address=None)
```

Delete the real server from the virtual service.

```
protocol  The service protocol (only support tcp, udp and fwmark service).
```

```
service_address  The LVS service address.
```

```
server_address  The real server address.
```

CLI Example:

```
salt '*' lvs.delete_server tcp 1.1.1.1:80 192.168.0.11:8080
```

```
salt.modules.lvs.delete_service(protocol=None, service_address=None)
```

Delete the virtual service.

```
protocol  The service protocol (only support tcp, udp and fwmark service).
```

```
service_address  The LVS service address.
```

CLI Example:

```
salt '*' lvs.delete_service tcp 1.1.1.1:80
```
salt.modules.lvs.edit_server(protocol=None, service_address=None, server_address=None, packet_forward_method=None, weight=None, **kwargs)

Edit a real server to a virtual service.

- **protocol** The service protocol (only support tcp, udp and fwmark service).
- **service_address** The LVS service address.
- **server_address** The real server address.
- **packet_forward_method** The LVS packet forwarding method (dr for direct routing, tunnel for tunneling, nat for network access translation).
- **weight** The capacity of a server relative to the others in the pool.

CLI Example:
```
salt '*' lvs.edit_server tcp 1.1.1.1:80 192.168.0.11:80080 nat 1
```

salt.modules.lvs.edit_service(protocol=None, service_address=None, scheduler=None)

Edit the virtual service.

- **protocol** The service protocol (only support tcp, udp and fwmark service).
- **service_address** The LVS service address.
- **scheduler** Algorithm for allocating TCP connections and UDP datagrams to real servers.

CLI Example:
```
salt '*' lvs.edit_service tcp 1.1.1.1:80 rr
```

salt.modules.lvs.get_rules()

Get the virtual server rules.

CLI Example:
```
salt '*' lvs.get_rules
```

salt.modules.lvs.list(protocol=None, service_address=None)

List the virtual server table if service_address is not specified. If a service_address is selected, list this service only.

CLI Example:
```
salt '*' lvs.list
```

salt.modules.lvs.zero(protocol=None, service_address=None)

Zero the packet, byte and rate counters in a service or all services.

CLI Example:
```
salt '*' lvs.zero
```

31.16.139 salt.modules.lxc

Control Linux Containers via Salt

- **depends** lxc package for distribution

lxc >= 1.0 (even beta alpha) is required
salt.modules.lxc.apply_network_profile(name, network_profile, nic_opts=None, path=None)

New in version 2015.5.0.

Apply a network profile to a container

network_profile profile name or default values (dict)
nic_opts values to override in defaults (dict) indexed by nic card names

path path to the container parent

New in version 2015.8.0.

CLI Examples:

```
salt 'minion' lxc.apply_network_profile web1 centos
salt 'minion' lxc.apply_network_profile web1 centos \n   nic_opts="{'eth0': {'mac': 'xx:xx:xx:xx:xx:xx'}}"
salt 'minion' lxc.apply_network_profile web1 \n   "{'eth0': {'mac': 'xx:xx:xx:xx:yy'}}" \n   nic_opts="{'eth0': {'mac': 'xx:xx:xx:xx:xx:xx'}}"
```

The special case to disable use of ethernet nics:

```
salt 'minion' lxc.apply_network_profile web1 centos \n   "{eth0: {disable: true}}"
```

salt.modules.lxc.attachable(name, path=None)

Return True if the named container can be attached to via the lxc-attach command

path path to the container parent default: /var/lib/lxc (system default)

New in version 2015.8.0.

CLI Example:

```
salt 'minion' lxc.attachable ubuntu
```

salt.modules.lxc.bootstrap(name, config=None, approve_key=True, install=True, pub_key=None, priv_key=None, bootstrap_url=None, force_install=False, unconditional_install=False, path=None, bootstrap_delay=None, bootstrap_args=None, bootstrap_shell=None)

Install and configure salt in a container.

config Minion configuration options. By default, the master option is set to the target host's master.

approve_key Request a pre-approval of the generated minion key. Requires that the salt-master be configured to either auto-accept all keys or expect a signing request from the target host. Default: True

path path to the container parent default: /var/lib/lxc (system default)

New in version 2015.8.0.

pub_key Explicit public key to pressed the minion with (optional). This can be either a filepath or a string representing the key

priv_key Explicit private key to pressed the minion with (optional). This can be either a filepath or a string representing the key
**bootstrap_delay** Delay in seconds between end of container creation and bootstrapping. Useful when waiting for container to obtain a DHCP lease.

    New in version 2015.5.0.

**bootstrap_url** url, content or filepath to the salt bootstrap script

**bootstrap_args** salt bootstrap script arguments

**bootstrap_shell** shell to execute the script into

**install** Whether to attempt a full installation of salt-minion if needed.

**force_install** Force installation even if salt-minion is detected, this is the way to run vendor bootstrap scripts even if a salt minion is already present in the container

**unconditional_install** Run the script even if the container seems seeded

CLI Examples:

```bash
salt 'minion' lxc.bootstrap container_name [config=config_data] \[approve_key=(True|False)] [install=(True|False)]
```

---

**salt.modules.lxc.clone**(name, orig, profile=None, network_profile=None, nic_opts=None, **kwargs)

Create a new container as a clone of another container

**name** Name of the container

**orig** Name of the original container to be cloned

**profile** Profile to use in container cloning (see `lxc.get_container_profile`). Values in a profile will be overridden by the Container Cloning Arguments listed below.

**path** path to the container parent directory default: /var/lib/lxc (system)

    New in version 2015.8.0.

**Container Cloning Arguments**

**snapshot** Use Copy On Write snapshots (LVM)

**size** [1G] Size of the volume to create. Only applicable if backing=lvm.

**backing** The type of storage to use. Set to lvm to use an LVM group. Defaults to filesystem within /var/lib/lxc.

**network_profile** Network profile to use for container

    New in version 2015.8.0.

**nic_opts** give extra opts overriding network profile values

    New in version 2015.8.0.

CLI Examples:

```bash
salt '*' lxc.clone myclone orig=orig_container
salt '*' lxc.clone myclone orig=orig_container snapshot=True
```

---

**salt.modules.lxc.cloud_init**(name, vm_=None, **kwargs)

Thin wrapper to lxc.init to be used from the saltcloud lxc driver

**name** Name of the container may be None and then guessed from saltcloud mapping

**vm_** saltcloud mapping defaults for the vm

CLI Example:

---

31.16. Full list of builtin execution modules
salt '*' lxc.cloud_init foo

salt.modules.lxc.cloud_init_interface(name, vm_=None, **kwargs)

Interface between salt.cloud.lxc driver and lxc.init vm_ is a mapping of vm opts in the salt.cloud format as documented for the lxc driver.

This can be used either:

- from the salt cloud driver
- because you find the argument to give easier here than using directly lxc.init

**Warning:** BE REALLY CAREFUL CHANGING DEFAULTS‼ IT'S A RETRO COMPATIBLE INTERFACE WITH THE SALT CLOUD DRIVER (ask kiorky).

- name: name of the lxc container to create
- pub_key: public key to preseed the minion with. Can be the key content or a filepath
- priv_key: private key to preseed the minion with. Can be the key content or a filepath
- path: path to the container parent directory (default: /var/lib/lxc)

  New in version 2015.8.0.

- profile: profile selection
- network_profile: network profile selection

- nic_opts: per interface settings compatibles with network profile (ipv4/ipv6/link/gateway/mac/netmask)

  eg:

  ```
  {'eth0': {'mac': '00:16:3e:01:29:40',
           'gateway': None, (default)
           'link': 'br0', (default)
           'gateway': None, (default)
           'netmask': '', (default)
           'ip': '22.1.4.25'}}
  ```

- unconditional_install: given to lxc.bootstrap (see relative doc)
- force_install: given to lxc.bootstrap (see relative doc)
- config: any extra argument for the salt minion config
- dnsservers: dns servers to set inside the container
- autostart: autostart the container at boot time
- password: administrative password for the container

**Warning:** Legacy but still supported options:

- from_container: which container we use as a template when running lxc.clone
- image: which template do we use when we are using lxc.create. This is the default mode unless you specify something in from_container
- backing: which backing store to use. Values can be: overlayfs, dir (default), lvm, zfs, btrfs
- fstype: When using a blockdevice level backing store, which filesystem to use on
- size: When using a blockdevice level backing store, which size for the filesystem to use on
**snapshot** Use snapshot when cloning the container source

**vgname** if using LVM: vname

**lvname** if using LVM: lvname

**ip** ip for the primary nic

**mac** mac address for the primary nic

**netmask** netmask for the primary nic (24) = vm_.get('netmask', '24')

**bridge** bridge for the primary nic (lxcbr0)

**gateway** network gateway for the container

**additional_ips** additional ips which will be wired on the main bridge (br0) which is connected to internet. Be aware that you may use manual virtual mac addresses provided by your provider (online, ovh, etc). This is a list of mappings [ip: '', mac: '', netmask: ''] Set gateway to None and an interface with a gateway to escape from another interface that eth0. eg:

```
- {'mac': '00:16:3e:01:29:40',
  'gateway': None, (default)
  'link': 'br0', (default)
  'netmask': '', (default)
  'ip': '22.1.4.25')
```

**users** administrative users for the container default: [root] and [root, ubuntu] on ubuntu

**default_nic** name of the first interface, you should really not override this

CLI Example:

```
salt '*' lxc.cloud_init_interface foo
```

salt.modules.lxc.copy_to(name, source, dest, overwrite=False, makedirs=False, path=No)

Changed in version 2015.8.0: Function renamed from lxc.cp to lxc.copy_to for consistency with other container types. lxc.cp will continue to work, however. For versions 2015.2.x and earlier, use lxc.cp.

Copy a file or directory from the host into a container

**name** Container name

**source** File to be copied to the container

**path** path to the container parent default: /var/lib/lxc (system default)

New in version 2015.8.0.

**dest** Destination on the container. Must be an absolute path.

Changed in version 2015.5.0: If the destination is a directory, the file will be copied into that directory.

**overwrite** [False] Unless this option is set to True, then if a file exists at the location specified by the dest argument, an error will be raised.

New in version 2015.8.0.

**makedirs** False

Create the parent directory on the container if it does not already exist.

New in version 2015.5.0.

CLI Example:
salt 'minion' lxc.copy_to /tmp/foo /root/foo
salt 'minion' lxc.cp /tmp/foo /root/foo

salt.modules.lxc.create(name, config=None, profile=None, network_profile=None, nic_opts=None, **kwargs)

Create a new container.

name Name of the container
config The config file to use for the container. Defaults to system-wide config (usually in /etc/lxc/lxc.conf).
profile Profile to use in container creation (see lxc.get_container_profile). Values in a profile will be overridden by the Container Creation Arguments listed below.
network_profile Network profile to use for container

New in version 2015.5.0.

Container Creation Arguments

template The template to use. For example, ubuntu or fedora. Conflicts with the image argument.

Note: The download template requires the following three parameters to be defined in options:
- dist - The name of the distribution
- release - Release name/version
- arch - Architecture of the container

The available images can be listed using the lxc.images function.

options Template-specific options to pass to the lxc-create command. These correspond to the long options (ones beginning with two dashes) that the template script accepts. For example:

```python
options={"dist": "centos", "release": "6", "arch": "amd64"}
```

image A tar archive to use as the rootfs for the container. Conflicts with the template argument.
backing The type of storage to use. Set to lvm to use an LVM group. Defaults to filesystem within /var/lib/lxc.
fstype Filesystem type to use on LVM logical volume
size [1G] Size of the volume to create. Only applicable if backing=lvm.
vgname [lxc] Name of the LVM volume group in which to create the volume for this container. Only applicable if backing=lvm.
lnname Name of the LVM logical volume in which to create the volume for this container. Only applicable if backing=lvm.
nic_opts give extra opts overriding network profile values
path parent path for the container creation (default: /var/lib/lxc)

New in version 2015.8.0.

salt.modules.lxc.destroy(name, stop=False, path=None)

Destroy the named container.

Warning: Destroys all data associated with the container.

path path to the container parent directory (default: /var/lib/lxc)

New in version 2015.8.0.
**stop**  [False] If True, the container will be destroyed even if it is running/frozen.

Changed in version 2015.5.0: Default value changed to False. This more closely matches the behavior of `lxc-destroy(1)`, and also makes it less likely that an accidental command will destroy a running container that was being used for important things.

CLI Examples:

```bash
salt '*' lxc.destroy foo
salt '*' lxc.destroy foo stop=True
```

```python
salt.modules.lxc.edit_conf(conf_file, out_format='simple', read_only=False, lxc_config=None, **kwargs)
```

Edit an LXC configuration file. If a setting is already present inside the file, its value will be replaced. If it does not exist, it will be appended to the end of the file. Comments and blank lines will be kept in-tact if they already exist in the file.

- **out_format**: Set to simple if you need backward compatibility (multiple items for a simple key is not supported)
- **read_only**: return only the edited configuration without applying it to the underlying lxc configuration file
- **lxc_config**: List of dict containing lxc configuration items For network configuration, you also need to add the device it belongs to, otherwise it will default to eth0. Also, any change to a network parameter will result in the whole network reconfiguration to avoid mismatches, be aware of that!

After the file is edited, its contents will be returned. By default, it will be returned in simple format, meaning an unordered dict (which may not represent the actual file order). Passing in an out_format of commented will return a data structure which accurately represents the order and content of the file.

CLI Example:

```bash
salt 'minion' lxc.edit_conf /etc/lxc/mycontainer.conf \
    out_format=commented lxc.network.type=veth
salt 'minion' lxc.edit_conf /etc/lxc/mycontainer.conf \
    out_format=commented \
    lxc_config="[[{'lxc.network.name': 'eth0', \n        'lxc.network.ipv4': '1.2.3.4'}, \n        {'lxc.network.name': 'eth2', \n        'lxc.network.ipv4': '1.2.3.5'}, \n        {'lxc.network.name': 'eth3', \n        'lxc.network.gateway': '1.2.3.1'}]]"
```

```python
salt.modules.lxc.exists(name, path=None)
```

Returns whether the named container exists.

- **path**  path to the container parent directory (default: /var/lib/lxc)

New in version 2015.8.0.

CLI Example:

```bash
salt '*' lxc.exists name
```

```python
salt.modules.lxc.freeze(name, **kwargs)
```

Freeze the named container

- **path**  path to the container parent directory default: /var/lib/lxc (system)

New in version 2015.8.0.

**start**  [False] If True and the container is stopped, the container will be started before attempting to freeze.

New in version 2015.5.0.
use_vt run the command through VT

New in version 2015.8.0.

CLI Example:

```
salt '*' lxc.freeze name
```

```
salt.modules.lxc.get_container_profile(name=None, **kwargs)
```

New in version 2015.5.0.

Gather a pre-configured set of container configuration parameters. If no arguments are passed, an empty profile is returned.

Profiles can be defined in the minion or master config files, or in pillar or grains, and are loaded using `config.get`. The key under which LXC profiles must be configured is `lxc.container_profile.profile_name`. An example container profile would be as follows:

```
lxc.container_profile:
  ubuntu:
    template: ubuntu
    backing: lvm
    vgname: lxc
    size: 1G
```

Parameters set in a profile can be overridden by passing additional container creation arguments (such as the ones passed to `lxc.create`) to this function.

A profile can be defined either as the name of the profile, or a dictionary of variable names and values. See the [LXC Tutorial] for more information on how to use LXC profiles.

CLI Example:

```
.. code-block:: bash

    salt-call lxc.get_container_profile centos salt-call lxc.get_container_profile ubuntu template=ubuntu backing=overlayfs
```

```
salt.modules.lxc.get_network_profile(name=None, **kwargs)
```

New in version 2015.5.0.

Gather a pre-configured set of network configuration parameters. If no arguments are passed, the following default profile is returned:

```
{ 'eth0': { 'link': 'br0', 'type': 'veth', 'flags': 'up' } }
```

Profiles can be defined in the minion or master config files, or in pillar or grains, and are loaded using `config.get`. The key under which LXC profiles must be configured is `lxc.network_profile`. An example network profile would be as follows:

```
lxc.network_profile.centos:
  eth0:
    link: br0
    type: veth
    flags: up
```

To disable networking entirely:

```
lxc.network_profile.centos:
  eth0:
    disable: true
```
Parameters set in a profile can be overridden by passing additional arguments to this function.

A profile can be passed either as the name of the profile, or a dictionary of variable names and values. See the LXCTutorial for more information on how to use network profiles.

**Warning:** The ipv4, ipv6, gateway, and link (bridge) settings in network profiles will only work if the container does not redefine the network configuration (for example in /etc/sysconfig/network-scripts/ifcfg-<interface_name> on RHEL/CentOS, or /etc/network/interfaces on Debian/Ubuntu/etc.)

CLI Example:

```bash
salt-call lxc.get_network_profile default
```

**salt.modules.lxc.get_parameter(name, parameter, path=None)**

Returns the value of a cgroup parameter for a container.

* path path to the container parent directory default: /var/lib/lxc (system)

New in version 2015.8.0.

CLI Example:

```bash
salt '*' lxc.get_parameter container_name memory.limit_in_bytes
```

**salt.modules.lxc.get_root_path(path)**

Get the configured lxc root for containers.

New in version 2015.8.0.

CLI Example:

```bash
salt '*' lxc.get_root_path
```

**salt.modules.lxc.images(dist=None)**

List the available images for LXC's download template.

* dist [None] Filter results to a single Linux distribution

CLI Examples:

```bash
salt myminion lxc.images
salt myminion lxc.images dist=centos
```

**salt.modules.lxc.info(name, path=None)**

Returns information about a container.

* path path to the container parent directory default: /var/lib/lxc (system)

New in version 2015.8.0.

CLI Example:

```bash
salt '*' lxc.info name
```
Initialize a new container.

This is a partial idempotent function as if it is already provisioned, we will reset a bit the lxc configuration file but much of the hard work will be escaped as markers will prevent re-execution of harmful tasks.

**name** Name of the container

**image** A tar archive to use as the rootfs for the container. Conflicts with the `template` argument.

**cpus** Select a random number of cpu cores and assign it to the cpuset, if the cpuset option is set then this option will be ignored

**cpuset** Explicitly define the cpus this container will be bound to

**cpushare** cgroups cpu shares

**autostart** autostart container on reboot

**memory** cgroups memory limit, in MB

Changed in version 2015.5.0: If no value is passed, no limit is set. In earlier Salt versions, not passing this value causes a 1024MB memory limit to be set, and it was necessary to pass `memory=0` to set no limit.

**gateway** the ipv4 gateway to use the default does nothing more than lxcutils does

**bridge** the bridge to use the default does nothing more than lxcutils does

**network_profile** Network profile to use for the container

New in version 2015.5.0.

**nic** Deprecated since version 2015.5.0: Use `network_profile` instead

**nic_opts** Extra options for network interfaces, will override

{"eth0": {"hwaddr": "aa:bb:cc:dd:ee:ff", "ipv4": "10.1.1.1", "ipv6": "2001:db8::ff00:42:8329"}}

or

{"eth0": {"hwaddr": "aa:bb:cc:dd:ee:ff", "ipv4": "10.1.1.1/24", "ipv6": "2001:db8::ff00:42:8329"}}

**users** Users for which the password defined in the `password` param should be set. Can be passed as a comma separated list or a python list. Defaults to just the root user.

**password** Set the initial password for the users defined in the `users` parameter

**password_encrypted** [False] Set to `True` to denote a password hash instead of a plaintext password

New in version 2015.5.0.

**profile** A LXC profile (defined in config or pillar). This can be either a real profile mapping or a string to retrieve it in configuration

**start** Start the newly-created container

**dnsservers** list of dns servers to set in the container, default `[]` (no setting)

**seed** Seed the container with the minion config. Default: True
install  If salt-minion is not already installed, install it. Default: True

config  Optional config parameters. By default, the id is set to the name of the container.

master  salt master (default to minion's master)

master_port  salt master port (default to minion's master port)

pub_key  Explicit public key to preseed the minion with (optional). This can be either a filepath or a string representing the key

priv_key  Explicit private key to preseed the minion with (optional). This can be either a filepath or a string representing the key

approve_key  If explicit preseeding is not used; Attempt to request key approval from the master. Default: True

path  path to the container parent directory default: /var/lib/lxc (system)

New in version 2015.8.0.

close  Deprecated since version 2015.5.0: Use close_from instead

close_from  Original from which to use a clone operation to create the container. Default: None

bootstrap_delay  Delay in seconds between end of container creation and bootstrapping. Useful when waiting for container to obtain a DHCP lease.

New in version 2015.5.0.

bootstrap_url  See lxc.bootstrap

bootstrap_shell  See lxc.bootstrap

bootstrap_args  See lxc.bootstrap

force_install  Force installation even if salt-minion is detected, this is the way to run vendor bootstrap scripts even if a salt minion is already present in the container

unconditional_install  Run the script even if the container seems seeded

CLI Example:

```
salt 'minion' lxc.init name [cpuset=cgroups_cpuset] \n    [cpushare=cgroups_cpushare] [memory=cgroups_memory] \n    [nic=nic_profile] [profile=lxc_profile] \n    [nic_opts=nic_opts] [start=(True|False)] \n    [seed=(True|False)] [install=(True|False)] \n    [config=minion_config] [approve_key=(True|False)] \n    [clone_from=original] [autostart=True] \n    [priv_key=/path_or_content] [pub_key=/path_or_content] \n    [bridge=lxcbr0] [gateway=10.0.3.1] \n    [dnsservers=[dns1,dns2]] \n    [users=[foo]] [password='secret'] \n    [password_encrypted=(True|False)]
```

salt.modules.lxc.list(extra=False, limit=None, path=None)

List containers classified by state

extra  Also get per-container specific info. This will change the return data. Instead of returning a list of containers, a dictionary of containers and each container's output from lxc.info.

path  path to the container parent directory default: /var/lib/lxc (system)

New in version 2015.8.0.
**limit**  Return output matching a specific state (frozen, running, or stopped).

New in version 2015.5.0.

CLI Examples:

salt `*` lxc.list
salt `*` lxc.list extra=True
salt `*` lxc.list limit=running

```
salt.modules.lxc.ls(active=None, cache=True, path=None)
```

Return a list of the containers available on the minion

- **path**  path to the container parent directory default: /var/lib/lxc (system)

New in version 2015.8.0.

- **active**  If True, return only active (i.e. running) containers

New in version 2015.5.0.

CLI Example:

```
salt `*` lxc.ls
salt `*` lxc.ls active=True
```

```
salt.modules.lxc.read_conf(conf_file, out_format='simple')
```

Read in an LXC configuration file. By default returns a simple, unsorted dict, but can also return a more detailed structure including blank lines and comments.

- **out_format**:  set to 'simple' if you need the old and unsupported behavior. This wont support the multiple lxc values (eg: multiple network nics)

CLI Examples:

```
salt 'minion' lxc.read_conf /etc/lxc/mycontainer.conf
salt 'minion' lxc.read_conf /etc/lxc/mycontainer.conf out_format=commented
```

```
salt.modules.lxc.reboot(name, path=None)
```

Reboot a container.

- **path**  path to the container parent default: /var/lib/lxc (system default)

New in version 2015.8.0.

CLI Examples:

```
salt 'minion' lxc.reboot myvm
```

```
salt.modules.lxc.reconfigure(name, cpu=None, cpuset=None, cpushare=None, memory=None, profile=None, network_profile=None, nic_opts=None, bridge=None, gateway=None, autostart=None, path=None, **kwargs)
```

Reconfigure a container.

This only applies to a few propert

- **name**  Name of the container.

- **cpu**  Select a random number of cpu cores and assign it to the cpuset, if the cpuset option is set then this option will be ignored

- **cpuset**  Explicitly define the cpus this container will be bound to

- **cpushare**  cgroups cpu shares.

- **autostart**  autostart container on reboot
memory  cgroups memory limit, in MB. (0 for nolimit, None for old default 1024MB)
gateway the ipv4 gateway to use the default does nothing more than lxcutils does
bridge  the bridge to use the default does nothing more than lxcutils does
nic  Network interfaces profile (defined in config or pillar).
nic_opts  Extra options for network interfaces, will override

    
    "eth0": {"mac": "aa:bb:cc:dd:ee:ff", "ipv4": "10.1.1.1", "ipv6": "2001:db8::ff00:42:8329"}

    or

    "eth0": {"mac": "aa:bb:cc:dd:ee:ff", "ipv4": "10.1.1.1/24", "ipv6": "2001:db8::ff00:42:8329"}

cpath  path to the container parent

    New in version 2015.8.0.

    CLI Example:

    salt-call -lall mc_lxc_fork.reconfigure foobar nic_opts="{'eth1': {'mac': '00:16:3e:dd:ee:44'}}"

salt.modules.lxc.restart(name, path=None, lxc_config=None, force=False)

    New in version 2015.5.0.

    Restart the named container. If the container was not running, the container will merely be started.

    name  The name of the container

    path  path to the container parent directory default: /var/lib/lxc (system)

        New in version 2015.8.0.

    lxc_config

        path to a lxc config file config file will be guessed from container name otherwise

        New in version 2015.8.0.

    force  [False] If True, the container will be force-stopped instead of gracefully shut down

    CLI Example:

    salt myminion lxc.restart name

salt.modules.lxc.retcodename, cmd, no_start=False, preserve_state=True, stdin=None,
python_shell=True, output_loglevel='debug', use_vt=False, path=None,
ignore_retcode=False, chroot_fallback=False, keep_env='http_proxy, https_proxy, no_proxy')

    New in version 2015.5.0.

    Run cmd.retcodename within a container

    Warning: Many shell builtins do not work, failing with stderr similar to the following:

    lxc_container: No such file or directory - failed to exec 'command'

    The same error will be displayed in stderr if the command being run does not exist. If the retcode is nonzero
    and not what was expected, try using lxc.run_stderr or lxc.run_all.

    name  Name of the container in which to run the command
cmd Command to run

no_start [False] If the container is not running, don’t start it

preserve_state [True] After running the command, return the container to its previous state

path path to the container parent default: /var/lib/lxc (system default)

    New in version 2015.8.0.

stdin [None] Standard input to be used for the command

output_loglevel [debug] Level at which to log the output from the command. Set to quiet to suppress logging.

use_vt [False] Use SaltStack’s utils.vt to stream output to console output=all.

keep_env [http_proxy,https_proxy,no_proxy] A list of env vars to preserve. May be passed as comma-delimited list.

croot_fallback if the container is not running, try to run the command using chroot default: false

CLI Example:

    salt myminion lxc.retcode mycontainer 'ip addr show'

salt.modules.lxc.run(name, cmd, no_start=False, preserve_state=True, stdin=None, python_shell=True, output_loglevel='debug', use_vt=False, path=None, ignore_retcode=False, chroot_fallback=False, keep_env='http_proxy,https_proxy,no_proxy')

New in version 2015.8.0.

Run cmd.run within a container

Warning: Many shell builtins do not work, failing with stderr similar to the following:

    lxc_container: No such file or directory - failed to exec 'command'

The same error will be displayed in stderr if the command being run does not exist. If no output is returned using this function, try using lxc.run_stderr or lxc.run_all.

name Name of the container in which to run the command

cmd Command to run

path path to the container parent default: /var/lib/lxc (system default)

    New in version 2015.8.0.

no_start [False] If the container is not running, don’t start it

preserve_state [True] After running the command, return the container to its previous state

stdin [None] Standard input to be used for the command

output_loglevel [debug] Level at which to log the output from the command. Set to quiet to suppress logging.

use_vt [False] Use SaltStack’s utils.vt to stream output to console. Assumes output=all.

croot_fallback if the container is not running, try to run the command using chroot default: false

keep_env [http_proxy,https_proxy,no_proxy] A list of env vars to preserve. May be passed as comma-delimited list.

CLI Example:
```
salt myminion lxc.run mycontainer 'ifconfig -a'
```

```python
salt.modules.lxc.run_all(name, cmd, no_start=False, preserve_state=True, stdin=None, python_shell=True, output_loglevel='debug', use_vt=False, path=None, ignore_retcode=False, chroot_fallback=False, keep_env='http_proxy, https_proxy, no_proxy')
```

New in version 2015.5.0.

Run `cmd.run_all` within a container

**Note:** While the command is run within the container, it is initiated from the host. Therefore, the PID in the return dict is from the host, not from the container.

**Warning:** Many shell builtins do not work, failing with stderr similar to the following:

```
lxc_container: No such file or directory - failed to exec 'command'
```

The same error will be displayed in stderr if the command being run does not exist.

- **name** Name of the container in which to run the command
- **path** path to the container parent default: /var/lib/lxc (system default)
  
  New in version 2015.8.0.
- **cmd** Command to run
- **no_start** [False] If the container is not running, don’t start it
- **preserve_state** [True] After running the command, return the container to its previous state
- **stdin** [None] Standard input to be used for the command
- **output_loglevel** [debug] Level at which to log the output from the command. Set to `quiet` to suppress logging.
- **use_vt** [False] Use SaltStack's `utils.vt` to stream output to console `output=all`.
- **keep_env** [http_proxy, https_proxy, no_proxy] A list of env vars to preserve. May be passed as comma-delimited list.
- **chroot_fallback** if the container is not running, try to run the command using chroot default: false

**CLI Example:**

```
salt myminion lxc.run_all mycontainer 'ip addr show'
```

```python
salt.modules.lxc.run_cmd(name, cmd, no_start=False, preserve_state=True, stdin=None, stdout=True, stderr=False, python_shell=True, output_loglevel='debug', use_vt=False, ignore_retcode=False, chroot_fallback=False, keep_env='http_proxy, https_proxy, no_proxy')
```

```
path path to the container parent default: /var/lib/lxc (system default)
  
  New in version 2015.8.0.
```

Deprecated since version 2015.5.0: Use `lxc.run` instead

```python
salt.modules.lxc.run_stderr(name, cmd, no_start=False, preserve_state=True, stdin=None, python_shell=True, output_loglevel='debug', use_vt=False, path=None, ignore_retcode=False, chroot_fallback=False, keep_env='http_proxy, https_proxy, no_proxy')
```

New in version 2015.5.0.

- **keep_env** [http_proxy,https_proxy,no_proxy] A list of env vars to preserve. May be passed as comma-delimited list.
- **chroot_fallback** if the container is not running, try to run the command using chroot default: false

**CLI Example:**

```bash
salt myminion lxc.run_stderr mycontainer 'ip addr show'
```

**salt.modules.lxc.run_stdout** *(name, cmd, no_start=False, preserve_state=True, stdin=None, python_shell=True, output_loglevel='debug', use_vt=False, path=None, ignore_retcode=False, chroot_fallback=False, keep_env='http_proxy, https_proxy, no_proxy')*

- New in version 2015.5.0.

Run `cmd.run_stdout` within a container

<table>
<thead>
<tr>
<th>Warning: Many shell builtins do not work, failing with stderr similar to the following:</th>
</tr>
</thead>
<tbody>
<tr>
<td>lxc_container: No such file or directory - failed to exec 'command'</td>
</tr>
</tbody>
</table>
| The same error will be displayed in stderr if the command being run does not exist. If no output is returned using this function, try using `lxc.run_stderr` or `lxc.run_all`.

- **name** Name of the container in which to run the command
- **cmd** Command to run
- **path** path to the container parent default: /var/lib/lxc (system default)
  - New in version 2015.8.0.
- **no_start** [False] If the container is not running, don’t start it
- **preserve_state** [True] After running the command, return the container to its previous state
- **stdin** [None] Standard input to be used for the command
```python
output_loglevel [debug] Level at which to log the output from the command. Set to quiet to suppress logging.

use_vt [False] Use SaltStack's utils.vt to stream output to console output=all.

keep_env [http_proxy, https_proxy, no_proxy] A list of env vars to preserve. May be passed as comma-delimited list.

chrootFallback if the container is not running, try to run the command using chroot default: false

CLI Example:
salt myminion lxc.run_stdout mycontainer 'ifconfig -a'
```

```python
salt.modules.lxc.running_systemd(name, cache=True, path=None)
Determine if systemd is running

path path to the container parent

New in version 2015.8.0.

CLI Example:
salt '*' lxc.running_systemd ubuntu
```

```python
salt.modules.lxc.search_lxc_bridge()
Search the first bridge which is potentially available as LXC bridge

CLI Example:
salt '*' lxc.search_lxc_bridge
```

```python
salt.modules.lxc.search_lxc_bridges()
Search which bridges are potentially available as LXC bridges

CLI Example:
salt '*' lxc.search_lxc_bridges
```

```python
salt.modules.lxc.set_dns(name, dnsservers=None, searchdomains=None, path=None)
Changed in version 2015.5.0: The dnsservers and searchdomains parameters can now be passed as a comma-separated list.
Update /etc/resolv.conf

path

path to the container parent default: /var/lib/lxc (system default)

New in version 2015.8.0.

CLI Example:
salt myminion lxc.set_dns ubuntu "['8.8.8.8', '4.4.4.4']"
```

```python
salt.modules.lxc.set_parameter(name, parameter, value, path=None)
Set the value of a cgroup parameter for a container.

path path to the container parent directory default: /var/lib/lxc (system)

New in version 2015.8.0.

CLI Example:
```
salt 's' lxc.set_parameter name parameter value

salt.modules.lxc.set_password(name, users, password, encrypted=True, path=None)

Changed in version 2015.5.0: Function renamed from set_pass to set_password. Additionally, this function now supports (and defaults to using) a password hash instead of a plaintext password.

Set the password of one or more system users inside containers

users Comma-separated list (or python list) of users to change password

password Password to set for the specified user(s)

encrypted [True] If true, password must be a password hash. Set to False to set a plaintext password (not recommended).

path path to the container parent directory default: /var/lib/lxc (system)

New in version 2015.8.0.

CLI Example:

salt 's' lxc.set_pass container-name root '$6$uJ2uAyLU$KoI67t8As/0fXtJ0PcHKGxUpcoYJcVR2K6x93walnShTCQvjRwq25yIkiCBOqgbfdKQSFnAo28/ek6716vEV1'
salt 's' lxc.set_pass container-name root foo encrypted=False

salt.modules.lxc.start(name, **kwargs)

Start the named container

restart [False] Deprecated since version 2015.5.0: Use lxc.restart

Restart the container if it is already running

path path to the container parent directory default: /var/lib/lxc (system)

New in version 2015.8.0.

lxc_config

path to a lxc config file config file will be guessed from container name otherwise

New in version 2015.8.0.

use_vt run the command through VT

New in version 2015.8.0.

CLI Example:

salt myminion lxc.start name

salt.modules.lxc.state(name, path=None)

Returns the state of a container.

path path to the container parent directory (default: /var/lib/lxc)

New in version 2015.8.0.

CLI Example:

salt 's' lxc.state name

salt.modules.lxc.stop(name, kill=False, path=None, use_vt=None)

Stop the named container
path path to the container parent directory default: /var/lib/lxc (system)
    New in version 2015.8.0.
kill: False Do not wait for the container to stop, kill all tasks in the container. Older LXC versions will stop
containers like this irrespective of this argument.
    Changed in version 2015.5.0: Default value changed to False
use_vt run the command through VT
    New in version 2015.8.0.
CLI Example:
    salt myminion lxc.stop name

salt.modules.lxc.systemd_running_state(name, path=\None)
Get the operational state of a systemd based container
path path to the container parent default: /var/lib/lxc (system default)
    New in version 2015.8.0.
CLI Example:
    salt myminion lxc.systemd_running_state ubuntu

salt.modules.lxc.templates()
List the available LXC template scripts installed on the minion
CLI Examples:
    salt myminion lxc.templates

salt.modules.lxc.test_bare_started_state(name, path=\None)
    Test if a non systemd container is fully started For now, it consists only to test if the container is attachable
path path to the container parent default: /var/lib/lxc (system default)
    New in version 2015.8.0.
CLI Example:
    salt myminion lxc.test_bare_started_state ubuntu

salt.modules.lxc.test_sd_started_state(name, path=\None)
    Test if a systemd container is fully started
path path to the container parent default: /var/lib/lxc (system default)
    New in version 2015.8.0.
CLI Example:
    salt myminion lxc.test_sd_started_state ubuntu

salt.modules.lxc.unfreeze(name, path=\None, use_vt=\None)
Unfreeze the named container.
path path to the container parent directory default: /var/lib/lxc (system)
    New in version 2015.8.0.
use_vt  run the command through VT

    New in version 2015.8.0.
    CLI Example:

    salt '*' lxc.unfreeze name

salt.modules.lxc.update_lxc_conf(name, lxc_conf, lxc_conf_unset, path=None)

    Edit LXC configuration options

    path

        path to the container parent default: /var/lib/lxc (system default)

        New in version 2015.8.0.
        CLI Example:

        salt myminion lxc.update_lxc_conf ubuntu
        lxc_conf="[{'network.ipv4.ip': '10.0.3.5'}]
        lxc_conf_unset=['lxc.utsname']"

salt.modules.lxc.version()

    Return the actual lxc client version

    New in version 2015.8.0.
    CLI Example:

    salt '*' lxc.version

salt.modules.lxc.wait_started(name, path=None, timeout=300)

    Check that the system has fully inited

    This is actually very important for systemd based containers

    see https://github.com/saltstack/salt/issues/23847

    path  path to the container parent default: /var/lib/lxc (system default)

    New in version 2015.8.0.
    CLI Example:

    salt myminion lxc.wait_started ubuntu

salt.modules.lxc.write_conf(conf_file, conf)

    Write out an LXC configuration file

    This is normally only used internally. The format of the data structure must match that which is returned from lxc.read_conf(), with out_format set to commented.

    An example might look like:

    ```
    [
        {'lxc.utsname': '$CONTAINER_NAME'},
        '# This is a commented line
        '
        {'lxc.mount': '$CONTAINER_FSTAB'},
        {'lxc.rootfs': {'comment': 'This is another test',
            'value': 'This is another test'}},
        '
        {'lxc.network.type': 'veth'},
        {'lxc.network.flags': 'up'},
    ```
{
    'lxc.network.link': 'br0',
    'lxc.network.mac': '${CONTAINER_MACADDR}',
    'lxc.network.ipv4': '${CONTAINER_IPADDR}',
    'lxc.network.name': '${CONTAINER_DEVICENAME}',
}

**CLI Example:**
```
salt 'minion' lxc.write_conf /etc/lxc/mycontainer.conf \
    out_format=commented
```

### 31.16.140 salt.modules.mac_group

Manage groups on Mac OS 10.7+

```python
salt.modules.mac_group.add(name, gid=None, **kwargs)
```
Add the specified group

**CLI Example:**
```
salt '*' group.add foo 3456
```

```python
salt.modules.mac_group.chgid(name, gid)
```
Change the gid for a named group

**CLI Example:**
```
salt '*' group.chgid foo 4376
```

```python
salt.modules.mac_group.delete(name)
```
Remove the named group

**CLI Example:**
```
salt '*' group.delete foo
```

```python
salt.modules.mac_group.getent(refresh=False)
```
Return info on all groups

**CLI Example:**
```
salt '*' group.getent
```

```python
salt.modules.mac_group.info(name)
```
Return information about a group

**CLI Example:**
```
salt '*' group.info foo
```

### 31.16.141 salt.modules.mac_user

Manage users on Mac OS 10.7+

```python
salt.modules.mac_user.add(name, uid=None, gid=None, groups=None, home=None, shell=None, fullname=None, createhome=True, **kwargs)
```
Add a user to the minion

**CLI Example:**
```
```
salt 'Ū' user.add name <uid> <gid> <groups> <home> <shell>

salt.modules.mac_user.chfullname(name, fullname)
    Change the user's Full Name
    CLI Example:
    salt 'Ū' user.chfullname foo 'Foo Bar'

salt.modules.mac_user.chgid(name, gid)
    Change the default group of the user
    CLI Example:
    salt 'Ū' user.chgid foo 4376

salt.modules.mac_user.chgroups(name, groups, append=False)
    Change the groups to which the user belongs. Note that the user's primary group does not have to be one of
    the groups passed, membership in the user's primary group is automatically assumed.
    groups  Groups to which the user should belong, can be passed either as a python list or a comma-separated
            string
    append  Instead of removing user from groups not included in the groups parameter, just add user to any
            groups for which they are not members
    CLI Example:
    salt 'Ū' user.chgroups foo wheel,root

salt.modules.mac_user.chhome(name, home)
    Change the home directory of the user
    CLI Example:
    salt 'Ū' user.chhome foo /Users/foo

salt.modules.mac_user.chshell(name, shell)
    Change the default shell of the user
    CLI Example:
    salt 'Ū' user.chshell foo /bin/zsh

salt.modules.mac_user.chuid(name, uid)
    Change the uid for a named user
    CLI Example:
    salt 'Ū' user.chuid foo 4376

salt.modules.mac_user.delete(name, 'args)
    Remove a user from the minion
    CLI Example:
    salt 'Ū' user.delete foo

salt.modules.mac_user.getent(refresh=False)
    Return the list of all info for all users
    CLI Example:
salt '*' user.getent

salt.modules.mac_user.info(name)
    Return user information
    CLI Example:
        salt '*' user.info root

salt.modules.mac_user.list_groups(name)
    Return a list of groups the named user belongs to
    CLI Example:
        salt '*' user.list_groups foo

salt.modules.mac_user.list_users()
    Return a list of all users
    CLI Example:
        salt '*' user.list_users

salt.modules.mac_user.rename(name, new_name)
    Change the username for a named user
    CLI Example:
        salt '*' user.rename name new_name

31.16.142 salt.modules.macports

Support for MacPorts under Mac OS X.

This module has some caveats.

1. Updating the database of available ports is quite resource-intensive. However, refresh=True is the default for all operations that need an up-to-date copy of available ports. Consider refresh=False when you are sure no db update is needed.

2. In some cases MacPorts doesn't always realize when another copy of itself is running and will gleefully trample all over the available ports database. This makes MacPorts behave in undefined ways until a fresh complete copy is retrieved.

Because of 1 and 2 it is possible to get the salt-minion into a state where salt mac-machine pkg./something/ won't want to return. Use

    salt-run jobs.active

on the master to check for potentially long-running calls to port.

Finally, ports database updates are always handled with port selfupdate as opposed to port sync. This makes sense in the MacPorts user community but may confuse experienced Linux admins as Linux package managers don't upgrade the packaging software when doing a package database update. In other words salt mac-machine pkg.refresh_db is more like apt-get update; apt-get upgrade dpkg apt-get than simply apt-get update.

salt.modules.macports.available_version(*names, **kwargs)
    Return the latest version of the named package available for upgrade or installation

Options:
    refresh Update ports with port selfupdate
CLI Example:

```bash
salt '*' pkg.latest_version <package name>
salt '*' pkg.latest_version <package1> <package2> <package3>
```

```python
salt.modules.macports.install(name=None, refresh=False, pkgs=None, **kwargs)
```

Install the passed package(s) with `port install`

**name** The name of the formula to be installed. Note that this parameter is ignored if `"pkgs"` is passed.

CLI Example:

```bash
salt '*' pkg.install <package name>
```

**version** Specify a version to `pkg` to install. Ignored if `pkgs` is specified.

CLI Example:

```bash
salt '*' pkg.install <package name>
salt '*' pkg.install git-core version='1.8.5.5'
```

**variant** Specify a variant to `pkg` to install. Ignored if `pkgs` is specified.

CLI Example:

```bash
salt '*' pkg.install <package name>
salt '*' pkg.install git-core version='1.8.5.5' variant='+credential_osxkeychain+doc+pcre'
```

Multiple Package Installation Options:

**pkgs** A list of formulas to install. Must be passed as a python list.

CLI Example:

```bash
salt '*' pkg.install pkgs=['"foo","bar"]
salt '*' pkg.install pkgs=['"foo@1.2","bar"']
salt '*' pkg.install pkgs=['"foo@1.2+ssl","bar@2.3"]
```

Returns a dict containing the new package names and versions:

```python
{
'package': {
'old': '<old-version>',
'new': '<new-version>'
}}
```

CLI Example:

```bash
salt '*' pkg.install 'package package package'
```

```python
salt.modules.macports.latest_version("names", **kwargs)
```

Return the latest version of the named package available for upgrade or installation

Options:

**refresh** Update ports with `port selfupdate`

CLI Example:

```bash
salt '*' pkg.latest_version <package name>
salt '*' pkg.latest_version <package1> <package2> <package3>
```

```python
salt.modules.macports.list_pkgs(versions_as_list=False, **kwargs)
```

List the packages currently installed in a dict:
{'<package_name>': '<version>'}

CLI Example:
salt '*' pkg.list_pkgs

salt.modules.macports.list_upgrades(refresh=True)
Check whether or not an upgrade is available for all packages

Options:
refresh Update ports with port selfupdate

CLI Example:
salt '*' pkg.list_upgrades

salt.modules.macports.refresh_db()
Update ports with port selfupdate

salt.modules.macports.remove(name=None, pkgs=None, **kwargs)
Removes packages with port uninstall.

name The name of the package to be deleted.

Multiple Package Options:

pkgs A list of packages to delete. Must be passed as a python list. The name parameter will be ignored if this option is passed.

New in version 0.16.0.

Returns a dict containing the changes.

CLI Example:
salt '*' pkg.remove <package name>
salt '*' pkg.remove <package1>,<package2>,<package3>
salt '*' pkg.remove pkgs=['foo', 'bar']

salt.modules.macports.upgrade(refresh=True)
Run a full upgrade using MacPorts 'port upgrade outdated'

Options:
refresh Update ports with port selfupdate

Return a dict containing the new package names and versions:

{'<package>': {'old': '<old-version>',
              'new': '<new-version>'}}

CLI Example:
salt '*' pkg.upgrade

salt.modules.macports.upgrade_available(pkg, refresh=True)
Check whether or not an upgrade is available for a given package

CLI Example:
salt '*' pkg.upgrade_available <package name>
salt.modules.macports.version(*names, **kwargs)
Returns a string representing the package version or an empty string if not installed. If more than one package name is specified, a dict of name/version pairs is returned.

CLI Example:

```
salt '*' pkg.version <package name>
salt '*' pkg.version <package1> <package2> <package3>
```

### 31.16.143 salt.modules.makeconf

Support for modifying make.conf under Gentoo

salt.modules.makeconf.append_cflags(value)
Add to or create a new CFLAGS in the make.conf
Return a dict containing the new value for variable:

```
{'<variable>': {'old': '<old-value>',
               'new': '<new-value>'}}
```

CLI Example:

```
salt '*' makeconf.append_cflags '-pipe'
```

salt.modules.makeconf.append_cxxflags(value)
Add to or create a new CXXFLAGS in the make.conf
Return a dict containing the new value for variable:

```
{'<variable>': {'old': '<old-value>',
                'new': '<new-value>'}}
```

CLI Example:

```
salt '*' makeconf.append_cxxflags '-pipe'
```

salt.modules.makeconf.append_emerge_default_opts(value)
Add to or create a new EMERGE_DEFAULT_OPTS in the make.conf
Return a dict containing the new value for variable:

```
{'<variable>': {'old': '<old-value>',
                'new': '<new-value>'}}
```

CLI Example:

```
salt '*' makeconf.append_emerge_default_opts '--jobs'
```

salt.modules.makeconf.append_features(value)
Add to or create a new FEATURES in the make.conf
Return a dict containing the new value for variable:

```
{'<variable>': {'old': '<old-value>',
                'new': '<new-value>'}}
```

CLI Example:
```python
salt '*' makeconf.append_features 'webrsync-gpg'
```

```python
salt.modules.makeconf.append_gentoo_mirrors(value)
    Add to or create a new GENTOO_MIRRORS in the make.conf
    Return a dict containing the new value for variable:
    ```
    {
        '<variable>': {
            'old': '<old-value>',
            'new': '<new-value>'
        }
    }
    ```
    CLI Example:
    ```
salt '*' makeconf.append_gentoo_mirrors 'http://distfiles.gentoo.org'
    ```
```

```python
salt.modules.makeconf.append_makeopts(value)
    Add to or create a new MAKEOPTS in the make.conf
    Return a dict containing the new value for variable:
    ```
    {
        '<variable>': {
            'old': '<old-value>',
            'new': '<new-value>'
        }
    }
    ```
    CLI Example:
    ```
salt '*' makeconf.append_makeopts '-j3'
    ```
```

```python
salt.modules.makeconf.append_var(var, value)
    Add to or create a new variable in the make.conf
    Return a dict containing the new value for variable:
    ```
    {
        '<variable>': {
            'old': '<old-value>',
            'new': '<new-value>'
        }
    }
    ```
    CLI Example:
    ```
salt '*' makeconf.append_var 'LINGUAS' 'en'
    ```
```

```python
salt.modules.makeconf.cflags_contains(value)
    Verify if CFLAGS variable contains a value in make.conf
    Return True if value is set for var
    CLI Example:
    ```
    salt '*' makeconf.cflags_contains '-pipe'
    ```
```

```python
salt.modules.makeconf.chost_contains(value)
    Verify if CHOST variable contains a value in make.conf
    Return True if value is set for var
    CLI Example:
    ```
    salt '*' makeconf.chost_contains 'x86_64-pc-linux-gnu'
    ```
```

```python
salt.modules.makeconf.cxxflags_contains(value)
    Verify if CXXFLAGS variable contains a value in make.conf
    Return True if value is set for var
    CLI Example:
    ```
salt '*' makeconf.cxxflags_contains '-pipe'

salt.modules.makeconf.emerge_default_opts_contains(value)
Verify if EMERGE_DEFAULT_OPTS variable contains a value in make.conf
Return True if value is set for var
CLI Example:
```
salt '*' makeconf.emerge_default_opts_contains '--jobs'
```

salt.modules.makeconf.features_contains(value)
Verify if FEATURES variable contains a value in make.conf
Return True if value is set for var
CLI Example:
```
salt '*' makeconf.features_contains 'webrsync-gpg'
```

salt.modules.makeconf.gentoo_mirrors_contains(value)
Verify if GENTOO_MIRRORS variable contains a value in make.conf
Return True if value is set for var
CLI Example:
```
salt '*' makeconf.gentoo_mirrors_contains 'http://distfiles.gentoo.org'
```

salt.modules.makeconf.get_cflags()
Get the value of CFLAGS variable in the make.conf
Return the value of the variable or None if the variable is not in the make.conf
CLI Example:
```
salt '*' makeconf.get_cflags
```

salt.modules.makeconf.get_chost()
Get the value of CHOST variable in the make.conf
Return the value of the variable or None if the variable is not in the make.conf
CLI Example:
```
salt '*' makeconf.get_chost
```

salt.modules.makeconf.get_cxxflags()
Get the value of CXXFLAGS variable in the make.conf
Return the value of the variable or None if the variable is not in the make.conf
CLI Example:
```
salt '*' makeconf.get_cxxflags
```

salt.modules.makeconf.get_emerge_default_opts()
Get the value of EMERGE_DEFAULT_OPTS variable in the make.conf
Return the value of the variable or None if the variable is not in the make.conf
CLI Example:
salt '*' makeconf.get_emerge_default_opts

salt.modules.makeconf.get_features()
   Get the value of FEATURES variable in the make.conf
   Return the value of the variable or None if the variable is not in the make.conf
   CLI Example:
   
   salt '*' makeconf.get_features

salt.modules.makeconf.get_gentoo_mirrors()
   Get the value of GENTOO_MIRRORS variable in the make.conf
   Return the value of the variable or None if the variable is not in the make.conf
   CLI Example:
   
   salt '*' makeconf.get_gentoo_mirrors

salt.modules.makeconf.get_makeopts()
   Get the value of MAKEOPTS variable in the make.conf
   Return the value of the variable or None if the variable is not in the make.conf
   CLI Example:
   
   salt '*' makeconf.get_makeopts

salt.modules.makeconf.get_sync()
   Get the value of SYNC variable in the make.conf
   Return the value of the variable or None if the variable is not in the make.conf
   CLI Example:
   
   salt '*' makeconf.get_sync

salt.modules.makeconf.get_var(var)
   Get the value of a variable in make.conf
   Return the value of the variable or None if the variable is not in make.conf
   CLI Example:
   
   salt '*' makeconf.get_var 'LINGUAS'

salt.modules.makeconf.makeopts_contains(value)
   Verify if MAKEOPTS variable contains a value in make.conf
   Return True if value is set for var
   CLI Example:
   
   salt '*' makeconf.makeopts_contains '-j3'

salt.modules.makeconf.remove_var(var)
   Remove a variable from the make.conf
   Return a dict containing the new value for the variable:
   
   {'<variable>': {'old': '<old-value>',
                'new': '<new-value>'}}
CLI Example:
```
salt '*' makeconf.remove_var 'LINGUAS'
```

```
salt.modules.makeconf.set_cflags(value)
Set the CFLAGS variable
Return a dict containing the new value for variable:
```
{'<variable>': {'old': '<old-value>', 'new': '<new-value>'}}
```

CLI Example:
```
salt '*' makeconf.set_cflags '-march=native -O2 -pipe'
```

```
salt.modules.makeconf.set_chost(value)
Set the CHOST variable
Return a dict containing the new value for variable:
```
{'<variable>': {'old': '<old-value>', 'new': '<new-value>'}}
```

CLI Example:
```
salt '*' makeconf.set_chost 'x86_64-pc-linux-gnu'
```

```
salt.modules.makeconf.set_cxxflags(value)
Set the CXXFLAGS variable
Return a dict containing the new value for variable:
```
{'<variable>': {'old': '<old-value>', 'new': '<new-value>'}}
```

CLI Example:
```
salt '*' makeconf.set_cxxflags '-march=native -O2 -pipe'
```

```
salt.modules.makeconf.set_emerge_default_opts(value)
Set the EMERGE_DEFAULT_OPTS variable
Return a dict containing the new value for variable:
```
{'<variable>': {'old': '<old-value>', 'new': '<new-value>'}}
```

CLI Example:
```
salt '*' makeconf.set_emerge_default_opts '--jobs'
```

```
salt.modules.makeconf.set_gentoo_mirrors(value)
Set the GENTOO_MIRRORS variable
Return a dict containing the new value for variable:
```
{'<variable>': {'old': '<old-value>', 'new': '<new-value>'}}
```

CLI Example:
salt '*' makeconf.set_gentoo_mirrors 'http://distfiles.gentoo.org'  

```python
salt.modules.makeconf.set_makeopts(value)
    Set the MAKEOPTS variable
    Return a dict containing the new value for variable:
    ```
    ```json
    {'<variable>': {'old': '<old-value>',
                    'new': '<new-value>'}}
    ```
    
    CLI Example:
    ```bash
    salt '*' makeconf.set_makeopts '-j3'
    ```

salt.modules.makeconf.set_sync(value)
    Set the SYNC variable
    Return a dict containing the new value for variable:
    ```
    ```json
    {'<variable>': {'old': '<old-value>',
                    'new': '<new-value>'}}
    ```
    
    CLI Example:
    ```bash
    salt '*' makeconf.set_sync 'rsync://rsync.namerica.gentoo.org/gentoo-portage'
    ```

salt.modules.makeconf.set_var(var, value)
    Set a variable in the make.conf
    Return a dict containing the new value for variable:
    ```
    ```json
    {'<variable>': {'old': '<old-value>',
                    'new': '<new-value>'}}
    ```
    
    CLI Example:
    ```bash
    salt '*' makeconf.set_var 'LINGUAS' 'en'
    ```

salt.modules.makeconf.sync_contains(value)
    Verify if SYNC variable contains a value in make.conf
    Return True if value is set for var
    CLI Example:
    ```bash
    salt '*' makeconf.sync_contains 'rsync://rsync.namerica.gentoo.org/gentoo-portage'
    ```

salt.modules.makeconf.trim_cflags(value)
    Remove a value from CFLAGS variable in the make.conf
    Return a dict containing the new value for variable:
    ```
    ```json
    {'<variable>': {'old': '<old-value>',
                    'new': '<new-value>'}}
    ```
    
    CLI Example:
    ```bash
    salt '*' makeconf.trim_cflags '-pipe'
    ```

salt.modules.makeconf.trim_cxxflags(value)
    Remove a value from CXXFLAGS variable in the make.conf
Return a dict containing the new value for variable:

```
{'<variable>': {'old': '<old-value>', 'new': '<new-value>'}}
```

CLI Example:

```
salt '*' makeconf.trim_cxxflags '-pipe'
```

`salt.modules.makeconf.trim_emerge_default_opts(value)`
Remove a value from EMERGE_DEFAULT_OPTS variable in the make.conf

Return a dict containing the new value for variable:

```
{'<variable>': {'old': '<old-value>', 'new': '<new-value>'}}
```

CLI Example:

```
salt '*' makeconf.trim_emerge_default_opts '--jobs'
```

`salt.modules.makeconf.trim_features(value)`
Remove a value from FEATURES variable in the make.conf

Return a dict containing the new value for variable:

```
{'<variable>': {'old': '<old-value>', 'new': '<new-value>'}}
```

CLI Example:

```
salt '*' makeconf.trim_features 'webrsync-gpg'
```

`salt.modules.makeconf.trim_gentoo_mirrors(value)`
Remove a value from GENTOO_MIRRORS variable in the make.conf

Return a dict containing the new value for variable:

```
{'<variable>': {'old': '<old-value>', 'new': '<new-value>'}}
```

CLI Example:

```
salt '*' makeconf.trim_gentoo_mirrors 'http://distfiles.gentoo.org'
```

`salt.modules.makeconf.trim_makeopts(value)`
Remove a value from MAKEOPTS variable in the make.conf

Return a dict containing the new value for variable:

```
{'<variable>': {'old': '<old-value>', 'new': '<new-value>'}}
```

CLI Example:

```
salt '*' makeconf.trim_makeopts '-j3'
```

`salt.modules.makeconf.trim_var(var, value)`
Remove a value from a variable in the make.conf

Return a dict containing the new value for variable:
{'<variable>': {'old': '<old-value>',
    'new': '<new-value>'}}

CLI Example:
salt '*' makeconf.trim_var 'LINGUAS' 'en'

salt.modules.makeconf.var_contains(var, value)
Verify if variable contains a value in make.conf
Return True if value is set for var
CLI Example:
salt '*' makeconf.var_contains 'LINGUAS' 'en'

31.16.144 salt.modules.match

The match module allows for match routines to be run and determine target specs
salt.modules.match.compound(tgt, minion_id=None)
Return True if the minion ID matches the given compound target

minion_id Specify the minion ID to match against the target expression
  New in version 2014.7.0.
CLI Example:
salt '*' match.compound 'L@cheese,foo and *'

salt.modules.match.data(tgt)
Return True if the minion matches the given data target
CLI Example:
salt '*' match.data 'spam:eggs'

salt.modules.match.filter_by(lookup, expr_form='compound', minion_id=None)
Return the first match in a dictionary of target patterns
  New in version 2014.7.0.
CLI Example:
salt '*' match.filter_by '{foo*: Foo!, bar*: Bar!}' minion_id=bar03

Pillar Example:
{
    {% set roles = salt['match.filter_by']({'
        'web*': ['app', 'caching'],
        'db*': ['db'],
    }) %}
}

salt.modules.match.glob(tgt, minion_id=None)
Return True if the minion ID matches the given glob target

minion_id Specify the minion ID to match against the target expression
  New in version 2014.7.0.
CLI Example:

```
salt '*' match.glob '*'  
```

`salt.modules.match.grain(tgt, delimiter=':')`
Return True if the minion matches the given grain target. The `delimiter` argument can be used to specify a different delimiter.

CLI Example:

```
salt '*' match.grain 'os:Ubuntu'
salt '*' match.grain 'ipv6|2001:db8::ff00:42:8329' delimiter='|'
```

- `delimiter` Specify an alternate delimiter to use when traversing a nested dict
  - New in version 2014.7.0.
- `delim` Specify an alternate delimiter to use when traversing a nested dict
  - New in version 0.16.4.
  - Deprecated since version 2015.8.0.

`salt.modules.match.grain_pcre(tgt, delimiter=':')`
Return True if the minion matches the given grain_pcre target. The `delimiter` argument can be used to specify a different delimiter.

CLI Example:

```
salt '*' match.grain_pcre 'os:Fedo.*'
salt '*' match.grain_pcre 'ipv6|2001:.*' delimiter='|'
```

- `delimiter` Specify an alternate delimiter to use when traversing a nested dict
  - New in version 2014.7.0.
- `delim` Specify an alternate delimiter to use when traversing a nested dict
  - New in version 0.16.4.
  - Deprecated since version 2015.8.0.

`salt.modules.match.ipcidr(tgt)`
Return True if the minion matches the given ipcidr target

CLI Example:

```
salt '*' match.ipcidr '192.168.44.0/24'
```

delimiter Pillar Example:

```
'172.16.0.0/12':
  - match: ipcidr
  - nodeclass: internal
```

`salt.modules.match.list(tgt, minion_id=None)`
Return True if the minion ID matches the given list target

- `minion_id` Specify the minion ID to match against the target expression
  - New in version 2014.7.0.
CLI Example:

```bash
salt '*' match.list 'server1,server2'
```

salt.modules.match.pcre(tgt, minion_id=None)

Return True if the minion ID matches the given pcre target

- `minion_id`: Specify the minion ID to match against the target expression

  New in version 2014.7.0.

CLI Example:

```bash
salt '*' match.pcre '.*'
```

salt.modules.match.pillar(tgt, delimiter=': ')

Return True if the minion matches the given pillar target. The `delimiter` argument can be used to specify a different delimiter.

CLI Example:

```bash
salt '*' match.pillar 'cheese:foo'

salt '*' match.pillar 'clone_url|https://github.com/saltstack/salt.git' delimiter='|'
```

- `delimiter`: Specify an alternate delimiter to use when traversing a nested dict

  New in version 2014.7.0.

- `delim`: Specify an alternate delimiter to use when traversing a nested dict

  New in version 0.16.4.

  Deprecated since version 2015.8.0.

salt.modules.match.pillar_pcre(tgt, delimiter=': ')

Return True if the minion matches the given pillar_pcre target. The `delimiter` argument can be used to specify a different delimiter.

CLI Example:

```bash
salt '*' match.pillar_pcre 'cheese:(swiss|american)'

salt '*' match.pillar_pcre 'clone_url|https://github\.com/.*\.git' delimiter='|'
```

- `delimiter`: Specify an alternate delimiter to use when traversing a nested dict

  New in version 2014.7.0.

- `delim`: Specify an alternate delimiter to use when traversing a nested dict

  New in version 0.16.4.

  Deprecated since version 2015.8.0.

31.16.145 salt.modules.mdadm

Salt module to manage RAID arrays with mdadm

salt.modules.mdadm.assemble(name, devices, test_mode=False, **kwargs)

Assemble a RAID device.

CLI Examples:
raid.assemble

### Parameters

- **name**: The name of the array to assemble.
- **devices**: The list of devices comprising the array to assemble.
- **kwargs**: Optional arguments to be passed to mdadm.

### Returns

- **test_mode=True**: Prints out the full command.
- **test_mode=False (Default)**: Executes command on the host(s) and prints out the mdadm output.

For more info, read the `mdadm` manpage.

```python
salt.modules.mdadm.create(name, level, devices, metadata='default', test_mode=False, **kwargs)
```

Create a RAID device.

Changed in version 2014.7.0.

**Warning**: Use with CAUTION, as this function can be very destructive if not used properly!

### CLI Examples:

```bash
salt '*' raid.create /dev/md0 level=1 chunk=256 devices="['/dev/xvdd', '/dev/xvde']" test_mode=True
```

Note: Adding `test_mode=True` as an argument will print out the mdadm command that would have been run.

### Parameters

- **name**: The name of the array to create.
- **level**: The RAID level to use when creating the raid.
- **devices**: A list of devices used to build the array.
- **metadata**: Version of metadata to use when creating the array.
- **kwargs**: Optional arguments to be passed to mdadm.

### Returns

- **test_mode=True**: Prints out the full command.
- **test_mode=False (Default)**: Executes command on remote the host(s) and Prints out the mdadm output.

Note: It takes time to create a RAID array. You can check the progress in `resync_status:` field of the results from the following command:

```bash
salt '*' raid.detail /dev/md0
```

For more info, read the `mdadm(8)` manpage.
salt.modules.mdadm.destroy(device)
    Destroy a RAID device.
    WARNING: This will zero the superblock of all members of the RAID array.
    CLI Example:
    ```
    salt '*' raid.destroy /dev/md0
    ```

salt.modules.mdadm.detail(device='/dev/md0')
    Show detail for a specified RAID device
    CLI Example:
    ```
    salt '*' raid.detail '/dev/md0'
    ```

salt.modules.mdadm.list()
    List the RAID devices.
    CLI Example:
    ```
    salt '*' raid.list
    ```

salt.modules.mdadm.save_config()
    Save RAID configuration to config file.
    Same as: mdadm --detail --scan >> /etc/mdadm/mdadm.conf
    Fixes this issue with Ubuntu REF: http://askubuntu.com/questions/209702/why-is-my-raid-dev-md1-showing-up-as-dev-md126-is-mdadm-conf-being-ignored
    CLI Example:
    ```
    salt '*' raid.save_config
    ```

salt.modules.mdadm.stop()
    Shut down all arrays that can be shut down (i.e. are not currently in use).
    CLI Example:
    ```
    salt '*' raid.stop
    ```

31.16.146 salt.modules.memcached

Module for Management of Memcached Keys
New in version 2014.1.0.

salt.modules.memcached.add(key, value, host='127.0.0.1', port=11211, time=0, min_compress_len=0)
    Add a key to the memcached server, but only if it does not exist. Returns False if the key already exists.
    CLI Example:
    ```
    salt '*' memcached.add <key> <value>
    ```

salt.modules.memcached.decrement(key, delta=1, host='127.0.0.1', port=11211)
    Decrement the value of a key
    CLI Example:
    ```
    salt '*' memcached.decrement <key>
    ```
    ```
    salt '*' memcached.decrement <key> 2
    ```

31.16. Full list of builtin execution modules
salt.modules.memcached.delete(key, host='127.0.0.1', port=11211, time=0)
Delete a key from memcache server
   CLI Example:
   
   salt '*' memcached.delete <key>

salt.modules.memcached.get(key, host='127.0.0.1', port=11211)
Retrieve value for a key
   CLI Example:
   
   salt '*' memcached.get <key>

salt.modules.memcached.increment(key, delta=1, host='127.0.0.1', port=11211)
Increment the value of a key
   CLI Example:
   
   salt '*' memcached.increment <key>
salt '*' memcached.increment <key> 2

salt.modules.memcached.replace(key, value, host='127.0.0.1', port=11211, time=0, min_compress_len=0)
Replace a key on the memcached server. This only succeeds if the key already exists. This is the opposite of memcached.add
   CLI Example:
   
   salt '*' memcached.replace <key> <value>

salt.modules.memcached.set(key, value, host='127.0.0.1', port=11211, time=0, min_compress_len=0)
Set a key on the memcached server, overwriting the value if it exists.
   CLI Example:
   
   salt '*' memcached.set <key> <value>

salt.modules.memcached.status(host='127.0.0.1', port=11211)
Get memcached status
   CLI Example:
   
   salt '*' memcached.status

31.16.147 salt.modules.mine
The function cache system allows for data to be stored on the master so it can be easily read by other minions

salt.modules.mine.delete(fun)
Remove specific function contents of minion. Returns True on success.
   CLI Example:
   
   salt '*' mine.delete 'network.interfaces'

salt.modules.mine.flush()
Remove all mine contents of minion. Returns True on success.
   CLI Example:
salt '/*' mine.flush

salt.modules.mine.get(tgt, fun, expr_form='glob')
Get data from the mine based on the target, function and expr_form

Targets can be matched based on any standard matching system that can be matched on the master via these keywords:

- glob
- pcre
- grain
- grain_pcre
- compound
- pillar
- pillar_pcre

Note that all pillar matches, whether using the compound matching system or the pillar matching system, will be exact matches, with globbing disabled.

CLI Example:

salt '/*' mine.get '/*' network.interfaces
salt '/*' mine.get 'os:Fedora' network.interfaces grain
salt '/*' mine.get 'os:Fedora and S@192.168.5.0/24' network.ipaddrs compound

salt.modules.mine.get_docker(interfaces=None, cidrs=None)
Get all mine data for `docker.get_containers' and run an aggregation routine. The `interfaces' parameter allows for specifying which network interfaces to select ip addresses from. The `cidrs' parameter allows for specifying a list of cidrs which the ip address must match.

CLI Example:

salt '/*' mine.get_docker
salt '/*' mine.get_docker interfaces='eth0'
salt '/*' mine.get_docker interfaces=['eth0', 'eth1']
salt '/*' mine.get_docker cidrs='107.170.147.0/24'
salt '/*' mine.get_docker cidrs=['107.170.147.0/24', '172.17.42.0/24']
salt '/*' mine.get_docker interfaces=['eth0', 'eth1'] cidrs=['107.170.147.0/24', '172.17.42.0/24']

salt.modules.mine.send(func, *args, **kwargs)
Send a specific function to the mine.

CLI Example:

salt '/*' mine.send network.ip_addrs eth0
salt '/*' mine.send eth0_ip_addrs mine_function=network.ip_addrs eth0

salt.modules.mine.update(clear=False)
Execute the configured functions and send the data back up to the master. The functions to be executed are merged from the master config, pillar and minion config under the option `function_cache':

mine_functions:
  network.ip_addrs:
    - eth0
disk.usage: []

The function cache will be populated with information from executing these functions.

CLI Example:
31.16.148 salt.modules.mod_random

New in version 2014.7.0.
Provides access to randomness generators.

salt.modules.mod_random.get_str(length=20)
New in version 2014.7.0.
Returns a random string of the specified length.
length  [20] Any valid number of bytes.

CLI Example:
```
salt '*' random.get_str 128
```

salt.modules.mod_random.hash(value, algorithm='sha512')
New in version 2014.7.0.
Encodes a value with the specified encoder.
value  The value to be hashed.
algorithm  [sha512] The algorithm to use. May be any valid algorithm supported by hashlib.

CLI Example:
```
salt '*' random.hash 'I am a string' md5
```

salt.modules.mod_random.rand_int(start=1, end=10)
Returns a random integer number between the start and end number.
start  [1] Any valid integer number
end  [10] Any valid integer number

CLI Example:
```
salt '*' random.rand_int 1 10
```

salt.modules.mod_random.seed(range=10, hash=None)
Returns a random number within a range. Optional hash argument can be any hashable object. If hash is omitted or None, the id of the minion is used.
hash: None  Any hashable object.
range: 10  Any valid integer number

CLI Example:
```
salt '*' random.seed 10 hash=None
```

salt.modules.mod_random.shadow_hash(crypt_salt=None, password=None, algorithm='sha512')
Generates a salted hash suitable for /etc/shadow.
crypt_salt  [None] Salt to be used in the generation of the hash. If one is not provided, a random salt will be generated.
password  [None] Value to be salted and hashed. If one is not provided, a random password will be generated.
algorithm  [sha512] Hash algorithm to use.
CLI Example:

```python
salt '*' random.shadow_hash 'My5alt' 'MyP@sswd' md5
```

```python
salt.modules.mod_random.str_encode(value, encoder='base64')
```

New in version 2014.7.0.

```
value: The value to be encoded.
encoder: [base64] The encoder to use on the subsequent string.
```

CLI Example:

```python
salt '*' random.str_encode 'I am a new string' base64
```

### 31.16.149 salt.modules.modjk

Below is an example of the configuration needed for this module. This configuration data can be placed either in *grains* or *pillar*.

If using grains, this can be accomplished *statically* or via a *grain module*.

If using pillar, the yaml configuration can be placed directly into a pillar SLS file, making this both the easier and more dynamic method of configuring this module.

```yaml
modjk:
  default:
    url: http://localhost/jkstatus
    user: modjk
    pass: secret
    realm: authentication realm for digest passwords
    timeout: 5
  otherVhost:
    url: http://otherVhost/jkstatus
    user: modjk
    pass: secret2
    realm: authentication realm2 for digest passwords
    timeout: 600
```

```python
salt.modules.modjk.bulk_activate(workers, lb, profile='default')
```

Activate all the given workers in the specific load balancer

CLI Examples:

```python
salt '*' modjk.bulk_activate node1,node2,node3 loadbalancer1
salt '*' modjk.bulk_activate node1,node2,node3 loadbalancer1 other-profile
```

```python
salt '*' modjk.bulk_activate ["node1","node2","node3"] loadbalancer1
salt '*' modjk.bulk_activate ["node1","node2","node3"] loadbalancer1 other-profile
```

```python
salt.modules.modjk.bulk_disable(workers, lb, profile='default')
```

Disable all the given workers in the specific load balancer

CLI Examples:

```python
salt '*' modjk.bulk_disable node1,node2,node3 loadbalancer1
salt '*' modjk.bulk_disable node1,node2,node3 loadbalancer1 other-profile
```
salt '*/' modjk.bulk_disable "['node1','node2','node3']" loadbalancer1
salt '*/' modjk.bulk_disable "['node1','node2','node3']" loadbalancer1 other-profile

salt.modules.modjk.bulk_recover(\'workers, lbn, profile='default'\')
Recover all the given workers in the specific load balancer

CLI Examples:
salt '*/' modjk.bulk_recover node1,node2,node3 loadbalancer1
salt '*/' modjk.bulk_recover node1,node2,node3 loadbalancer1 other-profile
salt '*/' modjk.bulk_recover "['node1','node2','node3']" loadbalancer1
salt '*/' modjk.bulk_recover "['node1','node2','node3']" loadbalancer1 other-profile

salt.modules.modjk.bulk_stop(\'workers, lbn, profile='default'\')
Stop all the given workers in the specific load balancer

CLI Examples:
salt '*/' modjk.bulk_stop node1,node2,node3 loadbalancer1
salt '*/' modjk.bulk_stop node1,node2,node3 loadbalancer1 other-profile
salt '*/' modjk.bulk_stop "['node1','node2','node3']" loadbalancer1
salt '*/' modjk.bulk_stop "['node1','node2','node3']" loadbalancer1 other-profile

salt.modules.modjk.dump_config(\'profile='default'\')
Dump the original configuration that was loaded from disk

CLI Examples:
salt '*/' modjk.dump_config
salt '*/' modjk.dump_config other-profile

salt.modules.modjk.get_running(\'profile='default'\')
Get the current running config (not from disk)

CLI Examples:
salt '*/' modjk.get_running
salt '*/' modjk.get_running other-profile

salt.modules.modjk.lb_edit(\'lbn, settings, profile='default'\')
Edit the loadbalancer settings

Note: http://tomcat.apache.org/connectors-doc/reference/status.html Data Parameters for the standard Update Action

CLI Examples:
salt '*/' modjk.lb_edit loadbalancer1 "{"vlr": 1, 'vlt': 60}"s
alt '*/' modjk.lb_edit loadbalancer1 "{"vlr": 1, 'vlt': 60}" other-profile

salt.modules.modjk.list_configured_members(\'lbn, profile='default'\')
Return a list of member workers from the configuration files

CLI Examples:
salt '*/' modjk.list_configured_members loadbalancer1
salt '*/' modjk.list_configured_members loadbalancer1 other-profile
salt.modules.modjk.recover_all(lbn, profile='default')
Set the all the workers in lbn to recover and activate them if they are not

CLI Examples:
```
salt '*' modjk.recover_all loadbalancer1
salt '*' modjk.recover_all loadbalancer1 other-profile
```

salt.modules.modjk.reset_stats(lbn, profile='default')
Reset all runtime statistics for the load balancer

CLI Examples:
```
salt '*' modjk.reset_stats loadbalancer1
salt '*' modjk.reset_stats loadbalancer1 other-profile
```

salt.modules.modjk.version(profile='default')
Return the modjk version

CLI Examples:
```
salt '*' modjk.version
salt '*' modjk.version other-profile
```

salt.modules.modjk.worker_activate(worker, lbn, profile='default')
Set the worker to activate state in the lbn load balancer

CLI Examples:
```
salt '*' modjk.worker_activate node1 loadbalancer1
salt '*' modjk.worker_activate node1 loadbalancer1 other-profile
```

salt.modules.modjk.worker_disable(worker, lbn, profile='default')
Set the worker to disable state in the lbn load balancer

CLI Examples:
```
salt '*' modjk.worker_disable node1 loadbalancer1
salt '*' modjk.worker_disable node1 loadbalancer1 other-profile
```

salt.modules.modjk.worker_edit(worker, lbn, settings, profile='default')
Edit the worker settings

CLI Examples:
```
salt '*' modjk.worker_edit node1 loadbalancer1 '{vwf: 500, vwd: 60}'
salt '*' modjk.worker_edit node1 loadbalancer1 '{vwf: 500, vwd: 60}' other-profile
```

salt.modules.modjk.worker_recover(worker, lbn, profile='default')
Set the worker to recover this module will fail if it is in OK state

CLI Examples:
```
salt '*' modjk.worker_recover node1 loadbalancer1
salt '*' modjk.worker_recover node1 loadbalancer1 other-profile
```

salt.modules.modjk.worker_status(worker, profile='default')
Return the state of the worker

CLI Examples:
salt '*/' modjk.worker_status node1
salt '*/' modjk.worker_status node1 other-profile

salt.modules.modjk.worker_stop(worker, lbn, profile='default')
Set the worker to stopped state in the lbn load balancer

CLI Examples:
salt '*/' modjk.worker_activate node1 loadbalancer1
salt '*/' modjk.worker_activate node1 loadbalancer1 other-profile

salt.modules.modjk.workers(profile='default')
Return a list of member workers and their status

CLI Examples:
salt '*/' modjk.workers
salt '*/' modjk.workers other-profile

31.16.150 salt.modules.mongodb

Module to provide MongoDB functionality to Salt

**configuration** This module uses PyMongo, and accepts configuration details as parameters as well as
configuration settings:

- `mongodb.host`: 'localhost'
- `mongodb.port`: 27017
- `mongodb.user`: ''
- `mongodb.password`: ''

This data can also be passed into pillar. Options passed into opts will overwrite options passed into
pillar.

salt.modules.mongodb.db_exists(name, user=None, password=None, host=None, port=None)
Checks if a database exists in Mongodb

CLI Example:
salt '*/' mongodb.db_exists <name> <user> <password> <host> <port>

salt.modules.mongodb.db_list(user=None, password=None, host=None, port=None)
List all Mongodb databases

CLI Example:
salt '*/' mongodb.db_list <user> <password> <host> <port>

salt.modules.mongodb.db_remove(name, user=None, password=None, host=None, port=None)
Remove a Mongodb database

CLI Example:
salt '*/' mongodb.db_remove <name> <user> <password> <host> <port>

salt.modules.mongodb.find(collection, query=None, user=None, password=None, host=None, port=None, database='admin')
salt.modules.mongodb.insert(objects, collection, user=None, password=None, host=None, port=None, database='admin')

Insert an object or list of objects into a collection

CLI Example:

    salt '*' mongodb.insert '[["foo": "FOO", "bar": "BAR"], {"foo": "BAZ", "bar": "BAM"}]' mycollection

salt.modules.mongodb.remove(collection, query=None, user=None, password=None, host=None, port=None, database='admin', w=1)

Remove an object or list of objects into a collection

CLI Example:

    salt '*' mongodb.remove mycollection '[["foo": "FOO", "bar": "BAR"], {"foo": "BAZ", "bar": "BAM"}]

salt.modules.mongodb.user_create(name, passwd, user=None, password=None, host=None, port=None, database='admin')

Create a Mongodb user

CLI Example:

    salt '*' mongodb.user_create <name> <user> <password> <host> <port> <database>

salt.modules.mongodb.user_exists(name, user=None, password=None, host=None, port=None, database='admin')

Checks if a user exists in Mongodb

CLI Example:

    salt '*' mongodb.user_exists <name> <user> <password> <host> <port> <database>

salt.modules.mongodb.user_grant_roles(name, roles, database, user=None, password=None, host=None, port=None)

Grant one or many roles to a Mongodb user

CLI Examples:

    salt '*' mongodb.user_grant_roles johndoe ['"readWrite"'] dbname admin adminpwd localhost 27017
    salt '*' mongodb.user_grant_roles janedoe ['"role": "readWrite", "db": "dbname"'], {"role": "read", "db": "otherdb"} dbname admin adminpwd localhost 27017

salt.modules.mongodb.user_list(user=None, password=None, host=None, port=None, database='admin')

List users of a Mongodb database

CLI Example:

    salt '*' mongodb.user_list <user> <password> <host> <port> <database>

salt.modules.mongodb.user_remove(name, user=None, password=None, host=None, port=None, database='admin')

Remove a Mongodb user

CLI Example:

    salt '*' mongodb.user_remove <name> <user> <password> <host> <port> <database>

salt.modules.mongodb.user_revoke_roles(name, roles, database, user=None, password=None, host=None, port=None)

Revoke one or many roles to a Mongodb user

CLI Examples:
salt '*' mongodb.user_revoke_roles johndoe "["readWrite"]" dbname admin adminpwd localhost 27017
salt '*' mongodb.user_revoke_roles janedoe "{"role": "readWrite", "db": "dbname"}" dbname admin adminpwd localhost 27017

salt.modules.mongodb.user_roles_exists(name, roles, database, user=None, password=None, host=None, port=None)
Checks if a user of a Mongodbdatabase has specified roles

CLI Examples:
salt '*' mongodb.user_roles_exists johndoe "["readWrite"]" dbname admin adminpwd localhost 27017
salt '*' mongodb.user_roles_exists johndoe "{"role": "readWrite", "db": "dbname"}" dbname admin adminpwd localhost 27017

salt.modules.monit
Monit service module. This module will create a monit typeservicewatcher.
salt.modules.monit.monitor(name)
monitor service via monit

   CLI Example:
   salt '*' monit.monitor <service name>

salt.modules.monit.restart(name)
Restart service via monit

   CLI Example:
   salt '*' monit.restart <service name>

salt.modules.monit.start(name)

   CLI Example:
   salt '*' monit.start <service name>

salt.modules.monit.status(svc_name='')
Display a process status from monit

   CLI Example:
   salt '*' monit.status
salt '*' monit.status <service name>

salt.modules.monit.stop(name)
Stopsservice via monit

   CLI Example:
   salt '*' monit.stop <service name>

salt.modules.monit.summary(svc_name='')
Display a summary from monit

   CLI Example:
   salt '*' monit.summary
salt '*' monit.summary <service name>
s.a1.modules.moni1.unmon1i1or(name)
    Unmonitorserviceviamonit
    CLIExample:
        salt '* monit.unmonitor <service name>

31.16.152 salt.modules.moosefs
ModuleforgatheringandmanaginginformationaboutMooseFS
s.a1.modules.moosefs.dirinfo(path, opts=None)
    ReturninformationonadirectorylocatedontheMoose
    CLIExample:
        salt '*' moosefs.dirinfo /path/to/dir/ [-n][h|H]]

s.a1.modules.moosefs.fileinfo(path)
    ReturninformationonafilelocatedontheMoose
    CLIExample:
        salt '*' moosefs.fileinfo /path/to/dir/

s.a1.modules.moosefs.getgoal(path, opts=None)
    Returngoalsforafileordirectory
    CLIExample:
        salt '*' moosefs.getgoal /path/to/file [-n][h|H]]
        salt '*' moosefs.getgoal /path/to/dir/ [-n][h|H][r]

s.a1.modules.moosefs.mounts()
    ReturnalistofcurrentMooseFSmounts
    CLIExample:
        salt '*' moosefs.mounts

31.16.153 salt.modules.mount
SaltmoduletoManagunixmountsandthefstabfile
s.a1.modules.mount.active(extended=False)
    Listtheactivemounts.
    CLIExample:
        salt '*' mount.active

s.a1.modules.mount.automaster(config='/etc/auto_salt')
    Listthecontentsofthefstab
    CLIExample:
        salt '*' mount.fstab
salt.modules.mount.fstab(config='/etc/fstab')
   List the contents of the fstab
   CLI Example:
   ```python
   salt '*' mount.fstab
   ```

salt.modules.mount.is_fuse_exec(cmd)
   Returns true if the command passed is a fuse mountable application.
   CLI Example:
   ```python
   salt '*' mount.is_fuse_exec sshfs
   ```

salt.modules.mount.is_mounted(name)
   New in version 2014.7.0.
   Provide information if the path is mounted
   CLI Example:
   ```python
   salt '*' mount.is_mounted /mnt/share
   ```

salt.modules.mount.mount(name, device, mkmnt=False, fstype='*', opts='defaults', user=None)
   Mount a device
   CLI Example:
   ```python
   salt '*' mount.mount /mnt/foo /dev/sdz1 True
   ```

salt.modules.mount.remount(name, device, mkmnt=False, fstype='*', opts='defaults', user=None)
   Attempt to remount a device, if the device is not already mounted, mount is called
   CLI Example:
   ```python
   salt '*' mount.remount /mnt/foo /dev/sdz1 True
   ```

salt.modules.mount.rm_automaster(name, device, config='/etc/auto_salt')
   Remove the mount point from the auto_master
   CLI Example:
   ```python
   salt '*' mount.rm_automaster /mnt/foo
   ```

salt.modules.mount.rm_fstab(name, device, config='/etc/fstab')
   Remove the mount point from the fstab
   CLI Example:
   ```python
   salt '*' mount.rm_fstab /mnt/foo
   ```

salt.modules.mount.set_automaster(name, device, fstype, opts='*', config='/etc/auto_salt', test=False, **kwargs)
   Verify that this mount is represented in the auto_salt, change the mount to match the data passed, or add the mount if it is not present.
   CLI Example:
   ```python
   salt '*' mount.set_automaster /mnt/foo /dev/sdz1 ext4
   ```

salt.modules.mount.set_fstab(name, device, fstype, opts='defaults', dump=0, pass_num=0, config='/etc/fstab', test=False, match_on='auto', **kwargs)
   Verify that this mount is represented in the fstab, change the mount to match the data passed, or add the mount if it is not present.
CLI Example:
```
salt '*' mount.set_fstab /mnt/foo /dev/sdz1 ext4
```

```
salt.modules.mount.swapoff(name)
    Deactivate a named swap mount
```

CLI Example:
```
salt '*' mount.swapoff /root/swapfile
```

```
salt.modules.mount.swapon(name, priority=None)
    Activate a swap disk
```

CLI Example:
```
salt '*' mount.swapon /root/swapfile
```

```
salt.modules.mount.swaps()
    Return a dict containing information on active swap
```

CLI Example:
```
salt '*' mount.swaps
```

```
salt.modules.mount.umount(name, device=None, user=None)
    Attempt to umount a device by specifying the directory it is mounted on
```

CLI Example:
```
salt '*' mount.umount /mnt/foo
```

```
salt '*' mount.umount /mnt/foo /dev/xvdc1
```

---

31.16.154 salt.modules.mssql

Module to provide MS SQL Server compatibility to salt.

**depends**
- FreeTDS
- pymssql Python module

**configuration** In order to connect to MS SQL Server, certain configuration is required in minion configs/pillars on the relevant minions. Some sample pillars might look like:

```
mssql.server: 'localhost'
mssql.port: 1433
mssql.user: 'sysdba'
mssql.password: 'Some preferable complex password'
mssql.database: ''
```

The default for the port is `1433` and for the database is `''` (empty string); in most cases they can be left at the default setting. Options that are directly passed into functions will overwrite options from configs or pillars.
<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
<th>CLI Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>salt.modules.mssql.db_exists(database_name, **kwargs)</td>
<td>Find if a specific database exists on the MS SQL server.</td>
<td><code>salt minion mssql.db_exists database_name='DBNAME'</code></td>
</tr>
<tr>
<td>salt.modules.mssql.db_list(**kwargs)</td>
<td>Return the database list created on a MS SQL server.</td>
<td><code>salt minion mssql.db_list</code></td>
</tr>
<tr>
<td>salt.modules.mssql.db_remove(database_name, **kwargs)</td>
<td>Drops a specific database from the MS SQL server. It will not drop any of 'master', 'model', 'msdb' or 'tempdb'.</td>
<td><code>salt minion mssql.db_remove database_name='DBNAME'</code></td>
</tr>
<tr>
<td>salt.modules.mssql.login_exists(login, **kwargs)</td>
<td>Find if a login exists in the MS SQL server.</td>
<td><code>salt minion mssql.login_exists 'LOGIN'</code></td>
</tr>
<tr>
<td>salt.modules.mssql.role_create(role, owner=None, **kwargs)</td>
<td>Creates a new database role. If no owner is specified, the role will be owned by the user that executes CREATE ROLE, which is the user argument or mssql.user option.</td>
<td><code>salt minion mssql.role_create role=product01 owner=sysdba</code></td>
</tr>
<tr>
<td>salt.modules.mssql.role_exists(role, **kwargs)</td>
<td>Checks if a role exists.</td>
<td><code>salt minion mssql.role_exists db_owner</code></td>
</tr>
<tr>
<td>salt.modules.mssql.role_list(**kwargs)</td>
<td>Lists database roles.</td>
<td><code>salt minion mssql.role_list</code></td>
</tr>
<tr>
<td>salt.modules.mssql.role_remove(role, **kwargs)</td>
<td>Remove a database role.</td>
<td><code>salt minion mssql.role_remove role=test_role01</code></td>
</tr>
<tr>
<td>salt.modules.mssql.tsql_query(query, **kwargs)</td>
<td>Run a SQL query and return query result as list of tuples, or a list of dictionaries if as_dict was passed, or an empty list if no data is available.</td>
<td><code>salt minion mssql.tsql_query</code></td>
</tr>
</tbody>
</table>
salt minion mssql.tsql_query 'SELECT @@version as version' as_dict=True

salt.modules.mssql.user_create(username, new_login_password=None, **kwargs)
    Creates a new user. If new_login_password is not specified, the user will be created without a login.
    CLI Example:
    salt minion mssql.user_create USERNAME database=DBNAME [new_login_password=PASSWORD]

salt.modules.mssql.user_exists(username, **kwargs)
    Find if an user exists in a specific database on the MS SQL server.
    Note: database argument is mandatory
    CLI Example:
    salt minion mssql.user_exists 'USERNAME' [database='DBNAME']

salt.modules.mssql.user_list(**kwargs)
    Get the user list for a specific database on the MS SQL server.
    CLI Example:
    salt minion mssql.user_list [database='DBNAME']

salt.modules.mssql.user_remove(username, **kwargs)
    Removes an user.
    CLI Example:
    salt minion mssql.user_remove USERNAME database=DBNAME

salt.modules.mssql.version(**kwargs)
    Return the version of a MS SQL server.
    CLI Example:
    salt minion mssql.version

31.16.155 salt.modules.munin

Run munin plugins/checks from salt and format the output as data.

salt.modules.munin.list_plugins()
    List all the munin plugins
    CLI Example:
    salt '*' munin.list_plugins

salt.modules.munin.run(plugins)
    Run one or more named munin plugins
    CLI Example:
    salt '*' munin.run uptime
    salt '*' munin.run uptime,cpu,load,memory

salt.modules.munin.run_all()
    Run all the munin plugins
CLI Example:
```
salt '*' munin.run_all
```

31.16.156 salt.modules.mysql

Module to provide MySQL compatibility to salt.

depends
- MySQLdb Python module

Note: On CentOS 5 (and possibly RHEL 5) both MySQL-python and python26-mysqldb need to be installed.

configuration

In order to connect to MySQL, certain configuration is required in /etc/salt/minion on the relevant minions. Some sample configs might look like:

```
mysql.host: 'localhost'
mysql.port: 3306
mysql.user: 'root'
mysql.pass: ''
mysql.db: 'mysql'
mysql.unix_socket: '/tmp/mysql.sock'
mysql.charset: 'utf8'
```

You can also use a defaults file:
```
mysql.default_file: '/etc/mysql/debian.cnf'
```

Changed in version 2014.1.0: charset connection argument added. This is a MySQL charset, not a python one

Changed in version 0.16.2: Connection arguments from the minion config file can be overridden on the CLI by using the arguments defined here. Additionally, it is now possible to setup a user with no password.

salt.modules.mysql.db_check(name, table=None, **connection_args)

Repairs the full database or just a given table

CLI Example:
```
salt '* mysql.db_check dbname
salt '* mysql.db_check dbname dbtable
```

salt.modules.mysql.db_create(name, character_set=None, collate=None, **connection_args)

Adds a databases to the MySQL server.

name  The name of the database to manage
character_set  The character set, if left empty the MySQL default will be used
collate  The collation, if left empty the MySQL default will be used

CLI Example:
```
salt '* mysql.db_create dbname
salt '* mysql.db_create dbname utf8 utf8_general_ci'
```

salt.modules.mysql.db_exists(name, **connection_args)

Checks if a database exists on the MySQL server.

CLI Example:
salt '(*' mysql.db_exists 'dbname'

salt.modules.mysql.db_list(**connection_args)
    Return a list of databases of a MySQL server using the output from the SHOW DATABASES query.
    CLI Example:
    salt '(*' mysql.db_list

salt.modules.mysql.db_optimize(name, table=none, **connection_args)
    Optimizes the full database or just a given table
    CLI Example:
    salt '(*' mysql.db_optimize dbname

salt.modules.mysql.db_remove(name, **connection_args)
    Removes a databases from the MySQL server.
    CLI Example:
    salt '(*' mysql.db_remove 'dbname'

salt.modules.mysql.db_repair(name, table=none, **connection_args)
    Repairs the full database or just a given table
    CLI Example:
    salt '(*' mysql.db_repair dbname

salt.modules.mysql.db_tables(name, **connection_args)
    Shows the tables in the given MySQL database (if exists)
    CLI Example:
    salt '(*' mysql.db_tables 'database'

salt.modules.mysql.free_slave(**connection_args)
    Frees a slave from its master. This is a WIP, do not use.
    CLI Example:
    salt '(*' mysql.free_slave

salt.modules.mysql.get_master_status(**connection_args)
    Retrieves the master status from the minion.
    Returns:
    {
    'host.domain.com': {
    'Binlog_Do_DB': '','',
    'Binlog_Ignore_DB': '',''
    'File': 'mysql-bin.000021','
    'Position': '107'}
    }
    CLI Example:
    salt '(*' mysql.get_master_status

salt.modules.mysql.get_slave_status(**connection_args)
    Retrieves the slave status from the minion.
    Returns:
CLI Example:
```
salt '*' mysql.get_slave_status
```

salt.modules.mysql.grant_add(grant, database, user, host='localhost', grant_option=False, escape=True, ssl_option=False, **connection_args)

Adds a grant to the MySQL server.

For database, make sure you specify database.table or database.*

CLI Example:
```
salt '*' mysql.grant_add  
SELECT,INSERT,UPDATE,...  'database.*'  'frank'  'localhost'
```

salt.modules.mysql.grant_exists(grant, database, user, host='localhost', grant_option=False, escape=True, **connection_args)

Checks to see if a grant exists in the database

CLI Example:
salt 'mysql.grant_exists' "SELECT,INSERT,UPDATE,...' 'database.*' 'frank' 'localhost'

salt.modules.mysql.grant_revoke(grant, database, user, host='localhost', grant_option=False, escape=True, **connection_args)

Removes a grant from the MySQL server.

CLI Example:
salt '*' mysql.grant_revoke 'SELECT,INSERT,UPDATE' 'database.*' 'frank' 'localhost'

salt.modules.mysql.processlist(**connection_args)
Retrieves the processlist from the MySQL server via `SHOW FULL PROCESSLIST`.

Returns: a list of dicts, with each dict representing a process:

```py
{
    'Command': 'Query',
    'Host': 'localhost',
    'Id': 39,
    'Info': 'SHOW FULL PROCESSLIST',
    'Rows_examined': 0,
    'Rows_read': 1,
    'Rows_sent': 0,
    'State': None,
    'Time': 0,
    'User': 'root',
    'db': 'mysql'
}
```

CLI Example:
salt '*' mysql.processlist

salt.modules.mysql.query(database, query, **connection_args)
Run an arbitrary SQL query and return the results or the number of affected rows.

CLI Example:
salt '*' mysql.query mydb "UPDATE mytable set myfield=1 limit 1"

Return data:

```json
{"query time": {"human": '39.0ms', 'raw': '0.03899'}, 'rows affected': 1L}
```

CLI Example:
salt '*' mysql.query mydb "SELECT id,name,cash from users limit 3"

Return data:

```json
{"columns": ('id', 'name', 'cash'),
 'query time': {"human": '1.0ms', 'raw': '0.001'},
 'results': ((1L, 'User 1', Decimal('110.000000')),
 (2L, 'User 2', Decimal('215.636756')),
 (3L, 'User 3', Decimal('0.040000'))),
 'rows returned': 3L}
```

CLI Example:
salt '*' mysql.query mydb 'INSERT into users values (null,"user 4", 5)'

Return data:

```json
{"query time": {"human": '25.6ms', 'raw': '0.02563'}, 'rows affected': 1L}
```

CLI Example:
salt '*' mysql.query mydb 'DELETE from users where id = 4 limit 1'

Return data:
{'query time': {'human': '39.0ms', 'raw': '0.03899'}, 'rows affected': 1L}

Jinja Example: Run a query on mydb and use row 0, column 0's data.

```{%
  salt['mysql.query']('mydb', 'SELECT info from mytable limit 1')['results'][0][0]
%
```

salt.modules.mysql.quote_identifier(identifier, for_grants=False)

Return an identifier name (column, table, database, etc) escaped for MySQL.

This means surrounded by ```'' character and escaping this character inside. It also means doubling the `%' character for MySQL db internal usage.

**Parameters**

- **identifier** -- the table, column or database identifier
- **for_grants** -- is False by default, when using database names on grant queries you should set it to True to also escape ````` and ```%``` characters as requested by MySQL. Note that these characters should only be escaped when requesting grants on the database level (`my_%db`) but not for table level grants (`my_%db.`foo`)

CLI Example:

```salt '*' mysql.quote_identifier 'foo`bar'
```

salt.modules.mysql.showglobal(**connection_args)**

Retrieves the show global variables from the minion.

**Returns**: show global variables full dict

CLI Example:

```salt '*' mysql.showglobal
```

salt.modules.mysql.showvariables(**connection_args)**

Retrieves the show variables from the minion.

**Returns**: show variables full dict

CLI Example:

```salt '*' mysql.showvariables
```

salt.modules.mysql.slave_lag(**connection_args)**

Return the number of seconds that a slave SQL server is lagging behind the master, if the host is not a slave it will return -1. If the server is configured to be a slave for replication but slave IO is not running then -2 will be returned. If there was an error connecting to the database or checking the slave status, -3 will be returned.

CLI Example:

```salt '*' mysql.slave_lag
```

salt.modules.mysql.status(**connection_args)**

Return the status of a MySQL server using the output from the SHOW STATUS query.

CLI Example:

```salt '*' mysql.status
```

salt.modules.mysql.tokenize_grant(grant)

External wrapper function :param grant: :return: dict

CLI Example:
salt 'localhost' mysql.tokenize_grant

```
GRANT SELECT, INSERT ON testdb.* TO 'testuser'@'localhost'
```

salt.modules.mysql.user_chpass(user, host='localhost', password=None, password_hash=None, allow_passwordless=False, unix_socket=None, **connection_args)

Change password for a MySQL user

host Host for which this user/password combo applies

password The password to set for the new user. Will take precedence over the password_hash option if both are specified.

password_hash The password in hashed form. Be sure to quote the password because YAML doesn’t like the `*`. A password hash can be obtained from the `mysql` command-line client like so:

```
mysql> SELECT PASSWORD('mypass');
+-------------------------------------------+
| PASSWORD('mypass')                     |
+-------------------------------------------+
| *6C8989366EAF75BB670AD8EA7A7FC1176A95CEF4 |
+-------------------------------------------+
1 row in set (0.00 sec)
```

allow_passwordless If True, then password and password_hash can be omitted (or set to None) to permit a passwordless login.

New in version 0.16.2: The allow_passwordless option was added.

CLI Examples:

```
salt 'localhost' mysql.user_chpass franks localhost newpassword
salt 'localhost' mysql.user_chpass franks localhost password_hash='hash'
salt 'localhost' mysql.user_chpass franks localhost allow_passwordless=True
```

salt.modules.mysql.user_create(user, host='localhost', password=None, password_hash=None, allow_passwordless=False, unix_socket=False, **connection_args)

Creates a MySQL user

host Host for which this user/password combo applies

password The password to use for the new user. Will take precedence over the password_hash option if both are specified.

password_hash The password in hashed form. Be sure to quote the password because YAML doesn’t like the `*`. A password hash can be obtained from the `mysql` command-line client like so:

```
mysql> SELECT PASSWORD('mypass');
+-------------------------------------------+
| PASSWORD('mypass')                     |
+-------------------------------------------+
| *6C8989366EAF75BB670AD8EA7A7FC1176A95CEF4 |
+-------------------------------------------+
1 row in set (0.00 sec)
```

allow_passwordless If True, then password and password_hash can be omitted (or set to None) to permit a passwordless login.

unix_socket If True and allow_passwordless is True then will be used unix_socket auth plugin.

New in version 0.16.2: The allow_passwordless option was added.

CLI Examples:
salt '*' mysql.user_create 'username' 'hostname' 'password'
salt '*' mysql.user_create 'username' 'hostname' password_hash='hash'
salt '*' mysql.user_create 'username' 'hostname' allow_passwordless=True

salt.modules.mysql.user_exists(user, host='localhost', password=None, password_hash=None, passwordless=False, **connection_args)

Checks if a user exists on the MySQL server. A login can be checked to see if passwordless login is permitted by omitting password and password_hash, and using passwordless=True.

New in version 0.16.2: The passwordless option was added.

CLI Example:

salt '*' mysql.user_exists 'username' 'hostname' 'password'
salt '*' mysql.user_exists 'username' 'hostname' password_hash='hash'
salt '*' mysql.user_exists 'username' passwordless=True

salt.modules.mysql.user_grants(user, host='localhost', **connection_args)

Shows the grants for the given MySQL user (if it exists)

CLI Example:
	salt '*' mysql.user_grants 'frank' 'localhost'

salt.modules.mysql.user_info(user, host='localhost', **connection_args)

Get full info on a MySQL user

CLI Example:
	salt '*' mysql.user_info root localhost

salt.modules.mysql.user_list(**connection_args)

Return a list of users on a MySQL server

CLI Example:
	salt '*' mysql.user_list

salt.modules.mysql.user_remove(user, host='localhost', **connection_args)

Delete MySQL user

CLI Example:
	salt '*' mysql.user_remove frank localhost

salt.modules.mysql.version(**connection_args)

Return the version of a MySQL server using the output from the SELECT VERSION() query.

CLI Example:
	salt '*' mysql.version

31.16.157 salt.modules.nacl

This module helps include encrypted passwords in pillars, grains and salt state files.

depends libnacl, https://github.com/saltstack/libnacl

This is often useful if you wish to store your pillars in source control or share your pillar data with others that you trust. I don’t advise making your pillars public regardless if they are encrypted or not.
When generating keys and encrypting passwords use --local when using salt-call for extra security. Also consider using just the salt runner nacl when encrypting pillar passwords.

The nacl lib uses 32byte keys, these keys are base64 encoded to make your life more simple. To generate your key or keyfile you can use:

```bash
salt-call --local nacl.keygen keyfile=/root/.nacl
```

Now with your key, you can encrypt some data:

```bash
salt-call --local nacl.enc mypass keyfile=/root/.nacl
DRB7Q6/X5gGSRCTpZyxS6hX05lnlJII34ivbmUlbWj0llUA+uaVyvou3vJ4=
```

To decrypt the data:

```bash
salt-call --local nacl.dec data='DRB7Q6/X5gGSRCTpZyxS6hX05lnlJII34ivbmUlbWj0llUA+uaVyvou3vJ4=' keyfile=/root/.nacl
mypass
```

The following optional configurations can be defined in the minion or master config. Avoid storing the config in pillars!

```bash
cat /etc/salt/master.d/nacl.conf
nacl.config:
  key: None
  keyfile: /root/.nacl
```

When the key is defined in the master config you can use it from the nacl runner:

```bash
salt-run nacl.enc 'myotherpass'
```

Now you can create a pillar with protected data like:

```bash
pillar example:
  user: root
  password: {{ salt.nacl.dec('DRB7Q6/X5gGSRCTpZyxS6hX05lnlJII34ivbmUlbWj0llUA+uaVyvou3vJ4=') }}
```

Or do something interesting with grains like:

```bash
salt-call nacl.enc minionname:dbrole
AL24Z2C50lkReer3DuQTFrNLchLuz3NGIhGjZkLtKRy/b/CksW809yskLwH2AGVLoEXISjAa
```

```bash
salt minionname grains.setval role 'AL24Z2C50lkReer3DuQTFrNLchLuz3NGIhGjZkLtKRy/b/CksW809yskLwH2AGVLoEXISjAa'
```

```bash
{%- set r = grains.get('role') %}
{%- set role = None %}
{%- if r and 'nacl.dec' in salt %}
  {%- set r = salt['nacl.dec'](r, keyfile='/root/.nacl').split(':') %}
  {%- if opts['id'] == r[0] %}
    {%- set role = r[1] %}
  {%- endif %}
{%- endif %}
{%- endif %}
base:
  {%- if role %}
    '{{ opts['id'] }}':
    - {{ role }}
  {%- endif %}
```

```bash
salt.modules.nacl.dec(data, **kwargs)
```
Takes a key generated from nacl.keygen and decrypt some data.

CLI Examples:
salt.call --local nacl.dec pEXHQM6cuaF7A=
salt-call --local nacl.dec data='pEXHQM6cuaF7A=' keyfile=/root/.nacl
salt-call --local nacl.dec data='pEXHQM6cuaF7A=' key='cKEzd4kXsbeCE7/nLTIqXwnUiD1ulg4NoeeYcCFpd9k='

salt.modules.nacl.enc(data, **kwargs)
    Takes a key generated from nacl.keygen and encrypt some data.

CLI Examples:
salt-call --local nacl.enc datatoenc
salt-call --local nacl.enc datatoenc keyfile=/root/.nacl
salt-call --local nacl.enc datatoenc key='cKEzd4kXsbeCE7/nLTIqXwnUiD1ulg4NoeeYcCFpd9k='

salt.modules.nacl.keygen(keyfile=None)
    Use libnacl to generate a private key

CLI Examples:
salt-call --local nacl.keygen
salt-call --local nacl.keygen keyfile=/root/.nacl
salt-call --local --out=newline_values_only nacl.keygen > /root/.nacl

31.16.158 salt.modules.nagios

Run nagios plugins/checks from salt and get the return as data.
salt.modules.nagios.list_plugins()
    List all the nagios plugins

CLI Example:
salt '*' nagios.list_plugins

salt.modules.nagios.retcode(plugin, args='`, key_name=None)
    Run one nagios plugin and return retcode of the execution

CLI Example:
salt '*' nagios.run check_apt
salt '*' nagios.run check_icmp '8.8.8.8'

salt.modules.nagios.retcode_pillar(pillar_name)
    Run one or more nagios plugins from pillar data and get the result of cmd.retcode The pillar have to be in this format:
    
    webserver:
        Ping_google:
            - check_icmp: 8.8.8.8
            - check_icmp: google.com
        Load:
            - check_load: -w 0.8 -c 1
        APT:
            - check_apt

    You must to group different checks(one o more) and always it will return the highest value of all the checks
CLI Example:

```bash
salt '*' nagios.retcode webserver
```

`salt.modules.nagios.run(plugin, args='')`

Run nagios plugin and return all the data execution with `cmd.run`

`salt.modules.nagios.run_all(plugin, args='')`

Run nagios plugin and return all the data execution with `cmd.run_all`

`salt.modules.nagios.run_all_pillar(pillar_name)`

Run one or more nagios plugins from pillar data and get the result of `cmd.run_all` The pillar have to be in this format:

```
-------
webserver:
  Ping_google:
    - check_icmp: 8.8.8.8
    - check_icmp: google.com
  Load:
    - check_load: -w 0.8 -c 1
  APT:
    - check_apt
-------
```

webserver is the role to check, the next keys are the group and the items the check with the arguments if needed

You have to group different checks in a group

CLI Example:

```bash
salt '*' nagios.run webserver
```

`salt.modules.nagios.run_pillar(pillar_name)`

Run one or more nagios plugins from pillar data and get the result of `cmd.run` The pillar have to be in this format:

```
-------
webserver:
  Ping_google:
    - check_icmp: 8.8.8.8
    - check_icmp: google.com
  Load:
    - check_load: -w 0.8 -c 1
  APT:
    - check_apt
-------
```

webserver is the role to check, the next keys are the group and the items the check with the arguments if needed

You have to group different checks in a group

CLI Example:

```bash
salt '*' nagios.run webserver
```

### 31.16.159 salt.modules.nagios_rpc

Check Host & Service status from Nagios via JSON RPC.

31.16. Full list of builtin execution modules
New in version 2015.8.0.

`salt.modules.nagios_rpc.host_status`(*hostname=None, **kwargs*)

Check status of a particular host. By default statuses are returned in a numeric format.

Parameters:

- **hostname** The hostname to check the status of the service in Nagios.
- **numeric** Turn to false in order to return status in text format (‘OK’ instead of 0, ‘Warning’ instead of 1 etc)

Returns status: ‘OK’, ‘Warning’, ‘Critical’ or ‘Unknown’

CLI Example:

```
salt '*' nagios_rpc.host_status hostname=webserver.domain.com
salt '*' nagios_rpc.host_status hostname=webserver.domain.com numeric=False
```

`salt.modules.nagios_rpc.service_status`(*hostname=None, service=None, **kwargs*)

Check status of a particular service on a host on it in Nagios. By default statuses are returned in a numeric format.

Parameters:

- **hostname** The hostname to check the status of the service in Nagios.
- **service** The service to check the status of in Nagios.
- **numeric** Turn to false in order to return status in text format (‘OK’ instead of 0, ‘Warning’ instead of 1 etc)

Returns status: ‘OK’, ‘Warning’, ‘Critical’ or ‘Unknown’

CLI Example:

```
salt '*' nagios_rpc.service_status hostname=webserver.domain.com service='HTTP'
salt '*' nagios_rpc.service_status hostname=webserver.domain.com service='HTTP' numeric=False
```

### 31.16.160 salt.modules.netbsd_sysctl

Module for viewing and modifying sysctl parameters

`salt.modules.netbsd_sysctl.assign(name, value)`

Assign a single sysctl parameter for this minion

CLI Example:

```
salt '*' sysctl.assign net.inet.icmp.icmplim 50
```

`salt.modules.netbsd_sysctl.get(name)`

Return a single sysctl parameter for this minion

CLI Example:

```
salt '*' sysctl.get hw.physmem
```

`salt.modules.netbsd_sysctl.persist(name, value, config='/etc/sysctl.conf')`

Assign and persist a simple sysctl parameter for this minion

CLI Example:
salt 'sysctl.persist net.inet.icmp.icmplim 50

salt.modules.netbsd_sysctl.show(config_file=False)
    Return a list of sysctl parameters for this minion
    CLI Example:
        salt '*' sysctl.show

### 31.16.161 salt.modules.netbsdservice

The service module for NetBSD

salt.modules.netbsdservice.available(name)
    Returns True if the specified service is available, otherwise returns False.
    CLI Example:
        salt '*' service.available sshd

salt.modules.netbsdservice.disable(name, **kwargs)
    Disable the named service to start at boot
    CLI Example:
        salt '*' service.disable <service name>

salt.modules.netbsdservice.disabled(name)
    Return True if the named service is enabled, false otherwise
    CLI Example:
        salt '*' service.disabled <service name>

salt.modules.netbsdservice.enable(name, **kwargs)
    Enable the named service to start at boot
    CLI Example:
        salt '*' service.enable <service name>

salt.modules.netbsdservice.enabled(name, **kwargs)
    Return True if the named service is enabled, false otherwise
    CLI Example:
        salt '*' service.enabled <service name>

salt.modules.netbsdservice.force_reload(name)
    Force-reload the named service
    CLI Example:
        salt '*' service.force_reload <service name>

salt.modules.netbsdservice.get_all()
    Return all available boot services
    CLI Example:
salt '*' service.get_all

salt.modules.netbsdservice.get_disabled()
    Return a set of services that are installed but disabled
    CLI Example:
        salt '*' service.get_disabled

salt.modules.netbsdservice.get_enabled()
    Return a list of service that are enabled on boot
    CLI Example:
        salt '*' service.get_enabled

salt.modules.netbsdservice.missing(name)
    The inverse of service.available. Returns True if the specified service is not available, otherwise returns False.
    CLI Example:
        salt '*' service.missing sshd

salt.modules.netbsdservice.reload(name)
    Reload the named service
    CLI Example:
        salt '*' service.reload <service name>

salt.modules.netbsdservice.restart(name)
    Restart the named service
    CLI Example:
        salt '*' service.restart <service name>

salt.modules.netbsdservice.start(name)
    Start the specified service
    CLI Example:
        salt '*' service.start <service name>

salt.modules.netbsdservice.status(name, sig=None)
    Return the status for a service, returns a bool whether the service is running.
    CLI Example:
        salt '*' service.status <service name>

salt.modules.netbsdservice.stop(name)
    Stop the specified service
    CLI Example:
        salt '*' service.stop <service name>
31.16.162  salt.modules.netscaler

salt.modules.netscaler.server_add(s_name, s_ip, s_state=None, **connection_args)
    Add a server
    Note: The default server state is ENABLED

    CLI Example:
    salt '*' netscaler.server_add 'serverName' 'serverIpAddress'
    salt '*' netscaler.server_add 'serverName' 'serverIpAddress' 'serverState'

salt.modules.netscaler.server_delete(s_name, **connection_args)
    Delete a server

    CLI Example:
    salt '*' netscaler.server_delete 'serverName'

salt.modules.netscaler.server_disable(s_name, **connection_args)
    Disable a server globally

    CLI Example:
    salt '*' netscaler.server_disable 'serverName'

salt.modules.netscaler.server_enable(s_name, **connection_args)
    Enables a server globally

    CLI Example:
    salt '*' netscaler.server_enable 'serverName'

salt.modules.netscaler.server_enabled(s_name, **connection_args)
    Check if a server is enabled globally

    CLI Example:
    salt '*' netscaler.server_enabled 'serverName'

salt.modules.netscaler.server_exists(s_name, ip=None, s_state=None, **connection_args)
    Checks if a server exists

    CLI Example:
    salt '*' netscaler.server_exists 'serverName'

salt.modules.netscaler.server_update(s_name, s_ip, **connection_args)
    Update a server's attributes

    CLI Example:
    salt '*' netscaler.server_update 'serverName' 'serverIP'

salt.modules.netscaler.service_disable(s_name, s_delay=None, **connection_args)
    Disable a service

    CLI Example:
    salt '*' netscaler.service_disable 'serviceName'
    salt '*' netscaler.service_disable 'serviceName' 'delayInSeconds'

salt.modules.netscaler.service_enable(s_name, **connection_args)
    Enable a service
salt.modules.netscaler.service_enable

```
salt '*' netscaler.service_enable 'serviceName'
```

Checks if a service exists

CLI Example:
```
salt '*' netscaler.service_enable 'serviceName'
```

salt.modules.netscaler.service_exists

```
salt.modules.netscaler.service_exists(s_name, **connection_args)
```

Checks if a service exists

CLI Example:
```
salt '*' netscaler.service_exists 'serviceName'
```

salt.modules.netscaler.service_up

```
salt.modules.netscaler.service_up(s_name, **connection_args)
```

Checks if a service is UP

CLI Example:
```
salt '*' netscaler.service_up 'serviceName'
```

salt.modules.netscaler.servicegroup_add

```
salt.modules.netscaler.servicegroup_add(sg_name, sg_type='HTTP', **connection_args)
```

Add a new service group If no service type is specified, HTTP will be used. Most common service types: HTTP, SSL, and SSL_BRIDGE

CLI Example:
```
salt '*' netscaler.servicegroup_add 'serviceGroupName'
salt '*' netscaler.servicegroup_add 'serviceGroupName' 'serviceGroupType'
```

salt.modules.netscaler.servicegroup_delete

```
salt.modules.netscaler.servicegroup_delete(sg_name, **connection_args)
```

Delete a new service group

CLI Example:
```
salt '*' netscaler.servicegroup_delete 'serviceGroupName'
```

salt.modules.netscaler.servicegroup_exists

```
salt.modules.netscaler.servicegroup_exists(sg_name, sg_type=None, **connection_args)
```

Checks if a service group exists

CLI Example:
```
salt '*' netscaler.servicegroup_exists 'serviceGroupName'
```

salt.modules.netscaler.servicegroup_server_add

```
salt.modules.netscaler.servicegroup_server_add(sg_name, s_name, s_port, **connection_args)
```

Add a server:port member to a service group

CLI Example:
```
salt '*' netscaler.servicegroup_server_add 'serviceGroupName' 'serverName' 'serverPort'
```

salt.modules.netscaler.servicegroup_server_delete

```
salt.modules.netscaler.servicegroup_server_delete(sg_name, s_name, s_port, **connection_args)
```

Remove a server:port member from a service group

CLI Example:
```
salt '*' netscaler.servicegroup_server_delete 'serviceGroupName' 'serverName' 'serverPort'
```

salt.modules.netscaler.servicegroup_server_disable

```
salt.modules.netscaler.servicegroup_server_disable(sg_name, s_name, s_port, **connection_args)
```

Disable a server:port member of a service group

CLI Example:
salt '*' netscaler.servicegroup_server_disable 'serviceGroupName' 'serverName' 'serverPort'

salt.modules.netscaler.servicegroup_server_enable(sg_name, s_name, s_port, **connection_args)
   Enable a server:port member of a servicegroup
   CLI Example:
      salt '*' netscaler.servicegroup_server_enable 'serviceGroupName' 'serverName' 'serverPort'

salt.modules.netscaler.servicegroup_server_exists(sg_name, s_name, s_port=None, **connection_args)
   Check if a server:port combination is a member of a servicegroup
   CLI Example:
      salt '*' netscaler.servicegroup_server_exists 'serviceGroupName' 'serverName' 'serverPort'

salt.modules.netscaler.servicegroup_server_up(sg_name, s_name, s_port, **connection_args)
   Check if a server:port combination is in state UP in a servicegroup
   CLI Example:
      salt '*' netscaler.servicegroup_server_up 'serviceGroupName' 'serverName' 'serverPort'

salt.modules.netscaler.vserver_add(v_name, v_ip, v_port, v_type, **connection_args)
   Add a new lb vserver
   CLI Example:
      salt '*' netscaler.vserver_add 'vserverName' 'vserverIP' 'vserverPort' 'vserverType'
      salt '*' netscaler.vserver_add 'alex.patate.chaude.443' '1.2.3.4' '443' 'SSL'

salt.modules.netscaler.vserver_delete(v_name, **connection_args)
   Delete a lb vserver
   CLI Example:
      salt '*' netscaler.vserver_delete 'vserverName'

salt.modules.netscaler.vserver_exists(v_name, v_ip=None, v_port=None, v_type=None, **connection_args)
   Checks if a vserver exists
   CLI Example:
      salt '*' netscaler.vserver_exists 'vserverName'

salt.modules.netscaler.vserver_servicegroup_add(v_name, sg_name, **connection_args)
   Bind a servicegroup to a vserver
   CLI Example:
      salt '*' netscaler.vserver_servicegroup_add 'vserverName' 'serviceGroupName'

salt.modules.netscaler.vserver_servicegroup_delete(v_name, sg_name, **connection_args)
   Unbind a servicegroup from a vserver
   CLI Example:
salt '*' netscaler.vserver_servicegroup_delete 'vserverName' 'serviceGroupName'

```
