Return a list of the loaded module names

CLI Example:
```
salt '*' kmod.mod_list
```

salt.modules.kmod.remove(mod, persist=False, comment=True)
Remove the specified kernel module

mod Name of module to remove
persist Also remove module from /etc/modules
comment If persist is set don’t remove line from /etc/modules but only comment it

CLI Example:
```
salt '*' kmod.remove kvm
```

32.17.133 salt.modules.launchctl

Module for the management of MacOS systems that use launchd/launchctl

Important: If you feel that Salt should be using this module to manage services on a minion, and it is using a different module (or gives an error similar to `service.start' is not available), see here.

depends

- plistlib Python module

32.17. Full list of builtin execution modules
salt.modules.launchctl.available(job_label)
Check that the given service is available.

CLI Example:
```
salt '*' service.available com.openssh.sshd
```

salt.modules.launchctl.get_all()
Return all installed services

CLI Example:
```
salt '*' service.get_all
```

salt.modules.launchctl.missing(job_label)
The inverse of service.available Check that the given service is not available.

CLI Example:
```
salt '*' service.missing com.openssh.sshd
```

salt.modules.launchctl.restart(job_label, runas=None)
Restart the named service

CLI Example:
```
salt '*' service.restart <service label>
```

salt.modules.launchctl.start(job_label, runas=None)
Start the specified service

CLI Example:
```
salt '*' service.start <service label>
salt '*' service.start org.ntp.ntpd
salt '*' service.start /System/Library/LaunchDaemons/org.ntp.ntpd.plist
```

salt.modules.launchctl.status(job_label, runas=None)
Return the status for a service, returns a bool whether the service is running.

CLI Example:
```
salt '*' service.status <service label>
```

salt.modules.launchctl.stop(job_label, runas=None)
Stop the specified service

CLI Example:
```
salt '*' service.stop <service label>
salt '*' service.stop org.ntp.ntpd
salt '*' service.stop /System/Library/LaunchDaemons/org.ntp.ntpd.plist
```

32.17.134 salt.modules.layman

Support for Layman
salt.modules.layman.add(overlay)

Add the given overlay from the cached remote list to your locally installed overlays. Specify `ALL` to add all overlays from the remote list.

Return a list of the new overlay(s) added:

CLI Example:

```
salt '*' layman.add <overlay name>
```

salt.modules.layman.delete(overlay)

Remove the given overlay from the your locally installed overlays. Specify `ALL` to remove all overlays.

Return a list of the overlays(s) that were removed:

CLI Example:

```
salt '*' layman.delete <overlay name>
```

salt.modules.layman.list_all()

List all overlays, including remote ones.

Return a list of available overlays:

CLI Example:

```
salt '*' layman.list_all
```

salt.modules.layman.list_local()

List the locally installed overlays.

Return a list of installed overlays:

CLI Example:

```
salt '*' layman.list_local
```

salt.modules.layman.sync(overlay='ALL')

Update the specified overlay. Use `ALL` to synchronize all overlays. This is the default if no overlay is specified.

**overlay** Name of the overlay to sync. (Defaults to `ALL`)

CLI Example:

```
salt '*' layman.sync
```

32.17.135 salt.modules.ldapmod

Salt interface to LDAP commands

**depends**

- ldap Python module

**configuration** In order to connect to LDAP, certain configuration is required in the minion config on the LDAP server. The minimum configuration items that must be set are:

```
ldap.basedn: dc=acme,dc=com (example values, adjust to suit)
```

If your LDAP server requires authentication then you must also set:
In addition, the following optional values may be set:

- `ldap.server`: `localhost` (default=`localhost`, see warning below)
- `ldap.port`: 389 (default=389, standard port)
- `ldap.tls`: False (default=False, no TLS)
- `ldap.no_verify`: False (default=False, verify TLS)
- `ldap.anonymous`: True (default=True, bind anonymous)
- `ldap.scope`: 2 (default=2, ldap.SCOPE_SUBTREE)
- `ldap.attrs`: `[saltAttr]` (default=None, return all attributes)

**Warning:** At the moment this module only recommends connection to LDAP services listening on localhost. This is deliberate to avoid the potentially dangerous situation of multiple minions sending identical update commands to the same LDAP server. It’s easy enough to override this behavior, but badness may ensue - you have been warned.

```
salt.modules.ldapmod.search(filter, dn=None, scope=None, attrs=None, **kwargs)
```

Run an arbitrary LDAP query and return the results.

CLI Example:

```
salt 'ldaphost' ldap.search "filter=cn=myhost"
```

Return data:

```
{'myhost': {'count': 1,
             'results': [[[cn=myhost,ou=hosts,o=acme,c=gb],
                  {'saltKeyValue': [ntpserver=ntp.acme.local,
                                    'foo=myfoo'],
                  'saltState': ['foo', 'bar']]],
             'time': {'human': '1.2ms', 'raw': '0.00123'}}}
```

Search and connection options can be overridden by specifying the relevant option as key=value pairs, for example:

```
salt 'ldaphost' ldap.search filter=cn=myhost dn=ou=hosts,o=acme,c=gb scope=1 attrs=' server=localhost port=7393 tls=True bindpw='ssh'
```

### 32.17.136 `salt.modules.linux_acl`

Support for Linux File Access Control Lists

```
salt.modules.linux_acl.delfacl(acl_type, acl_name='*', *args, **kwargs)
```

Remove specific FACL from the specified file(s)

CLI Examples:

```
salt '*' acl.delfacl user myuser /tmp/house/kitchen
salt '*' acl.delfacl default:group mygroup /tmp/house/kitchen
salt '*' acl.delfacl d:u myuser /tmp/house/kitchen
salt '*' acl.delfacl g myuser /tmp/house/kitchen /tmp/house/livingroom
salt '*' acl.delfacl user myuser /tmp/house/kitchen recursive=True
```
salt.modules.linux_acl.getfacl(*args, **kwargs)
    Return (extremely verbose) map of FACLs on specified file(s)
    
    CLI Examples:
    ```
salt '*' acl.getfacl /tmp/house/kitchen
salt '*' acl.getfacl /tmp/house/kitchen /tmp/house/livingroom
salt '*' acl.getfacl /tmp/house/kitchen /tmp/house/livingroom recursive=True
    ```

salt.modules.linux_acl.modfacl(acl_type, acl_name='`, perms='`, *args, **kwargs)
    Add or modify a FACL for the specified file(s)
    
    CLI Examples:
    ```
salt '*' acl.modfacl user myuser rwx /tmp/house/kitchen
salt '*' acl.modfacl default:group mygroup rx /tmp/house/kitchen
salt '*' acl.modfacl d:u myuser 7 /tmp/house/kitchen
salt '*' acl.modfacl g mygroup 0 /tmp/house/kitchen /tmp/house/livingroom
salt '*' acl.modfacl user myuser rwx /tmp/house/kitchen recursive=True
    ```

salt.modules.linux_acl.version()
    Return facl version from getfacl --version
    
    CLI Example:
    ```
salt '*' acl.version
    ```

salt.modules.linux_acl.wipefacls(*args, **kwargs)
    Remove all FACLs from the specified file(s)
    
    CLI Examples:
    ```
salt '*' acl.wipefacls /tmp/house/kitchen
salt '*' acl.wipefacls /tmp/house/kitchen /tmp/house/livingroom
salt '*' acl.wipefacls /tmp/house/kitchen /tmp/house/livingroom recursive=True
    ```

32.17.137 salt.modules.linux_lvm

Support for Linux LVM2

salt.modules.linux_lvm.fullversion()
    Return all version info from lvm version
    
    CLI Example:
    ```
salt '*' lvm.fullversion
    ```

salt.modules.linux_lvm.lvcreate(lvname, vgname, size=None, extents=None, snapshot=None, pv=None, **kwargs)
    Create a new logical volume, with option for which physical volume to be used
    
    CLI Examples:
    ```
salt '*' lvm.lvcreate new_volume_name vg_name size=10G
salt '*' lvm.lvcreate new_volume_name vg_name extents=100 pv=/dev/sdb
salt '*' lvm.lvcreate new_snapshot vg_name snapshot=volume_name size=3G
    ```

salt.modules.linux_lvm.lvdisplay(lvname='``
    Return information about the logical volume(s)
**CLI Examples:**

```bash
salt '*' lvm.lvdisplay
salt '*' lvm.lvdisplay /dev/vg_myserver/root
```

**salt.modules.linux_lvm.lvremove(lvname, vgname)**

Remove a given existing logical volume from a named existing volume group

**CLI Example:**

```bash
salt '*' lvm.lvremove lvname vgname force=True
```

**salt.modules.linux_lvm.lvresize(size, lvpth)**

Return information about the logical volume(s)

**CLI Examples:**

```bash
salt '*' lvm.lvresize +12M /dev/mapper/vg1-test
```

**salt.modules.linux_lvm.pvcreate(devices, override=True, **kwargs)**

Set a physical device to be used as an LVM physical volume

- `override` Skip devices, if they are already an LVM physical volumes

**CLI Examples:**

```bash
salt mymachine lvm.pvcreate /dev/sdb1,/dev/sdb2
salt mymachine lvm.pvcreate /dev/sdb1 dataalignmentoffset=7s
```

**salt.modules.linux_lvm.pvdisplay(pvname='`, real=False)**

Return information about the physical volume(s)

- `pvname` physical device name
- `real` dereference any symlinks and report the real device

New in version 2015.8.7.

**CLI Examples:**

```bash
salt '*' lvm.pvdisplay
salt '*' lvm.pvdisplay /dev/md0
```

**salt.modules.linux_lvm.pvremove(devices, override=True)**

Remove a physical device being used as an LVM physical volume

- `override` Skip devices, if they are already not used as an LVM physical volumes

**CLI Examples:**

```bash
salt mymachine lvm.pvremove /dev/sdb1,/dev/sdb2
```

**salt.modules.linux_lvm.version()**

Return LVM version from lvm version

**CLI Example:**

```bash
salt '*' lvm.version
```

**salt.modules.linux_lvm.vgcreate(vgname, devices, **kwargs)**

Create an LVM volume group
CLI Examples:

```bash
salt mymachine lvm.vgcreate my_vg /dev/sdb1,/dev/sdb2
salt mymachine lvm.vgcreate my_vg /dev/sdb1 clustered=y
```

```bash
salt.modules.linux_lvm.vgdisplay(vgname='')
Return information about the volume group(s)
```

```
salt '*' lvm.vgdisplay
salt '*' lvm.vgdisplay nova-volumes
```

```bash
salt.modules.linux_lvm.vgextend(vgname, devices)
Add physical volumes to an LVM volume group
```

```
salt mymachine lvm.vgextend my_vg /dev/sdb1,/dev/sdb2
salt mymachine lvm.vgextend my_vg /dev/sdb1
```

```bash
salt.modules.linux_lvm.vgremove(vgname)
Remove an LVM volume group
```

```
salt mymachine lvm.vgremove vgname
salt mymachine lvm.vgremove vgname force=True
```

### 32.17.138 `salt.modules.linux_sysctl`

Module for viewing and modifying sysctl parameters

`salt.modules.linux_sysctl.assign(name, value)`

Assign a single sysctl parameter for this minion

CLI Example:

```
salt '*' sysctl.assign net.ipv4.ip_forward 1
```

`salt.modules.linux_sysctl.default_config()`

Linux hosts using systemd 207 or later ignore /etc/sysctl.conf and only load from /etc/sysctl.d/*.conf. This function will do the proper checks and return a default config file which will be valid for the Minion. Hosts running systemd >= 207 will use /etc/sysctl.d/99-salt.conf.

CLI Example:

```
salt -G 'kernel:Linux' sysctl.default_config
```

`salt.modules.linux_sysctl.get(name)`

Return a single sysctl parameter for this minion

CLI Example:

```
salt '*' sysctl.get net.ipv4.ip_forward
```

`salt.modules.linux_sysctl.persist(name, value, config=None)`

Assign and persist a simple sysctl parameter for this minion. If `config` is not specified, a sensible default will be chosen using `sysctl.default_config`. 

### 32.17. Full list of builtin execution modules
CLI Example:

```bash
salt '*' sysctl.persist net.ipv4.ip_forward 1
```

**salt.modules.linux_sysctl.show**<code>(config_file=False)</code>

Return a list of sysctl parameters for this minion

- **config**: Pull the data from the system configuration file instead of the live data.

CLI Example:

```bash
salt '*' sysctl.show
```

### 32.17.139 salt.modules.localemod

Module for managing locales on POSIX-like systems.

**salt.modules.localemod.avail**<code>(locale)</code>

Check if a locale is available.

New in version 2014.7.0.

CLI Example:

```bash
salt '*' locale.avail 'en_US.UTF-8'
```

**salt.modules.localemod.gen_locale**<code>(locale, **kwargs)</code>

Generate a locale. Options:

New in version 2014.7.0.

- **Parameters locale** -- Any locale listed in /usr/share/i18n/locales or /usr/share/i18n/SUPPORTED for Debian and Gentoo based distributions, which require the charmap to be specified as part of the locale when generating it.

- **verbose** Show extra warnings about errors that are normally ignored.

CLI Example:

```bash
salt '*' locale.gen_locale en_US.UTF-8
salt '*' locale.gen_locale 'en_IE.UTF-8 UTF-8'  # Debian/Gentoo only
```

**salt.modules.localemod.get_locale()**

Get the current system locale

CLI Example:

```bash
salt '*' locale.get_locale
```

**salt.modules.localemod.list_avail()**

Lists available (compiled) locales

CLI Example:

```bash
salt '*' locale.list_avail
```

**salt.modules.localemod.set_locale**<code>(locale)</code>

Sets the current system locale
CLI Example:

```
salt '*' locale.set_locale 'en_US.UTF-8'
```

### 32.17.140 salt.modules.locate

Module for using the locate utilities

**salt.modules.locate**

```
locate(pattern, database='', limit=0, **kwargs)
```

Performs a file lookup. Valid options (and their defaults) are:

- `basename`=False
- `count`=False
- `existing`=False
- `follow`=True
- `ignore`=False
- `nfollo`w=False
- `wholename`=True
- `regex`=False
- `database`=locate's default database
- `limit`=<integer, not set by default>

See the manpage for `locate(1)` for further explanation of these options.

CLI Example:

```
salt '*' locate.locate
```

**salt.modules.locate.stats()**

Returns statistics about the locate database

CLI Example:

```
salt '*' locate.stats
```

**salt.modules.locate.updatedb()**

Updates the locate database

CLI Example:

```
salt '*' locate.updatedb
```

**salt.modules.locate.version()**

Returns the version of locate

CLI Example:

```
salt '*' locate.version
```

### 32.17.141 salt.modules.logadm

Module for managing Solaris logadm based log rotations.

**salt.modules.logadm.remove**

```
remove(name, conf_file='/etc/logadm.conf')
```

Remove log pattern from logadm

CLI Example:
salt 'salt '*' logadm.remove myapplog

salt.modules.logadm.rotate(name, pattern=False, count=False, age=False, size=False, copy=True, conf_file='/etc/logadm.conf')

Set up pattern for logging.

CLI Example:
salt '*' logadm.rotate myapplog pattern='/var/log/myapp/*.log' count=7

salt.modules.logadm.show_conf(conf_file='/etc/logadm.conf')

Show parsed configuration

CLI Example:
salt '*' logadm.show_conf

32.17.142 salt.modules.logrotate

Module for managing logrotate.

salt.modules.logrotate.set(key, value, setting=None, conf_file='/etc/logrotate.conf')

Set a new value for a specific configuration line

CLI Example:
salt '*' logrotate.set rotate 2

Can also be used to set a single value inside a multiline configuration block. For instance, to change rotate in the following block:

```bash
/var/log/wtmp {
    monthly
    create 0664 root root
    rotate 1
}
```

Use the following command:

```bash
salt '*' logrotate.set /var/log/wtmp rotate 2
```

This module also has the ability to scan files inside an include directory, and make changes in the appropriate file.

salt.modules.logrotate.show_conf(conf_file='/etc/logrotate.conf')

Show parsed configuration

CLI Example:

```bash
salt '*' logrotate.show_conf
```

32.17.143 salt.modules.lvs

Support for LVS (Linux Virtual Server)
salt.modules.lvs.add_server(protocol=None, service_address=None, server_address=None, packet_forward_method='dr', weight=1, **kwargs)
Add a real server to a virtual service.

protocol The service protocol(only support tcp, udp and fwmark service).

service_address The LVS service address.

server_address The real server address.

packet_forward_method The LVS packet forwarding method(dr for direct routing, tunnel for tunneling, nat for network access translation).

weight The capacity of a server relative to the others in the pool.

CLI Example:
```
salt '*' lvs.add_server tcp 1.1.1.1:80 192.168.0.11:8080 nat 1
```

salt.modules.lvs.add_service(protocol=None, service_address=None, scheduler='wlc')
Add a virtual service.

protocol The service protocol(only support tcp, udp and fwmark service).

service_address The LVS service address.

scheduler Algorithm for allocating TCP connections and UDP datagrams to real servers.

CLI Example:
```
salt '*' lvs.add_service tcp 1.1.1.1:80 rr
```

salt.modules.lvs.check_server(protocol=None, service_address=None, server_address=None, **kwargs)
Check the real server exists in the specified service.

CLI Example:
```
salt '*' lvs.check_server tcp 1.1.1.1:80 192.168.0.11:8080
```

salt.modules.lvs.check_service(protocol=None, service_address=None, **kwargs)
Check the virtual service exists.

CLI Example:
```
salt '*' lvs.check_service tcp 1.1.1.1:80
```

salt.modules.lvs.clear()
Clear the virtual server table

CLI Example:
```
salt '*' lvs.clear
```

salt.modules.lvs.delete_server(protocol=None, service_address=None, server_address=None)
Delete the realserver from the virtual service.

protocol The service protocol(only support tcp, udp and fwmark service).

service_address The LVS service address.

server_address The real server address.

CLI Example:
salt '***' lvs.delete_server tcp 1.1.1.1:80 192.168.0.11:8080

salt.modules.lvs.delete_service(protocol=None, service_address=None)
Delete the virtual service.

  protocol  The service protocol(only support tcp, udp and fwmark service).
  service_address  The LVS service address.

CLI Example:

salt '***' lvs.delete_service tcp 1.1.1.1:80

salt.modules.lvs.edit_server(protocol=None, service_address=None, server_address=None, packet_forward_method=None, weight=None, **kwargs)
Edit a real server to a virtual service.

  protocol  The service protocol(only support tcp, udp and fwmark service).
  service_address  The LVS service address.
  server_address  The real server address.
  packet_forward_method  The LVS packet forwarding method(dr for direct routing, tunnel for tunneling, nat for network access translation).
  weight  The capacity of a server relative to the others in the pool.

CLI Example:

salt '***' lvs.edit_server tcp 1.1.1.1:80 192.168.0.11:8080 nat 1

salt.modules.lvs.edit_service(protocol=None, service_address=None, scheduler=None)
Edit the virtual service.

  protocol  The service protocol(only support tcp, udp and fwmark service).
  service_address  The LVS service address.
  scheduler  Algorithm for allocating TCP connections and UDP datagrams to real servers.

CLI Example:

salt '***' lvs.edit_service tcp 1.1.1.1:80 rr

salt.modules.lvs.get_rules()
Get the virtual server rules

CLI Example:

salt '***' lvs.get_rules

salt.modules.lvs.list(protocol=None, service_address=None)
List the virtual server table if service_address is not specified. If a service_address is selected, list this service only.

CLI Example:

salt '***' lvs.list

salt.modules.lvs.zero(protocol=None, service_address=None)
Zero the packet, byte and rate counters in a service or all services.
CLI Example:

```bash
salt '*' lvs.zero
```

### 32.17.144 salt.modules.lxc

Control Linux Containers via Salt

- **depends**: lxc package for distribution
  - lxc >= 1.0 (even beta alpha) is required

salt.modules.lxc.apply_network_profile(name, network_profile, nic_opts=None, path=None)

New in version 2015.5.0.

Apply a network profile to a container

- **network_profile**: profile name or default values (dict)
- **nic_opts**: values to override in defaults (dict) indexed by nic card names
- **path**: path to the container parent

New in version 2015.8.0.

CLI Examples:

```bash
salt 'minion' lxc.apply_network_profile web1 centos
salt 'minion' lxc.apply_network_profile web1 centos \
    nic_opts="{'eth0': {'mac': 'xx:xx:xx:xx:xx:xx'}}"
salt 'minion' lxc.apply_network_profile web1 \
    "{'eth0': {'mac': 'xx:xx:xx:xx:yy'}}"
    nic_opts="{'eth0': {'mac': 'xx:xx:xx:xx:xx:xx'}}"
```

The special case to disable use of ethernet nics:

```bash
salt 'minion' lxc.apply_network_profile web1 centos \
    "{eth0: {disable: true}}"
```

salt.modules.lxc.attachable(name, path=None)

Return True if the named container can be attached to via the lxc-attach command

- **path**: path to the container parent default: /var/lib/lxc (system default)

New in version 2015.8.0.

CLI Example:

```bash
salt 'minion' lxc.attachable ubuntu
```

salt.modules.lxc.bootstrap(name, config=None, approve_key=True, install=True, pub_key=None, priv_key=None, bootstrap_url=None, force_install=False, unconditional_install=False, path=None, bootstrap_delay=None, bootstrap_args=None, bootstrap_shell=None)

Install and configure salt in a container.

- **config**: Minion configuration options. By default, the master option is set to the target host's master.
- **approve_key**: Request a pre-approval of the generated minion key. Requires that the salt-master be configured to either auto-accept all keys or expect a signing request from the target host. Default: True
path  path to the container parent default: /var/lib/lxc (system default)

    New in version 2015.8.0.

pub_key  Explicit public key to pressed the minion with (optional). This can be either a filepath or a string representing the key

priv_key  Explicit private key to pressed the minion with (optional). This can be either a filepath or a string representing the key

bootstrap_delay  Delay in seconds between end of container creation and bootstrapping. Useful when waiting for container to obtain a DHCP lease.

    New in version 2015.5.0.

bootstrap_url  url, content or filepath to the salt bootstrap script

bootstrap_args  salt bootstrap script arguments

bootstrap_shell  shell to execute the script into

install  Whether to attempt a full installation of salt-minion if needed.

force_install  Force installation even if salt-minion is detected, this is the way to run vendor bootstrap scripts even if a salt minion is already present in the container

unconditional_install  Run the script even if the container seems seeded

CLI Examples:

    salt 'minion' lxc.bootstrap container_name [config=config_data] \%
    [approve_key=(True|False)] [install=(True|False)]

salt.modules.lxc.clone(name, orig, profile=None, network_profile=None, nic_opts=None, **kwargs)

Create a new container as a clone of another container

name  Name of the container

orig  Name of the original container to be cloned

profile  Profile to use in container cloning (see lxc.get_container_profile). Values in a profile will be overridden by the Container Cloning Arguments listed below.

path  path to the container parent directory default: /var/lib/lxc (system)

    New in version 2015.8.0.

Container Cloning Arguments

snapshot  Use Copy On Write snapshots (LVM)

size  [1G] Size of the volume to create. Only applicable if backing=lvm.

backing  The type of storage to use. Set to lvm to use an LVM group. Defaults to filesystem within /var/lib/lxc.

network_profile  Network profile to use for container

    New in version 2015.8.0.

nic_opts  give extra opts overriding network profile values

    New in version 2015.8.0.

CLI Examples:

    salt '*' lxc.clone myclone orig=orig_container
    salt '*' lxc.clone myclone orig=orig_container snapshot=True
salt.modules.lxc.cloud_init(name, vm_=None, **kwargs)
Thin wrapper to lxc.init to be used from the saltcloud lxc driver

- **name** Name of the container may be None and then guessed from saltcloud mapping
- **vm_** saltcloud mapping defaults for the vm

CLI Example:
salt '*' lxc.cloud_init foo

salt.modules.lxc.cloud_init_interface(name, vm_=None, **kwargs)
Interface between salt.cloud.lxc driver and lxc.init vm_ is a mapping of vm opts in the salt.cloud format as documented for the lxc driver.
This can be used either:

- from the salt cloud driver
- because you find the argument to give easier here than using directly lxc.init

**Warning:** BE REALLY CAREFUL CHANGING DEFAULTS‼️ IT'S A RETRO COMPATIBLE INTERFACE WITH THE SALT CLOUD DRIVER (ask kiorky).

- **name** name of the lxc container to create
- **pub_key** public key to preseed the minion with. Can be the keycontent or a filepath
- **priv_key** private key to preseed the minion with. Can be the keycontent or a filepath
- **path** path to the container parent directory (default: /var/lib/lxc)
  New in version 2015.8.0.
- **profile** profile selection
- **network_profile** network profile selection
- **nic_opts** per interface settings compatibles with network profile (ipv4/ipv6/link/gateway/mac/netmask)
  eg:
  ```bash
  - {'eth0': {'mac': '00:16:3e:01:29:40',
            'gateway': 'None', (default)
            'link': 'br0', (default)
            'gateway': 'None', (default)
            'netmask': '255.255.255.0', (default)
            'ip': '22.1.4.25'}}
  ```
- **unconditional_install** given to lxc.bootstrap (see relative doc)
- **force_install** given to lxc.bootstrap (see relative doc)
- **config** any extra argument for the salt minion config
- **dnsservers** dns servers to set inside the container
- **autostart** autostart the container at boot time
- **password** administrative password for the container
- **bootstrap_delay** delay before launching bootstrap script at Container init
Warning: Legacy but still supported options:

**from_container** which container we use as a template when running lxc.clone

**image** which template do we use when we are using lxc.create. This is the default mode unless you specify something in from_container

**backing** which backing store to use. Values can be: overlayfs, dir(default), lvm, zfs, btrfs

**fstype** When using a blockdevice level backing store, which filesystem to use on

**size** When using a blockdevice level backing store, which size for the filesystem to use on

**snapshot** Use snapshot when cloning the container source

**vgname** if using LVM: vgname

**lvname** if using LVM: lvname

**ip** ip for the primary nic

**mac** mac address for the primary nic

**netmask** netmask for the primary nic (24) = vm_.get('netmask','24')

**bridge** bridge for the primary nic (lxcbr0)

**gateway** network gateway for the container

**additional_ips** additional ips which will be wired on the main bridge (br0) which is connected to internet. Be aware that you may use manual virtual mac addresses provided by you provider (online, ovh, etc). This is a list of mappings [ip: '', mac: '', netmask:''] Set gateway to None and an interface with a gateway to escape from another interface that eth0. eg:

```python
-
  {'mac': '00:16:3e:01:29:40',
   'gateway': None, (default)
   'link': 'br0', (default)
   'netmask': '', (default)
   'ip': '22.1.4.25'}
```

**users** administrative users for the container default: [root] and [root, ubuntu] on ubuntu

**default_nic** name of the first interface, you should really not override this

CLI Example:

```
salt '*' lxc.cloud_init_interface foo
```

salt.modules.lxc.copy_to(name, source, dest, overwrite=False, makedirs=False, path=None)

Changed in version 2015.8.0: Function renamed from lxc.cp to lxc.copy_to for consistency with other container types. lxc.cp will continue to work, however. For versions 2015.2.x and earlier, use lxc.cp.

Copy a file or directory from the host into a container

**name** Container name

**source** File to be copied to the container

**path** path to the container parent default: /var/lib/lxc (system default)

  New in version 2015.8.0.

**dest** Destination on the container. Must be an absolute path.

  Changed in version 2015.5.0: If the destination is a directory, the file will be copied into that directory.
**overwrite** [False] Unless this option is set to True, then if a file exists at the location specified by the **dest** argument, an error will be raised.

New in version 2015.8.0.

**makedirs : False**

Create the parent directory on the container if it does not already exist.

New in version 2015.5.0.

**CLI Example:**

```
salt 'minion' lxc.copy_to /tmp/foo /root/foo
salt 'minion' lxc.cp /tmp/foo /root/foo
```

**salt.modules.lxc.create**

Create a new container.

- **name** Name of the container
- **config** The config file to use for the container. Defaults to system-wide config (usually in /etc/lxc/lxc.conf).
- **profile** Profile to use in container creation (see **lxc.get_container_profile**). Values in a profile will be overridden by the **Container Creation Arguments** listed below.
- **network_profile** Network profile to use for container

New in version 2015.5.0.

**Container Creation Arguments**

- **template** The template to use. For example, ubuntu or fedora. Conflicts with the **image** argument.

  **Note:** The download template requires the following three parameters to be defined in **options**:

  - **dist** - The name of the distribution
  - **release** - Release name/version
  - **arch** - Architecture of the container

  The available images can be listed using the **lxc.images** function.

- **options** Template-specific options to pass to the lxc-create command. These correspond to the long options (ones beginning with two dashes) that the template script accepts. For example:

  ```python
  options='{"dist": "centos", "release": "6", "arch": "amd64"}"
  ```

- **image** A tar archive to use as the rootfs for the container. Conflicts with the **template** argument.
- **backing** The type of storage to use. Set to lvmp to use an LVM group. Defaults to filesystem within /var/lib/lxc.
- **fstype** Filesystem type to use on LVM logical volume
- **size** [1G] Size of the volume to create. Only applicable if **backing=lvm**.
- **vname** [lxc] Name of the LVM volume group in which to create the volume for this container. Only applicable if **backing=lvm**.
- **lvname** Name of the LVM logical volume in which to create the volume for this container. Only applicable if **backing=lvm**.
- **nic_opts** give extra opts overriding network profile values
path  parent path for the container creation (default: /var/lib/lxc)

    New in version 2015.8.0.

salt.modules.lxc.destroy(name, stop=False, path=None)
Destroy the named container.

    Warning: Destroys all data associated with the container.

path  path to the container parent directory (default: /var/lib/lxc)

    New in version 2015.8.0.

stop  [False] If True, the container will be destroyed even if it is running/frozen.

    Changed in version 2015.5.0: Default value changed to False. This more closely matches the behavior of lxc-destroy(1), and also makes it less likely that an accidental command will destroy a running container that was being used for important things.

CLI Examples:

salt '*lxc.destroy foo
salt '*lxc.destroy foo stop=True

salt.modules.lxc.edit_conf(conf_file, out_format='simple', read_only=False, lxc_config=None, **kwargs)
Edit an LXC configuration file. If a setting is already present inside the file, its value will be replaced. If it does not exist, it will be appended to the end of the file. Comments and blank lines will be kept in-tact if they already exist in the file.

out_format: Set to simple if you need backward compatibility (multiple items for a simple key is not supported)

read_only: return only the edited configuration without applying it to the underlying lxc configuration file

lxc_config: List of dict containing lxc configuration items For network configuration, you also need to add the device it belongs to, otherwise it will default to eth0. Also, any change to a network parameter will result in the whole network reconfiguration to avoid mismatches, be aware of that!

After the file is edited, its contents will be returned. By default, it will be returned in simple format, meaning an unordered dict (which may not represent the actual file order). Passing in an out_format of commented will return a data structure which accurately represents the order and content of the file.

CLI Example:

salt 'minion' lxc.edit_conf /etc/lxc/mycontainer.conf \\
    out_format=commented lxc.network.type=veth
salt 'minion' lxc.edit_conf /etc/lxc/mycontainer.conf \\
    out_format=commented \\
    lxc_config="[{{'lxc.network.name': 'eth0', \\
    'lxc.network.ipv4': '1.2.3.4'},\
    {'lxc.network.name': 'eth2', \\
    'lxc.network.ipv4': '1.2.3.5'},\
    ['lxc.network.gateway': '1.2.3.1']}]"

salt.modules.lxc.exists(name, path=None)
Returns whether the named container exists.
**path**  path to the container parent directory (default: /var/lib/lxc)

  New in version 2015.8.0.

  CLI Example:

  ```
  salt '*' lxc.exists name
  ```

**salt.modules.lxc.freeze**(name, **kwargs)

Freeze the named container

**path**  path to the container parent directory default: /var/lib/lxc (system)

  New in version 2015.8.0.

**start**  [False] If True and the container is stopped, the container will be started before attempting to freeze.

  New in version 2015.5.0.

**use_vt**  run the command through VT

  New in version 2015.8.0.

  CLI Example:

  ```
  salt '*' lxc.freeze name
  ```

**salt.modules.lxc.get_container_profile**(name=None, **kwargs)

Gather a pre-configured set of container configuration parameters. If no arguments are passed, an empty profile is returned.

Profiles can be defined in the minion or master config files, or in pillar or grains, and are loaded using `config.get`. The key under which LXC profiles must be configured is `lxc.container_profile.profile_name`. An example container profile would be as follows:

```
lxc.container_profile:
    ubuntu:
        template: ubuntu
        backing: lvm
        vgsname: lxc
        size: 1G
```

Parameters set in a profile can be overridden by passing additional container creation arguments (such as the ones passed to `lxc.create`) to this function.

A profile can be defined either as the name of the profile, or a dictionary of variable names and values. See the [LXC Tutorial](https://docs.saltstack.com) for more information on how to use LXC profiles.

  CLI Example:

  ```
  salt-call lxc.get_container_profile centos
  salt-call lxc.get_container_profile ubuntu template=ubuntu backing=overlayfs
  ```

**salt.modules.lxc.get_network_profile**(name=None, **kwargs)

Gather a pre-configured set of network configuration parameters. If no arguments are passed, the following default profile is returned:

```
{ 'eth0': { 'link': 'br0', 'type': 'veth', 'flags': 'up' } }
```
Profiles can be defined in the minion or master config files, or in pillar or grains, and are loaded using `config.get`. The key under which LXC profiles must be configured is `lxc.network_profile`. An example network profile would be as follows:

```yaml
lxc.network_profile.centos:
  eth0:
    link: br0
    type: veth
    flags: up
```

To disable networking entirely:

```yaml
lxc.network_profile.centos:
  eth0:
    disable: true
```

Parameters set in a profile can be overridden by passing additional arguments to this function. A profile can be passed either as the name of the profile, or a dictionary of variable names and values. See the LXC Tutorial for more information on how to use network profiles.

**Warning:** The `ipv4`, `ipv6`, `gateway`, and `link` (bridge) settings in network profiles will only work if the container doesn't redefine the network configuration (for example in `/etc/sysconfig/network-scripts/ifcfg-<interface_name>` on RHEL/CentOS, or `/etc/network/interfaces` on Debian/Ubuntu/etc.)

CLI Example:

```
salt-call lxc.get_network_profile default
```

`salt.modules.lxc.get_parameter(name, parameter, path=None)`
Returns the value of a cgroup parameter for a container

- **path** path to the container parent directory default: `/var/lib/lxc` (system)

  New in version 2015.8.0.

CLI Example:

```
salt '*' lxc.get_parameter container_name memory.limit_in_bytes
```

`salt.modules.lxc.get_root_path(path)`
Get the configured lxc root for containers

New in version 2015.8.0.

CLI Example:

```
salt '*' lxc.get_root_path
```

`salt.modules.lxc.images(dist=None)`
List the available images for LXC's download template.

- **dist** [None] Filter results to a single Linux distribution

CLI Examples:
salt myminion lxc.images
salt myminion lxc.images dist=centos

**salt.modules.lxc.info** *(name, path=None)*

Returns information about a container

**path** path to the container parent directory default: /var/lib/lxc (system)

New in version 2015.8.0.

CLI Example:

```
salt '*' lxc.info name
```

**salt.modules.lxc.init** *(name, config=None, cpuset=None, cpushare=None, memory=None, profile=None, network_profile=None, nic=<object object>, nic_opts=None, cpu=None, autostart=True, password=None, password_encrypted=None, users=None, dns_servers=None, search_domains=None, bridge=None, gateway=None, pub_key=None, priv_key=None, force_install=False, unconditional_install=False, bootstrap_delay=None, bootstrap_args=None, bootstrap_shell=None, bootstrap_url=None, **kwargs)*

Initialize a new container.

This is a partial idempotent function as if it is already provisioned, we will reset a bit the lxc configuration file but much of the hard work will be escaped as markers will prevent re-execution of harmful tasks.

**name** Name of the container

**image** A tar archive to use as the rootfs for the container. Conflicts with the `template` argument.

**cpus** Select a random number of cpu cores and assign it to the cpuset, if the cpuset option is set then this option will be ignored

**cpuset** Explicitly define the cpus this container will be bound to

**cpushare** cgroups cpu shares

**autostart** autostart container on reboot

**memory** cgroups memory limit, in MB

Changed in version 2015.5.0: If no value is passed, no limit is set. In earlier Salt versions, not passing this value causes a 1024MB memory limit to be set, and it was necessary to pass `memory=0` to set no limit.

**gateway** the ipv4 gateway to use the default does nothing more than lxcutils does

**bridge** the bridge to use the default does nothing more than lxcutils does

**network_profile** Network profile to use for the container

New in version 2015.5.0.

**nic** Deprecated since version 2015.5.0: Use `network_profile` instead

**nic_opts** Extra options for network interfaces, will override

```
{"eth0": {"hwaddr": "aa:bb:cc:dd:ee:ff","ipv4": "10.1.1.1","ipv6": "2001:db8::ff00:42:8329"}}
```

or

```
{"eth0": {"hwaddr": "aa:bb:cc:dd:ee:ff","ipv4": "10.1.1.1/24","ipv6": "2001:db8::ff00:42:8329"}}
```
users Users for which the password defined in the password param should be set. Can be passed as a comma separated list or a python list. Defaults to just the root user.

password Set the initial password for the users defined in the users parameter

password_encrypted [False] Set to True to denote a password hash instead of a plaintext password

New in version 2015.5.0.

profile A LXC profile (defined in config or pillar). This can be either a real profile mapping or a string to retrieve it in configuration

start Start the newly-created container
dnsservers list of dns servers to set in the container, default [] (no setting)

seed Seed the container with the minion config. Default: True

install If salt-minion is not already installed, install it. Default: True

config Optional config parameters. By default, the id is set to the name of the container.

master salt master (default to minion's master)

master_port salt master port (default to minion's master port)

pub_key Explicit public key to preseed the minion with (optional). This can be either a filepath or a string representing the key

priv_key Explicit private key to preseed the minion with (optional). This can be either a filepath or a string representing the key

approve_key If explicit preseeding is not used; Attempt to request key approval from the master. Default: True

path path to the container parent directory default: /var/lib/lxc (system)

New in version 2015.8.0.

clonedeprecated since version 2015.5.0: Use clone_from instead

clonefrom Original from which to use a clone operation to create the container. Default: None

bootstrap_delay Delay in seconds between end of container creation and bootstrapping. Useful when waiting for container to obtain a DHCP lease.

New in version 2015.5.0.

bootstrap_url See lxc.bootstrap

bootstrap_shell See lxc.bootstrap

bootstrap_args See lxc.bootstrap

force_install Force installation even if salt-minion is detected, this is the way to run vendor bootstrap scripts even if a salt minion is already present in the container

unconditional_install Run the script even if the container seems seeded

CLI Example:

```
salt 'minion' lxc.init name [cpuset=cgroups_cpuset] 
    [cpushare=cgroups_cpushare] [memory=cgroups_memory] 
    [nic=nic_profile] [profile=lxc_profile] 
    [nic_opts=nic_opts] [start=(True|False)] 
    [seed=(True|False)] [install=(True|False)] 
    [config=minion_config] [approve_key=(True|False)] 
```
salt.modules.lxc.list(extra=False, limit=None, path=None)
List containers classified by state

extra  Also get per-container specific info. This will change the return data. Instead of returning a list of
containers, a dictionary of containers and each container’s output from \texttt{lxc.info}.

path  path to the container parent directory default: /var/lib/lxc (system)

New in version 2015.8.0.

limit  Return output matching a specific state (frozen, running, or stopped).

New in version 2015.5.0.

CLI Examples:
salt '*' lxc.list
salt '*' lxc.list extra=True
salt '*' lxc.list limit=running

salt.modules.lxc.ls(active=None, cache=True, path=None)
Return a list of the containers available on the minion

path  path to the container parent directory default: /var/lib/lxc (system)

New in version 2015.8.0.

active  If True, return only active (i.e. running) containers

New in version 2015.5.0.

CLI Example:
salt '*' lxc.ls
salt '*' lxc.ls active=True

salt.modules.lxc.read_conf(conf_file, out_format='simple')
Read in an LXC configuration file. By default returns a simple, unsorted dict, but can also return a more
detailed structure including blank lines and comments.

out_format:  set to ‘simple’ if you need the old and unsupported behavior. This won’t support the multiple lxc
values (eg: multiple network nics)

CLI Examples:
salt 'minion' lxc.read_conf /etc/lxc/mycontainer.conf
salt 'minion' lxc.read_conf /etc/lxc/mycontainer.conf out_format=commented

salt.modules.lxc.reboot(name, path=None)
Reboot a container.

path  path to the container parent default: /var/lib/lxc (system default)

New in version 2015.8.0.

CLI Examples:
**salt.modules.lxc.reconfigure**

Reconfigure a container.

This only applies to a few properties

- **name** Name of the container.
- **cpu** Select a random number of cpu cores and assign it to the cpuset, if the cpuset option is set then this option will be ignored
- **cpuset** Explicitly define the cpus this container will be bound to
- **cpushare** cgroups cpu shares.
- **autostart** autostart container on reboot
- **memory** cgroups memory limit, in MB. (0 for nolimit, None for old default 1024MB)
- **gateway** the ipv4 gateway to use the default does nothing more than lxcutils does
- **bridge** the bridge to use the default does nothing more than lxcutils does
- **nic** Network interfaces profile (defined in config or pillar).
- **nic_opts** Extra options for network interfaces, will override

```
{"eth0": {"mac": "aa:bb:cc:dd:ee:ff","ipv4": "10.1.1.1","ipv6": "2001:db8::ff00:42:8329"}}
```

**salt.modules.lxc.restart**

New in version 2015.5.0.

Restart the named container. If the container was not running, the container will merely be started.

- **name** The name of the container
- **path** path to the container parent directory default: /var/lib/lxc (system)
- **lxc_config** path to a lxc config file config file will be guessed from container name otherwise
- **force** [False] If True, the container will be force-stopped instead of gracefully shut down

**CLI Example:**

```
salt-call -lall mc_lxc_fork.reconfigure foobar nic_opts="{'eth1': {'mac': '00:16:3e:dd:ee:44'}}" memory=4
```
**salt.myminion.lxc.restart**

```
salt myminion lxc.restart name
```

**salt.modules.lxc.retcod**

```
salt.modules.lxc.retcod(name, cmd, no_start=False, preserve_state=True, stdin=None, python_shell=True, output_loglevel='debug', use_vt=False, path=None, ignore_retcode=False, chroot_fallback=False, keep_env='http_proxy, https_proxy, no_proxy')
```

New in version 2015.5.0.

Run `cmd.retcod` within a container

**Warning:** Many shell builtins do not work, failing with stderr similar to the following:

```
lxc_container: No such file or directory - failed to exec 'command'
```

The same error will be displayed in stderr if the command being run does not exist. If the retcode is nonzero and not what was expected, try using `lxc.run_stderr` or `lxc.run_all`.

**name** Name of the container in which to run the command

**cmd** Command to run

**no_start** [False] If the container is not running, don’t start it

**preserve_state** [True] After running the command, return the container to its previous state

**path** path to the container parent default: `:/var/lib/lxc` (system default)

New in version 2015.8.0.

**stdin** [None] Standard input to be used for the command

**output_loglevel** [debug] Level at which to log the output from the command. Set to `quiet` to suppress logging.

**use_vt** [False] Use SaltStack’s `utils.vt` to stream output to console `output=all`.

**keep_env** [http_proxy,https_proxy,no_proxy] A list of env vars to preserve. May be passed as comma-separated list.

**chroot_fallback** if the container is not running, try to run the command using chroot default: false

CLI Example:

```
salt myminion lxc.retcod mycontainer 'ip addr show'
```

**salt.modules.lxc.run**

```
salt.modules.lxc.run(name, cmd, no_start=False, preserve_state=True, stdin=None, python_shell=True, output_loglevel='debug', use_vt=False, path=None, ignore_retcode=False, chroot_fallback=False, keep_env='http_proxy, https_proxy, no_proxy')
```

New in version 2015.8.0.

Run `cmd.run` within a container

**Warning:** Many shell builtins do not work, failing with stderr similar to the following:

```
lxc_container: No such file or directory - failed to exec 'command'
```

The same error will be displayed in stderr if the command being run does not exist. If no output is returned using this function, try using `lxc.run_stderr` or `lxc.run_all`.  

32.17. Full list of builtin execution modules 1129
name  Name of the container in which to run the command

cmd  Command to run

path  path to the container parent default: /var/lib/lxc (system default)

   New in version 2015.8.0.

no_start  [False] If the container is not running, don’t start it

preserve_state  [True] After running the command, return the container to its previous state

stdin  [None] Standard input to be used for the command

output_loglevel  [debug] Level at which to log the output from the command. Set to quiet to suppress logging.

use_vt  [False] Use SaltStack’s utils.vt to stream output to console. Assumes output=all.

chroot_fallback  if the container is not running, try to run the command using chroot default: false

keep_env  [http_proxy,https_proxy,no_proxy] A list of env vars to preserve. May be passed as comma-delimited list.

CLI Example:
salt myminion lxc.run mycontainer 'ifconfig -a'

salt.modules.lxc.run_all(name, cmd, no_start=False, preserve_state=True, stdin=None, 
   python_shell=True, output_loglevel='debug', use_vt=False, path=None, 
   ignore_retcode=False, chroot_fallback=False, keep_env='http_proxy, https_proxy, no_proxy')

New in version 2015.5.0.

Run cmd.run_all within a container

Note:  While the command is run within the container, it is initiated from the host. Therefore, the PID in the return dict is from the host, not from the container.

Warning:  Many shell builtins do not work, failing with stderr similar to the following:
lxc_container: No such file or directory - failed to exec 'command'

The same error will be displayed in stderr if the command being run does not exist.
use_vt [False] Use SaltStack’s utils.vt to stream output to console output=all.

keep_env [http_proxy,https_proxy,no_proxy] A list of env vars to preserve. May be passed as comma-delimited list.

chroot_fallback if the container is not running, try to run the command using chroot default: false

CLI Example:

```bash
salt myminion lxc.run_all mycontainer 'ip addr show'
```

salt.modules.lxc.run_cmd(name, cmd, no_start=False, preserve_state=True, stdin=None, stdout=True, stderr=False, python_shell=True, path=None, output_loglevel='debug', use_vt=False, ignore_retcode=False, chroot_fallback=False, keep_env='http_proxy, https_proxy, no_proxy')

path path to the container parent default: /var/lib/lxc (system default)

New in version 2015.8.0.

Deprecated since version 2015.5.0: Use lxc.run instead

salt.modules.lxc.run_stderr(name, cmd, no_start=False, preserve_state=True, stdin=None, python_shell=True, output_loglevel='debug', use_vt=False, path=None, ignore_retcode=False, chroot_fallback=False, keep_env='http_proxy, https_proxy, no_proxy')

New in version 2015.5.0.

Run cmd.run_stderr within a container

**Warning:** Many shell builtins do not work, failing with stderr similar to the following:

```
lxc_container: No such file or directory - failed to exec 'command'
```

The same error will be displayed if the command being run does not exist.

name Name of the container in which to run the command

cmd Command to run

path path to the container parent default: /var/lib/lxc (system default)

New in version 2015.8.0.

no_start [False] If the container is not running, don’t start it

preserve_state [True] After running the command, return the container to its previous state

stdin [None] Standard input to be used for the command

output_loglevel [debug] Level at which to log the output from the command. Set to quiet to suppress logging.

use_vt [False] Use SaltStack’s utils.vt to stream output to console output=all.

keep_env [http_proxy,https_proxy,no_proxy] A list of env vars to preserve. May be passed as comma-delimited list.

chroot_fallback if the container is not running, try to run the command using chroot default: false

CLI Example:
```python
salt myminion lxc.run_stdout mycontainer 'ip addr show'
```

```
salt.modules.lxc.run_stdout(name, cmd, no_start=False, preserve_state=True, stdin=None, python_shell=True, output_loglevel='debug', use_vt=False, path=None, ignore_retcode=False, chroot_fallback=False, keep_env='http_proxy, https_proxy, no_proxy')
```

New in version 2015.5.0.

Run `cmd.run_stdout` within a container

**Warning:** Many shell builtins do not work, failing with stderr similar to the following:

```
lxc_container: No such file or directory - failed to exec 'command'
```

The same error will be displayed in stderr if the command being run does not exist. If no output is returned using this function, try using `lxc.run_stderr` or `lxc.run_all`.

- **name** Name of the container in which to run the command
- **cmd** Command to run
- **path** path to the container parent default: `/var/lib/lxc` (system default)
  
  New in version 2015.8.0.
- **no_start** [False] If the container is not running, don't start it
- **preserve_state** [True] After running the command, return the container to its previous state
- **stdin** [None] Standard input to be used for the command
- **output_loglevel** [debug] Level at which to log the output from the command. Set to `quiet` to suppress logging.
- **use_vt** [False] Use SaltStack's `utils.vt` to stream output to console `output=all`.
- **keep_env** [http_proxy, https_proxy, no_proxy] A list of env vars to preserve. May be passed as comma-delimited list.
- **chroot_fallback** if the container is not running, try to run the command using chroot default: false

CLI Example:

```
salt myminion lxc.run_stdout mycontainer 'ifconfig -a'
```

```python
salt.modules.lxc.running_systemd(name, cache=True, path=None)
```

Determine if systemD is running

- **path** path to the container parent

  New in version 2015.8.0.

CLI Example:

```
salt '*' lxc.running_systemd ubuntu
```

```python
salt.modules.lxc.search_lxc_bridge()
```

Search the first bridge which is potentially available as LXC bridge

CLI Example:
salt '*' lxc.search_lxc_bridge

```
salt.modules.lxc.search_lxc_bridges()

Search which bridges are potentially available as LXC bridges

CLI Example:

salt '*' lxc.search_lxc_bridges
```

salt.modules.lxc.set_dns(name, dnsservers=None, searchdomains=None, path=None)

Changed in version 2015.5.0: The dnsservers and searchdomains parameters can now be passed as a comma-separated list.

Update /etc/resolv.conf

path

path to the container parent default: /var/lib/lxc (system default)

New in version 2015.8.0.

CLI Example:

```
salt myminion lxc.set_dns ubuntu "[8.8.8.8, 4.4.4.4]"
```

salt.modules.lxc.set_parameter(name, parameter, value, path=None)

Set the value of a cgroup parameter for a container.

path path to the container parent directory default: /var/lib/lxc (system)

New in version 2015.8.0.

CLI Example:

```
salt '*' lxc.set_parameter name parameter value
```

salt.modules.lxc.set_password(name, users, password, encrypted=True, path=None)

Changed in version 2015.5.0: Function renamed from set_pass to set_password. Additionally, this function now supports (and defaults to using) a password hash instead of a plaintext password.

Set the password of one or more system users inside containers

users Comma-separated list (or python list) of users to change password

password Password to set for the specified user(s)

encrypted [True] If true, password must be a password hash. Set to False to set a plaintext password (not recommended).

New in version 2015.5.0.

path path to the container parent directory default: /var/lib/lxc (system)

New in version 2015.8.0.

CLI Example:

```
salt '*' lxc.set_pass container-name root '$6$uJ2uAyLYUSkoI67t8As/...0Fx02HKGxMUpcoVUcVR2K6x93waih5ShQvjiRwq25yIkIBQgbdKQSFna28/ek6716vEv1'
salt '*' lxc.set_pass container-name root foo encrypted=False
```

salt.modules.lxc.start(name, **kwargs)

Start the named container
**restart** [False] Deprecated since version 2015.5.0: Use `lxc.restart`

Restart the container if it is already running

**path** path to the container parent directory default: /var/lib/lxc (system)

New in version 2015.8.0.

**lxc_config** path to a lxc config file config file will be guessed from container name otherwise

New in version 2015.8.0.

**use_vt** run the command through VT

New in version 2015.8.0.

CLI Example:

```
salt myminion lxc.start name
```

**salt.modules.lxc.state** *(name, path=None)*

Returns the state of a container.

**path** path to the container parent directory (default: /var/lib/lxc)

New in version 2015.8.0.

CLI Example:

```
salt * lxc.state name
```

**salt.modules.lxc.stop** *(name, kill=False, path=None, use_vt=None)*

Stop the named container

**path** path to the container parent directory default: /var/lib/lxc (system)

New in version 2015.8.0.

**kill** False Do not wait for the container to stop, kill all tasks in the container. Older LXC versions will stop containers like this irrespective of this argument.

Changed in version 2015.5.0: Default value changed to False

**use_vt** run the command through VT

New in version 2015.8.0.

CLI Example:

```
salt myminion lxc.stop name
```

**salt.modules.lxc.systemd_running_state** *(name, path=None)*

Get the operational state of a systemd based container

**path** path to the container parent default: /var/lib/lxc (system default)

New in version 2015.8.0.

CLI Example:

```
salt myminion lxc.systemd_running_state ubuntu
```

**salt.modules.lxc.templates** *

New in version 2015.5.0.

List the available LXC template scripts installed on the minion
CLI Examples:

```
salt myminion lxc.templates
```

`salt.modules.lxc.test_bare_started_state(name, path=None)`
Test if a non systemd container is fully started For now, it consists only to test if the container is attachable

**path** path to the container parent default: /var/lib/lxc (system default)

New in version 2015.8.0.

CLI Example:

```
salt myminion lxc.test_bare_started_state ubuntu
```

`salt.modules.lxc.test_sd_started_state(name, path=None)`
Test if a systemd container is fully started

**path** path to the container parent default: /var/lib/lxc (system default)

New in version 2015.8.0.

CLI Example:

```
salt myminion lxc.test_sd_started_state ubuntu
```

`salt.modules.lxc.unfreeze(name, path=None, use_vt=None)`
Unfreeze the named container.

**path** path to the container parent directory default: /var/lib/lxc (system)

New in version 2015.8.0.

**use_vt** run the command through VT

New in version 2015.8.0.

CLI Example:

```
salt '*' lxc.unfreeze name
```

`salt.modules.lxc.update_lxc_conf(name, lxc_conf, lxc_conf_unset, path=None)`
Edit LXC configuration options

**path** path to the container parent default: /var/lib/lxc (system default)

New in version 2015.8.0.

CLI Example:

```
salt myminion lxc.update_lxc_conf ubuntu \
    lxc_conf="[\'network.ipv4.ip'::'10.0.3.5']" \
    lxc_conf_unset="[\'lxc.utsname']"
```

`salt.modules.lxc.version()`
Return the actual lxc client version

New in version 2015.8.0.

CLI Example:

```
salt '*' lxc.version
```
salt.modules.lxc.wait_started(name, path=None, timeout=300)
Check that the system has fully init'd
This is actually very important for systemd based containers
see https://github.com/saltstack/salt/issues/23847
path  path to the container parent default: /var/lib/lxc (system default)

New in version 2015.8.0.

CLI Example:
```
salt myminion lxc.wait_started ubuntu
```

salt.modules.lxc.write_conf(conf_file, conf)
Write out an LXC configuration file
This is normally only used internally. The format of the data structure must match that which is returned from lxc.read_conf(), with out_format set to commented.

An example might look like:
```
[
    {'lxc.utsname': '$CONTAINER_NAME'},
    '# This is a commented line\n',
    '\n',
    {'lxc.mount': '$CONTAINER_FSTAB'},
    {'lxc.rootfs': {'comment': 'This is another test',
                    'value': 'This is another test'}},
    '\n',
    {'lxc.network.type': 'veth'},
    {'lxc.network.flags': 'up'},
    {'lxc.network.link': 'br0'},
    {'lxc.network.mac': '$CONTAINER_MACADDR'},
    {'lxc.network.ipv4': '$CONTAINER_IPADDR'},
    {'lxc.network.name': '$CONTAINER_DEVICENAME'},
]
```

CLI Example:
```
salt 'minion' lxc.write_conf /etc/lxc/mycontainer.conf \  
    out_format=commented
```

32.17.145  salt.modules.mac_group

Manage groups on Mac OS 10.7+
salt.modules.mac_group.add(name, gid=None, **kwargs)
Add the specified group

CLI Example:
```
salt '*' group.add foo 3456
```

salt.modules.mac_group.chgid(name, gid)
Change the gid for a named group

CLI Example:
salt '*/' group.chgid foo 4376

salt.modules.mac_group.delete(name)
Remove the named group

CLI Example:

salt '*/' group.delete foo

salt.modules.mac_group.getent(refresh=False)
Return info on all groups

CLI Example:

salt '*/' group.getent

salt.modules.mac_group.info(name)
Return information about a group

CLI Example:

salt '*/' group.info foo

32.17.146 salt.modules.mac_user
Manage users on Mac OS 10.7+

Important: If you feel that Salt should be using this module to manage users on a minion, and it is using a different module (or gives an error similar to 'user.info' is not available), see here.

salt.modules.mac_user.add(name, uid=None, gid=None, groups=None, home=None, shell=None, full-name=None, createhome=True, **kwargs)

Add a user to the minion

CLI Example:

salt '*/' user.add name <uid> <gid> <groups> <home> <shell>

salt.modules.mac_user.chfullname(name, fullname)
Change the user's Full Name

CLI Example:

salt '*/' user.chfullname foo 'Foo Bar'

salt.modules.mac_user.chgid(name, gid)
Change the default group of the user

CLI Example:

salt '*/' user.chgid foo 4376

salt.modules.mac_user.chgroups(name, groups, append=False)
Change the groups to which the user belongs. Note that the user's primary group does not have to be one of the groups passed, membership in the user's primary group is automatically assumed.
groups Groups to which the user should belong, can be passed either as a python list or a comma-separated string

append Instead of removing user from groups not included in the groups parameter, just add user to any groups for which they are not members

CLI Example:

```
salt '*' user.chgroups foo wheel,root
```

salt.modules.mac_user.chhome(name, home, **kwargs)
Change the home directory of the user

CLI Example:

```
salt '*' user.chhome foo /Users/foo
```

salt.modules.mac_user.chshell(name, shell)
Change the default shell of the user

CLI Example:

```
salt '*' user.chshell foo /bin/zsh
```

salt.modules.mac_user.chuid(name, uid)
Change the uid for a named user

CLI Example:

```
salt '*' user.chuid foo 4376
```

salt.modules.mac_user.delete(name, *args)
Remove a user from the minion

CLI Example:

```
salt '*' user.delete foo
```

salt.modules.mac_user.getent(refresh=False)
Return the list of all info for all users

CLI Example:

```
salt '*' user.getent
```

salt.modules.mac_user.info(name)
Return user information

CLI Example:

```
salt '*' user.info root
```

salt.modules.mac_user.list_groups(name)
Return a list of groups the named user belongs to

CLI Example:

```
salt '*' user.list_groups foo
```
salt.modules.mac_user.list_users()
    Return a list of all users
    CLI Example:
    ```
salt '*' user.list_users
    ```
	salt.modules.mac_user.rename(name, new_name)
    Change the username for a named user
    CLI Example:
    ```
salt '*' user.rename name new_name
    ```

32.17.147 salt.modules.macports

Support for MacPorts under Mac OSX.

This module has some caveats.

1. Updating the database of available ports is quite resource-intensive. However, refresh=True is the default for all operations that need an up-to-date copy of available ports. Consider refresh=False when you are sure no db update is needed.

2. In some cases MacPorts doesn't always realize when another copy of itself is running and will gleefully tromp all over the available ports database. This makes MacPorts behave in undefined ways until a fresh complete copy is retrieved.

Because of 1 and 2 it is possible to get the salt-minion into a state where salt mac-machine pkg./something/ won't want to return. Use
```
salt-run jobs.active
```
on the master to check for potentially long-running calls to port.

Finally, ports database updates are always handled with port selfupdate as opposed to port sync. This makes sense in the MacPorts user community but may confuse experienced Linux admins as Linux package managers don't upgrade the packaging software when doing a package database update. In other words salt mac-machine pkg.refresh_db is more like apt-get update; apt-get upgrade dpkg apt-get than simply apt-get update.

salt.modules.macports.available_version(*names, **kwargs)
    This function is an alias of latest_version.
    Return the latest version of the named package available for upgrade or installation
    Options:
    refresh Update ports with port selfupdate
    CLI Example:
    ```
salt '*' pkg.latest_version <package name>
salt '*' pkg.latest_version <package1> <package2> <package3>
    ```

salt.modules.macports.install(name=None, refresh=False, pkgs=None, **kwargs)
    Install the passed package(s) with port install
    name  The name of the formula to be installed. Note that this parameter is ignored if `"pkgs"` is passed.
    CLI Example:
version Specify a version to pkg to install. Ignored if pkgs is specified.

CLI Example:

```bash
salt '*' pkg.install <package name>
salt '*' pkg.install git-core version='1.8.5.5'
```

variant Specify a variant to pkg to install. Ignored if pkgs is specified.

CLI Example:

```bash
salt '*' pkg.install <package name>
salt '*' pkg.install git-core version='1.8.5.5' variant='+credential_osxkeychain+doc+pcre'
```

Multiple Package Installation Options:

pkgs A list of formulas to install. Must be passed as a python list.

CLI Example:

```bash
salt '*' pkg.install pkgs=['"foo","bar"]
salt '*' pkg.install pkgs=['"foo@1.2","bar"']
salt '*' pkg.install pkgs=['"foo@1.2+ssl","bar@2.3"']
```

Returns a dict containing the new package names and versions:

```json
{
 '"<package>': { 'old': '<old-version>', 'new': '<new-version>'
}
```

CLI Example:

```bash
salt '*' pkg.install 'package package package'
```

### salt.modules.macports.latest_version(*names, **kwargs)*

Return the latest version of the named package available for upgrade or installation

Options:

refresh Update ports with port selfupdate

CLI Example:

```bash
salt '*' pkg.latest_version <package name>
salt '*' pkg.latest_version <package1> <package2> <package3>
```

### salt.modules.macports.list_pkgs(versions_as_list=False, **kwargs)*

List the packages currently installed in a dict:

```json
[{'<package_name>': '<version>'}
```

CLI Example:

```bash
salt '*' pkg.list_pkgs
```

### salt.modules.macports.list_upgrades(refresh=True, **kwargs)*

Check whether or not an upgrade is available for all packages

Options:
refresh  Update ports with port selfupdate

CLI Example:

```
salt '*' pkg.list_upgrades
```

```
salt.modules.macports.refresh_db()
```

**salt.modules.macports.remove**(name=None, pkgs=None, **kwargs)

Removes packages with port uninstall.

- **name**  The name of the package to be deleted.

Multiple Package Options:

- **pkgs**  A list of packages to delete. Must be passed as a python list. The name parameter will be ignored if this option is passed.

New in version 0.16.0.

Returns a dict containing the changes.

CLI Example:

```
salt '*' pkg.remove <package name>
salt '*' pkg.remove <package1>,<package2>,<package3>
salt '*' pkg.remove pkgs=['"foo", "bar"]'
```

```
salt.modules.macports.upgrade(refresh=True)
```

Run a full upgrade using MacPorts `port upgrade outdated`

Options:

- **refresh**  Update ports with port selfupdate

Return a dict containing the new package names and versions:

```
{"<package>": {'old': '<old-version>',
  'new': '<new-version>'}}
```

CLI Example:

```
salt '*' pkg.upgrade
```

```
salt.modules.macports.upgrade_available(pkg, refresh=True)
```

Check whether or not an upgrade is available for a given package

CLI Example:

```
salt '*' pkg.upgrade_available <package name>
```

```
salt.modules.macports.version("names", **kwargs)
```

Returns a string representing the package version or an empty string if not installed. If more than one package name is specified, a dict of name/version pairs is returned.

CLI Example:

```
salt '*' pkg.version <package name>
salt '*' pkg.version <package1> <package2> <package3>
```
32.17.148 salt.modules.makeconf

Support for modifying make.conf under Gentoo

salt.modules.makeconf.append_cflags(value)
Add to or create a new CFLAGS in the make.conf

Return a dict containing the new value for variable:

```python
{'<variable>': {'old': '<old-value>', 'new': '<new-value>'}}
```

CLI Example:
```
salt '*' makeconf.append_cflags '-pipe'
```

salt.modules.makeconf.append_cxxflags(value)
Add to or create a new CXXFLAGS in the make.conf

Return a dict containing the new value for variable:

```python
{'<variable>': {'old': '<old-value>', 'new': '<new-value>'}}
```

CLI Example:
```
salt '*' makeconf.append_cxxflags '-pipe'
```

salt.modules.makeconf.append_emerge_default_opts(value)
Add to or create a new EMERGE_DEFAULT_OPTS in the make.conf

Return a dict containing the new value for variable:

```python
{'<variable>': {'old': '<old-value>', 'new': '<new-value>'}}
```

CLI Example:
```
salt '*' makeconf.append_emerge_default_opts '--jobs'
```

salt.modules.makeconf.append_features(value)
Add to or create a new FEATURES in the make.conf

Return a dict containing the new value for variable:

```python
{'<variable>': {'old': '<old-value>', 'new': '<new-value>'}}
```

CLI Example:
```
salt '*' makeconf.append_features 'webrsync-gpg'
```

salt.modules.makeconf.append_gentoo_mirrors(value)
Add to or create a new GENTOO_MIRRORS in the make.conf

Return a dict containing the new value for variable:

```python
{'<variable>': {'old': '<old-value>', 'new': '<new-value>'}}
```
CLI Example:

```
salt '*' makeconf.append_gentoo_mirrors 'http://distfiles.gentoo.org'
```

```python
salt.modules.makeconf.append_makeopts(value)
Add to or create a new MAKEOPTS in the make.conf
```

Return a dict containing the new value for variable:

```
{ '<variable>': {'old': '<old-value>',
                'new': '<new-value>'}}
```

CLI Example:

```
salt '*' makeconf.append_makeopts '-j3'
```

```python
salt.modules.makeconf.append_var(var, value)
Add to or create a new variable in the make.conf
```

Return a dict containing the new value for variable:

```
{ '<variable>': {'old': '<old-value>',
                'new': '<new-value>'}}
```

CLI Example:

```
salt '*' makeconf.append_var 'LINGUAS' 'en'
```

```python
salt.modules.makeconf.cflags_contains(value)
Verify if CFLAGS variable contains a value in make.conf
```

Return True if value is set for var

CLI Example:

```
salt '*' makeconf.cflags_contains '-pipe'
```

```python
salt.modules.makeconf.chost_contains(value)
Verify if CHOST variable contains a value in make.conf
```

Return True if value is set for var

CLI Example:

```
salt '*' makeconf.chost_contains 'x86_64-pc-linux-gnu'
```

```python
salt.modules.makeconf.cxxflags_contains(value)
Verify if CXXFLAGS variable contains a value in make.conf
```

Return True if value is set for var

CLI Example:

```
salt '*' makeconf.cxxflags_contains '-pipe'
```

```python
salt.modules.makeconf.emerge_default_opts_contains(value)
Verify if EMERGE_DEFAULT_OPTS variable contains a value in make.conf
```

Return True if value is set for var

CLI Example:
salt 'salt* makeconf.emerge_default_opts_contains '--jobs'

salt.modules.makeconf.features_contains(value)
Verify if FEATURES variable contains a value in make.conf
Return True if value is set for var
CLI Example:
salt 'salt* makeconf.features_contains 'webrsync-gpg''

salt.modules.makeconf.gentoo_mirrors_contains(value)
Verify if GENTOO_MIRRORS variable contains a value in make.conf
Return True if value is set for var
CLI Example:
salt 'salt* makeconf.gentoo_mirrors_contains 'http://distfiles.gentoo.org''

salt.modules.makeconf.get_cflags()
Get the value of CFLAGS variable in the make.conf
Return the value of the variable or None if the variable is not in the make.conf
CLI Example:
salt 'salt* makeconf.get_cflags'

salt.modules.makeconf.get_chost()
Get the value of CHOST variable in the make.conf
Return the value of the variable or None if the variable is not in the make.conf
CLI Example:
salt 'salt* makeconf.get_chost'

salt.modules.makeconf.get_cxxflags()
Get the value of CXXFLAGS variable in the make.conf
Return the value of the variable or None if the variable is not in the make.conf
CLI Example:
salt 'salt* makeconf.get_cxxflags'

salt.modules.makeconf.get_emerge_default_opts()
Get the value of EMERGE_DEFAULT_OPTS variable in the make.conf
Return the value of the variable or None if the variable is not in the make.conf
CLI Example:
salt 'salt* makeconf.get_emerge_default_opts'

salt.modules.makeconf.get_features()
Get the value of FEATURES variable in the make.conf
Return the value of the variable or None if the variable is not in the make.conf
CLI Example:
salt '*' makeconf.get_features

salt.modules.makeconf.get_gentoo_mirrors()
Get the value of GENTOO_MIRRORS variable in the make.conf

Return the value of the variable or None if the variable is not in the make.conf

CLI Example:

salt '*' makeconf.get_gentoo_mirrors

salt.modules.makeconf.get_makeopts()
Get the value of MAKEOPTS variable in the make.conf

Return the value of the variable or None if the variable is not in the make.conf

CLI Example:

salt '*' makeconf.get_makeopts

salt.modules.makeconf.get_sync()
Get the value of SYNC variable in the make.conf

Return the value of the variable or None if the variable is not in the make.conf

CLI Example:

salt '*' makeconf.get_sync

salt.modules.makeconf.get_var(var)
Get the value of a variable in make.conf

Return the value of the variable or None if the variable is not in make.conf

CLI Example:

salt '*' makeconf.get_var 'LINGUAS'

salt.modules.makeconf.makeopts_contains(value)
Verify if MAKEOPTS variable contains a value in make.conf

Return True if value is set for var

CLI Example:

salt '*' makeconf.makeopts_contains '-j3'

salt.modules.makeconf.remove_var(var)
Remove a variable from the make.conf

Return a dict containing the new value for the variable:

```
{'<variable>': {'old': '<old-value>',
    'new': '<new-value>'}}
```

CLI Example:

salt '*' makeconf.remove_var 'LINGUAS'
salt.modules.makeconf.set_cflags(value)
Set the CFLAGS variable
Return a dict containing the new value for variable:
{
  '<variable>': {
    'old': '<old-value>',
    'new': '<new-value>'
  }
}

CLI Example:
salt '*' makeconf.set_cflags '-march=native -O2 -pipe'

salt.modules.makeconf.set_chost(value)
Set the CHOST variable
Return a dict containing the new value for variable:
{
  '<variable>': {
    'old': '<old-value>',
    'new': '<new-value>'
  }
}

CLI Example:
salt '*' makeconf.set_chost 'x86_64-pc-linux-gnu'

salt.modules.makeconf.set_cxxflags(value)
Set the CXXFLAGS variable
Return a dict containing the new value for variable:
{
  '<variable>': {
    'old': '<old-value>',
    'new': '<new-value>'
  }
}

CLI Example:
salt '*' makeconf.set_cxxflags '-march=native -O2 -pipe'

salt.modules.makeconf.set_emerge_default_opts(value)
Set the EMERGE_DEFAULT_OPTS variable
Return a dict containing the new value for variable:
{
  '<variable>': {
    'old': '<old-value>',
    'new': '<new-value>'
  }
}

CLI Example:
salt '*' makeconf.set_emerge_default_opts '--jobs'

salt.modules.makeconf.set_gentoo_mirrors(value)
Set the GENTOO_MIRRORS variable
Return a dict containing the new value for variable:
{
  '<variable>': {
    'old': '<old-value>',
    'new': '<new-value>'
  }
}

CLI Example:
salt '*' makeconf.set_gentoo_mirrors 'http://distfiles.gentoo.org'

salt.modules.makeconf.set_makeopts(value)
Set the MAKEOPTS variable

Return a dict containing the new value for variable:

```python
{'<variable>': {'old': '<old-value>', 'new': '<new-value>'}}
```

CLI Example:

```
salt '*' makeconf.set_makeopts '-j3'
```

salt.modules.makeconf.set_sync(value)
Set the SYNC variable

Return a dict containing the new value for variable:

```python
{'<variable>': {'old': '<old-value>', 'new': '<new-value>'}}
```

CLI Example:

```
salt '*' makeconf.set_sync 'rsync://rsync.namerica.gentoo.org/gentoo-portage'
```

salt.modules.makeconf.set_var(var, value)
Set a variable in the make.conf

Return a dict containing the new value for variable:

```python
{'<variable>': {'old': '<old-value>', 'new': '<new-value>'}}
```

CLI Example:

```
salt '*' makeconf.set_var 'LINGUAS' 'en'
```

salt.modules.makeconf.sync_contains(value)
Verify if SYNC variable contains a value in make.conf

Return True if value is set for var

CLI Example:

```
salt '*' makeconf.sync_contains 'rsync://rsync.namerica.gentoo.org/gentoo-portage'
```

salt.modules.makeconf.trim_cflags(value)
Remove a value from CFLAGS variable in the make.conf

Return a dict containing the new value for variable:

```python
{'<variable>': {'old': '<old-value>', 'new': '<new-value>'}}
```

CLI Example:

```
salt '*' makeconf.trim_cflags '-pipe'
```
salt.modules.makeconf.trim_cxxflags\(\text{value}\)
Remove a value from CXXFLAGS variable in the make.conf
Return a dict containing the new value for variable:

```
{ '<variable>': { 'old': '<old-value>',
                     'new': '<new-value>' }}
```

CLI Example:
```
salt '* makeconf.trim_cxxflags '-pipe'
```

salt.modules.makeconf.trim_emerge_default_opts\(\text{value}\)
Remove a value from EMERGE_DEFAULT_OPTS variable in the make.conf
Return a dict containing the new value for variable:

```
{ '<variable>': { 'old': '<old-value>',
                     'new': '<new-value>' }}
```

CLI Example:
```
salt '* makeconf.trim_emerge_default_opts '--jobs'
```

salt.modules.makeconf.trim_features\(\text{value}\)
Remove a value from FEATURES variable in the make.conf
Return a dict containing the new value for variable:

```
{ '<variable>': { 'old': '<old-value>',
                     'new': '<new-value>' }}
```

CLI Example:
```
salt '* makeconf.trim_features 'webrsync-gpg'
```

salt.modules.makeconf.trim_gentoo_mirrors\(\text{value}\)
Remove a value from GENTOO_MIRRORS variable in the make.conf
Return a dict containing the new value for variable:

```
{ '<variable>': { 'old': '<old-value>',
                     'new': '<new-value>' }}
```

CLI Example:
```
salt '* makeconf.trim_gentoo_mirrors 'http://distfiles.gentoo.org'
```

salt.modules.makeconf.trim_makeopts\(\text{value}\)
Remove a value from MAKEOPTS variable in the make.conf
Return a dict containing the new value for variable:

```
{ '<variable>': { 'old': '<old-value>',
                     'new': '<new-value>' }}
```

CLI Example:
```python
salt '*' makeconf.trim_makeopts '-j3'
```

```python
salt.modules.makeconf.trim_var(var, value)

Remove a value from a variable in the make.conf

Return a dict containing the new value for variable:

```
{ '<variable>': {
    'old': '<old-value>',
    'new': '<new-value>'
}}
```

CLI Example:

```python
salt '*' makeconf.trim_var 'LINGUAS' 'en'
```

```python
salt.modules.makeconf.var_contains(var, value)

Verify if variable contains a value in make.conf

Return True if value is set for var

CLI Example:

```python
salt '*' makeconf.var_contains 'LINGUAS' 'en'
```

### 32.17.149 salt.modules.match

The match module allows for match routines to be run and determine target specs

```python
salt.modules.match.compound(tgt, minion_id=None)

Return True if the minion ID matches the given compound target

minion_id Specify the minion ID to match against the target expression

    New in version 2014.7.0.

CLI Example:

```python
salt '*' match.compound 'L@cheese,foo and *'
```

```python
salt.modules.match.data(tgt)

Return True if the minion matches the given data target

CLI Example:

```python
salt '*' match.data 'spam:eggs'
```

```python
salt.modules.match.filter_by(lookup, expr_form='compound', minion_id=None)

Return the first match in a dictionary of target patterns

    New in version 2014.7.0.

CLI Example:

```python
salt '*' match.filter_by '{foo*: Foo!, bar*: Bar!}' minion_id=bar03
```

Pillar Example:

```python
[% set roles = salt['match.filter_by']({
    'web*': ['app', 'caching'],
```

32.17. Full list of builtin execution modules 1149
salt.modules.match.glob(tgt, minion_id=None)
Return True if the minion ID matches the given glob target

minion_id Specify the minion ID to match against the target expression
New in version 2014.7.0.

CLI Example:
salt '*' match.glob '*'

delimiter Specify an alternate delimiter to use when traversing a nested dict

salt.modules.match.grain(tgt, delimiter=':')
Return True if the minion matches the given grain target. The delimiter argument can be used to specify a different delimiter.

CLI Example:
salt '*' match.grain 'os:Ubuntu'
salt '*' match.grain 'ipv6|2001:db8::ff00:42:8329' delimiter='|'

delimiter Specify an alternate delimiter to use when traversing a nested dict

salt.modules.match.grain_pcre(tgt, delimiter=':')
Return True if the minion matches the given grain_pcre target. The delimiter argument can be used to specify a different delimiter.

CLI Example:
salt '*' match.grain_pcre 'os:Fedo.*'
salt '*' match.grain_pcre 'ipv6|2001:.*' delimiter='|'

delimiter Specify an alternate delimiter to use when traversing a nested dict

salt.modules.match.ipcidr(tgt)
Return True if the minion matches the given ipcidr target

CLI Example:
salt '*' match.ipcidr '192.168.44.0/24'

delimiter Pillar Example:
'172.16.0.0/12':
    - match: ipcidr
    - nodeclass: internal

salt.modules.match.list(tgt, minion_id=None)
    Return True if the minion ID matches the given list target
    
    minion_id Specify the minion ID to match against the target expression
    
    New in version 2014.7.0.
    
    CLI Example:
    salt '*' match.list 'server1,server2'

salt.modules.match.pcre(tgt, minion_id=None)
    Return True if the minion ID matches the given pcre target
    
    minion_id Specify the minion ID to match against the target expression
    
    New in version 2014.7.0.
    
    CLI Example:
    salt '*' match.pcre '.', '*'

salt.modules.match.pillar(tgt, delimiter=':')
    Return True if the minion matches the given pillar target. The delimiter argument can be used to specify a different delimiter.
    
    CLI Example:
    salt '*' match.pillar 'cheese:foo'
salt '*' match.pillar 'clone_url|https://github.com/saltstack/salt.git' delimiter='|'

delimiter Specify an alternate delimiter to use when traversing a nested dict
    
    New in version 2014.7.0.

delim Specify an alternate delimiter to use when traversing a nested dict
    
    New in version 0.16.4.
    
    Deprecated since version 2015.8.0.

salt.modules.match.pillar_pcre(tgt, delimiter=':')
    Return True if the minion matches the given pillar_pcre target. The delimiter argument can be used to specify a different delimiter.
    
    CLI Example:
    salt '*' match.pillar_pcre 'cheese:(swiss|american)'
salt '*' match.pillar_pcre 'clone_url|https://github\.com/.*\.git' delimiter='|'

delimiter Specify an alternate delimiter to use when traversing a nested dict
    
    New in version 2014.7.0.
**delim** Specify an alternate delimiter to use when traversing a nested dict

New in version 0.16.4.

Deprecated since version 2015.8.0.

### 32.17.150 salt.modules.mdadm

Salt module to manage RAID arrays with mdadm

salt.modules.mdadm.assemble(name, devices, test_mode=False, **kwargs)

Assemble a RAID device.

**CLI Examples:**

```
salt '*' raid.assemble /dev/md0 ['/dev/xvdd', '/dev/xvde']
```

**Note:** Adding `test_mode=True` as an argument will print out the mdadm command that would have been run.

- **name** The name of the array to assemble.
- **devices** The list of devices comprising the array to assemble.
- **kwargs** Optional arguments to be passed to mdadm.
- **returns**
  - `test_mode=True`: Prints out the full command.
  - `test_mode=False (Default)`: Executes command on the host(s) and prints out the mdadm output.

For more info, read the mdadm manpage.

salt.modules.mdadm.create(name, level, devices, metadata='default', test_mode=False, **kwargs)

Create a RAID device.

Changed in version 2014.7.0.

**Warning:** Use with CAUTION, as this function can be very destructive if not used properly!

**CLI Examples:**

```
salt '*' raid.create /dev/md0 level=1 chunk=256 devices="['/dev/xvdd', '/dev/xvde']" test_mode=True
```

**Note:** Adding `test_mode=True` as an argument will print out the mdadm command that would have been run.

- **name** The name of the array to create.
- **level** The RAID level to use when creating the raid.
- **devices** A list of devices used to build the array.
**metadata**  Version of metadata to use when creating the array.

**kwargs**  Optional arguments to be passed to mdadm.

**returns**

- **test_mode=True**: Prints out the full command.
- **test_mode=False (Default)**: Executes command on remote the host(s) and Prints out the mdadm output.

---

**Note:** It takes time to create a RAID array. You can check the progress in `resync_status:` field of the results from the following command:

```
salt '*' raid.detail /dev/md0
```

For more info, read the `mdadm(8)` manpage

**salt.modules.mdadm.destroy**(*device*)

Destroy a RAID device.

**WARNING** This will zero the superblock of all members of the RAID array.

CLI Example:

```
salt '*' raid.destroy /dev/md0
```

**salt.modules.mdadm.detail**(*device=/dev/md0*)

Show detail for a specified RAID device

CLI Example:

```
salt '*' raid.detail '/dev/md0'
```

**salt.modules.mdadm.list()**

List the RAID devices.

CLI Example:

```
salt '*' raid.list
```

**salt.modules.mdadm.save_config()**

Save RAID configuration to config file.

Same as: `mdadm --detail --scan >> /etc/mdadm/mdadm.conf`

Fixes this issue with Ubuntu REF: [http://askubuntu.com/questions/209702/why-is-my-raid-dev-md1-showing-up-as-dev-md126-is-mdadm-conf-being-ignored](http://askubuntu.com/questions/209702/why-is-my-raid-dev-md1-showing-up-as-dev-md126-is-mdadm-conf-being-ignored)

CLI Example:

```
salt '*' raid.save_config
```

**salt.modules.mdadm.stop()**

Shut down all arrays that can be shut down (i.e. are not currently in use).

CLI Example:

```
salt '*' raid.stop
```
32.17.151 salt.modules.memcached

Module for Management of Memcached Keys

New in version 2014.1.0.

salt.modules.memcached.add(key, value, host=`127.0.0.1', port=11211, time=0, min_compress_len=0)

Add a key to the memcached server, but only if it does not exist. Returns False if the key already exists.

CLI Example:

```
salt '*' memcached.add <key> <value>
```

salt.modules.memcached.decrement(key, delta=1, host=`127.0.0.1', port=11211)

Decrement the value of a key

CLI Example:

```
salt '*' memcached.decrement <key>
salt '*' memcached.decrement <key> 2
```

salt.modules.memcached.delete(key, host=`127.0.0.1', port=11211, time=0)

Delete a key from memcache server

CLI Example:

```
salt '*' memcached.delete <key>
```

salt.modules.memcached.get(key, host=`127.0.0.1', port=11211)

Retrieve value for a key

CLI Example:

```
salt '*' memcached.get <key>
```

salt.modules.memcached.increment(key, delta=1, host=`127.0.0.1', port=11211)

Increment the value of a key

CLI Example:

```
salt '*' memcached.increment <key>
salt '*' memcached.increment <key> 2
```

salt.modules.memcached.replace(key, value, host=`127.0.0.1', port=11211, time=0, min_compress_len=0)

Replace a key on the memcached server. This only succeeds if the key already exists. This is the opposite of memcached.add

CLI Example:

```
salt '*' memcached.replace <key> <value>
```

salt.modules.memcached.set(key, value, host=`127.0.0.1', port=11211, time=0, min_compress_len=0)

Set a key on the memcached server, overwriting the value if it exists.

CLI Example:

```
salt '*' memcached.set <key> <value>
```
salt.modules.memcached.status(\texttt{host=`127.0.0.1', port=11211})
Get memcached status

CLI Example:

\texttt{salt 'x' memcached.status}

### 32.17.152 salt.modules.mine

The function cache system allows for data to be stored on the master so it can be easily read by other minions

salt.modules.mine.delete(\texttt{fun})
Remove specific function contents of minion. Returns True on success.

CLI Example:

\texttt{salt 'x' mine.delete 'network.interfaces'}

salt.modules.mine.flush()
Remove all mine contents of minion. Returns True on success.

CLI Example:

\texttt{salt 'x' mine.flush}

salt.modules.mine.get(\texttt{tgt, fun, expr_form='glob'})
Get data from the mine based on the target, function and expr_form

Targets can be matched based on any standard matching system that can be matched on the master via these keywords:

\begin{itemize}
  \item \texttt{glob}
  \item \texttt{pcre}
  \item \texttt{grain}
  \item \texttt{grain_pcre}
  \item \texttt{compound}
  \item \texttt{pillar}
  \item \texttt{pillar_pcre}
\end{itemize}

Note that all pillar matches, whether using the compound matching system or the pillar matching system, will be exact matches, with globbing disabled.

CLI Example:

\texttt{salt 'x' mine.get 'x' network.interfaces}
\texttt{salt 'x' mine.get 'os:Fedora' network.interfaces grain}
\texttt{salt 'x' mine.get 'os:Fedora and S@192.168.5.0/24' network.ipaddrs compound}

salt.modules.mine.get_docker(\texttt{interfaces=None, cidrs=None, with_container_id=False})
Get all mine data for `docker.get_containers' and run an aggregation routine. The "interfaces" parameter allows for specifying which network interfaces to select ip addresses from. The "cidrs" parameter allows for specifying a list of cidrs which the ip address must match.

\begin{itemize}
  \item \texttt{with_container_id}  Boolean, to expose container_id in the list of results
\end{itemize}

New in version 2015.8.2.

CLI Example:
Salt modules.mine.send(func, *args, **kwargs)

Send a specific function to the mine.

CLI Example:

```
salt '*' mine.send network.ip_addrs eth0
salt '*' mine.send eth0_ip_addrs mine_function=network.ip_addrs eth0
```

Salt modules.mine.update(clear=False)

Execute the configured functions and send the data back up to the master. The functions to be executed are merged from the master config, pillar and minion config under the option `function_cache`:

```
machine_functions:
    network.ip_addrs:
        - eth0
    disk.usage: []
```

The function cache will be populated with information from executing these functions.

CLI Example:

```
salt '*' mine.update
```

32.17.153 salt.modules.mod_random

Provides access to randomness generators.

New in version 2014.7.0.

Salt modules.mod_random.get_str(length=20)

New in version 2014.7.0.

Returns a random string of the specified length.

**length** [20] Any valid number of bytes.

CLI Example:

```
salt '*' random.get_str 128
```

Salt modules.mod_random.hash(value, algorithm='sha512')

New in version 2014.7.0.

Encodes a value with the specified encoder.

**value** The value to be hashed.

**algorithm** [sha512] The algorithm to use. May be any valid algorithm supported by hashlib.

CLI Example:
salt '*' random.hash 'I am a string' md5

salt.modules.mod_random.rand_int(start=1, end=10)
  Returns a random integer number between the start and end number.
  start [1] Any valid integer number
  end [10] Any valid integer number
  CLI Example:
    salt '*' random.rand_int 1 10

salt.modules.mod_random.seed(range=10, hash=None)
  Returns a random number within a range. Optional hash argument can be any hashable object. If hash is
  omitted or None, the id of the minion is used.
  hash: None  Any hashable object.
  range: 10  Any valid integer number
  CLI Example:
    salt '*' random.seed 10 hash=None

salt.modules.mod_random.shadow_hash(crypt_salt=None, password=None, algorithm='sha512')
  Generates a salted hash suitable for /etc/shadow.
  crypt_salt [None] Salt to be used in the generation of the hash. If one is not provided, a random salt will be
  generated.
  password [None] Value to be salted and hashed. If one is not provided, a random password will be generated.
  algorithm [sha512] Hash algorithm to use.
  CLI Example:
    salt '*' random.shadow_hash 'My5alT' 'MyP@sswd' md5

salt.modules.mod_random.str_encode(value, encoder='base64')
  New in version 2014.7.0.
  value  The value to be encoded.
  encoder [base64] The encoder to use on the subsequent string.
  CLI Example:
    salt '*' random.str_encode 'I am a new string' base64

32.17.154 salt.modules.modjk

Control Modjk via the Apache Tomcat ```Status``` worker (http://tomcat.apache.org/connectors-doc/reference/status.html)

Below is an example of the configuration needed for this module. This configuration data can be placed either in
grains or pillar.

If using grains, this can be accomplished **statically** or via a **grain module.**
If using pillar, the yaml configuration can be placed directly into a pillar SLS file, making this both the easier and more dynamic method of configuring this module.

```yaml
modjk:
  default:
    url: http://localhost/jkstatus
    user: modjk
    pass: secret
    realm: authentication realm for digest passwords
    timeout: 5
  otherVhost:
    url: http://otherVhost/jkstatus
    user: modjk
    pass: secret2
    realm: authentication realm2 for digest passwords
    timeout: 600
```

salt.modules.modjk.bulk_activate(workers, lbn, profile='default')
Activate all the given workers in the specific load balancer

CLI Examples:

```
salt '*' modjk.bulk_activate node1,node2,node3 loadbalancer1
salt '*' modjk.bulk_activate node1,node2,node3 loadbalancer1 other-profile
salt '*' modjk.bulk_activate ['node1','node2','node3'] loadbalancer1
salt '*' modjk.bulk_activate ['node1','node2','node3'] loadbalancer1 other-profile
```

class.modules.modjk.bulk_disable(workers, lbn, profile='default')
Disable all the given workers in the specific load balancer

CLI Examples:

```
salt '*' modjk.bulk_disable node1,node2,node3 loadbalancer1
salt '*' modjk.bulk_disable node1,node2,node3 loadbalancer1 other-profile
salt '*' modjk.bulk_disable ['node1','node2','node3'] loadbalancer1
salt '*' modjk.bulk_disable ['node1','node2','node3'] loadbalancer1 other-profile
```

class.modules.modjk.bulk_recover(workers, lbn, profile='default')
Recover all the given workers in the specific load balancer

CLI Examples:

```
salt '*' modjk.bulk_recover node1,node2,node3 loadbalancer1
salt '*' modjk.bulk_recover node1,node2,node3 loadbalancer1 other-profile
salt '*' modjk.bulk_recover ['node1','node2','node3'] loadbalancer1
salt '*' modjk.bulk_recover ['node1','node2','node3'] loadbalancer1 other-profile
```

class.modules.modjk.bulk_stop(workers, lbn, profile='default')
Stop all the given workers in the specific load balancer

CLI Examples:

```
salt '*' modjk.bulk_stop node1,node2,node3 loadbalancer1
salt '*' modjk.bulk_stop node1,node2,node3 loadbalancer1 other-profile
salt '*' modjk.bulk_stop ['node1','node2','node3'] loadbalancer1
salt '*' modjk.bulk_stop ['node1','node2','node3'] loadbalancer1 other-profile
```
salt.modules.modjk.dump_config(profile='default')
Dump the original configuration that was loaded from disk

CLI Examples:

```bash
salt '*' modjk.dump_config
salt '*' modjk.dump_config other-profile
```

salt.modules.modjk.get_running(profile='default')
Get the current running config (not from disk)

CLI Examples:

```bash
salt '*' modjk.get_running
salt '*' modjk.get_running other-profile
```

salt.modules.modjk.lb_edit(lbn, settings, profile='default')
Edit the loadbalancer settings

Note: http://tomcat.apache.org/connectors-doc/reference/status.html Data Parameters for the standard Update Action

CLI Examples:

```bash
salt '*' modjk.lb_edit loadbalancer1 "{'vlr': 1, 'vlt': 60}"
salt '*' modjk.lb_edit loadbalancer1 "{'vlr': 1, 'vlt': 60}" other-profile
```

salt.modules.modjk.list_configured_members(lbn, profile='default')
Return a list of member workers from the configuration files

CLI Examples:

```bash
salt '*' modjk.list_configured_members loadbalancer1
salt '*' modjk.list_configured_members loadbalancer1 other-profile
```

salt.modules.modjk.recover_all(lbn, profile='default')
Set the all the workers in lbn to recover and activate them if they are not

CLI Examples:

```bash
salt '*' modjk.recover_all loadbalancer1
salt '*' modjk.recover_all loadbalancer1 other-profile
```

salt.modules.modjk.reset_stats(lbn, profile='default')
Reset all runtime statistics for the load balancer

CLI Examples:

```bash
salt '*' modjk.reset_stats loadbalancer1
salt '*' modjk.reset_stats loadbalancer1 other-profile
```

salt.modules.modjk.version(profile='default')
Return the modjk version

CLI Examples:

```bash
salt '*' modjk.version
salt '*' modjk.version other-profile
```
salt.modules.modjk.worker_activate(worker, lbn, profile='default')
Set the worker to activate state in the lbn load balancer

CLI Examples:
```
salt '*' modjk.worker_activate node1 loadbalancer1
salt '*' modjk.worker_activate node1 loadbalancer1 other-profile
```

salt.modules.modjk.worker_disable(worker, lbn, profile='default')
Set the worker to disable state in the lbn load balancer

CLI Examples:
```
salt '*' modjk.worker_disable node1 loadbalancer1
salt '*' modjk.worker_disable node1 loadbalancer1 other-profile
```

salt.modules.modjk.worker_edit(worker, lbn, settings, profile='default')
Edit the worker settings

CLI Examples:
```
salt '*' modjk.worker_edit node1 loadbalancer1 "{"vwf": 500, 'vwd': 60}" 
salt '*' modjk.worker_edit node1 loadbalancer1 "{"vwf": 500, 'vwd': 60}" other-profile
```

salt.modules.modjk.worker_recover(worker, lbn, profile='default')
Set the worker to recover this module will fail if it is in OK state

CLI Examples:
```
salt '*' modjk.worker_recover node1 loadbalancer1
salt '*' modjk.worker_recover node1 loadbalancer1 other-profile
```

salt.modules.modjk.worker_status(worker, profile='default')
Return the state of the worker

CLI Examples:
```
salt '*' modjk.worker_status node1
salt '*' modjk.worker_status node1 other-profile
```

salt.modules.modjk.worker_stop(worker, lbn, profile='default')
Set the worker to stopped state in the lbn load balancer

CLI Examples:
```
salt '*' modjk.worker_activate node1 loadbalancer1
salt '*' modjk.worker_activate node1 loadbalancer1 other-profile
```

salt.modules.modjk.workers(profile='default')
Return a list of member workers and their status

CLI Examples:
```
salt '*' modjk.workers
salt '*' modjk.workers other-profile
```
32.17.155 salt.modules.mongodb

Module to provide MongoDB functionality to Salt

configuration  This module uses PyMongo, and accepts configuration details as parameters as well as configuration settings:

```
mongodb.host: 'localhost'
mongodb.port: 27017
mongodb.user: ''
mongodb.password: ''
```

This data can also be passed into pillar. Options passed into opts will overwrite options passed into pillar.

salt.modules.mongodb.db_exists(name, user=None, password=None, host=None, port=None)
Checks if a database exists in Mongodb

CLI Example:

```
salt '*' mongodb.db_exists <name> <user> <password> <host> <port>
```

salt.modules.mongodb.db_list(user=None, password=None, host=None, port=None)
List all Mongodb databases

CLI Example:

```
salt '*' mongodb.db_list <user> <password> <host> <port>
```

salt.modules.mongodb.db_remove(name, user=None, password=None, host=None, port=None)
Remove a Mongodb database

CLI Example:

```
salt '*' mongodb.db_remove <name> <user> <password> <host> <port>
```

salt.modules.mongodb.find(collection, query=None, user=None, password=None, host=None, port=None, database='admin')
Find an object or list of objects in a collection

CLI Example:

```
salt '*' mongodb.find mycollection '[["foo": "FOO", "bar": "BAR"]]' <user> <password> <host> <port> <database>
```

salt.modules.mongodb.insert(objects, collection, user=None, password=None, host=None, port=None, database='admin')
Insert an object or list of objects into a collection

CLI Example:

```
salt '*' mongodb.insert '[["foo": "FOO", "bar": "BAR"], {"foo": "BAZ", "bar": "BAM --"}]'] mycollection <user> <password> <host> <port> <database>
```

salt.modules.mongodb.remove(collection, query=None, user=None, password=None, host=None, port=None, database='admin', w=1)
Remove an object or list of objects into a collection

CLI Example:
salt documentation, release 2015.8.12

salt '*' mongodb.remove mycollection '[["foo": "FOO", "bar": "BAR"], ["foo": "BAZ", "bar": "BAM"]]' <user> <password> <host> <port> <database>

salt.modules.mongodb.user_create(name, passwd, user=None, password=None, host=None, port=None, database='admin')
Create a Mongodb user
CLI Example:
salt '*' mongodb.user_create <name> <user> <password> <host> <port> <database>

salt.modules.mongodb.user_exists(name, user=None, password=None, host=None, port=None, database='admin')
Checks if a user exists in Mongodb
CLI Example:
salt '*' mongodb.user_exists <name> <user> <password> <host> <port> <database>

salt.modules.mongodb.user_grant_roles(name, roles, database, user=None, password=None, host=None, port=None)
Grant one or many roles to a Mongodb user
CLI Examples:
salt '*' mongodb.user_grant_roles johndoe ['"readWrite"'] dbname admin adminpwd localhost 27017
salt '*' mongodb.user_grant_roles janedoe ["{"role": "readWrite", "db": "dbname" }, {"role": "read", "db": "otherdb"}] dbname admin adminpwd localhost 27017

salt.modules.mongodb.user_list(user=None, password=None, host=None, port=None, database='admin')
List users of a Mongodb database
CLI Example:
salt '*' mongodb.user_list <user> <password> <host> <port> <database>

salt.modules.mongodb.user_remove(name, user=None, password=None, host=None, port=None, database='admin')
Remove a Mongodb user
CLI Example:
salt '*' mongodb.user_remove <name> <user> <password> <host> <port> <database>

salt.modules.mongodb.user_revoke_roles(name, roles, database, user=None, password=None, host=None, port=None)
Revoke one or many roles to a Mongodb user
CLI Examples:
salt '*' mongodb.user_revoke_roles johndoe ['"readWrite"'] dbname admin adminpwd localhost 27017
salt '*' mongodb.user_revoke_roles janedoe ["{"role": "readWrite", "db": "dbname" }, {"role": "read", "db": "otherdb"}] dbname admin adminpwd localhost 27017
salt.modules.mongodb.user_roles_exists(name, roles, database, user=None, password=None, host=None, port=None)

Checks if a user of a Mongodb database has specified roles

CLI Examples:
```
salt '*' mongodb.user_roles_exists johndoe ['"readWrite"] dbname admin adminpwd
→ localhost 27017
```

```
salt '*' mongodb.user_roles_exists johndoe ['{"role": "readWrite", "db": "dbname"}', "{"role": "read", "db": "otherdb"}'] dbname admin adminpwd localhost 27017
```

### 32.17.156 salt.modules.monit

Monit service module. This module will create a monit type service watcher.

salt.modules.monit.monitor(name)

monitor service via monit

CLI Example:
```
salt '*' monit.monitor <service name>
```

salt.modules.monit.restart(name)

Restart service via monit

CLI Example:
```
salt '*' monit.restart <service name>
```

salt.modules.monit.start(name)

CLI Example:
```
salt '*' monit.start <service name>
```

salt.modules.monit.status(svc_name='')

Display a process status from monit

CLI Example:
```
salt '*' monit.status
salt '*' monit.status <service name>
```

salt.modules.monit.stop(name)

Stops service via monit

CLI Example:
```
salt '*' monit.stop <service name>
```

salt.modules.monit.summary(svc_name='')

Display a summary from monit

CLI Example:
```
salt '*' monit.summary
salt '*' monit.summary <service name>
```
salt.modules.monit.unmonitor(name)
    Unmonitor service via monit
    CLI Example:
    ```
salt '*' monit.unmonitor <service name>
    ```

32.17.157 salt.modules.moosefs

Module for gathering and managing information about MooseFS

salt.modules.moosefs.dirinfo(path, opts=None)
    Return information on a directory located on the Moose
    CLI Example:
    ```
salt '*' moosefs.dirinfo /path/to/dir/ [-n][h|H]]
    ```

salt.modules.moosefs.fileinfo(path)
    Return information on a file located on the Moose
    CLI Example:
    ```
salt '*' moosefs.fileinfo /path/to/dir/
    ```

salt.modules.moosefs.getgoal(path, opts=None)
    Return goal(s) for a file or directory
    CLI Example:
    ```
salt '*' moosefs.getgoal /path/to/file [-n][h|H]]
salt '*' moosefs.getgoal /path/to/dir/ [-n][h|H][r]
    ```

salt.modules.moosefs.mounts()
    Return a list of current MooseFS mounts
    CLI Example:
    ```
salt '*' moosefs.mounts
    ```

32.17.158 salt.modules.mount

Salt module to manage Unix mounts and the fstab file

salt.modules.mount.active(extended=False)
    List the active mounts.
    CLI Example:
    ```
salt '*' mount.active
    ```

salt.modules.mount.automaster(config='/etc/auto_salt')
    List the contents of the auto master
    CLI Example:
    ```
salt '*' mount.automaster
    ```
salt.modules.mount.fstab(config='/etc/fstab')
    List the contents of the fstab
    CLI Example:
    ```
salt '*' mount.fstab
    ```

salt.modules.mount.is_fuse_exec(cmd)
    Returns true if the command passed is a fuse mountable application.
    CLI Example:
    ```
salt '*' mount.is_fuse_exec sshfs
    ```

salt.modules.mount.is_mounted(name)
    New in version 2014.7.0.
    Provide information if the path is mounted
    CLI Example:
    ```
salt '*' mount.is_mounted /mnt/share
    ```

salt.modules.mount.mount(name, device, mkmnt=False, fstype='', opts='defaults', user=None)
    Mount a device
    CLI Example:
    ```
salt '*' mount.mount /mnt/foo /dev/sdz1 True
    ```

salt.modules.mount.remount(name, device, mkmnt=False, fstype='', opts='defaults', user=None)
    Attempt to remount a device, if the device is not already mounted, mount is called
    CLI Example:
    ```
salt '*' mount.remount /mnt/foo /dev/sdz1 True
    ```

salt.modules.mount.rm_automaster(name, device, config='/etc/auto_salt')
    Remove the mount point from the auto_master
    CLI Example:
    ```
salt '*' mount.rm_automaster /mnt/foo /dev/sdg
    ```

salt.modules.mount.rm_fstab(name, device, config='/etc/fstab')
    Remove the mount point from the fstab
    CLI Example:
    ```
salt '*' mount.rm_fstab /mnt/foo /dev/sdg
    ```

salt.modules.mount.set_automaster(name, device, fstype, opts='', config='/etc/auto_salt', test=False, **kwargs)
    Verify that this mount is represented in the auto_salt, change the mount to match the data passed, or add the mount if it is not present.
    CLI Example:
    ```
salt '*' mount.set_automaster /mnt/foo /dev/sdz1 ext4
    ```
**salt.modules.mount**

### set_fstab

```
set_fstab(name, device, fstype, opts='defaults', dump=0, pass_num=0, config='/etc/fstab', test=False, match_on='auto', **kwargs)
```

Verify that this mount is represented in the fstab, change the mount to match the data passed, or add the mount if it is not present.

**CLI Example:**

```
salt '*' mount.set_fstab /mnt/foo /dev/sdz1 ext4
```

### swapoff

```
swapoff(name)
```

Deactivate a named swap mount

**CLI Example:**

```
salt '*' mount.swapoff /root/swapfile
```

### swapon

```
swapon(name, priority=None)
```

Activate a swap disk

**CLI Example:**

```
salt '*' mount.swapon /root/swapfile
```

### swaps

```
swaps()
```

Return a dict containing information on active swap

**CLI Example:**

```
salt '*' mount.swaps
```

### umount

```
umount(name, device=None, user=None)
```

Attempt to unmount a device by specifying the directory it is mounted on

**CLI Example:**

```
salt '*' mount.umount /mnt/foo
```

New in version 2015.5.0.

```
salt '*' mount.umount /mnt/foo /dev/xvdc1
```

### 32.17.159 salt.modules.mssql

Module to provide MS SQL Server compatibility to salt.

**depends**

- FreetDS
- pymssql Python module

**configuration** In order to connect to MS SQL Server, certain configuration is required in minion config/pillars on the relevant minions. Some sample pillars might look like:

```
mssql.server: 'localhost'
mssql.port: 1433
mssql.user: 'sysdba'
mssql.password: 'Some preferable complex password'
mssql.database: '1166 Chapter 32. Reference'```
The default for the port is `1433` and for the database is `''` (empty string); in most cases they can be left at the default setting. Options that are directly passed into functions will overwrite options from configs or pillars.

```python
salt.modules.mssql.db_exists(database_name, **kwargs)
Find if a specific database exists on the MS SQL server.
```

**CLI Example:**
```
salt minion mssql.db_exists database_name='DBNAME'
```

```python
salt.modules.mssql.db_list(**kwargs)
Return the database list created on a MS SQL server.
```

**CLI Example:**
```
salt minion mssql.db_list
```

```python
salt.modules.mssql.db_remove(database_name, **kwargs)
Drops a specific database from the MS SQL server. It will not drop any of `master`, `model`, `msdb` or `tempdb`.
```

**CLI Example:**
```
salt minion mssql.db_remove database_name='DBNAME'
```

```python
salt.modules.mssql.login_exists(login, **kwargs)
Find if a login exists in the MS SQL server.
```

**CLI Example:**
```
salt minion mssql.login_exists 'LOGIN'
```

```python
salt.modules.mssql.role_create(role, owner=None, **kwargs)
Creates a new database role. If no owner is specified, the role will be owned by the user that executes CREATE ROLE, which is the user argument or mssql.user option.
```

**CLI Example:**
```
salt minion mssql.role_create role=product01 owner=sysdba
```

```python
salt.modules.mssql.role_exists(role, **kwargs)
Checks if a role exists.
```

**CLI Example:**
```
salt minion mssql.role_exists db_owner
```

```python
salt.modules.mssql.role_list(**kwargs)
Lists database roles.
```

**CLI Example:**
```
salt minion mssql.role_list
```

```python
salt.modules.mssql.role_remove(role, **kwargs)
Remove a database role.
```

**CLI Example:**
salt minion mssql.role_create role=test_role01

salt.modules.mssql.tsql_query(query, **kwargs)
Run a SQL query and return query result as list of tuples, or a list of dictionaries if as_dict was passed, or an empty list if no data is available.

CLI Example:
```
salt minion mssql.tsql_query 'SELECT @@version as version' as_dict=True
```

salt.modules.mssql.user_create(username, new_login_password=None, **kwargs)
Creates a new user. If new_login_password is not specified, the user will be created without a login.

CLI Example:
```
salt minion mssql.user_create USERNAME database=DBNAME [new_login_password=PASSWORD]
```

salt.modules.mssql.user_exists(username, **kwargs)
Find if an user exists in a specific database on the MS SQL server.

Note: database argument is mandatory

CLI Example:
```
salt minion mssql.user_exists 'USERNAME' [database='DBNAME']
```

salt.modules.mssql.user_list(**kwargs)
Get the user list for a specific database on the MS SQL server.

CLI Example:
```
salt minion mssql.user_list [database='DBNAME']
```

salt.modules.mssql.user_remove(username, **kwargs)
Removes an user.

CLI Example:
```
salt minion mssql.user_remove USERNAME database=DBNAME
```

salt.modules.mssql.version(**kwargs)
Return the version of a MS SQL server.

CLI Example:
```
salt minion mssql.version
```

**32.17.160 salt.modules.munin**

Run munin plugins/checks from salt and format the output as data.

salt.modules.munin.list_plugins()
List all the munin plugins

CLI Example:
salt '*' munin.list_plugins

salt.modules.munin.run(plugins)
Run one or more named munin plugins

CLI Example:
salt '*' munin.run uptime
salt '*' munin.run uptime,cpu,load,memory

salt.modules.munin.run_all()
Run all the munin plugins

CLI Example:
salt '*' munin.run_all

32.17.161 salt.modules.mysql

Module to provide MySQL compatibility to salt.

depends
- MySQLdb Python module

Note: On CentOS 5 (and possibly RHEL 5) both MySQL-python and python26-mysqldb need to be installed.

configuration In order to connect to MySQL, certain configuration is required in /etc/salt/minion on the relevant minions. Some sample configs might look like:

```python
dict = {
    'mysql.host': 'localhost',
    'mysql.port': 3306,
    'mysql.user': 'root',
    'mysql.pass': '',
    'mysql.db': 'mysql',
    'mysql.unix_socket': '/tmp/mysql.sock',
    'mysql.charset': 'utf8'
}
```

You can also use a defaults file:

```python
dict = {
    'mysql.default_file': '/etc/mysql/debian.cnf'
}
```

Changed in version 2014.1.0: charset connection argument added. This is a MySQL charset, not a python one.

Changed in version 0.16.2: Connection arguments from the minion config file can be overridden on the CLI by using the arguments defined here. Additionally, it is now possible to setup a user with no password.

salt.modules.mysql.db_check(name, table=None, **connection_args)
Repairs the full database or just a given table

CLI Example:
salt '*' mysql.db_check dbname
salt '*' mysql.db_check dbname dbtable

salt.modules.mysql.db_create(name, character_set=None, collate=None, **connection_args)
Adds a databases to the MySQL server.
name  The name of the database to manage
character_set  The character set, if left empty the MySQL default will be used
collate  The collation, if left empty the MySQL default will be used

CLI Example:

```
salt '*' mysql.db_create 'dbname'
salt '*' mysql.db_create 'dbname' 'utf8' 'utf8_general_ci'
```

salt.modules.mysql.db_exists(name, **connection_args)
Checks if a database exists on the MySQL server.

CLI Example:

```
salt '*' mysql.db_exists 'dbname'
```

salt.modules.mysql.db_list(**connection_args)
Return a list of databases of a MySQL server using the output from the SHOW DATABASES query.

CLI Example:

```
salt '*' mysql.db_list
```

salt.modules.mysql.db_optimize(name, table=None, **connection_args)
Optimizes the full database or just a given table

CLI Example:

```
salt '*' mysql.db_optimize dbname
```

salt.modules.mysql.db_remove(name, **connection_args)
Removes a databases from the MySQL server.

CLI Example:

```
salt '*' mysql.db_remove 'dbname'
```

salt.modules.mysql.db_repair(name, table=None, **connection_args)
Repairs the full database or just a given table

CLI Example:

```
salt '*' mysql.db_repair dbname
```

salt.modules.mysql.db_tables(name, **connection_args)
Shows the tables in the given MySQL database (if exists)

CLI Example:

```
salt '*' mysql.db_tables 'database'
```

salt.modules.mysql.free_slave(**connection_args)
Frees a slave from its master. This is a WIP, do not use.

CLI Example:

```
salt '*' mysql.free_slave
```
salt.modules.mysql.get_master_status(**connection_args)
Retrieves the master status from the minion.

Returns:

```python
{'host.domain.com': {'Binlog_Do_DB': '',
                     'Binlog_Ignore_DB': '',
                     'File': 'mysql-bin.000021',
                     'Position': 107}}
```

CLI Example:

```
salt '*' mysql.get_master_status
```

salt.modules.mysql.get_slave_status(**connection_args)
Retrieves the slave status from the minion.

Returns:

```python
{'host.domain.com': {'Connect_Retry': 60,
                     'Exec_Master_Log_Pos': 107,
                     'Last_Errno': 0,
                     'Last_Error': '',
                     'Last_IO_Errno': 0,
                     'Last_IO_Error': '',
                     'Last_SQL_Errno': 0,
                     'Last_SQL_Error': '',
                     'Master_Host': 'comet.scion-eng.com',
                     'Master_Log_File': 'mysql-bin.000021',
                     'Master_Port': 3306,
                     'Master_SSL_Allowed': 'No',
                     'Master_SSL_CA_File': '',
                     'Master_SSL_CA_Path': '',
                     'Master_SSL_Cert': '',
                     'Master_SSL_Key': '',
                     'Master_SSL_Verify_Server_Cert': 'No',
                     'Master_Server_Id': 1,
                     'Master_User': 'replu',
                     'Read_Master_Log_Pos': 107,
                     'Relay_Log_File': 'klo-relay-bin.000071',
                     'Relay_Log_Pos': 253,
                     'Relay_Log_Space': 553,
                     'Relay_Master_Log_File': 'mysql-bin.000021',
                     'Replicate_Do_DB': '',
                     'Replicate_Do_Table': '',
                     'Replicate_Ignore_DB': '',
                     'Replicate_Ignore_Server_Ids': '',
                     'Replicate_Ignore_Table': '',
                     'Replicate_Wild_Do_Table': '',
                     'Replicate_Wild_Ignore_Table': '',
                     'Seconds_Behind_Master': 0,
                     'Skip_Counter': 0,
                     'Slave_IO_Running': 'Yes',
                     'Slave_IO_State': 'Waiting for master to send event',
                     'Slave_SQL_Running': 'Yes',
                     'Until_Condition': 'None',
                     'Until_Log_File': '',
                     'Until_Log_Pos': 0}}
```
CLI Example:

```
salt '*' mysql.get_slave_status
```

```
salt.modules.mysql.grant_add(grant, database, user, host='localhost', grant_option=False, escape=True, ssl_option=False, **connection_args)
```

Adds a grant to the MySQL server.

For database, make sure you specify database.table or database.*

CLI Example:

```
salt '*' mysql.grant_add 'SELECT,INSERT,UPDATE,...' 'database.*' 'frank' !'localhost'
```

```
salt.modules.mysql.grant_exists(grant, database, user, host='localhost', grant_option=False, escape=True, **connection_args)
```

Checks to see if a grant exists in the database

CLI Example:

```
salt '*' mysql.grant_exists 'SELECT,INSERT,UPDATE,...' 'database.*' 'frank' !'localhost'
```

```
salt.modules.mysql.grant_revoke(grant, database, user, host='localhost', grant_option=False, escape=True, **connection_args)
```

Removes a grant from the MySQL server.

CLI Example:

```
salt '*' mysql.grant_revoke 'SELECT,INSERT,UPDATE' 'database.*' 'frank' !'localhost'
```

```
salt.modules.mysql.processlist(**connection_args)
```

Retrieves the processlist from the MySQL server via `SHOW FULL PROCESSLIST`.

Returns: a list of dicts, with each dict representing a process:

```
```

CLI Example:

```
salt '*' mysql.processlist
```

```
salt.modules.mysql.query(database, query, **connection_args)
```

Run an arbitrary SQL query and return the results or the number of affected rows.

CLI Example:

```
salt '*' mysql.query mydb "UPDATE mytable set myfield=1 limit 1"
```

Return data:

```
{‘query time’: {‘human’: ‘39.0ms’, ‘raw’: ‘0.03899’}, ‘rows affected’: 1L}
```

CLI Example:

```
salt '*' mysql.query mydb "SELECT id,name,cash from users limit 3"
```
Return data:

```
{
    'columns': ('id', 'name', 'cash'),
    'query time': {'human': '1.001', 'raw': '0.001'},
    'results': ((1L, 'User 1', Decimal('110.000000')),  
                 (2L, 'User 2', Decimal('215.636756')),  
                 (3L, 'User 3', Decimal('0.040000'))),
    'rows returned': 3L
}
```

CLI Example:

```
salt '*' mysql.query mydb 'INSERT into users values (null,"user 4", 5)'
```

Return data:

```
{
    'query time': {'human': '25.6ms', 'raw': '0.02563'}, 'rows affected': 1L
}
```

CLI Example:

```
salt '*' mysql.query mydb 'DELETE from users where id = 4 limit 1'
```

Return data:

```
{
    'query time': {'human': '39.0ms', 'raw': '0.03899'}, 'rows affected': 1L
}
```

Jinja Example: Run a query on mydb and use row 0, column 0's data.

```
{{ salt['mysql.query']('mydb', 'SELECT info from mytable limit 1') | results ~['0'][0][0] }}
```

salt.modules.mysql.quote_identifier(identifier, for_grants=False)

Return an identifier name (column, table, database, etc) escaped for MySQL.

This means surrounded by ```'`` character and escaping this character inside. It also means doubling the '%'
character for MySQLdb internal usage.

**Parameters**

- **identifier** -- the table, column or database identifier
- **for_grants** -- is False by default, when using database names on grant queries you
  should set it to True to also escape ```"`` and ```'`` characters as requested by MySQL. Note
  that these characters should only be escaped when requesting grants on the database level
  (my_%db) but not for table level grants (my_%db.`foo`)

CLI Example:

```
salt '*' mysql.quote_identifier 'foo\'bar'
```

salt.modules.mysql.showglobal(**connection_args**)

Retrieves the show global variables from the minion.

**Returns**: show global variables full dict

CLI Example:

```
salt '*' mysql.showglobal
```

salt.modules.mysql.showvariables(**connection_args**)

Retrieves the show variables from the minion.
Returns: show variables full dict

CLI Example:
```
salt '*' mysql.showvariables
```

```
salt.modules.mysql.slave_lag(**connection_args)
```

Returns the number of seconds that a slave SQL server is lagging behind the master, if the host is not a slave it will return -1. If the server is configured to be a slave for replication but slave IO is not running then -2 will be returned. If there was an error connecting to the database or checking the slave status, -3 will be returned.

CLI Example:
```
salt '*' mysql.slave_lag
```

```
salt.modules.mysql.status(**connection_args)
```

Return the status of a MySQL server using the output from the SHOW STATUS query.

CLI Example:
```
salt '*' mysql.status
```

```
salt.modules.mysql.tokenize_grant(grant)
```

External wrapper function:
```
:param grant: :return: dict
```

CLI Example:
```
salt '*' mysql.tokenize_grant
```

```
salt.modules.mysql.user_chpass(user, host='localhost', password=None, password_hash=None, allow_passwordless=False, unix_socket=None, **connection_args)
```

Change password for a MySQL user

host Host for which this user/password combo applies

password The password to set for the new user. Will take precedence over the password_hash option if both are specified.

password_hash The password in hashed form. Be sure to quote the password because YAML doesn't like the *

A password hash can be obtained from the mysql command-line client like so:

```
mysql> SELECT PASSWORD('mypass');
+---------------------------------------------------+
| PASSWORD('mypass')                                  |
| +---------------------------------------------------+
| *6C8989366EAF75BB67AD8E7A7FC1176A95CEF4             |
| +---------------------------------------------------+
1 row in set (0.00 sec)
```

allow_passwordless If True, then password and password_hash can be omitted (or set to None) to
permit a passwordless login.

New in version 0.16.2: The allow_passwordless option was added.

CLI Examples:
```
salt '*' mysql.user_chpass frank localhost newpassword
salt '*' mysql.user_chpass frank localhost password_hash='hash'
salt '*' mysql.user_chpass frank localhost allow_passwordless=True
```
salt.modules.mysql.user_create(user, host='localhost', password=None, password_hash=None, allow_passwordless=False, unix_socket=False, **connection_args)

Creates a MySQL user

**host** Host for which this user/password combo applies

**password** The password to use for the new user. Will take precedence over the password_hash option if both are specified.

**password_hash** The password in hashed form. Be sure to quote the password because YAML doesn’t like the * character. A password hash can be obtained from the mysql command-line client like so:

```sql
mysql> SELECT PASSWORD('mypass');
+----------------------------------------+
| PASSWORD('mypass')                     |
| +6C8989366EAF7B675AD8EA7A7FC1177A89CEF4 |
+----------------------------------------+
1 row in set (0.00 sec)
```

**allow_passwordless** If True, then password and password_hash can be omitted (or set to None) to permit a passwordless login.

**unix_socket** If True and allow_passwordless is True then will be used unix_socket auth plugin.

New in version 0.16.2: The allow_passwordless option was added.

CLI Examples:

```bash
salt '*' mysql.user_create 'username' 'hostname' 'password'
salt '*' mysql.user_create 'username' 'hostname' password_hash='hash'
salt '*' mysql.user_create 'username' 'hostname' allow_passwordless=True
```

salt.modules.mysql.user_exists(user, host='localhost', password=None, password_hash=None, passwordless=False, unix_socket=False, **connection_args)

Checks if a user exists on the MySQL server. A login can be checked to see if passwordless login is permitted by omitting password and password_hash, and using passwordless=True.

New in version 0.16.2: The passwordless option was added.

CLI Example:

```bash
salt '*' mysql.user_exists 'username' 'hostname' 'password'
salt '*' mysql.user_exists 'username' 'hostname' password_hash='hash'
salt '*' mysql.user_exists 'username' passwordless=True
```

salt.modules.mysql.user_grants(user, host='localhost', **connection_args)

Shows the grants for the given MySQL user (if it exists)

CLI Example:

```bash
salt '*' mysql.user_grants 'frank' 'localhost'
```

salt.modules.mysql.user_info(user, host='localhost', **connection_args)

Get full info on a MySQL user

CLI Example:

```bash
salt '*' mysql.user_info root localhost
```

salt.modules.mysql.user_list(**connection_args)

Return a list of users on a MySQL server
CLI Example:

```
salt '*' mysql.user_list
```

```
salt.modules.mysql.user_remove(user, host='localhost', **connection_args)
Delete MySQL user
```

CLI Example:

```
salt '*' mysql.user_remove frank localhost
```

```
salt.modules.mysql.version(**connection_args)
Return the version of a MySQL server using the output from the SELECT VERSION() query.
```

CLI Example:

```
salt '*' mysql.version
```

### 32.17.162 salt.modules.nacl

This module helps include encrypted passwords in pillars, grains and salt state files.

**depends** libnacl, https://github.com/saltstack/libnacl

This is often useful if you wish to store your pillars in source control or share your pillar data with others that you trust. I don’t advise making your pillars public regardless if they are encrypted or not.

When generating keys and encrypting passwords use --local when using salt-call for extra security. Also consider using just the salt runner nacl when encrypting pillar passwords.

The nacl lib uses 32byte keys, these keys are base64 encoded to make your life more simple. To generate your key or keyfile you can use:

```
salt-call --local nacl.keygen keyfile=/root/.nacl
```

Now with your key, you can encrypt some data:

```
salt-call --local nacl.enc mypass keyfile=/root/.nacl
DRB7Q6/X5gGSRCTpZyxS6hXO5LnlJIIIJ4ivbmUlbWj0llUA+uaVyvou3vJ4=
```

To decrypt the data:

```
salt-call --local nacl.dec data='DRB7Q6/
→X5gGSRCTpZyxS6hXO5LnlJIIIJ4ivbmUlbWj0llUA+uaVyvou3vJ4=' keyfile=/root/.nacl
mypass
```

The following optional configurations can be defined in the minion or master config. Avoid storing the config in pillars!

```
cat /etc/salt/master.d/nacl.conf
nacl.config:
  key: 'cKEzd4kXsbeCE7/nLTIqXwnUiD1ulg4NoeeYcCFpd9k='
  keyfile: /root/.nacl
```

When the key is defined in the master config you can use it from the nacl runner:

```
salt-run nacl.enc 'myotherpass'
```
Now you can create a pillar with protected data like:

```yaml
pillar.example:
  user: root
  password: {{ salt.nacl.dec('DRB7Q6/→X5gGSRCTpZyxS6hX05LnJIIJ4ivbmUlbWj0llUA+uaYvyou3vJ4=') }}
```

Or do something interesting with grains like:

```python
salt-call nacl.enc minionname:dbrole AL24Z2C50lkReer3DuQTFdrNLchLuz3NGIhGjZkLtKRYry/b/CksWM809yskJhw2AGVLoEXI5jAa

salt minionname grains.setval role 'AL24Z2C50lkReer3DuQTFdrNLchLuz3NGIhGjZkLtKRYry/b/CksWM809yskJhw2AGVLoEXI5jAa'

```

```python
{% set r = grains.get('role') %}
{% set role = None %}
{% if r and 'nacl.dec' in salt %}
  {% set r = salt['nacl.dec'](r,keyfile='/root/.nacl').split(':') %}
  {% if opts['id'] == r[0] %}
    {% set role = r[1] %}
  {% endif %}
{% endif %}

base:
  '{% if role %}
    '{{ opts['id'] }}':
      - {{ role }}
  {% endif %}

salt.modules.nacl.dec(data, **kwargs)
Takes a key generated from nacl.keygen and decrypt some data.

CLI Examples:

```bash
salt-call --local nacl.dec pEXHQM6cuaF7A=
salt-call --local nacl.dec data='pEXHQM6cuaF7A=' keyfile=/root/.nacl
salt-call --local nacl.dec data='pEXHQM6cuaF7A=' key='cKEzd4kXsbeCE7/
  →nLTIqXwnUiD1ulg4NoeeYcCFpd9k=
```

salt.modules.nacl.enc(data, **kwargs)
Takes a key generated from nacl.keygen and encrypt some data.

CLI Examples:

```bash
salt-call --local nacl.enc datatoenc
salt-call --local nacl.enc datatoenc keyfile=/root/.nacl
salt-call --local nacl.enc datatoenc key='cKEzd4kXsbeCE7/
  →nLTIqXwnUiD1ulg4NoeeYcCFpd9k=
```

salt.modules.nacl.keygen(keyfile=None)
Use libnacl to generate a private key

CLI Examples:

```bash
salt-call --local nacl.keygen
salt-call --local nacl.keygen keyfile=/root/.nacl
salt-call --local --out=newline_values_only nacl.keygen > /root/.nacl
```
32.17.163  **salt.modules.nagios**

Run nagios plugins/checks from salt and get the return as data.

**salt.modules.nagios.list_plugins()**

List all the nagios plugins

CLI Example:

```
salt '*' nagios.list_plugins
```

**salt.modules.nagios.retcode(plugin, args='`, key_name=None)**

Run one nagios plugin and return retcode of the execution

CLI Example:

```
salt '*' nagios.run check_apt
salt '*' nagios.run check_icmp '8.8.8.8'
```

**salt.modules.nagios.retcode_pillar(pillar_name)**

Run one or more nagios plugins from pillar data and get the result of cmd.retcode The pillar have to be in this format:

```
webserver:
    Ping_google:
        - check_icmp: 8.8.8.8
        - check_icmp: google.com
    Load:
        - check_load: -w 0.8 -c 1
    APT:
        - check_apt
```

webserver is the role to check, the next keys are the group and the items the check with the arguments if needed

You must to group different checks(one o more) and always it will return the highest value of all the checks

CLI Example:

```
salt '*' nagios.retcode webserver
```

**salt.modules.nagios.run(plugin, args='`)**

Run nagios plugin and return all the data execution with cmd.run

**salt.modules.nagios.run_all(plugin, args='`)**

Run nagios plugin and return all the data execution with cmd.run_all

**salt.modules.nagios.run_all_pillar(pillar_name)**

Run one or more nagios plugins from pillar data and get the result of cmd.run_all The pillar have to be in this format:

```
webserver:
    Ping_google:
        - check_icmp: 8.8.8.8
        - check_icmp: google.com
    Load:
        - check_load: -w 0.8 -c 1
```
**APT:**

- check_apt

webserver is the role to check, the next keys are the group and the items the check with the arguments if needed

You have to group different checks in a group

CLI Example:

```bash
salt '*' nagios.run webserver
```

**salt.modules.nagios.run_pillar(pillar_name)**

Run one or more nagios plugins from pillar data and get the result of cmd.run The pillar have to be in this format:

```yaml
webserver:
  Ping_google:
    - check_icmp: 8.8.8.8
    - check_icmp: google.com
  Load:
    - check_load: -w 0.8 -c 1
  APT:
    - check_apt
```

webserver is the role to check, the next keys are the group and the items the check with the arguments if needed

You have to group different checks in a group

CLI Example:

```bash
salt '*' nagios.run webserver
```

### 32.17.164 **salt.modules.nagios_rpc**

Check Host & Service status from Nagios via JSON RPC.

New in version 2015.8.0.

**salt.modules.nagios_rpc.host_status(hostname=None, **kwargs)**

Check status of a particular host By default statuses are returned in a numeric format.

Parameters:

- **hostname** The hostname to check the status of the service in Nagios.
- **numeric** Turn to false in order to return status in text format (`OK` instead of 0, `Warning` instead of 1 etc)

Returns status: `OK`, `Warning`, `Critical` or `Unknown`

CLI Example:

```bash
salt '*' nagios_rpc.host_status hostname=webserver.domain.com
salt '*' nagios_rpc.host_status hostname=webserver.domain.com numeric=False
```
salt.modules.nagios_rpc.service_status(\n    hostname=None, service=None, **kwargs)\n
    Check status of a particular service on a host on it in Nagios. By default statuses are returned in a numeric format.

    Parameters:
    hostname  The hostname to check the status of the service in Nagios.
    service   The service to check the status of in Nagios.
    numeric   Turn to false in order to return status in text format (‘OK’ instead of 0, ‘Warning’ instead of 1 etc)

    Returns  status: ‘OK’, ‘Warning’, ‘Critical’ or ‘Unknown’

CLI Example:

```
salt '*' nagios_rpc.service_status hostname=webserver.domain.com service='HTTP'
salt '*' nagios_rpc.service_status hostname=webserver.domain.com service='HTTP' numeric=False
```

### 32.17.165 salt.modules.netbsd_sysctl

Module for viewing and modifying sysctl parameters

salt.modules.netbsd_sysctl.assign(name, value)

Assign a single sysctl parameter for this minion

CLI Example:

```
salt '*' sysctl.assign net.inet.icmp.icmplim 50
```

salt.modules.netbsd_sysctl.get(name)

Return a single sysctl parameter for this minion

CLI Example:

```
salt '*' sysctl.get hw.physmem
```

salt.modules.netbsd_sysctl.persist(name, value, config='/etc/sysctl.conf')

Assign and persist a simple sysctl parameter for this minion

CLI Example:

```
salt '*' sysctl.persist net.inet.icmp.icmplim 50
```

salt.modules.netbsd_sysctl.show(config_file=False)

Return a list of sysctl parameters for this minion

CLI Example:

```
salt '*' sysctl.show
```

### 32.17.166 salt.modules.netbdservice

The service module for NetBSD
Important: If you feel that Salt should be using this module to manage services on a minion, and it is using a different module (or gives an error similar to `service.start' is not available), see here.

salt.modules.netbsdservice.available(name)
    Returns True if the specified service is available, otherwise returns False.
    CLI Example:
    ```
salt '*' service.available sshd
    ```

salt.modules.netbsdservice.disable(name, **kwargs)
    Disable the named service to start at boot
    CLI Example:
    ```
salt '*' service.disable <service name>
    ```

salt.modules.netbsdservice.disabled(name)
    Return True if the named service is enabled, false otherwise
    CLI Example:
    ```
salt '*' service.disabled <service name>
    ```

salt.modules.netbsdservice.enable(name, **kwargs)
    Enable the named service to start at boot
    CLI Example:
    ```
salt '*' service.enable <service name>
    ```

salt.modules.netbsdservice.enabled(name, **kwargs)
    Return True if the named service is enabled, false otherwise
    CLI Example:
    ```
salt '*' service.enabled <service name>
    ```

salt.modules.netbsdservice.force_reload(name)
    Force-reload the named service
    CLI Example:
    ```
salt '*' service.force_reload <service name>
    ```

salt.modules.netbsdservice.get_all()
    Return all available boot services
    CLI Example:
    ```
salt '*' service.get_all
    ```

salt.modules.netbsdservice.get_disabled()
    Return a set of services that are installed but disabled
    CLI Example:
salt '*' service.get_disabled

salt.modules.netbsdservice.get_enabled()
Return a list of service that are enabled on boot

CLI Example:

```
salt '*' service.get_enabled
```

salt.modules.netbsdservice.missing(name)
The inverse of service.available. Returns True if the specified service is not available, otherwise returns False.

CLI Example:

```
salt '*' service.missing sshd
```

salt.modules.netbsdservice.reload(name)
Reload the named service

CLI Example:

```
salt '*' service.reload <service name>
```

salt.modules.netbsdservice.restart(name)
Restart the named service

CLI Example:

```
salt '*' service.restart <service name>
```

salt.modules.netbsdservice.start(name)
Start the specified service

CLI Example:

```
salt '*' service.start <service name>
```

salt.modules.netbsdservice.status(name, sig=None)
Return the status for a service, returns a bool whether the service is running.

CLI Example:

```
salt '*' service.status <service name>
```

salt.modules.netbsdservice.stop(name)
Stop the specified service

CLI Example:

```
salt '*' service.stop <service name>
```

32.17.167  salt.modules.netscaler

Module to provide Citrix Netscaler compatibility to Salt (compatible with netscaler 9.2+)
New in version 2015.2.0.

depends
• nsnitro Python module

**Note:** You can install nsnitro using:

```bash
pip install nsnitro
```

**configuration** This module accepts connection configuration details either as parameters, or as configuration settings in `/etc/salt/minion` on the relevant minions:

```python
netscaler.host: 1.2.3.4
netscaler.user: user
netscaler.pass: password
```

This data can also be passed into pillar. Options passed into `opts` will overwrite options passed into pillar.

**CLI Examples** Calls relying on configuration passed using `/etc/salt/minion`, grains, or pillars:

```bash
salt-call netscaler.server_exists server_name
```

Calls passing configuration as `opts`:

```bash
salt-call netscaler.server_exists server_name
netscaler_host=1.2.3.4
netscaler_user=username
netscaler_pass=password
```

```bash
salt-call netscaler.server_exists server_name
netscaler_host=1.2.3.5
netscaler_user=username2
netscaler_pass=password2
```

```bash
salt-call netscaler.server_enable server_name
netscaler_host=1.2.3.5
```

**salt.modules.netscaler.server_add**

Add a server Note: The default server state is ENABLED

CLI Example:

```bash
salt '*' netscaler.server_add 'serverName' 'serverIpAddress'
```

```bash
salt '*' netscaler.server_add 'serverName' 'serverIpAddress' 'serverState'
```

**salt.modules.netscaler.server_delete**

Delete a server

CLI Example:

```bash
salt '*' netscaler.server_delete 'serverName'
```

**salt.modules.netscaler.server_disable**

Disable a server globally

CLI Example:

```bash
salt '*' netscaler.server_disable 'serverName'
```

**salt.modules.netscaler.server_enable**

Enables a server globally

CLI Example:

```bash
salt '*' netscaler.server_enable 'serverName'
```
salt.modules.netscaler.server_enabled(s_name, **connection_args)
Check if a server is enabled globally

CLI Example:
```
salt '*' netscaler.server_enabled 'serverName'
```

salt.modules.netscaler.server_exists(s_name, ip=None, s_state=None, **connection_args)
Checks if a server exists

CLI Example:
```
salt '*' netscaler.server_exists 'serverName'
```

salt.modules.netscaler.server_update(s_name, s_ip, **connection_args)
Update a server's attributes

CLI Example:
```
salt '*' netscaler.server_update 'serverName' 'serverIP'
```

salt.modules.netscaler.service_disable(s_name, s_delay=None, **connection_args)
Disable a service

CLI Example:
```
salt '*' netscaler.service_disable 'serviceName'
salt '*' netscaler.service_disable 'serviceName' 'delayInSeconds'
```

salt.modules.netscaler.service_enable(s_name, **connection_args)
Enable a service

CLI Example:
```
salt '*' netscaler.service_enable 'serviceName'
```

salt.modules.netscaler.service_exists(s_name, **connection_args)
Checks if a service exists

CLI Example:
```
salt '*' netscaler.service_exists 'serviceName'
```

salt.modules.netscaler.service_up(s_name, **connection_args)
Checks if a service is UP

CLI Example:
```
salt '*' netscaler.service_up 'serviceName'
```

salt.modules.netscaler.servicegroup_add(sg_name, sg_type='HTTP', **connection_args)
Add a new service group If no service type is specified, HTTP will be used. Most common service types: HTTP, SSL, and SSL_BRIDGE

CLI Example:
```
salt '*' netscaler.servicegroup_add 'serviceGroupName'
salt '*' netscaler.servicegroup_add 'serviceGroupName' 'serviceGroupType'
```
salt.modules.netscaler.servicegroup_delete(sg_name, **connection_args)
Delete a new service group

CLI Example:
```
salt '*' netscaler.servicegroup_delete 'serviceGroupName'
```

salt.modules.netscaler.servicegroup_exists(sg_name, sg_type=None, **connection_args)
Checks if a service group exists

CLI Example:
```
salt '*' netscaler.servicegroup_exists 'serviceGroupName'
```

salt.modules.netscaler.servicegroup_server_add(sg_name, s_name, s_port, **connection_args)
Add a server:port member to a servicegroup

CLI Example:
```
salt '*' netscaler.servicegroup_server_add 'serviceGroupName' 'serverName' ‘serverPort'
```

salt.modules.netscaler.servicegroup_server_delete(sg_name, s_name, s_port, **connection_args)
Remove a server:port member from a servicegroup

CLI Example:
```
salt '*' netscaler.servicegroup_server_delete 'serviceGroupName' 'serverName' ‘serverPort'
```

salt.modules.netscaler.servicegroup_server_disable(sg_name, s_name, s_port, **connection_args)
Disable a server:port member of a servicegroup

CLI Example:
```
salt '*' netscaler.servicegroup_server_disable 'serviceGroupName' 'serverName' ‘serverPort'
```

salt.modules.netscaler.servicegroup_server_enable(sg_name, s_name, s_port, **connection_args)
Enable a server:port member of a servicegroup

CLI Example:
```
salt '*' netscaler.servicegroup_server_enable 'serviceGroupName' 'serverName' ‘serverPort'
```

salt.modules.netscaler.servicegroup_server_exists(sg_name, s_name, s_port=None, **connection_args)
Check if a server:port combination is a member of a servicegroup

CLI Example:
```
salt '*' netscaler.servicegroup_server_exists 'serviceGroupName' 'serverName' ‘serverPort'
```
salt.modules.netscaler.servicegroup_server_up(sg_name, s_name, s_port, **connection_args)

Check if a server:port combination is in state UP in a servicegroup

CLI Example:
```
salt '*' netscaler.servicegroup_server_up 'serviceGroupName' 'serverName'
```

salt.modules.netscaler.vserver_add(v_name, v_ip, v_port, v_type, **connection_args)

Add a new lb vserver

CLI Example:
```
salt '*' netscaler.vserver_add 'vserverName' 'vserverIP' 'vserverPort'
```
```
salt '*' netscaler.vserver_add 'alex.patate.chaude.443' '1.2.3.4' '443' 'SSL'
```

salt.modules.netscaler.vserver_delete(v_name, **connection_args)

Delete a lb vserver

CLI Example:
```
salt '*' netscaler.vserver_delete 'vserverName'
```

salt.modules.netscaler.vserver_exists(v_name, v_ip=None, v_port=None, v_type=None, **connection_args)

Checks if a vserver exists

CLI Example:
```
salt '*' netscaler.vserver_exists 'vserverName'
```

salt.modules.netscaler.vserver_servicegroup_add(v_name, sg_name, **connection_args)

Bind a servicegroup to a vserver

CLI Example:
```
salt '*' netscaler.vserver_servicegroup_add 'vserverName' 'serviceGroupName'
```

salt.modules.netscaler.vserver_servicegroup_delete(v_name, sg_name, **connection_args)

Unbind a servicegroup from a vserver

CLI Example:
```
salt '*' netscaler.vserver_servicegroup_delete 'vserverName' 'serviceGroupName'
```

salt.modules.netscaler.vserver_servicegroup_exists(v_name, sg_name, **connection_args)

Checks if a servicegroup is tied to a vserver

CLI Example:
```
salt '*' netscaler.vserver_servicegroup_exists 'vserverName' 'serviceGroupName'
```

salt.modules.netscaler.vserver_sslcert_add(v_name, sc_name, **connection_args)

Binds a SSL certificate to a vserver

CLI Example:
Salt Documentation, Release 2015.8.12

```python
salt '*' netscaler.vserver_sslcert_add 'vserverName' 'sslCertificateName'
```

```
salt.modules.netscaler.vserver_sslcert_delete(v_name, sc_name, **connection_args)
    Unbinds a SSL certificate from a vserver
    CLI Example:
    salt '*' netscaler.vserver_sslcert_delete 'vserverName' 'sslCertificateName'
```

```
salt.modules.netscaler.vserver_sslcert_exists(v_name, sc_name, **connection_args)
    Checks if a SSL certificate is tied to a vserver
    CLI Example:
    salt '*' netscaler.vserver_sslcert_exists 'vserverName' 'sslCertificateName'
```

### 32.17.168 salt.modules.network

Module for gathering and managing network information

```
salt.modules.network.active_tcp()
    Return a dict containing information on all of the running TCP connections (currently linux and solaris only)
    Changed in version 2015.8.4: Added support for SunOS
    CLI Example:
    salt '*' network.active_tcp
```

```
salt.modules.network.arp()
    Return the arp table from the minion
    Changed in version 2015.8.0: Added support for SunOS
    CLI Example:
    salt '*' network.arp
```

```
salt.modules.network.calc_net(ip_addr, netmask=None)
    Returns the CIDR of a subnet based on an IP address (CIDR notation supported) and optional netmask.
    CLI Example:
    salt '*' network.calc_net 172.17.0.5 255.255.255.240
    salt '*' network.calc_net 2a02:f6e:a000:80:84d8:8332:7866:4e07/64
    New in version 2015.8.0.
```

```
salt.modules.network.connect(host, port=None, **kwargs)
    Test connectivity to a host using a particular port from the minion.
    New in version 2014.7.0.
    CLI Example:
    salt '*' network.connect archlinux.org 80
    salt '*' network.connect archlinux.org 80 timeout=3
```

32.17. Full list of builtin execution modules
salt '*/' network.connect archlinux.org 80 timeout=3 family=ipv4
salt '*/' network.connect google-public-dns-a.google.com port=53 proto=udp timeout=3

salt.modules.network.default_route(family=None)
Return default route(s) from routing table

   Changed in version 2015.8.0: Added support for SunOS (Solaris 10, Illumos, SmartOS)
   CLI Example:
   salt '*/' network.default_route

salt.modules.network.dig(host)
Perform a DNS lookup with dig

   CLI Example:
   salt '*/' network.dig archlinux.org

salt.modules.network.get_bufsize(iface)
Return network buffer sizes as a dict (currently linux only)

   CLI Example:
   salt '*/' network.get_bufsize eth0

salt.modules.network.get_hostname()
Get hostname

   CLI Example:
   salt '*/' network.get_hostname

salt.modules.network.get_route(ip)
Return routing information for given destination ip

   New in version 2015.5.3.
   Changed in version 2015.8.0: Added support for SunOS (Solaris 10, Illumos, SmartOS) Added support for OpenBSD
   CLI Example:
   salt '*/' network.get_route 10.10.10.10

salt.modules.network.hw_addr(iface)
Return the hardware address (a.k.a. MAC address) for a given interface

   CLI Example:
   salt '*/' network.hw_addr eth0

salt.modules.network.hwaddr(iface)
This function is an alias of hw_addr.

   Return the hardware address (a.k.a. MAC address) for a given interface
   CLI Example:
Salt modules.

**in_subnet**

Returns True if host is within specified subnet, otherwise False.

CLI Example:

```
salt '*' network.in_subnet 10.0.0.0/16
```

**interface**

Return the inet address for a given interface

New in version 2014.7.0.

CLI Example:

```
salt '*' network.interface eth0
```

**interface_ip**

Return the inet address for a given interface

New in version 2014.7.0.

CLI Example:

```
salt '*' network.interface_ip eth0
```

**interfaces**

Return a dictionary of information about all the interfaces on the minion

CLI Example:

```
salt '*' network.interfaces
```

**ip_addrs**

Returns a list of IPv4 addresses assigned to the host. 127.0.0.1 is ignored, unless `include_loopback=True` is indicated. If `interface` is provided, then only IP addresses from that interface will be returned. Providing a CIDR via `cidr='10.0.0.0/8'` will return only the addresses which are within that subnet.

CLI Example:

```
salt '*' network.ip_addrs
```

**ip_addrs6**

Returns a list of IPv6 addresses assigned to the host. ::1 is ignored, unless `include_loopback=True` is indicated. If `interface` is provided, then only IP addresses from that interface will be returned. Providing a CIDR via `cidr='2000::/3'` will return only the addresses which are within that subnet.

CLI Example:

```
salt '*' network.ip_addrs6
```

**ip_in_subnet**

Returns True if given IP is within specified subnet, otherwise False.

CLI Example:

```
salt '*' network.ip_in_subnet 172.17.0.4 172.16.0.0/12
```
salt.modules.network.ipaddrs(interface=None, include_loopback=False, cidr=None)
This function is an alias of ip_addrs.

Returns a list of IPv4 addresses assigned to the host. 127.0.0.1 is ignored, unless `include_loopback=True` is indicated. If `interface` is provided, then only IP addresses from that interface will be returned. Providing a CIDR via `cidr="10.0.0.0/8"` will return only the addresses which are within that subnet.

CLI Example:
```
salt '*' network.ip_addrs
```

salt.modules.network.ipaddrs6(interface=None, include_loopback=False, cidr=None)
This function is an alias of ip_addrs6.

Returns a list of IPv6 addresses assigned to the host. ::1 is ignored, unless `include_loopback=True` is indicated. If `interface` is provided, then only IP addresses from that interface will be returned. Providing a CIDR via `cidr="2000::/3"` will return only the addresses which are within that subnet.

CLI Example:
```
salt '*' network.ip_addrs6
```

salt.modules.network.is_loopback(ip_addr)
Check if the given IP address is a loopback address

New in version 2014.7.0.

Changed in version 2015.8.0: IPv6 support

CLI Example:
```
salt '*' network.is_loopback 127.0.0.1
```

salt.modules.network.is_private(ip_addr)
Check if the given IP address is a private address

New in version 2014.7.0.

Changed in version 2015.8.0: IPv6 support

CLI Example:
```
salt '*' network.is_private 10.0.0.3
```

salt.modules.network.mod_bufsize(iface, *args, **kwargs)
Modify network interface buffers (currently linux only)

CLI Example:
```
salt '*' network.mod_bufsize tx=<val> rx=<val> rx-mini=<val> rx-jumbo=<val>
```

salt.modules.network.mod_hostname(hostname)
Modify hostname

Changed in version 2015.8.0: Added support for SunOS (Solaris 10, Illumos, SmartOS)

CLI Example:
```
salt '*' network.mod_hostname master.saltstack.com
```
salt.modules.network.netstat()
Return information on open ports and states

Note: On BSD minions, the output contains PID info (where available) for each netstat entry, fetched from sockstat/fstat output.

Changed in version 2014.1.4: Added support for OpenBSD, FreeBSD, and NetBSD
Changed in version 2015.8.0: Added support for SunOS

CLI Example:
```
salt '*' network.netstat
```

salt.modules.network.ping(host, timeout=False, return_boolean=False)
Performs an ICMP ping to a host

Changed in version 2015.8.0: Added support for SunOS

CLI Example:
```
salt '*' network.ping archlinux.org
```

New in version 2015.5.0.
Return a True or False instead of ping output.
```
salt '*' network.ping archlinux.org return_boolean=True
```

Set the time to wait for a response in seconds.
```
salt '*' network.ping archlinux.org timeout=3
```

salt.modules.network.reverse_ip(ip_addr)
Returns the reversed IP address

Changed in version 2015.8.0: IPv6 support

CLI Example:
```
salt '*' network.reverse_ip 172.17.0.4
```

salt.modules.network.routes(family=None)
Return currently configured routes from routing table

Changed in version 2015.8.0: Added support for SunOS (Solaris 10, Illumos, SmartOS)

CLI Example:
```
salt '*' network.routes
```

salt.modules.network.subnets(interfaces=None)
Returns a list of IPv4 subnets to which the host belongs

CLI Example:
```
salt '*' network.subnets
salt '*' network.subnets interfaces=eth1
```
salt.modules.network.subnets6()
Returns a list of IPv6 subnets to which the host belongs

CLI Example:
```
salt '*' network.subnets
```

salt.modules.network.traceroute(host)
Performs a traceroute to a 3rd party host

Changed in version 2015.8.0: Added support for SunOS

CLI Example:
```
salt '*' network.traceroute archlinux.org
```

salt.modules.network.wol(mac, bcast='255.255.255.255', destport=9)
Send Wake On Lan packet to a host

CLI Example:
```
salt '*' network.wol 08-00-27-13-69-77
salt '*' network.wol 080027136977 255.255.255.255 7
salt '*' network.wol 08:00:27:13:69:77 255.255.255.255 7
```

32.17.169  salt.modules.neutron

Module for handling OpenStack Neutron calls

depends

• neutronclient Python module

collection

This module is not usable until the user, password, tenant, and auth URL are specified either in a pillar or in the minion's config file. For example:

```
keystone.user: 'admin'
keystone.password: 'password'
keystone.tenant: 'admin'
keystone.auth_url: 'http://127.0.0.1:5000/v2.0/
keystone.region_name: 'RegionOne'
keystone.service_type: 'network'
```

If configuration for multiple OpenStack accounts is required, they can be set up as different configuration profiles: For example:

```
openstack1:
  keystone.user: 'admin'
  keystone.password: 'password'
  keystone.tenant: 'admin'
  keystone.auth_url: 'http://127.0.0.1:5000/v2.0/
  keystone.region_name: 'RegionOne'
  keystone.service_type: 'network'

openstack2:
  keystone.user: 'admin'
  keystone.password: 'password'
  keystone.tenant: 'admin'
  keystone.auth_url: 'http://127.0.0.2:5000/v2.0/
```
With this configuration in place, any of the neutron functions can make use of a configuration profile by declaring it explicitly. For example:

```
salt '*' neutron.network_list profile=openstack1
```

**salt.modules.neutron.add_gateway_router** *(router, ext_network, profile=None)*

Adds an external network gateway to the specified router

**CLI Example:**

```
salt '*' neutron.add_gateway_router router-name ext-network-name
```

**Parameters**
- **router** -- ID or name of the router
- **ext_network** -- ID or name of the external network the gateway
- **profile** -- Profile to build on (Optional)

**Returns** Added Gateway router information

**salt.modules.neutron.add_interface_router** *(router, subnet, profile=None)*

Adds an internal network interface to the specified router

**CLI Example:**

```
salt '*' neutron.add_interface_router router-name subnet-name
```

**Parameters**
- **router** -- ID or name of the router
- **subnet** -- ID or name of the subnet
- **profile** -- Profile to build on (Optional)

**Returns** Added interface information

**salt.modules.neutron.create_floatingip** *(floating_network, port=None, profile=None)*

Creates a new floatingIP

**CLI Example:**

```
salt '*' neutron.create_floatingip network-name port-name
```

**Parameters**
- **floating_network** -- Network name or ID to allocate floatingIP from
- **port** -- Of the port to be associated with the floatingIP (Optional)
- **profile** -- Profile to build on (Optional)

**Returns** Created floatingIP information
salt.modules.neutron.create_ikepolicy(name, profile=None, **kwargs)

Creates a new IKEPolicy

CLI Example:
```
salt '*' neutron.create_ikepolicy ikepolicy-name
    phase1_negotiation_mode=main auth_algorithm=sha1
    encryption_algorithm=aes-128 pfs=group5
```

Parameters

- **name** -- Name of the IKE policy
- **phase1_negotiation_mode** -- IKE Phase1 negotiation mode in lowercase, default: main (Optional)
- **auth_algorithm** -- Authentication algorithm in lowercase, default: sha1 (Optional)
- **encryption_algorithm** -- Encryption algorithm in lowercase. default:aes-128 (Optional)
- **pfs** -- Prefect Forward Security in lowercase, default: group5 (Optional)
- **units** -- IKE lifetime attribute. default: seconds (Optional)
- **value** -- IKE lifetime attribute. default: 3600 (Optional)
- **ike_version** -- IKE version in lowercase, default: v1 (Optional)
- **profile** -- Profile to build on (Optional)
- **kwargs** -- Additional keyword arguments

Returns

Created IKE policy information

salt.modules.neutron.create_ipsec_site_connection(name, ipsec_policy, ikepolicy, vpnservice, peer_cidrs, peer_address, peer_id, psk, admin_state_up=True, profile=None, **kwargs)

Creates a new IPsecSiteConnection

CLI Example:
```
salt '*' neutron.show_ipsec_site_connection connection-name
    ipsec-policy-name ikepolicy-name vpnservice-name
    192.168.XXX.XXX/24 192.168.XXX.XXX 192.168.XXX.XXX secret
```

Parameters

- **name** -- Set friendly name for the connection
- **ipsecpolicy** -- IPSec policy ID or name associated with this connection
- **ikepolicy** -- IKE policy ID or name associated with this connection
- **vpnservice** -- VPN service instance ID or name associated with this connection
- **peer_cidrs** -- Remote subnet(s) in CIDR format
- **peer_address** -- Peer gateway public IPv4/IPv6 address or FQDN
- **peer_id** -- Peer router identity for authentication Can be IPv4/IPv6 address, e-mail address, key id, or FQDN
• **psk** -- Pre-shared key string
• **initiator** -- Initiator state in lowercase, default: bi-directional
• **admin_state_up** -- Set admin state up to true or false, default: True (Optional)
• **mtu** -- size for the connection, default: 1500 (Optional)
• **dpd_action** -- Dead Peer Detection attribute: hold/clear/disabled/restart/restart-by-peer (Optional)
• **dpd_interval** -- Dead Peer Detection attribute (Optional)
• **dpd_timeout** -- Dead Peer Detection attribute (Optional)
• **profile** -- Profile to build on (Optional)

**Returns**  Created IPSec site connection information

```python
salt.modules.neutron.create_ipsecpolicy(name, profile=None, **kwargs)
```

Creates a new IPsecPolicy

**CLI Example:**

```bash
salt '*' neutron.create_ipsecpolicy ipsecpolicy-name
transform_protocol=esp auth_algorithm=sha1
encapsulation_mode=tunnel encryption_algorithm=aes-128
```

**Parameters**

• **name** -- Name of the IPSec policy
• **transform_protocol** -- Transform protocol in lowercase, default: esp (Optional)
• **auth_algorithm** -- Authentication algorithm in lowercase, default: sha1 (Optional)
• **encapsulation_mode** -- Encapsulation mode in lowercase, default: tunnel (Optional)
• **encryption_algorithm** -- Encryption algorithm in lowercase, default: aes-128 (Optional)
• **pfs** -- Prefect Forward Security in lowercase, default: group5 (Optional)
• **units** -- IPSec lifetime attribute. default: seconds (Optional)
• **value** -- IPSec lifetime attribute. default: 3600 (Optional)
• **profile** -- Profile to build on (Optional)

**Returns**  Created IPsec policy information

```python
salt.modules.neutron.create_network(name, router_ext=None, admin_state_up=True, network_type=None, physical_network=None, segmentation_id=None, shared=None, profile=None)
```

Creates a new network

**CLI Example:**

```bash
salt '*' neutron.create_network network-name
salt '*' neutron.create_network network-name profile=openstack1
```

**Parameters**

• **name** -- Name of network to create
- **admin_state_up** -- should the state of the network be up? default: True (Optional)
- **router_ext** -- True then if create the external network (Optional)
- **network_type** -- the Type of network that the provider is such as GRE, VXLAN, VLAN, FLAT, or LOCAL (Optional)
- **physical_network** -- the name of the physical network as neutron knows it (Optional)
- **segmentation_id** -- the vlan id or GRE id (Optional)
- **shared** -- is the network shared or not (Optional)
- **profile** -- Profile to build on (Optional)

Returns Created network information

salt.modules.neutron.create_port(name, network, device_id=None, admin_state_up=True, profile=None)

Creates a new port

CLI Example:
```
salt '*' neutron.create_port network-name port-name
```

Parameters
- **name** -- Name of port to create
- **network** -- Network name or ID
- **device_id** -- ID of device (Optional)
- **admin_state_up** -- Set admin state up to true or false, default: true (Optional)
- **profile** -- Profile to build on (Optional)

Returns Created port information

salt.modules.neutron.create_router(name, ext_network=None, admin_state_up=True, profile=None)

Creates a new router

CLI Example:
```
salt '*' neutron.create_router new-router-name
```

Parameters
- **name** -- Name of router to create (must be first)
- **ext_network** -- ID or name of the external for the gateway (Optional)
- **admin_state_up** -- Set admin state up to true or false, default: true (Optional)
- **profile** -- Profile to build on (Optional)

Returns Created router information

salt.modules.neutron.create_security_group(name=None, description=None, profile=None)

Creates a new security group

CLI Example:
Parameters

- `name` -- Name of security group (Optional)
- `description` -- Description of security group (Optional)
- `profile` -- Profile to build on (Optional)

Returns

Created security group information

```
salt.modules.neutron.create_security_group_rule(
    security_group,
    remote_group_id=None,
    direction='ingress',
    protocol=None,
    port_range_min=None,
    port_range_max=None,
    ethertype='IPv4',
    profile=None)
```

Creates a new security group rule

CLI Example:

```
salt '*' neutron.show_security_group_rule security-group-rule-id
```

Parameters

- `security_group` -- Security group name or ID to add rule
- `remote_group_id` -- Remote security group name or ID to apply rule (Optional)
- `direction` -- Direction of traffic: ingress/egress, default: ingress (Optional)
- `protocol` -- Protocol of packet: null/icmp/tcp/udp, default: null (Optional)
- `port_range_min` -- Starting port range (Optional)
- `port_range_max` -- Ending port range (Optional)
- `ethertype` -- IPv4/IPv6, default: IPv4 (Optional)
- `profile` -- Profile to build on (Optional)

Returns

Created security group rule information

```
salt.modules.neutron.create_subnet(
    network, cidr, name=None, ip_version=4, profile=None)
```

Creates a new subnet

CLI Example:

```
salt '*' neutron.create_subnet network-name 192.168.1.0/24
```

Parameters

- `network` -- Network ID or name this subnet belongs to
- `cidr` -- CIDR of subnet to create (Ex. `192.168.1.0/24`)
- `name` -- Name of the subnet to create (Optional)
- `ip_version` -- Version to use, default is 4(IPv4) (Optional)
- `profile` -- Profile to build on (Optional)
**Returns**  Created subnet information

```
salt.modules.neutron.create_vpnservice(subnet, router, name, admin_state_up=True, profile=None)
```

Creates a new VPN service

CLI Example:
```
salt '*' neutron.create_vpnservice router-name name
```

**Parameters**
- **subnet** -- Subnet unique identifier for the VPN service deployment
- **router** -- Router unique identifier for the VPN service
- **name** -- Set a name for the VPN service
- **admin_state_up** -- Set admin state up to true or false, default:True (Optional)
- **profile** -- Profile to build on (Optional)

**Returns**  Created VPN service information

```
salt.modules.neutron.delete_floatingip(floatingip_id, profile=None)
```

Deletes the specified floating IP

CLI Example:
```
salt '*' neutron.delete_floatingip floatingip-id
```

**Parameters**
- **floatingip_id** -- ID of floatingIP to delete
- **profile** -- Profile to build on (Optional)

**Returns**  True(Succeed) or False

```
salt.modules.neutron.delete_ikepolicy(ikepolicy, profile=None)
```

Deletes the specified IKEPolicy

CLI Example:
```
salt '*' neutron.delete_ikepolicy ikepolicy-name
```

**Parameters**
- **ikepolicy** -- ID or name of IKE policy to delete
- **profile** -- Profile to build on (Optional)

**Returns**  True(Succeed) or False

```
salt.modules.neutron.delete_ipsec_site_connection(ipsec_site_connection, profile=None)
```

Deletes the specified IPsecSiteConnection

CLI Example:
```
salt '*' neutron.delete_ipsec_site_connection connection-name
```
Parameters

• `ipsec_site_connection` -- ID or name of ipsec site connection to delete

• `profile` -- Profile to build on (Optional)

Returns True(Succeed) or False

```
salt.modules.neutron.delete_ipsecpolicy(ipsecpolicy, profile=None)
```

Deletes the specified IPsecPolicy

CLI Example:

```
salt '*' neutron.delete_ipsecpolicy ipsecpolicy-name
```

Parameters

• `ipsecpolicy` -- ID or name of IPSec policy to delete

• `profile` -- Profile to build on (Optional)

Returns True(Succeed) or False

```
salt.modules.neutron.delete_network(network, profile=None)
```

Deletes the specified network

CLI Example:

```
salt '*' neutron.delete_network network-name
salt '*' neutron.delete_network network-name profile=openstack1
```

Parameters

• `network` -- ID or name of network to delete

• `profile` -- Profile to build on (Optional)

Returns True(Succeed) or False

```
salt.modules.neutron.delete_port(port, profile=None)
```

Deletes the specified port

CLI Example:

```
salt '*' neutron.delete_port port-name
salt '*' neutron.delete_port port-name profile=openstack1
```

Parameters

• `port` -- port name or ID

• `profile` -- Profile to build on (Optional)

Returns True(Succeed) or False

```
salt.modules.neutron.delete_quota(tenant_id, profile=None)
```

Delete the specified tenant’s quota value

CLI Example:

```
salt '*' neutron.update_quota tenant-id
salt '*' neutron.update_quota tenant-id profile=openstack1
```
Parameters

- **tenant_id** -- ID of tenant to quota delete
- **profile** -- Profile to build on (Optional)

Returns True(Delete succeed) or False(Delete failed)

```python
salt.modules.neutron.delete_router(router, profile=None)
```

Delete the specified router

CLI Example:
```
salt '*' neutron.delete_router router-name
```

Parameters

- **router** -- ID or name of router to delete
- **profile** -- Profile to build on (Optional)

Returns True(Succeed) or False

```python
salt.modules.neutron.delete_security_group(security_group, profile=None)
```

Deletes the specified security group

CLI Example:
```
salt '*' neutron.delete_security_group security-group-name
```

Parameters

- **security_group** -- ID or name of security group to delete
- **profile** -- Profile to build on (Optional)

Returns True(Succeed) or False

```python
salt.modules.neutron.delete_security_group_rule(security_group_rule_id, profile=None)
```

Deletes the specified security group rule

CLI Example:
```
salt '*' neutron.delete_security_group_rule security-group-rule-id
```

Parameters

- **security_group_rule_id** -- ID of security group rule to delete
- **profile** -- Profile to build on (Optional)

Returns True(Succeed) or False

```python
salt.modules.neutron.delete_subnet(subnet, profile=None)
```

Deletes the specified subnet

CLI Example:
salt '*' neutron.delete_subnet subnet-name
salt '*' neutron.delete_subnet subnet-name profile=openstack1

Parameters
- **subnet** -- ID or name of subnet to delete
- **profile** -- Profile to build on (Optional)

Returns  True(Succeed) or False

salt.modules.neutron.delete_vpnservice(vpnservice, profile=None)
Deletes the specified VPN service

CLI Example:
salt '*' neutron.delete_vpnservice vpnservice-name

Parameters
- **vpnservice** -- ID or name of vpn service to delete
- **profile** -- Profile to build on (Optional)

Returns  True(Succeed) or False

salt.modules.neutron.get_quotas_tenant(profile=None)
Fetches tenant info in server's context for following quota operation

CLI Example:
salt '*' neutron.get_quotas_tenant
salt '*' neutron.get_quotas_tenant profile=openstack1

Parameters  **profile** -- Profile to build on (Optional)

Returns  Quotas information

salt.modules.neutron.list_extensions(profile=None)
Fetches a list of all extensions on server side

CLI Example:
salt '*' neutron.list_extensions
salt '*' neutron.list_extensions profile=openstack1

Parameters  **profile** -- Profile to build on (Optional)

Returns  List of extensions

salt.modules.neutron.list_floatingips(profile=None)
Fetch a list of all floatingIPs for a tenant

CLI Example:
salt '*' neutron.list_floatingips
salt '*' neutron.list_floatingips profile=openstack1

32.17. Full list of builtin execution modules
Parameters **profile** -- Profile to build on (Optional)

Returns List of floatingIP

```
salt.modules.neutron.list_ikepolicies(profile=None)
Fetches a list of all configured IKEPolicies for a tenant
```

CLI Example:
```
salt '*' neutron.list_ikepolicies
salt '*' neutron.list_ikepolicies profile=openstack1
```

Parameters **profile** -- Profile to build on (Optional)

Returns List of IKE policy

```
salt.modules.neutron.list_ipsec_site_connections(profile=None)
Fetches all configured IPsec Site Connections for a tenant
```

CLI Example:
```
salt '*' neutron.list_ipsec_site_connections
salt '*' neutron.list_ipsec_site_connections profile=openstack1
```

Parameters **profile** -- Profile to build on (Optional)

Returns List of IPSec site connection

```
salt.modules.neutron.list_ipsecpolicies(profile=None)
Fetches a list of all configured IPsecPolicies for a tenant
```

CLI Example:
```
salt '*' neutron.list_ipsecpolicies ispecpolicy-name
salt '*' neutron.list_ipsecpolicies ispecpolicy-name profile=openstack1
```

Parameters **profile** -- Profile to build on (Optional)

Returns List of IPSec policy

```
salt.modules.neutron.list_networks(profile=None)
Fetches a list of all networks for a tenant
```

CLI Example:
```
salt '*' neutron.list_networks
salt '*' neutron.list_networks profile=openstack1
```

Parameters **profile** -- Profile to build on (Optional)

Returns List of network

```
salt.modules.neutron.list_ports(profile=None)
Fetches a list of all networks for a tenant
```

CLI Example:
```
salt '*' neutron.list_ports
salt '*' neutron.list_ports profile=openstack1
```
Parameters **profile** -- Profile to build on (Optional)

Returns List of port

```
salt.modules.neutron.list_quotas(profile=None)
```
Fetches all tenants quotas

CLI Example:
```
salt '*' neutron.list_quotas
salt '*' neutron.list_quotas profile=openstack1
```

Parameters **profile** -- Profile to build on (Optional)

Returns List of quotas

```
salt.modules.neutron.list_routers(profile=None)
```
Fetches a list of all routers for a tenant

CLI Example:
```
salt '*' neutron.list_routers
salt '*' neutron.list_routers profile=openstack1
```

Parameters **profile** -- Profile to build on (Optional)

Returns List of router

```
salt.modules.neutron.list_security_group_rules(profile=None)
```
Fetches a list of all security group rules for a tenant

CLI Example:
```
salt '*' neutron.list_security_group_rules
salt '*' neutron.list_security_group_rules profile=openstack1
```

Parameters **profile** -- Profile to build on (Optional)

Returns List of security group rule

```
salt.modules.neutron.list_security_groups(profile=None)
```
Fetches a list of all security groups for a tenant

CLI Example:
```
salt '*' neutron.list_security_groups
salt '*' neutron.list_security_groups profile=openstack1
```

Parameters **profile** -- Profile to build on (Optional)

Returns List of security group

```
salt.modules.neutron.list_subnets(profile=None)
```
Fetches a list of all networks for a tenant

CLI Example:
Parameters **profile** -- Profile to build on (Optional)

Returns List of subnet

```
salt '*' neutron.list_subnets
salt '*' neutron.list_subnets profile=openstack1
```

salt.modules.neutron.list_vpnServices(retrieve_all=True, profile=None, **kwargs)
Fetches a list of all configured VPN services for a tenant

CLI Example:
```
salt '*' neutron.list_vpnServices
```

Parameters
- **retrieve_all** -- True or False, default: True (Optional)
- **profile** -- Profile to build on (Optional)

Returns List of VPN service

salt.modules.neutron.remove_gateway_router(router, profile=None)
Removes an external network gateway from the specified router

CLI Example:
```
salt '*' neutron.remove_gateway_router router-name
```

Parameters
- **router** -- ID or name of router
- **profile** -- Profile to build on (Optional)

Returns True(Succeed) or False

salt.modules.neutron.remove_interface_router(router, subnet, profile=None)
Removes an internal network interface from the specified router

CLI Example:
```
salt '*' neutron.remove_interface_router router-name subnet-name
```

Parameters
- **router** -- ID or name of the router
- **subnet** -- ID or name of the subnet
- **profile** -- Profile to build on (Optional)

Returns True(Succeed) or False

salt.modules.neutron.show_floatingip(floatingip_id, profile=None)
Fetches information of a certain floatingIP

CLI Example:
salt '*' neutron.show_floatingip floatingip-id

Parameters

- `floatingip_id` -- ID of floatingIP to look up
- `profile` -- Profile to build on (Optional)

Returns  Floating IP information

salt.modules.neutron.show_ikepolicy(ikepolicy, profile=None)

Fetches information of a specific IKEPolicy

CLI Example:
(salt '*' neutron.show_ikepolicy ikepolicy-name)

Parameters

- `ikepolicy` -- ID or name of ikepolicy to look up
- `profile` -- Profile to build on (Optional)

Returns  IKE policy information

salt.modules.neutron.show_ipsec_site_connection(ipsec_site_connection, profile=None)

Fetches information of a specific IPsecSiteConnection

CLI Example:
(salt '*' neutron.show_ipsec_site_connection connection-name)

Parameters

- `ipsec_site_connection` -- ID or name of ipsec site connection to look up
- `profile` -- Profile to build on (Optional)

Returns  IPSec site connection information

salt.modules.neutron.show_ipsecpolicy(ipsecpolicy, profile=None)

Fetches information of a specific IPsecPolicy

CLI Example:
(salt '*' neutron.show_ipsecpolicy ipsecpolicy-name)

Parameters

- `ipsecpolicy` -- ID or name of IPSec policy to look up
- `profile` -- Profile to build on (Optional)

Returns  IPSec policy information

salt.modules.neutron.show_network(network, profile=None)

Fetches information of a certain network

CLI Example:
salt '*' neutron.show_network network-name
salt '*' neutron.show_network network-name profile=openstack1

Parameters

- **network** -- ID or name of network to look up
- **profile** -- Profile to build on (Optional)

Returns  Network information

salt.modules.neutron.show_port(port, profile=None)
Fetches information of a certain port

CLI Example:

salt '*' neutron.show_port port-id
salt '*' neutron.show_port port-id profile=openstack1

Parameters

- **port** -- ID or name of port to look up
- **profile** -- Profile to build on (Optional)

Returns  Port information

salt.modules.neutron.show_quota(tenant_id, profile=None)
Fetches information of a certain tenant's quotas

CLI Example:

salt '*' neutron.show_quota tenant-id
salt '*' neutron.show_quota tenant-id profile=openstack1

Parameters

- **tenant_id** -- ID of tenant
- **profile** -- Profile to build on (Optional)

Returns  Quota information

salt.modules.neutron.show_router(router, profile=None)
Fetches information of a certain router

CLI Example:

salt '*' neutron.show_router router-name

Parameters

- **router** -- ID or name of router to look up
- **profile** -- Profile to build on (Optional)

Returns  Router information
salt.modules.neutron.show_security_group(security_group, profile=None)
Fetches information of a certain security group

CLI Example:
```bash
salt '*' neutron.show_security_group security-group-name
```

Parameters
- **security_group** -- ID or name of security group to look up
- **profile** -- Profile to build on (Optional)

Returns Security group information

salt.modules.neutron.show_security_group_rule(security_group_rule_id, profile=None)
Fetches information of a certain security group rule

CLI Example:
```bash
salt '*' neutron.show_security_group_rule security-group-rule-id
```

Parameters
- **security_group_rule_id** -- ID of security group rule to look up
- **profile** -- Profile to build on (Optional)

Returns Security group rule information

salt.modules.neutron.show_subnet(subnet, profile=None)
Fetches information of a certain subnet

CLI Example:
```bash
salt '*' neutron.show_subnet subnet-name
```

Parameters
- **subnet** -- ID or name of subnet to look up
- **profile** -- Profile to build on (Optional)

Returns Subnet information

salt.modules.neutron.show_vpnservice(vpnservice, profile=None, **kwargs)
Fetches information of a specific VPN service

CLI Example:
```bash
salt '*' neutron.show_vpnservice vpnservice-name
```

Parameters
- **vpnservice** -- ID or name of vpn service to look up
- **profile** -- Profile to build on (Optional)

Returns VPN service information
salt.modules.neutron.update_floatingip(floatingip_id, port, profile=None)

Updates a floatingIP

CLI Example:

```
salt '*.' neutron.update_floatingip network-name port-name
```

Parameters

- **floatingip_id** -- ID of floatingIP
- **port** -- ID or name of port
- **profile** -- Profile to build on (Optional)

Returns Value of updated floating IP information

salt.modules.neutron.update_network(network, name, profile=None)

Updates a network

CLI Example:

```
salt '*.' neutron.update_network network-name new-network-name
```

Parameters

- **network** -- ID or name of network to update
- **name** -- Name of this network
- **profile** -- Profile to build on (Optional)

Returns Value of updated network information

salt.modules.neutron.update_port(port, name, admin_state_up=True, profile=None)

Updates a port

CLI Example:

```
salt '*.' neutron.update_port port-name network-name new-port-name
```

Parameters

- **port** -- Port name or ID
- **name** -- Name of this port
- **admin_state_up** -- Set admin state up to true or false, default: true (Optional)
- **profile** -- Profile to build on (Optional)

Returns Value of updated port information

salt.modules.neutron.update_quota(tenant_id, subnet=None, router=None, network=None, floatingip=None, port=None, security_group=None, security_group_rule=None, profile=None)

Update a tenant's quota

CLI Example:

```
salt '*.' neutron.update_quota tenant-id subnet=40 router=50 network=10 floatingip=30 port=30
```
Parameters

- **tenant_id** -- ID of tenant
- **subnet** -- Value of subnet quota (Optional)
- **router** -- Value of router quota (Optional)
- **network** -- Value of network quota (Optional)
- **floatingip** -- Value of floatingip quota (Optional)
- **port** -- Value of port quota (Optional)
- **security_group** -- Value of security group (Optional)
- **security_group_rule** -- Value of security group rule (Optional)
- **profile** -- Profile to build on (Optional)

Returns  Value of updated quota

```
salt.modules.neutron.update_router(router, name=None, admin_state_up=None, profile=None, **kwargs)
```

Updates a router

CLI Example:
```
salt '*' neutron.update_router router_id name=new-router-name admin_state_up=True
```

Parameters

- **router** -- ID or name of router to update
- **name** -- Name of this router
- **ext_network** -- ID or name of the external for the gateway (Optional)
- **admin_state_up** -- Set admin state up to true or false, default: true (Optional)
- **profile** -- Profile to build on (Optional)
- **kwargs** --

Returns  Value of updated router information

```
salt.modules.neutron.update_security_group(security_group, name=None, description=None, profile=None)
```

Updates a security group

CLI Example:
```
salt '*' neutron.update_security_group security-group-name new-
←security-group-name
```

Parameters

- **security_group** -- ID or name of security group to update
- **name** -- Name of this security group (Optional)
- **description** -- Description of security group (Optional)
- **profile** -- Profile to build on (Optional)
Returns Value of updated security group information

salt.modules.neutron.update_subnet(subnet, name, profile=None)

Updates a subnet

CLI Example:

```
salt '*' neutron.update_subnet subnet-name new-subnet-name
```

Parameters

- **subnet** -- ID or name of subnet to update
- **name** -- Name of this subnet
- **profile** -- Profile to build on (Optional)

Returns Value of updated subnet information

salt.modules.neutron.update_vpnservice(vpnservice, desc, profile=None)

Updates a VPN service

CLI Example:

```
salt '*' neutron.update_vpnservice vpnservice-name desc='VPN Service1'
```

Parameters

- **vpnservice** -- ID or name of vpn service to update
- **desc** -- Set a description for the VPN service
- **profile** -- Profile to build on (Optional)

Returns Value of updated VPN service information

32.17.170 salt.modules.nfs3

Module for managing NFS version 3.

salt.modules.nfs3.del_export(exports='/etc/exports', path=None)

Remove an export

CLI Example:

```
salt '*' nfs.del_export /media/storage
```

salt.modules.nfs3.list_exports(exports='/etc/exports')

List configured exports

CLI Example:

```
salt '*' nfs.list_exports
```

32.17.171 salt.modules.nftables

Support for nftables
salt.modules.nftables.append(table='filter', chain=None, rule=None, family='ipv4')

Append a rule to the specified table & chain.

This function accepts a rule in a standard nftables command format, starting with the chain. Trying to force users to adapt to a new method of creating rules would be irritating at best, and we already have a parser that can handle it.

CLI Example:

```bash
salt '*' nftables.append filter input
    rule='input tcp dport 22 log accept'

IPv6:
salt '*' nftables.append filter input
    rule='input tcp dport 22 log accept'
    family=ipv6
```

salt.modules.nftables.build_rule(table=None, chain=None, command=None, position='-', full=None, family='ipv4', **kwargs)

Build a well-formed nftables rule based on kwargs. A table and chain are not required, unless full is True.

If full is True, then table, chain and command are required. command may be specified as either insert, append, or delete. This will return the nftables command, exactly as it would be used from the command line.

If a position is required (as with insert or delete), it may be specified as position. This will only be useful if full is True.

If connstate is passed in, it will automatically be changed to state.

CLI Examples:

```bash
salt '*' nftables.build_rule match=state \
    connstate=RELATED,ESTABLISHED jump=ACCEPT
salt '*' nftables.build_rule filter input command=insert position=3 \
    full=True match=state state=related,established jump=accept

IPv6:
salt '*' nftables.build_rule match=state \
    connstate=related,established jump=accept \n    family=ipv6
salt '*' nftables.build_rule filter input command=insert position=3 \
    full=True match=state state=related,established jump=accept \n    family=ipv6
```

salt.modules.nftables.check(table='filter', chain=None, rule=None, family='ipv4')

Check for the existence of a rule in the table and chain

This function accepts a rule in a standard nftables command format, starting with the chain. Trying to force users to adapt to a new method of creating rules would be irritating at best, and we already have a parser that can handle it.

CLI Example:

```bash
salt '*' nftables.check filter input \
    rule='input tcp dport 22 log accept'

IPv6:
salt '*' nftables.check filter input \
    rule='input tcp dport 22 log accept' \n    family=ipv6
```
salt.modules.nftables.check_chain(\textit{table}='filter', \textit{chain}=None, \textit{family}='ipv4')

New in version 2014.7.0.

Check for the existence of a chain in the table

CLI Example:

\begin{verbatim}
nftables.check_chain filter input
\end{verbatim}\hfill

IPv6:

\begin{verbatim}
nftables.check_chain filter input family=ipv6
\end{verbatim}\hfill

salt.modules.nftables.check_table(\textit{table}=None, \textit{family}='ipv4')

Check for the existence of a table

CLI Example:

\begin{verbatim}
nftables.check_table nat
\end{verbatim}\hfill

salt.modules.nftables.delete(\textit{table}, \textit{chain}=None, \textit{position}=None, \textit{rule}=None, \textit{family}='ipv4')

Delete a rule from the specified table & chain, specifying either the rule in its entirety, or the rule's position in the chain.

This function accepts a rule in a standard nftables command format, starting with the chain. Trying to force users to adapt to a new method of creating rules would be irritating at best, and we already have a parser that can handle it.

CLI Examples:

\begin{verbatim}
nftables.delete filter input position=3
\end{verbatim}\hfill

\begin{verbatim}
nftables.delete filter input \rule='input tcp dport 22 log accept'
\end{verbatim}\hfill

IPv6:

\begin{verbatim}
nftables.delete filter input position=3 family=ipv6
\end{verbatim}\hfill

\begin{verbatim}
nftables.delete filter input \rule='input tcp dport 22 log accept' \family=ipv6
\end{verbatim}\hfill

salt.modules.nftables.delete_chain(\textit{table}='filter', \textit{chain}=None, \textit{family}='ipv4')

New in version 2014.7.0.

Delete the chain from the specified table.

CLI Example:

\begin{verbatim}
nftables.delete_chain filter input
\end{verbatim}\hfill

\begin{verbatim}
nftables.delete_chain filter foo
\end{verbatim}\hfill

IPv6:

\begin{verbatim}
nftables.delete_chain filter input family=ipv6
\end{verbatim}\hfill

\begin{verbatim}
nftables.delete_chain filter foo family=ipv6
\end{verbatim}\hfill

salt.modules.nftables.delete_table(\textit{table}, \textit{family}='ipv4')

New in version 2014.7.0.
Create new custom table.

CLI Example:

```
salt '*' nftables.delete_table filter
IPv6:
salt '*' nftables.delete_table filter family=ipv6
```

**salt.modules.nftables.flush** *(table=’filter’, chain=’’, family=’ipv4’)*

Flush the chain in the specified table, flush all chains in the specified table if chain is not specified.

CLI Example:

```
salt '*' nftables.flush filter
salt '*' nftables.flush filter input
IPv6:
salt '*' nftables.flush filter input family=ipv6
```

**salt.modules.nftables.get_rule_handle** *(table=’filter’, chain=None, rule=None, family=’ipv4’)*

Get the handle for a particular rule

This function accepts a rule in a standard nftables command format, starting with the chain. Trying to force users to adapt to a new method of creating rules would be irritating at best, and we already have a parser that can handle it.

CLI Example:

```
salt '*' nftables.get_rule_handle filter input \
    rule='input tcp dport 22 log accept'
IPv6:
salt '*' nftables.get_rule_handle filter input \
    rule='input tcp dport 22 log accept' \
    family=ipv6
```

**salt.modules.nftables.get_rules** *(family=’ipv4’)*

Return a data structure of the current, in-memory rules

CLI Example:

```
salt '*' nftables.get_rules
salt '*' nftables.get_rules family=ipv6
```

**salt.modules.nftables.get_saved_rules** *(conf_file=None, family=’ipv4’)*

Return a data structure of the rules in the conf file

CLI Example:

```
salt '*' nftables.get_saved_rules
```

**salt.modules.nftables.insert** *(table=’filter’, chain=None, position=None, rule=None, family=’ipv4’)*

Insert a rule into the specified table & chain, at the specified position.

If position is not specified, rule will be inserted in first position.
This function accepts a rule in a standard nftables command format, starting with the chain. Trying to force users to adapt to a new method of creating rules would be irritating at best, and we already have a parser that can handle it.

CLI Examples:

```bash
salt '*' nftables.insert filter input \
    rule='input tcp dport 22 log accept'
salt '*' nftables.insert filter input position=3 \
    rule='input tcp dport 22 log accept'

IPv6:
salt '*' nftables.insert filter input \
    rule='input tcp dport 22 log accept' \
    family=ipv6
salt '*' nftables.insert filter input position=3 \
    rule='input tcp dport 22 log accept' \
    family=ipv6
```

```python
salt.modules.nftables.new_chain(table='filter', chain=None, table_type=None, hook=None, priority=None, family='ipv4')
```

New in version 2014.7.0.
Create new chain to the specified table.

CLI Example:

```bash
salt '*' nftables.new_chain filter input
salt '*' nftables.new_chain filter input \n    table_type=filter hook=input priority=0
salt '*' nftables.new_chain filter foo

IPv6:
salt '*' nftables.new_chain filter input family=ipv6
salt '*' nftables.new_chain filter input \n    table_type=filter hook=input priority=0 family=ipv6
salt '*' nftables.new_chain filter foo family=ipv6
```

```python
salt.modules.nftables.new_table(table, family='ipv4')
```

New in version 2014.7.0.
Create new custom table.

CLI Example:

```bash
salt '*' nftables.new_table filter
IPv6:
salt '*' nftables.new_table filter family=ipv6
```

```python
salt.modules.nftables.save(filename=None, family='ipv4')
```

Save the current in-memory rules to disk

CLI Example:
salt '*' nftables.save /etc/nftables

**salt.modules.nftables.version()**

Return version from nftables --version

CLI Example:

```
salt '*' nftables.version
```

### 32.17.172 salt.modules.nginx

Support for nginx

**salt.modules.nginx.build_info()**

Return server and build arguments

CLI Example:

```
salt '*' nginx.build_info
```

**salt.modules.nginx.configtest()**

test configuration and exit

CLI Example:

```
salt '*' nginx.configtest
```

**salt.modules.nginx.signal(signal=None)**

Signals nginx to start, reload, reopen or stop.

CLI Example:

```
salt '*' nginx.signal reload
```

**salt.modules.nginx.status(url='http://127.0.0.1/status')**

Return the data from an Nginx status page as a dictionary. [http://wiki.nginx.org/HttpStubStatusModule](http://wiki.nginx.org/HttpStubStatusModule)

url The URL of the status page. Defaults to 'http://127.0.0.1/status'

CLI Example:

```
salt '*' nginx.status
```

**salt.modules.nginx.version()**

Return server version from nginx -v

CLI Example:

```
salt '*' nginx.version
```

### 32.17.173 salt.modules.node

Module for full system inspection.

**salt.modules.node.inspect(mode='all', priority=19, **kwargs)**

Start node inspection and save the data to the database for further query.

Parameters:
• **mode**: Clarify inspection mode: configuration, payload, all (default)
  
  payload
  
  – **filter**: Comma-separated directories to track payload.
  
  • **priority**: (advanced) Set priority of the inspection. Default is low priority.

CLI Example:

```
salt '*' node.inspect
salt '*' node.inspect configuration
salt '*' node.inspect payload filter=/opt,/ext/oracle
```

salt.modules.node.**query**(scope, **kwargs)

Query the node for specific information.

Parameters:

• **scope**: Specify scope of the query.
  
  – **System**: Return system data.
  
  – **Software**: Return software information.
  
  – **Services**: Return known services.
  
  – **Identity**: Return user accounts information for this system.

     accounts Can be either `local`, `remote` or `all` (equal to `local,remote`). Remote accounts cannot be resolved on all systems, but only those, which supports `passwd -S -a`.

     disabled True (or False, default) to return only disabled accounts.

• **payload**: Payload scope parameters:

  – **filter**: Include only results which path starts from the filter string.
  
  – **time**: Display time in Unix ticks or format according to the configured TZ (default) Values: ticks, tz (default)
  
  – **size**: Format size. Values: B, KB, MB, GB
  
  – **type**: Include payload type. Values (comma-separated): directory (or dir), link, file (default) Example (returns everything): type=directory,link,file
  
  – **owners**: Resolve UID/GID to an actual names or leave them numeric (default). Values: name (default), id
  
  – **brief**: Return just a list of payload elements, if True. Default: False.

• **all**: Return all information (default).

CLI Example:

```
salt '*' node.query scope=os
salt '*' node.query payload type=file,link filter=/etc size=Kb brief=False
```

32.17.174 salt.modules.nova

Module for handling OpenStack Nova calls

- **depends**

  • novaclient Python module
**configuration** This module is not usable until the user, password, tenant, and auth URL are specified either in a pillar or in the minion's config file. For example:

```yaml
keystone.user: admin
keystone.password: verybadpass
keystone.tenant: admin
keystone.auth_url: 'http://127.0.0.1:5000/v2.0/
# Optional
keystone.region_name: 'regionOne'
```

If configuration for multiple OpenStack accounts is required, they can be set up as different configuration profiles: For example:

```yaml
openstack1:
  keystone.user: admin
  keystone.password: verybadpass
  keystone.tenant: admin
  keystone.auth_url: 'http://127.0.0.1:5000/v2.0/

openstack2:
  keystone.user: admin
  keystone.password: verybadpass
  keystone.tenant: admin
  keystone.auth_url: 'http://127.0.0.2:5000/v2.0/
```

With this configuration in place, any of the nova functions can make use of a configuration profile by declaring it explicitly. For example:

```bash
salt '*' nova.flavor_list profile=openstack1
```

```bash
salt.modules.nova.boot(name, flavor_id=0, image_id=0, profile=None, timeout=300)
```

- **name** Name of the new instance
- **flavor_id** Unique integer ID for the flavor
- **image_id** Unique integer ID for the image
- **timeout** How long to wait, after creating the instance, for the provider to return information about it (default 300 seconds).

New in version 2014.1.0.

CLI Example:

```bash
salt '*' nova.boot myinstance flavor_id=4596 image_id=2
```

The flavor_id and image_id are obtained from nova.flavor_list and nova.image_list

```bash
salt '*' nova.flavor_list
salt '*' nova.image_list
```

```bash
salt.modules.nova.delete(instance_id, profile=None)
```

- **instance_id** ID of the instance to be deleted

CLI Example:  

```bash
```
salt.modules.nova.

**flavor_create**(*name*, *flavor_id=0, *ram=0, *disk=0, *vcpus=1, *profile=None*)

Add a flavor to nova (nova flavor-create). The following parameters are required:

- **name** Name of the new flavor (must be first)
- **flavor_id** Unique integer ID for the new flavor
- **ram** Memory size in MB
- **disk** Disk size in GB
- **vcpus** Number of vcpus

CLI Example:

```
salt '*' nova.flavor_create myflavor flavor_id=6 ram=4096 disk=10
vcpus=1
```

salt.modules.nova.

**flavor_delete**(*flavor_id, *profile=None*)

Delete a flavor from nova by id (nova flavor-delete)

CLI Example:

```
salt '*' nova.flavor_delete 7
```

salt.modules.nova.

**flavor_list**(*profile=None*)

Return a list of available flavors (nova flavor-list)

CLI Example:

```
salt '*' nova.flavor_list
```

salt.modules.nova.

**image_list**(*name=None, *profile=None*)

Return a list of available images (nova images-list + nova image-show) If a name is provided, only that image will be displayed.

CLI Examples:

```
salt '*' nova.image_list
salt '*' nova.image_list myimage
```

salt.modules.nova.

**image_meta_delete**(*image_id=None, *name=None, *keys=None, *profile=None*)

Delete a key=value pair from the metadata for an image (nova image-meta set)

CLI Examples:

```
salt '*' nova.image_meta_delete 6f52b2ff-0b31-4d84-8fd1-
af45b84824f6 keys=cheese
salt '*' nova.image_meta_delete name=myimage keys=salad,beans
```

salt.modules.nova.

**image_meta_set**(*image_id=None, *name=None, *profile=None, **kwargs*)

Sets a key=value pair in the metadata for an image (nova image-meta set)

CLI Examples:

```
salt '*' nova.image_meta_set 6f52b2ff-0b31-4d84-8fd1-
af45b84824f6 cheese=gruyere
salt '*' nova.image_meta_set name=myimage salad=pasta beans=baked
```
salt.modules.nova.keypair_add(name, pubfile=None, pubkey=None, profile=None)
Add a keypair to nova (nova keypair-add)

CLI Examples:

```bash
salt '*' nova.keypair_add mykey pubfile='/home/myuser/.ssh/id_rsa.pub'
salt '*' nova.keypair_add mykey pubkey='ssh-rsa <key> myuser@mybox'
```

salt.modules.nova.keypair_delete(name, profile=None)
Add a keypair to nova (nova keypair-delete)

CLI Example:

```bash
salt '*' nova.keypair_delete mykey'
```

salt.modules.nova.keypair_list(profile=None)
Return a list of available keypairs (nova keypair-list)

CLI Example:

```bash
salt '*' nova.keypair_list
```

salt.modules.nova.list(profile=None)
To maintain the feel of the nova command line, this function simply calls the server_list function.

CLI Example:

```bash
salt '*' nova.list
```

salt.modules.nova.lock(instance_id, profile=None)
Lock an instance

instance_id  ID of the instance to be locked

CLI Example:

```bash
salt '*' nova.lock 1138
```

salt.modules.nova.resume(instance_id, profile=None)
Resume an instance

instance_id  ID of the instance to be resumed

CLI Example:

```bash
salt '*' nova.resume 1138
```

salt.modules.nova.secggroup_create(name, description, profile=None)
Add a secgroup to nova (nova secgroup-create)

CLI Example:

```bash
salt '*' nova.secggroup_create mygroup 'This is my security group'
```

salt.modules.nova.secggroup_delete(name, profile=None)
Delete a secgroup to nova (nova secgroup-delete)

CLI Example:

```bash
salt '*' nova.secggroup_delete mygroup
```
salt.modules.nova.secgroup_list( profile=None )
Return a list of available security groups (nova items-list)

    CLI Example:
    salt '*' nova.secgroup_list

salt.modules.nova.server_by_name( name, profile=None )
Return information about a server

    name  Server Name

    CLI Example:
    salt '*' nova.server_by_name myserver profile=openstack

salt.modules.nova.server_list( profile=None )
Return list of active servers

    CLI Example:
    salt '*' nova.show

salt.modules.nova.server_list_detailed( profile=None )
Return detailed list of active servers

    CLI Example:
    salt '*' nova.server_list_detailed

salt.modules.nova.server_show( server_id, profile=None )
Return detailed information for an active server

    CLI Example:
    salt '*' nova.server_show <server_id>

salt.modules.nova.show( server_id, profile=None )
To maintain the feel of the nova command line, this function simply calls the server_show function.

    CLI Example:
    salt '*' nova.show

salt.modules.nova.suspend( instance_id, profile=None )
Suspend an instance

    instance_id  ID of the instance to be suspended

    CLI Example:
    salt '*' nova.suspend 1138

salt.modules.nova.volume_attach( name, server_name, device='/dev/xvdb', profile=None, timeout=300 )
Attach a block storage volume

    name  Name of the new volume to attach

    server_name  Name of the server to attach to

    device  Name of the device on the server
profile Profile to build on

CLI Example:

```
salt '*' nova.volume_attach myblock slice.example.com profile=openstack
salt '*' nova.volume_attach myblock server.example.com device='/dev/xvdb'
```

```
salt.modules.nova.volume_create(name, size=100, snapshot=None, voltype=None, profile=None)
```

Create a block storage volume

- **name** Name of the new volume (must be first)
- **size** Volume size
- **snapshot** Block storage snapshot id
- **voltype** Type of storage
- **profile** Profile to build on

CLI Example:

```
salt '*' nova.volume_create myblock size=300 profile=openstack
```

```
salt.modules.nova.volume_delete(name, profile=None)
```

Destroy the volume

- **name** Name of the volume
- **profile** Profile to build on

CLI Example:

```
salt '*' nova.volume_delete myblock profile=openstack
```

```
salt.modules.nova.volume_detach(name, profile=None, timeout=300)
```

Attach a block storage volume

- **name** Name of the new volume to attach
- **server_name** Name of the server to detach from
- **profile** Profile to build on

CLI Example:

```
salt '*' nova.volume_detach myblock profile=openstack
```

```
salt.modules.nova.volume_list(search_opts=None, profile=None)
```

List storage volumes

- **search_opts** Dictionary of search options
- **profile** Profile to use

CLI Example:

```
salt '*' nova.volume_list search_opts='{"display_name": "myblock"}' profile=openstack
```

```
salt.modules.nova.volume_show(name, profile=None)
```

Create a block storage volume

- **name** Name of the volume

---

32.17. Full list of builtin execution modules
profile Profile to use

CLI Example:

```
salt '*' nova.volume_show myblock profile=openstack
```

32.17.175 salt.modules.npm

Manage and query NPM packages.

salt.modules.npm.install(pkg=None, pkgs=None, dir=None, runas=None, registry=None, env=None, dry_run=False, silent=True)

Install an NPM package.

If no directory is specified, the package will be installed globally. If no package is specified, the dependencies (from package.json) of the package in the given directory will be installed.

- **pkg**: A package name in any format accepted by NPM, including a version identifier
- **pkgs**: A list of package names in the same format as the name parameter

New in version 2014.7.0.

- **dir**: The target directory in which to install the package, or None for global installation
- **runas**: The user to run NPM with
- **registry**: The NPM registry to install the package from.

New in version 2014.7.0.

- **env**: Environment variables to set when invoking npm. Uses the same env format as the cmd.run execution function.

New in version 2014.7.0.

- **dry_run**: Whether or not to run NPM install with --dry-run flag.

New in version 2015.8.4.

- **silent**: Whether or not to run NPM install with --silent flag.

New in version 2015.8.5.

CLI Example:

```
salt '*' npm.install coffee-script
salt '*' npm.install coffee-script@1.0.1
```

salt.modules.npm.list(pkg=None, dir=None, runas=None, env=None)

List installed NPM packages.

If no directory is specified, this will return the list of globally installed packages.

- **pkg**: Limit package listing by name
- **dir**: The directory whose packages will be listed, or None for global installation
- **runas**: The user to run NPM with

New in version 2014.7.0.
env  Environment variables to set when invoking npm. Uses the same env format as the cmd.run execution function.

New in version 2014.7.0.

CLI Example:
```
salt '*' npm.list
```

```python
salt.modules.npm.uninstall(pkg, dir=None, runas=None, env=None)
```
Uninstall an NPM package.

If no directory is specified, the package will be uninstalled globally.

pkg  A package name in any format accepted by NPM

dir  The target directory from which to uninstall the package, or None for global installation

runas  The user to run NPM with

env  Environment variables to set when invoking npm. Uses the same env format as the cmd.run execution function.

New in version 2015.5.3.

CLI Example:
```
salt '*' npm.uninstall coffee-script
```

32.17.176 salt.modules.nspawn

Manage nspawn containers

New in version 2015.8.0.

```python
systemd-nspawn(1)
```
is a tool used to manage lightweight namespace containers. This execution module provides several functions to help manage these containers.

Minions running systemd >= 219 will place new containers in /var/lib/machines, while those running systemd < 219 will place them in /var/lib/container.

```python
salt.modules.nspawn.bootstrap_container(name, dist=None, version=None)
```
Bootstrap a container from package servers, if dist is None the os the minion is running as will be created, otherwise the needed bootstrapping tools will need to be available on the host.

CLI Example:
```
salt myminion nspawn.bootstrap_container <name>
```

```python
salt.modules.nspawn.bootstrap_salt(name, config=None, approve_key=True, install=True, pub_key=None, priv_key=None, bootstrap_url=None, force_install=False, unconditional_install=False, bootstrap_delay=None, bootstrap_args=None, bootstrap_shell=None)
```
Bootstrap a container from package servers, if dist is None the os the minion is running as will be created, otherwise the needed bootstrapping tools will need to be available on the host.

CLI Example:
```
salt '*' nspawn.bootstrap_salt arch1
```
salt.modules.nspawn.copy_to(name, *args, **kwargs)
Copy a file from the host into a container

name Container name
source File to be copied to the container
dest Destination on the container. Must be an absolute path.
overwrite [False] Unless this option is set to True, then if a file exists at the location specified by the dest argument, an error will be raised.
makedirs : False
    Create the parent directory on the container if it does not already exist.

CLI Example:
salt 'minion' nspawn.copy_to /tmp/foo /root/foo

salt.modules.nspawn.disable(name, *args, **kwargs)
Set the named container to not be launched at boot

CLI Example:
salt myminion nspawn.enable <name>

salt.modules.nspawn.enable(name, *args, **kwargs)
Set the named container to be launched at boot

CLI Example:
salt myminion nspawn.enable <name>

salt.modules.nspawn.exists(name)
Returns true if the named container exists

CLI Example:
salt myminion nspawn.exists <name>

salt.modules.nspawn.info(name, **kwargs)
Return info about a container

Note: The container must be running for machinectl to gather information about it. If the container is stopped, then this function will start it.

start [False] If True, then the container will be started to retrieve the info. A Started key will be in the return data if the container was started.

CLI Example:
salt myminion nspawn.info arch1
salt myminion nspawn.info arch1 force_start=False

salt.modules.nspawn.list_all()
Lists all nspawn containers

CLI Example:
salt myminion nspawn.list_all

salt.modules.nspawn.list_running()
Lists running nspawn containers

*Note*: nspawn.list also works to list running containers

CLI Example:

salt myminion nspawn.list_running
salt myminion nspawn.list

salt.modules.nspawn.list_stopped()
Lists stopped nspawn containers

CLI Example:

salt myminion nspawn.list_stopped

salt.modules.nspawn.pid(name, *args, **kwargs)
Returns the PID of a container

```
name  Container name
```

CLI Example:

salt myminion nspawn.pid arch1

salt.modules.nspawn.poweroff(name)
Issue a clean shutdown to the container. Equivalent to running machinectl poweroff on the named container.

For convenience, running nspawn.stop``(as shown in the CLI examples below) is equivalent to running `nspawn.poweroff`.

*:machinectl poweroff is only supported in systemd >= 219. On earlier systemd versions, running this function will simply issue a clean shutdown via systemctl.*

CLI Examples:

salt myminion nspawn.poweroff arch1
salt myminion nspawn.stop arch1

salt.modules.nspawn.pull_dkr(url, name, index)
Execute a machinectl pull-dkr to download a docker image and add it to /var/lib/machines as a new container.

*:Requires systemd >= 219*

```
url  URL from which to download the container
name  Name for the new container
index  URL of the Docker index server from which to pull (must be an http:// or https:// URL).
```
CLI Examples:

```bash
salt myminion nspawn.pull_dkr centos/centos6 cent6 index=https://get.docker.com
salt myminion nspawn.pull_docker centos/centos6 cent6 index=https://get.docker.com
```

```python
salt.modules.nspawn.pull_raw(url, name, verify=False)
```
Execute a machinectl pull-raw to download a qcow2 or raw disk image, and add it to /var/lib/machines as a new container.

**Note:** Requires systemd >= 219

```python
url URL from which to download the container
name Name for the new container
verify [False] Perform signature or checksum verification on the container. See the machinectl(1) man page (section titled `Image Transfer Commands`) for more information on requirements for image verification. To perform signature verification, use verify=signature. For checksum verification, use verify=checksum. By default, no verification will be performed.
```

CLI Examples:

```bash
```

```python
salt.modules.nspawn.pull_tar(url, name, verify=False)
```
Execute a machinectl pull-raw to download a .tar container image, and add it to /var/lib/machines as a new container.

**Note:** Requires systemd >= 219

```python
url URL from which to download the container
name Name for the new container
verify [False] Perform signature or checksum verification on the container. See the machinectl(1) man page (section titled `Image Transfer Commands`) for more information on requirements for image verification. To perform signature verification, use verify=signature. For checksum verification, use verify=checksum. By default, no verification will be performed.
```

CLI Examples:

```bash
salt myminion nspawn.pull_tar http://foo.domain.tld/containers/archlinux-2015.02.01.tar.gz arch2
```

```python
salt.modules.nspawn.reboot(name, *args, **kwargs)
```
Reboot the container by sending a SIGINT to its init process. Equivalent to running machinectl reboot on the named container.

For convenience, running nspawn.restart (as shown in the CLI examples below) is equivalent to running nspawn.reboot.
Note: `machinectl reboot` is only supported in systemd >= 219. On earlier systemd versions, running this function will instead restart the container via `systemctl`.

CLI Examples:

```bash
salt myminion nspawn.reboot arch1
salt myminion nspawn.restart arch1
```

`salt.modules.nspawn.remove(name, *args, **kwargs)`
Remove the named container

**Warning:** This function will remove all data associated with the container. It will not, however, remove the btrfs subvolumes created by pulling container images (`nspawn.pull_raw`, `nspawn.pull_tar`, `nspawn.pull_dkr`).

**stop** [False] If True, the container will be destroyed even if it is running/frozen.

CLI Examples:

```bash
salt '*' nspawn.remove foo
salt '*' nspawn.remove foo stop=True
```

`salt.modules.nspawn.run(name, cmd, no_start=False, preserve_state=True, stdin=None, python_shell=True, output_loglevel='debug', use_vt=False, ignore_retcode=False, keep_env=None)`
Run `cmd.run` within a container

- **name** Name of the container in which to run the command
- **cmd** Command to run
- **no_start** [False] If the container is not running, don't start it
- **preserve_state** [True] After running the command, return the container to its previous state
- **stdin** [None] Standard input to be used for the command
- **output_loglevel** ['debug'] Level at which to log the output from the command. Set to 'quiet' to suppress logging.
- **use_vt** [False] Use SaltStack's utils.vt to stream output to console. Assumes output=all.
- **keep_env** [None] If not passed, only a sane default PATH environment variable will be set. If True, all environment variables from the container's host will be kept. Otherwise, a comma-separated list (or Python list) of environment variable names can be passed, and those environment variables will be kept.

CLI Example:

```bash
salt myminion nspawn.runcode mycontainer 'ip addr show'
```

`salt.modules.nspawn.run(name, cmd, no_start=False, preserve_state=True, stdin=None, python_shell=True, output_loglevel='debug', use_vt=False, ignore_retcode=False, keep_env=None)`
Run `cmd.run` within a container

- **name** Name of the container in which to run the command
- **cmd** Command to run
no_start [False] If the container is not running, don't start it

preserve_state [True] After running the command, return the container to its previous state

stdin [None] Standard input to be used for the command

output_loglevel [debug] Level at which to log the output from the command. Set to quiet to suppress logging.

use_vt [False] Use SaltStack's utils.vt to stream output to console.

keep_env [None] If not passed, only a sane default PATH environment variable will be set. If True, all environment variables from the container's host will be kept. Otherwise, a comma-separated list (or Python list) of environment variable names can be passed, and those environment variables will be kept.

CLI Example:

```
salt myminion nspawn.run mycontainer 'ifconfig -a'
```

salt.modules.nspawn.run_all(name, cmd, no_start=False, preserve_state=True, stdin=None, python_shell=True, output_loglevel='debug', use_vt=False, ignore_retcode=False, keep_env=None)

Run cmd.run_all within a container

Note: While the command is run within the container, it is initiated from the host. Therefore, the PID in the return dict is from the host, not from the container.

name Name of the container in which to run the command

cmd Command to run

no_start [False] If the container is not running, don't start it

preserve_state [True] After running the command, return the container to its previous state

stdin [None] Standard input to be used for the command

output_loglevel [debug] Level at which to log the output from the command. Set to quiet to suppress logging.

use_vt [False] Use SaltStack's utils.vt to stream output to console. Assumes output=all.

keep_env [None] If not passed, only a sane default PATH environment variable will be set. If True, all environment variables from the container's host will be kept. Otherwise, a comma-separated list (or Python list) of environment variable names can be passed, and those environment variables will be kept.

CLI Example:

```
salt myminion nspawn.run_all mycontainer 'ip addr show'
```

salt.modules.nspawn.run_stderr(name, cmd, no_start=False, preserve_state=True, stdin=None, python_shell=True, output_loglevel='debug', use_vt=False, ignore_retcode=False, keep_env=None)

Run cmd.run_stderr within a container

name Name of the container in which to run the command

cmd Command to run

no_start [False] If the container is not running, don't start it

preserve_state [True] After running the command, return the container to its previous state
stdin [None] Standard input to be used for the command

output_loglevel [debug] Level at which to log the output from the command. Set to quiet to suppress logging.

use_vt [False] Use SaltStack's utils.vt to stream output to console. Assumes output=all.

keep_env [None] If not passed, only a sane default PATH environment variable will be set. If True, all environment variables from the container's host will be kept. Otherwise, a comma-separated list (or Python list) of environment variable names can be passed, and those environment variables will be kept.

CLI Example:

```
salt myminion nspawn.run_stderr mycontainer 'ip addr show'
```

```
salt.modules.nspawn.run_stdout(name, cmd, no_start=False, preserve_state=True, stdin=None, python_shell=True, output_loglevel='debug', use_vt=False, ignore_retcode=False, keep_env=None)
```

Run cmd.run_stdout within a container

name Name of the container in which to run the command

cmd Command to run

no_start [False] If the container is not running, don't start it

preserve_state [True] After running the command, return the container to its previous state

stdin [None] Standard input to be used for the command

output_loglevel [debug] Level at which to log the output from the command. Set to quiet to suppress logging.

use_vt [False] Use SaltStack's utils.vt to stream output to console. Assumes output=all.

keep_env [None] If not passed, only a sane default PATH environment variable will be set. If True, all environment variables from the container's host will be kept. Otherwise, a comma-separated list (or Python list) of environment variable names can be passed, and those environment variables will be kept.

CLI Example:

```
salt myminion nspawn.run_stdout mycontainer 'ifconfig -a'
```

```
salt.modules.nspawn.start(name, *args, **kwargs)
```

Start the named container

CLI Example:

```
salt myminion nspawn.start <name>
```

```
salt.modules.nspawn.state(name, *args, **kwargs)
```

Return state of container (running or stopped)

CLI Example:

```
salt myminion nspawn.state <name>
```

```
salt.modules.nspawn.terminate(name)
```

Kill all processes in the container without issuing a clean shutdown. Equivalent to running machinectl terminate on the named container.

For convenience, running nspawn.stop and passing kill=True (as shown in the CLI examples below) is equivalent to running nspawn.terminate.
Salt Documentation, Release 2015.8.12

---

**Note:** `machinectl terminate` is only supported in `systemd >= 219`. On earlier `systemd` versions, running this function will simply issue a clean shutdown via `systemctl`.

---

CLI Examples:

```bash
salt myminion nspawn.terminate arch1
salt myminion nspawn.stop arch1 kill=True
```

### 32.17.177 salt.modules.omapi

This module interacts with an ISC DHCP Server via OMAPI. `server_ip` and `server_port` params may be set in the minion config or pillar:

```ini
omapi.server_ip: 127.0.0.1
omapi.server_port: 7991
```

**depends** pypureomapi Python module

#### salt.modules.omapi.add_host

```python
def add_host(mac=None, name=None, ip=None, ddns=False, group=None, supercede_host=False)
```

Add a host object for the given mac.

CLI Example:

```bash
salt dhcp-server omapi.add_host ab:ab:ab:ab:ab:ab name=host1
```

Add ddns-hostname and a fixed-ip statements:

```bash
salt dhcp-server omapi.add_host ab:ab:ab:ab:ab:ab name=host1 ip=10.1.1.1 ddns=true
```

#### salt.modules.omapi.delete_host

```python
def delete_host(mac=None, name=None)
```

Delete the host with the given mac or name.

CLI Examples:

```bash
salt dhcp-server omapi.delete_host name=host1
salt dhcp-server omapi.delete_host mac=ab:ab:ab:ab:ab:ab
```

### 32.17.178 salt.modules.openbsd_sysctl

Module for viewing and modifying OpenBSD sysctl parameters

#### salt.modules.openbsd_sysctl.assign

```python
def assign(name, value)
```

Assign a single sysctl parameter for this minion

CLI Example:

```bash
salt '*' sysctl.assign net.inet.ip.forwarding 1
```

#### salt.modules.openbsd_sysctl.get

```python
def get(name)
```

Return a single sysctl parameter for this minion

CLI Example:
salt '*' sysctl.get hw.physmem

**salt.modules.openbsd_sysctl.persist**(name, value, config='/etc/sysctl.conf')
Assign and persist a simple sysctl parameter for this minion

**CLI Example:**
salt '*' sysctl.persist net.inet.ip.forwarding 1

**salt.modules.openbsd_sysctl.show**(config_file=False)
Return a list of sysctl parameters for this minion

**CLI Example:**
salt '*' sysctl.show

32.17.179 **salt.modules.openbsdpkg**
Package support for OpenBSD

**Important:** If you feel that Salt should be using this module to manage packages on a minion, and it is using a different module (or gives an error similar to `pkg.install' is not available), see [here](#).

**salt.modules.openbsdpkg.install**(name=None, pkgs=None, sources=None, **kwargs)
Install the passed package

Return a dict containing the new package names and versions:

```python
{'<package>': {'old': '<old-version>', 'new': '<new-version>'}}
```

**CLI Example, Install one package:**
salt '*' pkg.install <package name>

**CLI Example, Install more than one package:**
salt '*' pkg.install pkgs='["<package name>", "<package name>"]'

**CLI Example, Install more than one package from a alternate source (e.g. salt file-server, HTTP, FTP, local filesystem):**
salt '*' pkg.install sources='[["<pkg name>": "salt://pkgs/<pkg filename>"]'

**salt.modules.openbsdpkg.latest_version**(names, **kwargs)
The available version of the package in the repository

**CLI Example:**
salt '*' pkg.latest_version <package name>

**salt.modules.openbsdpkg.list_pkgs**(versions_as_list=False, **kwargs)
List the packages currently installed as a dict:
{'<package_name>': '<version>'}

CLI Example:
```
salt '*' pkg.list_pkgs
```

```python
salt.modules.openbsdpkg.purge(name=None, pkgs=None, **kwargs)
```
Package purges are not supported, this function is identical to `remove()`.

- **name**: The name of the package to be deleted.
- **pkgs**: A list of packages to delete. Must be passed as a python list. The `name` parameter will be ignored if this option is passed.

New in version 0.16.0.

Returns a dict containing the changes.

CLI Example:
```
salt '*' pkg.purge <package name>
salt '*' pkg.purge <package1>,<package2>,<package3>
salt '*' pkg.purge pkgs=['"foo", "bar"]'
```

```python
salt.modules.openbsdpkg.remove(name=None, pkgs=None, **kwargs)
```
Remove a single package with `pkg_delete`

- **pkgs**: A list of packages to delete. Must be passed as a python list. The `name` parameter will be ignored if this option is passed.

New in version 0.16.0.

Returns a dict containing the changes.

CLI Example:
```
salt '*' pkg.remove <package name>
salt '*' pkg.remove <package1>,<package2>,<package3>
salt '*' pkg.remove pkgs=['"foo", "bar"]'
```

```python
salt.modules.openbsdpkg.version(*names, **kwargs)
```
Returns a string representing the package version or an empty string if not installed. If more than one package name is specified, a dict of name/version pairs is returned.

CLI Example:
```
salt '*' pkg.version <package name>
salt '*' pkg.version <package1> <package2> <package3> ...
```

### 32.17.180 `salt.modules.openbsdrcctl`

The rcctl service module for OpenBSD

```python
salt.modules.openbsdrcctl.available(name)
```
Return True if the named service is available.

CLI Example:
salt '*' service.available sshd

```
salt.modules.openbsdrcctl.disable(name, **kwargs)
    Disable the named service to not start at boot.
    CLI Example:
    
salt '*' service.disable <service name>
```

```
salt.modules.openbsdrcctl.disabled(name)
    Return True if the named service is disabled at boot, False otherwise.
    CLI Example:
    
salt '*' service.disabled <service name>
```

```
salt.modules.openbsdrcctl.enable(name, **kwargs)
    Enable the named service to start at boot.
    flags [None] Set optional flags to run the service with.
    service.flags can be used to change the default flags.
    CLI Example:
    
salt '*' service.enable <service name>
salt '*' service.enable <service name> flags=<flags>
```

```
salt.modules.openbsdrcctl.enabled(name, **kwargs)
    Return True if the named service is enabled at boot and the provided flags match the configured ones (if any). Return False otherwise.
    name Service name
    CLI Example:
    
salt '*' service.enabled <service name>
salt '*' service.enabled <service name> flags=<flags>
```

```
salt.modules.openbsdrcctl.get_all()
    Return all installed services.
    CLI Example:
    
salt '*' service.get_all
```

```
salt.modules.openbsdrcctl.get_disabled()
    Return what services are available but not enabled to start at boot.
    CLI Example:
    
salt '*' service.get_disabled
```

```
salt.modules.openbsdrcctl.get_enabled()
    Return what services are set to run on boot.
    CLI Example:
    
salt '*' service.get_enabled
```

32.17. Full list of builtin execution modules
salt.modules.openbsdrcctl.missing(name)
The inverse of service.available. Return True if the named service is not available.

CLI Example:

```
salt '*' service.missing sshd
```

salt.modules.openbsdrcctl.reload(name)
Reload the named service.

CLI Example:

```
salt '*' service.reload <service name>
```

salt.modules.openbsdrcctl.restart(name)
Restart the named service.

CLI Example:

```
salt '*' service.restart <service name>
```

salt.modules.openbsdrcctl.start(name)
Start the named service.

CLI Example:

```
salt '*' service.start <service name>
```

salt.modules.openbsdrcctl.status(name, sig=None)
Return the status for a service, returns a bool whether the service is running.

CLI Example:

```
salt '*' service.status <service name>
```

salt.modules.openbsdrcctl.stop(name)
Stop the named service.

CLI Example:

```
salt '*' service.stop <service name>
```

32.17.181 salt.modules.openbsdservice

The service module for OpenBSD

**Important:** If you feel that Salt should be using this module to manage services on a minion, and it is using a
different module (or gives an error similar to `service.start' is not available), see here.

salt.modules.openbsdservice.available(name)
New in version 2014.7.0.

Returns True if the specified service is available, otherwise returns False.

CLI Example:
salt 'salt '*' service.available sshd

salt.modules.openbsdservice.disabled(name)
   New in version 2014.7.0.
   Return True if the named service is disabled, false otherwise
   CLI Example:
   ```
salt 'salt '*' service.disabled <service name>
   ```

salt.modules.openbsdservice.enabled(name, **kwargs)
   New in version 2014.7.0.
   Return True if the named service is enabled, false otherwise
   CLI Example:
   ```
salt 'salt '*' service.enabled <service name>
   ```

salt.modules.openbsdservice.get_all()
   New in version 2014.7.0.
   Return all available boot services
   CLI Example:
   ```
salt 'salt '*' service.get_all
   ```

salt.modules.openbsdservice.get_disabled()
   New in version 2014.7.0.
   Return a set of services that are installed but disabled
   CLI Example:
   ```
salt 'salt '*' service.get_disabled
   ```

salt.modules.openbsdservice.get_enabled()
   New in version 2014.7.0.
   Return a list of service that are enabled on boot
   CLI Example:
   ```
salt 'salt '*' service.get_enabled
   ```

salt.modules.openbsdservice.missing(name)
   New in version 2014.7.0.
   The inverse of service.available. Returns True if the specified service is not available, otherwise returns False.
   CLI Example:
   ```
salt 'salt '*' service.missing sshd
   ```

salt.modules.openbsdservice.reload(name)
   New in version 2014.7.0.
   Reload the named service
CLI Example:
```
salt '*' service.reload <service name>
```

```python
salt.modules.openbsdservice.restart(name)
```
Restart the named service

CLI Example:
```
salt '*' service.restart <service name>
```

```python
salt.modules.openbsdservice.start(name)
```
Start the specified service

CLI Example:
```
salt '*' service.start <service name>
```

```python
salt.modules.openbsdservice.status(name, sig=None)
```
Return the status for a service, returns a bool whether the service is running.

CLI Example:
```
salt '*' service.status <service name>
```

```python
salt.modules.openbsdservice.stop(name)
```
Stop the specified service

CLI Example:
```
salt '*' service.stop <service name>
```

### 32.17.182 `salt.modules.openstack_config`

Modify, retrieve, or delete values from OpenStack configuration files.

- **maintainer** Jeffrey C. Ollie <jeff@ocjtech.us>
- **maturity** new
- **depends**
- **platform** linux

```python
salt.modules.openstack_config.delete(filename, section, parameter)
```
Delete a value from an OpenStack configuration file.

- **filename** The full path to the configuration file
- **section** The section from which to delete the parameter
- **parameter** The parameter to delete

CLI Example:
```
salt-call openstack_config.delete /etc/keystone/keystone.conf sql connection
```

```python
salt.modules.openstack_config.get(filename, section, parameter)
```
Get a value from an OpenStack configuration file.

- **filename** The full path to the configuration file
**section**  The section from which to search for the parameter

**parameter**  The parameter to return

CLI Example:

```
salt-call openstack_config.get /etc/keystone/keystone.conf sql connection
```

```
salt.modules.openstack_config.set(filename, section, parameter, value)
```

Set a value in an OpenStack configuration file.

**filename**  The full path to the configuration file

**section**  The section in which the parameter will be set

**parameter**  The parameter to change

**value**  The value to set

CLI Example:

```
salt-call openstack_config.set /etc/keystone/keystone.conf sql connection foo
```

### 32.17.183  salt.modules.oracle

Oracle DataBase connection module

**maintainer**  Vladimir Bormotov <bormotov@gmail.com>

**maturity**  new

**depends**  cx_Oracle

**platform**  all

**configuration**  module provide connections for multiple Oracle DB instances.

**OS Environment**

```
ORACLE_HOME: path to oracle product
PATH: path to Oracle Client libs need to be in PATH
```

**pillar**

```
oracle.dbs: list of known based
oracle.dbs.<db>.uri: connection credentials in format:
user/password@host[:port]/sid[ as {sysdba|sysoper}]
```

```
salt.modules.oracle.client_version()
```

Oracle Client Version

CLI Example:

```
salt '*' oracle.client_version
```

```
salt.modules.oracle.run_query(db, query)
```

Run SQL query and return result

CLI Example:

```
salt '*' oracle.run_query my_db "select * from my_table"
```
salt.modules.oracle.show_dbs(*dbs)
Show databases configuration from pillar. Filter by *args

CLI Example:

```
salt '*' oracle.show_dbs
salt '*' oracle.show_dbs my_db
```

salt.modules.oracle.show_env()
Show Environment used by Oracle Client

CLI Example:

```
salt '*' oracle.show_env
```

Note: at first _connect() NLS LANG will forced to `.AL32UTF8`

salt.modules.oracle.show_pillar(item=None)
Show Pillar segment oracle.* and subitem with notation `item:subitem`

CLI Example:

```
salt '*' oracle.show_pillar
salt '*' oracle.show_pillar dbs:my_db
```

salt.modules.oracle.version(*dbs)
Server Version (select banner from v$version)

CLI Example:

```
salt '*' oracle.version
salt '*' oracle.version my_db
```

32.17.184 salt.modules.osquery

New in version 2015.8.0.

salt.modules.osquery.acpi_tables(*attrs=None, where=None)
Return acpi_tables information from osquery

CLI Example:

```
salt '*' osquery.acpi_tables
```

salt.modules.osquery.alf(*attrs=None, where=None)
Return alf information from osquery

CLI Example:

```
salt '*' osquery.alf
```

salt.modules.osquery.alf_exceptions(*attrs=None, where=None)
Return alf_exceptions information from osquery

CLI Example:
salt '*' osquery.alf_exceptions

```
salt.modules.osquery.alf_explicit_auths
    (attrs=None, where=None)
    Return alf_explicit_auths information from osquery
    CLI Example:
    salt '*' osquery.alf_explicit_auths
```

salt.modules.osquery.alf_services
    (attrs=None, where=None)
    Return alf_services information from osquery
    CLI Example:
    salt '*' osquery.alf_services

salt.modules.osquery.apps
    (attrs=None, where=None)
    Return apps information from osquery
    CLI Example:
    salt '*' osquery.apps

salt.modules.osquery.apt_sources
    (attrs=None, where=None)
    Return apt_sources information from osquery
    CLI Example:
    salt '*' osquery.apt_sources

salt.modules.osquery.arp_cache
    (attrs=None, where=None)
    Return arp_cache information from osquery
    CLI Example:
    salt '*' osquery.arp_cache

salt.modules.osquery.block_devices
    (attrs=None, where=None)
    Return block_devices information from osquery
    CLI Example:
    salt '*' osquery.block_devices

salt.modules.osquery.certificates
    (attrs=None, where=None)
    Return certificates information from osquery
    CLI Example:
    salt '*' osquery.certificates

salt.modules.osquery.chrome_extensions
    (attrs=None, where=None)
    Return chrome_extensions information from osquery
    CLI Example:
    salt '*' osquery.chrome_extensions
salt.modules.osquery.cpuid(*args, **kwargs)
    Return cpuid information from osquery
    CLI Example:
    ```
salt '*' osquery.cpuid
    ```

salt.modules.osquery.crontab(*args, **kwargs)
    Return crontab information from osquery
    CLI Example:
    ```
salt '*' osquery.crontab
    ```

salt.modules.osquery.deb_packages(*args, **kwargs)
    Return deb_packages information from osquery
    CLI Example:
    ```
salt '*' osquery.deb_packages
    ```

salt.modules.osquery.etc_hosts(*args, **kwargs)
    Return etc_hosts information from osquery
    CLI Example:
    ```
salt '*' osquery.etc_hosts
    ```

salt.modules.osquery.etc_services(*args, **kwargs)
    Return etc_services information from osquery
    CLI Example:
    ```
salt '*' osquery.etc_services
    ```

salt.modules.osquery.file(*args, **kwargs)
    Return file information from osquery
    CLI Example:
    ```
salt '*' osquery.file
    ```

salt.modules.osquery.file_changes(*args, **kwargs)
    Return file_changes information from osquery
    CLI Example:
    ```
salt '*' osquery.file_changes
    ```

salt.modules.osquery.firefox_addons(*args, **kwargs)
    Return firefox_addons information from osquery
    CLI Example:
    ```
salt '*' osquery.firefox_addons
    ```

salt.modules.osquery.groups(*args, **kwargs)
    Return groups information from osquery
    CLI Example:
salt ' '*' osquery.groups

salt.modules.osquery.hardware_events(attrs=None, where=None)
Return hardware_events information from osquery

   CLI Example:
   salt ' '*' osquery.hardware_events

salt.modules.osquery.hash(attrs=None, where=None)
Return hash information from osquery

   CLI Example:
   salt ' '*' osquery.hash

salt.modules.osquery.homebrew_packages(attrs=None, where=None)
Return homebrew_packages information from osquery

   CLI Example:
   salt ' '*' osquery.homebrew_packages

salt.modules.osquery.interface_addresses(attrs=None, where=None)
Return interface_addresses information from osquery

   CLI Example:
   salt ' '*' osquery.interface_addresses

salt.modules.osquery.interface_details(attrs=None, where=None)
Return interface_details information from osquery

   CLI Example:
   salt ' '*' osquery.interface_details

salt.modules.osquery.iokit_devicetree(attrs=None, where=None)
Return iokit_devicetree information from osquery

   CLI Example:
   salt ' '*' osquery.iokit_devicetree

salt.modules.osquery.iokit_registry(attrs=None, where=None)
Return iokit_registry information from osquery

   CLI Example:
   salt ' '*' osquery.iokit_registry

salt.modules.osquery.kernel_extensions(attrs=None, where=None)
Return kernel_extensions information from osquery

   CLI Example:
   salt ' '*' osquery.kernel_extensions

32.17. Full list of builtin execution modules  1241
salt.modules.osquery.kernel_info

Return kernel_info information from osquery

CLI Example:
salt '*' osquery.kernel_info

salt.modules.osquery.kernel_integrity

Return kernel_integrity information from osquery

CLI Example:
salt '*' osquery.kernel_integrity

salt.modules.osquery.kernel_modules

Return kernel_modules information from osquery

CLI Example:
salt '*' osquery.kernel_modules

salt.modules.osquery.keychain_items

Return keychain_items information from osquery

CLI Example:
salt '*' osquery.keychain_items

salt.modules.osquery.last

Return last information from osquery

CLI Example:
salt '*' osquery.last

salt.modules.osquery.launchd

Return launchd information from osquery

CLI Example:
salt '*' osquery.launchd

salt.modules.osquery.listening_ports

Return listening_ports information from osquery

CLI Example:
salt '*' osquery.listening_ports

salt.modules.osquery.logged_in_users

Return logged_in_users information from osquery

CLI Example:
salt '*' osquery.logged_in_users

salt.modules.osquery.memory_map

Return memory_map information from osquery

CLI Example:
salt '*' osquery.memory_map

salt.modules.osquery.mounts(*\nattr=None, \nwhere=None*\n)\n
Return mounts information from osquery

CLI Example:

```
salt '*' osquery.mounts
```

salt.modules.osquery.nfs_shares(*\nattr=None, \nwhere=None*\n)\n
Return nfs_shares information from osquery

CLI Example:

```
salt '*' osquery.nfs_shares
```

salt.modules.osquery.nvram(*\nattr=None, \nwhere=None*\n)\n
Return nvram information from osquery

CLI Example:

```
salt '*' osquery.nvram
```

salt.modules.osquery.os_version(*\nattr=None, \nwhere=None*\n)\n
Return os_version information from osquery

CLI Example:

```
salt '*' osquery.os_version
```

salt.modules.osquery.osquery_extensions(*\nattr=None, \nwhere=None*\n)\n
Return osquery_extensions information from osquery

CLI Example:

```
salt '*' osquery.osquery_extensions
```

salt.modules.osquery.osquery_flags(*\nattr=None, \nwhere=None*\n)\n
Return osquery_flags information from osquery

CLI Example:

```
salt '*' osquery.osquery_flags
```

salt.modules.osquery.osquery_info(*\nattr=None, \nwhere=None*\n)\n
Return osquery_info information from osquery

CLI Example:

```
salt '*' osquery.osquery_info
```

salt.modules.osquery.osquery_registry(*\nattr=None, \nwhere=None*\n)\n
Return osquery_registry information from osquery

CLI Example:

```
salt '*' osquery.osquery_registry
```
salt.modules.osquery.passwd_changes\((\text{attrs=None, where=None})\)
Return passwd_changes information from osquery

CLI Example:
```
salt '*' osquery.passwd_changes
```

salt.modules.osquery.pci_devices\((\text{attrs=None, where=None})\)
Return pci_devices information from osquery

CLI Example:
```
salt '*' osquery.pci_devices
```

salt.modules.osquery.preferences\((\text{attrs=None, where=None})\)
Return preferences information from osquery

CLI Example:
```
salt '*' osquery.preferences
```

salt.modules.osquery.process_envs\((\text{attrs=None, where=None})\)
Return process_envs information from osquery

CLI Example:
```
salt '*' osquery.process_envs
```

salt.modules.osquery.process_memory_map\((\text{attrs=None, where=None})\)
Return process_memory_map information from osquery

CLI Example:
```
salt '*' osquery.process_memory_map
```

salt.modules.osquery.process_open_files\((\text{attrs=None, where=None})\)
Return process_open_files information from osquery

CLI Example:
```
salt '*' osquery.process_open_files
```

salt.modules.osquery.process_open_sockets\((\text{attrs=None, where=None})\)
Return process_open_sockets information from osquery

CLI Example:
```
salt '*' osquery.process_open_sockets
```

salt.modules.osquery.processes\((\text{attrs=None, where=None})\)
Return processes information from osquery

CLI Example:
```
salt '*' osquery.processes
```

salt.modules.osquery.quarantine\((\text{attrs=None, where=None})\)
Return quarantine information from osquery

CLI Example:
Salt Documentation, Release 2015.8.12

```python
salt '*' osquery.quarantine
```

**salt.modules.osquery.query**(sql=None)
Return time information from osquery

CLI Example:

```python
salt '*' osquery.query "select * from users;"
```

**salt.modules.osquery.routes**(attrs=None, where=None)
Return routes information from osquery

CLI Example:

```python
salt '*' osquery.routes
```

**salt.modules.osquery.rpm_packages**(attrs=None, where=None)
Return cpuid information from osquery

CLI Example:

```python
salt '*' osquery.rpm_packages
```

**salt.modules.osquery.safari_extensions**(attrs=None, where=None)
Return safari_extensions information from osquery

CLI Example:

```python
salt '*' osquery.safari_extensions
```

**salt.modules.osquery.shared_memory**(attrs=None, where=None)
Return shared_memory information from osquery

CLI Example:

```python
salt '*' osquery.shared_memory
```

**salt.modules.osquery.shell_history**(attrs=None, where=None)
Return shell_history information from osquery

CLI Example:

```python
salt '*' osquery.shell_history
```

**salt.modules.osquery.smbios_tables**(attrs=None, where=None)
Return smbios_tables information from osquery

CLI Example:

```python
salt '*' osquery.smbios_tables
```

**salt.modules.osquery.startup_items**(attrs=None, where=None)
Return startup_items information from osquery

CLI Example:

```python
salt '*' osquery.startup_items
```
salt.modules.osquery.suid_bin(attrs=None, where=None)
Return suid_bin information from osquery

CLI Example:
```
salt '*' osquery.suid_bin
```

salt.modules.osquery.system_controls(attrs=None, where=None)
Return system_controls information from osquery

CLI Example:
```
salt '*' osquery.system_controls
```

salt.modules.osquery.time(attrs=None)
Return time information from osquery

CLI Example:
```
salt '*' osquery.time
```

salt.modules.osquery.usb_devices(attrs=None, where=None)
Return usb_devices information from osquery

CLI Example:
```
salt '*' osquery.usb_devices
```

salt.modules.osquery.users(attrs=None, where=None)
Return users information from osquery

CLI Example:
```
salt '*' osquery.users
```

salt.modules.osquery.version()
Return version of osquery

CLI Example:
```
salt '*' osquery.version
```

salt.modules.osquery.xattr_where_from(attrs=None, where=None)
Return xattr_where_from information from osquery

CLI Example:
```
salt '*' osquery.xattr_where_from
```

salt.modules.osquery.xprotect_entries(attrs=None, where=None)
Return xprotect_entries information from osquery

CLI Example:
```
salt '*' osquery.xprotect_entries
```

salt.modules.osquery.xprotect_reports(attrs=None, where=None)
Return xprotect_reports information from osquery

CLI Example:
32.17.185 salt.modules.osxdesktop

Mac OS X implementations of various commands in the `desktop` interface

```python
salt.modules.osxdesktop.get_output_volume()
```
Get the output volume (range 0 to 100)

CLI Example:

```
salt '*' desktop.get_output_volume
```

```python
salt.modules.osxdesktop.lock()
```
Lock the desktop session

CLI Example:

```
salt '*' desktop.lock
```

```python
salt.modules.osxdesktop.say('words')
```
Say some words.

CLI Example:

```
salt '*' desktop.say <word0> <word1> ... <wordN>
```

```python
salt.modules.osxdesktop.screensaver()
```
Launch the screensaver

CLI Example:

```
salt '*' desktop.screensaver
```

```python
salt.modules.osxdesktop.set_output_volume(volume)
```
Set the volume of sound (range 0 to 100)

CLI Example:

```
salt '*' desktop.set_output_volume <volume>
```

32.17.186 salt.modules.pacman

A module to wrap pacman calls, since Arch is the best (https://wiki.archlinux.org/index.php/Arch_is_the_best)

**Important:** If you feel that Salt should be using this module to manage packages on a minion, and it is using a different module (or gives an error similar to `pkg.install' is not available), see here.

```python
salt.modules.pacman.file_dict(*packages)
```
List the files that belong to a package, grouped by package. Not specifying any packages will return a list of _every_ file on the system's package database (not generally recommended).

CLI Examples:
salt.modules.pacman.file_list("packages")
List the files that belong to a package. Not specifying any packages will return a list of _every_ file on the system's package database (not generally recommended).

CLI Examples:

```
salt '*' pkg.file_list httpd
salt '*' pkg.file_list httpd postfix
salt '*' pkg.file_list
```

salt.modules.pacman.install(name=None, refresh=False, sysupgrade=False, pkgs=None, sources=None, **kwargs)
Changed in version 2015.8.12, 2016.3.3, Carbon: On minions running systemd>=205, `systemd-run(1)` is now used to isolate commands which modify installed packages from the salt-minion daemon's control group. This is done to keep systemd from killing any pacman commands spawned by Salt when the salt-minion service is restarted. (see KillMode in the `systemd.kill(5)` manpage for more information). If desired, usage of `systemd-run(1)` can be suppressed by setting a config option called `systemd.scope`, with a value of False (no quotes).

Install (`pacman -S`) the specified package(s). Add `refresh=True` to install with `-y`, add `sysupgrade=True` to install with `-u`.

**name** The name of the package to be installed. Note that this parameter is ignored if either `pkgs` or `sources` is passed. Additionally, please note that this option can only be used to install packages from a software repository. To install a package file manually, use the `sources` option.

CLI Example:

```
salt '*' pkg.install <package name>
```

**refresh** Whether or not to refresh the package database before installing.

**sysupgrade** Whether or not to upgrade the system packages before installing.

Multiple Package Installation Options:

**pkgs** A list of packages to install from a software repository. Must be passed as a python list. A specific version number can be specified by using a single-element dict representing the package and its version. As with the `version` parameter above, comparison operators can be used to target a specific version of a package.

CLI Examples:

```
salt '*' pkg.install pkgs='["foo", "bar"]'
salt '*' pkg.install pkgs='["foo", {"bar": "1.2.3-4"}]
salt '*' pkg.install pkgs='["foo", {"bar": "<1.2.3-4"}]
```

**sources** A list of packages to install. Must be passed as a list of dicts, with the keys being package names, and the values being the source URI or local path to the package.

CLI Example:

```
salt '*' pkg.install sources='[{"foo": "salt://foo.pkg.tar.xz"},
{"bar": "salt://bar.pkg.tar.xz"}]
```
Returns a dict containing the new package names and versions:

```python
{'<package>': {'old': '<old-version>',
              'new': '<new-version>'}}
```

**salt.modules.pacman.latest_version(names, **kwargs)**

Return the latest version of the named package available for upgrade or installation. If more than one package name is specified, a dict of name/version pairs is returned.

If the latest version of a given package is already installed, an empty string will be returned for that package.

CLI Example:

```bash
salt '*' pkg.latest_version <package name>
salt '*' pkg.latest_version <package1> <package2> <package3> ...
```

**salt.modules.pacman.list_pkgs(versions_as_list=False, **kwargs)**

List the packages currently installed as a dict:

```python
{'<package_name>': '<version>'}
```

CLI Example:

```bash
salt '*' pkg.list_pkgs
```

**salt.modules.pacman.list_upgrades(refresh=False, **kwargs)**

List all available package upgrades on this system

CLI Example:

```bash
salt '*' pkg.list_upgrades
```

**salt.modules.pacman.owner(paths)**

New in version 2014.7.0.

Return the name of the package that owns the file. Multiple file paths can be passed. Like `pkg.version` `<salt.modules.yumpkg.version`, if a single path is passed, a string will be returned, and if multiple paths are passed, a dictionary of file/package name pairs will be returned.

If the file is not owned by a package, or is not present on the minion, then an empty string will be returned for that path.

CLI Example:

```bash
salt '*' pkg.owner /usr/bin/apachectl salt '*' pkg.owner /usr/bin/apachectl /usr/bin/zsh
```

**salt.modules.pacman.purge(name=None, pkgs=None, **kwargs)**

Changed in version 2015.8.12,2016.3.3,Carbon: On minions running systemd>=205, `systemd-run(1)` is now used to isolate commands which modify installed packages from the `salt-minion` daemon's control group. This is done to keep systemd from killing any pacman commands spawned by Salt when the salt-minion service is restarted. (see `KillMode` in the `systemd.kill(5)` manpage for more information). If desired, usage of `systemd-run(1)` can be suppressed by setting a config option called `systemd.scope`, with a value of `False` (no quotes).

Recursively remove a package and all dependencies which were installed with it, this will call a `pacman -Rsc` name The name of the package to be deleted.

Multiple Package Options:

pkgs A list of packages to delete. Must be passed as a python list. The name parameter will be ignored if this option is passed.
Salt Documentation, Release 2015.8.12

New in version 0.16.0.

Returns a dict containing the changes.

CLI Example:

```
salt '*' pkg.purge <package name>
salt '*' pkg.purge <package1>,<package2>,<package3>
salt '*' pkg.purge pkgs='["foo", "bar"]'
```

```
salt '*' pkg.purge <package name>
salt '*' pkg.purge <package1>,<package2>,<package3>
salt '*' pkg.purge pkgs='["foo", "bar"]'
```

salt.modules.pacman.refresh_db()
Just run a pacman -Sy, return a dict:

```
{'<database name>': Bool}
```

CLI Example:

```
salt '*' pkg.refresh_db
```

salt.modules.pacman.remove(name=None, pkgs=None, **kwargs)
Changed in version 2015.8.12,2016.3.3,Carbon: On minions running systemd>=205, systemd-run(1) is now used to isolate commands which modify installed packages from the salt-minion daemon's control group. This is done to keep systemd from killing any pacman commands spawned by Salt when the salt-minion service is restarted. (see KillMode in the systemd.kill(5) manpage for more information). If desired, usage of systemd-run(1) can be suppressed by setting a config option called systemd.scope, with a value of False (no quotes).

Remove packages with pacman -R.

name The name of the package to be deleted.

Multiple Package Options:

pkgs A list of packages to delete. Must be passed as a python list. The name parameter will be ignored if this option is passed.

New in version 0.16.0.

Returns a dict containing the changes.

CLI Example:

```
salt '*' pkg.remove <package name>
salt '*' pkg.remove <package1>,<package2>,<package3>
salt '*' pkg.remove pkgs='["foo", "bar"]'
```

salt.modules.pacman.upgrade(refresh=False, **kwargs)
Changed in version 2015.8.12,2016.3.3,Carbon: On minions running systemd>=205, systemd-run(1) is now used to isolate commands which modify installed packages from the salt-minion daemon's control group. This is done to keep systemd from killing any pacman commands spawned by Salt when the salt-minion service is restarted. (see KillMode in the systemd.kill(5) manpage for more information). If desired, usage of systemd-run(1) can be suppressed by setting a config option called systemd.scope, with a value of False (no quotes).

Run a full system upgrade, a pacman -Syu.

refresh Whether or not to refresh the package database before installing.

Return a dict containing the new package names and versions:

```
{'<package>': {'old': '<old-version>',
              'new': '<new-version>'}}
```
salt.modules.pacman.upgrade_available(name)
Check whether or not an upgrade is available for a given package
CLI Example:
salt '*' pkg.upgrade_available <package name>

salt.modules.pacman.version(*names, **kwargs)
Returns a string representing the package version or an empty string if not installed. If more than one package name is specified, a dict of name/version pairs is returned.
CLI Example:
salt '*' pkg.version <package name>
salt '*' pkg.version <package1> <package2> <package3> ...

32.17.187 salt.modules.pagerduty
Module for Firing Events via PagerDuty
New in version 2014.1.0.

configuration This module can be used by specifying the name of a configuration profile in the minion config, minion pillar, or master config.
For example:

my-pagerduty-account:
    pagerduty.api_key: F3Rbyjbve43rfWf2214
    pagerduty.subdomain: mysubdomain

salt.modules.pagerduty.create_event(service_key=None, description=None, details=None, incident_key=None, profile=None)
Create an event in PagerDuty. Designed for use in states.
CLI Example:
salt myminion pagerduty.create_event <service_key> <description> <details> --profile=my-pagerduty-account

The following parameters are required:

  service_key  This key can be found by using pagerduty.list_services.
  description  This is a short description of the event.
  details      This can be a more detailed description of the event.
  profile      This refers to the configuration profile to use to connect to the PagerDuty service.

salt.modules.pagerduty.list_escalation_policies(profile=None, api_key=None)
This function is an alias of list_policies.
List escalation policies belonging to this account
CLI Example:
```
salt myminion pagerduty.list_policies my-pagerduty-account
salt.myminion pagerduty.list_escalation_policies my-pagerduty-account

salt.modules.pagerduty.list_incidents(profile=None, api_key=None)
List incidents belonging to this account

CLI Example:
    salt myminion pagerduty.list_incidents my-pagerduty-account

salt.modules.pagerduty.list_maintenance_windows(profile=None, api_key=None)
This function is an alias of list_windows.
List maintenance windows belonging to this account

CLI Example:
    salt myminion pagerduty.list_windows my-pagerduty-account
salt.modules.pagerduty.list_maintenance_windows my-pagerduty-account

salt.modules.pagerduty.list_policies(profile=None, api_key=None)
List escalation policies belonging to this account

CLI Example:
    salt myminion pagerduty.list_policies my-pagerduty-account
salt.myminion pagerduty.list_escalation_policies my-pagerduty-account

salt.modules.pagerduty.list_schedules(profile=None, api_key=None)
List schedules belonging to this account

CLI Example:
    salt myminion pagerduty.list_schedules my-pagerduty-account

salt.modules.pagerduty.list_services(profile=None, api_key=None)
List services belonging to this account

CLI Example:
    salt myminion pagerduty.list_services my-pagerduty-account

salt.modules.pagerduty.list_users(profile=None, api_key=None)
List users belonging to this account

CLI Example:
    salt myminion pagerduty.list_users my-pagerduty-account

salt.modules.pagerduty.list_windows(profile=None, api_key=None)
List maintenance windows belonging to this account

CLI Example:
    salt myminion pagerduty.list_windows my-pagerduty-account
salt.myminion pagerduty.list_maintenance_windows my-pagerduty-account

```

### 32.17.188 salt.modules.pagerduty_util

Module for managing PagerDuty resource

- `configuration` This module can be used by specifying the name of a configuration profile in the minion config, minion pillar, or master config. The default configuration profile name is `pagerduty`.

For example:
For PagerDuty API details, see https://developer.pagerduty.com/documentation/rest

```
salt.modules.pagerduty_util.create_or_update_resource(resource_name, identifier_fields, data, diff=None, profile='pagerduty', subdomain=None, api_key=None)
```

create or update any pagerduty resource Helper method for present().

Determining if two resources are the same is different for different PD resource, so this method accepts a
diff function. The diff function will be invoked as diff(state_information, object_returned_from_pagerduty),
and should return a dict of data to pass to the PagerDuty update API method, or None if no update is to be
performed. If no diff method is provided, the default behavior is to scan the keys in the state_information,
comparing the matching values in the object_returned_from_pagerduty, and update any values that differ.

```
examples: create_or_update_resource(``user'',``id'',''name'',''email'')
```

```
salt.modules.pagerduty_util.delete_resource(resource_name, key, identifier_fields, profile='pagerduty', subdomain=None, api_key=None)
```

delete any pagerduty resource

Helper method for absent()

```
exmple: delete_resource(``users'', key, ``id'',''name'',''email'') # delete by id or name or email
```

```
salt.modules.pagerduty_util.get_escalation_policies(profile='pagerduty', subdomain=None, api_key=None)
```

List escalation_policies belonging to this account

CLI Example:

```
salt myminion pagerduty.get_escalation_policies
```

```
salt.modules.pagerduty_util.get_resource(resource_name, key, identifier_fields, profile='pagerduty', subdomain=None, api_key=None)
```

Get any single pagerduty resource by key.

We allow flexible lookup by any of a list of identifier_fields. So, for example, you can look up users by email
address or name by calling:

```
get_resource(``users'', key, [``name'',''email''], ...)
```

This method is mainly used to translate state sls into pagerduty id's for dependent objects. For example, a
pagerduty escalation policy contains one or more schedules, which must be passed by their pagerduty id. We
look up the schedules by name (using this method), and then translate the names into id's.

This method is implemented by getting all objects of the resource type (cached into __context__), then brute
force searching through the list and trying to match any of the identifier_fields. The __context__ cache is
purged after any create, update or delete to the resource.

```
salt.modules.pagerduty_util.get_schedules(profile='pagerduty', subdomain=None, api_key=None)
```

List schedules belonging to this account

CLI Example:

```
salt myminion pagerduty.get_schedules
```

---

**32.17. Full list of builtin execution modules** 1253
salt.modules.pagerduty_util.get_services(profile='pagerduty', api_key=None)

List services belonging to this account

CLI Example:

salt myminion pagerduty.get_services

salt.modules.pagerduty_util.get_users(profile='pagerduty', subdomain=None, api_key=None)

List users belonging to this account

CLI Example:

salt myminion pagerduty.get_users

salt.modules.pagerduty_util.resource_absent(resource, identifier_fields, profile='pagerduty', subdomain=None, api_key=None, **kwargs)

Generic resource.absent state method. Pagerduty state modules should be a thin wrapper over this method, with a custom diff function.

This method calls delete_resource() and formats the result as a salt state return value.

example: resource_absent(``users'', [``id'',``name'',``email''])

salt.modules.pagerduty_util.resource_present(resource, identifier_fields, diff=None, profile='pagerduty', subdomain=None, api_key=None, **kwargs)

Generic resource.present state method. Pagerduty state modules should be a thin wrapper over this method, with a custom diff function.

This method calls create_or_update_resource() and formats the result as a salt state return value.

example: resource_present(``users'', [``id'',``name'',``email''])

32.17.189 salt.modules.pam

Support for pam

salt.modules.pam.read_file(file_name)

This is just a test function, to make sure parsing works

CLI Example:

code:
salt '*' pam.read_file /etc/pam.d/login

32.17.190 salt.modules.parted

Module for managing partitions on POSIX-like systems.

depends

- parted, partprobe, lsblk (usually parted and util-linux packages)

Some functions may not be available, depending on your version of parted.

Check the manpage for parted(8) for more information, or the online docs at:

In light of parted not directly supporting partition IDs, some of this module has been written to utilize sfdisk instead.

For further information, please reference the man page for sfdisk(8).
**salt.modules.parted.align_check** *(device, part_type, partition)*  
Check if partition satisfies the alignment constraint of part_type. Type must be `"minimal"` or `"optimal"`.  

CLI Example:
```
salt '*' partition.align_check /dev/sda minimal 1
```

**salt.modules.parted.check** *(device, minor)*  
Checks if the file system on partition <minor> has any errors.  

CLI Example:
```
salt '*' partition.check 1
```

**salt.modules.parted.cp** *(device, from_minor, to_minor)*  
Copies the file system on the partition <from-minor> to partition <to-minor>, deleting the original contents of the destination partition.  

CLI Example:
```
salt '*' partition.cp /dev/sda 2 3
```

**salt.modules.parted.exists** *(device="")*  
Check to see if the partition exists  

CLI Example:
```
salt '*' partition.exists /dev/sdb1
```

**salt.modules.parted.get_block_device** ()  
Retrieve a list of disk devices  
New in version 2014.7.0.  

CLI Example:
```
salt '*' partition.get_block_device
```

**salt.modules.parted.get_id** *(device, minor)*  
Prints the system ID for the partition. Some typical values are:

- `b`: FAT32 (vfat)
- `7`: HPFS/NTFS
- `82`: Linux Swap
- `83`: Linux
- `8e`: Linux LVM
- `fd`: Linux RAID Auto

CLI Example:
```
salt '*' partition.get_id /dev/sda 1
```

**salt.modules.parted.list** *(device, unit=None)*  
Prints partition information of given <device>  

CLI Examples:
```
salt '*' partition.list /dev/sda
salt '*' partition.list /dev/sda unit=s
salt '*' partition.list /dev/sda unit=kB
```
salt.modules.parted.mkfs(*device, fs_type*)

Makes a file system `<fs_type>` on partition `<device>`, destroying all data that resides on that partition. `<fs_type>` must be one of `"ext2", "fat32", "fat16", "linux-swap"` or `"reiserfs"` (if libreiserfs is installed)

CLI Example:

```
salt '*' partition.mkfs /dev/sda2 fat32
```

salt.modules.parted.mklabel(*device, label_type*)

Create a new disklabel (partition table) of label_type.

Type should be one of `"aix", "amiga", "bsd", "dvh", "gpt", "loop", "mac", "msdos", "pc98", or "sun"`.

CLI Example:

```
salt '*' partition.mklabel /dev/sda msdos
```

salt.modules.parted.mkpart(*device, part_type, fs_type=None, start=None, end=None*)

Make a `<part_type>` partition for filesystem `<fs_type>`, beginning at `<start>` and ending at `<end>` (by default in megabytes). `<part_type>` should be one of `"primary", "logical", or "extended"`.

CLI Examples:

```
salt '*' partition.mkpart /dev/sda primary fs_type=fat32 start=0 end=639
salt '*' partition.mkpart /dev/sda primary start=0 end=639
```

salt.modules.parted.mkpartfs(*device, part_type, fs_type, start, end*)

Make a `<part_type>` partition with a new filesystem of `<fs_type>`, beginning at `<start>` and ending at `<end>` (by default in megabytes).

 `<part_type>` should be one of `"primary", "logical", or "extended"`. `<fs_type>` must be one of `"ext2", "fat32", "fat16", "linux-swap"` or `"reiserfs"` (if libreiserfs is installed)

CLI Example:

```
salt '*' partition.mkpartfs /dev/sda logical ext2 440 670
```

salt.modules.parted.name(*device, partition, name*)

Set the name of partition to name. This option works only on Mac, PC98, and GPT disklabels. The name can be placed in quotes, if necessary.

CLI Example:

```
salt '*' partition.name /dev/sda 1 'My Documents'
```

salt.modules.parted.probe(*devices*)

Ask the kernel to update its local partition data. When no args are specified all block devices are tried.

Caution: Generally only works on devices with no mounted partitions and may take a long time to return if specified devices are in use.

CLI Examples:

```
salt '*' partition.probe
salt '*' partition.probe /dev/sda
salt '*' partition.probe /dev/sda /dev/sdb
```

salt.modules.parted.rescue(*device, start, end*)

Rescue a lost partition that was located somewhere between `<start>` and `<end>`. If a partition is found, parted will ask if you want to create an entry for it in the partition table.
CLI Example:

```
salt '*' partition.rescue /dev/sda 0 8056
```

**salt.modules.parted.resize**(*device, minor, start, end*)

Resizes the partition with number `<minor>`.

The partition will start `<start>` from the beginning of the disk, and end `<end>` from the beginning of the disk. resize never changes the minor number. Extended partitions can be resized, so long as the new extended partition completely contains all logical partitions.

CLI Example:

```
salt '*' partition.resize /dev/sda 3 200 850
```

**salt.modules.parted.rm**(*device, minor*)

Removes the partition with number `<minor>`.

CLI Example:

```
salt '*' partition.rm /dev/sda 5
```

**salt.modules.parted.set**(*device, minor, flag, state*)

Changes a flag on the partition with number `<minor>`.

A flag can be either `'on'` or `'off'`. Some or all of these flags will be available, depending on what disk label you are using.

CLI Example:

```
salt '*' partition.set /dev/sda 1 boot on
```

**salt.modules.parted.set_id**(*device, minor, system_id*)

Sets the system ID for the partition. Some typical values are:

```
b: FAT32 (vfat)
7: HPFS/NTFS
82: Linux Swap
83: Linux
8e: Linux LVM
fd: Linux RAID Auto
```

CLI Example:

```
salt '*' partition.set_id /dev/sda 1 83
```

**salt.modules.parted.system_types()**

List the system types that are supported by the installed version of sfdisk

CLI Example:

```
salt '*' partition.system_types
```

**salt.modules.parted.toggle**(*device, partition, flag*)

Toggle the state of `<flag>` on `<partition>`

CLI Example:

```
salt '*' partition.name /dev/sda 1 boot
```
32.17.191  salt.modules.pecl

Manage PHP pecl extensions.

salt.modules.pecl.install(pecls, defaults=False, force=False, preferred_state='stable')

New in version 0.17.0.

Installs one or several pecl extensions.

pecls The pecl extensions to install.

defaults Use default answers for extensions such as pecl_http which ask questions before installation. Without this option, the pecl.installed state will hang indefinitely when trying to install these extensions.

force Whether to force the installed version or not

CLI Example:

salt '*' pecl.install fuse

salt.modules.pecl.list(channel=None)

List installed pecl extensions.

CLI Example:

salt '*' pecl.list

salt.modules.pecl.uninstall(pecls)

Uninstall one or several pecl extensions.

pecls The pecl extensions to uninstall.

CLI Example:

salt '*' pecl.uninstall fuse

salt.modules.pecl.update(pecls)

Update one or several pecl extensions.

pecls The pecl extensions to update.

CLI Example:

salt '*' pecl.update fuse

32.17.192  salt.modules.pillar

Extract the pillar data for this minion

salt.modules.pillar.ext(external, pillar=None)

Generate the pillar and apply an explicit external pillar

CLI Example:

pillar [None] If specified, allows for a dictionary of pillar data to be made available to pillar and ext_pillar rendering. These pillar variables will also override any variables of the same name in pillar or ext_pillar.

New in version 2015.5.0.

salt '*' pillar.ext '{libvirt: _}'
salt.modules.pillar.get(key, default=<type 'exceptions.KeyError'>, merge=False, delimiter=': ')

New in version 0.14.

Attempt to retrieve the named value from pillar, if the named value is not available return the passed default. The default return is an empty string except __opts__['pillar_raise_on_missing'] is set to True, in which case a KeyError will be raised.

If the merge parameter is set to True, the default will be recursively merged into the returned pillar data.

The value can also represent a value in a nested dict using a ":" delimiter for the dict. This means that if a dict in pillar looks like this:

```plaintext
{'pkg': {'apache': 'httpd'}}
```

To retrieve the value associated with the apache key in the pkg dict this key can be passed:

```
pkg:apache
```

**merge** Specify whether or not the retrieved values should be recursively merged into the passed default.

New in version 2014.7.0.

**delimiter** Specify an alternate delimiter to use when traversing a nested dict

New in version 2014.7.0.

CLI Example:

```
salt '*' pillar.get pkg:apache
```

salt.modules.pillar.item(*args, **kwargs)

New in version 0.16.2.

Return one or more pillar entries

**pillar** [none] if specified, allows for a dictionary of pillar data to be made available to pillar and ext_pillar rendering. these pillar variables will also override any variables of the same name in pillar or ext_pillar.

New in version 2015.5.0.

CLI Examples:

```
salt '*' pillar.item foo
salt '*' pillar.item foo bar baz
```

salt.modules.pillar.items(*args, **kwargs)

Calls the master for a fresh pillar and generates the pillar data on the fly

Contrast with raw() which returns the pillar data that is currently loaded into the minion.

**pillar** [none] if specified, allows for a dictionary of pillar data to be made available to pillar and ext_pillar rendering. these pillar variables will also override any variables of the same name in pillar or ext_pillar.

New in version 2015.5.0.

CLI Example:

```
salt '*' pillar.items
```

salt.modules.pillar.keys(key, delimiter=': ')

New in version 2015.8.0.
Attempt to retrieve a list of keys from the named value from the pillar.

The value can also represent a value in a nested dict using a ":" delimiter for the dict, similar to how pillar.get works.

**delimiter** Specify an alternate delimiter to use when traversing a nested dict

CLI Example:

```
salt '*' pillar.keys web:sites
```

**salt.modules.pillar.ls(**args**)**

New in version 2015.8.0.

Calls the master for a fresh pillar, generates the pillar data on the fly (same as `items()`), but only shows the available main keys.

CLI Examples:

```
salt '*' pillar.ls
```

**salt.modules.pillar.obfuscate(**args**)**

New in version 2015.8.0.

Same as `items()`, but replace pillar values with a simple type indication.

This is useful to avoid displaying sensitive information on console or flooding the console with long output, such as certificates. For many debug or control purposes, the stakes lie more in dispatching than in actual values.

In case the value is itself a collection type, obfuscation occurs within the value. For mapping types, keys are not obfuscated. Here are some examples:

- `secret password` becomes `<str>`
- `['secret',1]` becomes `['<str>', '<int>']`
- `{'login': 'somelogin','pwd': 'secret'}` becomes `{'login': '<str>','pwd': '<str>'}

CLI Examples:

```
salt '*' pillar.obfuscate
```

**salt.modules.pillar.raw** *(key=None)*

Return the raw pillar data that is currently loaded into the minion.

Contrast with `items()` which calls the master to fetch the most up-to-date Pillar.

CLI Example:

```
salt '*' pillar.raw
```

With the optional key argument, you can select a subtree of the pillar raw data:

```
salt '*' pillar.raw key='roles'
```

### 32.17.193 salt.modules.pip

Install Python packages with pip to either the system or a virtualenv
Windows Support

New in version 2014.7.4.

Salt now uses a portable python. As a result the entire pip module is now functional on the salt installation itself. You can pip install dependencies for your custom modules. You can even upgrade salt itself using pip. For this to work properly, you must specify the Current Working Directory (cwd) and the Pip Binary (bin_env) salt should use. The variable `pip_bin` can be either a virtualenv path or the path to the pip binary itself.

For example, the following command will list all software installed using pip to your current salt environment:

```
salt <minion> pip.list cwd='C:\salt\bin\Scripts' bin_env='C:\salt\bin\Scripts\pip.exe'
```

Specifying the `cwd` and `bin_env` options ensures you're modifying the salt environment. If these are omitted, it will default to the local installation of python. If python is not installed locally it will fail saying it couldn't find pip.

State File Support

This functionality works in states as well. If you need to pip install colorama with a state, for example, the following will work:

```
install_colorama:
  pip.installed:
    - name: colorama
    - cwd: 'C:\salt\bin\Scripts'
    - bin_env: 'C:\salt\bin\Scripts\pip.exe'
    - upgrade: True
```

Upgrading Salt using Pip

You can now update salt using pip to any version from the 2014.7 branch forward. Previous version require recompiling some of the dependencies which is painful in windows.

To do this you just use pip with git to update to the version you want and then restart the service. Here is a sample state file that upgrades salt to the head of the 2015.5 branch:

```
install_salt:
  pip.installed:
    - cwd: 'C:\salt\bin\Scripts'
    - bin_env: 'C:\salt\bin\Scripts\pip.exe'
    - editable: git+https://github.com/saltstack/salt@2015.5#egg=salt
    - upgrade: True

restart_service:
  service.running:
    - name: salt-minion
    - enable: True
    - watch:
      - pip: install_salt
```

Note: If you're having problems, you might try doubling the back slashes. For example, cwd: `C:\salt\bin\scripts`. Sometimes python thinks the single back slash is an escape character.
salt.modules.pip.freeze(bin_env=None, user=None, cwd=None, use_vt=False)

Return a list of installed packages either globally or in the specified virtualenv

bin_env path to pip bin or path to virtualenv. If doing an uninstall from the system python and want to use a specific pip bin (pip-2.7, pip-2.6, etc..) just specify the pip bin you want. If uninstalling from a virtualenv, just use the path to the virtualenv (/home/code/path/to/virtualenv/)

user The user under which to run pip

cwd Current working directory to run pip from

CLI Example:

```
salt '*' pip.freeze /home/code/path/to/virtualenv/
```

salt.modules.pip.install(pkgs=None, requirements=None, env=None, bin_env=None, use_wheel=False, no_use_wheel=False, log=None, proxy=None, timeout=None, editable=None, find_links=None, index_url=None, extra_index_url=None, no_index=False, mirrors=None, build=None, target=None, download=None, download_cache=None, source=None, upgrade=False, force_reinstall=False, ignore_installed=False, exists_action=None, no_deps=False, no_install=False, no_download=False, process_dependency_links=False, __env__=None, saltenv='base', env_vars=None, use_vt=False, trusted_host=None)

Install packages with pip

Install packages individually or from a pip requirements file. Install packages globally or to a virtualenv.

pkgs Comma separated list of packages to install

requirements Path to requirements

bin_env Path to pip bin or path to virtualenv. If doing a system install, and want to use a specific pip bin (pip-2.7, pip-2.6, etc..) just specify the pip bin you want.

Note: If installing into a virtualenv, just use the path to the virtualenv (e.g. /home/code/path/to/virtualenv/)

env Deprecated, use bin_env now

use_wheel Prefer wheel archives (requires pip>=1.4)

no_use_wheel Force to not use wheel archives (requires pip>=1.4)

log Log file where a complete (maximum verbosity) record will be kept

proxy Specify a proxy in the form user:passwd@proxy.server:port. Note that the user:password@ is optional and required only if you are behind an authenticated proxy. If you provide user@proxy.server:port then you will be prompted for a password.

timeout Set the socket timeout (default 15 seconds)

editable install something editable (e.g. git+https://github.com/worldcompany/djangoembed.git#egg=djangoembed)

find_links URL to search for packages

index_url Base URL of Python Package Index

eextra_index_url Extra URLs of package indexes to use in addition to index_url
no_index  Ignore package index
mirrors   Specific mirror URL(s) to query (automatically adds --use-mirrors)
build    Unpack packages into build dir
target   Install packages into target dir
download Download packages into download instead of installing them
download_cache Cache downloaded packages in download_cache dir
source   Check out editable packages into source dir
upgrade  Upgrade all packages to the newest available version
force_reinstall When upgrading, reinstall all packages even if they are already up-to-date.
ignore_installed Ignore the installed packages (reinstalling instead)
exists_action Default action when a path already exists: (s)witch, (i)gnore, (w)ipe, (b)ackup
no_deps  Ignore package dependencies
no_install Download and unpack all packages, but don't actually install them
no_download Don't download any packages, just install the ones already downloaded (completes an install run with --no-install)
install_options Extra arguments to be supplied to the setup.py install command (e.g. like --install-option='--install-scripts=/usr/local/bin'). Use multiple --install-option options to pass multiple options to setup.py install. If you are using an option with a directory path, be sure to use absolute path.
global_options Extra global options to be supplied to the setup.py call before the install command.
user The user under which to run pip
no_chown When user is given, do not attempt to copy and chown a requirements file
cwd Current working directory to run pip from
activate Activates the virtual environment, if given via bin_env, before running install.
Conflicting with version 2014.7.2: If bin_env is given, pip will already be sourced from that virtualenv, making activate effectively a noop.
pre_releases Include pre-releases in the available versions
cert Provide a path to an alternate CA bundle
allow_all_external Allow the installation of all externally hosted files
allow_external Allow the installation of externally hosted files (comma separated list)
allow_unverified Allow the installation of insecure and unverifiable files (comma separated list)
process_dependency_links Enable the processing of dependency links
env_vars Set environment variables that some builds will depend on. For example, a Python C-module may have a Makefile that needs INCLUDE_PATH set to pick up a header file while compiling. This must be in the form of a dictionary or a mapping.

Example:

```
salt '*' pip.install django_app env_vars="{'CUSTOM_PATH': '/opt/django_app'}"
```

trusted_host Mark this host as trusted, even though it does not have valid or any HTTPS.
use_vt  Use VT terminal emulation (see output while installing)

CLI Example:

salt '*' pip.install <package name>,<package2 name>
salt '*' pip.install requirements=/path/to/requirements.txt
salt '*' pip.install <package name> bin_env=/path/to/virtualenv
salt '*' pip.install <package name> bin_env=/path/to/pip_bin

Complicated CLI example:

salt '*' pip.install markdown,django editable=git+https://github.com/worldcompany/djangoembed.git#egg=djangoembed upgrade=True no_deps=True

salt.modules.pip.list(prefix=None, bin_env=None, user=None, cwd=None)
Filter list of installed apps from freeze and check to see if prefix exists in the list of packages installed.

CLI Example:

salt '*' pip.list salt

salt.modules.pip.list_upgrades(bin_env=None, user=None, cwd=None)
Check whether or not an upgrade is available for all packages

CLI Example:

salt '*' pip.list_upgrades

salt.modules.pip.uninstall(pkgs=None, requirements=None, bin_env=None, log=None, proxy=None, timeout=None, user=None, no_chown=False, cwd=None, __env__=None, saltenv='base', use_vt=False)
Uninstall packages with pip
Uninstall packages individually or from a pip requirements file. Uninstall packages globally or from a virtualenv.

pkgs  comma separated list of packages to install
requirements  path to requirements.

bin_env  path to pip bin or path to virtualenv. If doing an uninstall from the system python and want to use a specific pip bin (pip-2.7, pip-2.6, etc.) just specify the pip bin you want. If uninstalling from a virtualenv, just use the path to the virtualenv (/home/code/path/to/virtualenv/)

log  Log file where a complete (maximum verbosity) record will be kept
proxy  Specify a proxy in the form user:passwd@proxy.server:port. Note that the user:password@ is optional and required only if you are behind an authenticated proxy. If you provide user@proxy.server:port then you will be prompted for a password.

timeout  Set the socket timeout (default 15 seconds)
user  The user under which to run pip

no_chown  When user is given, do not attempt to copy and chown a requirements file (needed if the requirements file refers to other files via relative paths, as the copy-and-chown procedure does not account for such files)
cwd  Current working directory to run pip from

use_vt  Use VT terminal emulation (see output while installing)

CLI Example:
salt modules.pip.upgrade

New in version 2015.5.0.

Upgrades outdated pip packages

Returns a dict containing the changes.

\{
  'package': {
    'old': '<old-version>',
    'new': '<new-version>'
  }
\}

CLI Example:
salt '*' pip.upgrade

salt modules.pip.upgrade_available

New in version 2015.5.0.

Check whether or not an upgrade is available for a given package

CLI Example:
salt '*' pip.upgrade_available <package name>

salt modules.pip.version

New in version 0.17.0.

Returns the version of pip. Use \texttt{bin\_env} to specify the path to a virtualenv and get the version of pip in that virtualenv.

If unable to detect the pip version, returns \texttt{None}.

CLI Example:
salt '*' pip.version

\section{salt modules.pkg_resource}

Resources needed by pkg providers

salt modules.pkg_resource.add_pkg

Add a package to a dict of installed packages.

CLI Example:
salt '*' pkg_resource.add_pkg '{} bind 9

salt modules.pkg_resource.check_extra_requirements

Check if the installed package already has the given requirements. This function will return the result of pkg.check_extra_requirements if this function exists for the minion, otherwise it will return True.

CLI Example:
salt '*' pkg_resource.check_extra_requirements <pkgename> <extra_requirements>

\section{Full list of builtin execution modules}

1265
salt.modules.pkg_resource.pack_sources(sources, normalize=True)
Accepts list of dicts (or a string representing a list of dicts) and packs the key/value pairs into a single dict.

'[{"foo": "salt://foo.rpm"},{"bar": "salt://bar.rpm"}]' would become {"foo": "salt://foo.rpm","bar": "salt://bar.rpm"}

normalize [True] Normalize the package name by removing the architecture, if the architecture of the package is different from the architecture of the operating system. The ability to disable this behavior is useful for poorly-created packages which include the architecture as an actual part of the name, such as kernel modules which match a specific kernel version.

New in version 2015.8.0.

CLI Example:
```
salt '*' pkg_resource.pack_sources '[["foo": "salt://foo.rpm"],{"bar": "salt://bar.rpm"}]'
```

salt.modules.pkg_resource.parse_targets(name=None, pkgs=None, sources=None, saltenv='base', normalize=True, **kwargs)
Parses the input to pkg.install and returns back the package(s) to be installed. Returns a list of packages, as well as a string noting whether the packages are to come from a repository or a binary package.

CLI Example:
```
salt '*' pkg_resource.parse_targets
```

salt.modules.pkg_resource.sort_pkglist(pkgs)
Accepts a dict obtained from pkg.list_pkgs() and sorts in place the list of versions for any packages that have multiple versions installed, so that two package lists can be compared to one another.

CLI Example:
```
salt '*' pkg_resource.sort_pkglist '[["3.45", "2.13"]]
```

salt.modules.pkg_resource.stringify(pkgs)
Takes a dict of package name/version information and joins each list of installed versions into a string.

CLI Example:
```
salt '*' pkg_resource.stringify 'vim: 7.127'
```

salt.modules.pkg_resource.version(*names, **kwargs)
Common interface for obtaining the version of installed packages.

CLI Example:
```
salt '*' pkg_resource.version vim
salt '*' pkg_resource.version foo bar baz
salt '*' pkg_resource.version 'python*'
```

salt.modules.pkg_resource.version_clean(verstr)
Clean the version string removing extra data. This function will simply try to call pkg.version_clean.

CLI Example:
```
salt '*' pkg_resource.version_clean <version_string>
```
32.17.195  salt.modules.pkgin

Package support for pkgin based systems, inspired from freebsdpkg module

**Important:** If you feel that Salt should be using this module to manage packages on a minion, and it is using a different module (or gives an error similar to `pkg.install' is not available), see here.

```
salt.modules.pkgin.available_version(*names, **kwargs)
```

This function is an alias of latest_version.

Return the latest version of the named package available for upgrade or installation.

If the latest version of a given package is already installed, an empty string will be returned for that package.

CLI Example:
```
salt '*' pkg.latest_version <package name>
salt '*' pkg.latest_version <package1> <package2> ...
```

```
salt.modules.pkgin.file_dict(package)
```

List the files that belong to a package.

CLI Examples:
```
salt '*' pkg.file_list nginx
```

```
salt.modules.pkgin.file_list(package)
```

List the files that belong to a package.

CLI Examples:
```
salt '*' pkg.file_list nginx
```

```
salt.modules.pkgin.install(name=None, refresh=False, fromrepo=None, pkgs=None, sources=None, **kwargs)
```

Install the passed package

- **name**  The name of the package to be installed.
- **refresh**  Whether or not to refresh the package database before installing.
- **fromrepo**  Specify a package repository to install from.

Multiple Package Installation Options:

- **pkgs**  A list of packages to install from a software repository. Must be passed as a python list.

CLI Example:
```
salt '*' pkg.install pkgs=["foo","bar"]
```

- **sources**  A list of packages to install. Must be passed as a list of dicts, with the keys being package names, and the values being the source URI or local path to the package.

CLI Example:
```
salt '*' pkg.install sources=[{"foo": "salt://foo.deb"},{"bar": "salt://bar.deb"}]'
```

32.17.  Full list of built-in execution modules
Return a dict containing the new package names and versions:

```python
{'<package>': {'old': '<old-version>',
               'new': '<new-version>'}}
```

CLI Example:

```
salt '*' pkg.install <package name>
```

```
salt.modules.pkgin.latest_version("names", **"kwargs")
```

Return the latest version of the named package available for upgrade or installation.

CLI Example:

```
salt '*' pkg.latest_version <package name>
salt '*' pkg.latest_version <package1> <package2> ...
```

```
salt.modules.pkgin.list_pkgs(versions_as_list=False, **"kwargs")
```

List the packages currently installed as a dict:

```python
{'<package_name>': '<version>'}
```

CLI Example:

```
salt '*' pkg.list_pkgs
```

```
salt.modules.pkgin.purge(name=None, pkgs=None, **"kwargs")
```

Package purges are not supported, this function is identical to remove().

- **name** The name of the package to be deleted.

Multiple Package Options:

- **pkgs** A list of packages to delete. Must be passed as a python list. The name parameter will be ignored if this option is passed.

New in version 0.16.0.

Returns a dict containing the changes.

CLI Example:

```
salt '*' pkg.purge <package name>
salt '*' pkg.purge <package1>,<package2>,<package3>
salt '*' pkg.purge pkgs='["foo", "bar"]'
```

```
salt.modules.pkgin.refresh_db()
```

Use pkg update to get latest pkg_summary

CLI Example:

```
salt '*' pkg.refresh_db
```

```
salt.modules.pkgin.remove(name=None, pkgs=None, **"kwargs")
```

- **name** The name of the package to be deleted.

Multiple Package Options:
pkgs  A list of packages to delete. Must be passed as a python list. The name parameter will be ignored if this option is passed.

New in version 0.16.0.

Returns a list containing the removed packages.

CLI Example:

```bash
salt '*' pkg.remove <package name>
salt '*' pkg.remove <package1>,<package2>,<package3>
salt '*' pkg.remove pkgs='["foo", "bar"]'
```

salt.modules.pkgin.search(pkg_name)

Searches for an exact match using pkgin ^package$

CLI Example:

```bash
salt '*' pkg.search 'mysql-server'
```

salt.modules.pkgin.upgrade()

Run pkg upgrade, if pkgin used. Otherwise do nothing

Return a dict containing the new package names and versions:

```python
{'<package>': {'old': '<old-version>',
              'new': '<new-version>'}}
```

CLI Example:

```bash
salt '*' pkg.upgrade
```

salt.modules.pkgin.version(*names, **kwargs)

Returns a string representing the package version or an empty string if not installed. If more than one package name is specified, a dict of name/version pairs is returned.

CLI Example:

```bash
salt '*' pkg.version <package name>
salt '*' pkg.version <package1> <package2> <package3> ...
```

32.17.196  salt.modules.pkgng

Support for pkgng, the new package manager for FreeBSD

**Important:**  If you feel that Salt should be using this module to manage packages on a minion, and it is using a different module (or gives an error similar to `pkg.install' is not available), see here.

**Warning:**  This module has been completely rewritten. Up to and including version 0.17.x, it was available as the pkgng module (pkgng.install, pkgng.delete, etc.), but moving forward this module will no longer be available as pkgng, as it will behave like a normal Salt pkg provider. The documentation below should not be considered to apply to this module in versions <= 0.17.x. If your minion is running a 0.17.x release or older, then the documentation for this module can be viewed using the sys.doc function:

```bash
salt bsdminion sys.doc pkgng
```
This module provides an interface to `pkg(8)`. It acts as the default package provider for FreeBSD 10 and newer. For FreeBSD hosts which have been upgraded to use pkgng, you will need to override the `pkg` provider by setting the `providers` parameter in your Minion config file, in order to use this module to manage packages, like so:

```yaml
providers:
  pkg: pkgng
```

### `salt.modules.pkgng.audit` *(jail=None, chroot=None)*

Audits installed packages against known vulnerabilities

CLI Example:

```
salt '*' pkg.audit
```

**jail**  Audit packages within the specified jail

CLI Example:

```
salt '*' pkg.audit jail=<jail name or id>
```

**chroot**  Audit packages within the specified chroot (ignored if `jail` is specified)

CLI Example:

```
salt '*' pkg.audit chroot=/path/to/chroot
```

### `salt.modules.pkgng.autoremove` *(jail=None, chroot=None, dryrun=False)*

Delete packages which were automatically installed as dependencies and are not required anymore.

**dryrun**  Dry-run mode. The list of changes to packages is always printed, but no changes are actually made.

CLI Example:

```
salt '*' pkg.autoremove
salt '*' pkg.autoremove jail=<jail name or id>
salt '*' pkg.autoremove dryrun=True
salt '*' pkg.autoremove jail=<jail name or id> dryrun=True
```

### `salt.modules.pkgng.backup` *(file_name, jail=None, chroot=None)*

Export installed packages into yaml+mtree file

CLI Example:

```
salt '*' pkg.backup /tmp/pkg
```

**jail**  Backup packages from the specified jail. Note that this will run the command within the jail, and so the path to the backup file will be relative to the root of the jail

CLI Example:

```
salt '*' pkg.backup /tmp/pkg jail=<jail name or id>
```

**chroot**  Backup packages from the specified chroot (ignored if `jail` is specified). Note that this will run the command within the chroot, and so the path to the backup file will be relative to the root of the chroot.

CLI Example:

```
salt '*' pkg.backup /tmp/pkg chroot=/path/to/chroot
```
salt.modules.pkgng.check(jail=None, chroot=None, depends=False, recompute=False, checksum=False)
Sanity checks installed packages

- **jail** Perform the sanity check in the specified jail
  CLI Example:
  ```shell
  salt '*' pkg.check jail=<jail name or id>
  ```

- **chroot** Perform the sanity check in the specified chroot (ignored if jail is specified)
  CLI Example:
  ```shell
  salt '*' pkg.check chroot=/path/to/chroot
  ```

Of the below, at least one must be set to True.

- **depends** Check for and install missing dependencies.
  CLI Example:
  ```shell
  salt '*' pkg.check depends=True
  ```

- **recompute** Recompute sizes and checksums of installed packages.
  CLI Example:
  ```shell
  salt '*' pkg.check recompute=True
  ```

- **checksum** Find invalid checksums for installed packages.
  CLI Example:
  ```shell
  salt '*' pkg.check checksum=True
  ```

salt.modules.pkgng.clean(jail=None, chroot=None)
Cleans the local cache of fetched remote packages

CLI Example:
```shell
salt '*' pkg.clean
salt '*' pkg.clean jail=<jail name or id>
salt '*' pkg.clean chroot=/path/to/chroot
```

salt.modules.pkgng.fetch(name, jail=None, chroot=None, fetch_all=False, quiet=False, from_repo=None, glob=True, regex=False, pcre=False, local=False, depends=False)
Fetches remote packages

CLI Example:
```shell
salt '*' pkg.fetch <package name>
```

- **jail** Fetch package in the specified jail
  CLI Example:
  ```shell
  salt '*' pkg.fetch <package name> jail=<jail name or id>
  ```
**chroot**  Fetch package in the specified chroot (ignored if **jail** is specified)

**CLI Example:**

```
salt '*' pkg.fetch <package name> chroot=/path/to/chroot
```

**fetch_all**  Fetch all packages.

**CLI Example:**

```
salt '*' pkg.fetch <package name> fetch_all=True
```

**quiet**  Quiet mode. Show less output.

**CLI Example:**

```
salt '*' pkg.fetch <package name> quiet=True
```

**fromrepo**  Fetches packages from the given repo if multiple repo support is enabled. See **pkg.conf(5)**.

**CLI Example:**

```
salt '*' pkg.fetch <package name> fromrepo=repo
```

**glob**  Treat pkg_name as a shell glob pattern.

**CLI Example:**

```
salt '*' pkg.fetch <package name> glob=True
```

**regex**  Treat pkg_name as a regular expression.

**CLI Example:**

```
salt '*' pkg.fetch <regular expression> regex=True
```

**pcre**  Treat pkg_name as an extended regular expression.

**CLI Example:**

```
salt '*' pkg.fetch <extended regular expression> pcre=True
```

**local**  Skip updating the repository catalogs with pkg-update(8). Use the local cache only.

**CLI Example:**

```
salt '*' pkg.fetch <package name> local=True
```

**depends**  Fetch the package and its dependencies as well.

**CLI Example:**

```
salt '*' pkg.fetch <package name> depends=True
```

salt.modules.pkgng.**install**(name=None, fromrepo=None, pkgs=None, sources=None, jail=None, chroot=None, orphan=False, force=False, glob=False, local=False, dryrun=False, quiet=False, reinstallRequires=False, regex=False, pcre=False, **kwargs)

Install package(s) from a repository.
name  The name of the package to install

    CLI Example:
    
    salt '*' pkg.install <package name>

jail  Install the package into the specified jail

chroot  Install the package into the specified chroot (ignored if jail is specified)

orphan  Mark the installed package as orphan. Will be automatically removed if no other packages depend
         on them. For more information please refer to pkg-autoremove(8).

    CLI Example:
    
    salt '*' pkg.install <package name> orphan=True

force  Force the reinstallation of the package if already installed.

    CLI Example:
    
    salt '*' pkg.install <package name> force=True

glob  Treat the package names as shell glob patterns.

    CLI Example:
    
    salt '*' pkg.install <package name> glob=True

local  Do not update the repository catalogs with pkg-update(8). A value of True here is equivalent to
        using the -U flag with pkg install.

    CLI Example:
    
    salt '*' pkg.install <package name> local=True

dryrun  Dry-run mode. The list of changes to packages is always printed, but no changes are actually made.

    CLI Example:
    
    salt '*' pkg.install <package name> dryrun=True

quiet  Force quiet output, except when dryrun is used, where pkg install will always show packages to be
        installed, upgraded or deleted.

    CLI Example:
    
    salt '*' pkg.install <package name> quiet=True

reinstall_requires  When used with force, reinstalls any packages that require the given package.

    CLI Example:
    
    salt '*' pkg.install <package name> reinstall_requires=True force=True

    Changed in version 2014.7.0: require kwarg renamed to reinstall_requires

fromrepo  In multi-repo mode, override the pkg.conf ordering and only attempt to download packages from
          the named repository.

    CLI Example:
salt 'x' pkg.install <package name> fromrepo=repo

regex  Treat the package names as a regular expression

CLI Example:

salt 'x' pkg.install <regular expression> regex=True

pcre  Treat the package names as extended regular expressions.

CLI Example:

salt 'x' pkg.install <extended regular expression> pcre=True

salt.modules.pkgng.latest_version(*names, **kwargs)
Return the latest version of the named package available for upgrade or installation. If more than one package
name is specified, a dict of name/version pairs is returned.
If the latest version of a given package is already installed, an empty string will be returned for that package.

CLI Example:

salt 'x' pkg.latest_version <package name>
salt 'x' pkg.latest_version <package name> jail=<jail name or id>
salt 'x' pkg.latest_version <package name> chroot=/path/to/chroot

salt.modules.pkgng.list_pkgs(versions_as_list=False, jail=None, chroot=None, with_origin=False, **kwargs)
List the packages currently installed as a dict:

`{<package_name>': '<version>'}

jail  List the packages in the specified jail
chroot  List the packages in the specified chroot (ignored if jail is specified)
with_origin  [False] Return a nested dictionary containing both the origin name and version for each installed
    package.

    New in version 2014.1.0.

CLI Example:

salt 'x' pkg.list_pkgs
salt 'x' pkg.list_pkgs jail=<jail name or id>
salt 'x' pkg.list_pkgs chroot=/path/to/chroot

salt.modules.pkgng.parse_config(file_name='/usr/local/etc/pkg.conf')
Return dict of uncommented global variables.

CLI Example:

salt 'x' pkg.parse_config

NOTE: not working properly right now

salt.modules.pkgng.refresh_db(jail=None, chroot=None, force=False)
Refresh PACKAGESITE contents
Note: This function can accessed using `pkg.update` in addition to `pkg.refresh_db`, to more closely match the CLI usage of `pkg(8)`.

CLI Example:
```
salt '*' pkg.refresh_db
```

```js
jail
```
Refresh the pkg database within the specified jail
```js
chroot
```
Refresh the pkg database within the specified chroot (ignored if `jail` is specified)
```js
force
```
Force a full download of the repository catalog without regard to the respective ages of the local and remote copies of the catalog.
```

CLI Example:
```
salt '*' pkg.refresh_db force=True
```

```js
salt.modules.pkgng.remove(name=None, pkgs=None, jail=None, chroot=None, all_installed=False, force=False, glob=False, dryrun=False, recurse=False, regex=False, pcre=False, **kwargs)
```

Remove a package from the database and system

Note: This function can accessed using `pkg.delete` in addition to `pkg.remove`, to more closely match the CLI usage of `pkg(8)`.

```js
name
```
The package to remove
```

CLI Example:
```
salt '*' pkg.remove <package name>
```

```js
jail
```
Delete the package from the specified jail
```

```
chroot
```
Delete the package from the specified chroot (ignored if `jail` is specified)
```

```js
all_installed
```
Deletes all installed packages from the system and empties the database. USE WITH CAUTION!
```

CLI Example:
```
salt '*' pkg.remove all all_installed=True force=True
```

```js
force
```
Forces packages to be removed despite leaving unresolved dependencies.
```

CLI Example:
```
salt '*' pkg.remove <package name> force=True
```

```js
glob
```
Treat the package names as shell glob patterns.
```

CLI Example:
```
salt '*' pkg.remove <package name> glob=True
```

```js
dryrun
```
Dry run mode. The list of packages to delete is always printed, but no packages are actually deleted.
```

CLI Example:
salt 'x' pkg.remove <package name> dryrun=True

**recurse**  Delete all packages that require the listed package as well.

CLI Example:

salt 'x' pkg.remove <package name> recurse=True

**regex**  Treat the package names as regular expressions.

CLI Example:

salt 'x' pkg.remove <regular expression> regex=True

**pcre**  Treat the package names as extended regular expressions.

CLI Example:

salt 'x' pkg.remove <extended regular expression> pcre=True

salt.modules.pkgng.restore(file_name, jail=None, chroot=None)

Reads archive created by pkg backup -d and recreates the database.

CLI Example:

salt 'x' pkg.restore /tmp/pkg

**jail**  Restore database to the specified jail. Note that this will run the command within the jail, and so the path to the file from which the pkg database will be restored is relative to the root of the jail.

CLI Example:

salt 'x' pkg.restore /tmp/pkg jail=<jail name or id>

**chroot**  Restore database to the specified chroot (ignored if jail is specified). Note that this will run the command within the chroot, and so the path to the file from which the pkg database will be restored is relative to the root of the chroot.

CLI Example:

salt 'x' pkg.restore /tmp/pkg chroot=/path/to/chroot

salt.modules.pkgng.search(name, jail=None, chroot=None, exact=False, glob=False, regex=False, pcre=False, comment=False, desc=False, full=False, depends=False, size=False, quiet=False, origin=False, prefix=False)

Searches in remote package repositories

CLI Example:

salt 'x' pkg.search pattern

**jail**  Perform the search using the pkg.conf(5) from the specified jail

CLI Example:

salt 'x' pkg.search pattern jail=<jail name or id>
chroot  Perform the search using the `pkg.conf(5)` from the specified chroot (ignored if `jail` is specified)

CLI Example:
```
salt 'ié' pkg.search pattern chroot=/path/to/chroot
```

exact  Treat pattern as exact pattern.

CLI Example:
```
salt 'ié' pkg.search pattern exact=True
```

glob  Treat pattern as a shell glob pattern.

CLI Example:
```
salt 'ié' pkg.search pattern glob=True
```

regex  Treat pattern as a regular expression.

CLI Example:
```
salt 'ié' pkg.search pattern regex=True
```

pcre  Treat pattern as an extended regular expression.

CLI Example:
```
salt 'ié' pkg.search pattern pcre=True
```

comment  Search for pattern in the package comment one-line description.

CLI Example:
```
salt 'ié' pkg.search pattern comment=True
```

desc  Search for pattern in the package description.

CLI Example:
```
salt 'ié' pkg.search pattern desc=True
```

full  Displays full information about the matching packages.

CLI Example:
```
salt 'ié' pkg.search pattern full=True
```

depends  Displays the dependencies of pattern.

CLI Example:
```
salt 'ié' pkg.search pattern depends=True
```

size  Displays the size of the package

CLI Example:
```
salt 'ié' pkg.search pattern size=True
```
quiet Be quiet. Prints only the requested information without displaying many hints.

   CLI Example:
   
   ```
   salt '*' pkg.search pattern quiet=True
   ```

origin Displays pattern origin.

   CLI Example:
   
   ```
   salt '*' pkg.search pattern origin=True
   ```

prefix Displays the installation prefix for each package matching pattern.

   CLI Example:
   
   ```
   salt '*' pkg.search pattern prefix=True
   ```

```
salt.modules.pkgng.stats``(local=False, remote=False, jail=None, chroot=None)

Return pkgng stats.

   CLI Example:
   
   ```
   salt '*' pkg.stats
   ```

local Display stats only for the local package database.

   CLI Example:
   
   ```
   salt '*' pkg.stats local=True
   ```

remote Display stats only for the remote package database(s).

   CLI Example:
   
   ```
   salt '*' pkg.stats remote=True
   ```

jail Retrieve stats from the specified jail.

   CLI Example:
   
   ```
   salt '*' pkg.stats jail=<jail name or id>
   salt '*' pkg.stats jail=<jail name or id> local=True
   salt '*' pkg.stats jail=<jail name or id> remote=True
   ```

chroot Retrieve stats from the specified chroot (ignored if jail is specified).

   CLI Example:
   
   ```
   salt '*' pkg.stats chroot=/path/to/chroot
   salt '*' pkg.stats chroot=/path/to/chroot local=True
   salt '*' pkg.stats chroot=/path/to/chroot remote=True
   ```

```
salt.modules.pkgng.update_package_site``(new_url)

Updates remote package repo URL, PACKAGESITE var to be exact.

   Must use http://, ftp://, or https:// protocol

   CLI Example:
   
   ```
salt '*' pkg.update_package_site http://127.0.0.1/

salt.modules.pkgng.updating(name, jail=None, chroot=None, filedate=None, filename=None)
Display UPDATING entries of software packages

CLI Example:
salt '*' pkg.updating foo

jail Perform the action in the specified jail

CLI Example:
salt '*' pkg.updating foo jail=<jail name or id>

chroot Perform the action in the specified chroot (ignored if jail is specified)

CLI Example:
salt '*' pkg.updating foo chroot=/path/to/chroot

filedate Only entries newer than date are shown. Use a YYYYMMDD date format.

CLI Example:
salt '*' pkg.updating foo filedate=20130101

filename Defines an alternative location of the UPDATING file.

CLI Example:
salt '*' pkg.updating foo filename=/tmp/UPDATING

salt.modules.pkgng.upgrade('*names, **kwargs)
Upgrade named or all packages (run a pkg upgrade). If <package name> is omitted, the operation is executed on all packages.

CLI Example:
salt '*' pkg.upgrade <package name>

jail Audit packages within the specified jail

CLI Example:
salt '*' pkg.upgrade <package name> jail=<jail name or id>

chroot Audit packages within the specified chroot (ignored if jail is specified)

CLI Example:
salt '*' pkg.upgrade <package name> chroot=/path/to/chroot

Any of the below options can also be used with jail or chroot.

force Force reinstalling/upgrading the whole set of packages.

CLI Example:
```
salt '*' pkg.upgrade <package name> force=True
```

**local**  Do not update the repository catalogs with pkg-update(8). A value of True here is equivalent to using the -U flag with pkg upgrade.

CLI Example:
```
salt '*' pkg.upgrade <package name> local=True
```

**dryrun**  Dry-run mode: show what packages have updates available, but do not perform any upgrades. Repository catalogs will be updated as usual unless the local option is also given.

CLI Example:
```
salt '*' pkg.upgrade <package name> dryrun=True
```

```
salt.modules.pkgng.version(*names,**kwargs)

Returns a string representing the package version or an empty string if not installed. If more than one package name is specified, a dict of name/version pairs is returned.

**Note:** This function can accessed using pkg.info in addition to pkg.version, to more closely match the CLI usage of pkg(8).
```

**jail**  Get package version information for the specified jail

**chroot**  Get package version information for the specified chroot (ignored if jail is specified)

**with_origin**  [False] Return a nested dictionary containing both the origin name and version for each specified package.

    New in version 2014.1.0.

CLI Example:
```
salt '*' pkg.version <package name>
salt '*' pkg.version <package name> jail=<jail name or id>
salt '*' pkg.version <package1> <package2> <package3> ...
```

```
salt.modules.pkgng.version_cmp(pkg1, pkg2, ignore_epoch=False)

Do a cmp-style comparison on two packages. Return -1 if pkg1 < pkg2, 0 if pkg1 == pkg2, and 1 if pkg1 > pkg2. Return None if there was a problem making the comparison.

CLI Example:
```
salt '*' pkg.version_cmp '2.1.11' '2.1.12'
```

```
salt.modules.pkgng.which(path, jail=None, chroot=None, origin=False, quiet=False)

Displays which package installed a specific file

CLI Example:
```
salt '*' pkg.which <file name>
```

**jail**  Perform the check in the specified jail

    CLI Example:
salt 'x' pkg.which <file name> jail=<jail name or id>

**chroot**  Perform the check in the specified chroot (ignored if jail is specified)

CLI Example:

```shell
salt 'x' pkg.which <file name> chroot=/path/to/chroot
```

**origin**  Shows the origin of the package instead of name-version.

CLI Example:

```shell
salt 'x' pkg.which <file name> origin=True
```

**quiet**  Quiet output.

CLI Example:

```shell
salt 'x' pkg.which <file name> quiet=True
```

### 32.17.197 salt.modules.pkgutil

Pkgutil support for Solaris

**Important:**  If you feel that Salt should be using this module to manage packages on a minion, and it is using a different module (or gives an error similar to `pkg.install' is not available), see [here](#).

**salt.modules.pkgutil.install**

Install packages using the pkgutil tool.

CLI Example:

```shell
salt '*' pkg.install <package_name>
salt '*' pkg.install SMClgcc346
```

**pkgs**  A list of packages to install from OpenCSW. Must be passed as a python list.

CLI Example:

```shell
salt '*' pkg.install pkgs='["foo", "bar"]'
salt '*' pkg.install pkgs='["foo", {"bar": "1.2.3"}]'
```

Returns a dict containing the new package names and versions:

```python
{'<package>': {'old': '<old-version>',
              'new': '<new-version>'}}
```

**salt.modules.pkgutil.latest_version**

Return the latest version of the named package available for upgrade or installation. If more than one package name is specified, a dict of name/version pairs is returned. If the latest version of a given package is already installed, an empty string will be returned for that package.

CLI Example:
salt '*' pkgutil.latest_version CSWpython
salt '*' pkgutil.latest_version <package1> <package2> <package3> ...

salt.modules.pkgutil.list_pkgs(versions_as_list=False, **kwargs)

List the packages currently installed as a dict:

```
{'<package_name>': '<version>'}
```

CLI Example:

```
salt '*' pkg.list_pkgs
salt '*' pkg.list_pkgs versions_as_list=True
```

salt.modules.pkgutil.list_upgrades(refresh=True, **kwargs)

List all available package upgrades on this system

CLI Example:

```
salt '*' pkgutil.list_upgrades
```

salt.modules.pkgutil.purge(name=None, pkgs=None, **kwargs)

Package purges are not supported, this function is identical to remove().

name The name of the package to be deleted.

Multiple Package Options:

pkgs A list of packages to delete. Must be passed as a python list. The name parameter will be ignored if this option is passed.

New in version 0.16.0.

Returns a dict containing the changes.

CLI Example:

```
salt '*' pkg.purge <package name>
salt '*' pkg.purge <package1>,<package2>,<package3>
salt '*' pkg.purge pkgs='["foo", "bar"]'
```

salt.modules.pkgutil.refresh_db()

Updates the pkgutil repo database (pkgutil -U)

CLI Example:

```
salt '*' pkgutil.refresh_db
```

salt.modules.pkgutil.remove(name=None, pkgs=None, **kwargs)

Remove a package and all its dependencies which are not in use by other packages.

name The name of the package to be deleted.

Multiple Package Options:

pkgs A list of packages to delete. Must be passed as a python list. The name parameter will be ignored if this option is passed.

New in version 0.16.0.

Returns a dict containing the changes.

CLI Example:
**salt.modules.pkgutil**

- **upgrade** *(refresh=True)*
  
  Upgrade all of the packages to the latest available version.
  
  Returns a dict containing the changes:

  ```
  {'<package>': {'old': '<old-version>', 'new': '<new-version>'}}
  ```

  CLI Example:

  ```
salt '*' pkgutil.upgrade
  ```

- **upgrade_available** *(name)*
  
  Check if there is an upgrade available for a certain package.

  CLI Example:

  ```
salt '*' pkgutil.upgrade_available CSWpython
  ```

- **version** *(names, **kwargs)*
  
  Returns a version if the package is installed, else returns an empty string.

  CLI Example:

  ```
salt '*' pkgutil.version CSWpython
  ```

---

**32.17.198 salt.modules.portage_config**

Configure portage(5)

- **append_to_package_conf** *(conf, atom='*', flags=None, string='*', overwrite=False)*
  
  Append a string or a list of flags for a given package or DEPEND atom to a given configuration file.

  CLI Example:

  ```
salt '*' portage_config.append_to_package_conf use string="app-admin/salt ldap -\nlibvirt"
salt '*' portage_config.append_to_package_conf use atom"> = app-admin/salt-0.14.1
\nflags="['ldap', '-libvirt']"
  ```

- **append_use_flags** *(atom, uses=None, overwrite=False)*
  
  Append a list of use flags for a given package or DEPEND atom.

  CLI Example:

  ```
salt '*' portage_config.append_use_flags "app-admin/salt[ldap, -libvirt]"
salt '*' portage_config.append_use_flags ">=app-admin/salt-0.14.1" "[\'ldap', \'-\n\nlibvirt']"
  ```

- **enforce_nice_config** *
  
  Enforce a nice tree structure for /etc/portage/package.* configuration files.

  See also:
For information on automatically running this when pkg is used:

```
salt '*' portage_config.enforce_nice_config
```

Filter function to remove hidden or otherwise not normally visible USE flags from a list:

```
salt.modules.portage_config.filter_flags(use, use_expand_hidden, usemasked, useforced)
```

Uses portage to determine final USE flags and settings for an emerge:

```
salt.modules.portage_config.get_all_cpv_use(cp)
```

Uses portage for compare use flags which is used for installing package and use flags which now exist int /etc/portage/package.use:

```
salt.modules.portage_config.get_cleared_flags(cp)
```

Find out which of the given flags are currently not set. CLI Example:

```
salt '*' portage_config.get_missing_flags use salt "['ldap', '-libvirt', 'openssl]
```
**Salt Documentation, Release 2015.8.12**

salt.modules.portage_config.has_flag\(\text{conf, atom, flag}\)

Verify if the given package or DEPEND atom has the given flag. Warning: This only works if the configuration files tree is in the correct format (the one enforced by enforce_nice_config)

CLI Example:

```
salt '*' portage_config.has_flag license salt Apache-2.0
```

salt.modules.portage_config.has_use\(\text{atom, use}\)

Verify if the given package or DEPEND atom has the given use flag. Warning: This only works if the configuration files tree is in the correct format (the one enforced by enforce_nice_config)

CLI Example:

```
salt '*' portage_config.has_use salt libvirt
```

salt.modules.portage_config.is_changed_uses\(\text{cp}\)

New in version 2015.8.0.

Uses portage for determine if the use flags of installed package is compatible with use flags in portage configs.

@type cp: string @param cp: eg cat/pkg

salt.modules.portage_config.is_present\(\text{conf, atom}\)

Tell if a given package or DEPEND atom is present in the configuration files tree. Warning: This only works if the configuration files tree is in the correct format (the one enforced by enforce_nice_config)

CLI Example:

```
salt '*' portage_config.is_present unmask salt
```

### 32.17.199 salt.modules.postfix

Support for Postfix

This module is currently little more than a config file viewer and editor. It is able to read the master.cf file (which is one style) and files in the style of main.cf (which is a different style, that is used in multiple postfix configuration files).

The design of this module is such that when files are edited, a minimum of changes are made to them. Each file should look as if it has been edited by hand; order, comments and whitespace are all preserved.

salt.modules.postfix.delete\(\text{queue_id}\)

Delete message(s) from the mail queue

CLI Example:

```
salt '*' postfix.delete 5C33CA0DEA
salt '*' postfix.delete ALL
```

salt.modules.postfix.hold\(\text{queue_id}\)

Put message(s) on hold from the mail queue

CLI Example:

```
salt '*' postfix.hold 5C33CA0DEA
salt '*' postfix.hold ALL
```

32.17. Full list of builtin execution modules 1285
salt.modules.postfix.requeue(\textit{queue\_id})

Requeue message(s) in the mail queue

CLI Example:

\begin{verbatim}
salt '*' postfix.requeue 5C33CA0DEA
salt '*' postfix.requeue ALL
\end{verbatim}

salt.modules.postfix.set\_main(\textit{key}, \textit{value}, \textit{path}='\texttt{/etc/postfix/main.cf}')

Set a single config value in the main.cf file. If the value does not already exist, it will be appended to the end.

CLI Example:

\begin{verbatim}
salt <minion> postfix.set\_main mailq\_path /usr/bin/mailq
\end{verbatim}

salt.modules.postfix.set\_master(\textit{service}, \textit{conn\_type}, \textit{private}='\texttt{y}', \textit{unpriv}='\texttt{y}', \textit{chroot}='\texttt{y}',
\textit{wakeup}='\texttt{n}', \textit{maxproc}='\texttt{100}', \textit{command}='\texttt{''}', \textit{write\_conf}=True,
\textit{path}='\texttt{/etc/postfix/master.cf}')</p>

Set a single config value in the master.cf file. If the value does not already exist, it will be appended to the end.

Because of shell parsing issues, `\texttt{-}` cannot be set as a value, as is normal in the master.cf file; either `\texttt{y}`, `\texttt{n}` or a number should be used when calling this function from the command line. If the value used matches the default, it will internally be converted to a `\texttt{-}`. Calling this function from the Python API is not affected by this limitation.

The settings and their default values, in order, are: service (required), conn\_type (required), private (y), unpriv (y), chroot (y), wakeup (n), maxproc (100), command (required).

By default, this function will write out the changes to the master.cf file, and then returns the full contents of the file. By setting the \texttt{write\_conf} option to \texttt{False}, it will skip writing the file.

CLI Example:

\begin{verbatim}
salt <minion> postfix.set\_master smtp inet n y n n 100 smtpd
\end{verbatim}

salt.modules.postfix.show\_main(\textit{path}='\texttt{/etc/postfix/main.cf}')

Return a dict of active config values. This does not include comments, spacing or order. Bear in mind that order is functionally important in the main.cf file, since keys can be referred to as variables. This means that the data returned from this function should not be used for direct modification of the main.cf file; other functions are available for that.

CLI Examples:

\begin{verbatim}
salt <minion> postfix.show\_main salt <minion> postfix.show\_main path=/path/to/main.cf
\end{verbatim}

salt.modules.postfix.show\_master(\textit{path}='\texttt{/etc/postfix/master.cf}')

Return a dict of active config values. This does not include comments, spacing or order.

The data returned from this function should not be used for direct modification of the main.cf file; other functions are available for that.

CLI Examples:

\begin{verbatim}
salt <minion> postfix.show\_master salt <minion> postfix.show\_master path=/path/to/master.cf
\end{verbatim}

salt.modules.postfix.show\_queue()

Show contents of the mail queue

CLI Example:

\begin{verbatim}
salt '*' postfix.show\_queue
\end{verbatim}
salt.modules.postfix.unhold(queue_id)
Set held message(s) in the mail queue to unheld

CLI Example:
```
salt '*' postfix.unhold 5C33CA0DEA
salt '*' postfix.unhold ALL
```

32.17.200  salt.modules.postgres

Module to provide Postgres compatibility to salt.

**configuration**  In order to connect to Postgres, certain configuration is required in /etc/salt/minion on the relevant minions. Some sample configs might look like:

```
postgres.host: 'localhost'
p没见过.postgres.port: '5432'
p没见过.postgres.user: 'postgres' -> db user
postgres.password: '
p没见过.postgres.maintenance.db: 'postgres'
```

The default for the maintenance_db is 'postgres' and in most cases it can be left at the default setting. This data can also be passed into pillar. Options passed into opts will overwrite options passed into pillar.

**note**  This module uses MD5 hashing which may not be compliant with certain security audits.

salt.modules.postgres.available_extensions(user=None, host=None, port=None, maintenance_db=None, password=None, runas=None)
List available postgresql extensions

CLI Example:
```
salt '*' postgres.available_extensions
```

salt.modules.postgres.create_extension(name, if_not_exists=None, schema=None, ext_version=None, from_version=None, user=None, host=None, port=None, maintenance_db=None, password=None, runas=None)
Install a postgresql extension

CLI Example:
```
salt '*' postgres.create_extension 'adminpack'
```

salt.modules.postgres.create_metadata(name, ext_version=None, schema=None, user=None, host=None, port=None, maintenance_db=None, password=None, runas=None)
Get lifecycle information about an extension

CLI Example:
```
salt '*' postgres.create_metadata adminpack
```
salt.modules.postgres.db_alter(name, user=None, host=None, port=None, maintenance_db=None, password=None, tablespace=None, owner=None, owner_recurse=False, runas=None)

Change tablespace or/and owner of database.

CLI Example:
```
salt '*' postgres.db_alter dbname owner=otheruser
```

salt.modules.postgres.db_create(name, user=None, host=None, port=None, maintenance_db=None, password=None, tablespace=None, encoding=None, lc_collate=None, lc_ctype=None, owner=None, template=None, runas=None)

Adds a databases to the Postgres server.

CLI Example:
```
salt '*' postgres.db_create 'dbname'
salt '*' postgres.db_create 'dbname' template=template_postgis
```

salt.modules.postgres.db_exists(name, user=None, host=None, port=None, maintenance_db=None, password=None, runas=None)

Checks if a database exists on the Postgres server.

CLI Example:
```
salt '*' postgres.db_exists 'dbname'
```

salt.modules.postgres.db_list(user=None, host=None, port=None, maintenance_db=None, password=None, runas=None)

Return dictionary with information about databases of a Postgres server.

CLI Example:
```
salt '*' postgres.db_list
```

salt.modules.postgres.db_remove(name, user=None, host=None, port=None, maintenance_db=None, password=None, runas=None)

Removes a databases from the Postgres server.

CLI Example:
```
salt '*' postgres.db_remove 'dbname'
```

salt.modules.postgres.drop_extension(name, if_exists=None, restrict=None, cascade=None, user=None, host=None, port=None, maintenance_db=None, password=None, runas=None)

Drop an installed postgresql extension

CLI Example:
```
salt '*' postgres.drop_extension 'adminpack'
```

salt.modules.postgres.get_available_extension(name, if_exists=None, restrict=None, cascade=None, user=None, host=None, port=None, maintenance_db=None, password=None, runas=None)

Get info about an available postgresql extension

CLI Example:
salt '*' postgres.get_available_extension plpgsql

salt.modules.postgres.get_installed_extension(name, user=None, host=None, port=None, maintenance_db=None, password=None, runas=None)

Get info about an installed postgresql extension

CLI Example:

```
salt '*' postgres.get_installed_extension plpgsql
```

salt.modules.postgres.group_create(groupname, user=None, host=None, port=None, maintenance_db=None, password=None, createdb=None, createdb=None, createuser=None, createroles=None, encrypted=None, login=None, inherit=None, superuser=None, replication=None, rolepassword=None, groups=None, runas=None)

Creates a Postgres group. A group is postgres is similar to a user, but cannot login.

CLI Example:

```
salt '*' postgres.group_create groupname user='user' \ host='hostname' port='port' password='password' \ rolepassword='rolepassword'
```

salt.modules.postgres.group_remove(groupname, user=None, host=None, port=None, maintenance_db=None, password=None, runas=None)

Removes a group from the Postgres server.

CLI Example:

```
salt '*' postgres.group_remove 'groupname'
```

salt.modules.postgres.group_update(groupname, user=None, host=None, port=None, maintenance_db=None, password=None, createdb=None, createdb=None, createuser=None, createroles=None, encrypted=None, login=None, inherit=None, superuser=None, replication=None, rolepassword=None, groups=None, runas=None)

Updates a postgres group

CLI Examples:

```
salt '*' postgres.group_update 'username' user='user' \ host='hostname' port='port' password='password' \ rolepassword='rolepassword'
```

salt.modules.postgres.installed_extensions(user=None, host=None, port=None, maintenance_db=None, password=None, runas=None)

List installed postgresql extensions

CLI Example:

```
salt '*' postgres.installed_extensions
```

salt.modules.postgres.is_available_extension(name, user=None, host=None, port=None, maintenance_db=None, password=None, runas=None)

Test if a specific extension is available
CLI Example:
```
salt '*' postgres.is_available_extension
```

salt.modules.postgres.is_installed_extension(\n    name, \n    user=None, \n    host=None, \n    port=None, \n    maintenance_db=None, \n    password=None, \n    runas=None)

Test if a specific extension is installed

CLI Example:
```
salt '*' postgres.is_installed_extension
```

salt.modules.postgres.owner_to(\n    dbname, \n    ownername, \n    user=None, \n    host=None, \n    port=None, \n    password=None, \n    runas=None)

Set the owner of all schemas, functions, tables, views and sequences to the given username.

CLI Example:
```
salt '*' postgres.owner_to 'dbname' 'username'
```

salt.modules.postgres.psql_query(\n    query, \n    user=None, \n    host=None, \n    port=None, \n    maintenance_db=None, \n    password=None, \n    runas=None)

Run an SQL-Query and return the results as a list. This command only supports SELECT statements. This limitation can be worked around with a query like this:

```sql
WITH updated AS (UPDATE pg_authid SET rolconnlimit = 2000 WHERE rolname = 'rolename' RETURNING rolconnlimit) SELECT * FROM updated;
```

query The query string.
user Database username, if different from config or default.
host Database host, if different from config or default.
port Database port, if different from the config or default.
maintenance_db The database to run the query against.
password User password, if different from the config or default.
runas User to run the command as.

CLI Example:
```
salt '*' postgres.psql_query 'select * from pg_stat_activity'
```

salt.modules.postgres.role_get(\n    name, \n    user=None, \n    host=None, \n    port=None, \n    maintenance_db=None, \n    password=None, \n    runas=None, \n    return_password=False)

Return a dict with information about users of a Postgres server.

Set return_password to True to get password hash in the result.

CLI Example:
```
salt '*' postgres.role_get postgres
```

salt.modules.postgres.schema_create(\n    dbname, \n    name, \n    owner=None, \n    user=None, \n    db_user=None, \n    db_password=None, \n    db_host=None, \n    db_port=None)

Creates a Postgres schema.

CLI Example:
salt ' * ' postgres.schema_create dbname name owner='owner' \ 
    user='user' \ 
    db_user='user' db_password='password' 
    db_host='hostname' db_port='port'

salt.modules.postgres.schema_exists(dbname, name, db_user=None, db_password=None, 
    db_host=None, db_port=None)

Checks if a schema exists on the Postgres server.

CLI Example:

salt ' * ' postgres.schema_exists dbname schemaname

dbname Database name we query on
name Schema name we look for
db_user database username if different from config or default
db_password user password if any password for a specified user
db_host Database host if different from config or default
db_port Database port if different from config or default

salt.modules.postgres.schema_get(dbname, name, db_user=None, db_password=None, 
    db_host=None, db_port=None)

Return a dict with information about schemas in a database.

CLI Example:

salt ' * ' postgres.schema_get dbname name

dbname Database name we query on
name Schema name we look for
db_user database username if different from config or default
db_password user password if any password for a specified user
db_host Database host if different from config or default
db_port Database port if different from config or default

salt.modules.postgres.schema_list(dbname, db_user=None, db_password=None, db_host=None, 
    db_port=None)

Return a dict with information about schemas in a Postgres database.

CLI Example:

salt ' * ' postgres.schema_list dbname

dbname Database name we query on
db_user database username if different from config or default
db_password user password if any password for a specified user
db_host Database host if different from config or default
db_port Database port if different from config or default
salt.modules.postgres.schema_remove (dbname, name, user=None, db_user=None, 
  db_password=None, db_host=None, db_port=None)

Removes a schema from the Postgres server.

CLI Example:
```
salt '*' postgres.schema_remove dbname schemaname
```

dbname  Database name we work on

schemaname  The schema's name we'll remove

user  System user all operations should be performed on behalf of

db_user  database username if different from config or default

db_password  user password if any password for a specified user

db_host  Database host if different from config or default

db_port  Database port if different from config or default

salt.modules.postgres.tablespace_alter (name, user=None, host=None, port=None, mainte-
nance_db=None, password=None, new_name=None, 
  new_owner=None, set_option=None, re-
set_option=None, runas=None)

Change tablespace name, owner, or options.

CLI Example:
```
salt '*' postgres.tablespace_alter tsname new_owner=otheruser
salt '*' postgres.tablespace_alter index_space new_name=fast_raid
salt '*' postgres.tablespace_alter test set_option="{"seq_page_cost": "1.1"}"
```

New in version 2015.8.0.

salt.modules.postgres.tablespace_create (name, location, options=None, owner=None, 
  user=None, host=None, port=None, mainte-
nance_db=None, password=None, runas=None)

Adds a tablespace to the Postgres server.

CLI Example:
```
salt '*' postgres.tablespace_create tablespacename '/path/datadir'
```

New in version 2015.8.0.

salt.modules.postgres.tablespace_exists (name, user=None, host=None, port=None, mainte-
nance_db=None, password=None, runas=None)

Checks if a tablespace exists on the Postgres server.

CLI Example:
```
salt '*' postgres.tablespace_exists 'dbname'
```

New in version 2015.8.0.

salt.modules.postgres.tablespace_list (user=None, host=None, port=None, mainte-
nance_db=None, password=None, runas=None)

Return dictionary with information about tablespaces of a Postgres server.
CLI Example:

```
salt '*' postgres.tablespace_list
```

New in version 2015.8.0.

**salt.modules.postgres.tablespace_remove**(name, user=None, host=None, port=None, maintenance_db=None, password=None, runas=None)

Removes a tablespace from the Postgres server.

CLI Example:

```
salt '*' postgres.tablespace_remove tsname
```

New in version 2015.8.0.

**salt.modules.postgres.user_create**(username, user=None, host=None, port=None, maintenance_db=None, password=None, createdb=None, createroles=None, inherit=None, login=None, connlimit=None, encrypted=None, superuser=None, replication=None, rolepassword=None, groups=None, runas=None)

Creates a Postgres user.

CLI Examples:

```
salt '*' postgres.user_create 'username' user='user' \ host='hostname' port='port' password='password' \ rolepassword='rolepassword'
```

**salt.modules.postgres.user_exists**(name, user=None, host=None, port=None, maintenance_db=None, password=None, runas=None)

Checks if a user exists on the Postgres server.

CLI Example:

```
salt '*' postgres.user_exists 'username'
```

**salt.modules.postgres.user_list**(user=None, host=None, port=None, maintenance_db=None, password=None, runas=None, return_password=False)

Return a dict with information about users of a Postgres server.

Set return_password to True to get password hash in the result.

CLI Example:

```
salt '*' postgres.user_list
```

**salt.modules.postgres.user_remove**(username, user=None, host=None, port=None, maintenance_db=None, password=None, runas=None)

Removes a user from the Postgres server.

CLI Example:

```
salt '*' postgres.user_remove 'username'
```

**salt.modules.postgres.user_update**(username, user=None, host=None, port=None, maintenance_db=None, password=None, createdb=None, createroles=None, inherit=None, login=None, connlimit=None, encrypted=None, superuser=None, replication=None, rolepassword=None, groups=None, runas=None)
Updates a Postgres user.

CLI Examples:

```
salt '*' postgres.user_update 'username' user='user'
    host='hostname' port='port' password='password'
    rolepassword='rolepassword'
```

`salt.modules.postgres.version(user=None, host=None, port=None, maintenance_db=None, password=None, runas=None)`

Return the version of a Postgres server.

CLI Example:

```
salt '*' postgres.version
```

### 32.17.201 `salt.modules.poudriere`

Support for poudriere

`salt.modules.poudriere.bulk_build(jail, pkg_file, keep=False)`

Run bulk build on poudriere server.

Return number of pkg builds, failures, and errors, on error dump to CLI

CLI Example:

```
salt -N buildbox_group poudriere.bulk_build 90amd64 /root/pkg_list
```

`salt.modules.poudriere.create_jail(name, arch, version=`9.0-RELEASE`)`

Creates a new poudriere jail if one does not exist

**NOTE** creating a new jail will take some time the master is not hanging

CLI Example:

```
salt '*' poudriere.create_jail 90amd64 amd64
```

`salt.modules.poudriere.create_ports_tree()`

Not working need to run portfetch non interactive

`salt.modules.poudriere.delete_jail(name)`

Deletes poudriere jail with `name`

CLI Example:

```
salt '*' poudriere.delete_jail 90amd64
```

`salt.modules.poudriere.is_jail(name)`

Return True if jail exists False if not

CLI Example:

```
salt '*' poudriere.is_jail <jail name>
```

`salt.modules.poudriere.list_jails()`

Return a list of current jails managed by poudriere

CLI Example:
salt '*' poudriere.list_jails

salt.modules.poudriere.list_ports()
Return a list of current port trees managed by poudriere
CLI Example:

salt '*' poudriere.list_ports

salt.modules.poudriere.make_pkgng_aware(jname)
Make jail jname pkgng aware
CLI Example:

salt '*' poudriere.make_pkgng_aware <jail name>

salt.modules.poudriere.parse_config(config_file=None)
Returns a dict of poudriere main configuration definitions
CLI Example:

salt '*' poudriere.parse_config

salt.modules.poudriere.update_jail(name)
Run freebsd-update on name poudriere jail
CLI Example:

salt '*' poudriere.update_jail freebsd:10:x86:64

salt.modules.poudriere.update_ports_tree(ports_tree)
Updates the ports tree, either the default or the ports_tree specified
CLI Example:

salt '*' poudriere.update_ports_tree staging

salt.modules.poudriere.version()
Return poudriere version
CLI Example:

salt '*' poudriere.version

32.17.202 salt.modules.powerpath

powerpath support.
Assumes RedHat
salt.modules.powerpath.add_license(key)
Add a license
salt.modules.powerpath.has_powerpath()

salt.modules.powerpath.list_licenses()
returns a list of applied powerpath license keys
salt.modules.powerpath.remove_license(key)
Remove a license
32.17.203  salt.modules.ps

A salt interface to psutil, a system and process library. See http://code.google.com/p/psutil.

depends

• psutil Python module, version 0.3.0 or later
• python-utmp package (optional)

salt.modules.ps.boot_time(time_format=None)
Return the boot time in number of seconds since the epoch began.

CLI Example:

time_format  Optionally specify a strftime format string. Use time_format='%c' to get a nicely-formatted locale specific date and time (i.e. Fri May 2 19:08:32 2014).

New in version 2014.1.4.

salt '*' ps.boot_time

salt.modules.ps.cpu_percent(interval=0.1, per_cpu=False)
Return the percent of time the CPU is busy.

interval  the number of seconds to sample CPU usage over

per_cpu  if True return an array of CPU percent busy for each CPU, otherwise aggregate all percents into one number

CLI Example:

salt '*' ps.cpu_percent

salt.modules.ps.cpu_times(per_cpu=False)
Return the percent of time the CPU spends in each state, e.g. user, system, idle, nice, iowait, irq, softirq.

per_cpu  if True return an array of percents for each CPU, otherwise aggregate all percents into one number

CLI Example:

salt '*' ps.cpu_times

salt.modules.ps.disk_io_counters(device=None)
Return disk I/O statistics.

CLI Example:

salt '*' ps.disk_io_counters
salt '*' ps.disk_io_counters device=sda1

salt.modules.ps.disk_partition_usage(all=False)
Return a list of disk partitions plus the mount point, filesystem and usage statistics.

CLI Example:

salt '*' ps.disk_partition_usage

salt.modules.ps.disk_partitions(all=False)
Return a list of disk partitions and their device, mount point, and filesystem type.
all if set to False, only return local, physical partitions (hard disk, USB, CD/DVD partitions). If True, return all filesystems.

CLI Example:

```
salt '*' ps.disk_partitions
```

**salt.modules.ps.disk_usage**(path)
Given a path, return a dict listing the total available space as well as the free space, and used space.

CLI Example:

```
salt '*' ps.disk_usage /home
```

**salt.modules.ps.get_pid_list()**
Return a list of process ids (PIDs) for all running processes.

CLI Example:

```
salt '*' ps.get_pid_list
```

**salt.modules.ps.get_users()**
Return logged-in users.

CLI Example:

```
salt '*' ps.get_users
```

**salt.modules.ps.kill_pid**(pid, signal=15)
Kill a process by PID.

```
salt 'minion' ps.kill_pid pid [signal=signal_number]
```

*pid*  PID of process to kill.

*signal*  Signal to send to the process. See manpage entry for kill for possible values. Default: 15 (SIGTERM).

Example:

Send SIGKILL to process with PID 2000:

```
salt 'minion' ps.kill_pid 2000 signal=9
```

**salt.modules.ps.network_io_counters**(interface=None)
Return network I/O statistics.

CLI Example:

```
salt '*' ps.network_io_counters
```

```
salt '*' ps.network_io_counters interface=eth0
```

**salt.modules.ps.num_cpus()**
Return the number of CPUs.

CLI Example:

```
salt '*' ps.num_cpus
```

32.17. Full list of builtin execution modules
salt.modules.ps.pgrep(pattern, user=None, full=False)

Return the pids for processes matching a pattern.

If full is true, the full command line is searched for a match, otherwise only the name of the command is searched.

```
salt '*' ps.pgrep pattern [user=username] [full=(true|false)]
```

**pattern** Pattern to search for in the process list.

**user** Limit matches to the given username. Default: All users.

**full** A boolean value indicating whether only the name of the command or the full command line should be matched against the pattern.

**Examples:**

Find all httpd processes on all `www` minions:

```
salt 'www.*' ps.pgrep httpd
```

Find all bash processes owned by user `tom`:

```
salt '*' ps.pgrep bash user=tom
```

salt.modules.ps.pkill(pattern, user=None, signal=15, full=False)

Kill processes matching a pattern.

```
salt '*' ps.pkill pattern [user=username] [signal=signal_number] \ [full=(true|false)]
```

**pattern** Pattern to search for in the process list.

**user** Limit matches to the given username. Default: All users.

**signal** Signal to send to the process(es). See manpage entry for kill for possible values. Default: 15 (SIGTERM).

**full** A boolean value indicating whether only the name of the command or the full command line should be matched against the pattern.

**Examples:**

Send SIGHUP to all httpd processes on all `www` minions:

```
salt 'www.*' ps.pkill httpd signal=1
```

Send SIGKILL to all bash processes owned by user `tom`:

```
salt '*' ps.pkill bash signal=9 user=tom
```

salt.modules.ps.proc_info(pid, attrs=None)

Return a dictionary of information for a process id (PID).

**CLI Example:**

```
salt '*' ps.proc_info 2322
salt '*' ps.proc_info 2322 attrs=['"pid", "name"]'
```

**pid** PID of process to query.
**attrs** Optional list of desired process attributes. The list of possible attributes can be found here: http://pythonhosted.org/psutil/#psutil.Process

salt.modules.ps.swap_memory()

New in version 2014.7.0.

Return a dict that describes swap memory statistics.

**Note:** This function is only available in psutil version 0.6.0 and above.

CLI Example:

```
salt '*' ps.swap_memory
```

salt.modules.ps.top(num_processes=5, interval=3)

Return a list of top CPU consuming processes during the interval. num_processes = return the top N CPU consuming processes interval = the number of seconds to sample CPU usage over

CLI Examples:

```
salt '*' ps.top
salt '*' ps.top 5 10
```

salt.modules.ps.total_physical_memory()

Return the total number of bytes of physical memory.

CLI Example:

```
salt '*' ps.total_physical_memory
```

salt.modules.ps.virtual_memory()

New in version 2014.7.0.

Return a dict that describes statistics about system memory usage.

**Note:** This function is only available in psutil version 0.6.0 and above.

CLI Example:

```
salt '*' ps.virtual_memory
```

### 32.17.204 salt.modules.publish

Publish a command from a minion to a target

salt.modules.publish.full_data(tgt, fun, arg=None, expr_form='glob', returner='', timeout=5)

Return the full data about the publication, this is invoked in the same way as the publish function

CLI Example:

```
salt system.example.com publish.full_data '*' cmd.run 'ls -la /tmp'
```

**Attention**
If you need to pass a value to a function argument and that value contains an equal sign, you **must** include the argument name. For example:

```bash
salt '*' publish.full_data test.kwarg arg='cheese=spam'
```

**salt.modules.publish.publish** *(tgt, fun, arg=None, expr_form='glob', returner='*', timeout=5)*

Publish a command from the minion out to other minions.

Publications need to be enabled on the Salt master and the minion needs to have permission to publish the command. The Salt master will also prevent a recursive publication loop, this means that a minion cannot command another minion to command another minion as that would create an infinite command loop.

The `expr_form` argument is used to pass a target other than a glob into the execution, the available options are:

- `glob`
- `pcre`
- `grain`
- `grain_pcre`
- `pillar`
- `pillar_pcre`
- `ipcidr`
- `range`
- `compound`

Note that for pillar matches must be exact, both in the pillar matcher and the compound matcher. No globbing is supported.

The arguments sent to the minion publish function are separated with commas. This means that for a minion executing a command with multiple args it will look like this:

```bash
salt system.example.com publish.publish '*' user.add 'foo,1020,1020'
salt system.example.com publish.publish 'os:Fedora' network.interfaces '' grain
```

**CLI Example:**

```bash
salt system.example.com publish.publish '*' cmd.run 'ls -la /tmp'
```

---

**Attention**

If you need to pass a value to a function argument and that value contains an equal sign, you **must** include the argument name. For example:

```bash
salt '*' publish.publish test.kwarg arg='cheese=spam'
```

Multiple keyword arguments should be passed as a list.

```bash
salt '*' publish.publish test.kwarg arg,['cheese=spam','spam=cheese']
```

**salt.modules.publish.runner** *(fun, arg=None, timeout=5)*

Execute a runner on the master and return the data from the runner function.
32.17.205 salt.modules.puppet

Execute puppet routines

salt.modules.puppet.disable(message=None)

New in version 2014.7.0.

Disable the puppet agent

message New in version 2015.5.2.

Disable message to send to puppet

CLI Example:

```
salt '*' puppet.disable
salt '*' puppet.disable 'Disabled, contact XYZ before enabling'
```

salt.modules.puppet.enable()

New in version 2014.7.0.

Enable the puppet agent

CLI Example:

```
salt '*' puppet.enable
```

salt.modules.puppet.fact(name, puppet=False)

Run facter for a specific fact

CLI Example:

```
salt '*' puppet.fact kernel
```

salt.modules.puppet.facts(puppet=False)

Run facter and return the results

CLI Example:

```
salt '*' puppet.facts
```

salt.modules.puppet.noop(*args, **kwargs)

Execute a puppet noop run and return a dict with the stderr, stdout, return code, etc. Usage is the same as for puppet.run.

CLI Example:

```
salt '*' puppet.noop
salt '*' puppet.noop tags=basefiles::edit,apache::server
salt '*' puppet.noop debug
salt '*' puppet.noop apply /a/b/manifest.pp modulepath=/a/b/modules
    →tags=basefiles::edit,apache::server
```

salt.modules.puppet.plugin_sync()

Runs a plugin synch between the puppet master and agent
CLI Example: .. code-block:: bash

    salt '*' puppet.plugin_sync

salt.modules.puppet.run(`*args`, **kwargs)
Execute a puppet run and return a dict with the stderr, stdout, return code, etc. The first positional argument given is checked as a subcommand. Following positional arguments should be ordered with arguments required by the subcommand first, followed by non-keyword arguments. Tags are specified by a tag keyword and comma separated list of values. -- http://docs.puppetlabs.com/puppet/latest/reference/lang_tags.html

CLI Examples:

    salt '*' puppet.run
    salt '*' puppet.run tags=basefiles::edit,apache::server
    salt '*' puppet.run agent onetime no-daemonize no-usecacheonfailure no-splay ignorecache
    salt '*' puppet.run debug
    salt '*' puppet.run apply /a/b/manifest.pp modulepath=/a/b/modules tags=basefiles::edit,apache::server

salt.modules.puppet.status()
New in version 2014.7.0.
Display puppet agent status

CLI Example:

    salt '*' puppet.status

salt.modules.puppet.summary()
New in version 2014.7.0.
Show a summary of the last puppet agent run

CLI Example:

    salt '*' puppet.summary

32.17.206 salt.modules.pushover_notify

Module for sending messages to Pushover (https://www.pushover.net)

New in version Boron.

configuration This module can be used by either passing an api key and version directly or by specifying both in a configuration profile in the salt master/minion config.

For example:

    pushover:
        token: abAHuZyCLtdH8P4zhmFZmgUHUsv1ei8

salt.modules.pushover_notify.post_message(user=None, device=None, message=None, title=None, priority=None, expire=None, retry=None, sound=None, api_version=1, token=None)

Send a message to a Pushover user or group.

Parameters

- **user** -- The user or group to send to, must be key of user or group not email address.
- **message** -- The message to send to the PushOver user or group.
- **title** -- Specify who the message is from.
- **priority** -- The priority of the message, defaults to 0.
- **expire** -- The message should expire after N number of seconds.
- **retry** -- The number of times the message should be retried.
- **sound** -- The sound to associate with the message.
- **api_version** -- The PushOver API version, if not specified in the configuration.
- **token** -- The PushOver token, if not specified in the configuration.

**Returns**  Boolean if message was sent successfully.

CLI Example:

```bash
salt '*' pushover.post_message user='xxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx' title='Message from Salt' message='Build is done'
salt '*' pushover.post_message user='xxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx' title='Message from Salt' message='Build is done' priority='2' expire='720' retry='5'
```

### 32.17.207 salt.modules.pw_group

Manage groups on FreeBSD

**Important:** If you feel that Salt should be using this module to manage groups on a minion, and it is using a different module (or gives an error similar to 'group.info' is not available), see [here](#).

#### salt.modules.pw_group.add(name, gid=None, **kwargs)
Add the specified group

CLI Example:

```bash
salt '*' group.add foo 3456
```

#### salt.modules.pw_group.chgid(name, gid)
Change the gid for a named group

CLI Example:

```bash
salt '*' group.chgid foo 4376
```

#### salt.modules.pw_group.delete(name)
Remove the named group

CLI Example:

```bash
salt '*' group.delete foo
```

#### salt.modules.pw_group.getent(refresh=False)
Return info on all groups

CLI Example:
salt '*' group.getent

**salt.modules.pw_group.info**(name)
Return information about a group

   CLI Example:
   
   salt '*' group.info foo

**salt.modules.pw_group.members**(name, members_list)
Replaces members of the group with a provided list.

New in version 2015.5.4.

   CLI Example:
   
   salt '*' group.members foo `user1,user2,user3,...`

   Replaces a membership list for a local group `foo'.

### 32.17.208 salt.modules.pw_user

Manage users with the useradd command

**Important:** If you feel that Salt should be using this module to manage users on a minion, and it is using a different module (or gives an error similar to `user.info` is not available), see [here](#).

**salt.modules.pw_user.add**(name, uid=None, gid=None, groups=None, home=None, shell=None, unique=True, fullname='`, roomnumber='`, workphone='`, homephone='`, createhome=True, **kwargs)
Add a user to the minion

   CLI Example:
   
   salt '*' user.add name <uid> <gid> <groups> <home> <shell>

**salt.modules.pw_user.chfullname**(name, fullname)
Change the user's Full Name

   CLI Example:
   
   salt '*' user.chfullname foo "Foo Bar"

**salt.modules.pw_user.chgid**(name, gid)
Change the default group of the user

   CLI Example:
   
   salt '*' user.chgid foo 4376

**salt.modules.pw_user.chgroups**(name, groups, append=False)
Change the groups this user belongs to, add append to append the specified groups

   CLI Example:
   
   salt '*' user.chgroups foo wheel,root True
salt.modules.pw_user.chhome(name, home, persist=False)
  Change the home directory of the user, pass true for persist to copy files to the new home dir
  CLI Example:
  ```
salt '*' user.chhome foo /home/users/foo True
  ```

salt.modules.pw_user.chhomephone(name, homephone)
  Change the user's Home Phone
  CLI Example:
  ```
salt '*' user.chhomephone foo "7735551234"
  ```

salt.modules.pw_user.chroomnumber(name, roomnumber)
  Change the user's Room Number
  CLI Example:
  ```
salt '*' user.chroomnumber foo 123
  ```

salt.modules.pw_user.chshell(name, shell)
  Change the default shell of the user
  CLI Example:
  ```
salt '*' user.chshell foo /bin/zsh
  ```

salt.modules.pw_user.chuid(name, uid)
  Change the uid for a named user
  CLI Example:
  ```
salt '*' user.chuid foo 4376
  ```

salt.modules.pw_user.chworkphone(name, workphone)
  Change the user's Work Phone
  CLI Example:
  ```
salt '*' user.chworkphone foo "7735550123"
  ```

salt.modules.pw_user.delete(name, remove=False, force=False)
  Remove a user from the minion
  CLI Example:
  ```
salt '*' user.delete name remove=True force=True
  ```

salt.modules.pw_user.getent(refresh=False)
  Return the list of all info for all users
  CLI Example:
  ```
salt '*' user.getent
  ```

salt.modules.pw_user.info(name)
  Return user information
  CLI Example:
salt 'salt '*' user.info root

salt.modules.pw_user.list_groups(name)
   Return a list of groups the named user belongs to
   CLI Example:
   salt 'salt '*' user.list_groups foo

salt.modules.pw_user.list_users()
   Return a list of all users
   CLI Example:
   salt 'salt '*' user.list_users

salt.modules.pw_user.rename(name, new_name)
   Change the username for a named user
   CLI Example:
   salt 'salt '*' user.rename name new_name

32.17.209 salt.modules.pyenv

Manage python installations with pyenv.
New in version v2014.04.

salt.modules.pyenv.default(python=None, runas=None)
   Returns or sets the currently defined default python.
   python=None The version to set as the default. Should match one of the versions listed by
   pyenv.versions. Leave blank to return the current default.
   CLI Example:
   salt 'salt '*' pyenv.default
   salt 'salt '*' pyenv.default 2.0.0-p0

salt.modules.pyenv.do(cmdline=None, runas=None)
   Execute a python command with pyenv's shims from the user or the system.
   CLI Example:
   salt 'salt '*' pyenv.do 'gem list bundler'
salt 'salt '*' pyenv.do 'gem list bundler' deploy

salt.modules.pyenv.do_with_python(python, cmdline, runas=None)
   Execute a python command with pyenv's shims using a specific python version.
   CLI Example:
   salt 'salt '*' pyenv.do_with_python 2.0.0-p0 'gem list bundler'
salt 'salt '*' pyenv.do_with_python 2.0.0-p0 'gem list bundler' deploy

salt.modules.pyenv.install(runas=None, path=None)
   Install pyenv systemwide
CLI Example:

```text
salt '*' pyenv.install
```

**salt.modules.pyenv.install_python**(python, runas=None)
Install a python implementation.
- **python** The version of python to install, should match one of the versions listed by `pyenv.list`

CLI Example:

```text
salt '*' pyenv.install_python 2.0.0-p0
```

**salt.modules.pyenv.is_installed**(runas=None)
Check if pyenv is installed.

CLI Example:

```text
salt '*' pyenv.is_installed
```

**salt.modules.pyenv.list**(runas=None)
List the installable versions of python.

CLI Example:

```text
salt '*' pyenv.list
```

**salt.modules.pyenv.rehash**(runas=None)
Run pyenv rehash to update the installed shims.

CLI Example:

```text
salt '*' pyenv.rehash
```

**salt.modules.pyenv.uninstall_python**(python, runas=None)
Uninstall a python implementation.
- **python** The version of python to uninstall. Should match one of the versions listed by `pyenv.versions`

CLI Example:

```text
salt '*' pyenv.uninstall_python 2.0.0-p0
```

**salt.modules.pyenv.update**(runas=None, path=None)
Updates the current versions of pyenv and python-Build

CLI Example:

```text
salt '*' pyenv.update
```

**salt.modules.pyenv.versions**(runas=None)
List the installed versions of python.

CLI Example:

```text
salt '*' pyenv.versions
```
32.17.210  salt.modules.qemu_img

Qemu-img Command Wrapper

The qemu-img command is wrapped for specific functions

```python
depends qemu-img

salt.modules.qemu_img.make_image(location, size, fmt)

Create a blank virtual machine image file of the specified size in megabytes. The image can be created in any format supported by qemu

CLI Example:

```bash
salt '*' qemu_img.make_image /tmp/image.qcow 2048 qcow2
salt '*' qemu_img.make_image /tmp/image.raw 10240 raw
```

32.17.211  salt.modules.qemu_nbd

Qemu Command Wrapper

The qemu system comes with powerful tools, such as qemu-img and qemu-nbd which are used here to build up kvm images.

```python
salt.modules.qemu_nbd.clear(mnt)

Pass in the mnt dict returned from nbd_mount to unmount and disconnect the image from nbd. If all of the partitions are unmounted return an empty dict, otherwise return a dict containing the still mounted partitions

CLI Example:

```bash
salt '*' qemu_nbd.clear '{{"/mnt/foo": "/dev/nbd0p1"}}'
```

salt.modules.qemu_nbd.connect(image)

Activate nbd for an image file.

CLI Example:

```bash
salt '*' qemu_nbd.connect /tmp/image.raw
```

salt.modules.qemu_nbd.init(image)

Mount the named image via qemu-nbd and return the mounted roots

CLI Example:

```bash
salt '*' qemu_nbd.init /srv/image.qcow2
```

salt.modules.qemu_nbd.mount(nbd)

Pass in the nbd connection device location, mount all partitions and return a dict of mount points

CLI Example:

```bash
salt '*' qemu_nbd.mount /dev/nbd0
```

32.17.212  salt.modules.quota

Module for managing quotas on POSIX-like systems.
salt.modules.quota.get_mode(device)
    Report whether the quota system for this device is on or off

    CLI Example:
    ```
salt '*' quota.get_mode
    ```

salt.modules.quota.off(device)
    Turns off the quota system

    CLI Example:
    ```
salt '*' quota.off
    ```

salt.modules.quota.on(device)
    Turns on the quota system

    CLI Example:
    ```
salt '*' quota.on
    ```

salt.modules.quota.report(mount)
    Report on quotas for a specific volume

    CLI Example:
    ```
salt '*' quota.report /media/data
    ```

salt.modules.quota.set(device, **kwargs)
    Calls out to setquota, for a specific user or group

    CLI Example:
    ```
salt '*' quota.set /media/data user=larry block-soft-limit=1048576
salt '*' quota.set /media/data group=painters file-hard-limit=1000
    ```

salt.modules.quota.stats()
    Runs the quotastats command, and returns the parsed output

    CLI Example:
    ```
salt '*' quota.stats
    ```

salt.modules.quota.warn()
    Runs the warnquota command, to send warning emails to users who are over their quota limit.

    CLI Example:
    ```
salt '*' quota.warn
    ```

32.17.213  salt.modules.rabbitmq

Module to provide RabbitMQ compatibility to Salt. Todo: A lot, need to add cluster support, logging, and minion configuration data.

salt.modules.rabbitmq.add_user(name, password=None, runas=None)
    Add a rabbitMQ user via rabbitmqctl user_add <user> <password>

    CLI Example:
salt '*' rabbitmq.add_user rabbit_user password

salt.modules.rabbitmq.add_vhost(vhost, runas=None)
    Adds a vhost via rabbitmqctl add_vhost.
    CLI Example:
    salt '*' rabbitmq.add_vhost '<vhost_name>'

salt.modules.rabbitmq.change_password(name, password, runas=None)
    Changes a user's password.
    CLI Example:
    salt '*' rabbitmq.change_password rabbit_user password

salt.modules.rabbitmq.clear_password(name, runas=None)
    Removes a user's password.
    CLI Example:
    salt '*' rabbitmq.clear_password rabbit_user

salt.modules.rabbitmq.cluster_status(runas=None)
    return rabbitmq cluster_status
    CLI Example:
    salt '*' rabbitmq.cluster_status

salt.modules.rabbitmq.delete_policy(vhost, name, runas=None)
    Delete a policy based on rabbitmqctl clear_policy.
    Reference: http://www.rabbitmq.com/ha.html
    CLI Example:
    salt '*' rabbitmq.delete_policy / HA'

salt.modules.rabbitmq.delete_user(name, runas=None)
    Deletes a user via rabbitmqctl delete_user.
    CLI Example:
    salt '*' rabbitmq.delete_user rabbit_user

salt.modules.rabbitmq.delete_vhost(vhost, runas=None)
    Deletes a vhost rabbitmqctl delete_vhost.
    CLI Example:
    salt '*' rabbitmq.delete_vhost '<vhost_name>'

salt.modules.rabbitmq.disable_plugin(name, runas=None)
    Disable a RabbitMQ plugin via the rabbitmq-plugins command.
    CLI Example:
    salt '*' rabbitmq.disable_plugin foo
salt.modules.rabbitmq.enable_plugin(name, runas=None)

Enable a RabbitMQ plugin via the rabbitmq-plugins command.

CLI Example:

```
salt '*' rabbitmq.enable_plugin foo
```

salt.modules.rabbitmq.force_reset(runas=None)

Forcefully Return a RabbitMQ node to its virgin state.

CLI Example:

```
salt '*' rabbitmq.force_reset
```

salt.modules.rabbitmq.join_cluster(host, user='rabbit', ram_node=None, runas=None)

Join a rabbit cluster.

CLI Example:

```
salt '*' rabbitmq.join_cluster 'rabbit.example.com' 'rabbit'
```

salt.modules.rabbitmq.list_permissions(vhost, runas=None)

Lists permissions for vhost via rabbitmqctl list_permissions.

CLI Example:

```
salt '*' rabbitmq.list_permissions '/myvhost'
```

salt.modules.rabbitmq.list_policies(vhost='/', runas=None)

Return a dictionary of policies nested by vhost and name based on the data returned from rabbitmqctl list_policies.

CLI Example:

```
salt '*' rabbitmq.list_policies'
```

salt.modules.rabbitmq.list_queues(runas=None, **kwargs)

Returns queue details of the / virtual host.

CLI Example:

```
salt '*' rabbitmq.list_queues messages consumers
```

salt.modules.rabbitmq.list_queues_vhost(vhost, runas=None, **kwargs)

Returns queue details of specified virtual host. This command will consider first parameter as the vhost name and rest will be treated as queueinfoitem. For getting details on vhost /, use list_queues instead.

CLI Example:

```
salt '*' rabbitmq.list_queues_vhost'
```

salt.modules.rabbitmq.list_user_permissions(name, runas=None)

List permissions for a user via rabbitmqctl list_user_permissions.

CLI Example:

```
salt '*' rabbitmq.list_user_permissions 'user'
```
salt.modules.rabbitmq.list_users(runas=None)
Return a list of users based off of rabbitmqctl user_list.
CLI Example:
```
salt '*' rabbitmq.list_users
```

salt.modules.rabbitmq.list_vhosts(runas=None)
Return a list of vhost based on rabbitmqctl list_vhosts.
CLI Example:
```
salt '*' rabbitmq.list_vhosts
```

salt.modules.rabbitmq.plugin_is_enabled(name, runas=None)
Return whether the plugin is enabled.
CLI Example:
```
salt '*' rabbitmq.plugin_is_enabled foo
```

salt.modules.rabbitmq.policy_exists(vhost, name, runas=None)
Return whether the policy exists based on rabbitmqctl list_policies.
Reference: http://www.rabbitmq.com/ha.html
CLI Example:
```
salt '*' rabbitmq.policy_exists / HA
```

salt.modules.rabbitmq.reset(runas=None)
Return a RabbitMQ node to its virgin state
CLI Example:
```
salt '*' rabbitmq.reset
```

salt.modules.rabbitmq.set_permissions(vhost, user, conf='.*', write='.*', read='.*', runas=None)
Sets permissions for vhost via rabbitmqctl set_permissions
CLI Example:
```
salt '*' rabbitmq.set_permissions 'myvhost' 'myuser'
```

salt.modules.rabbitmq.set_policy(vhost, name, pattern, definition, priority=None, runas=None)
Set a policy based on rabbitmqctl set_policy.
Reference: http://www.rabbitmq.com/ha.html
CLI Example:
```
salt '*' rabbitmq.set_policy / HA '.*' '{"ha-mode":"all"}'
```

salt.modules.rabbitmq.set_user_tags(name, tags, runas=None)
Add user tags via rabbitmqctl set_user_tags
CLI Example:
```
salt '*' rabbitmq.set_user_tags 'myadmin' 'administrator'
```
salt.modules.rabbitmq.start_app(runas=None)
Start the RabbitMQ application.

CLI Example:
salt '*' rabbitmq.start_app

salt.modules.rabbitmq.status(runas=None)
return rabbitmq status

CLI Example:
salt '*' rabbitmq.status

salt.modules.rabbitmq.stop_app(runas=None)
Stops the RabbitMQ application, leaving the Erlang node running.

CLI Example:
salt '*' rabbitmq.stop_app

salt.modules.rabbitmq.user_exists(name, runas=None)
Return whether the user exists based on rabbitmqctl list_users.

CLI Example:
salt '*' rabbitmq.user_exists rabbit_user

salt.modules.rabbitmq.vhost_exists(name, runas=None)
Return whether the vhost exists based on rabbitmqctl list_vhosts.

CLI Example:
salt '*' rabbitmq.vhost_exists rabbit_host

32.17.214 salt.modules.raet_publish
Publish a command from a minion to a target

salt.modules.raet_publish.full_data(tgt, fun, arg=None, expr_form='glob', returner='', timeout=5)
Return the full data about the publication, this is invoked in the same way as the publish function

CLI Example:
salt system.example.com publish.full_data '*' cmd.run 'ls -la /tmp'

Attention
If you need to pass a value to a function argument and that value contains an equal sign, you must include the argument name. For example:
salt '*' publish.full_data test.kwarg arg='cheese=spam'

salt.modules.raet_publish.publish(tgt, fun, arg=None, expr_form='glob', returner=' ', timeout=5)
Publish a command from the minion out to other minions.
Publications need to be enabled on the Salt master and the minion needs to have permission to publish the command. The Salt master will also prevent a recursive publication loop, this means that a minion cannot command another minion to command another minion as that would create an infinite command loop.

The `expr_form` argument is used to pass a target other than a glob into the execution, the available options are:

- `glob`
- `pcre`
- `grain`
- `grain_pcre`
- `pillar`
- `pillar_pcre`
- `ipcidr`
- `range`
- `compound`

The arguments sent to the minion publish function are separated with commas. This means that for a minion executing a command with multiple args it will look like this:

```
salt system.example.com publish.publish '*' user.add 'foo,1020,1020'
salt system.example.com publish.publish 'os:Fedora' network.interfaces '' grain
```

CLI Example:

```
salt system.example.com publish.publish '*' cmd.run 'ls -la /tmp'
```

**Attention**

If you need to pass a value to a function argument and that value contains an equal sign, you **must** include the argument name. For example:

```
salt '*' publish.publish test.kwarg arg='cheese=spam'
```

```python
salt.modules.raet_publish.runner(fun, arg=None, timeout=5)
```

Execute a runner on the master and return the data from the runner function

CLI Example:

```
salt publish.runner manage.down
```

### 32.17.215 `salt.modules.rallydev`

Support for RallyDev

New in version 2015.8.0.

Requires a username and a password in `/etc/salt/minion`:

```python
salt.modules.rallydev.list_items(name)
```

List items of a particular type
CLI Examples:

```
salt myminion rallydev.list_<item name>s
salt myminion rallydev.list_users
salt myminion rallydev.list_artifacts
```

```python
salt.modules.rallydev.list_users()
```
List the users

CLI Example:

```
salt myminion rallydev.list_users
```

```python
salt.modules.rallydev.query_item(name, query_string, order='Rank')
```
Query a type of record for one or more items. Requires a valid query string. See https://rally1.rallydev.com/slm/doc/webservice/introduction.jsp for information on query syntax.

CLI Example:

```
salt myminion rallydev.query_<item name> <query string>
```

```python
salt.modules.rallydev.query_user(query_string, order='UserName')
```
Update a user

CLI Example:

```
salt myminion rallydev.query_user '(Name contains Jo)'
```

```python
salt.modules.rallydev.show_artifact(id_)
```
Show an artifact

CLI Example:

```
salt myminion rallydev.show_artifact <artifact id>
```

```python
salt.modules.rallydev.show_item(name, id_)
```
Show an item

CLI Example:

```
salt myminion rallydev.show_<item name> <item id>
```

```python
salt.modules.rallydev.show_user(id_)
```
Show a user

CLI Example:

```
salt myminion rallydev.show_user <user id>
```

```python
salt.modules.rallydev.update_item(name, id_, field=None, value=None, postdata=None)
```
Update an item. Either a field and a value, or a chunk of POST data, may be used, but not both.

CLI Example:

```
salt myminion rallydev.update_<item name> <item id> field=<field> value=<value>
salt myminion rallydev.update_<item name> <item id> postdata=<post data>
```
salt.modules.rallydev.update_user(id, field, value)

Update a user

CLI Example:
salt myminion rallydev.update_user <user id> <field> <new value>

32.17.216 salt.modules.random_org

Module for retrieving random information from Random.org

New in version 2015.5.0.

configuration This module can be used by either passing an api key and version directly or by specifying both in a configuration profile in the salt master/minion config.

For example:

```yaml
random_org:
  api_key: 7be1402d-5719-5bd3-a306-3def9f135da5
  api_version: 1
```

salt.modules.random_org.generateBlobs(api_key=None, api_version=None, **kwargs)

List all Slack users.

Parameters

- **api_key** -- The Random.org api key.
- **api_version** -- The Random.org api version.
- **format** -- Specifies the format in which the blobs will be returned. Values allowed are base64 and hex.

Returns The user list.

CLI Example:

```bash
salt '*' get_integers number=5 min=1 max=6
salt '*' get_integers number=5 min=1 max=6
```

salt.modules.random_org.generateDecimalFractions(api_key=None, api_version=None, **kwargs)

Generates true random decimal fractions

Parameters

- **api_key** -- The Random.org api key.
- **api_version** -- The Random.org api version.
- **number** -- How many random decimal fractions you need. Must be within the [1,1e4] range.
- **decimalPlaces** -- The number of decimal places to use. Must be within the [1,20] range.
- **replacement** -- Specifies whether the random numbers should be picked with replacement. The default (true) will cause the numbers to be picked with replacement, i.e., the resulting numbers may contain duplicate values (like a series of dice rolls). If you want the numbers picked to be unique (like raffle tickets drawn from a container), set this value to false.
Returns  A list of decimal fraction

CLI Example:

```
salt '*' random_org.generateDecimalFractions number=10 decimalPlaces=4
salt '*' random_org.generateDecimalFractions number=10 decimalPlaces=4
```

salt.modules.random_org.generateGaussians (api_key=None, api_version=None, **kwargs)

This method generates true random numbers from a Gaussian distribution (also known as a normal distribution).

Parameters

- **api_key** -- The Random.org api key.
- **api_version** -- The Random.org api version.
- **number** -- How many random numbers you need. Must be within the [1,1e4] range.
- **mean** -- The distribution's mean. Must be within the [-1e6,1e6] range.
- **standardDeviation** -- The distribution's standard deviation. Must be within the [-1e6,1e6] range.
- **significantDigits** -- The number of significant digits to use. Must be within the [2,20] range.

Returns  The user list.

CLI Example:

```
salt '*' random_org.generateGaussians number=10 mean=0.0 standardDeviation=1.0
   replacement=True
```

salt.modules.random_org.generateIntegers (api_key=None, api_version=None, **kwargs)

Generate random integers

Parameters

- **api_key** -- The Random.org api key.
- **api_version** -- The Random.org api version.
- **number** -- The number of integers to generate
- **minimum** -- The lower boundary for the range from which the random numbers will be picked. Must be within the [-1e9,1e9] range.
- **maximum** -- The upper boundary for the range from which the random numbers will be picked. Must be within the [-1e9,1e9] range.
- **replacement** -- Specifies whether the random numbers should be picked with replacement. The default (true) will cause the numbers to be picked with replacement, i.e., the resulting numbers may contain duplicate values (like a series of dice rolls). If you want the numbers picked to be unique (like raffle tickets drawn from a container), set this value to false.
- **base** -- Specifies the base that will be used to display the numbers. Values allowed are 2, 8, 10 and 16. This affects the JSON types and formatting of the resulting data as discussed below.

Returns  A list of integers.
CLI Example:

```
salt '*' random_org.generateIntegers  number=5  minimum=1  maximum=6
salt '*' random_org.generateIntegers  number=5  minimum=2  maximum=255  base=2
```

salt.modules.random_org.generateStrings

Generate random strings.

Parameters

- **api_key** -- The Random.org api key.
- **api_version** -- The Random.org api version.
- **number** -- The number of strings to generate.
- **length** -- The length of each string. Must be within the [1,20] range. All strings will be of the same length
- **characters** -- A string that contains the set of characters that are allowed to occur in the random strings. The maximum number of characters is 80.
- **replacement** -- Specifies whether the random strings should be picked with replacement. The default (true) will cause the strings to be picked with replacement, i.e., the resulting list of strings may contain duplicates (like a series of dice rolls). If you want the strings to be unique (like raffle tickets drawn from a container), set this value to false.

Returns
A list of strings.

CLI Example:

```
salt '*' random_org.generateStrings  number=5  length=8  characters='abcdefghijklmnopqrstuvwxyz'
salt '*' random_org.generateStrings  number=10  length=16  characters='abcdefghijklmnopqrstuvwxyz'
```

salt.modules.random_org.generateUUIDs

Generate a list of random UUIDs.

Parameters

- **api_key** -- The Random.org api key.
- **api_version** -- The Random.org api version.
- **number** -- How many random UUIDs you need. Must be within the [1,1e3] range.

Returns
A list of UUIDs.

CLI Example:

```
salt '*' random_org.generateUUIDs  number=5
```

salt.modules.random_org.getUsage

Show current usages statistics.

Parameters

- **api_key** -- The Random.org api key.
- **api_version** -- The Random.org api version.

Returns
The current usage statistics.
32.17.217 salt.modules.rbenv

Manage ruby installations with rbenv. Rbenv is supported on Linux and Mac OS X. Rbenv doesn't work on Windows (and isn't really necessary on Windows as there is no system Ruby on Windows). On Windows, the RubyInstaller and/or Pik are both good alternatives to work with multiple versions of Ruby on the same box.

http://misheska.com/blog/2013/06/15/using-rbenv-to-manage-multiple-versions-of-ruby/

New in version 0.16.0.

salt.modules.rbenv.default(ruby=None, runas=None)
Returns or sets the currently defined default ruby.

    ruby=None The version to set as the default. Should match one of the versions listed by rbenv.versions. Leave blank to return the current default.

    CLI Example:

        salt '*' rbenv.default
        salt '*' rbenv.default 2.0.0-p0

salt.modules.rbenv.do(cmdline=None, runas=None, env=None)
Execute a ruby command with rbenv's shims from the user or the system.

    CLI Example:

        salt '*' rbenv.do 'gem list bundler'
        salt '*' rbenv.do 'gem list bundler' deploy

salt.modules.rbenv.do_with_ruby(ruby, cmdline, runas=None)
Execute a ruby command with rbenv's shims using a specific ruby version.

    CLI Example:

        salt '*' rbenv.do_with_ruby 2.0.0-p0 'gem list bundler'
        salt '*' rbenv.do_with_ruby 2.0.0-p0 'gem list bundler' deploy

salt.modules.rbenv.install(runas=None, path=None)
Install Rbenv systemwide

    CLI Example:

        salt '*' rbenv.install

salt.modules.rbenv.install_ruby(ruby, runas=None)
Install a ruby implementation.

    ruby The version of Ruby to install, should match one of the versions listed by rbenv.list

    Additional environment variables can be configured in pillar / grains / master:

        rbenv:
            build_env: 'CONFIGURE_OPTS="--no-tcmalloc" CFLAGS="-fno-tree-dce"'

32.17. Full list of builtin execution modules

1319
**CLI Example:**
```
salt '*' rbenv.install_ruby 2.0.0-p0
```

**salt.modules.rbenv.is_installed(runas=None)**
Check if Rbenv is installed.

**CLI Example:**
```
salt '*' rbenv.is_installed
```

**salt.modules.rbenv.list(runas=None)**
List the installable versions of ruby.

**CLI Example:**
```
salt '*' rbenv.list
```

**salt.modules.rbenv.rehash(runas=None)**
Run rbenv rehash to update the installed shims.

**CLI Example:**
```
salt '*' rbenv.rehash
```

**salt.modules.rbenv.uninstall_ruby(ruby, runas=None)**
Uninstall a ruby implementation.

- **ruby** The version of ruby to uninstall. Should match one of the versions listed by `rbenv.versions`

**CLI Example:**
```
salt '*' rbenv.uninstall_ruby 2.0.0-p0
```

**salt.modules.rbenv.update(runas=None, path=None)**
Updates the current versions of Rbenv and Ruby-Build

**CLI Example:**
```
salt '*' rbenv.update
```

**salt.modules.rbenv.versions(runas=None)**
List the installed versions of ruby.

**CLI Example:**
```
salt '*' rbenv.versions
```

### 32.17.218 salt.modules.rdp

Manage RDP Service on Windows servers

**salt.modules.rdp.disable()**
Disable RDP the service on the server

**CLI Example:**
```
salt '*' rdp.disable```
salt.modules.rdp.enable()
Enable RDP the service on the server

CLI Example:
```
salt '*' rdp.enable
```

salt.modules.rdp.status()
Show if rdp is enabled on the server

CLI Example:
```
salt '*' rdp.status
```

32.17.219 salt.modules.redis

Module to provide redis functionality to Salt
New in version 2014.7.0.

configuration This module requires the redis python module and uses the following defaults which may be overridden in the minion configuration:

```
redis.host: 'localhost'
redis.port: 6379
redis.db: 0
redis.password: None
```

salt.modules.redismod.bgrewriteaof( host=host, port=port, db=db, password=password )
Asynchronously rewrite the append-only file

CLI Example:
```
salt '*' redis.bgrewriteaof
```

salt.modules.redismod.bgsave( host=host, port=port, db=db, password=password )
Asynchronously save the dataset to disk

CLI Example:
```
salt '*' redis.bgsave
```

salt.modules.redismod.config_get( pattern='', host=host, port=port, db=db, password=password )
Get redis server configuration values

CLI Example:
```
salt '*' redis.config_get
salt '*' redis.config_get port
```

salt.modules.redismod.config_set( name, value, host=host, port=port, db=db, password=password )
Set redis server configuration values

CLI Example:
```
salt '*' redis.config_set masterauth luv_kittens
```
salt.modules.redismod.dbsize(host=None, port=None, db=None, password=None)
Return the number of keys in the selected database

CLI Example:
```
salt '*' redis.dbsize
```

salt.modules.redismod.delete(*keys, **connection_args)
Deletes the keys from redis, returns number of keys deleted

CLI Example:
```
salt '*' redis.delete foo
```

salt.modules.redismod.exists(key, host=None, port=None, db=None, password=None)
Return true if the key exists in redis

CLI Example:
```
salt '*' redis.exists foo
```

salt.modules.redismod.expire(key, seconds, host=None, port=None, db=None, password=None)
Set a keys time to live in seconds

CLI Example:
```
salt '*' redis.expire foo 300
```

salt.modules.redismod.expireat(key, timestamp, host=None, port=None, db=None, password=None)
Set a keys expire at given UNIX time

CLI Example:
```
salt '*' redis.expireat foo 1400000000
```

salt.modules.redismod.flushall(host=None, port=None, db=None, password=None)
Remove all keys from all databases

CLI Example:
```
salt '*' redis.flushall
```

salt.modules.redismod.flushdb(host=None, port=None, db=None, password=None)
Remove all keys from the selected database

CLI Example:
```
salt '*' redis.flushdb
```

salt.modules.redismod.get_key(key, host=None, port=None, db=None, password=None)
Get redis key value

CLI Example:
```
salt '*' redis.get_key foo
```

salt.modules.redismod.hget(key, field, host=None, port=None, db=None, password=None)
Get specific field value from a redis hash, returns dict

CLI Example:
salt.modules.redismod.hgetall

Get all fields and values from a redis hash, returns dict

CLI Example:

```
salt '*' redis.hgetall foo_hash
```

salt.modules.redismod.info

Get information and statistics about the server

CLI Example:

```
salt '*' redis.info
```

salt.modules.redismod.key_type

Get redis key type

CLI Example:

```
salt '*' redis.type foo
```

salt.modules.redismod.keys

Get redis keys, supports glob style patterns

CLI Example:

```
salt '*' redis.keys
salt '*' redis.keys test*
```

salt.modules.redismod.lrange

Get a range of values from a list inRedis

CLI Example:

```
salt '*' redis.lrange foo_list 0 10
```

salt.modules.redismod.ping

Ping the server, returns False on connection errors

CLI Example:

```
salt '*' redis.ping
```
salt.modules.redismod.save(host=None, port=None, db=None, password=None)
Synchronously save the dataset to disk

CLI Example:
```
salt '*' redis.save
```

salt.modules.redismod.set_key(key, value, host=None, port=None, db=None, password=None)
Set redis key value

CLI Example:
```
salt '*' redis.set_key foo bar
```

salt.modules.redismod.shutdown(host=None, port=None, db=None, password=None)
Synchronously save the dataset to disk and then shut down the server

CLI Example:
```
salt '*' redis.shutdown
```

salt.modules.redismod.slaveof(master_host=None, master_port=None, host=None, port=None, db=None, password=None)
Make the server a slave of another instance, or promote it as master

CLI Example:
```
# Become slave of redis-n01.example.com:6379
salt '*' redis.slaveof redis-n01.example.com 6379
salt '*' redis.slaveof redis-n01.example.com
# Become master
salt '*' redis.slaveof
```

salt.modules.redismod.smembers(key, host=None, port=None, db=None, password=None)
Get members in a Redis set

CLI Example:
```
salt '*' redis.smembers foo_set
```

salt.modules.redismod.time(host=None, port=None, db=None, password=None)
Return the current server UNIX time in seconds

CLI Example:
```
salt '*' redis.time
```

salt.modules.redismod.zcard(key, host=None, port=None, db=None, password=None)
Get the length of a sorted set in Redis

CLI Example:
```
salt '*' redis.zcard foo_sorted
```

salt.modules.redismod.zrange(key, start, stop, host=None, port=None, db=None, password=None)
Get a range of values from a sorted set in Redis by index

CLI Example:
32.17.220 salt.modules.reg

Manage the Windows registry

The read_key and set_key functions will be updated in Boron to reflect proper registry usage. The registry has three main components. Hives, Keys, and Values.

Hives

Hives are the main sections of the registry and all begin with the word HKEY. - HKEY_LOCAL_MACHINE - HKEY_CURRENT_USER - HKEY_USER

Keys

Keys are the folders in the registry. Keys can have many nested subkeys. Keys can have a value assigned to them under the (Default)

Values or Entries

Values/Entries are name/data pairs. There can be many values in a key. The (Default) value corresponds to the Key, the rest are their own value pairs.

depends

- winreg Python module

class salt.modules.reg.Registry
    Delay `_winreg` usage until this module is used

class salt.modules.reg.broadcast_change()
    Refresh the windows environment. :return:

class salt.modules.reg.create_key(hkey, path, key=None, value=None, reflection=True, use_32bit_registry=False)

**Important:** The name of this function is misleading and will be changed to reflect proper usage in the Boron release of Salt. The path option will be removed and the key will be the actual key. See the following issue:

https://github.com/saltstack/salt/issues/25618

In order to not break existing state files this function will call the set_value function if key is passed. Key will be passed as the value name. If key is not passed, this function will return the default value for the key.

In the Boron release path will be removed and key will be the path. You will not pass value.

Create a registry key

CLI Example:
Important: The name of this function is misleading and will be changed to reflect proper usage in the Boron release of Salt. The path option will be removed and the key will be the actual key. See the following issue: https://github.com/saltstack/salt/issues/25618

In order to not break existing state files this function will call the delete_value function if a key is passed. Key will be passed as the value name. If key is not passed, this function will return the default value for the key. In the Boron release path will be removed and key will be the path. reflection will also be removed.

Delete a registry key

CLI Example:

```
salt '*' reg.delete_key HKEY_CURRENT_USER 'SOFTWARE\Salt'
```

Parameters

- **hkey** (*str*) -- (will be changed to hive) The name of the hive. Can be one of the following
  - HKEY_LOCAL_MACHINE or HKLM
  - HKEY_CURRENT_USER or HKCU
  - HKEY_USER or HKU

- **path** (*str*) -- (will be changed to key) The key (looks like a path) to remove.

Parameters

- **key** (*str*) -- (used incorrectly) Will be removed in Boron

- **reflection** (*bool*) -- A boolean value indicating that the value should also be removed from the Wow6432Node portion of the registry. Only applies to 64 bit Windows. This setting is ignored for 32 bit Windows.

Only applies to delete value. If the key parameter is passed, this function calls delete_value instead. Will be changed in Boron.

- **force** (*bool*) -- A boolean value indicating that all subkeys should be removed as well. If this is set to False (default) and there are subkeys, the delete_key function will fail.

Returns Returns True if successful, False if not. If force=True, the results of delete_key_recursive are returned. :rtype: bool

New in version 2015.5.4.

```
salt.modules.reg.delete_key_recursive(hive, key, use_32bit_registry=False)
```

Delete a registry key to include all subkeys.

Parameters

- **hive** -- The name of the hive. Can be one of the following
- HKEY_LOCAL_MACHINE or HKLM
- HKEY_CURRENT_USER or HKCU
- HKEY_USER or HKU

**Parameters**

- **key** -- The key to remove (looks like a path)

**Returns**

A dictionary listing the keys that deleted successfully as well as those that failed to delete. :rtype: dict

The following example will remove salt and all its subkeys from the SOFTWARE key in HKEY_LOCAL_MACHINE:

**CLI Example:**

```
salt '*' reg.delete_key_recursive HKLM SOFTWARE\salt
```

salt.modules.reg.delete_value(hive, key, vname=None, reflection=True, use_32bit_registry=False)

Delete a registry value entry or the default value for a key.

**Parameters**

- **hive** (str) -- The name of the hive. Can be one of the following
  - HKEY_LOCAL_MACHINE or HKLM
  - HKEY_CURRENT_USER or HKCU
  - HKEY_USER or HKU

**Parameters**

- **key** (str) -- The key (looks like a path) to the value name.
- **vname** (str) -- The value name. These are the individual name/data pairs under the key. If not passed, the key (Default) value will be deleted.

**Parameters**

- **reflection** (bool) -- A boolean value indicating that the value should also be set in the Wow6432Node portion of the registry. Only applies to 64 bit Windows. This setting is ignored for 32 bit Windows.

Deprecated since version 2015.8.2: Use use_32bit_registry instead. The parameter seems to have no effect since Windows 7 / Windows 2008R2 removed support for reflection. The parameter will be removed in Boron.

**Returns**

Returns True if successful, False if not

**Return type**

bool

**CLI Example:**

```
salt '*' reg.delete_value HKEY_CURRENT_USER 'SOFTWARE\Salt\version'
```

salt.modules.reg.read_key(hkey, path, key=None, use_32bit_registry=False)

**Important:** The name of this function is misleading and will be changed to reflect proper usage in the Boron release of Salt. The path option will be removed and the key will be the actual key. See the following issue:

https://github.com/saltstack/salt/issues/25618
In order to not break existing state files this function will call the read_value function if a key is passed. Key will be passed as the value name. If key is not passed, this function will return the default value for the key.

In the Boron release this function will be removed in favor of read_value.

Read registry key value

Returns the first unnamed value (Default) as a string. Returns none if first unnamed value is empty. Returns False if key not found.

CLI Example:

```
salt '*' reg.read_key HKEY_LOCAL_MACHINE 'SOFTWARE\Salt' 'version'
```

salt.modules.reg.read_value(hive, key, vname=None, use_32bit_registry=False)

Reads a registry value entry or the default value for a key.

**Parameters**

- **hive** *(str)* -- The name of the hive. Can be one of the following
  - HKEY_LOCAL_MACHINE or HKLM
  - HKEY_CURRENT_USER or HKCU
  - HKEY_USER or HKU

- **key** *(str)* -- The key (looks like a path) to the value name.

- **vname** *(str)* -- The value name. These are the individual name/data pairs under the key. If not passed, the key (Default) value will be returned

**Parameters**

- **use_32bit_registry** *(bool)* -- Accesses the 32bit portion of the registry on 64 bit installations. On 32bit machines this is ignored.

**Returns**

A dictionary containing the passed settings as well as the value_data if successful. If unsuccessful, sets success to False

If vname is not passed:

- Returns the first unnamed value (Default) as a string.
- Returns none if first unnamed value is empty.
- Returns False if key not found.

**Return type**

**dict**

CLI Example:

```
salt '*' reg.read_value HKEY_LOCAL_MACHINE 'SOFTWARE\Salt' 'version'
```

salt.modules.reg.set_key(hkey, path, value, key=None, vtype='REG_DWORD', reflection=True, use_32bit_registry=False)

**Important**: The name of this function is misleading and will be changed to reflect proper usage in the Boron release of Salt. The path option will be removed and the key will be the actual key. See the following issue:

https://github.com/saltstack/salt/issues/25618
In order to not break existing state files this function will call the set_value function if a key is passed. Key will be passed as the value name. If key is not passed, this function will return the default value for the key.

In the Boron release this function will be removed in favor of set_value.

Set a registry key

vtype: http://docs.python.org/2/library/_winreg.html#value-types

CLI Example:

```
salt '*' reg.set_key HKEY_CURRENT_USER 'SOFTWARE\Salt' 'version' '0.97' REG_DWORD
```

salt.modules.reg.set_value(hive, key, vname=None, vdata=None, vtype='REG_SZ', reflection=True, use_32bit_registry=False)

Sets a registry value entry or the default value for a key.

**Parameters**

- **hive (str)** -- The name of the hive. Can be one of the following:
  
  - HKEY_LOCAL_MACHINE or HKLM
  - HKEY_CURRENT_USER or HKCU
  - HKEY_USER or HKU

- **key (str)** -- The key (looks like a path) to the value name.

- **vname (str)** -- The value name. These are the individual name/data pairs under the key. If not passed, the key (Default) value will be set.

**Parameters**

- **vdata (str)** -- The value data to be set.

- **vtype (str)** -- The value type. Can be one of the following:
  
  - REG_BINARY
  - REG_DWORD
  - REG_EXPAND_SZ
  - REG_MULTI_SZ
  - REG_SZ

- **reflection (bool)** -- A boolean value indicating that the value should also be set in the Wow6432Node portion of the registry. Only applies to 64 bit Windows. This setting is ignored for 32 bit Windows.

Deprecation since version 2015.8.2: Use use_32bit_registry instead. The parameter seems to have no effect since Windows 7 / Windows 2008R2 removed support for reflection. The parameter will be removed in Boron.

**Returns** Returns True if successful, False if not

**Return type** bool

CLI Example:
32.17.221 salt.modules.rest_package

Package support for the REST example

salt.modules.rest_package.install(name=None, refresh=False, fromrepo=None, pkgs=None, sources=None, **kwargs)
salt.modules.rest_package.installed(name, version=None, refresh=False, fromrepo=None, skip_verify=False, pkgs=None, sources=None, **kwargs)
salt.modules.rest_package.list_pkgs(versions_as_list=False, **kwargs)
salt.modules.rest_package.remove(name=None, pkgs=None, **kwargs)
salt.modules.rest_package.upgrade(refresh=True, skip_verify=True, **kwargs)
salt.modules.rest_package.version(*names, **kwargs)

Returns a string representing the package version or an empty string if not installed. If more than one package name is specified, a dict of name/version pairs is returned.

CLI Example:

salt '*' pkg.version <package name>
salt '*' pkg.version <package1> <package2> <package3> ...

32.17.222 salt.modules.rest_service

Provide the service module for the proxy-minion REST sample

salt.modules.rest_service.enabled(name, sig=None)

Only the `redbull' service is `enabled' in the test

salt.modules.rest_service.get_all()

Return a list of all available services

New in version 2015.8.0.

CLI Example:

salt '*' service.get_all

salt.modules.rest_service.list()

Return a list of all available services.

CLI Example:

salt '*' service.list

salt.modules.rest_service.restart(name, sig=None)

Restart the specified service with rest_sample

New in version 2015.8.0.

CLI Example:
salt '*' service.restart <service name>

salt.modules.rest_service.running(name, sig=None)
    Return whether this service is running.
    New in version 2015.8.0.

salt.modules.rest_service.start(name, sig=None)
    Start the specified service on the rest_sample
    New in version 2015.8.0.
    CLI Example:
    ```
salt '*' service.start <service name>
    ```

salt.modules.rest_service.status(name, sig=None)
    Return the status for a service via rest_sample, returns a bool whether the service is running.
    New in version 2015.8.0.
    CLI Example:
    ```
salt '*' service.status <service name>
    ```

salt.modules.rest_service.stop(name, sig=None)
    Stop the specified service on the rest_sample
    New in version 2015.8.0.
    CLI Example:
    ```
salt '*' service.stop <service name>
    ```

32.17.223 salt.modules.ret

Module to integrate with the returner system and retrieve data sent to a salt returner

salt.modules.ret.get_fun(returner, fun)
    Return info about last time fun was called on each minion
    CLI Example:
    ```
salt '*' ret.get_fun mysql network.interfaces
    ```

salt.modules.ret.get_jid(returner, jid)
    Return the information for a specified job id
    CLI Example:
    ```
salt '*' ret.get_jid redis 20421104181954700505
    ```

salt.modules.ret.get_jids(returner)
    Return a list of all job ids
    CLI Example:
    ```
salt '*' ret.get_jids mysql
    ```

32.17. Full list of builtin execution modules
salt.modules.ret.get_minions (returner)
Return a list of all minions

CLI Example:
salt '*' ret.get_minions mysql

32.17.224 salt.modules.rh_ip

The networking module for RHEL/Fedora based distros

salt.modules.rh_ip.apply_network_settings (**settings)
Apply global network configuration.

CLI Example:
salt '*' ip.apply_network_settings

salt.modules.rh_ip.build_bond (iface, **settings)
Create a bond script in /etc/modprobe.d with the passed settings and load the bonding kernel module.

CLI Example:
salt '*' ip.build_bond bond0 mode=balance-alb

salt.modules.rh_ip.build_interface (iface, iface_type, enabled, **settings)
Build an interface script for a network interface.

CLI Example:
salt '*' ip.build_interface eth0 eth <settings>

salt.modules.rh_ip.build_network_settings (**settings)
Build the global network script.

CLI Example:
salt '*' ip.build_network_settings <settings>

salt.modules.rh_ip.build_routes (iface, **settings)
Build a route script for a network interface.

CLI Example:
salt '*' ip.build_routes eth0 <settings>

salt.modules.rh_ip.down (iface, iface_type)
Shutdown a network interface

CLI Example:
salt '*' ip.down eth0

salt.modules.rh_ip.get_bond (iface)
Return the content of a bond script

CLI Example:
salt '!' ip.get_bond bond0

salt.modules.rh_ip.get_interface(iface)
Retum the contents of an interface script

CLI Example:
salt '*' ip.get_interface eth0

salt.modules.rh_ip.get_network_settings()
Return the contents of the global network script.

CLI Example:
salt '*' ip.get_network_settings

salt.modules.rh_ip.get_routes(iface)
Return the contents of the interface routes script.

CLI Example:
salt '*' ip.get_routes eth0

salt.modules.rh_ip.up(iface, iface_type)
Start up a network interface

CLI Example:
salt '*' ip.up eth0

32.17.225 salt.modules.rh_service

Service support for RHEL-based systems, including support for both upstart and sysvinit

Important: If you feel that Salt should be using this module to manage services on a minion, and it is using a different module (or gives an error similar to `service.start is not available), see here.

salt.modules.rh_service.available(name, limit='')
Return True if the named service is available. Use the limit param to restrict results to services of that type.

CLI Examples:
salt '*' service.available sshd
salt '*' service.available sshd limit=upstart
salt '*' service.available sshd limit=sysvinit

salt.modules.rh_service.disable(name, **kwargs)
Disable the named service to start at boot

CLI Example:
salt '*' service.disable <service name>

salt.modules.rh_service.disabled(name)
Check to see if the named service is disabled to start on boot

32.17. Full list of builtin execution modules 1333
CLI Example:

```bash
salt '*' service.disabled <service name>
```

`salt.modules.rh_service.enable(name, **kwargs)`
Enable the named service to start at boot

CLI Example:

```bash
salt '*' service.enable <service name>
```

`salt.modules.rh_service.enabled(name, **kwargs)`
Check to see if the named service is enabled to start on boot

CLI Example:

```bash
salt '*' service.enabled <service name>
```

`salt.modules.rh_service.get_all(limit='')`  
Return all installed services. Use the `limit` param to restrict results to services of that type.

CLI Example:

```bash
salt '*' service.get_all
salt '*' service.get_all limit=sysvinit
salt '*' service.get_all limit=upstart
```

`salt.modules.rh_service.get_disabled(limit='')`  
Return the disabled services. Use the `limit` param to restrict results to services of that type.

CLI Example:

```bash
salt '*' service.get_disabled
salt '*' service.get_disabled limit=sysvinit
salt '*' service.get_disabled limit=upstart
```

`salt.modules.rh_service.get_enabled(limit='')`  
Return the enabled services. Use the `limit` param to restrict results to services of that type.

CLI Examples:

```bash
salt '*' service.get_enabled
salt '*' service.get_enabled limit=sysvinit
salt '*' service.get_enabled limit=upstart
```

`salt.modules.rh_service.missing(name, limit='')`  
The inverse of service.available. Return True if the named service is not available. Use the `limit` param to restrict results to services of that type.

CLI Examples:

```bash
salt '*' service.missing sshd
salt '*' service.missing sshd limit=sysvinit
salt '*' service.missing sshd limit=upstart
```

`salt.modules.rh_service.reload(name)`  
Reload the named service

CLI Example:
salt '*' service.reload <service name>

```bash
salt.modules.rh_service.restart(name)
    Restart the named service
    CLI Example:
    salt '*' service.restart <service name>
```

```bash
salt.modules.rh_service.start(name)
    Start the specified service
    CLI Example:
    salt '*' service.start <service name>
```

```bash
salt.modules.rh_service.status(name, sig=None)
    Return the status for a service, returns a bool whether the service is running.
    CLI Example:
    salt '*' service.status <service name>
```

```bash
salt.modules.rh_service.stop(name)
    Stop the specified service
    CLI Example:
    salt '*' service.stop <service name>
```

### 32.17.226 salt.modules.riak

Riak Salt Module

```bash
salt.modules.riak.cluster_commit()
    Commit Cluster Changes
    Changed in version 2015.8.0.
    CLI Example:
    salt '*' riak.cluster_commit
```

```bash
salt.modules.riak.cluster_join(username, hostname)
    Join a Riak cluster
    Changed in version 2015.8.0.
    CLI Example:
    salt '*' riak.cluster_join <user> <host>
```

username - The riak username to join the cluster
hostname - The riak hostname you are connecting to

```bash
salt.modules.riak.cluster_leave(username, hostname)
    Leave a Riak cluster
    New in version 2015.8.0.
    CLI Example:
```
salt 'salt '*' riak.cluster_leave <username> <host>

username - The riak username to join the cluster
hostname - The riak hostname you are connecting to

salt.modules.riak.cluster_plan()
Review Cluster Plan
Changed in version 2015.8.0.
CLI Example:
salt 'salt '*' riak.cluster_plan

salt.modules.riak.member_status()
Get cluster member status
Changed in version 2015.8.0.
CLI Example:
salt 'salt '*' riak.member_status

salt.modules.riak.services()
List available services on a node
New in version 2015.8.0.
CLI Example:
salt 'salt '*' riak.services

salt.modules.riak.start()
Start Riak
CLI Example:
salt 'salt '*' riak.start

salt.modules.riak.status()
Current node status
New in version 2015.8.0.
CLI Example:
salt 'salt '*' riak.status

salt.modules.riak.stop()
Stop Riak
Changed in version 2015.8.0.
CLI Example:
salt 'salt '*' riak.stop

salt.modules.riak.test()
Runs a test of a few standard Riak operations
New in version 2015.8.0.
CLI Example:
32.17.227  **salt.modules.rpm**

Support for rpm

**salt.modules.rpm.bin_pkg_info**(*path, saltenv='base')

New in version 2015.8.0.

Parses RPM metadata and returns a dictionary of information about the package (name, version, etc.).

**path**  Path to the file. Can either be an absolute path to a file on the minion, or a salt fileserver URL (e.g. `salt://path/to/file.rpm`). If a salt fileserver URL is passed, the file will be cached to the minion so that it can be examined.

**saltenv**  [base] Salt fileserver environment from which to retrieve the package. Ignored if **path** is a local file path on the minion.

CLI Example:

```
salt '*' lowpkg.bin_pkg_info /root/salt-2015.5.1-2.el7.noarch.rpm
salt '*' lowpkg.bin_pkg_info salt://salt-2015.5.1-2.el7.noarch.rpm
```

**salt.modules.rpm.checksum**(*paths)

Return if the signature of a RPM file is valid.

CLI Example:

```
salt '*' lowpkg.checksum /path/to/package1.rpm
salt '*' lowpkg.checksum /path/to/package1.rpm /path/to/package2.rpm
```

**salt.modules.rpm.diff**(*package, path)

Return a formatted diff between current file and original in a package. NOTE: this function includes all files (configuration and not), but does not work on binary content.

**Parameters**

- **package** -- The name of the package
- **path** -- Full path to the installed file

**Returns**  Difference or empty string. For binary files only a notification.

CLI example:

```
salt '*' lowpkg.diff apache2 /etc/apache2/httpd.conf
```

**salt.modules.rpm.file_dict**(*packages*)

List the files that belong to a package, sorted by group. Not specifying any packages will return a list of _every_ file on the system's rpm database (not generally recommended).

CLI Examples:

```
salt '*' lowpkg.file_dict httpd
salt '*' lowpkg.file_dict httpd postfix
salt '*' lowpkg.file_dict
```

**salt.modules.rpm.file_list**(*packages*)

List the files that belong to a package. Not specifying any packages will return a list of _every_ file on the system's rpm database (not generally recommended).
CLI Examples:

```bash
salt '*' lowpkg.file_list httpd
salt '*' lowpkg.file_list httpd postfix
salt '*' lowpkg.file_list
```

**salt.modules.rpm.info('packages', 'attr')**

Return a detailed package(s) summary information. If no packages specified, all packages will be returned.

Parameters

- **packages** --
- **attr** -- Comma-separated package attributes. If no `attr` is specified, all available attributes returned.

Valid attributes are: version, vendor, release, build_date, build_date_time_t, install_date, install_date_time_t, build_host, group, source_rpm, arch, epoch, size, license, signature, packager, url, summary, description.

Returns

CLI example:

```bash
salt '*' lowpkg.info apache2 bash
salt '*' lowpkg.info apache2 bash attr=version
salt '*' lowpkg.info apache2 bash attr=version,build_date_iso,size
```

**salt.modules.rpm.list_pkgs('packages')**

List the packages currently installed in a dict:

```bash
{'<package_name>': '<version>'}
```

CLI Example:

```bash
salt '*' lowpkg.list_pkgs
```

**salt.modules.rpm.modified('packages', 'flags')**

List the modified files that belong to a package. Not specifying any packages will return a list of _all_ modified files on the system's RPM database.

New in version 2015.5.0.

CLI examples:

```bash
salt '*' lowpkg.modified httpd
salt '*' lowpkg.modified httpd postfix
salt '*' lowpkg.modified
```

**salt.modules.rpm.owner('paths')**

Return the name of the package that owns the file. Multiple file paths can be passed. If a single path is passed, a string will be returned, and if multiple paths are passed, a dictionary of file/package name pairs will be returned.

If the file is not owned by a package, or is not present on the minion, then an empty string will be returned for that path.

CLI Examples:

```bash
salt '*' lowpkg.owner /usr/bin/apachectl
salt '*' lowpkg.owner /usr/bin/apachectl /etc/httpd/conf/httpd.conf
```
salt.modules.rpm.verify(*package, **kwargs)
   Runs an rpm -Va on a system, and returns the results in a dict

   Files with an attribute of config, doc, ghost, license or readme in the package header can be ignored using the
   ignore_types keyword argument

   CLI Example:
   
   salt '*' lowpkg.verify
   salt '*' lowpkg.verify httpd
   salt '*' lowpkg.verify 'httpd postfix'
   salt '*' lowpkg.verify 'httpd postfix' ignore_types=['config', 'doc']

salt.modules.rpm.version_cmp(ver1, ver2, ignore_epoch=False)
   New in version 2015.8.9.

   Do a cmp-style comparison on two packages. Return -1 if ver1 < ver2, 0 if ver1 == ver2, and 1 if ver1 > ver2.
   Return None if there was a problem making the comparison.

   ignore_epoch [False] Set to True to ignore the epoch when comparing versions

   New in version 2015.8.10,2016.3.2.

   CLI Example:

   salt '*' pkg.version_cmp '0.2-001' '0.2.0.1-002'

32.17.228 salt.modules.rpmbuild

RPM Package builder system

New in version 2015.8.0.

This system allows for all of the components to build rpms safely in chrooted environments. This also provides a
function to generate yum repositories

This module implements the pkgbuild interface

salt.modules.rpmbuild.build(runas, tgt, dest_dir, spec, sources, deps, env, template, saltenv='base',
   log_dir='/var/log/salt/pkgbuild')

   Given the package destination directory, the spec file source and package sources, use mock to safely build the
   rpm defined in the spec file

   CLI Example:

   salt '*' pkgbuild.build mock epel-7-x86_64 /var/www/html https://raw.githubusercontent.com/saltstack/libnacl/master/pkg/rpm/python-libnacl.spec  https://pypi.python.org/packages/source/l/libnacl/libnacl-1.3.5.tar.gz

   This example command should build the libnacl package for rhel 7 using user mock and place it in
   /var/www/html/ on the minion

salt.modules.rpmbuild.make_repo(repodir, keyid=None, env=None)

   Given the repodir, create a yum repository out of the rpms therein

   CLI Example:

   salt '*' pkgbuild.make_repo /var/www/html/

salt.modules.rpmbuild.make_src_pkg(dest_dir, spec, sources, env=None, template=None, saltenv='base')

   Create a source rpm from the given spec file and sources

32.17. Full list of builtin execution modules
CLI Example:

```bash
```

This example command should build the libnacl SOURCE package and place it in /var/www/html/ on the minion.

### 32.17.229 salt.modules.rsync

Wrapper for rsync

New in version 2014.1.0.

This data can also be passed into `pillar`. Options passed into `opts` will overwrite options passed into `pillar`.

```python
salt.modules.rsync.config(confile='/etc/rsyncd.conf')
```

Returns rsync config

CLI Example:

```bash
salt '*' rsync.config
```

```python
salt.modules.rsync.rsync(src, dst, delete=False, force=False, update=False, passwordfile=None, exclude=None, excludefrom=None)
```

Rsync files from src to dst

CLI Example:

```bash
salt '*' rsync.rsync {src} {dst} {delete=True} {update=True} {passwordfile=/etc/ --pass.crt} {exclude=xx}
salt '*' rsync.rsync {src} {dst} {delete=True} {excludefrom=/xx.ini}
```

```python
salt.modules.rsync.version()
```

Returns rsync version

CLI Example:

```bash
salt '*' rsync.version
```

### 32.17.230 salt.modules.runit

runit service module

This module is compatible with the `service` states, so it can be used to maintain services using the `provider` argument:

```python
myservice:
    service:
        - running
        - provider: runit
```

Note that the `enabled` argument is not available with this provider.

```python
salt.modules.runit.available(name)
```

Returns `True` if the specified service is available, otherwise returns `False`.

CLI Example:
`salt '*' runit.available foo`

**salt.modules.runit.full_restart(name)**
Calls runit.restart() function

CLI Example:
```
salt '*' runit.full_restart <service name>
```

**salt.modules.runit.get_all()**
Return a list of all available services

CLI Example:
```
salt '*' runit.get_all
```

**salt.modules.runit.missing(name)**
The inverse of runit.available. Returns True if the specified service is not available, otherwise returns False.

CLI Example:
```
salt '*' runit.missing foo
```

**salt.modules.runit.reload(name)**
Send a HUP to service via runit

CLI Example:
```
salt '*' runit.reload <service name>
```

**salt.modules.runit.restart(name)**
Restart service via runit. This will stop/start service

CLI Example:
```
salt '*' runit.restart <service name>
```

**salt.modules.runit.start(name)**
Starts service via runit

CLI Example:
```
salt '*' runit.start <service name>
```

**salt.modules.runit.status(name, sig=None)**
Return the status for a service via runit, return pid if running

CLI Example:
```
salt '*' runit.status <service name>
```

**salt.modules.runit.stop(name)**
Stops service via runit

CLI Example:
```
salt '*' runit.stop <service name>
```
salt.modules.runit.term(name)
   Send a TERM to service via runit
   CLI Example:
   ```
salt '*' runit.term <service name>
   ```

32.17.231 salt.modules.rvm

Manage ruby installations and gemsets with RVM, the Ruby Version Manager.
salt.modules.rvm.do(ruby, command, runas=None, cwd=None)
   Execute a command in an RVM controlled environment.
   **ruby:** The ruby to use.
   **command:** The command to execute.
   **runas** [None] The user to run rvm as.
   **cwd** [None] The current working directory.
   CLI Example:
   ```
salt '*' rvm.do 2.0.0 <command>
   ```
salt.modules.rvm.gemset_copy(source, destination, runas=None)
   Copy all gems from one gemset to another.
   **source** The name of the gemset to copy, complete with ruby version.
   **destination** The destination gemset.
   **runas** [None] The user to run rvm as.
   CLI Example:
   ```
salt '*' rvm.gemset_copy foobar bazquo
   ```
salt.modules.rvm.gemset_create(ruby, gemset, runas=None)
   Creates a gemset.
   **ruby** The ruby version to create the gemset for.
   **gemset** The name of the gemset to create.
   **runas** [None] The user to run rvm as.
   CLI Example:
   ```
salt '*' rvm.gemset_create 2.0.0 foobar
   ```
salt.modules.rvm.gemset_delete(ruby, gemset, runas=None)
   Deletes a gemset.
   **ruby** The ruby version the gemset belongs to.
   **gemset** The gemset to delete.
   **runas** [None] The user to run rvm as.
   CLI Example:
salt ' '*'rvm.gemset_delete 2.0.0 foobar

salt.modules.rvm.gemset_empty(ruby, gemset, runas=None)
Remove all gems from a gemset.
  ruby  The ruby version the gemset belongs to.
  gemset The gemset to empty.
  runas  [None] The user to run rvm as.
CLI Example:
salt ' '*'rvm.gemset_empty 2.0.0 foobar

salt.modules.rvm.gemset_list(ruby='default', runas=None)
List all gemsets for the given ruby.
  ruby  [default] The ruby version to list the gemsets for
  runas  [None] The user to run rvm as.
CLI Example:
salt '*' rvm.gemset_list

salt.modules.rvm.gemset_list_all(runas=None)
List all gemsets for all installed rubies.
Note that you must have set a default ruby before this can work.
  runas  [None] The user to run rvm as.
CLI Example:
salt '*' rvm.gemset_list_all

salt.modules.rvm.get(version='stable', runas=None)
Update RVM.
  version  [stable] Which version of RVM to install, e.g. stable or head.
  ruby  The version of ruby to reinstall.
CLI Example:
salt '*' rvm.get

salt.modules.rvm.install(runas=None)
Install RVM system wide.
CLI Example:
salt '*' rvm.install

salt.modules.rvm.install_ruby(ruby, runas=None)
Install a ruby implementation.
  ruby  The version of ruby to install.
  runas  [None] The user to run rvm as.
CLI Example:
salt '*' rvm.install_ruby 1.9.3-p385

salt.modules.rvm.is_installed(runas=None)
Check if RVM is installed.
CLI Example:
salt '*' rvm.is_installed

salt.modules.rvm.list(runas=None)
List all rvm installed rubies.
runas [None] The user to run rvm as.
CLI Example:
salt '*' rvm.list

salt.modules.rvm.reinstall_ruby(ruby, runas=None)
Reinstall a ruby implementation.
ruby The version of ruby to reinstall.
runas [None] The user to run rvm as.
CLI Example:
salt '*' rvm.reinstall_ruby 1.9.3-p385

salt.modules.rvm.rubygems(ruby, version, runas=None)
Installs a specific rubygems version in the given ruby.
ruby The ruby to install rubygems for.
version The version of rubygems to install or 'remove' to use the version that ships with 1.9
runas [None] The user to run rvm as.
CLI Example:
salt '*' rvm.rubygems 2.0.0 1.8.24

salt.modules.rvm.set_default(ruby, runas=None)
Set the default ruby.
ruby The version of ruby to make the default.
runas [None] The user to run rvm as.
CLI Example:
salt '*' rvm.set_default 2.0.0

salt.modules.rvm.wrapper(ruby_string, wrapper_prefix, runas=None, *binaries)
Install RVM wrapper scripts.
ruby_string Ruby/gemset to install wrappers for.
wrapper_prefix What to prepend to the name of the generated wrapper binaries.
runas [None] The user to run rvm as.
binaries  [None] The names of the binaries to create wrappers for. When nothing is given, wrappers for ruby, gem, rake, irb, rdoc, ri and testrb are generated.

CLI Example:

```
salt 'x' rvm.wrapper <ruby_string> <wrapper_prefix>
```

### 32.17.232 salt.modules.s3

Connection module for Amazon S3

**configuration**  This module accepts explicit s3 credentials but can also utilize IAM roles assigned to the instance through Instance Profiles. Dynamic credentials are then automatically obtained from AWS API and no further configuration is necessary. More Information available at:

```
```

If IAM roles are not used you need to specify them either in a pillar or in the minion's config file:

```
s3.keyid: GKTADJGHEIQSXMKKRBJ08H
s3.key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
```

A service_url may also be specified in the configuration:

```
s3.service_url: s3.amazonaws.com
```

A role_arn may also be specified in the configuration:

```
s3.role_arn: arn:aws:iam::111111111111:role/my-role-to-assume
```

If a service_url is not specified, the default is s3.amazonaws.com. This may appear in various documentation as an `''endpoint'`. A comprehensive list for Amazon S3 may be found at:

```
http://docs.aws.amazon.com/general/latest/gr/rande.html#s3_region
```

The service_url will form the basis for the final endpoint that is used to query the service.

SSL verification may also be turned off in the configuration:

```
s3.verify_ssl: False
```

This is required if using S3 bucket names that contain a period, as these will not match Amazon's S3 wildcard certificates. Certificate verification is enabled by default.

AWS region may be specified in the configuration:

```
s3.location: eu-central-1
```

Default is us-east-1.

This module should be usable to query other S3-like services, such as Eucalyptus.

**depends**  requests

**salt.modules.s3.delete**(bucket, path=None, action=None, key=None, keyid=None, service_url=None, verify_ssl=None, location=None, role_arn=None)

Delete a bucket, or delete an object from a bucket.

CLI Example to delete a bucket:

```
```
CLI Example to delete an object from a bucket:

```
salt myminion s3.delete mybucket remoteobject
```

```
salt.modules.s3.get(bucket=None, path=None, return_bin=False, action=None, local_file=None, key=None, keyid=None, service_url=None, verify_ssl=None, location=None, role_arn=None)
```

List the contents of a bucket, or return an object from a bucket. Set return_bin to True in order to retrieve an object wholesale. Otherwise, Salt will attempt to parse an XML response.

CLI Example to list buckets:

```
salt myminion s3.get
```

CLI Example to list the contents of a bucket:

```
salt myminion s3.get mybucket
```

CLI Example to return the binary contents of an object:

```
salt myminion s3.get mybucket myfile.png return_bin=True
```

CLI Example to save the binary contents of an object to a local file:

```
salt myminion s3.get mybucket myfile.png local_file=/tmp/myfile.png
```

It is also possible to perform an action on a bucket. Currently, S3 supports the following actions:

```
acl
cors
lifecycle
policy
location
logging
notification
tagging
versions
requestPayment
versioning
website
```

To perform an action on a bucket:

```
salt myminion s3.get mybucket myfile.png action=acl
```

```
salt.modules.s3.head(bucket, path=None, key=None, keyid=None, service_url=None, verify_ssl=None, location=None, role_arn=None)
```

Return the metadata for a bucket, or an object in a bucket.

CLI Examples:

```
salt myminion s3.head mybucket
salt myminion s3.head mybucket myfile.png
```

```
salt.modules.s3.put(bucket, path=None, return_bin=False, action=None, local_file=None, key=None, keyid=None, service_url=None, verify_ssl=None, location=None, role_arn=None)
```

Create a new bucket, or upload an object to a bucket.
CLI Example to create a bucket:

```
salt myminion s3.put mybucket
```

CLI Example to upload an object to a bucket:

```
salt myminion s3.put mybucket remotepath local_file=/path/to/file
```

### 32.17.233 salt.modules.saltcloudmod

Control a salt cloud system

salt.modules.saltcloudmod.create(name, profile)

Create the named vm

CLI Example:

```
salt <minion-id> saltcloud.create webserver rackspace_centos_512
```

### 32.17.234 salt.modules.saltutil

The Saltutil module is used to manage the state of the salt minion itself. It is used to manage minion modules as well as automate updates to the salt minion.

```
depends
  • esky Python module for update functionality
```

salt.modules.saltutil.clear_cache()

Forcibly removes all caches on a minion.

New in version 2014.7.0.

WARNING: The safest way to clear a minion cache is by first stopping the minion and then deleting the cache files before restarting it.

CLI Example:

```
salt '*' saltutil.clear_cache
```

salt.modules.saltutil.cmd(tgt, fun, arg=(), timeout=None, expr_form='glob', ret='`, kwarg=None, ssh=False, **kwargs)

Assuming this minion is a master, execute a salt command

CLI Example:

```
salt '*' saltutil.cmd
```

salt.modules.saltutil.cmd_iter(tgt, fun, arg=(), timeout=None, expr_form='glob', ret='`, kwarg=None, ssh=False, **kwargs)

Assuming this minion is a master, execute a salt command

CLI Example:

```
salt '*' saltutil.cmd_iter
```

32.17. Full list of builtin execution modules
salt.modules.saltutil.find_cached_job(jid)
Return the data for a specific cached job id

CLI Example:
salt '*' saltutil.find_cached_job <job id>

salt.modules.saltutil.find_job(jid)
Return the data for a specific job id that is currently running.

jid The job id to search for and return data.

CLI Example:
salt '*' saltutil.find_job <job id>

Note that the find_job function only returns job information when the job is still running. If the job is currently running, the output looks something like this:

```
# salt my-minion saltutil.find_job 20160503150049487736
my-minion:
    ----------
    arg:
      - 30
    fun:
      test.sleep
    jid:
      20160503150049487736
    pid:
      9601
    ret:
    tgt:
      my-minion
    tgt_type:
      glob
    user:
      root
```

If the job has already completed, the job cannot be found and therefore the function returns an empty dictionary, which looks like this on the CLI:

```
# salt my-minion saltutil.find_job 20160503150049487736
my-minion:
    ----------
```

salt.modules.saltutil.is_running(fun)
If the named function is running return the data associated with it/them. The argument can be a glob

CLI Example:
salt '*' saltutil.is_running state.highstate

salt.modules.saltutil.kill_job(jid)
Sends a kill signal (SIGKILL 9) to the named salt job's process

CLI Example:
salt '*' saltutil.kill_job <job id>
salt.modules.saltutil.mmodule\(saltenv, fun, *args, **kwargs\)

Loads minion modules from an environment so that they can be used in pillars for that environment.

CLI Example:

```
salt '*' saltutil.mmodule base test.ping
```

salt.modules.saltutil.refresh_beacons()

Signal the minion to refresh the beacons.

CLI Example:

```
salt '*' saltutil.refresh_beacons
```

salt.modules.saltutil.refresh_modules\(async=True\)

Signal the minion to refresh the module and grain data.

The default is to refresh module asynchronously. To block until the module refresh is complete, set the `async` flag to False.

CLI Example:

```
salt '*' saltutil.refresh_modules
```

salt.modules.saltutil.refresh_pillar()

Signal the minion to refresh the pillar data.

CLI Example:

```
salt '*' saltutil.refresh_pillar
```

salt.modules.saltutil.regen_keys()

Used to regenerate the minion keys.

CLI Example:

```
salt '*' saltutil.regen_keys
```

salt.modules.saltutil.revoke_auth\(preserve_minion_cache=False\)

The minion sends a request to the master to revoke its own key. Note that the minion session will be revoked and the minion may not be able to return the result of this command back to the master.

If the `preserve_minion_cache` flag is set to True, the master cache for this minion will not be removed.

CLI Example:

```
salt '*' saltutil.revoke_auth
```

salt.modules.saltutil.runner\(name, **kwargs\)

Execute a runner module (this function must be run on the master)

New in version 2014.7.0.

name The name of the function to run

kwargs Any keyword arguments to pass to the runner function

CLI Example:

```
salt '*' saltutil.runner jobs.list_jobs
```

32.17. Full list of builtin execution modules
salt.modules.saltutil.running()

Return the data on all running salt processes on the minion

CLI Example:

```
salt '*' saltutil.running
```

salt.modules.saltutil.signal_job(jid, sig)

Sends a signal to the named salt job's process

CLI Example:

```
salt '*' saltutil.signal_job <job id> 15
```

salt.modules.saltutil.sync_all(saltenv=None, refresh=True)

Changed in version 2015.8.11, 2016.3.2: On masterless minions, pillar modules are now synced, and refreshed when refresh is set to True.

Sync down all of the dynamic modules from the file server for a specific environment. This function synchronizes custom modules, states, beacons, grains, returners, output modules, renderers, and utils.

**refresh** [True] Also refresh the execution modules available to the minion.

**Important:** If this function is executed using a `module.run` state, the SLS file will not have access to newly synced execution modules unless a refresh argument is added to the state, like so:

```
load_my_custom_module:
  module.run:
    - name: saltutil.sync_all
    - refresh: True
```

See [here](#) for a more detailed explanation of why this is necessary.

CLI Example:

```
salt '*' saltutil.sync_all
salt '*' saltutil.sync_all saltenv=dev
```

salt.modules.saltutil.sync_beacons(saltenv=None, refresh=True)

New in version 2015.5.1.

Sync the beacons from the `salt://_beacons` directory on the Salt fileserver. This function is environment-aware, pass the desired environment to grab the contents of the `_beacons` directory from that environment.

The default environment, if none is specified, is base.

**refresh** [True] Also refresh the beacons available to the minion.

CLI Example:

```
salt '*' saltutil.sync_beacons
salt '*' saltutil.sync_beacons saltenv=dev
```

salt.modules.saltutil.sync_grains(saltenv=None, refresh=True)

Sync the grains from the `salt://_grains` directory on the Salt fileserver. This function is environment-aware, pass the desired environment to grab the contents of the `_grains` directory from that environment.

The default environment, if none is specified, is base.

**refresh** [True] Also refresh the execution modules available to the minion, and refresh pillar data.
CLI Example:

```
salt '*' saltutil.sync_grains
salt '*' saltutil.sync_grains saltenv=dev
```

**salt.modules.saltutil.sync_log_handlers** (*saltenv=None, refresh=True*)

New in version 2015.8.0.

Sync utility source files from the `salt://_log_handlers` directory on the Salt fileserver. This function is environment-aware, pass the desired environment to grab the contents of the `_log_handlers` directory from that environment. The default environment, if none is specified, is `base`.

CLI Example:

```
salt '*' saltutil.sync_log_handlers
salt '*' saltutil.sync_log_handlers saltenv=dev
```

**salt.modules.saltutil.sync_modules** (*saltenv=None, refresh=True*)

Sync the modules from the `salt://_modules` directory on the Salt fileserver. This function is environment-aware, pass the desired environment to grab the contents of the `_modules` directory from that environment. The default environment, if none is specified, is `base`.

`refresh` [True] Also refresh the execution modules available to the minion.

**Important**: If this function is executed using a `module.run` state, the SLS file will not have access to newly synced execution modules unless a `refresh` argument is added to the state, like so:

```
load_my_custom_module:
  module.run:
    - name: saltutil.sync_modules
    - refresh: True
```

See [here](#) for a more detailed explanation of why this is necessary.

CLI Example:

```
salt '*' saltutil.sync_modules
salt '*' saltutil.sync_modules saltenv=dev
```

**salt.modules.saltutil.sync_output** (*saltenv=None, refresh=True*)

Sync the output modules from the `salt://_output` directory on the Salt fileserver. This function is environment-aware, pass the desired environment to grab the contents of the `_output` directory from that environment. The default environment, if none is specified, is `base`.

`refresh` [True] Also refresh the execution modules available to the minion.

CLI Example:

```
salt '*' saltutil.sync_output
salt '*' saltutil.sync_output saltenv=dev
```

**salt.modules.saltutil.sync_outputters** (*saltenv=None, refresh=True*)

This function is an alias of `sync_output`.

Sync the output modules from the `salt://_output` directory on the Salt fileserver. This function is environment-aware, pass the desired environment to grab the contents of the `_output` directory from that environment. The default environment, if none is specified, is `base`. 

---

32.17. Full list of builtin execution modules
refresh [True] Also refresh the execution modules available to the minion.

CLI Example:

```
salt '*' saltutil.sync_output
salt '*' saltutil.sync_output saltenv=dev
```

```
salt.modules.saltutil.sync_pillar(saltenv=None, refresh=True)
```

New in version 2015.8.11, 2016.3.2.

Sync pillar modules from the salt://_pillar directory on the Salt fileserver. This function is environment-aware, pass the desired environment to grab the contents of the _pillar directory from that environment. The default environment, if none is specified, is base.

refresh [True] Also refresh the execution modules available to the minion, and refresh pillar data.

Note: This function will raise an error if executed on a traditional (i.e. not masterless) minion

CLI Examples:

```
salt '*' saltutil.sync_pillar
salt '*' saltutil.sync_pillar saltenv=dev
```

```
salt.modules.saltutil.sync_proxymodules(saltenv=None, refresh=False)
```

New in version 2015.8.2.

Sync the proxy modules from the salt://_proxy directory on the Salt fileservicer. This function is environment-aware, pass the desired environment to grab the contents of the _proxy directory from that environment. The default environment, if none is specified, is base.

CLI Example:

```
salt '*' saltutil.sync_proxymodules
salt '*' saltutil.sync_proxymodules saltenv=dev
```

```
salt.modules.saltutil.sync_renderers(saltenv=None, refresh=True)
```

Sync the renderers from the salt://_renderers directory on the Salt fileserver. This function is environment-aware, pass the desired environment to grab the contents of the _renderers directory from that environment. The default environment, if none is specified, is base.

refresh [True] Also refresh the execution modules available to the minion.

CLI Example:

```
salt '*' saltutil.sync_renderers
salt '*' saltutil.sync_renderers saltenv=dev
```

```
salt.modules.saltutil.sync_returners(saltenv=None, refresh=True)
```

Sync the returners from the salt://_returners directory on the Salt fileserver. This function is environment-aware, pass the desired environment to grab the contents of the _returners directory from that environment. The default environment, if none is specified, is base.

refresh [True] Also refresh the execution modules available to the minion.

CLI Example:

```
salt '*' saltutil.sync_returners
salt '*' saltutil.sync_returners saltenv=dev
```
salt.modules.saltutil.sync_sdb(saltenv=None, refresh=False)

New in version 2015.5.7.

Sync sdb modules from the salt://_sdb directory on the Salt fileserver. This function is environment-aware, pass the desired environment to grab the contents of the _sdb directory from that environment. The default environment, if none is specified, is base.

refresh  [False] This argument has no affect and is included for consistency with the other sync functions.

CLI Example:

```bash
salt '*' saltutil.sync_sdb
salt '*' saltutil.sync_sdb saltenv=dev
```

salt.modules.saltutil.sync_states(saltenv=None, refresh=True)

Sync the states from the salt://_states directory on the Salt fileserver. This function is environment-aware, pass the desired environment to grab the contents of the _states directory from that environment. The default environment, if none is specified, is base.

refresh  [True] Also refresh the execution modules available to the minion.

CLI Example:

```bash
salt '*' saltutil.sync_states
salt '*' saltutil.sync_states saltenv=dev
```

salt.modules.saltutil.sync_utils(saltenv=None, refresh=True)

New in version 2014.7.0.

Sync utility source files from the salt://_utils directory on the Salt fileserver. This function is environment-aware, pass the desired environment to grab the contents of the _utils directory from that environment. The default environment, if none is specified, is base.

refresh  [True] Also refresh the execution modules available to the minion.

CLI Example:

```bash
salt '*' saltutil.sync_utils
salt '*' saltutil.sync_utils saltenv=dev
```

salt.modules.saltutil.term_job(jid)

Sends a termination signal (SIGTERM 15) to the named salt job's process

CLI Example:

```bash
salt '*' saltutil.term_job <job id>
```

salt.modules.saltutil.update(version=None)

Update the salt minion from the URL defined in opts['update_url'] SaltStack, Inc provides the latest builds here: update_url: https://repo.saltstack.com/windows/

Be aware that as of 2014-8-11 there's a bug in esky such that only the latest version available in the update_url can be downloaded and installed.

This feature requires the minion to be running a bdist_esky build.

The version number is optional and will default to the most recent version available at opts['update_url'].

Returns details about the transaction upon completion.

CLI Example:
salt '.*' saltutil.update
salt '.*' saltutil.update 0.10.3

salt.modules.saltutil.wheel(name, *args, **kwargs)
Execute a wheel module (this function must be run on the master)

    New in version 2014.7.0.

    name  The name of the function to run

    args  Any positional arguments to pass to the wheel function. A common example of this would be the match
           arg needed for key functions.

            New in version v2015.8.11.

    kwargs  Any keyword arguments to pass to the wheel function

    CLI Example:

        salt '.*' saltutil.wheel key.accept jerry

32.17.235 salt.modules.schedule

Module for managing the Salt schedule on a minion

    New in version 2014.7.0.

salt.modules.schedule.add(name, **kwargs)
Add a job to the schedule

    CLI Example:

        salt '.*' schedule.add job1 function='test.ping' seconds=3600
        # If function have some arguments, use job_args
        salt '.*' schedule.add job2 function='cmd.run' job_args="['date >> /tmp/date.log']"
        # seconds=60

salt.modules.schedule.build_schedule_item(name, **kwargs)
Build a schedule job

    CLI Example:

        salt '.*' schedule.build_schedule_item job1 function='test.ping' seconds=3600

salt.modules.schedule.copy(name, target, **kwargs)
Copy scheduled job to another minion or minions.

    CLI Example:

        salt '.*' schedule.copy jobname target

salt.modules.schedule.delete(name, **kwargs)
Delete a job from the minion's schedule

    CLI Example:

        salt '.*' schedule.delete job1
salt.modules.schedule.disable(**kwargs)
Disable all scheduled jobs on the minion

CLI Example:
salt '*' schedule.disable

salt.modules.schedule.disable_job(name, **kwargs)
Disable a job in the minion's schedule

CLI Example:
salt '*' schedule.disable_job job1

salt.modules.schedule.enable(**kwargs)
Enable all scheduled jobs on the minion

CLI Example:
salt '*' schedule.enable

salt.modules.schedule.enable_job(name, **kwargs)
Enable a job in the minion's schedule

CLI Example:
salt '*' schedule.enable_job job1

salt.modules.schedule.is_enabled(name)
List a Job only if its enabled

New in version 2015.5.3.

CLI Example:
salt '*' schedule.is_enabled name=job_name

salt.modules.schedule.list(show_all=False, where=None, return_yaml=True)
List the jobs currently scheduled on the minion

CLI Example:
salt '*' schedule.list
salt '*' schedule.list show_all=True

salt.modules.schedule.modify(name, **kwargs)
Modify an existing job in the schedule

CLI Example:
salt '*' schedule.modify job1 function='test.ping' seconds=3600

salt.modules.schedule.move(name, target, **kwargs)
Move scheduled job to another minion or minions.

CLI Example:
salt '*' schedule.move jobname target
salt.modules.schedule.purge(**kwargs)
    Purge all the jobs currently scheduled on the minion
    CLI Example:
    
    salt '*' schedule.purge

salt.modules.schedule.reload()
    Reload saved scheduled jobs on the minion
    CLI Example:
    
    salt '*' schedule.reload

salt.modules.schedule.run_job(name, force=False)
    Run a scheduled job on the minion immediately
    CLI Example:
    
    salt '*' schedule.run_job job1
    salt '*' schedule.run_job job1 force=True
    Force the job to run even if it is disabled.

salt.modules.schedule.save(**kwargs)
    Save all scheduled jobs on the minion
    CLI Example:
    
    salt '*' schedule.save

32.17.236 salt.modules.scsi

SCSI administration module

salt.modules.scsi.ls(get_size=True)
    List SCSI devices, with details
    CLI Examples:
    
    salt '*' scsi.ls
    salt '*' scsi.ls get_size=False

    get_size [True] Get the size information for scsi devices. This option should be set to False for older OS distributions (RHEL6 and older) due to lack of support for the `-s` option in lsscsi.

    New in version 2015.5.10.

salt.modules.scsi.rescan_all(host)
    List scsi devices
    CLI Example:
    
    salt '*' scsi.rescan_all(0)
32.17.237  salt.modules.sdb

Module for Manipulating Data via the Salt DB API

salt.modules.sdb.get(uri)
Get a value from a db, using a uri in the form of sdb://<profile>/<key>. If the uri provided does not start with sdb://, then it will be returned as-is.

CLI Example:
```
salt '*' sdb.get sdb://mymemcached/foo
```

salt.modules.sdb.set(uri, value)
Set a value in a db, using a uri in the form of sdb://<profile>/<key>. If the uri provided does not start with sdb:// or the value is not successfully set, return False.

CLI Example:
```
salt '*' sdb.set sdb://mymemcached/foo bar
```

32.17.238  salt.modules.seed

Virtual machine image management tools

salt.modules.seed.apply(path, id_=None, config=None, approve_key=True, install=True, prev_install=False, pub_key=None, priv_key=None)
Seed a location (disk image, directory, or block device) with the minion config, approve the minion’s key, and/or install salt-minion.

CLI Example:
```
salt 'minion' seed.apply path id [config=config_data] \   [gen_key=(true|false)] [approve_key=(true|false)] \   [install=(true|false)]
```

path Full path to the directory, device, or disk image on the target minion's file system.
id  Minion id with which to seed the path.
config  Minion configuration options. By default, the `master` option is set to the target host's `master`.
approve_key  Request a pre-approval of the generated minion key. Requires that the salt-master be configured to either auto-accept all keys or expect a signing request from the target host. Default: true.
install  Install salt-minion, if absent. Default: true.
prev_install  Prepare the bootstrap script, but don't run it. Default: false

salt.modules.seed.mkconfig(config=None, tmp=None, id_=None, approve_key=True, pub_key=None, priv_key=None)
Generate keys and config and put them in a tmp directory.

pub_key  absolute path or file content of an optional preseeded salt key
priv_key  absolute path or file content of an optional preseeded salt key

CLI Example:
salt 'minion' seed.mkconfig [config=config_data] [tmp=tmp_dir] \[id_=minion_id] [approve_key=(true|false)]

salt.modules.seed.prep_bootstrap(mpt)

Update and get the random script to a random place

CLI Example:

salt '*' seed.prep_bootstrap /tmp

### 32.17.239 salt.modules.selinux

Execute calls on selinux

**Note:** This module requires the semanage and setsebool commands to be available on the minion. On RHEL-based distributions, ensure that the policycoreutils-python package is installed. On Fedora 23 and up, ensure that the policycoreutils-python-utils package is installed. If not on a Fedora or RHEL-based distribution, consult the selinux documentation for your distro to ensure that the proper packages are installed.

salt.modules.selinux.getenforce()

Return the mode selinux is running in

CLI Example:

salt '*' selinux.getenforce

salt.modules.selinux.getsebool(boolean)

Return the information on a specific selinux boolean

CLI Example:

salt '*' selinux.getsebool virt_use_usb

salt.modules.selinux.list_sebool()

Return a structure listing all of the selinux booleans on the system and what state they are in

CLI Example:

salt '*' selinux.list_sebool

salt.modules.selinux.selinux_fs_path(*args)

Return the location of the SELinux VFS directory

CLI Example:

salt '*' selinux.selinux_fs_path

salt.modules.selinux.setenforce(mode)

Set the SELinux enforcing mode

CLI Example:

salt '*' selinux.setenforce enforcing
salt.modules.selinux.setsebool(boolean, value, persist=False)
Set the value for a boolean
CLI Example:
```
salt '*' selinux.setsebool virt_use_usb off
```

salt.modules.selinux.setsebools(pairs, persist=False)
Set the value of multiple booleans
CLI Example:
```
salt '*' selinux.setsebools '{virt_use_usb: on, squid_use_tproxy: off}'
```

32.17.240 salt.modules.sensors

Read lm-sensors
New in version 2014.1.3.
salt.modules.sensors.sense(chip, fahrenheit=False)
Gather lm-sensors data from a given chip
To determine the chip to query, use the `sensors` command and see the leading line in the block.
Example:
```
/usr/bin/sensors
```
coretemp-isa-0000 Adapter: ISA adapter Physical id 0: +56.0℃ (high = +87.0℃, crit = +105.0℃) Core 0: +52.0℃ (high = +87.0℃, crit = +105.0℃) Core 1: +50.0℃ (high = +87.0℃, crit = +105.0℃) Core 2: +56.0℃ (high = +87.0℃, crit = +105.0℃) Core 3: +53.0℃ (high = +87.0℃, crit = +105.0℃)
Given the above, the chip is `coretemp-isa-0000'.

32.17.241 salt.modules.serverdensity_device

Wrapper around Server Density API
New in version 2014.7.0.
salt.modules.serverdensity_device.create(name, **params)
Function to create device in Server Density. For more info, see the API docs.
CLI Example:
```
salt '*' serverdensity_device.create lama
salt '*' serverdensity_device.create rich_lama group=lama_band installedRAM=32768
```
salt.modules.serverdensity_device.delete(device_id)
Delete a device from Server Density. For more information, see the API docs.
CLI Example:
```
salt '*' serverdensity_device.delete 51f7eafcda4bb235e000ae4
```
salt.modules.serverdensity_device.get_sd_auth(val, sd_auth_pillar_name='serverdensity')
Returns requested Server Density authentication value from pillar.
**CLI Example:**
```
salt '*' serverdensity_device.get_sd_auth <val>
```

`salt.modules.serverdensity_device.install_agent(agent_key)`  
Function downloads Server Density installation agent, and installs sd-agent with agent_key.  
**CLI Example:**  
```
salt '*' serverdensity_device.install_agent c2bbdd6689ff46282bdaa07555641498
```

`salt.modules.serverdensity_device.ls(**params)`  
List devices in Server Density  
Results will be filtered by any params passed to this function. For more information, see the API docs on listing and searching.  
**CLI Example:**  
```
salt '*' serverdensity_device.ls
salt '*' serverdensity_device.ls name=lama
salt '*' serverdensity_device.ls name=lama group=lama_band installedRAM=32768
```

`salt.modules.serverdensity_device.update(device_id, **params)`  
Updates device information in Server Density. For more information see the API docs.  
**CLI Example:**  
```
salt '*' serverdensity_device.update 51f7eafcdba4bb35e000ae4 name=lama
  <group=lama_band
salt '*' serverdensity_device.update 51f7eafcdba4bb35e000ae4 name=better_lama
  <group=rock_lamas swapSpace=512
```

### 32.17.242 `salt.modules.service`

`service` is a virtual module that is fulfilled by one of the following modules:

<table>
<thead>
<tr>
<th>Execution Module</th>
<th>Used for</th>
</tr>
</thead>
<tbody>
<tr>
<td>debian_service</td>
<td>Debian Wheezy and earlier</td>
</tr>
<tr>
<td>freebsd-service</td>
<td>FreeBSD-based OSes using service(8)</td>
</tr>
<tr>
<td>gentoo_service</td>
<td>Gentoo Linux using sysvinit and rc-update(8)</td>
</tr>
<tr>
<td>launchctl</td>
<td>Mac OS hosts using launchctl(1)</td>
</tr>
<tr>
<td>netbsd-service</td>
<td>NetBSD-based OSes</td>
</tr>
<tr>
<td>openbsd-service</td>
<td>OpenBSD-based OSes</td>
</tr>
<tr>
<td>rh_service</td>
<td>RedHat-based distros and derivatives using service(8) and chkconfig(8). Supports both pure sysvinit and mixed sysvinit/upstart systems.</td>
</tr>
<tr>
<td>service</td>
<td>Fallback which simply wraps sysvinit scripts</td>
</tr>
<tr>
<td>smf</td>
<td>Solaris-based OSes which use SMF</td>
</tr>
<tr>
<td>systemd</td>
<td>Linux distros which use systemd</td>
</tr>
<tr>
<td>upstart</td>
<td>Ubuntu-based distros using upstart</td>
</tr>
<tr>
<td>win_service</td>
<td>Windows</td>
</tr>
</tbody>
</table>
If Salt’s OS detection does not identify a different virtual service module, the minion will fall back to using this basic module, which simply wraps sysvinit scripts.

salt.modules.service.available(name)
Returns True if the specified service is available, otherwise returns False.

CLI Example:
```
salt '*' service.available sshd
```

salt.modules.service.get_all()
Return a list of all available services

CLI Example:
```
salt '*' service.get_all
```

salt.modules.service.missing(name)
The inverse of service.available. Returns True if the specified service is not available, otherwise returns False.

CLI Example:
```
salt '*' service.missing sshd
```

salt.modules.service.reload(name)
Refreshes config files by calling service reload. Does not perform a full restart.

CLI Example:
```
salt '*' service.reload <service name>
```

salt.modules.service.restart(name)
Restart the specified service

CLI Example:
```
salt '*' service.restart <service name>
```

salt.modules.service.start(name)
Start the specified service

CLI Example:
```
salt '*' service.start <service name>
```

salt.modules.service.status(name, sig=None)
Return the status for a service, returns the PID or an empty string if the service is running or not, pass a signature to use to find the service via ps

CLI Example:
```
salt '*' service.status <service name> [service signature]
```

salt.modules.service.stop(name)
Stop the specified service
32.17.243 salt.modules.shadow

shadow is a virtual module that is fulfilled by one of the following modules:

<table>
<thead>
<tr>
<th>Execution Module</th>
<th>Used for</th>
</tr>
</thead>
<tbody>
<tr>
<td>shadow</td>
<td>Linux</td>
</tr>
<tr>
<td>bsd_shadow</td>
<td>FreeBSD, OpenBSD, NetBSD</td>
</tr>
<tr>
<td>solaris_shadow</td>
<td>Solaris-based OSes</td>
</tr>
<tr>
<td>win_shadow</td>
<td>Windows</td>
</tr>
</tbody>
</table>

Manage the shadow file on Linux systems

**Important**: If you feel that Salt should be using this module to manage passwords on a minion, and it is using a different module (or gives an error similar to `shadow.info' is not available), see here.

salt.modules.shadow.default_hash()

Returns the default hash used for unset passwords

CLI Example:

```
salt '*' shadow.default_hash
```

salt.modules.shadow.del_password(name)

Delete the password from name user

New in version 2014.7.0.

CLI Example:

```
salt '*' shadow.del_password username
```

salt.modules.shadow.gen_password(password, crypt_salt=None, algorithm='sha512')

Generate hashed password

New in version 2014.7.0.

**Note**: When called this function is called directly via remote-execution, the password argument may be displayed in the system’s process list. This may be a security risk on certain systems.

password  Plaintext password to be hashed.

crypt_salt  Cryptographic salt. If not given, a random 8-character salt will be generated.

algorithm  The following hash algorithms are supported:

- md5
- blowfish (not in mainline glibc, only available in distros that add it)
• sha256
• sha512 (default)

CLI Example:

```plaintext
salt '*' shadow.gen_password 'I_am_password'
salt '*' shadow.gen_password 'I_am_password' crypt_salt='I_am_salt'\n   →algorithm=sha256
```

salt.modules.shadow.info(name)
Return information for the specified user

CLI Example:

```plaintext
salt '*' shadow.info root
```

salt.modules.shadow.set_date(name, date)
Sets the value for the date the password was last changed to days since the epoch (January 1, 1970). See man chage.

CLI Example:

```plaintext
salt '*' shadow.set_date username 0
```

salt.modules.shadow.set_expire(name, expire)
Changed in version 2014.7.0.
Sets the value for the date the account expires as days since the epoch (January 1, 1970). Using a value of -1 will clear expiration. See man chage.

CLI Example:

```plaintext
salt '*' shadow.set_expire username -1
```

salt.modules.shadow.set_inactdays(name, inactdays)
Set the number of days of inactivity after a password has expired before the account is locked. See man chage.

CLI Example:

```plaintext
salt '*' shadow.set_inactdays username 7
```

salt.modules.shadow.set_maxdays(name, maxdays)
Set the maximum number of days during which a password is valid. See man chage.

CLI Example:

```plaintext
salt '*' shadow.set_maxdays username 90
```

salt.modules.shadow.set_mindays(name, mindays)
Set the minimum number of days between password changes. See man chage.

CLI Example:

```plaintext
salt '*' shadow.set_mindays username 7
```

salt.modules.shadow.set_password(name, password, use_usermod=False)
Set the password for a named user. The password must be a properly defined hash. The password hash can be generated with this command:

```python
python -c "import crypt; print crypt.crypt('password','\$6\$SALTsalt')"
```
SALTsalt is the 8-character cryptographic salt. Valid characters in the salt are ., /, and any alphanumeric character.

Keep in mind that the $6 represents a sha512 hash, if your OS is using a different hashing algorithm this needs to be changed accordingly

CLI Example:

```
salt '*' shadow.set_password root '$1$UYCIxa628.9qXjpQCjM4a..'
```

salt.modules.shadow.set_warndays(name, warndays)
Set the number of days of warning before a password change is required. See man chage.

CLI Example:

```
salt '*' shadow.set_warndays username 7
```

### 32.17.244 salt.modules.slack_notify

Module for sending messages to Slack

New in version 2015.5.0.

**configuration** This module can be used by either passing an api key and version directly or by specifying both in a configuration profile in the salt master/minion config.

For example:

```
slack:
  api_key: peWcBiMOS9HrZG15peWcBiMOS9HrZG15
```

salt.modules.slack_notify.find_room(name, api_key=None)
Find a room by name and return it.

**Parameters**

- **name** -- The room name.
- **api_key** -- The Slack admin api key.

**Returns** The room object.

CLI Example:

```
salt '*' slack.find_room name="random"
salt '*' slack.find_room name="random" api_key=peWcBiMOS9HrZG15peWcBiMOS9HrZG15
```

salt.modules.slack_notify.find_user(name, api_key=None)
Find a user by name and return it.

**Parameters**

- **name** -- The user name.
- **api_key** -- The Slack admin api key.

**Returns** The user object.

CLI Example:
salt.modules.slack_notify.list_rooms(api_key=None)
List all Slack rooms.

Parameters api_key -- The Slack admin api key.

Returns The room list.

CLI Example:

```
salt '*' slack.list_rooms

salt '*' slack.list_rooms api_key=peWcBiMOS9HrZG15peWcBiMOS9HrZG15
```

salt.modules.slack_notify.list_users(api_key=None)
List all Slack users.

Parameters api_key -- The Slack admin api key.

Returns The user list.

CLI Example:

```
salt '*' slack.list_users

salt '*' slack.list_users api_key=peWcBiMOS9HrZG15peWcBiMOS9HrZG15
```

salt.modules.slack_notify.post_message(channel, message, from_name, api_key=None)
Send a message to a Slack channel.

Parameters

- channel -- The channel name, either will work.
- message -- The message to send to the Slack channel.
- from_name -- Specify who the message is from.
- api_key -- The Slack api key, if not specified in the configuration.

Returns Boolean if message was sent successfully.

CLI Example:

```
salt '*' slack.post_message channel="Development Room" message="Build is done" from_name="Build Server"
```

32.17.245 salt.modules.slsutil

Utility functions for use with or in SLS files

32.17.246 salt.modules.smartos_imgadm

Module for running imgadm command on SmartOS
salt.modules.smartos_imgadm.avail(search=None, verbose=False)
   Return a list of available images
   search  [string] Specifies search keyword
   verbose [boolean (False)] Specifies verbose output
   CLI Example:
   
```
salt '*' imgadm.avail [percona]
salt '*' imgadm.avail verbose=True
```

salt.modules.smartos_imgadm.delete(uuid=None)
   Remove an installed image
   uuid  [string] Specifies uuid to import
   CLI Example:
   
```
salt '*' imgadm.delete e42f8c84-bbea-11e2-b920-078fab2aab1f
```

salt.modules.smartos_imgadm.get(uuid=None)
   Return info on an installed image
   CLI Example:
   
```
salt '*' imgadm.get e42f8c84-bbea-11e2-b920-078fab2aab1f
```

salt.modules.smartos_imgadm.import(uuid=None, verbose=False)
   Import an image from the repository
   uuid  [string] Specifies uuid to import
   verbose [boolean (False)] Specifies verbose output
   CLI Example:
   
```
salt '*' imgadm.import e42f8c84-bbea-11e2-b920-078fab2aab1f [verbose=True]
```

salt.modules.smartos_imgadm.list(verbos=False)
   Return a list of installed images
   verbose [boolean (False)] Specifies verbose output
   CLI Example:
   
```
salt '*' imgadm.list [verbose=True]
```

salt.modules.smartos_imgadm.show(uuid=None)
   Show manifest of a given image
   CLI Example:
   
```
salt '*' imgadm.show e42f8c84-bbea-11e2-b920-078fab2aab1f
```

salt.modules.smartos_imgadm.update(uuid='')
   Gather info on unknown image(s) (locally installed)
   uuid  [string] Specifies uuid of image
   CLI Example:
salt '!' imgadm.update [uuid]

```python
salt.modules.smartos_imgadm.vacuum(verbos=Falsen)
Remove unused images

  verbose  [boolean (False)] Specifies verbose output

  CLI Example:

  salt '!' imgadm.vacuum [verbose=True]
```

salt.modules.smartos_imgadm.version()
Return imgadm version

```python
salt '!' imgadm.version
```

### 32.17.247 salt.modules.smartos_virt

Module for managing VMs on SmartOS

salt.modules.smartos_virt.create(domain)
Start a defined domain

```
salt '!' virt.create <domain>
```

salt.modules.smartos_virt.destroy(domain)
Power off a defined domain

```
salt '!' virt.destroy <domain>
```

salt.modules.smartos_virt.get_macs(uuid)
Return a list off MAC addresses from the named VM

```
salt '!' virt.get_macs <uuid>
```

salt.modules.smartos_virt.init(**kwargs)
Initialize a new VM

```
salt '!' virt.init image_uuid='...' alias='...' [...]'
```

salt.modules.smartos_virt.list_active_vms()
Return a list of uuids for active virtual machine on the minion

```
```
salt '*' virt.list_active_vms

salt.modules.smartos_virt.list_domains()
    Return a list of virtual machine names on the minion
    CLI Example:
    
    salt '*' virt.list_domains

salt.modules.smartos_virt.list_inactive_vms()
    Return a list of uuids for inactive virtual machine on the minion
    CLI Example:
    
    salt '*' virt.list_inactive_vms

salt.modules.smartos_virt.list_vms()
    Deprecated since version Boron: Use list_domains() instead.
    List all virtual machines.
    CLI Example:
    
    salt '*' virt.list_vms <domain>

salt.modules.smartos_virt.reboot(uuid)
    Reboot a domain via ACPI request
    CLI Example:
    
    salt '*' virt.reboot <uuid>

salt.modules.smartos_virt.setmem(uuid, memory)
    Change the amount of memory allocated to VM. <memory> is to be specified in MB.
    Note for KVM: this would require a restart of the VM.
    CLI Example:
    
    salt '*' virt.setmem <uuid> 512

salt.modules.smartos_virt.shutdown(uuid)
    Send a soft shutdown signal to the named vm
    CLI Example:
    
    salt '*' virt.shutdown <uuid>

salt.modules.smartos_virt.start(uuid)
    Start a defined domain
    CLI Example:
    
    salt '*' virt.start <uuid>

salt.modules.smartos_virt.stop(uuid)
    Hard power down the virtual machine, this is equivalent to powering off the hardware.
    CLI Example:
salt '*' virt.destroy <uuid>

salt.modules.smartos_virt.vm_info(uuid)
Return a dict with information about the specified VM on this CN

CLI Example:
salt '*' virt.vm_info <uuid>

salt.modules.smartos_virt.vm_virt_type(uuid)
Return VM virtualization type: OS or KVM

CLI Example:
salt '*' virt.vm_virt_type <uuid>

32.17.248 salt.modules.smartos_vmadm

Module for running vmadm command on SmartOS

salt.modules.smartos_vmadm.create(**kwargs)
Create a new vm

from_file  [string] Specifies the json file to create the vm from. Note: when this is present all other options will be ignored.

:: string[int]... Specifies options to set for the vm. Example: image_uuid=UUID, will specify the image_uuid for the vm to be created.

   nics=[{"nic_tag": "admin", "ip": "198.51.100.123", "netmask": "255.255.255.0"}], adds 1 nic over the admin tag

CLI Example:
salt 'vmadm.create from_file=/tmp/new_vm.json
salt 'vmadm.create image_uuid=... alias=... nics=[{"nic_tag": "admin", "ip": "198.51.100.123", ...}, [...]']

salt.modules.smartos_vmadm.create_snapshot(vm=None, name=None, key='uuid')
Create snapshot of a vm

vm  [string] Specifies the vm

name  [string] Name of snapshot. The snapname must be 64 characters or less and must only contain alphanumeric characters and characters in the set [-_.:%] to comply with ZFS restrictions.

key  [string] Specifies what `vm` is. Value = uuid|alias|hostname

CLI Example:
salt 'vmadm.create_snapshot 186da9ab-7392-4f55-91a5-b8f1fe770543 baseline
salt 'vmadm.create_snapshot nacl baseline key=alias

salt.modules.smartos_vmadm.delete(vm=None, key='uuid')
Delete a vm

vm  [string] Specifies the vm

key  [string] Specifies what `vm` is. Value = uuid|alias|hostname

32.17. Full list of builtin execution modules 1369
CLI Example:

```
salt '*' vmadm.delete 186da9ab-7392-4f55-91a5-b8f1fe770543
salt '*' vmadm.delete nacl key=alias
```

```python
salt.modules.smartos_vmadm.delete_snapshot(vm=None, name=None, key='uuid')
```
Delete snapshot of a vm

- **vm** [string] Specifies the vm
- **name** [string] Name of snapshot. The snapname must be 64 characters or less and must only contain alphanumeric characters and characters in the set [-_:.%] to comply with ZFS restrictions.
- **key** [string] Specifies what `vm' is. Value = uuid|alias|hostname

CLI Example:

```
salt '*' vmadm.delete_snapshot 186da9ab-7392-4f55-91a5-b8f1fe770543 baseline
salt '*' vmadm.delete_snapshot nacl baseline key=alias
```

```python
salt.modules.smartos_vmadm.get(vm=None, key='uuid')
```
Output the JSON object describing a VM

- **vm** [string] Specifies the vm
- **key** [string] Specifies what `vm' is. Value = uuid|alias|hostname

CLI Example:

```
salt '*' vmadm.get 186da9ab-7392-4f55-91a5-b8f1fe770543
salt '*' vmadm.get nacl key=alias
```

```python
salt.modules.smartos_vmadm.info(vm=None, info_type='all', key='uuid')
```
Lookup info on running kvm

- **vm** [string] Specifies the vm
- **info_type** [string] Specifies what info to return. Value = all|block|blockstats|chardev|cpus|kvm|pci|spice|version|vnc
- **key** [string] Specifies what `vm' is. Value = uuid|alias|hostname

CLI Example:

```
salt '*' vmadm.info 186da9ab-7392-4f55-91a5-b8f1fe770543
salt '*' vmadm.info nacl vnc key=alias
```

```python
salt.modules.smartos_vmadm.list(search=None, sort=None, order='uuid, type, ram, state, alias', keyed=False)
```
Return a list of VMs

- **search** [string] Specifies the vmadm filter property
- **sort** [string] Specifies the vmadm sort (-s) property
- **order** [string] Specifies the vmadm order (-o) property Default: uuid,type,ram,state,alias
- **keyed** [boolean]

  Specified if the output should be an array (False) or dict (True) Dict key is first field from order parameter. Note: if key is not unique last vm wins.

CLI Example:
salt.modules.smartos_vmadm.list

```
salt '*' vmadm.list
salt '*' vmadm.list order=alias,ram,cpu_cap sort=-ram,-cpu_cap
salt '*' vmadm.list search='type=KVM'
```

salt.modules.smartos_vmadm.lookup(search=None, order=None, one=False)

Return a list of VMs using lookup

- **search** [string] Specifies the vmadm filter property
- **order** [string] Specifies the vmadm order (-o) property Default: uuid,type,ram,state,alias
- **one** [boolean] Specifies if you to one result only (-1)

CLI Example:

```
salt '*' vmadm.lookup search='state=running'
salt '*' vmadm.lookup search='state=running' order=uuid,alias,hostname
salt '*' vmadm.lookup search='alias=nacl' one=True
```

salt.modules.smartos_vmadm.reboot(vm=None, force=False, key='uuid')

Reboot a vm

- **vm** [string] Specifies the vm to be rebooted
- **force** [boolean] Specifies if the vm should be force rebooted
- **key** [string] Specifies if `vm` is a uuid, alias or hostname.

CLI Example:

```
salt '*' vmadm.reboot 186da9ab-7392-4f55-91a5-b8f1fe770543
salt '*' vmadm.reboot 186da9ab-7392-4f55-91a5-b8f1fe770543 True
salt '*' vmadm.reboot vm=nacl key=alias
salt '*' vmadm.reboot vm=nina.example.org key=hostname
```

salt.modules.smartos_vmadm.receive(uuid=None, source=None)

Receive a vm from a directory

- **uuid** [string] Specifies uuid of vm to receive
- **source** [string] Specifies the target. Can be a directory path.

CLI Example:

```
salt '*' vmadm.receive 186da9ab-7392-4f55-91a5-b8f1fe770543 /opt/backups
```

salt.modules.smartos_vmadm.reprovision(vm=None, image=None, key='uuid')

Reprovision a vm

- **vm** [string] Specifies the vm
- **image** [string] uuid of new image
- **key** [string] Specifies what `vm` is. Value = uuid|alias|hostname

CLI Example:

```
salt '*' vmadm.reprovision 186da9ab-7392-4f55-91a5-b8f1fe770543 c02a2044-c1bd-11e4-bd8c-dfc1db8b0182
salt '*' vmadm.reprovision nacl c02a2044-c1bd-11e4-bd8c-dfc1db8b0182 key=alias
```

salt.modules.smartos_vmadm.rollback_snapshot(vm=None, name=None, key='uuid')

Rollback snapshot of a vm

32.17. Full list of builtin execution modules 1371
vm  [string] Specifies the vm
name  [string] Name of snapshot. The snapname must be 64 characters or less and must only contain alphanumeric characters and characters in the set [-_:,%] to comply with ZFS restrictions.
key  [string] Specifies what `vm' is. Value = uuid|alias|hostname

CLI Example:
```
salt '*' vmadm.rollback_snapshot 186da9ab-7392-4f55-91a5-b8f1fe770543 baseline
salt '*' vmadm.rollback_snapshot nacl baseline key=alias
```

salt.modules.smartos_vmadm.send(vm=None, target=None, key='uuid')
Send a vm to a directory
vm  [string] Specifies the vm to be started
target  [string] Specifies the target. Can be a directory path.
key  [string] Specifies if `vm' is a uuid, alias or hostname.

CLI Example:
```
salt '*' vmadm.send 186da9ab-7392-4f55-91a5-b8f1fe770543 /opt/backups
salt '*' vmadm.send vm=nacl target=/opt/backups key=alias
```

salt.modules.smartos_vmadm.start(vm=None, options=None, key='uuid')
Start a vm
vm  [string] Specifies the vm to be started
options  [string] Specifies additional options
key  [string] Specifies if `vm' is a uuid, alias or hostname.

CLI Example:
```
salt '*' vmadm.start 186da9ab-7392-4f55-91a5-b8f1fe770543
salt '*' vmadm.start 186da9ab-7392-4f55-91a5-b8f1fe770543 'order=c,once=d cdrom=/'
salt '*' vmadm.start vm=nacl key=alias
salt '*' vmadm.start vm=nina.example.org key=hostname
```

salt.modules.smartos_vmadm.stop(vm=None, force=False, key='uuid')
Stop a vm
vm  [string] Specifies the vm to be stopped
force  [boolean] Specifies if the vm should be force stopped
key  [string] Specifies if `vm' is a uuid, alias or hostname.

CLI Example:
```
salt '*' vmadm.stop 186da9ab-7392-4f55-91a5-b8f1fe770543
salt '*' vmadm.stop 186da9ab-7392-4f55-91a5-b8f1fe770543 True
salt '*' vmadm.stop vm=nacl key=alias
salt '*' vmadm.stop vm=nina.example.org key=hostname
```

salt.modules.smartos_vmadm.sysrq(vm=None, action='nmi', key='uuid')
Send non-maskable interrupt to vm or capture a screenshot
vm  [string] Specifies the vm
**action** [string] Specifies the action nmi or screenshot

**key** [string] Specifies what `vm` is. Value = uuid|alias|hostname

CLI Example:

```
salt '*' vmadm.sysrq 186da9ab-7392-4f55-91a5-b8f1fe770543 nmi
salt '*' vmadm.sysrq 186da9ab-7392-4f55-91a5-b8f1fe770543 screenshot
salt '*' vmadm.sysrq nacl nmi key=alias
```

```
salt.modules.smartos_vmadm.update(**kwargs)
Update a new vm

vm [string] Specifies the vm to be updated

key [string] Specifies if `vm` is a uuid, alias or hostname.

from_file [string] Specifies the json file to update the vm with. Note: when this is present all other options except `vm` and `key` will be ignored.

:: string[int]... Specifies options to update for the vm. Example: image_uuid=UUID, will specify the image_uuid for the vm to be created.

add_nics='[``nic_tag'': ``admin'', ``ip'': ``198.51.100.123'', ``netmask'': ``255.255.255.0'']', adds 1 nic over the admin tag

CLI Example:

```
salt '*' vmadm.update vm=186da9ab-7392-4f55-91a5-b8f1fe770543 from_file=/tmp/new_vm
salt '*' vmadm.update vm=nacl key=alias from_file=/tmp/new_vm.json
salt '*' vmadm.update vm=186da9ab-7392-4f55-91a5-b8f1fe770543 max_physical_memory=1024
```

### 32.17.249 salt.modules.smbios

Interface to SMBIOS/DMI

(Parsing through dmidecode)

**External References**

Desktop Management Interface (DMI)
System Management BIOS
DMIDecode

```
salt.modules.smbios.get(string, clean=True)
Get an individual DMI string from SMBIOS info

string
The string to fetch. DMIDecode supports:

- bios-vendor
- bios-version
```

32.17. Full list of builtin execution modules
• bios-release-date
• system-manufacturer
• system-product-name
• system-version
• system-serial-number
• system-uuid
• baseboard-manufacturer
• baseboard-product-name
• baseboard-version
• baseboard-serial-number
• baseboard-asset-tag
• chassis-manufacturer
• chassis-type
• chassis-version
• chassis-serial-number
• chassis-asset-tag
• processor-family
• processor-manufacturer
• processor-version
• processor-frequency

**clean**

Don't return well-known false information
(invalid UUID's, serial 000000000's, etcetera)
Defaults to True

**CLI Example:**

```
salt '*' smbios.get system-uuid clean=False
```

salt.modules.smbios.records*(rec_type=None, fields=None, clean=True)*

Return DMI records from SMBIOS

**type**  Return only records of type(s) The SMBIOS specification defines the following DMI types:

<table>
<thead>
<tr>
<th>Type</th>
<th>Information</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>BIOS</td>
</tr>
<tr>
<td>1</td>
<td>System</td>

</tbody>
</table>

**clean**

Don't return well-known false information
(invalid UUID's, serial 000000000's, etcetera)

Defaults to **True**

CLI Example:

```ruby
salt '*' smbios.records clean=False
salt '*' smbios.records 14
salt '*' smbios.records 4 core_count,thread_count,current_speed
```
32.17.250 salt.modules.smf

Service support for Solaris 10 and 11, should work with other systems that use SMF also. (e.g. SmartOS)

**Important:** If you feel that Salt should be using this module to manage services on a minion, and it is using a different module (or gives an error similar to `service.start' is not available), see [here](#).

salt.modules.smf.available(name)

Returns True if the specified service is available, otherwise returns False.

We look up the name with the svcs command to get back the FMRI This allows users to use simpler service names

CLI Example:

```
salt '*' service.available net-snmp
```

salt.modules.smf.disable(name, **kwargs)

Disable the named service to start at boot

CLI Example:

```
salt '*' service.disable <service name>
```

salt.modules.smf.disabled(name)

Check to see if the named service is disabled to start on boot

CLI Example:

```
salt '*' service.disabled <service name>
```

salt.modules.smf.enable(name, **kwargs)

Enable the named service to start at boot

CLI Example:

```
salt '*' service.enable <service name>
```

salt.modules.smf.enabled(name, **kwargs)

Check to see if the named service is enabled to start on boot

CLI Example:

```
salt '*' service.enabled <service name>
```

salt.modules.smf.get_all()

Return all installed services

CLI Example:

```
salt '*' service.get_all
```

salt.modules.smf.get_disabled()

Return the disabled services

CLI Example:

```
salt '*' service.get_disabled
```
salt.modules.smf.get_enabled()
Return the enabled services

CLI Example:
```
salt '*' service.get_enabled
```

salt.modules.smf.get_running()
Return the running services

CLI Example:
```
salt '*' service.get_running
```

salt.modules.smf.get_stopped()
Return the stopped services

CLI Example:
```
salt '*' service.get_stopped
```

salt.modules.smf.missing(name)
The inverse of service.available. Returns True if the specified service is not available, otherwise returns False.

CLI Example:
```
salt '*' service.missing net-snmp
```

salt.modules.smf.reload(name)
Reload the named service

CLI Example:
```
salt '*' service.reload <service name>
```

salt.modules.smf.restart(name)
Restart the named service

CLI Example:
```
salt '*' service.restart <service name>
```

salt.modules.smf.start(name)
Start the specified service

CLI Example:
```
salt '*' service.start <service name>
```

salt.modules.smf.status(name, sig=None)
Return the status for a service, returns a bool whether the service is running.

CLI Example:
```
salt '*' service.status <service name>
```

salt.modules.smf.stop(name)
Stop the specified service

CLI Example:
32.17.251 salt.modules.smtp

Module for Sending Messages via SMTP

New in version 2014.7.0.

depends

- smtplib python module

configuration This module can be used by either passing a jid and password directly to send_message, or by specifying the name of a configuration profile in the minion config, minion pillar, or master config.

For example:

```
my-smtp-login:
    smtp.server: smtp.domain.com
    smtp.tls: True
    smtp.sender: admin@domain.com
    smtp.username: myuser
    smtp.password: verybadpass
```

The resourcename refers to the resource that is using this account. It is user-definable, and optional. The following configurations are both valid:

```
my-smtp-login:
    smtp.server: smtp.domain.com
    smtp.tls: True
    smtp.sender: admin@domain.com
    smtp.username: myuser
    smtp.password: verybadpass

another-smtp-login:
    smtp.server: smtp.domain.com
    smtp.tls: True
    smtp.sender: admin@domain.com
    smtp.username: myuser
    smtp.password: verybadpass
```

```
salt.modules.smtp.send_msg(recipient, message, subject='Message from Salt', sender=None, server=None, use_ssl='True', username=None, password=None, profile=None)
```

Send a message to an SMTP recipient. Designed for use in states.

CLI Examples:

```
salt.send_msg 'admin@example.com' 'This is a salt module test'

salt.send_msg 'admin@example.com' 'This is a salt module test'
    server='smtp.domain.com'
    username='myuser' password='verybadpass' sender='admin@example.com'
```
32.17.252 `salt.modules.softwareupdate`

Support for the softwareupdate command on MacOS.

`salt.modules.softwareupdate.download(*updates)`

Download a named update so that it can be installed later with the install or upgrade function. It returns a list of all updates that are now downloaded.

CLI Example:

```
salt '*' softwareupdate.download <update name>
salt '*' softwareupdate.download "<update with whitespace>"
salt '*' softwareupdate.download <update1> <update2> <update3>
```

`salt.modules.softwareupdate.download_all(rec=False, restart=True)`

Download all available updates so that they can be installed later with the install or upgrade function. It returns a list of updates that are now downloaded.

CLI Example:

```
salt '*' softwareupdate.download_all
```

`salt.modules.softwareupdate.ignore(*updates)`

Ignore a specific program update. When an update is ignored the `-` and version number at the end will be omitted, so `SecUpd2014-001-1.0` becomes `SecUpd2014-001`. It will be removed automatically if present. An update is successfully ignored when it no longer shows up after list_upgrades.

CLI Example:

```
salt '*' softwareupdate.ignore <update-name>
salt '*' softwareupdate.ignore "<update with whitespace>"
salt '*' softwareupdate.ignore <update1> <update2> <update3>
```

`salt.modules.softwareupdate.install(*updates)`

Install a named upgrade. Returns a dictionary containing the name of the update and the status of its installation.

Return values: - `True`: The update was installed. - `False`: The update was not installed. - `None`: There is no update available with that name.

CLI Example:

```
salt '*' softwareupdate.install <update-name>
salt '*' softwareupdate.install "<update with whitespace>"
salt '*' softwareupdate.install <update1> <update2> <update3>
```

`salt.modules.softwareupdate.list_downloads()`

Return a list of all updates that have been downloaded locally.

CLI Example:

```
salt '*' softwareupdate.list_downloads
```

`salt.modules.softwareupdate.list_ignored()`

List all upgrades that has been ignored. Ignored updates are shown without the `-` and version number at the end, this is how the softwareupdate command works.

CLI Example:
salt '*' softwareupdate.list_ignored

salt.modules.softwareupdate.list_upgrades(\text{\texttt{rec=False, restart=False}})

List all available updates.

\texttt{rec} Return only the recommended updates.

\texttt{restart} Return only the updates that require a restart.

CLI Example:

\begin{verbatim}
salt '*' softwareupdate.list_upgrades
\end{verbatim}

salt.modules.softwareupdate.reset_ignored()

Make sure the ignored updates are not ignored anymore, returns a list of the updates that are no longer ignored.

CLI Example:

\begin{verbatim}
salt '*' softwareupdate.reset_ignored
\end{verbatim}

salt.modules.softwareupdate.schedule('\textit{status})

Decide if automatic checking for upgrades should be on or off. If no arguments are given it will return the current status. Append on or off to change the status.

Return values: - True: Automatic checking is now on, - False: Automatic checking is now off, - None: Invalid argument.

CLI Example:

\begin{verbatim}
salt '*' softwareupdate.schedule
salt '*' softwareupdate.schedule on|off
\end{verbatim}

salt.modules.softwareupdate.upgrade(\text{\texttt{rec=False, restart=True}})

Install all available upgrades. Returns a dictionary containing the name of the update and the status of its installation.

Return values: - True: The update was installed. - False: The update was not installed.

\texttt{rec} If set to True, only install all the recommended updates.

\texttt{restart} Set this to False if you do not want to install updates that require a restart.

CLI Example:

\begin{verbatim}
salt '*' softwareupdate.upgrade
\end{verbatim}

salt.modules.softwareupdate.upgrade_available(update)

Check whether or not an upgrade is available with a given name.

CLI Example:

\begin{verbatim}
salt '*' softwareupdate.upgrade_available <update-name>
salt '*' softwareupdate.upgrade_available "<update with whitespace>"
\end{verbatim}

\subsection{32.17.253 salt.modules.solaris_group}

Manage groups on Solaris
**Important:** If you feel that Salt should be using this module to manage groups on a minion, and it is using a different module (or gives an error similar to ‘group.info’ is not available), see here.

```python
salt.modules.solaris_group.add(name, gid=None, **kwargs)
Add the specified group

CLI Example:
```salt '*' group.add foo 3456```

```python
salt.modules.solaris_group.chgid(name, gid)
Change the gid for a named group

CLI Example:
```salt '*' group.chgid foo 4376```

```python
salt.modules.solaris_group.delete(name)
Remove the named group

CLI Example:
```salt '*' group.delete foo```

```python
salt.modules.solaris_group.getent(refresh=False)
Return info on all groups

CLI Example:
```salt '*' group.getent```

```python
salt.modules.solaris_group.info(name)
Return information about a group

CLI Example:
```salt '*' group.info foo```

**32.17.254** `salt.modules.solaris_shadow`

Manage the password database on Solaris systems

**Important:** If you feel that Salt should be using this module to manage passwords on a minion, and it is using a different module (or gives an error similar to ‘shadow.info’ is not available), see here.

```python
salt.modules.solaris_shadow.default_hash()
Returns the default hash used for unset passwords

CLI Example:
```salt '*' shadow.default_hash```

```python
salt.modules.solaris_shadow.del_password(name)
```
Delete the password from name user

CLI Example:
```
$ salt '*' shadow.del_password username
```

salt.modules.solaris_shadow.gen_password(password, crypt_salt=None, algorithm='sha512')

Generate hashed password

**Note:** When called this function is called directly via remote-execution, the password argument may be displayed in the system's process list. This may be a security risk on certain systems.

- **password**  Plaintext password to be hashed.
- **crypt_salt**  Cryptographic salt. If not given, a random 8-character salt will be generated.
- **algorithm**  The following hash algorithms are supported:
  - md5
  - blowfish (not in mainline glibc, only available in distros that add it)
  - sha256
  - sha512 (default)

CLI Example:
```
$ salt '*' shadow.gen_password 'I_am_password'
$ salt '*' shadow.gen_password 'I_am_password' crypt_salt='I_am_salt' algorithm=sha256
```

salt.modules.solaris_shadow.info(name)

Return information for the specified user

CLI Example:
```
$ salt '*' shadow.info root
```

salt.modules.solaris_shadow.set_maxdays(name, maxdays)

Set the maximum number of days during which a password is valid. See man passwd.

CLI Example:
```
$ salt '*' shadow.set_maxdays username 90
```

salt.modules.solaris_shadow.set_mindays(name, mindays)

Set the minimum number of days between password changes. See man passwd.

CLI Example:
```
$ salt '*' shadow.set_mindays username 7
```

salt.modules.solaris_shadow.set_password(name, password)

Set the password for a named user. The password must be a properly defined hash, the password hash can be generated with this command: openssl passwd -1 <plaintext password>

CLI Example:
salt '*' shadow.set_password root $1$UYCIxa628.$9qXjpQCjM4a..

salt.modules.solaris_shadow.set_warndays(name, warndays)
Set the number of days of warning before a password change is required. See man passwd.

CLI Example:
salt '*' shadow.set_warndays username 7

32.17.255 salt.modules.solaris_user

Manage users with the useradd command

Important: If you feel that Salt should be using this module to manage users on a minion, and it is using a different module (or gives an error similar to `user.info` is not available), see here.

salt.modules.solaris_user.add(name, uid=None, gid=None, groups=None, home=None, shell=None, unique=True, fullname='', roomnumber='', workphone='', homephone='', createhome=True, **kwargs)
Add a user to the minion

CLI Example:
salt '*' user.add name <uid> <gid> <groups> <home> <shell>

salt.modules.solaris_user.chfullname(name, fullname)
Change the user's Full Name

CLI Example:
salt '*' user.chfullname foo "Foo Bar"

salt.modules.solaris_user.chgid(name, gid)
Change the default group of the user

CLI Example:
salt '*' user.chgid foo 4376

salt.modules.solaris_user.chgroups(name, groups, append=False)
Change the groups this user belongs to, add append to append the specified groups

CLI Example:
salt '*' user.chgroups foo wheel,root True

salt.modules.solaris_user.chhome(name, home, persist=False)
Change the home directory of the user, pass true for persist to copy files to the new home dir

CLI Example:
salt '*' user.chhome foo /home/users/foo True

salt.modules.solaris_user.chhomephone(name, homephone)
Change the user's Home Phone

32.17. Full list of builtin execution modules
CLI Example:

```
salt '*' user.chhomephone foo "7735551234"
```

salt.modules.solaris_user.chroomnumber(name, roomnumber)
Change the user's Room Number

CLI Example:

```
salt '*' user.chroomnumber foo 123
```

salt.modules.solaris_user.chshell(name, shell)
Change the default shell of the user

CLI Example:

```
salt '*' user.chshell foo /bin/zsh
```

salt.modules.solaris_user.chuid(name, uid)
Change the uid for a named user

CLI Example:

```
salt '*' user.chuid foo 4376
```

salt.modules.solaris_user.chworkphone(name, workphone)
Change the user's Work Phone

CLI Example:

```
salt '*' user.chworkphone foo "7735550123"
```

salt.modules.solaris_user.delete(name, remove=False, force=False)
Remove a user from the minion

CLI Example:

```
salt '*' user.delete name remove=True force=True
```

salt.modules.solaris_user.getent(refresh=False)
Return the list of all info for all users

CLI Example:

```
salt '*' user.getent
```

salt.modules.solaris_user.info(name)
Return user information

CLI Example:

```
salt '*' user.info root
```

salt.modules.solaris_user.list_groups(name)
Return a list of groups the named user belongs to

CLI Example:

```
salt '*' user.list_groups foo
```
salt.modules.solaris_user.rename(name, new_name)

Change the username for a named user

CLI Example:

```
salt '*' user.rename name new_name
```

### 32.17.256 salt.modules.solarisips

IPS pkg support for Solaris

**Important:** If you feel that Salt should be using this module to manage packages on a minion, and it is using a different module (or gives an error similar to `pkg.install' is not available), see here.

This module provides support for Solaris 11 new package management - IPS (Image Packaging System). This is the default pkg module for Solaris 11 (and later).

If you want to use also other packaging module (e.g. pkgutil) together with IPS, you need to override the pkg provider in sls for each package:

```
mypackage:
  pkg.installed:
    - provider: pkgutil
```

Or you can override it globally by setting the `providers` parameter in your Minion config file like this:

```
providers:
  pkg: pkgutil
```

Or you can override it globally by setting the `providers` parameter in your Minion config file like this:

```
providers:
  pkg: pkgutil
```

salt.modules.solarisips.available_version(name, **kwargs)

This function is an alias of latest_version.

The available version of the package in the repository. In case of multiple match, it returns list of all matched packages. Accepts full or partial FMRI. Please use pkg.latest_version as pkg.available_version is being deprecated.

CLI Example:

```
salt '*' pkg.latest_version pkg://solaris/entire
```

salt.modules.solarisips.get_fmri(name, **kwargs)

Returns FMRI from partial name. Returns empty string ("") if not found. In case of multiple match, the function returns list of all matched packages.

CLI Example:

```
salt '*' pkg.get_fmri bash
```

salt.modules.solarisips.install(name=None, refresh=False, pkgs=None, version=None, test=False, **kwargs)

Install the named package using the IPS pkg command. Accepts full or partial FMRI.
Returns a dict containing the new package names and versions:

```python
{'<package>': {'old': '<old-version>', 'new': '<new-version>'}}
```

Multiple Package Installation Options:

- **pkgs** A list of packages to install. Must be passed as a python list.

**CLI Example:**

```
salt '*' pkg.install vim
salt '*' pkg.install pkg://solaris/editor/vim
salt '*' pkg.install pkg://solaris/editor/vim refresh=True
salt '*' pkg.install pkgs=['foo', 'bar']
```

**salt.modules.solarisips.is_installed(name, **kwargs)**

Returns True if the package is installed. Otherwise returns False. Name can be full or partial FMRI. In case of multiple match from partial FMRI name, it returns True.

**CLI Example:**

```
salt '*' pkg.is_installed bash
```

**salt.modules.solarisips.latest_version(name, **kwargs)**

The available version of the package in the repository. In case of multiple match, it returns list of all matched packages. Accepts full or partial FMRI. Please use pkg.latest_version as pkg.available_version is being deprecated.

**CLI Example:**

```
salt '*' pkg.latest_version pkg://solaris/entire
```

**salt.modules.solarisips.list_pkgs(versions_as_list=False, **kwargs)**

List the currently installed packages as a dict:

```python
{'<package_name>': '<version>'}
```

**CLI Example:**

```
salt '*' pkg.list_pkgs
```

**salt.modules.solarisips.list_upgrades(refresh=False, **kwargs)**

Lists all packages available for update.

When run in global zone, it reports only upgradable packages for the global zone.

When run in non-global zone, it can report more upgradable packages than pkg update -vn, because pkg update hides packages that require newer version of pkg://solaris/entire (which means that they can be upgraded only from the global zone). If pkg://solaris/entire is found in the list of upgrades, then the global zone should be updated to get all possible updates. Use refresh=True to refresh the package database.

**CLI Example:**

```
salt '*' pkg.list_upgrades
salt '*' pkg.list_upgrades refresh=True
```
salt.modules.solarisips.normalize_name(name, **kwargs)
Internal function. Normalizes pkg name to full FMRI before running pkg.install. In case of multiple match or no match, it returns the name without modifications and lets the `pkg install` to decide what to do.

CLI Example:
```
salt '*' pkg.normalize_name vim
```

salt.modules.solarisips.purge(name, **kwargs)
Remove specified package. Accepts full or partial FMRI.

Returns a list containing the removed packages.

CLI Example:
```
salt '*' pkg.purge <package name>
```

salt.modules.solarisips.refresh_db(full=False)
Updates the remote repos database. You can force the full pkg DB refresh from all publishers regardless the last refresh time.

CLI Example:
```
salt '*' pkg.refresh_db
salt '*' pkg.refresh_db full=True
```

salt.modules.solarisips.remove(name=None, pkgs=None, **kwargs)
Remove specified package. Accepts full or partial FMRI. In case of multiple match, the command fails and won't modify the OS.

name The name of the package to be deleted.

Multiple Package Options:

pkgs A list of packages to delete. Must be passed as a python list. The name parameter will be ignored if this option is passed.

Returns a list containing the removed packages.

CLI Example:
```
salt '*' pkg.remove <package name>
salt '*' pkg.remove tcsh
salt '*' pkg.remove pkg://solaris/shell/tcsh
salt '*' pkg.remove pkgs=['"foo", "bar"]'
```

salt.modules.solarisips.search(name, versions_as_list=False, **kwargs)
Searches the repository for given pkg name. The name can be full or partial FMRI. All matches are printed. Globes are also supported.

CLI Example:
```
salt '*' pkg.search bash
```

salt.modules.solarisips.upgrade(refresh=False, **kwargs)
Upgrade all packages to the latest possible version. When run in global zone, it updates also all non-global zones. In non-global zones upgrade is limited by dependency constraints linked to the version of pkg://solaris/entire.

Returns also a raw output of `pkg update` command (because if update creates a new boot environment, no immediate changes are visible in `pkg list`).

32.17. Full list of builtin execution modules
**CLI Example:**

```
salt '*' pkg.upgrade
```

salt.modules.solarisips.upgrade_available(name)
Check if there is an upgrade available for a certain package. Accepts full or partial FMRI. Returns all matches found.

**CLI Example:**

```
salt '*' pkg.upgrade_available apache-22
```

salt.modules.solarisips.version(*names, **kwargs)
Common interface for obtaining the version of installed packages. Accepts full or partial FMRI. If called using pkg_resource, full FMRI is required.

**CLI Example:**

```
salt '*' pkg.version vim
salt '*' pkg.version foo bar baz
salt '*' pkg_resource.version pkg://solaris/entire
```

## 32.17.257 salt.modules.solarispkg

Package support for Solaris

**Important:** If you feel that Salt should be using this module to manage packages on a minion, and it is using a different module (or gives an error similar to `pkg.install` is not available), see here.

salt.modules.solarispkg.install(name=None, sources=None, saltenv='base', **kwargs)
Install the passed package. Can install packages from the following sources:

- Locally (package already exists on the minion)
- HTTP/HTTPS server
- FTP server
- Salt master

Returns a dict containing the new package names and versions:

```python
{'<package>': {'old': '<old-version>',
               'new': '<new-version>'}}
```

**CLI Example**, installing a data stream pkg that already exists on the minion:

```
salt '*' pkg.install sources='["<pkg name>": "/dir/on/minion/<pkg filename>"]'
salt '*' pkg.install sources='["SMClgcc346": "/var/spool/pkg/gcc-3.4.6-sol10-sparc-local.pkg"]'
```

**CLI Example**, installing a data stream pkg that exists on the salt master:

```
salt '*' pkg.install sources='["<pkg name>": "salt://pkgs/<pkg filename>"]'
salt '*' pkg.install sources='["SMClgcc346": "salt://pkgs/gcc-3.4.6-sol10-sparc-local.pkg"]'
```

**CLI Example**, installing a data stream pkg that exists on a HTTP server:
If working with Solaris zones and you want to install a package only in the global zone you can pass `current_zone_only=True` to `salt` to have the package only installed in the global zone. (Behind the scenes this is passing `-G` to the `pkgadd` command.) Solaris default when installing a package in the global zone is to install it in all zones. This overrides that and installs the package only in the global.

CLI Example, installing a data stream package only in the global zone:

```sh
salt 'global_zone' pkg.install sources='["SMClgcc346": "/var/spool/pkg/gcc-3.4.6-sol10-sparc-local.pkg"]' current_zone_only=True
```

By default Salt automatically provides an adminfile, to automate package installation, with these options set:

```sh
e-mail=
instance=quit
partial=nocheck
runlevel=nocheck
idepend=nocheck
rdepend=nocheck
space=nocheck
setuid=nocheck
conflict=nocheck
action=nocheck
basedir=default
```

You can override any of these options in two ways. First you can optionally pass any of the options as a kwarg to the module/state to override the default value or you can optionally pass the `admin_source` option providing your own adminfile to the minions.

Note: You can find all of the possible options to provide to the adminfile by reading the `admin` man page:

```sh
man -s 4 admin
```

CLI Example - Overriding the `instance` adminfile option when calling the module directly:

```sh
salt '*' pkg.install sources='["<pkg name>": "salt://pkgs/<pkg filename>"]' --instance="overwrite"
```

CLI Example - Overriding the `instance` adminfile option when used in a state:

```sh
SMClgcc346:
  pkginstalled:
  - sources:
  - SMClgcc346: salt://srv/salt/pkgs/gcc-3.4.6-sol10-sparc-local.pkg
  - instance: overwrite
```

Note: the ID declaration is ignored, as the package name is read from the `sources` parameter.

CLI Example - Providing your own adminfile when calling the module directly:

```sh
salt '*' pkg.install sources='["<pkg name>": "salt://pkgs/<pkg filename>"]' --admin_source='salt://pkgs/<adminfile filename>'
```

CLI Example - Providing your own adminfile when using states:
pkg name: pkg
installed:
- sources:
  - <pkg name>: salt://pkgs/<pkg filename>
  - admin_source: salt://pkgs/<adminfile filename>

Note: the ID declaration is ignored, as the package name is read from the "sources" parameter.

salt.modules.solarispkg.latest_version(*names, **kwargs)
Return the latest version of the named package available for upgrade or installation. If more than one package name is specified, a dict of name/version pairs is returned.
If the latest version of a given package is already installed, an empty string will be returned for that package.
CLI Example:

```bash
salt '*' pkg.latest_version <package name>
salt '*' pkg.latest_version <package1> <package2> <package3> ...
```

NOTE: As package repositories are not presently supported for Solaris pkgadd, this function will always return an empty string for a given package.

salt.modules.solarispkg.list_pkgs(versions_as_list=False, **kwargs)
List the packages currently installed as a dict:

```json
{"<package_name>": "<version>"}
```

CLI Example:

```bash
salt '*' pkg.list_pkgs
```

salt.modules.solarispkg.purge(name=None, pkgs=None, **kwargs)
Package purges are not supported, this function is identical to remove().

name The name of the package to be deleted

Multiple Package Options:

pkgs A list of packages to delete. Must be passed as a python list. The name parameter will be ignored if this option is passed.

New in version 0.16.0.
Returns a dict containing the changes.

CLI Example:

```bash
salt '*' pkg.purge <package name>
salt '*' pkg.purge <package1>,<package2>,<package3>
salt '*' pkg.purge pkgs='["foo", "bar"]'
```

salt.modules.solarispkg.remove(name=None, pkgs=None, saltenv='base', **kwargs)
Remove packages with pkgrm

name The name of the package to be deleted

By default salt automatically provides an adminfile, to automate package removal, with these options set:

```bash
email=
instance=quit
partial=nocheck
```
You can override any of these options in two ways. First you can optionally pass any of the options as a kwarg to the module/state to override the default value or you can optionally pass the `admin_source` option providing your own adminfile to the minions.

Note: You can find all of the possible options to provide to the adminfile by reading the admin man page:

```
man -s 4 admin
```

Multiple Package Options:

**pkgs** A list of packages to delete. Must be passed as a python list. The name parameter will be ignored if this option is passed.

New in version 0.16.0.

Returns a dict containing the changes.

CLI Example:

```
salt '*' pkg.remove <package name>
salt '*' pkg.remove SUNWgit
salt '*' pkg.remove <package1>,<package2>,<package3>
salt '*' pkg.remove pkgs='["foo", "bar"]'
```

```
salt.modules.solarispkg.upgrade_available(name)
```

Check whether or not an upgrade is available for a given package

CLI Example:

```
salt '*' pkg.upgrade_available <package name>
```

```
salt.modules.solarispkg.version('names', **kwargs)
```

Returns a string representing the package version or an empty string if not installed. If more than one package name is specified, a dict of name/version pairs is returned.

CLI Example:

```
salt '*' pkg.version <package name>
salt '*' pkg.version <package1> <package2> <package3> ...
```

32.17.258 salt.modules.solr

Apache Solr Salt Module

Author: Jed Glazner Version: 0.2.1 Modified: 12/09/2011

This module uses HTTP requests to talk to the apache solr request handlers to gather information and report errors. Because of this the minion doesn't necessarily need to reside on the actual slave. However if you want to use the signal function the minion must reside on the physical solr host.
This module supports multi-core and standard setups. Certain methods are master/slave specific. Make sure you set the solr.type. If you have questions or want a feature request please ask.

Coming Features in 0.3

1. Add command for checking for replication failures on slaves
2. Improve match_index_versions since it’s pointless on busy solr masters
3. Add additional local fs checks for backups to make sure they succeeded

Override these in the minion config

solr.cores  A list of core names e.g. ['core1','core2']. An empty list indicates non-multicore setup.
solr.baseurl  The root level URL to access solr via HTTP
solr.request_timeout  The number of seconds before timing out an HTTP/HTTPS/FTP request. If nothing is specified then the python global timeout setting is used.
solr.type  Possible values are `master` or `slave`
solr.backup_path  The path to store your backups. If you are using cores and you can specify to append the core name to the path in the backup method.
solr.num_backups  For versions of solr >= 3.5. Indicates the number of backups to keep. This option is ignored if your version is less.
solr.init_script  The full path to your init script with start/stop options
solr.dih.options  A list of options to pass to the DIH.

Required Options for DIH

clean  [False] Clear the index before importing
commit  [True] Commit the documents to the index upon completion
optimize  [True] Optimize the index after commit is complete
verbose  [True] Get verbose output

salt.modules.solr.abort_import(handler, host=None, core_name=None, verbose=False)

MASTER ONLY Aborts an existing import command to the specified handler. This command can only be run if the minion is configured with solr.type=master

handler  [str] The name of the data import handler.
host  [str (None)] The solr host to query. __opts__['host'] is default.
core  [str (None)] The core the handler belongs to.
verbose  [boolean (False)] Run the command with verbose output.

Return : dict:<str,obj>:

{'success':boolean, 'data':dict, 'errors':list, 'warnings':list}

CLI Example:
salt 'salt '*' solr.abort_import dataimport None music {'clean':True}

salt.modules.solr.backup

Tell solr make a backup. This method can be misleading since it uses the backup API. If an error happens during the backup you are not notified. The status: `OK` in the response simply means that solr received the request successfully.

host [str (None)] The solr host to query. __opts__['host'] is default.

core_name [str (None)] The name of the solr core if using cores. Leave this blank if you are not using cores or if you want to check all cores.

append_core_to_path [boolean (False)] If True add the name of the core to the backup path. Assumes that minion backup path is not None.

Return: dict<str,obj>:

{ 'success':boolean, 'data':dict, 'errors':list, 'warnings':list }

CLI Example:

salt 'salt '*' solr.backup music

salt.modules.solr.core_status

MULTI-CORE HOSTS ONLY Get the status for a given core or all cores if no core is specified.

host [str (None)] The solr host to query. __opts__['host'] is default.

core_name [str] The name of the core to reload

Return: dict<str,obj>:

{ 'success':boolean, 'data':dict, 'errors':list, 'warnings':list }

CLI Example:

salt 'salt '*' solr.core_status None music

salt.modules.solr.delta_import

Submits an import command to the specified handler using specified options. This command can only be run if the minion is configured with solr.type=master

handler [str] The name of the data import handler.

host [str (None)] The solr host to query. __opts__['host'] is default.

core [str (None)] The core the handler belongs to.

options [dict (__opts__)] A list of options such as clean, optimize commit, verbose, and pause_replication. leave blank to use __opts__ defaults. options will be merged with __opts__

extra [dict ([)]) Extra name value pairs to pass to the handler. e.g. ["name=value"]

Return: dict<str,obj>:

{ 'success':boolean, 'data':dict, 'errors':list, 'warnings':list }

CLI Example:

salt 'salt '*' solr.delta_import dataimport None music {'clean':True}
salt.modules.solr.full_import(handler, host=None, core_name=None, options=None, extra=None)

MASTER ONLY Submits an import command to the specified handler using specified options. This command
can only be run if the minion is configured with solr.type=master

handler [str] The name of the data import handler.
host [str (None)] The solr host to query. __opts__['host'] is default.
core [str (None)] The core the handler belongs to.
options [dict (__opts__)] A list of options such as clean, optimize commit, verbose, and pause_replication.
leave blank to use __opts__ defaults. options will be merged with __opts__
extra [dict ([])]} Extra name value pairs to pass to the handler. e.g. ['name=value']

Return : dict<str,obj>:

{'success':boolean, 'data':dict, 'errors':list, 'warnings':list}

CLI Example:
salt '*' solr.full_import dataimport None music {'clean':True}

salt.modules.solr.import_status(handler, host=None, core_name=None, verbose=False)

Submits an import command to the specified handler using specified options. This command can only be run
if the minion is configured with solr.type: 'master'

handler [str] The name of the data import handler.
host [str (None)] The solr host to query. __opts__['host'] is default.
core [str (None)] The core the handler belongs to.
verbose [boolean (False)] Specifies verbose output

Return : dict<str,obj>:

{'success':boolean, 'data':dict, 'errors':list, 'warnings':list}

CLI Example:
salt '*' solr.import_status dataimport None music False

salt.modules.solr.is_replication_enabled(host=None, core_name=None)

SLAVE CALL Check for errors, and determine if a slave is replicating or not.
host [str (None)] The solr host to query. __opts__['host'] is default.
core_name [str (None)] The name of the solr core if using cores. Leave this blank if you are not using cores
or if you want to check all cores.

Return : dict<str,obj>:

{'success':boolean, 'data':dict, 'errors':list, 'warnings':list}

CLI Example:
salt '*' solr.is_replication_enabled music

salt.modules.solr.lucene_version(core_name=None)

Gets the lucene version that solr is using. If you are running a multi-core setup you should specify a core name
since all the cores run under the same servlet container, they will all have the same version.
**core_name** [str (None)] The name of the solr core if using cores. Leave this blank if you are not using cores or if you want to check all cores.

Return: dict<str,obj>:

```py
{'success':boolean, 'data':dict, 'errors':list, 'warnings':list}
```

CLI Example:

```sh
salt '*' solr.lucene_version
```

### sls.modules.solr.match_index_versions

SLAVE CALL Verifies that the master and the slave versions are in sync by comparing the index version. If you are constantly pushing updates the index the master and slave versions will seldom match. A solution to this is pause indexing every so often to allow the slave to replicate and then call this method before allowing indexing to resume.

**host** [str (None)] The solr host to query. __opts__['host'] is default.

**core_name** [str (None)] The name of the solr core if using cores. Leave this blank if you are not using cores or if you want to check all cores.

Return: dict<str,obj>:

```py
{'success':boolean, 'data':dict, 'errors':list, 'warnings':list}
```

CLI Example:

```sh
salt '*' solr.match_index_versions music
```

### sls.modules.solr.optimize

Search queries fast, but it is a very expensive operation. The ideal process is to run this with a master/slave configuration. Then you can optimize the master, and push the optimized index to the slaves. If you are running a single solr instance, or if you are going to run this on a slave be aware than search performance will be horrible while this command is being run. Additionally it can take a LONG time to run and your HTTP request may timeout. If that happens adjust your timeout settings.

**host** [str (None)] The solr host to query. __opts__['host'] is default.

**core_name** [str (None)] The name of the solr core if using cores. Leave this blank if you are not using cores or if you want to check all cores.

Return: dict<str,obj>:

```py
{'success':boolean, 'data':dict, 'errors':list, 'warnings':list}
```

CLI Example:

```sh
salt '*' solr.optimize music
```

### sls.modules.solr.ping

Does a health check on solr, makes sure solr can talk to the indexes.

**host** [str (None)] The solr host to query. __opts__['host'] is default.

**core_name** [str (None)] The name of the solr core if using cores. Leave this blank if you are not using cores or if you want to check all cores.

Return: dict<str,obj>:
{'success':boolean, 'data':dict, 'errors':list, 'warnings':list}

CLI Example:
salt '*' solr.ping music

salt.modules.solr.reload_core(host=host, core_name=None)
MULTI-CORE HOSTS ONLY Load a new core from the same configuration as an existing registered core. While the ``new`` core is initializing, the ```old``` one will continue to accept requests. Once it has finished, all new request will go to the ```new``` core, and the ```old``` core will be unloaded.

host [str (None)] The solr host to query. __opts__['host'] is default.
core_name [str] The name of the core to reload

Return : dict<str,obj>:

{'success':bool, 'data':dict, 'errors':list, 'warnings':list}

CLI Example:
salt '*' solr.reload_core None music

Return data is in the following format:

{'success':bool, 'data':dict, 'errors':list, 'warnings':list}

salt.modules.solr.reload_import_config(handler, host=host, core_name=None, verbose=False)
MASTER ONLY re-loads the handler config XML file. This command can only be run if the minion is a ```master``` type

handler [str] The name of the data import handler.
host [str (None)] The solr host to query. __opts__['host'] is default.
core [str (None)] The core the handler belongs to.
verbose [boolean (False)] Run the command with verbose output.

Return : dict<str,obj>:

{'success':bool, 'data':dict, 'errors':list, 'warnings':list}

CLI Example:
salt '*' solr.reload_import_config dataimport None music {'clean':True}

salt.modules.solr.replication_details(host=host, core_name=None)
Get the full replication details.

host [str (None)] The solr host to query. __opts__['host'] is default.
core_name [str (None)] The name of the solr core if using cores. Leave this blank if you are not using cores or if you want to check all cores.

Return : dict<str,obj>:

{'success':bool, 'data':dict, 'errors':list, 'warnings':list}

CLI Example:
salt '*>* solr.replication_details music

salt.modules.solr.set_is_polling(polling, host=None, core_name=None)
SLAVE CALL Prevent the slaves from polling the master for updates.

polling  [boolean] True will enable polling. False will disable it.
host  [str (None)] The solr host to query. __opts__['host'] is default.
core_name  [str (None)] The name of the solr core if using cores. Leave this blank if you are not using cores or if you want to check all cores.

Return : dict<str,obj>:
{'success':boolean, 'data':dict, 'errors':list, 'warnings':list}

CLI Example:
salt '*>* solr.set_is_polling False

salt.modules.solr.set_replication_enabled(status, host=None, core_name=None)
MASTER ONLY Sets the master to ignore poll requests from the slaves. Useful when you don't want the slaves replicating during indexing or when clearing the index.

status  [boolean] Sets the replication status to the specified state.
host  [str (None)] The solr host to query. __opts__['host'] is default.
core_name  [str (None)] The name of the solr core if using cores. Leave this blank if you are not using cores or if you want to set the status on all cores.

Return : dict<str,obj>:
{'success':boolean, 'data':dict, 'errors':list, 'warnings':list}

CLI Example:
salt '*>* solr.set_replication_enabled false, None, music

salt.modules.solr.signal(signal=None)
Signals Apache Solr to start, stop, or restart. Obviously this is only going to work if the minion resides on the solr host. Additionally Solr doesn't ship with an init script so one must be created.

signal  [str (None)] The command to pass to the apache solr init valid values are `start', `stop', and `restart'

CLI Example:
salt '*>* solr.signal restart

salt.modules.solr.version(core_name=None)
Gets the solr version for the core specified. You should specify a core here as all the cores will run under the same servlet container and so will all have the same version.

core_name  [str (None)] The name of the solr core if using cores. Leave this blank if you are not using cores or if you want to check all cores.

Return : dict<str,obj>:
{'success':boolean, 'data':dict, 'errors':list, 'warnings':list}

CLI Example:
32.17.259  salt.modules.splay

Splay function calls across targeted minions

```python
salt.modules.splay.show(splaytime=600)
```
Show calculated splaytime for this minion Will use default value of 600 (seconds) if splaytime value not provided

CLI Example:  salt example-host splay.show salt example-host splay.show 60

```python
salt.modules.splay.splay(*args, **kwargs)
```
Splay a salt function call execution time across minions over a number of seconds (default: 600)

Note: You probably want to use `--async` here and look up the job results later. If you're dead set on getting the output from the CLI command, then make sure to set the timeout (with the `-t` flag) to something greater than the splaytime (max splaytime + time to execute job). Otherwise, it's very likely that the cli will time out before the job returns.

CLI Examples:

```shell
salt --async 'splay.splay pkg.install cowsay version=3.03-8.el6
```

# With specified splaytime (5 minutes) and timeout with 10 second buffer
```
salt -t 310 'splay.splay 300 pkg.version cowsay
```

32.17.260  salt.modules.splunk_search

Module for interop with the Splunk API

New in version 2015.5.0.

depends

- splunk-sdk python module

configuration Configure this module by specifying the name of a configuration profile in the minion config, minion pillar, or master config. The module will use the `splunk` key by default, if defined.

For example:

```
splunk:
    username: alice
    password: abc123
    host: example.splunkcloud.com
    port: 8080
```

```python
salt.modules.splunk_search.create(name, profile='splunk', **kwargs)
```
Create a splunk search

CLI Example:

```
splunk_search.create 'my search name' search='error msg'
```
salt.modules.splunk_search.delete(name, profile='splunk')
Delete a splunk search

CLI Example:
splunk_search.delete 'my search name'

salt.modules.splunk_search.get(name, profile='splunk')
Get a splunk search

CLI Example:
splunk_search.get 'my search name'

salt.modules.splunk_search.list(profile='splunk')
List splunk searches (names only)

CLI Example: splunk_search.list

salt.modules.splunk_search.list_all(prefix=None, app=None, owner=None, description_contains=None, name_not_contains=None, profile='splunk')
Get all splunk search details. Produces results that can be used to create an sls file.
if app or owner are specified, results will be limited to matching saved searches.
if description_contains is specified, results will be limited to those where ``description_contains in description'' is true if name_not_contains is specified, results will be limited to those where ``name_not_contains not in name'' is true.
If prefix parameter is given, alarm names in the output will be prepended with the prefix; alarms that have the prefix will be skipped. This can be used to convert existing alarms to be managed by salt, as follows:

CLI example:

1. Make a '``backup'' of all existing searches $ salt-call splunk_search.list_all --out=txt | sed `s/local: //'' > legacy_searches.sls
2. Get all searches with new prefixed names $ salt-call splunk_search.list_all `prefix="**MANAGED BY SALT**" --out=txt | sed `s/local: //'' > managed_searches.sls
3. Insert the managed searches into splunk $ salt-call state.sls managed_searches.sls
4. Manually verify that the new searches look right
5. Delete the original searches $ sed s/present/absent/ legacy_searches.sls > remove_legacy_searches.sls $ salt-call state.sls remove_legacy_searches.sls
6. Get all searches again, verify no changes $ salt-call splunk_search.list_all --out=txt | sed `s/local: //'' > final_searches.sls $ diff final_searches.sls managed_searches.sls

salt.modules.splunk_search.update(name, profile='splunk', **kwargs)
Update a splunk search

CLI Example:
splunk_search.update 'my search name' sharing=app

32.17.261 salt.modules.sqlite3

Support for SQLite3
salt.modules.sqlite3.fetch(db=None, sql=None)
Retrieve data from an sqlite3 db (returns all rows, be careful!)

CLI Example:
```
salt '*' sqlite3.fetch /root/test.db 'SELECT * FROM test;'
```

salt.modules.sqlite3.indexes(db=None)
Show all indices in the database, for people with poor spelling skills

CLI Example:
```
salt '*' sqlite3.indexes /root/test.db
```

salt.modules.sqlite3.indices(db=None)
Show all indices in the database

CLI Example:
```
salt '*' sqlite3.indices /root/test.db
```

salt.modules.sqlite3.modify(db=None, sql=None)
Issue an SQL query to sqlite3 (with no return data), usually used to modify the database in some way (insert, delete, create, etc)

CLI Example:
```
salt '*' sqlite3.modify /root/test.db 'CREATE TABLE test(id INT, testdata TEXT);'
```

salt.modules.sqlite3.sqlite_version()
Return version of sqlite

CLI Example:
```
salt '*' sqlite3.sqlite_version
```

salt.modules.sqlite3.tables(db=None)
Show all tables in the database

CLI Example:
```
salt '*' sqlite3.tables /root/test.db
```

salt.modules.sqlite3.version()
Return version of pysqlite

CLI Example:
```
salt '*' sqlite3.version
```

32.17.262 salt.modules.ssh

Manage client ssh components

Note: This module requires the use of MD5 hashing. Certain security audits may not permit the use of MD5. For those cases, this module should be disabled or removed.
salt.modules.ssh.auth_keys(user=None, config='ssh/authorized_keys')
Return the authorized keys for users

CLI Example:
```
salt '*' ssh.auth_keys
salt '*' ssh.auth_keys root
salt '*' ssh.auth_keys user=root
salt '*' ssh.auth_keys user="[user1, user2]"
```

salt.modules.ssh.check_key(user, key, enc, comment, options, config='ssh/authorized_keys', cache_keys=None)
Check to see if a key needs updating, returns ``update'', ``add'' or ``exists''

CLI Example:
```
salt '*' ssh.check_key <user> <key> <enc> <comment> <options>
```

salt.modules.ssh.check_key_file(user, source, config='ssh/authorized_keys', saltenv='base', env=None)
Check a keyfile from a source destination against the local keys and return the keys to change

CLI Example:
```
salt '*' ssh.check_key_file root salt://ssh/keyfile
```

salt.modules.ssh.check_known_host(user=None, hostname=None, key=None, fingerprint=None, config=None, port=None)
Check the record in known_hosts file, either by its value or by fingerprint (it's enough to set up either key or fingerprint, you don't need to set up both).

If provided key or fingerprint doesn't match with stored value, return ``update'', if no value is found for a given host, return ``add'', otherwise return ``exists''.

If neither key, nor fingerprint is defined, then additional validation is not performed.

CLI Example:
```
salt '*' ssh.check_known_host <user> <hostname> key='AAAA...FAaQ=='
```

salt.modules.ssh.get_known_host(user, hostname, config=None, port=None)
Return information about known host from the config file, if any. If there is no such key, return None.

CLI Example:
```
salt '*' ssh.get_known_host <user> <hostname>
```

salt.modules.ssh.hash_known_hosts(user=None, config=None)
Hash all the hostnames in the known hosts file.

New in version 2014.7.0.

user hash known hosts of this user
config path to known hosts file: can be absolute or relative to user's home directory

CLI Example:
```
salt '*' ssh.hash_known_hosts
```

salt.modules.ssh.host_keys(keydir=None, private=True)
Return the minion's host keys
salt.modules.ssh.key_is_encrypted(key)

New in version 2015.8.7.

Function to determine whether or not a private key is encrypted with a passphrase.

Checks key for a Proc-Type header with ENCRYPTED in the value. If found, returns True, otherwise returns False.

CLI Example:

```
salt '*' ssh.key_is_encrypted /root/id_rsa
```

salt.modules.ssh.recv_known_host(hostname, enc=None, port=None, hash_hostname=True, hash_known_hosts=True)

Retrieve information about host public key from remote server

hostname The name of the remote host (e.g. `github.com`)

enc Defines what type of key is being used, can be ed25519, ecdsa ssh-rsa or ssh-dss

port optional parameter, denoting the port of the remote host, which will be used in case, if the public key will be requested from it. By default the port 22 is used.

hash_hostname [True] Hash all hostnames and addresses in the known hosts file.

hash_known_hosts [True] Hash all hostnames and addresses in the known hosts file.

CLI Example:

```
salt '*' ssh.recv_known_host <hostname> enc=<enc> port=<port>
```

salt.modules.ssh.rm_auth_key(user, key, config='.ssh/authorized_keys')

Remove an authorized key from the specified user's authorized key file

CLI Example:

```
salt '*' ssh.rm_auth_key <user> <key>
```

salt.modules.ssh.rm_auth_key_from_file(user, source, config='.ssh/authorized_keys', saltenv='base', env=None)

Remove an authorized key from the specified user's authorized key file, using a file as source

CLI Example:

```
salt '*' ssh.rm_auth_key_from_file <user> salt://ssh_keys/<user>.id_rsa.pub
```

salt.modules.ssh.rm_known_host(user=None, hostname=None, config=None, port=None)

Remove all keys belonging to hostname from a known_hosts file.

CLI Example:

```
salt '*' ssh.rm_known_host <user> <hostname>
```
salt.modules.ssh.set_auth_key(user, key, enc='ssh-rsa', comment='', options=None, config='.ssh/authorized_keys', cache_keys=None)

Add a key to the authorized_keys file. The `key` parameter must only be the string of text that is the encoded key. If the key begins with `ssh-rsa` or ends with `user@host`, remove those from the key before passing it to this function.

CLI Example:

```
salt '*' ssh.set_auth_key <user> '<key>' enc='dsa'
```

salt.modules.ssh.set_auth_key_from_file(user, source, config='.ssh/authorized_keys', saltenv='base', env=None)

Add a key to the authorized_keys file, using a file as the source.

CLI Example:

```
salt '*' ssh.set_auth_key_from_file <user> salt://ssh_keys/<user>.id_rsa.pub
```

salt.modules.ssh.set_known_host(user=None, hostname=None, fingerprint=None, key=None, port=None, enc=None, hash_hostname=True, config=None, hash_known_hosts=True)

Download SSH public key from remote host `hostname`, optionally validate its fingerprint against `fingerprint` variable and save the record in the known_hosts file.

If such a record does already exists in there, do nothing.

user The user who owns the ssh authorized keys file to modify

hostname The name of the remote host (e.g. `github.com`)

fingerprint The fingerprint of the key which must be presented in the known_hosts file (optional if key specified)

key The public key which must be presented in the known_hosts file (optional if fingerprint specified)

port optional parameter, denoting the port of the remote host, which will be used in case, if the public key will be requested from it. By default the port 22 is used.

enc Defines what type of key is being used, can be ed25519, edsa ssh-rsa or ssh-dss

hash_hostname [True] Hash all hostnames and addresses in the known hosts file.

Deprecated since version Carbon: Please use hash_known_hosts instead.

config The location of the authorized keys file relative to the user's home directory, defaults to `~/.ssh/known_hosts`. If no user is specified, defaults to `~/etc/ssh/ssh_known_hosts`. If present, must be an absolute path when a user is not specified.

hash_known_hosts [True] Hash all hostnames and addresses in the known hosts file.

CLI Example:

```
salt '*' ssh.set_known_host <user> fingerprint='xx:xx:..:xx' enc='ssh-rsa' config=~'.ssh/known_hosts'
```

salt.modules.ssh.user_keys(user=None, pubfile=None, prvfile=None)

Return the user's ssh keys on the minion

New in version 2014.7.0.

CLI Example:
As you can see you can tell Salt not to read from the user’s private (or public) key file by setting the file path to False. This can be useful to prevent Salt from publishing private data via Salt Mine or others.

32.17.263 salt.modules.state

Control the state system on the minion.

State Caching

When a highstate is called, the minion automatically caches a copy of the last high data. If you then run a highstate with cache=True it will use that cached highdata and won’t hit the fileserver except for salt:// links in the states themselves.

```python
salt.modules.state.apply(mods=None, **kwargs)
```

New in version 2015.5.0.

This function will call state.highstate or state.sls based on the arguments passed to this function. It exists as a more intuitive way of applying states.

**APPLYING ALL STATES CONFIGURED IN TOP.SLS (A.K.A. HIGHSTATE)**

To apply all configured states, simply run state.apply:

```python
salt '*' state.apply
```

The following additional arguments are also accepted when applying all states configured in top.sls:

- **test** Run states in test-only (dry-run) mode
- **pillar** Custom Pillar values, passed as a dictionary of key-value pairs

```python
salt '*' state.apply test pillar='{"foo": "bar"}'
```

**Note:** Values passed this way will override Pillar values set via pillar_roots or an external Pillar source.

- **queue** [False] Instead of failing immediately when another state run is in progress, queue the new state run to begin running once the other has finished.

```
This option starts a new thread for each queued state run, so use this option sparingly.
```

- **localconfig** Optionally, instead of using the minion config, load minion opts from the file specified by this argument, and then merge them with the options from the minion config. This functionality allows for specific states to be run with their own custom minion configuration, including different pillars, file_roots, etc.
Salt Documentation, Release 2015.8.12

salt '*' state.apply localconfig=/path/to/minion.yml

APPLYING INDIVIDUAL SLS FILES (A.K.A. STATE.SLS)
To apply individual SLS ﬁles, pass them as a comma-separated list:
# Run the states configured in salt://test.sls (or salt://test/init.sls)
salt '*' state.apply test
# Run the states configured in salt://test.sls (or salt://test/init.sls)
# and salt://pkgs.sls (or salt://pkgs/init.sls).
salt '*' state.apply test,pkgs

e following additional arguments are also accepted when applying individual SLS ﬁles:
test Run states in test-only (dry-run) mode
pillar Custom Pillar values, passed as a dictionary of key-value pairs
salt '*' state.apply test pillar='{"foo": "bar"}'

Note: Values passed this way will override Pillar values set via pillar_roots or an external Pillar
source.
queue [False] Instead of failing immediately when another state run is in progress, queue the new state run
to begin running once the other has ﬁnished.
is option starts a new thread for each queued state run, so use this option sparingly.
concurrent [False] Execute state runs concurrently instead of serially
Warning: is ﬂag is potentially dangerous. It is designed for use when multiple state runs can
safely be run at the same time. Do not use this ﬂag for performance optimization.
saltenv [None] Specify a salt ﬁleserver environment to be used when applying states
Changed in version 0.17.0: Argument name changed from env to saltenv
Changed in version 2014.7.0: If no saltenv is speciﬁed, the minion conﬁg will be checked for a saltenv
parameter and if found, it will be used. If none is found, base will be used. In prior releases, the minion
conﬁg was not checked and base would always be assumed when the saltenv was not explicitly set.
pillarenv Specify a Pillar environment to be used when applying states. By default, all Pillar environments
will be merged together and used.
localconﬁg Optionally, instead of using the minion conﬁg, load minion opts from the ﬁle speciﬁed by this
argument, and then merge them with the options from the minion conﬁg. is functionality allows
for speciﬁc states to be run with their own custom minion conﬁguration, including diﬀerent pillars,
ﬁle_roots, etc.
salt '*' state.apply test localconfig=/path/to/minion.yml

salt.modules.state.check_request(name=None)
New in version 2015.5.0.
Return the state request information, if any
32.17. Full list of builtin execution modules

1405


salt.modules.state.clear_cache()
Clear out cached state files, forcing even cache runs to refresh the cache on the next state execution.
Remember that the state cache is completely disabled by default, this execution only applies if cache=True is used in states
CLI Example:

```bash
salt '*' state.clear_cache
```

salt.modules.state.clear_request(name=None)
New in version 2015.5.0.
Clear out the state execution request without executing it
CLI Example:

```bash
salt '*' state.clear_request
```

salt.modules.state.disable(states)
Disable state runs.
CLI Example:

```bash
salt '*' state.disable highstate
salt '*' state.disable highstate,test.succeed_without_changes
```

**Note:** To disable a state file from running provide the same name that would be passed in a state.sls call.

```bash
clear_cache
```

salt.modules.state.enable(states)
Enable state function or sls run
CLI Example:

```bash
salt '*' state.enable highstate
salt '*' state.enable test.succeed_without_changes
```

**Note:** To enable a state file from running provide the same name that would be passed in a state.sls call.

```bash
disable highstate
```

salt.modules.state.high(data, test=None, queue=False, **kwargs)
Execute the compound calls stored in a single set of high data
This function is mostly intended for testing the state system and is not likely to be needed in everyday usage.
CLI Example:

```bash
salt '*' state.high '{"vim": {"pkg": ["installed"]}}'
```
salt.modules.state.highstate(test=None, queue=False, **kwargs)

Retrieve the state data from the salt master for this minion and execute it

test Run states in test-only (dry-run) mode

pillar Custom Pillar values, passed as a dictionary of key-value pairs

```
salt '*' state.apply test pillar='{"foo": "bar"}'
```

Note: Values passed this way will override Pillar values set via pillar_roots or an external Pillar source.

queue [False] Instead of failing immediately when another state run is in progress, queue the new state run to begin running once the other has finished.

This option starts a new thread for each queued state run, so use this option sparingly.

localconfig Optionally, instead of using the minion config, load minion opts from the file specified by this argument, and then merge them with the options from the minion config. This functionality allows for specific states to be run with their own custom minion configuration, including different pillars, file_roots, etc.

mock: The mock option allows for the state run to execute without actually calling any states. This then returns a mocked return which will show the requisite ordering as well as fully validate the state run.

New in version 2015.8.4.

CLI Examples:

```
salt '*' state.highstate
salt '*' state.highstate whitelist=sls1_to_run,sls2_to_run
salt '*' state.highstate exclude=sls_to_exclude
salt '*' state.highstate exclude="[{'id': 'id_to_exclude'}, {'sls': 'sls_to_exclude'}]"
salt '*' state.highstate pillar="{foo: 'Foo!', bar: 'Bar!'}"
```

salt.modules.state.list_disabled()

List the states which are currently disabled

CLI Example:

```
salt '*' state.list_disabled
```

salt.modules.state.low(data, queue=False, **kwargs)

Execute a single low data call

This function is mostly intended for testing the state system and is not likely to be needed in everyday usage.

CLI Example:

```
salt '*' state.low '{"state": "pkg", "fun": "installed", "name": "vi"}"
```

salt.modules.state.pkg(pkg_path, pkg_sum, hash_type, test=None, **kwargs)

Execute a packaged state run, the packaged state run will exist in a tarball available locally. This packaged state can be generated using salt-ssh.

CLI Example:
salt '*' state.pkg /tmp/state_pkg.tgz

salt.modules.state.request(mods=None, **kwargs)

New in version 2015.5.0.
Request that the local admin execute a state run via `salt-call state.run_request` All arguments match `state.apply`

CLI Example:

```
salt '*' state.request
salt '*' state.request test
salt '*' state.request test,pkgs
```

salt.modules.state.run_request(name='default', **kwargs)

New in version 2015.5.0.
Execute the pending state request

CLI Example:

```
salt '*' state.run_request
```

salt.modules.state.running(concurrent=False)

Return a list of strings that contain state return data if a state function is already running. This function is used to prevent multiple state calls from being run at the same time.

CLI Example:

```
salt '*' state.running
```

salt.modules.state.show_highstate(queue=False, **kwargs)

Retrieve the highstate data from the salt master and display it

Custom Pillar data can be passed with the `pillar` kwarg.

CLI Example:

```
salt '*' state.show_highstate
```

salt.modules.state.show_low_sls(mods, saltenv='base', test=None, queue=False, env=None, **kwargs)

Display the low data from a specific sls. The default environment is `base`, use `saltenv` (env in Salt 0.17.x and older) to specify a different environment.

CLI Example:

```
salt '*' state.show_low_sls foo
```

salt.modules.state.show_lowstate(queue=False, **kwargs)

List out the low data that will be applied to this minion

CLI Example:

```
salt '*' state.show_lowstate
```

salt.modules.state.show_sls(mods, saltenv='base', test=None, queue=False, env=None, **kwargs)

Display the state data from a specific sls or list of sls files on the master. The default environment is `base`, use `saltenv` (env in Salt 0.17.x and older) to specify a different environment.

This function does not support topfiles. For `top.sls` please use `show_top` instead.
Custom Pillar data can be passed with the `pillar` kwarg.

CLI Example:

```
salt '*' state.show_sls core,edit.vim dev
```

```
salt.modules.state.show_top(queue=False, **kwargs)
```

Return the top data that the minion will use for a highstate

CLI Example:

```
salt '*' state.show_top
```

```
salt.modules.state.single(fun, name, test=None, queue=False, **kwargs)
```

Execute a single state function with the named kwargs, returns False if insufficient data is sent to the command

By default, the values of the kwargs will be parsed as YAML. So, you can specify lists values, or lists of single entry key-value maps, as you would in a YAML salt file. Alternatively, JSON format of keyword values is also supported.

CLI Example:

```
salt '*' state.single pkg.installed name=vim
```

```
salt.modules.state.sls(mods, saltenv=None, test=None, exclude=None, queue=False, env=None, pillarenv=None, **kwargs)
```

Execute the states in one or more SLS files

- `test` Run states in test-only (dry-run) mode
- `pillar` Custom Pillar values, passed as a dictionary of key-value pairs

```
salt '*' state.apply test pillar='{"foo": "bar"}'
```

**Note:** Values passed this way will override Pillar values set via `pillar_roots` or an external Pillar source.

```
saltenv [None] Specify a salt fileserver environment to be used when applying states
```

Changed in version 0.17.0: Argument name changed from `env` to `saltenv`

Changed in version 2014.7.0: If no saltenv is specified, the minion config will be checked for a saltenv parameter and if found, it will be used. If none is found, base will be used. In prior releases, the minion config was not checked and base would always be assumed when the saltenv was not explicitly set.

```
pillarenv Specify a Pillar environment to be used when applying states. By default, all Pillar environments will be merged together and used.
```

**Warning:** This flag is potentially dangerous. It is designed for use when multiple state runs can safely be run at the same time. Do *not* use this flag for performance optimization.
localconfig

Optionally, instead of using the minion config, load minion opts from the file specified by this argument, and then merge them with the options from the minion config. This functionality allows for specific states to be run with their own custom minion configuration, including different pillars, file_roots, etc.

mock: The mock option allows for the state run to execute without actually calling any states. This then returns a mocked return which will show the requisite ordering as well as fully validate the state run.

New in version 2015.8.4.

CLI Example:

```
salt '*' state.sls core,edit.vim dev
salt '*' state.sls core exclude="[{'id': 'id_to_exclude'}, {'sls': 'sls_to_exclude'}]"
salt '*' state.sls myslsfile pillar="{foo: 'Foo!', bar: 'Bar!'}"
```

salt.modules.state.sls_id(id_, mods, saltenv='base', test=None, queue=False, **kwargs)

Call a single ID from the named module(s) and handle all requisites

New in version 2014.7.0.

CLI Example:

```
salt '*' state.sls_id apache http
```

salt.modules.state.template(tem, queue=False, **kwargs)

Execute the information stored in a template file on the minion.

This function does not ask a master for a SLS file to render but instead directly processes the file at the provided path on the minion.

CLI Example:

```text
salt '*' state.template 'Path to template on the minion'
```

salt.modules.state.template_str(tem, queue=False, **kwargs)

Execute the information stored in a string from an sls template

CLI Example:

```text
salt '*' state.template_str 'Template String'
```

salt.modules.state.top(topfn, test=None, queue=False, saltenv=None, **kwargs)

Execute a specific top file instead of the default. This is useful to apply configurations from a different environment (for example, dev or prod), without modifying the default top file.

CLI Example:

```text
salt '*' state.top reverse_top.sls
salt '*' state.top prod_top.sls exclude=sls_to_exclude
salt '*' state.top dev_top.sls exclude="[{'id': 'id_to_exclude'}, {'sls': 'sls_to_exclude'}]"
```
32.17.264 salt.modules.status

Module for returning various status data about a minion. These data can be useful for compiling into stats later.

**salt.modules.status.all_status()**

Return a composite of all status data and info for this minion. Warning: There is a LOT here!

CLI Example:

```
salt '*' status.all_status
```

**salt.modules.status.cpuinfo()**

Return the CPU info for this minion

CLI Example:

```
salt '*' status.cpuinfo
```

**salt.modules.status.cpustats()**

Return the CPU stats for this minion

CLI Example:

```
salt '*' status.cpustats
```

**salt.modules.status.custom()**

Return a custom composite of status data and info for this minion, based on the minion config file. An example config like might be:

```
status.cpustats.custom: ['cpu', 'ctxt', 'btime', 'processes']
```

Where status refers to status.py, cpustats is the function where we get our data, and custom is this function. It is followed by a list of keys that we want returned.

This function is meant to replace all_status(), which returns anything and everything, which we probably don’t want.

By default, nothing is returned. Warning: Depending on what you include, there can be a LOT here!

CLI Example:

```
salt '*' status.custom
```

**salt.modules.status.diskstats()**

Return the disk stats for this minion

CLI Example:

```
salt '*' status.diskstats
```

**salt.modules.status.diskusage(*args)**

Return the disk usage for this minion

Usage:

```
salt '*' status.diskusage [paths and/or filesystem types]
```

CLI Example:
salt `*` status.diskusage # usage for all filesystems
salt `*` status.diskusage / /tmp # usage for / and /tmp
salt `*` status.diskusage ext? # usage for ext[234] filesystems
salt `*` status.diskusage / ext? # usage for / and all ext filesystems

salt.modules.status.loadavg()
Return the load averages for this minion

CLI Example:
salt `*` status.loadavg

salt.modules.status.master(master=None, connected=True)
New in version 2014.7.0.
Fire an event if the minion gets disconnected from its master. This function is meant to be run via a scheduled job from the minion. If master_ip is an FQDN/Hostname, is must be resolvable to a valid IPv4 address.

CLI Example:
salt `*` status.master

salt.modules.status.meminfo()
Return the memory info for this minion

CLI Example:
salt `*` status.meminfo

salt.modules.status.netdev()
Return the network device stats for this minion

CLI Example:
salt `*` status.netdev

salt.modules.status.netstats()
Return the network stats for this minion

CLI Example:
salt `*` status.netstats

salt.modules.status.nproc()
Return the number of processing units available on this system

CLI Example:
salt `*` status.nproc

salt.modules.status.pid(sig)
Return the PID or an empty string if the process is running or not. Pass a signature to use to find the process via ps. Note you can pass a Python-compatible regular expression to return all pids of processes matching the regexp.

CLI Example:
salt `*` status.pid <sig>
salt.modules.status.procs()  
Return the process data  
CLI Example:  
```
salt '*' status.procs
```

salt.modules.status.version()  
Return the system version for this minion  
CLI Example:  
```
salt '*' status.version
```

salt.modules.status.vmstats()  
Return the virtual memory stats for this minion  
CLI Example:  
```
salt '*' status.vmstats
```

salt.modules.status.w()  
Return a list of logged in users for this minion, using the w command  
CLI Example:  
```
salt '*' status.w
```

### 32.17.265 salt.modules.stormpath

Support for Stormpath

New in version 2015.8.0.

salt.modules.stormpath.create_account(directory_id, email, password, givenName, surname, **kwargs)  
Create an account  
CLI Examples:  
```
salt myminion stormpath.create_account <directory_id> shemp@example.com letmein Shemp Howard
```

salt.modules.stormpath.delete_account(account_id)  
Delete an account.  
CLI Examples:  
```
salt myminion stormpath.delete_account <account_id>
```

salt.modules.stormpath.list_accounts()  
Show all accounts.  
CLI Example:  
```
salt myminion stormpath.list_accounts
```

salt.modules.stormpath.list_directories()  
Show all directories.  
CLI Example:
salt myminion stormpath.list_directories

salt.modules.stormpath.show_account(account_id=None, email=None, directory_id=None, application_id=None, group_id=None, **kwargs)

Show a specific account.

CLI Example:

    salt myminion stormpath.show_account <account_id>

salt.modules.stormpath.show_tenant()

Get the tenant for the login being used.

salt.modules.stormpath.update_account(account_id, key=None, value=None, items=None)

Update one or more items for this account. Specifying an empty value will clear it for that account.

CLI Examples:

    salt myminion stormpath.update_account <account_id> givenName shemp
    salt myminion stormpath.update_account <account_id> middleName ''
    salt myminion stormpath.update_account <account_id> items='{`givenName`: `Shemp`}
    salt myminion stormpath.update_account <account_id> items='{`middlename`: ''}

32.17.266 salt.modules.sudo

Allow for the calling of execution modules via sudo.

This module is invoked by the minion if the sudo_user minion config is present.

Example minion config:

```
sudo_user: saltdev
```

Once this setting is made, any execution module call done by the minion will be run under sudo -u <sudo_user> salt-call. For example, with the above minion config,

```
salt sudo_minion cmd.run 'cat /etc/sudoers'
```

is equivalent to

```
sudo -u saltdev salt-call cmd.run 'cat /etc/sudoers'
```

being run on sudo_minion.

salt.modules.sudo.salt_call(runas, fun, *args, **kwargs)

Wrap a shell execution out to salt call with sudo.

Example:

```
/etc/salt/minion
```

```
sudo_user: saltdev
```

```
salt '*' test.ping # is run as saltdev user
```

32.17.267 salt.modules.supervisord

Provide the service module for system supervisord or supervisord in a virtualenv
salt.modules.supervisord.add(name, user=None, conf_file=None, bin_env=None)
Activates any updates in config for process/group.

user user to run supervisorctl as
conf_file path to supervisord config file
bin_env path to supervisorctl bin or path to virtualenv with supervisor installed

CLI Example:
```
salt '*' supervisord.add <name>
```

salt.modules.supervisord.custom(command, user=None, conf_file=None, bin_env=None)
Run any custom supervisorctl command

user user to run supervisorctl as
conf_file path to supervisord config file
bin_env path to supervisorctl bin or path to virtualenv with supervisor installed

CLI Example:
```
salt '*' supervisord.custom "mstop '*gunicorn*'"
```

salt.modules.supervisord.options(name, conf_file=None)
New in version 2014.1.0.
Read the config file and return the config options for a given process

name Name of the configured process
conf_file path to supervisord config file

CLI Example:
```
salt '*' supervisord.options foo
```

salt.modules.supervisord.remove(name, user=None, conf_file=None, bin_env=None)
Removes process/group from active config

user user to run supervisorctl as
conf_file path to supervisord config file
bin_env path to supervisorctl bin or path to virtualenv with supervisor installed

CLI Example:
```
salt '*' supervisord.remove <name>
```

salt.modules.supervisord.reread(user=None, conf_file=None, bin_env=None)
Reload the daemon's configuration files

user user to run supervisorctl as
conf_file path to supervisord config file
bin_env path to supervisorctl bin or path to virtualenv with supervisor installed

CLI Example:
```
salt '*' supervisord.reread
```
salt.modules.supervisord.restart(name='all', user=None, conf_file=None, bin_env=None)

Restart the named service. Process group names should not include a trailing asterisk.

user  user to run supervisorctl as
conf_file  path to supervisord config file
bin_env  path to supervisorctl bin or path to virtualenv with supervisor installed

CLI Example:

```
salt '*' supervisord.restart <service>
salt '*' supervisord.restart <group>:
```

salt.modules.supervisord.start(name='all', user=None, conf_file=None, bin_env=None)

Start the named service. Process group names should not include a trailing asterisk.

user  user to run supervisorctl as
conf_file  path to supervisord config file
bin_env  path to supervisorctl bin or path to virtualenv with supervisor installed

CLI Example:

```
salt '*' supervisord.start <service>
salt '*' supervisord.start <group>:
```

salt.modules.supervisord.status(name=None, user=None, conf_file=None, bin_env=None)

List programs and its state

user  user to run supervisorctl as
conf_file  path to supervisord config file
bin_env  path to supervisorctl bin or path to virtualenv with supervisor installed

CLI Example:

```
salt '*' supervisord.status
```

salt.modules.supervisord.status_raw(name=None, user=None, conf_file=None, bin_env=None)

Display the raw output of status

user  user to run supervisorctl as
conf_file  path to supervisord config file
bin_env  path to supervisorctl bin or path to virtualenv with supervisor installed

CLI Example:

```
salt '*' supervisord.status_raw
```

salt.modules.supervisord.stop(name='all', user=None, conf_file=None, bin_env=None)

Stop the named service. Process group names should not include a trailing asterisk.

user  user to run supervisorctl as
conf_file  path to supervisord config file
bin_env  path to supervisorctl bin or path to virtualenv with supervisor installed

CLI Example:
```
salt '*' supervisord.stop <service>
salt '*' supervisord.stop <group>:
```

**salt.modules.supervisord.update**(*user=None, conf_file=None, bin_env=None*)
Reload config and add/remove as necessary

- `user` user to run supervisorctl as
- `conf_file` path to supervisord config file
- `bin_env` path to supervisorctl bin or path to virtualenv with supervisor installed

CLI Example:
```
salt '*' supervisord.update
```

### 32.17.268 salt.modules.svn

**Subversion SCM**

**salt.modules.svn.add**(*cwd, targets, user=None, username=None, password=None, *opts*)
Add files to be tracked by the Subversion working-copy checkout

- `cwd` The path to the Subversion repository
- `targets` [None] files and directories to pass to the command as arguments
- `user` [None] Run svn as a user other than what the minion runs as
- `username` [None] Connect to the Subversion server as another user
- `password` [None] Connect to the Subversion server with this password

New in version 0.17.0.

CLI Example:
```
salt '*' svn.add /path/to/repo /path/to/new/file
```

**salt.modules.svn.checkout**(*cwd, remote, target=None, user=None, username=None, password=None, *opts*)
Download a working copy of the remote Subversion repository directory or file

- `cwd` The path to the Subversion repository
- `remote` [None] URL to checkout
- `target` [None] The name to give the file or directory working copy Default: svn uses the remote basename
- `user` [None] Run svn as a user other than what the minion runs as
- `username` [None] Connect to the Subversion server as another user
- `password` [None] Connect to the Subversion server with this password

New in version 0.17.0.

CLI Example:
```
salt '*' svn.checkout /path/to/repo svn://remote/repo
```
salt.modules.svn.commit(cwd, targets=None, msg=None, user=None, username=None, password=None, **opts)
Commit the current directory, files, or directories to the remote Subversion repository

cwd  The path to the Subversion repository
targets [None] files and directories to pass to the command as arguments Default: svn uses `.
msg   [None] Message to attach to the commit log
user  [None] Run svn as a user other than what the minion runs as
username [None] Connect to the Subversion server as another user
password [None] Connect to the Subversion server with this password

New in version 0.17.0.

CLI Example:
```
salt '*' svn.commit /path/to/repo
```

salt.modules.svn.diff(cwd, targets=None, user=None, username=None, password=None, **opts)
Return the diff of the current directory, files, or directories from the remote Subversion repository

cwd  The path to the Subversion repository
targets [None] files and directories to pass to the command as arguments Default: svn uses `.
user  [None] Run svn as a user other than what the minion runs as
username [None] Connect to the Subversion server as another user
password [None] Connect to the Subversion server with this password

New in version 0.17.0.

CLI Example:
```
salt '*' svn.diff /path/to/repo
```

salt.modules.svn.export(cwd, remote, target=None, user=None, username=None, password=None, revision='HEAD', **opts)
Create an unversioned copy of a tree.

cwd  The path to the Subversion repository
remote  [None] URL and path to file or directory checkout
target [None] The name to give the file or directory working copy Default: svn uses the remote basename
user  [None] Run svn as a user other than what the minion runs as
username [None] Connect to the Subversion server as another user
password [None] Connect to the Subversion server with this password

New in version 0.17.0.

CLI Example:
```
salt '*' svn.export /path/to/repo svn://remote/repo
```

salt.modules.svn.info(cwd, targets=None, user=None, username=None, password=None, fmt='str')
Display the Subversion information from the checkout.

cwd  The path to the Subversion repository
 targets [None] files, directories, and URLs to pass to the command as arguments svn uses `.' by default
 user [None] Run svn as a user other than what the minion runs as
 username [None] Connect to the Subversion server as another user
 password [None] Connect to the Subversion server with this password

 New in version 0.17.0.

 fmt [str] How to fmt the output from info. (str, xml, list, dict)

 CLI Example:

```bash
salt '.*' svn.info /path/to/svn/repo
```

```
salt.modules.svn.remove(cwd, targets=None, user=None, username=None, password=None, *opts)
``` Remove files and directories from the Subversion repository

```
cwd` The path to the Subversion repository
 targets [None] files, directories, and URLs to pass to the command as arguments 
 msg [None] Message to attach to the commit log 
 user [None] Run svn as a user other than what the minion runs as 
 username [None] Connect to the Subversion server as another user 
 password [None] Connect to the Subversion server with this password

 New in version 0.17.0.

 CLI Example:

```bash
salt '.*' svn.remove /path/to/repo /path/to/repo/remove
```

```
salt.modules.svn.status(cwd, targets=None, user=None, username=None, password=None, *opts)
``` Display the status of the current directory, files, or directories in the Subversion repository

```
cwd` The path to the Subversion repository
 targets [None] files, directories, and URLs to pass to the command as arguments Default: svn uses `.'
 user [None] Run svn as a user other than what the minion runs as 
 username [None] Connect to the Subversion server as another user 
 password [None] Connect to the Subversion server with this password

 New in version 0.17.0.

 CLI Example:

```bash
salt '.*' svn.status /path/to/repo
```

```
salt.modules.svn.switch(cwd, remote, target=None, user=None, username=None, password=None, *opts)
``` New in version 2014.1.0.

 Switch a working copy of a remote Subversion repository directory

```
cwd` The path to the Subversion repository
 remote [None] URL to switch
 target [None] The name to give the file or directory working copy Default: svn uses the remote basename

32.17. Full list of builtin execution modules
user  [None] Run svn as a user other than what the minion runs as
username  [None] Connect to the Subversion server as another user
password  [None] Connect to the Subversion server with this password

CLI Example:

```shell
salt '*' svn.switch /path/to/repo svn://remote/repo
```

salt.modules.svn.update(cwd, targets=None, user=None, username=None, password=None, *opts)
Update the current directory, files, or directories from the remote Subversion repository

cwd  The path to the Subversion repository

targets  [None] files and directories to pass to the command as arguments Default: svn uses `.'
user  [None] Run svn as a user other than what the minion runs as
password  [None] Connect to the Subversion server with this password

New in version 0.17.0.

username  [None] Connect to the Subversion server as another user

CLI Example:

```shell
salt '*' svn.update /path/to/repo
```

32.17.269  salt.modules.swift

Module for handling OpenStack Swift calls Author: Anthony Stanton <anthony.stanton@gmail.com>

Inspired by the S3 and Nova modules

depends

- swiftclient Python module

configuration  This module is not usable until the user, tenant, auth URL, and password or auth_key are specified either in a pillar or in the minion's config file. For example:

```yaml
keystone.user: admin
keystone.tenant: admin
keystone.auth_url: 'http://127.0.0.1:5000/v2.0/'
keystone.password: verybadpass
# or
keystone.auth_key: 203802934809284k2j34lkj2l3kj43k
```

If configuration for multiple OpenStack accounts is required, they can be set up as different configuration profiles: For example:

```yaml
openstack1:
  keystone.user: admin
  keystone.tenant: admin
  keystone.auth_url: 'http://127.0.0.1:5000/v2.0/'
  keystone.password: verybadpass
  # or
  keystone.auth_key: 203802934809284k2j34lkj2l3kj43k

openstack2:
  keystone.user: admin
```

1420 Chapter 32. Reference
With this configuration in place, any of the swift functions can make use of a configuration profile by declaring it explicitly. For example:

```
salt '*' swift.get mycontainer myfile /tmp/file profile=openstack1
```

NOTE: For Rackspace cloud files setting `keystone.auth_version = 1` is recommended.

### `salt.modules.swift.delete`

Delete a container, or delete an object from a container.

**CLI Example to delete a container:**

```
salt myminion swift.delete mycontainer
```

**CLI Example to delete an object from a container:**

```
salt myminion swift.delete mycontainer remoteobject
```

### `salt.modules.swift.get`

List the contents of a container, or return an object from a container. Set `return_bin` to True in order to retrieve an object wholesale. Otherwise, Salt will attempt to parse an XML response.

**CLI Example to list containers:**

```
salt myminion swift.get
```

**CLI Example to list the contents of a container:**

```
salt myminion swift.get mycontainer
```

**CLI Example to return the binary contents of an object:**

```
salt myminion swift.get mycontainer myfile.png return_bin=True
```

**CLI Example to save the binary contents of an object to a local file:**

```
salt myminion swift.get mycontainer myfile.png local_file=/tmp/myfile.png
```

### `salt.modules.swift.head`

### `salt.modules.swift.put`

Create a new container, or upload an object to a container.

**CLI Example to create a container:**

```
salt myminion swift.put mycontainer
```

**CLI Example to upload an object to a container:**

```
salt myminion swift.put mycontainer remotepath local_file=/path/to/file
```
32.17.270 salt.modules.sysbench

The 'sysbench' module is used to analyze the performance of the minions, right from the master! It measures various system parameters such as CPU, Memory, File I/O, Threads and Mutex.

salt.modules.sysbench.cpu()
Tests for the CPU performance of minions.

CLI Examples:
salt '*' sysbench.cpu

salt.modules.sysbench.fileio()
This tests for the file read and write operations. Various modes of operations are:
  • sequential write
  • sequential rewrite
  • sequential read
  • random read
  • random write
  • random read and write

The test works with 32 files with each file being 1Gb in size. The test consumes a lot of time. Be patient!

CLI Examples:
salt '*' sysbench.fileio

salt.modules.sysbench.memory()
This tests the memory for read and write operations.

CLI Examples:
salt '*' sysbench.memory

salt.modules.sysbench.mutex()
Tests the implementation of mutex

CLI Examples:
salt '*' sysbench.mutex

salt.modules.sysbench.ping()

salt.modules.sysbench.threads()
This tests the performance of the processor's scheduler

CLI Example:
salt '*' sysbench.threads

32.17.271 salt.modules.syslog_ng

Module for getting information about syslog-ng

maintainer Tibor Benke <btibi@sch.bme.hu>
This module is capable of managing syslog-ng instances which were installed via a package manager or from source. Users can use a directory as a parameter in the case of most functions, which contains the syslog-ng and syslog-ng-ctl binaries.

Syslog-ng can be installed via a package manager or from source. In the latter case, the syslog-ng and syslog-ng-ctl binaries are not available from the PATH, so users should set location of the sbin directory with `syslog_ng.set_binary_path`.

Similarly, users can specify the location of the configuration file with `syslog_ng.set_config_file`, then the module will use it. If it is not set, syslog-ng uses the default configuration file.

```python
class salt.modules.syslog_ng.Argument(value='``

A TypedParameterValue has one or more Arguments. For example this can be the value of key_file.

Does not need examples.
```
class salt.modules.syslog_ng.Parameter(\n    iterable=None, join_body_on='``')

An Option has one or more Parameter instances.

Does not need examples.

class salt.modules.syslog_ng.ParameterValue(\n    iterable=None, join_body_on='``')

A TypedParameter can have one or more values.

Does not need examples.

class salt.modules.syslog_ng.SimpleParameter(\n    value='``')

A Parameter is a SimpleParameter, if it's just a simple type, like a string.

For example:

```python
destination d_file {
    file("/var/log/messages"');
}
```

/\n\n/var/log/messages is a SimpleParameter.

Does not need examples.

build()

class salt.modules.syslog_ng.SimpleParameterValue(\n    value='``')

A ParameterValue which holds a simple type, like a string or a number.

For example in ip(127.0.0.1) 127.0.0.1 is a SimpleParameterValue.

Does not need examples.

build()

class salt.modules.syslog_ng.Statement(\n    type, id='`, options=None, has_name=True)

It represents a syslog-ng configuration statement, e.g. source, destination, filter.

Does not need examples.

add_child(option)

build_header()

build_tail()

exception salt.modules.syslog_ng.SyslogNgError

class salt.modules.syslog_ng.TypedParameter(\n    type='`, values=None)

A Parameter, which has a type:

```python
destination d_tcp {
    tcp(\n        ip(127.0.0.1)\n    );
}
```

ip(127.0.0.1) is a TypedParameter.

Does not need examples.

add_value(value)

build()
class salt.modules.syslog_ng.TypedParameterValue(type='`, arguments=None)

We have to go deeper...

A TypedParameter can have a `parameter', which also have a type. For example key_file and cert_file:

```python
source demo_tls_source {
    tcp(
        ip(0.0.0.0)
        port(1999)
        tls(
            key_file("/opt/syslog-ng/etc/syslog-ng/key.d/syslog-ng.key")
            cert_file("/opt/syslog-ng/etc/syslog-ng/cert.d/syslog-ng.cert")
        )
    );
};
```

Does not need examples.

add_argument(arg)

build()

class salt.modules.syslog_ng.UnnamedStatement(type, options=None)

It represents a configuration statement, which doesn't have a name, e.g. a log path.

Does not need examples.

salt.modules.syslog_ng.config(name, config, write=True)

Builds syslog-ng configuration. This function is intended to be used from the state module, users should not use it directly!

name : the id of the Salt document or it is the format of <statement name>.id
config : the parsed YAML code
write : if True, it writes the config into the configuration file, otherwise just returns it

CLI Example:

```bash
salt '*' syslog_ng.config name="s_local" config="[{'tcp':[{'ip':'127.0.0.1'}, {'port':1233}]},

salt.modules.syslog_ng.config_test(syslog-ng_sbin_dir=None, cfgfile=None)

Runs syntax check against cfgfile. If syslog_ng_sbin_dir is specified, it is added to the PATH during the test.

CLI Example:

```bash
salt '*' syslog_ng.config_test
salt '*' syslog_ng.config_test /home/user/install/syslog-ng/sbin
salt '*' syslog_ng.config_test /home/user/install/syslog-ng/sbin /etc/syslog-ng/"syslog-ng.conf"
```

salt.modules.syslog_ng.get_config_file()

Returns the configuration directory, which contains syslog-ng.conf.

CLI Example:

```bash
salt '*' syslog_ng.get_config_file
```

salt.modules.syslog_ng.modules(syslog-ng_sbin_dir=None)

Returns the available modules. If syslog-ng_sbin_dir is specified, it is added to the PATH during the execution of the command syslog-ng.

CLI Example:
salt '*' syslog_ng.modules
salt '*' syslog_ng.modules /home/user/install/syslog-ng/sbin

salt.modules.syslog_ng.reload(name)
Reloads syslog-ng. This function is intended to be used from states.
If syslog_ng.set_config_file, is called before, this function will use the set binary path.
CLI Example:
salt '*' syslog_ng.reload

salt.modules.syslog_ng.set_binary_path(name)
Sets the path, where the syslog-ng binary can be found. This function is intended to be used from states.
If syslog-ng is installed via a package manager, users don't need to use this function.
CLI Example:
salt '*' syslog_ng.set_binary_path name="/usr/sbin"

salt.modules.syslog_ng.set_config_file(name)
Sets the configuration's name. This function is intended to be used from states.
CLI Example:
salt '*' syslog_ng.set_config_file name="/etc/syslog-ng"

salt.modules.syslog_ng.set_parameters(version=None, binary_path=None, config_file=None, *args, **kwargs)
Sets variables.
CLI Example:
salt '*' syslog_ng.set_parameters version="3.6"
salt '*' syslog_ng.set_parameters binary_path="/home/user/install/syslog-ng/sbin"
config_file="/home/user/install/syslog-ng/etc/syslog-ng.conf"

salt.modules.syslog_ng.start(name=None, user=None, group=None, chroot=None, caps=None, no_caps=False, pidfile=None, enable_core=False, fd_limit=None, verbose=False, debug=False, trace=False, yydebug=False, persist_file=None, control=None, worker_threads=None)
Ensures, that syslog-ng is started via the given parameters. This function is intended to be used from the state module.
Users shouldn't use this function, if the service module is available on their system. If syslog_ng.set_config_file, is called before, this function will use the set binary path.
CLI Example:
salt '*' syslog_ng.start

salt.modules.syslog_ng.stats(syslog_ng_sbin_dir=None)
Returns statistics from the running syslog-ng instance. If syslog_ng_sbin_dir is specified, it is added to the PATH during the execution of the command syslog-ng-ctl.
CLI Example:
salt '*' syslog_ng.stats
salt '*' syslog_ng.stats /home/user/install/syslog-ng/sbin
salt.modules.syslog_ng.stop(name=None)

Kills syslog-ng. This function is intended to be used from the state module.

Users shouldn’t use this function, if the service module is available on their system. If syslog_ng.set_config_file is called before, this function will use the set binary path.

CLI Example:

```
salt '*' syslog_ng.stop
```

salt.modules.syslog_ng.version(syslog_ng_sbin_dir=None)

Returns the version of the installed syslog-ng. If syslog_ng_sbin_dir is specified, it is added to the PATH during the execution of the command syslog-ng.

CLI Example:

```
salt '*' syslog_ng.version
salt '*' syslog_ng.version /home/user/install/syslog-ng/sbin
```

salt.modules.syslog_ng.write_config(config, newlines=2)

Writes the given parameter config into the config file. This function is intended to be used from states.

If syslog_ng.set_config_file, is called before, this function will use the set config file.

CLI Example:

```
salt '*' syslog_ng.write_config config=# comment
```

salt.modules.syslog_ng.write_version(name)

Removes the previous configuration file, then creates a new one and writes the name line. This function is intended to be used from states.

If syslog_ng.set_config_file, is called before, this function will use the set config file.

CLI Example:

```
salt '*' syslog_ng.write_version name=3.6
```

32.17.272 salt.modules.sysmod

The sys module provides information about the available functions on the minion

salt.modules.sysmod.argspec(module='')

Return the argument specification of functions in Salt execution modules.

CLI Example:

```
salt '*' sys[argspec pkg.install
salt '*' sys[argspec sys
salt '*' sys[argspec
```

Module names can be specified as globs.

New in version 2015.5.0.

```
salt '*' sys[argspec 'pkg.*'
```

salt.modules.sysmod.doc(args)

Return the docstrings for all modules. Optionally, specify a module or a function to narrow the selection.
The strings are aggregated into a single document on the master for easy reading.

Multiple modules/functions can be specified.

CLI Example:

```bash
salt '*' sys.doc
salt '*' sys.doc sys
salt '*' sys.doc sys.doc
salt '*' sys.doc network.traceroute user.info
```

Modules can be specified as globs.

New in version 2015.5.0.

```bash
salt '*' sys.doc 'sys.*'
salt '*' sys.doc 'sys.list_*'
```

`salt.modules.sysmod.list_functions(*args, **kwargs)`

List the functions for all modules. Optionally, specify a module or modules from which to list.

CLI Example:

```bash
salt '*' sys.list_functions
salt '*' sys.list_functions sys
salt '*' sys.list_functions sys user
```

Function names can be specified as globs.

New in version 2015.5.0.

```bash
salt '*' sys.list_functions 'sys.list_*'
```

`salt.modules.sysmod.list_modules(*args)`

List the modules loaded on the minion

New in version 2015.5.0.

CLI Example:

```bash
salt '*' sys.list_modules
```

Module names can be specified as globs.

```bash
salt '*' sys.list_modules 's*'
```

`salt.modules.sysmod.list_renderers(*args)`

List the renderers loaded on the minion

New in version 2015.5.0.

CLI Example:

```bash
salt '*' sys.list_renderers
```

Render names can be specified as globs.

```bash
salt '*' sys.list_renderers 'yaml*'
```
salt.modules.sysmod.list_returner_functions(*args, **kwargs)
List the functions for all returner modules. Optionally, specify a returner module or modules from which to list.

New in version 2014.7.0.

CLI Example:
```
salt '*' sys.list_returner_functions
salt '*' sys.list_returner_functions mysql
salt '*' sys.list_returner_functions mysql etcd
```

Returner names can be specified as globs.

New in version 2015.5.0.
```
salt '*' sys.list_returner_functions 'sqlite3.get_*'
```

salt.modules.sysmod.list_returners(*args)
List the returners loaded on the minion

New in version 2014.7.0.

CLI Example:
```
salt '*' sys.list_returners
```

Returner names can be specified as globs.

New in version 2015.5.0.
```
salt '*' sys.list_returners 's*'
```

salt.modules.sysmod.list_runner_functions(*args, **kwargs)
List the functions for all runner modules. Optionally, specify a runner module or modules from which to list.

New in version 2014.7.0.

CLI Example:
```
salt '*' sys.list_runner_functions
salt '*' sys.list_runner_functions state
salt '*' sys.list_runner_functions state virt
```

Runner function names can be specified as globs.

New in version 2015.5.0.
```
salt '*' sys.list_runner_functions 'state.*' 'virt.*'
```

salt.modules.sysmod.list_runners(*args)
List the runners loaded on the minion

New in version 2014.7.0.

CLI Example:
```
salt '*' sys.list_runners
```

Runner names can be specified as globs.

New in version 2015.5.0.
```python
salt '*' sys.list_runners 'm*'
```

```python
salt.modules.sysmod.list_state_functions(*args, **kwargs)
```

List the functions for all state modules. Optionally, specify a state module or modules from which to list.

New in version 2014.7.0.

CLI Example:

```bash
salt '*' sys.list_state_functions
salt '*' sys.list_state_functions file
salt '*' sys.list_state_functions pkg user
```

State function names can be specified as globs.

New in version 2015.5.0.

```bash
sicl '*' sys.list_state_functions 'file.*'
salt '*' sys.list_state_functions 'file.s*'
```

```python
salt.modules.sysmod.list_state_modules(*args)
```

List the modules loaded on the minion.

New in version 2014.7.0.

CLI Example:

```bash
sicl '*' sys.list_state_modules
```

State module names can be specified as globs.

New in version 2015.5.0.

```bash
sicl '*' sys.list_state_modules 'mysql_*'
```

```python
salt.modules.sysmod.reload_modules()
```

Tell the minion to reload the execution modules.

CLI Example:

```bash
sicl '*' sys.reload_modules
```

```python
salt.modules.sysmod.renderer_doc(*args)
```

Return the docstrings for all renderers. Optionally, specify a renderer or a function to narrow the selection.

The strings are aggregated into a single document on the master for easy reading.

Multiple renderers can be specified.

New in version 2015.5.0.

CLI Example:

```bash
sicl '*' sys.renderer_doc
salt '*' sys.renderer_doc cheetah
salt '*' sys.renderer_doc jinja json
```

Renderer names can be specified as globs.

```bash
sicl '*' sys.renderer_doc 'c*' 'j*'```
salt.modules.sysmod.returner_argspec(module='')

Return the argument specification of functions in Salt returner modules.

New in version 2015.5.0.

CLI Example:

```bash
salt '*' sys.returner_argspec xmpp
salt '*' sys.returner_argspec xmpp smtp
salt '*' sys.returner_argspec
```

Returner names can be specified as globs.

```bash
salt '*' sys.returner_argspec 'sqlite3.*'
```

salt.modules.sysmod.returner_doc(args)

Return the docstrings for all returners. Optionally, specify a returner or a function to narrow the selection.

The strings are aggregated into a single document on the master for easy reading.

Multiple returners/functions can be specified.

New in version 2014.7.0.

CLI Example:

```bash
salt '*' sys.returner_doc
salt '*' sys.returner_doc sqlite3
salt '*' sys.returner_doc sqlite3.get_fun
salt '*' sys.returner_doc sqlite3.get_fun etcd.get_fun
```

Returner names can be specified as globs.

New in version 2015.5.0.

```bash
salt '*' sys.returner_doc 'sqlite3.get_*'
```

salt.modules.sysmod.runner_argspec(module='')

Return the argument specification of functions in Salt runner modules.

New in version 2015.5.0.

CLI Example:

```bash
salt '*' sys.runner_argspec state
salt '*' sys.runner_argspec http
salt '*' sys.runner_argspec
```

Runner names can be specified as globs.

```bash
salt '*' sys.runner_argspec 'winrepo.*'
```

salt.modules.sysmod.runner_doc(args)

Return the docstrings for all runners. Optionally, specify a runner or a function to narrow the selection.

The strings are aggregated into a single document on the master for easy reading.

Multiple runners/functions can be specified.

New in version 2014.7.0.

CLI Example:
Runner names can be specified as globs.

New in version 2015.5.0.

```bash
salt '*' sys.runner_doc 'cache.clear_*'
```

`salt.modules.sysmod.state_argspec(module='')`

Return the argument specification of functions in Salt state modules.

New in version 2015.5.0.

CLI Example:

```bash
salt '*' sys.state_argspec pkg.installed
salt '*' sys.state_argspec file
salt '*' sys.state_argspec
```

State names can be specified as globs.

```bash
salt '*' sys.state_argspec 'pkg.*'
```

`salt.modules.sysmod.state_doc(*args)`

Return the docstrings for all states. Optionally, specify a state or a function to narrow the selection.

The strings are aggregated into a single document on the master for easy reading.

Multiple states/functions can be specified.

New in version 2014.7.0.

CLI Example:

```bash
salt '*' sys.state_doc
salt '*' sys.state_doc service
salt '*' sys.state_doc service.running
salt '*' sys.state_doc service.running ipables.append
```

State names can be specified as globs.

New in version 2015.5.0.

```bash
salt '*' sys.state_doc 'service.*' 'iptables.*'
```

### 32.17.273 `salt.modules.sysrc`

sysrc module for FreeBSD

`salt.modules.sysrc.get(**kwargs)`

Return system rc configuration variables

CLI Example:

```bash
salt '*' sysrc.get includeDefaults=True
```
salt.modules.sysrc.remove(name, **kwargs)
    Remove system rc configuration variables
    CLI Example:
    
    salt '*' sysrc.remove name=sshd_enable

salt.modules.sysrc.set(name, value, **kwargs)
    Set system rc configuration variables
    CLI Example:
    
    salt '*' sysrc.set name=sshd_flags value="-p 2222"

32.17.274 salt.modules.system

Support for reboot, shutdown, etc

salt.modules.system.halt()
    Halt a running system
    CLI Example:
    
    salt '*' system.halt

salt.modules.system.init(runlevel)
    Change the system runlevel on sysV compatible systems
    CLI Example:
    
    salt '*' system.init 3

salt.modules.system.poweroff()
    Poweroff a running system
    CLI Example:
    
    salt '*' system.poweroff

salt.modules.system.reboot(at_time=None)
    Reboot the system
    at_time  The wait time in minutes before the system will be shutdown.
    CLI Example:
    
    salt '*' system.reboot

salt.modules.system.shutdown(at_time=None)
    Shutdown a running system
    at_time  The wait time in minutes before the system will be shutdown.
    CLI Example:
    
    salt '*' system.shutdown 5
32.17.275 salt.modules.system_profiler

System Profiler Module

Interface with Mac OSX's command-line System Profiler utility to get information about package receipts and installed applications.

New in version 2015.5.0.

salt.modules.system_profiler.applications()

Return the results of a call to system_profiler -xml -detail full SPApplicationsDataType as a dictionary. Top-level keys of the dictionary are the names of each set of install receipts, since there can be multiple receipts with the same name. Contents of each key are a list of dictionaries.

Note that this can take a long time depending on how many applications are installed on the target Mac.

CLI Example:

```
salt '*' systemprofiler.applications
```

salt.modules.system_profiler.receipts()

Return the results of a call to system_profiler -xml -detail full SPIInstallHistoryDataType as a dictionary. Top-level keys of the dictionary are the names of each set of install receipts, since there can be multiple receipts with the same name. Contents of each key are a list of dictionaries.

CLI Example:

```
salt '*' systemprofiler.receipts
```

32.17.276 salt.modules.systemd

Provides the service module for systemd

New in version 0.10.0.

Important: If you feel that Salt should be using this module to manage services on a minion, and it is using a different module (or gives an error similar to `service.start` is not available), see here.

salt.modules.systemd.available(name)

New in version 0.10.4.

Check that the given service is available taking into account template units.

CLI Example:

```
salt '*' service.available sshd
```

salt.modules.systemd.disable(name, **kwargs)

Changed in version 2015.8.12, 2016.3.3, Carbon: On minions running systemd>=205, systemctl-run() is now used to isolate commands run by this function from the salt-minion daemon's control group. This is done to avoid a race condition in cases where the salt-minion service is restarted while a service is being modified. If desired, usage of systemctl-run() can be suppressed by setting a config option called systemd.scope, with a value of False (no quotes).

Disable the named service to not start when the system boots

CLI Example:
salt 'service disable' <service name>

salt.modules.systemd.disabled(name)
Return if the named service is disabled to start on boot

salt 'service disable' <service name>

salt.modules.systemd.enable(name, **kwargs)
Changed in version 2015.8.12, 2016.3.3, Carbon: On minions running systemd>=205, systemd-run(1) is now used to isolate commands run by this function from the salt-minion daemon's control group. This is done to avoid a race condition in cases where the salt-minion service is restarted while a service is being modified. If desired, usage of systemd-run(1) can be suppressed by setting a config option called systemd.scope, with a value of False (no quotes).

Enable the named service to start when the system boots

salt 'service enable' <service name>

salt.modules.systemd.enabled(name, **kwargs)
Return if the named service is enabled to start on boot

salt 'service enabled' <service name>

salt.modules.systemd.execs()
New in version 2014.7.0.

Return a list of all files specified as ExecStart for all services.

salt 'service execs'

salt.modules.systemd.force_reload(name)
Changed in version 2015.8.12, 2016.3.3, Carbon: On minions running systemd>=205, systemd-run(1) is now used to isolate commands run by this function from the salt-minion daemon's control group. This is done to avoid a race condition in cases where the salt-minion service is restarted while a service is being modified. If desired, usage of systemd-run(1) can be suppressed by setting a config option called systemd.scope, with a value of False (no quotes).

New in version 0.12.0.

Force-reload the specified service with systemd

salt 'service force_reload' <service name>

salt.modules.systemd.get_all()
Return a list of all available services

salt 'service get_all'
salt.modules.systemd.get_disabled()
Return a list of all disabled services

CLI Example:
```
salt '*' service.get_disabled
```

salt.modules.systemd.get_enabled()
Return a list of all enabled services

CLI Example:
```
salt '*' service.get_enabled
```

salt.modules.systemd.get_static()
New in version 2015.8.5.
Return a list of all static services

CLI Example:
```
salt '*' service.get_static
```

salt.modules.systemd.mask(name, runtime=False)
New in version 2015.5.0.
Changed in version 2015.8.12, 2016.3.3, Carbon: On minions running systemd>=205, systemd-run(1) is now used to isolate commands run by this function from the salt-minion daemon's control group. This is done to avoid a race condition in cases where the salt-minion service is restarted while a service is being modified. If desired, usage of systemd-run(1) can be suppressed by setting a config option called systemd.scope, with a value of False (no quotes).

Mask the specified service with systemd

runtime [False] Set to True to mask this service only until the next reboot

New in version 2015.8.5.

CLI Example:
```
salt '*' service.mask <service name>
```

salt.modules.systemd.masked(name)
New in version 2015.8.0.

Changed in version 2015.8.5: The return data for this function has changed. If the service is masked, the return value will now be the output of the systemctl is-enabled command (so that a persistent mask can be distinguished from a runtime mask). If the service is not masked, then False will be returned.
Check whether or not a service is masked

CLI Example:
```
salt '*' service.masked <service name>
```

salt.modules.systemd.missing(name)
New in version 2014.1.0.
The inverse of service.available. Returns True if the specified service is not available, otherwise returns False.

CLI Example:
salt '*' service.missing sshd

salt.modules.systemd.reload(name)
Changed in version 2015.8.12,2016.3.3,Carbon: On minions running systemd>=205, `systemd-run()` is now used to isolate commands run by this function from the salt-minion daemon's control group. This is done to avoid a race condition in cases where the salt-minion service is restarted while a service is being modified. If desired, usage of `systemd-run()` can be suppressed by setting a config option called `systemd.scope`, with a value of False (no quotes).

Reload the specified service with systemd

CLI Example:

```
salt '*' service.reload <service name>
```

salt.modules.systemd.restart(name)
Changed in version 2015.8.12,2016.3.3,Carbon: On minions running systemd>=205, `systemd-run()` is now used to isolate commands run by this function from the salt-minion daemon's control group. This is done to avoid a race condition in cases where the salt-minion service is restarted while a service is being modified. If desired, usage of `systemd-run()` can be suppressed by setting a config option called `systemd.scope`, with a value of False (no quotes).

Restart the specified service with systemd

CLI Example:

```
salt '*' service.restart <service name>
```

salt.modules.systemd.show(name)
New in version 2014.7.0.

Show properties of one or more units/jobs or the manager

CLI Example:

```
salt '*' service.show <service name>
```

salt.modules.systemd.start(name)
Changed in version 2015.8.12,2016.3.3,Carbon: On minions running systemd>=205, `systemd-run()` is now used to isolate commands run by this function from the salt-minion daemon's control group. This is done to avoid a race condition in cases where the salt-minion service is restarted while a service is being modified. If desired, usage of `systemd-run()` can be suppressed by setting a config option called `systemd.scope`, with a value of False (no quotes).

Start the specified service with systemd

CLI Example:

```
salt '*' service.start <service name>
```

salt.modules.systemd.status(name, sig=None)

Return the status for a service via systemd, returns a bool whether the service is running.

CLI Example:

```
salt '*' service.status <service name>
```

salt.modules.systemd.stop(name)
Changed in version 2015.8.12,2016.3.3,Carbon: On minions running systemd>=205, `systemd-run()` is now used to isolate commands run by this function from the salt-minion daemon's control group. This is
done to avoid a race condition in cases where the salt-minion service is restarted while a service is being modified. If desired, usage of systemctl-run() can be suppressed by setting a config option called systemd.scope, with a value of False (no quotes).

Stop the specified service with systemd

CLI Example:

```
salt '*' service.stop <service name>
```

```
salt.modules.systemd.systemctl_reload()
```

New in version 0.15.0.

Reloads systemctl, an action needed whenever unit files are updated.

CLI Example:

```
salt '*' service.systemctl_reload
```

```
salt.modules.systemd.unmask(name)
```

New in version 2015.5.0.

Changed in version 2015.8.12,2016.3.3,Carbon: On minions running systemd>=205, systemctl-run() is now used to isolate commands run by this function from the salt-minion daemon's control group. This is done to avoid a race condition in cases where the salt-minion service is restarted while a service is being modified. If desired, usage of systemctl-run() can be suppressed by setting a config option called systemd.scope, with a value of False (no quotes).

Unmask the specified service with systemd

CLI Example:

```
salt '*' service.unmask <service name>
```

### 32.17.277 salt.modules.temp

Simple module for creating temporary directories and files

This is a thin wrapper around Pythons tempfile module

New in version 2015.8.0.

```
salt.modules.temp.dir(suffix='', prefix='tmp', parent=None)
```

Create a temporary directory

CLI Example:

```
salt '*' temp.dir
salt '*' temp.dir prefix='mytemp-' parent='/var/run/
```

```
salt.modules.temp.file(suffix='', prefix='tmp', parent=None)
```

Create a temporary file

CLI Example:

```
salt '*' temp.file
salt '*' temp.file prefix='mytemp-' parent='/var/run/
```
32.17.278 salt.modules.test

Module for running arbitrary tests

```python
salt.modules.test.arg(*args, **kwargs)
```

Print out the data passed into the function `*args` and `**kwargs`, this is used to both test the publication data and cli argument passing, but also to display the information available within the publication data. Returns `{``args'': args, ``kwargs'': kwargs}`.

CLI Example:

```
salt '*' test.arg 1 "two" 3.1 txt="hello" wow='{a: 1, b: "hello"}"
```

```python
salt.modules.test.arg_repr(*args, **kwargs)
```

Print out the data passed into the function `*args` and `**kwargs`, this is used to both test the publication data and cli argument passing, but also to display the information available within the publication data. Returns `{``args'': repr(args), ``kwargs'': repr(kwargs)}`.

CLI Example:

```
salt '*' test.arg_repr 1 "two" 3.1 txt="hello" wow='{a: 1, b: "hello"}"
```

```python
salt.modules.test.arg_type(*args, **kwargs)
```

Print out the types of the args and kwargs. This is used to test the types of the args and kwargs passed down to the minion.

CLI Example:

```
salt '*' test.arg_type 1 'int'
```

```python
salt.modules.test.assertion(assertion)
```

Assert the given argument

CLI Example:

```
salt '*' test.assertion False
```

```python
salt.modules.test.attr_call()
```

Call grains.items via the attribute

CLI Example:

```
.. code-block:: bash

    salt '*' test.attr_call
```

```python
salt.modules.test.collatz(start)
```

Execute the collatz conjecture from the passed starting number, returns the sequence and the time it took to compute. Used for performance tests.

CLI Example:

```
salt '*' test.collatz 3
```

```python
salt.modules.test.conf_test()
```

Return the value for test.foo in the minion configuration file, or return the default value

CLI Example:

```
```
salt '*' test.conf_test

salt.modules.test.cross_test(func, args=None)
Execute a minion function via the __salt__ object in the test module, used to verify that the minion functions can be called via the __salt__ module.

CLI Example:
salt '*' test.cross_test file.gid_to_group 0

salt.modules.test.echo(text)
Return a string - used for testing the connection

CLI Example:
salt '*' test.echo 'foo bar baz quo qux'

salt.modules.test.exception(message='Test Exception')
Raise an exception
Optionally provide an error message or output the full stack.

CLI Example:
salt '*' test.exception 'Oh noes!'

salt.modules.test.false()
Always return False

CLI Example:
salt '*' test.false

salt.modules.test.fib(num)
Return the num-th Fibonacci number, and the time it took to compute in seconds. Used for performance tests.

This function is designed to have terrible performance.

CLI Example:
salt '*' test.fib 3

salt.modules.test.get_opts()
Return the configuration options passed to this minion

CLI Example:
salt '*' test.get_opts

salt.modules.test.kwarg(**kwargs)
Print out the data passed into the function **kwargs, this is used to both test the publication data and cli kwarg passing, but also to display the information available within the publication data.

CLI Example:
salt '*' test.kwarg num=1 txt="two" env='{"a: 1, b: "hello"}''

salt.modules.test.missing_func()
salt.modules.test.module_report()
Return a dict containing all of the execution modules with a report on the overall availability via different references

CLI Example:
```bash
salt '*' test.module_report
```

salt.modules.test.not_loaded()
List the modules that were not loaded by the salt loader system

CLI Example:
```
salt '*' test.not_loaded
```

salt.modules.test.opts_pkg()
Return an opts package with the grains and opts for this minion. This is primarily used to create the options used for master side state compiling routines

CLI Example:
```
salt '*' test.opts_pkg
```

salt.modules.test.outputter(data)
Test the outputter, pass in data to return

CLI Example:
```
salt '*' test.outputter foobar
```

salt.modules.test.ping()
Used to make sure the minion is up and responding. Not an ICMP ping.
Returns True.

CLI Example:
```
salt '*' test.ping
```

salt.modules.test.provider(module)
Pass in a function name to discover what provider is being used

CLI Example:
```
salt '*' test.provider service
```

salt.modules.test.providers()
Return a dict of the provider names and the files that provided them

CLI Example:
```
salt '*' test.providers
```

salt.modules.test.rand_sleep(max=60)
Sleep for a random number of seconds, used to test long-running commands and minions returning at differing intervals

CLI Example:
salt 'x' test.rand_sleep 60

```python
salt.modules.test.rand_str(size=9999999999, hash_type=None)

Return a random string

size size of the string to generate
hash_type hash type to use

New in version 2015.5.2.
```

CLI Example:
```bash
salt 'x' test.rand_str
```

salt.modules.test.retcode(code=42)

Test that the returncode system is functioning correctly

CLI Example:
```bash
salt 'x' test.retcode 42
```

salt.modules.test.sleep(length)

Instruct the minion to initiate a process that will sleep for a given period of time.

CLI Example:
```bash
salt 'x' test.sleep 20
```

salt.modules.test.stack()

Return the current stack trace

CLI Example:
```bash
salt 'x' test.stack
```

salt.modules.test.true()

Always return True

CLI Example:
```bash
salt 'x' test.true
```

salt.modules.test.try_(module, return_try_exception=False, **kwargs)

Try to run a module command. On an exception return None. If return_try_exception is set True return the exception. This can be helpful in templates where running a module might fail as expected.

CLI Example:
```bash
<pre>
{% for i in range(0,230) %}
  {{ salt['test.try'](module='ipmi.get_users', bmc_host='172.2.2.' +i) | yaml(False) }}
{% endfor %}
</pre>
```

salt.modules.test.tty(*args, **kwargs)

Deprecated! Moved to cmdmod.

CLI Example:
salt.modules.test.version()
Return the version of salt on the minion

CLI Example:
```
salt '*' test.version
```

salt.modules.test.versions()
This function is an alias of versions_report.

Returns versions of components used by salt

CLI Example:
```
salt '*' test.versions_report
```

salt.modules.test.versions_information()
Report the versions of dependent and system software

CLI Example:
```
salt '*' test.versions_information
```

salt.modules.test.versions_report()
Returns versions of components used by salt

CLI Example:
```
salt '*' test.versions_report
```

32.17.279 salt.modules.test_virtual
Module for running arbitrary tests with a __virtual__ function

salt.modules.test_virtual.ping()

32.17.280 salt.modules.timezone
Module for managing timezone on POSIX-like systems.

salt.modules.timezone.get_hwclock()
Get current hardware clock setting (UTC or localtime)

CLI Example:
```
salt '*' timezone.get_hwclock
```

salt.modules.timezone.get_offset()
Get current numeric timezone offset from UCT (i.e. -0700)

CLI Example:
```
salt '*' timezone.get_offset
```
salt.modules.timezone.get_zone()  
Get current timezone (i.e. America/Denver)  

CLI Example:  
```
salt '*' timezone.get_zone
```

salt.modules.timezone.get_zonecode()  
Get current timezone (i.e. PST, MDT, etc)  

CLI Example:  
```
salt '*' timezone.get_zonecode
```

salt.modules.timezone.set_hwclock(clock)  
Sets the hardware clock to be either UTC or localtime  

CLI Example:  
```
salt '*' timezone.set_hwclock UTC
```

salt.modules.timezone.set_zone(timezone)  
Unlinks, then symlinks /etc/localtime to the set timezone.  

The timezone is crucial to several system processes, each of which SHOULD be restarted (for instance, whatever you system uses as its cron and syslog daemons). This will not be automagically done and must be done manually!

CLI Example:  
```
salt '*' timezone.set_zone 'America/Denver'
```

salt.modules.timezone.zone_compare(timezone)  
Checks the hash sum between the given timezone, and the one set in /etc/localtime. Returns True if they match, and False if not. Mostly useful for running state checks.

CLI Example:  
```
salt '*' timezone.zone_compare 'America/Denver'
```

32.17.281 salt.modules.tls

A salt module for SSL/TLS. Can create a Certificate Authority (CA) or use Self-Signed certificates.

**depends**

- PyOpenSSL Python module (0.10 or later, 0.14 or later for X509 extension support)

**configuration** Add the following values in /etc/salt/minion for the CA module to function properly:

```
ca.cert_base_path: '/etc/pki'
```

CLI Example #1 Creating a CA, a server request and its signed certificate:

```
# salt-call tls.create_ca my_little 

days=5 

CN='My Little CA' 

C=US 
```
ST=Utah \
L=Salt Lake City \
O=Saltstack \
emailAddress=pleasedontemail@thisisnot.coms

Created Private Key: "/etc/pki/my_little/my_little_ca_cert.key"
Created CA "my_little_ca": "/etc/pki/my_little_ca/my_little_ca_cert.crt"

# salt-call tls.create_csr my_little CN=www.thisisnot.coms
Created Private Key: "/etc/pki/my_little/certs/www.thisisnot.coms.key"
Created CSR for "www.thisisnot.coms": "/etc/pki/my_little/certs/www.thisisnot.coms.csr"

# salt-call tls.create_ca_signed_cert my_little CN=www.thisisnot.coms
Created Certificate for "www.thisisnot.coms": "/etc/pki/my_little/certs/www.thisisnot.coms.crt"

CLI Example #2: Creating a client request and its signed certificate

# salt-call tls.create_csr my_little CN=DBReplica_No.1 cert_type=client
Created Private Key: "/etc/pki/my_little/certs//DBReplica_No.1.key." 
Created CSR for "DBReplica_No.1": "/etc/pki/my_little/certs/DBReplica_No.1.csr." 

# salt-call tls.create_ca_signed_cert my_little CN=DBReplica_No.1
Created Certificate for "DBReplica_No.1": "//etc/pki/my_little/certs/DBReplica_No.1.crt"

CLI Example #3: Creating both a server and client req + cert for the same CN

# salt-call tls.create_csr my_little CN=MasterDBReplica_No.2 
  cert_type=client
Created Private Key: "/etc/pki/my_little/certs/MasterDBReplica_No.2.key." 
Created CSR for "MasterDBReplica_No.2": "/etc/pki/my_little/certs/MasterDBReplica_No.2.csr." 

# salt-call tls.create_ca_signed_cert my_little CN=MasterDBReplica_No.2
Created Certificate for "DBReplica_No.1": "//etc/pki/my_little/certs/DBReplica_No.1.crt"

# salt-call tls.create_csr my_little CN=MasterDBReplica_No.2 
  cert_type=server
Certificate "MasterDBReplica_No.2" already exists 
(doh!)

# salt-call tls.create_csr my_little CN=MasterDBReplica_No.2 
  cert_type=server type_ext=True
Created Private Key: "/etc/pki/my_little/certs/DBReplica_No.1_client.key." 
Created CSR for "DBReplica_No.1": "/etc/pki/my_little/certs/DBReplica_No.1_client.csr." 

# salt-call tls.create_ca_signed_cert my_little CN=MasterDBReplica_No.2
Certificate "MasterDBReplica_No.2" already exists 
(DOH!)

# salt-call tls.create_ca_signed_cert my_little CN=MasterDBReplica_No.2 
  cert_type=server type_ext=True
Created Certificate for "MasterDBReplica_No.2": "//etc/pki/my_little/certs/ 
  DBReplica_No.2_server.crt"

CLI Example #4: Create a server req + cert with non-CN filename for the cert

32.17. Full list of builtin execution modules 1445
Salt Documentation, Release 2015.8.12

salt.modules.tls.ca_exists(ca_name, cacert_path=None, ca_filename=None)
Verify whether a Certificate Authority (CA) already exists

c_a_name name of the CA
cacert_path absolute path to ca certificates root directory
ca_filename alternative filename for the CA

New in version 2015.5.3.

CLI Example:
```
salt '*' tls.ca_exists test_ca /etc/certs
```

salt.modules.tls.cert_base_path(cacert_path=None)
Return the base path for certs from CLI or from options

 cacert_path absolute path to ca certificates root directory

CLI Example:
```
salt '*' tls.cert_base_path
```

salt.modules.tls.cert_info(cert_path, digest='sha256')
Return information for a particular certificate

cert_path path to the cert file
digest what digest to use for fingerprinting

CLI Example:
```
salt '*' tls.cert_info /dir/for/certs/cert.pem
```

salt.modules.tls.create_ca(ca_name, bits=2048, days=365, CN='localhost', C='US', ST='Utah', L='Salt Lake City', O='SaltStack', OU=None, emailAddress='xyz@pdq.net', fix-mode=False, cacert_path=None, ca_filename=None, digest='sha256', onlyif=None, unless=None, replace=False)
Create a Certificate Authority (CA)

c_a_name name of the CA
bits number of RSA key bits, default is 2048
days number of days the CA will be valid, default is 365
CN common name in the request, default is "localhost"
C country, default is "US"
ST state, default is "Utah"
locality, default is `Centerville`, the city where SaltStack originated
organization, default is `SaltStack`
organizational unit, default is None
email address for the CA owner, default is `xyz@pdq.net`
absolute path to ca certificates root directory
alternative filename for the CA
New in version 2015.5.3.
The message digest algorithm. Must be a string describing a digest algorithm supported by OpenSSL
(by EVP_get_digestbyname, specifically). For example, `md5` or `sha1`. Default: `sha256`
Replace this certificate even if it exists
New in version 2015.5.1.
Writes out a CA certificate based upon defined config values. If the file already exists, the function just returns
assuming the CA certificate already exists.
If the following values were set:
cert_base_path = `/etc/pki`
cert_base_path = `/etc/pki`
the resulting CA, and corresponding key, would be written in the following location:
cert_base_path = `/etc/pki`
cert_base_path = `/etc/pki`

CLI Example:
salt '*' tls.create_ca test_ca

Create a Certificate (CERT) signed by a named Certificate Authority (CA)
If the certificate file already exists, the function just returns assuming the CERT already exists.
The CN must match an existing CSR generated by create_csr. If it does not, this method does nothing.
cert_base_path = `/etc/pki`
cert_base_path = `/etc/pki`
full path to the certificates directory
alternative filename for the certificate, useful when using special characters in the CN. If this
option is set it will override the certificate filename output effects of cert_type. type_ext will be
completely overridden.
New in version 2015.5.3.

**digest**  The message digest algorithm. Must be a string describing a digest algorithm supported by OpenSSL (by `EVP_get_digestbyname`, specifically). For example, `'md5'` or `'sha1'`. Default: `'sha256'`

**replace**  Replace this certificate even if it exists

New in version 2015.5.1.

**cert_type**  string. Either `'server'` or `'client'` (see `create_csr()` for details).

If `create_csr(type_ext=True)` this function must be called with the same `cert_type` so it can find the CSR file.

**Note:** `create_csr()` defaults to `cert_type='server'`; therefore, if it was also called with `type_ext`, `cert_type` becomes a required argument for `create_ca_signed_cert()`

**type_ext**  bool. If set True, use `cert_type` as an extension to the CN when formatting the filename.

e.g.: `some_subject_CN_server.crt` or `some_subject_CN_client.crt`

This facilitates the context where both types are required for the same subject

If `cert_filename` is not `None`, setting `type_ext` has no effect

If the following values were set:

```
ca.cert_base_path='/etc/pki'
certificate_name='koji'
CN='test.egavas.org'
```

the resulting signed certificate would be written in the following location:

```
/etc/pki/koji/certs/test.egavas.org.crt
```

CLI Example:

```
salt '*' tls.create_ca_signed_cert test localhost
```

```python
salt.modules.tls.create_csr(ca_name, bits=2048, CN='localhost', C='US', ST='Utah', L='Salt Lake City', O='SaltStack', OU=None, emailAddress='xyz@pdq.net', subjectAltName=None, cacert_path=None, ca_filename=None, csr_path=None, csr_filename=None, digest='sha256', type_ext=False, replace=False)
```

Create a Certificate Signing Request (CSR) for a particular Certificate Authority (CA)

**ca_name**  name of the CA

**bits**  number of RSA key bits, default is 2048

**CN**  common name in the request, default is `''localhost``

**C**  country, default is `''US``

**ST**  state, default is `''Utah``

**L**  locality, default is `''Centerville``, the city where SaltStack originated

**O**  organization, default is `''SaltStack`` NOTE: Must the same as CA certificate or an error will be raised

**OU**  organizational unit, default is None
**emailAddress**  email address for the request, default is `xyz@pdq.net`

**subjectAltName**  valid subjectAltNames in full form, e.g. to add DNS entry you would call this function with this value:

```python
examples: ['DNS:somednsname.com', 'DNS:1.2.3.4', 'IP:1.2.3.4', 'IP:2001:4801:7821:77:be76:4eff:fe11:e51', 'email:me@i.like.pie.com']
```

**Note:** some libraries do not properly query IP prefixes, instead looking for the given req. source with a DNS prefix. To be thorough, you may want to include both DNS and IP entries if you are using subjectAltNames for destinations for your TLS connections. e.g.: requests to `https://1.2.3.4` will fail from python's requests library w/out the second entry in the above list

New in version 2015.8.0.

**cert_type**  Specify the general certificate type. Can be either *server* or *client*. Indicates the set of common extensions added to the CSR.

```
server: {
  'basicConstraints': 'CA:FALSE',
  'extendedKeyUsage': 'serverAuth',
  'keyUsage': 'digitalSignature, keyEncipherment'
}

client: {
  'basicConstraints': 'CA:FALSE',
  'extendedKeyUsage': 'clientAuth',
  'keyUsage': 'nonRepudiation, digitalSignature, keyEncipherment'
}
```

**type_ext**  boolean. Whether or not to extend the filename with CN_[cert_type] This can be useful if a server and client certificate are needed for the same CN. Defaults to False to avoid introducing an unexpected file naming pattern

The files normally named some_subject_CN.csr and some_subject_CN.key will then be saved

**replace**  Replace this signing request even if it exists

New in version 2015.5.1.

Writes out a Certificate Signing Request (CSR) If the file already exists, the function just returns assuming the CSR already exists.

If the following values were set:

```
ca.cert_base_path='/etc/pki'
c_name='koji'
CN='test.egavas.org'
```

the resulting CSR, and corresponding key, would be written in the following location:

```
/etc/pki/koji/certs/test.egavas.org.csr
/etc/pki/koji/certs/test.egavas.org.key
```

**CLI Example:**

```
salt '*' tls.create_csr test
```
salt.modules.tls.create_empty_crl(ca_name, cacert_path=None, ca_filename=None, crl_file=None)

Create an empty Certificate Revocation List.

New in version 2015.8.0.

- **ca_name**: name of the CA
- **cacert_path**: absolute path to ca certificates root directory
- **ca_filename**: alternative filename for the CA

New in version 2015.5.3.

- **crl_file**: full path to the CRL file

CLI Example:

```bash
salt '*' tls.create_empty_crl ca_name='koji' ca_filename='ca'
crl_file='/etc/openvpn/team1/crl.pem'
```

salt.modules.tls.create_pkcs12(ca_name, CN, passphrase='`', cacert_path=None, replace=False)

Create a PKCS#12 browser certificate for a particular Certificate (CN)

- **ca_name**: name of the CA
- **CN**: common name matching the certificate signing request
- **passphrase**: used to unlock the PKCS#12 certificate when loaded into the browser
- **cacert_path**: absolute path to ca certificates root directory
- **replace**: Replace this certificate even if it exists

New in version 2015.5.1.

If the following values were set:

```ini
ca.cert_base_path='/etc/pki'
cia_name='koji'
CN='test.egavas.org'
```

the resulting signed certificate would be written in the following location:

```
/etc/pki/koji/certs/test.egavas.org.p12
```

CLI Example:

```bash
salt '*' tls.create_pkcs12 test localhost
```

salt.modules.tls.create_self_signed_cert(tls_dir='tls', bits=2048, days=365, CN='localhost', C='US', ST='Utah', L='Salt Lake City', O='SaltStack', OU=None, emailAddress='xyz@pdq.net', cacert_path=None, cert_filename=None, digest='sha256', replace=False)

Create a Self-Signed Certificate (CERT)

- **tls_dir**: location appended to the ca.cert_base_path, default is `tls`
- **bits**: number of RSA key bits, default is 2048
- **CN**: common name in the request, default is `localhost`
- **C**: country, default is `US`
ST  state, default is ``Utah''
L locality, default is ``Centerville'', the city where SaltStack originated
O organization, default is ``SaltStack'' NOTE: Must the same as CA certificate or an error will be raised
OU organizational unit, default is None
emailAddress  email address for the request, default is `xyz@pdq.net`
cacert_path  absolute path to ca certificates root directory
digest  The message digest algorithm. Must be a string describing a digest algorithm supported by OpenSSL (by EVP_get_digestbyname, specifically). For example, ``md5'' or ``sha1''. Default: `sha256'
replace  Replace this certificate even if it exists

New in version 2015.5.1.

Writes out a Self-Signed Certificate (CERT). If the file already exists, the function just returns.

If the following values were set:

```
ca.cert_base_path='/etc/pki'
tls_dir='koji'
CN='test.egavas.org'
```

the resulting CERT, and corresponding key, would be written in the following location:

```
/etc/pki/koji/certs/test.egavas.org.crt
/etc/pki/koji/certs/test.egavas.org.key
```

CLI Example:

```
salt '*' tls.create_self_signed_cert
```

Passing options from the command line:

```
salt 'minion' tls.create_self_signed_cert CN='test.mysite.org'
```

salt.modules.tls.get_ca(ca_name, as_text=False, cacert_path=None)
Get the certificate path or content

c_name  name of the CA
as_text  if true, return the certificate content instead of the path
cacert_path  absolute path to ca certificates root directory

CLI Example:

```
salt '*' tls.get_ca test_ca as_text=False cacert_path=/etc/certs
```

salt.modules.tls.get_ca_signed_cert(ca_name, CN='localhost', as_text=False, cacert_path=None, cert_filename=None)
Get the certificate path or content

c_name  name of the CA
CN  common name of the certificate
as_text  if true, return the certificate content instead of the path
cacert_path  absolute path to certificates root directory
cert_filename alternative filename for the certificate, useful when using special characters in the CN

New in version 2015.5.3.

CLI Example:

```bash
salt '*' tls.get_ca_signed_cert test_ca CN=localhost as_text=False cacert_path=/etc/certs
```

salt.modules.tls.get_ca_signed_key(ca_name, CN='localhost', as_text=False, cacert_path=None, key_filename=None)

Get the certificate path or content

ca_name name of the CA

CN common name of the certificate

as_text if true, return the certificate content instead of the path

cacert_path absolute path to certificates root directory

key_filename alternative filename for the key, useful when using special characters

New in version 2015.5.3.

CLI Example:

```bash
salt '*' tls.get_ca_signed_key test_ca CN=localhost as_text=False cacert_path=/etc/certs
```

salt.modules.tls.get_extensions(cert_type)

Fetch X509 and CSR extension definitions from tls:extensions: (common|server|client) or set them to standard defaults.

New in version 2015.8.0.

cert_type: The type of certificate such as server or client.

CLI Example:

```bash
salt '*' tls.get_extensions client
```

salt.modules.tls.maybe_fix_ssl_version(ca_name, cacert_path=None, ca_filename=None)

Check that the X509 version is correct (was incorrectly set in previous salt versions). This will fix the version if needed.

ca_name ca authority name

cacert_path absolute path to ca certificates root directory

ca_filename alternative filename for the CA

New in version 2015.5.3.

CLI Example:

```bash
salt '*' tls.maybe_fix_ssl_version test_ca /etc/certs
```

salt.modules.tls.revoke_cert(ca_name, CN, cacert_path=None, ca_filename=None, cert_path=None, cert_filename=None, crl_file=None)

Revoke a certificate.

New in version 2015.8.0.
ca_name  Name of the CA.
CN  Common name matching the certificate signing request.
cacert_path  Absolute path to ca certificates root directory.
ca_filename  Alternative filename for the CA.
cert_path  Path to the cert file.
cert_filename  Alternative filename for the certificate, useful when using special characters in the CN.
crl_file  Full path to the CRL file.

CLI Example:

```
salt '*' tls.revoke_cert ca_name='koji' ca_filename='ca'
    ->  crl_file='/etc/openvpn/team1/crl.pem'
```

```
salt.modules.tls.set_ca_path(cacert_path)

If wanted, store the aforementioned cacert_path in context to be used as the basepath for further operations

CLI Example:

```
salt '*' tls.set_ca_path /etc/certs
```

32.17.282  salt.modules.tomcat

Support for Tomcat

This module uses the manager webapp to manage Apache tomcat webapps. If the manager webapp is not configured some of the functions won’t work.

configuration

- Java bin path should be in default path
- If ipv6 is enabled make sure you permit manager access to ipv6 interface `::0:0:0:0:0:0:1`
- If you are using tomcat.tar.gz it has to be installed or symlinked under /opt, preferably using name tomcat
  - `''tomcat.signal start/stop''` works but it does not use the startup scripts

The following grains/pillar should be set:

```
tomcat-manager:
    user: <username>
    passwd: <password>
```

or the old format:

```
tomcat-manager.user: <username>
tomcat-manager.passwd: <password>
```

Also configure a user in the conf/tomcat-users.xml file:

```
<?xml version='1.0' encoding='utf-8'?>
<tomcat-users>
    <role rolename="manager-script"/>
    <user username="tomcat" password="tomcat" roles="manager-script"/>
</tomcat-users>
```
Note:

- if you use only this module for deployments you’ve might want to strict access to the manager only from localhost for more info: http://tomcat.apache.org/tomcat-7.0-doc/manager-howto.html#Configuring_Manager_Application_Access
- Tested on:
  
  JVM Vendor: Sun Microsystems Inc.
  JVM Version: 1.6.0_43-b01
  OS Architecture: amd64
  OS Name: Linux
  OS Version: 2.6.32-358.el6.x86_64
  Tomcat Version: Apache Tomcat/7.0.37

salt.modules.tomcat.deploy_war

```
salt.modules.tomcat.deploy_war (war, context, force='no', url='http://localhost:8080/manager', saltenv='base', timeout=180, env=None, temp_war_location=None, version='``')
```

Deploy a WAR file

- **war** absolute path to WAR file (should be accessible by the user running tomcat) or a path supported by the salt.modules.cp.get_file function
- **context** the context path to deploy
- **force** [False] set True to deploy the webapp even one is deployed in the context
- **url** [http://localhost:8080/manager] the URL of the server manager webapp
- **saltenv** [base] the environment for WAR file in used by salt.modules.cp.get_url function
- **timeout** [180] timeout for HTTP request
- **temp_war_location** [None] use another location to temporarily copy to war file by default the system's temp directory is used
- **version** [''] Specify the war version. If this argument is provided, it overrides the version encoded in the war file name, if one is present.

Examples:

```
salt '*' tomcat.deploy_war salt://salt-2015.8.6.war version=2015.08.r6
```

CLI Examples:

```
salt '*' tomcat.deploy_war salt://application.war /api
salt '*' tomcat.deploy_war salt://application.war /api no
salt '*' tomcat.deploy_war salt://application.war /api yes http://localhost:8080/
```

minion local file system
salt.modules.tomcat.fullversion()
Return all server information from catalina.sh version

CLI Example:
salt '*' tomcat.fullversion

salt.modules.tomcat.leaks(url='http://localhost:8080/manager', timeout=180)
Find memory leaks in tomcat

url [http://localhost:8080/manager] the URL of the server manager webapp

timeout [180] timeout for HTTP request

CLI Examples:
salt '*' tomcat.leaks

salt.modules.tomcat.ls(url='http://localhost:8080/manager', timeout=180)
list all the deployed webapps

url [http://localhost:8080/manager] the URL of the server manager webapp

timeout [180] timeout for HTTP request

CLI Examples:
salt '*' tomcat.ls
salt '*' tomcat.ls http://localhost:8080/manager

salt.modules.tomcat.passwd(passwd, user='`, alg='sha1', realm=None)
This function replaces the $CATALINA_HOME/bin/digest.sh script convert a clear-text password to the $CATALINA_BASE/conf/tomcat-users.xml format

CLI Examples:
salt '*' tomcat.passwd secret
salt '*' tomcat.passwd secret tomcat sha1
salt '*' tomcat.passwd secret tomcat sha1 'Protected Realm'

salt.modules.tomcat.reload(app, url='http://localhost:8080/manager', timeout=180)
Reload the webapp

app the webapp context path

url [http://localhost:8080/manager] the URL of the server manager webapp

timeout [180] timeout for HTTP request

CLI Examples:
salt '*' tomcat.reload /jenkins
salt '*' tomcat.reload /jenkins http://localhost:8080/manager

salt.modules.tomcat.serverinfo(url='http://localhost:8080/manager', timeout=180)
return details about the server
url [http://localhost:8080/manager] the URL of the server manager webapp

**timeout** [180] timeout for HTTP request

CLI Examples:

```
salt '*' tomcat.serverinfo
salt '*' tomcat.serverinfo http://localhost:8080/manager
```

`salt.modules.tomcat.sessions()`
app the webapp context path
url [http://localhost:8080/manager] the URL of the server manager webapp

**timeout** [180] timeout for HTTP request

CLI Examples:

```
salt '*' tomcat.sessions /jenkins
salt '*' tomcat.sessions /jenkins http://localhost:8080/manager
```

`salt.modules.tomcat.signal()`

Signals catalina to start, stop, securestart, forcestop.

CLI Example:

```
salt '*' tomcat.signal start
```

`salt.modules.tomcat.start()`
app the webapp context path
url [http://localhost:8080/manager] the URL of the server manager webapp

**timeout** timeout for HTTP request

CLI Examples:

```
salt '*' tomcat.start /jenkins
salt '*' tomcat.start /jenkins http://localhost:8080/manager
```

`salt.modules.tomcat.status()`

Used to test if the tomcat manager is up

url [http://localhost:8080/manager] the URL of the server manager webapp

**timeout** [180] timeout for HTTP request

CLI Examples:

```
salt '*' tomcat.status
salt '*' tomcat.status http://localhost:8080/manager
```

`salt.modules.tomcat.status_webapp()`
app the webapp context path
url [http://localhost:8080/manager] the URL of the server manager webapp

**timeout** [180] timeout for HTTP request
CLI Examples:

```
salt '*' tomcat.status_webapp /jenkins
salt '*' tomcat.status_webapp /jenkins http://localhost:8080/manager
```

```
salt '*' tomcat.status_webapp /jenkins http://localhost:8080/manager
```

salt.modules.tomcat.stop(app, url='http://localhost:8080/manager', timeout=180)
Stop the webapp

- **app** the webapp context path
- **url** the URL of the server manager webapp
- **timeout** [180] timeout for HTTP request

CLI Examples:

```
salt '*' tomcat.stop /jenkins
salt '*' tomcat.stop /jenkins http://localhost:8080/manager
```

salt.modules.tomcat.undeploy(app, url='http://localhost:8080/manager', timeout=180)
Undeploy a webapp

- **app** the webapp context path
- **url** the URL of the server manager webapp
- **timeout** [180] timeout for HTTP request

CLI Examples:

```
salt '*' tomcat.undeploy /jenkins
salt '*' tomcat.undeploy /jenkins http://localhost:8080/manager
```

salt.modules.tomcat.version()

Return server version from catalina.sh version

CLI Example:

```
salt '*' tomcat.version
```

### 32.17.283 salt.modules.trafficserver

Apache Traffic Server execution module.

New in version 2015.8.0.

traffic_line is used to execute individual Traffic Server commands and to script multiple commands in a shell.

salt.modules.trafficserver.alarms()

List all alarm events that have not been acknowledged (cleared).

```
salt '*' trafficserver.alarms
```

salt.modules.trafficserver.bounce_cluster()

```
salt '*' trafficserver.bounce_cluster
```
salt.modules.trafficserver.bounce_local\(\text{\texttt{\(\text{\textbackslash{drain}=\text{\texttt{False}}\)}}\)}

This option modifies the behavior of traffic_line \(-\text{\texttt{b}}\) and traffic_line \(-\text{\texttt{L}}\) such that traffic_server is not shut down until the number of active client connections drops to the number given by the proxy.config.restart.active_client_threshold configuration variable.

```
salt '*' trafficserver.bounce_local
salt '*' trafficserver.bounce_local drain=True
```

salt.modules.trafficserver.clear_alarms\(\text{\texttt{\(\text{\textbackslash{alarm}}\)}}\)
Clear (acknowledge) an alarm event. The arguments are "all" for all current alarms, a specific alarm number (e.g. "1"), or an alarm string identifier (e.g. "MGMT_ALARM_PROXY_CONFIG_ERROR").

```
salt '*' trafficserver.clear_alarms [all | #event | name]
```

salt.modules.trafficserver.clear_cluster()
Clears accumulated statistics on all nodes in the cluster.

```
salt '*' trafficserver.clear_cluster
```

salt.modules.trafficserver.clear_node()
Clears accumulated statistics on the local node.

```
salt '*' trafficserver.clear_node
```

salt.modules.trafficserver.match_var\(\text{\texttt{\(\text{\textbackslash{regex}}\)}}\)
Display the current values of all performance statistics or configuration variables whose names match the given regular expression.

```
salt '*' trafficserver.match_var regex
```

salt.modules.trafficserver.offline\(\text{\texttt{\(\text{\textbackslash{path}}\)}}\)
Mark a cache storage device as offline. The storage is identified by a path which must match exactly a path specified in storage.config. This removes the storage from the cache and redirects requests that would have used this storage to other storage. This has exactly the same effect as a disk failure for that storage. This does not persist across restarts of the traffic_server process.

```
salt '*' trafficserver.offline /path/to/cache
```

salt.modules.trafficserver.read_var\(\text{\texttt{\(\text{\textbackslash{\textasciitilde{args}}}\)}}\)
Read variable definitions from the traffic_line command
This allows reading arbitrary key=value pairs from within trafficserver

```
salt '*' trafficserver.read_var proxy.process.http.tcp_hit_count_stat
```

salt.modules.trafficserver.refresh()
Initiate a Traffic Server configuration file reread. Use this command to update the running configuration after any configuration file modification.

The timestamp of the last reconfiguration event (in seconds since epoch) is published in the proxy.node.config.reconfigure_time metric.

```
salt '*' trafficserver.refresh
```
salt.modules.trafficserver.restart_cluster()
    Restart the traffic_manager process and the traffic_server process on all the nodes in a cluster.

    salt '*' trafficserver.restart_cluster

salt.modules.trafficserver.restart_local(drain=False)
    Restart the traffic_manager and traffic_server processes on the local node.
    This option modifies the behavior of traffic_line -b and traffic_line -L such that traffic_server is
    not shut down until the number of active client connections drops to the number given by the
    proxy.config.restart.active_client_threshold configuration variable.

    salt '*' trafficserver.restart_local
    salt '*' trafficserver.restart_local drain=True

salt.modules.trafficserver.set_var(variable, value)

    salt '*' trafficserver.set_var proxy.config.http.server_ports

salt.modules.trafficserver.shutdown()
    Shut down Traffic Server on the local node.

    salt '*' trafficserver.shutdown

salt.modules.trafficserver.startup()
    Start Traffic Server on the local node.

    salt '*' trafficserver.start

salt.modules.trafficserver.status()
    Show the current proxy server status, indicating if we’re running or not.

    salt '*' trafficserver.status

salt.modules.trafficserver.zero_cluster()
    Reset performance statistics to zero across the cluster.

    salt '*' trafficserver.zero_cluster

salt.modules.trafficserver.zero_node()
    Reset performance statistics to zero on the local node.

    salt '*' trafficserver.zero_cluster

32.17.284 salt.modules.tuned

Interface to Red Hat tuned-adm module
    maintainer  Syed Ali <alicsyed@gmail.com>
    maturity    new
    depends      tuned-adm
    platform    Linux
salt.modules.tuned.active()
Return current active profile

CLI Example:
salt '*' tuned.active

salt.modules.tuned.list()
List the profiles available

CLI Example:
salt '*' tuned.list

salt.modules.tuned.off()
   Turn off all profiles

CLI Example:
salt '*' tuned.off

salt.modules.tuned.profile(profile_name)
   Activate specified profile

CLI Example:
salt '*' tuned.profile virtual-guest

32.17.285 salt.modules.twilio_notify
Module for notifications via Twilio
New in version 2014.7.0.

depends
   • twilio python module

configuration Configure this module by specifying the name of a configuration profile in the minion config, minion pillar, or master config.

For example:

my-twilio-account:
   twilio.account_sid: AC32a3c83990934481add5ce1659f04d2
   twilio.auth_token: mytoken

salt.modules.twilio_notify.send_sms(profile, body, to, from_)
Send an sms

CLI Example:
twilio.send_sms twilio-account 'Test sms' '+18019999999' '+18011111111'

32.17.286 salt.modules.udev
Manage and query udev info
New in version 2015.8.0.
salt.modules.udev.env(dev)
Return all environment variables udev has for dev
CLI Example:
salt '*' udev.env /dev/sda
salt '*' udev.env /sys/class/net/eth0

salt.modules.udev.info(dev)
Extract all info delivered by udevadm
CLI Example:
salt '*' udev.info /dev/sda
salt '*' udev.info /sys/class/net/eth0

salt.modules.udev.links(dev)
Return all udev-created device symlinks
CLI Example:
salt '*' udev.links /dev/sda
salt '*' udev.links /sys/class/net/eth0

salt.modules.udev.name(dev)
Return the actual dev name(s?) according to udev for dev
CLI Example:
salt '*' udev.dev /dev/sda
salt '*' udev.dev /sys/class/net/eth0

salt.modules.udev.path(dev)
Return the physical device path(s?) according to udev for dev
CLI Example:
salt '*' udev.path /dev/sda
salt '*' udev.path /sys/class/net/eth0

32.17.287 salt.modules.upstart
Module for the management of upstart systems. The Upstart system only supports service starting, stopping and restarting.

**Important:** If you feel that Salt should be using this module to manage services on a minion, and it is using a different module (or gives an error similar to `service.start` is not available), see here.

Currently (as of Ubuntu 12.04) there is no tool available to disable Upstart services (like update-rc.d). This[1] is the recommended way to disable an Upstart service. So we assume that all Upstart services that have not been disabled in this manner are enabled.

But this is broken because we do not check to see that the dependent services are enabled. Otherwise we would have to do something like parse the output of `"initctl show-config"` to determine if all service dependencies are enabled to start on boot. For example, see the `"start on"` condition for the lightdm service below[2]. And this would be too hard. So we wait until the upstart developers have solved this problem. :) This is to say that an Upstart service that is enabled may not really be enabled.

32.17. Full list of builtin execution modules
Also, when an Upstart service is enabled, should the dependent services be enabled too? Probably not. But there should be a notice about this, at least.

[2] example upstart configuration file:

```plaintext
lightdm
emits login-session-start
emits desktop-session-start
emits desktop-shutdown
start on (((filesystem and runlevel ![06]) and started dbus) and (drm-device-added --card0 PRIMARY_DEVICE_FOR_DISPLAY=1 or stopped udev-fallback-graphics)) or runlevel ![PRELEVEL=S])
stop on runlevel [016]
```

**Warning:** This module should not be used on Red Hat systems. For these, the `rh_service` module should be used, as it supports the hybrid upstart/sysvinit system used in RHEL/CentOS 6.

`salt.modules.upstart.available(name)`
Returns True if the specified service is available, otherwise returns False.

CLI Example:
```
salt '*' service.available sshd
```

`salt.modules.upstart.disable(name, **kwargs)`
Disable the named service from starting on boot

CLI Example:
```
salt '*' service.disable <service name>
```

`salt.modules.upstart.disabled(name)`
Check to see if the named service is disabled to start on boot

CLI Example:
```
salt '*' service.disabled <service name>
```

`salt.modules.upstart.enable(name, **kwargs)`
Enable the named service to start at boot

CLI Example:
```
salt '*' service.enable <service name>
```

`salt.modules.upstart.enabled(name, **kwargs)`
Check to see if the named service is enabled to start on boot

CLI Example:
```
salt '*' service.enabled <service name>
```

`salt.modules.upstart.force_reload(name)`
Force-reload the named service

CLI Example:
salt '*' service.force_reload <service name>

**salt.modules.upstart.full_restart**(name)

Do a full restart (stop/start) of the named service

CLI Example:

```
salt '*' service.full_restart <service name>
```

**salt.modules.upstart.get_all()**

Return all installed services

CLI Example:

```
salt '*' service.get_all
```

**salt.modules.upstart.get_disabled()**

Return the disabled services

CLI Example:

```
salt '*' service.get_disabled
```

**salt.modules.upstart.get_enabled()**

Return the enabled services

CLI Example:

```
salt '*' service.get_enabled
```

**salt.modules.upstart.missing**(name)

The inverse of service.available. Returns `True` if the specified service is not available, otherwise returns `False`.

CLI Example:

```
salt '*' service.missing sshd
```

**salt.modules.upstart.reload**(name)

Reload the named service

CLI Example:

```
salt '*' service.reload <service name>
```

**salt.modules.upstart.restart**(name)

Restart the named service

CLI Example:

```
salt '*' service.restart <service name>
```

**salt.modules.upstart.start**(name)

Start the specified service

CLI Example:

```
salt '*' service.start <service name>
```
salt.modules.upstart.status(name, sig=None)
Return the status for a service, returns a bool whether the service is running.

CLI Example:
```
salt '*' service.status <service name>
```

salt.modules.upstart.stop(name)
Stop the specified service

CLI Example:
```
salt '*' service.stop <service name>
```

32.17.288 salt.modules.uptime

Wrapper around uptime API

salt.modules.uptime.check_exists(name)
Check if a given URL is in being monitored by uptime

CLI Example:
```
salt '*' uptime.check_exists http://example.org
```

salt.modules.uptime.checks_list()
List URL checked by uptime

CLI Example:
```
salt '*' uptime.checks_list
```

salt.modules.uptime.create(name, **params)
Create a check on a given URL.

Additional parameters can be used and are passed to API (for example interval, maxTime, etc). See the documentation https://github.com/fzaninotto/uptime for a full list of the parameters.

CLI Example:
```
salt '*' uptime.create http://example.org
```

salt.modules.uptime.delete(name)
Delete a check on a given URL

CLI Example:
```
salt '*' uptime.delete http://example.org
```

32.17.289 salt.modules.useradd

Manage users with the useradd command

Important: If you feel that Salt should be using this module to manage users on a minion, and it is using a different module (or gives an error similar to `user.info is not available`), see here.
salt.modules.useradd.add(name, uid=None, gid=None, groups=None, home=None, shell=None, unique=True, system=False, fullname='`, roomnumber='`, workphone='`, homephone='`, createhome=True, loginclass=None)

Add a user to the minion

CLI Example:
```
salt '*' user.add name <uid> <gid> <groups> <home> <shell>
```

salt.modules.useradd.chfullname(name, fullname)

Change the user's Full Name

CLI Example:
```
salt '*' user.chfullname foo "Foo Bar"
```

salt.modules.useradd.chgid(name, gid)

Change the default group of the user

CLI Example:
```
salt '*' user.chgid foo 4376
```

salt.modules.useradd.chgroups(name, groups, append=False)

Change the groups to which this user belongs

name  User to modify

groups Groups to set for the user

append  [False] If True, append the specified group(s). Otherwise, this function will replace the user's groups with the specified group(s).

CLI Examples:
```
salt '*' user.chgroups foo wheel,root
salt '*' user.chgroups foo wheel,root append=True
```

salt.modules.useradd.chhome(name, home, persist=False)

Change the home directory of the user, pass True for persist to move files to the new home directory if the old home directory exist.

CLI Example:
```
salt '*' user.chhome foo /home/users/foo True
```

salt.modules.useradd.chhomephone(name, homephone)

Change the user's Home Phone

CLI Example:
```
salt '*' user.chhomephone foo 7735551234
```

salt.modules.useradd.chloginclass(name, loginclass)

Change the default login class of the user

Note: This function only applies to OpenBSD systems.

CLI Example:
salt '*$' user.chloginclass foo staff

```
salt.modules.useradd.chroomnumber(name, roomnumber)
  Change the user's Room Number
  CLI Example:
  salt '*$' user.chroomnumber foo 123
```

salt.modules.useradd.chshell(name, shell)
  Change the default shell of the user
  CLI Example:
  salt '*$' user.chshell foo /bin/zsh

salt.modules.useradd.chuid(name, uid)
  Change the uid for a named user
  CLI Example:
  salt '*$' user.chuid foo 4376

salt.modules.useradd.chworkphone(name, workphone)
  Change the user's Work Phone
  CLI Example:
  salt '*$' user.chworkphone foo 7735550123

salt.modules.useradd.delete(name, remove=False, force=False)
  Remove a user from the minion
  CLI Example:
  salt '*$' user.delete name remove=True force=True

salt.modules.useradd.get_loginclass(name)
  Get the login class of the user

  Note: This function only applies to OpenBSD systems.
  CLI Example:
  salt '*$' user.get_loginclass foo

salt.modules.useradd.getent(refresh=False)
  Return the list of all info for all users
  CLI Example:
  salt '*$' user.getent

salt.modules.useradd.info(name)
  Return user information
  CLI Example:
salt '*' user.info root

cssalt.modules.useradd.list_groups(name)
Return a list of groups the named user belongs to

CLI Example:
salt '*' user.list_groups foo

cssalt.modules.useradd.list_users()
Return a list of all users

CLI Example:
salt '*' user.list_users

salt.modules.useradd.rename(name, new_name)
Change the username for a named user

CLI Example:
salt '*' user.rename name new_name

32.17.290 salt.modules.uwsgi

maintainer Peter Baumgartner <pete@lincolnloop.com>
maturity new
platform all

salt.modules.uwsgi.stats(socket)
Return the data from uwsgi --connect-and-read as a dictionary.

socket The socket the uWSGI stats server is listening on

CLI Example:
salt '*' uwsgi.stats /var/run/mystatsserver.sock
salt '*' uwsgi.stats 127.0.0.1:5050

32.17.291 salt.modules.varnish

Support for Varnish

New in version 2014.7.0.

Note: These functions are designed to work with all implementations of Varnish from 3.x onwards

salt.modules.varnish.ban(ban_expression)
Add ban to the varnish cache

CLI Example:
salt '//' varnish.ban ban_expression

salt.modules.varnish.ban_list()
    List varnish cache current bans
    CLI Example:
    salt '//' varnish.ban_list

salt.modules.varnish.param_set(param, value)
    Set a param in varnish cache
    CLI Example:
    salt '//' varnish.param_set param value

salt.modules.varnish.param_show(param=None)
    Show params of varnish cache
    CLI Example:
    salt '//' varnish.param_show param

salt.modules.varnish.purge()
    Purge the varnish cache
    CLI Example:
    salt '//' varnish.purge

salt.modules.varnish.version()
    Return server version from varnishd -V
    CLI Example:
    salt '//' varnish.version

32.17.292 salt.modules.vbox_guest

VirtualBox Guest Additions installer

salt.modules.vbox_guest.additions_install(*args, **kwargs)
    Install VirtualBox Guest Additions. Uses the CD, connected by VirtualBox.
    To connect VirtualBox Guest Additions via VirtualBox graphical interface press 'Host+D' ('Host' is usually 'Right Ctrl').
    See https://www.virtualbox.org/manual/ch04.html#idp52733088 for more details.
    CLI Example:
    salt '//' vbox_guest.additions_install
    salt '//' vbox_guest.additions_install reboot=True
    salt '//' vbox_guest.additions_install upgrade_os=True

Parameters
    - reboot (bool) -- reboot computer to complete installation
• `upgrade_os(bool)` -- upgrade OS (to ensure the latests version of kernel and developer tools are installed)

**Returns** version of VirtualBox Guest Additions or string with error

```
salt.modules.vbox_guest.additions_mount()
Mount VirtualBox Guest Additions CD to the temp directory.

To connect VirtualBox Guest Additions via VirtualBox graphical interface press 'Host+D' ('Host' is usually 'Right Ctrl').

CLI Example:
```
    salt '*' vbox_guest.additions_mount
```

**Returns** True or OSError exception

```
salt.modules.vbox_guest.additions_remove(**kwargs)
Remove VirtualBox Guest Additions.

Firstly it tries to uninstall itself by executing '/opt/VBoxGuestAdditions-VERSION/uninstall.run uninstall'. It uses the CD, connected by VirtualBox if it failes.

CLI Example:
```
    salt '*' vbox_guest.additions_remove
    salt '*' vbox_guest.additions_remove force=True
```

**Parameters** force (bool) -- force VirtualBox Guest Additions removing

**Returns** True if VirtualBox Guest Additions were removed successfully else False

```
salt.modules.vbox_guest.additions_umount(mount_point)
Unmount VirtualBox Guest Additions CD from the temp directory.

CLI Example:
```
    salt '*' vbox_guest.additions_umount
```

**Parameters** mount_point -- directory VirtualBox Guest Additions is mounted to

**Returns** True or an string with error

```
salt.modules.vbox_guest.additions_version()
Check VirtualBox Guest Additions version.

CLI Example:
```
    salt '*' vbox_guest.additions_version
```

**Returns** version of VirtualBox Guest Additions or False if they are not installed

```
salt.modules.vbox_guest.grant_access_to_shared_folders_to(name, users=None)
Grant access to auto-mounted shared folders to the users.

User is specified by it's name. To grant access for several users use argument `users`. Access will be denied to the users not listed in `users` argument.

See https://www.virtualbox.org/manual/ch04.html#sf_mount_auto for more details.
```

32.17. Full list of builtin execution modules
CLI Example:

```
salt '*' vbox_guest.grant_access_to_shared_folders_to fred
salt '*' vbox_guest.grant_access_to_shared_folders_to users ['fred', 'roman']
```

Parameters

- **name (str)** -- name of the user to grant access to auto-mounted shared folders to
- **users (list of str)** -- list of names of users to grant access to auto-mounted shared folders to (if specified, name will not be taken into account)

Returns list of users who have access to auto-mounted shared folders

```
salt.modules.vbox_guest.list_shared_folders_users()
```

List users who have access to auto-mounted shared folders.

See https://www.virtualbox.org/manual/ch04.html#sf_mount_auto for more details.

CLI Example:

```
salt '*' vbox_guest.list_shared_folders_users
```

Returns list of users who have access to auto-mounted shared folders

### 32.17.293 salt.modules.victorops

Support for VictorOps

New in version 2015.8.0.

Requires an **api_key** in /etc/salt/minion:

```
salt.modules.victorops.create_event(message_type=None, routing_key='everybody', **kwargs)
```

Create an event in VictorOps. Designed for use in states.

The following parameters are required:

**Parameters**

- **message_type** -- One of the following values: INFO, WARNING, ACKNOWLEDGEMENT, CRITICAL, RECOVERY.

The following parameters are optional:

**Parameters**

- **routing_key** -- The key for where messages should be routed. By default, sent to `everyone` route.
- **entity_id** -- The name of alerting entity. If not provided, a random name will be assigned.
- **timestamp** -- Timestamp of the alert in seconds since epoch. Defaults to the time the alert is received at VictorOps.

:|param timestamp_fmt| The date format for the timestamp parameter.

**Parameters**

- **state_start_time** -- The time this entity entered its current state (seconds since epoch). Defaults to the time alert is received.
- **state_start_time_fmt** -- The date format for the timestamp parameter.
- **state_message** -- Any additional status information from the alert item.
- **entity_is_host** -- Used within VictorOps to select the appropriate display format for the incident.
- **entity_display_name** -- Used within VictorOps to display a human-readable name for the entity.
- **ack_message** -- A user entered comment for the acknowledgment.
- **ack_author** -- The user that acknowledged the incident.

**Returns**  A dictionary with result, entity_id, and message if result was failure.

**CLI Example:**

```bash
salt myminion victorops.create_event message_type='CRITICAL' routing_key='everyone' entity_id='hostname/diskspace'

salt myminion victorops.create_event message_type='ACKNOWLEDGEMENT' routing_key='everyone' entity_id='hostname/diskspace' ack_message='Acknowledged' ack_author='username'

salt myminion victorops.create_event message_type='RECOVERY' routing_key='everyone' entity_id='hostname/diskspace'
```

The following parameters are required: message_type

### 32.17.294 salt.modules.virt

Work with virtual machines managed by libvirt

**depends** libvirt Python module

**salt.modules.virt.create**(vm_)

Start a defined domain

**CLI Example:**

```bash
salt '*' virt.create <vm name>
```

**salt.modules.virt.create_xml_path**(path)

Start a domain based on the XML-file path passed to the function

**CLI Example:**

```bash
salt '*' virt.create_xml_path <path to XML file on the node>
```

**salt.modules.virt.create_xml_str**(xml)

Start a domain based on the XML passed to the function

**CLI Example:**

```bash
salt '*' virt.create_xml_str <XML in string format>
```

**salt.modules.virt.ctrl_alt_del**(vm_)

Sends CTRL+ALT+DEL to a VM

**CLI Example:**

```bash
```
salt '*' virtctrl_alt_del <vm name>

salt.modules.virt.define_vol_xml_path(path)
Define a volume based on the XML-file path passed to the function

CLI Example:
salt '*' virt.define_vol_xml_path <path to XML file on the node>

salt.modules.virt.define_vol_xml_str(xml)
Define a volume based on the XML passed to the function

CLI Example:
salt '*' virt.define_vol_xml_str <XML in string format>

salt.modules.virt.define_xml_path(path)
Define a domain based on the XML-file path passed to the function

CLI Example:
salt '*' virt.define_xml_path <path to XML file on the node>

salt.modules.virt.define_xml_str(xml)
Define a domain based on the XML passed to the function

CLI Example:
salt '*' virt.define_xml_str <XML in string format>

salt.modules.virt.destroy(vm_)
Hard power down the virtual machine, this is equivalent to pulling the power

CLI Example:
salt '*' virt.destroy <vm name>

salt.modules.virt.freecpu()
Return an int representing the number of unallocated cpus on this hypervisor

CLI Example:
salt '*' virt.freecpu

salt.modules.virt.freemem()
Return an int representing the amount of memory (in MB) that has not been given to virtual machines on this node

CLI Example:
salt '*' virt.freemem

salt.modules.virt.full_info()
Return the node_info, vm_info and freemem

CLI Example:
salt '*' virt.full_info
salt.modules.virt.get_disks(vm_)
    Return the disks of a named vm
    CLI Example:
    ```
salt '*' virt.get_disks <vm name>
    ```

salt.modules.virt.get_graphics(vm_)
    Returns the information on vnc for a given vm
    CLI Example:
    ```
salt '*' virt.get_graphics <vm name>
    ```

salt.modules.virt.get_macs(vm_)
    Return a list off MAC addresses from the named vm
    CLI Example:
    ```
salt '*' virt.get_macs <vm name>
    ```

salt.modules.virt.get_nics(vm_)
    Return info about the network interfaces of a named vm
    CLI Example:
    ```
salt '*' virt.get_nics <vm name>
    ```

salt.modules.virt.get_profiles(hypervisor=None)
    Return the virt profiles for hypervisor.
    Currently there are profiles for:
    • nic
    • disk
    CLI Example:
    ```
salt '*' virt.get_profiles
salt '*' virt.get_profiles hypervisor=esxi
    ```

salt.modules.virt.get_xml(vm_)
    Returns the XML for a given vm
    CLI Example:
    ```
salt '*' virt.get_xml <vm name>
    ```

salt.modules.virt.init(name, cpu, mem, image=None, nic='default', hypervisor='kvm', start=True,
                        disk='default', saltenv='base', seed=True, install=True, pub_key=None,
                        priv_key=None, seed_cmd='seed.apply', **kwargs)
    Initialize a new vm
    CLI Example:
    ```
salt 'hypervisor' virt.init vm_name 4 512 salt://path/to/image.raw
salt 'hypervisor' virt.init vm_name 4 512 nic=profile disk=profile
    ```

salt.modules.virt.is_hyper()
    Returns a bool whether or not this node is a hypervisor of any kind
CLI Example:

```
salt '*' virt.is_hyper
```

`salt.modules.virt.is_kvm_hyper()`
Returns a bool whether or not this node is a KVM hypervisor

CLI Example:

```
salt '*' virt.is_kvm_hyper
```

`salt.modules.virt.is_xen_hyper()`
Returns a bool whether or not this node is a XEN hypervisor

CLI Example:

```
salt '*' virt.is_xen_hyper
```

`salt.modules.virt.list_active_vms()`
Return a list of names for active virtual machine on the minion

CLI Example:

```
salt '*' virt.list_active_vms
```

`salt.modules.virt.list_inactive_vms()`
Return a list of names for inactive virtual machine on the minion

CLI Example:

```
salt '*' virt.list_inactive_vms
```

`salt.modules.virt.list_vms()`
Return a list of virtual machine names on the minion

CLI Example:

```
salt '*' virt.list_vms
```

`salt.modules.virt.migrate(vm_, target, ssh=False)`
Shared storage migration

CLI Example:

```
salt '*' virt.migrate <vm name> <target hypervisor>
```

`salt.modules.virt.migrate_non_shared(vm_, target, ssh=False)`
Attempt to execute non-shared storage ``all'' migration

CLI Example:

```
salt '*' virt.migrate_non_shared <vm name> <target hypervisor>
```

`salt.modules.virt.migrate_non_shared_inc(vm_, target, ssh=False)`
Attempt to execute non-shared storage ``all'' migration

CLI Example:

```
salt '*' virt.migrate_non_shared_inc <vm name> <target hypervisor>
```
salt.modules.virt.node_info()
Return a dict with information about this node

CLI Example:
salt '*' virt.node_info

salt.modules.virt.pause(vm_)
Pause the named vm

CLI Example:
salt '*' virt.pause <vm name>

salt.modules.virt.purge(vm_, dirs=False)
Recursively destroy and delete a virtual machine, pass True for dir's to also delete the directories containing the virtual machine disk images - USE WITH EXTREME CAUTION!

CLI Example:
salt '*' virt.purge <vm name>

salt.modules.virt.reboot(vm_)
Reboot a domain via ACPI request

CLI Example:
salt '*' virt.reboot <vm name>

salt.modules.virt.reset(vm_)
Reset a VM by emulating the reset button on a physical machine

CLI Example:
salt '*' virt.reset <vm name>

salt.modules.virt.resume(vm_)
Resume the named vm

CLI Example:
salt '*' virt.resume <vm name>

salt.modules.virt.seed_non_shared_migrate(disks, force=False)
Non shared migration requires that the disks be present on the migration destination, pass the disks information via this function, to the migration destination before executing the migration.

CLI Example:
salt '*' virt.seed_non_shared_migrate <disks>

salt.modules.virt.set_autostart(vm_, state='on')
Set the autostart flag on a VM so that the VM will start with the host system on reboot.

CLI Example:
salt "*" virt.set_autostart <vm name> <on | off>

salt.modules.virt.setmem(vm_, memory, config=False)
Changes the amount of memory allocated to VM. The VM must be shutdown for this to work.
memory is to be specified in MB If config is True then we ask libvirt to modify the config as well

**CLI Example:**
```
salt '*' virt.setmem myvm 768
```

```
salt.modules.virt.setvcpus(vm_, vcpus, config=False)
Changes the amount of vcpus allocated to VM. The VM must be shutdown for this to work.
vcpus is an int representing the number to be assigned If config is True then we ask libvirt to modify the config as well
**CLI Example:**
```
salt '*' virt.setvcpus myvm 2
```

```
salt.modules.virt.shutdown(vm_)
Send a soft shutdown signal to the named vm
**CLI Example:**
```
salt '*' virt.shutdown <vm name>
```

```
salt.modules.virt.start(vm_)
Alias for the obscurely named `create' function
**CLI Example:**
```
salt '*' virt.start <vm name>
```

```
salt.modules.virt.stop(vm_)
Alias for the obscurely named `destroy' function
**CLI Example:**
```
salt '*' virt.stop <vm name>
```

```
salt.modules.virt.undefine(vm_)
Remove a defined vm, this does not purge the virtual machine image, and this only works if the vm is powered down
**CLI Example:**
```
salt '*' virt.undefine <vm name>
```

```
salt.modules.virt.virt_type()
Returns the virtual machine type as a string
**CLI Example:**
```
salt '*' virt.virt_type
```

```
salt.modules.virt.vm_cputime(vm_=None)
Return cputime used by the vms on this hyper in a list of dicts:
```
[
    'your-vm': {
        'cputime' <int>
        'cputime_percent' <int>
    },
]
If you pass a VM name in as an argument then it will return info for just the named VM, otherwise it will return all VMs.

CLI Example:

```
salt '*' virt.vm_cputime
```

```
salt.modules.virt.vm_diskstats(*None*)
```

Return disk usage counters used by the vms on this hyper in a list of dicts:

```
[
    'your-vm': {
        'rd_req'  : 0,
        'rd_bytes': 0,
        'wr_req'  : 0,
        'wr_bytes': 0,
        'errs'    : 0
    },
    ...
]
```

If you pass a VM name in as an argument then it will return info for just the named VM, otherwise it will return all VMs.

CLI Example:

```
salt '*' virt.vm_blockstats
```

```
salt.modules.virt.vm_info(*None*)
```

Return detailed information about the vms on this hyper in a list of dicts:

```
[
    'your-vm': {
        'cpu': <int>,
        'maxMem': <int>,
        'mem': <int>,
        'state': '<state>',
        'cputime': <int>
    },
    ...
]
```

If you pass a VM name in as an argument then it will return info for just the named VM, otherwise it will return all VMs.

CLI Example:

```
salt '*' virt.vm_info
```

```
salt.modules.virt.vm_netstats(*None*)
```

Return combined network counters used by the vms on this hyper in a list of dicts:

```
[
    'your-vm': {
        'rx_bytes': 0,
        ...
    }
]
```
{'rx_packets': 0, 'rx_errs': 0, 'rx_drop': 0, 'tx_bytes': 0, 'tx_packets': 0, 'tx_errs': 0, 'tx_drop': 0},
...
}

If you pass a VM name in as an argument then it will return info for just the named VM, otherwise it will return all VMs.

CLI Example:

```bash
salt '*' virt.vm_netstats
```

```python
salt.modules.virt.vm_state(vm_=None)
```

Return list of all the vms and their state.

If you pass a VM name in as an argument then it will return info for just the named VM, otherwise it will return all VMs.

CLI Example:

```bash
salt '*' virt.vm_state <vm name>
```

### 32.17.295 `salt.modules.virtualenv`

Create virtualenv environments.

New in version 0.17.0.

```python
salt.modules.virtualenv_mod.create(path, venv_bin=None, system_site_packages=False, distribute=False, clear=False, python=None, extra_search_dir=None, never_download=None, prompt=None, pip=False, symlinks=None, upgrade=None, user=None, use_vt=False, saltenv='base')
```

Create a virtualenv

**path** The path to create the virtualenv

**venv_bin** [None (default `virtualenv`)] The name (and optionally path) of the virtualenv command. This can also be set globally in the minion config file as `virtualenv.venv_bin`.

**system_site_packages** [False] Passthrough argument given to virtualenv or pyenv

**distribute** [False] Passthrough argument given to virtualenv

**pip** [False] Install pip after creating a virtual environment, implies distribute=True

**clear** [False] Passthrough argument given to virtualenv or pyenv

**python** [None (default)] Passthrough argument given to virtualenv

**extra_search_dir** [None (default)] Passthrough argument given to virtualenv

**never_download** [None (default)] Passthrough argument given to virtualenv if True

**prompt** [None (default)] Passthrough argument given to virtualenv if not None
symlinks  [None] Passthrough argument given to pyenv if True
upgrade  [None] Passthrough argument given to pyenv if True
user  [None] Set ownership for the virtualenv
runas  [None] Set ownership for the virtualenv
use_vt  [False] Use VT terminal emulation (see output while installing)

    New in version 2015.5.0.
saltenv  ['base'] Specify a different environment. The default environment is base.

    New in version 2014.1.0.

Note: The runas argument is deprecated as of 2014.1.0. user should be used instead.

CLI Example:

```bash
salt '*' virtualenv.create /path/to/new/virtualenv
```

```
salt.modules.virtualenv_mod.get_resource_content(venv, package_or_requirement, resource_name)
```

Returns the content of a resource of a package or a distribution inside a virtualenv

New in version 2015.5.0.

venv  Path to the virtualenv.

package_or_requirement  Name of the package where the resource resides in.

resource_name  Name of the resource of which the content is to be returned.

CLI Example:

```bash
salt '*' virtualenv.get_resource_content /path/to/my/venv my_package my/resource.xml
```

```
salt.modules.virtualenv_mod.get_resource_path(venv, package_or_requirement, resource_name)
```

Returns the path to a resource of a package or a distribution inside a virtualenv

New in version 2015.5.0.

venv  Path to the virtualenv.

package_or_requirement  Name of the package where the resource resides in.

resource_name  Name of the resource of which the path is to be returned.

CLI Example:

```bash
salt '*' virtualenv.get_resource_path /path/to/my/venv my_package my/resource.xml
```

```
salt.modules.virtualenv_mod.get_site_packages(venv)
```

Returns the path to the site-packages directory inside a virtualenv

venv  Path to the virtualenv.

CLI Example:

```bash
salt '*' virtualenv.get_site_packages /path/to/my/venv
```
32.17.296 salt.modules.vsphere

Manage VMware vCenter servers and ESXi hosts.
New in version 2015.8.4.

Dependencies

- pyVmomi Python Module
- ESXCLI

PyVmomi

PyVmomi can be installed via pip:

```
pip install pyVmomi
```

**Note:** Version 6.0 of pyVmomi has some problems with SSL error handling on certain versions of Python. If using version 6.0 of pyVmomi, Python 2.6, Python 2.7.9, or newer must be present. This is due to an upstream dependency in pyVmomi 6.0 that is not supported in Python versions 2.7 to 2.7.8. If the version of Python is not in the supported range, you will need to install an earlier version of pyVmomi. See Issue #29537 for more information.

Based on the note above, to install an earlier version of pyVmomi than the version currently listed in PyPi, run the following:

```
pip install pyVmomi==5.5.0.2014.1.1
```

The 5.5.0.2014.1.1 is a known stable version that this original vSphere Execution Module was developed against.

ESXCLI

Currently, about a third of the functions used in the vSphere Execution Module require the ESXCLI package be installed on the machine running the Proxy Minion process.

The ESXCLI package is also referred to as the VMware vSphere CLI, or vCLI. VMware provides vCLI package installation instructions for vSphere 5.5 and vSphere 6.0.

Once all of the required dependencies are in place and the vCLI package is installed, you can check to see if you can connect to your ESXi host or vCenter server by running the following command:

```
esxcli -s <host-location> -u <username> -p <password> system syslog config get
```

If the connection was successful, ESXCLI was successfully installed on your system. You should see output related to the ESXi host's syslog configuration.

**Note:** Be aware that some functionality in this execution module may depend on the type of license attached to a vCenter Server or ESXi host(s).

For example, certain services are only available to manipulate service state or policies with a VMware vSphere Enterprise or Enterprise Plus license, while others are available with a Standard license. The ntpd service is restricted to an Enterprise Plus license, while ssh is available via the Standard license.
About

This execution module was designed to be able to handle connections both to a vCenter Server, as well as to an ESXi host. It utilizes the pyVmomi Python library and the ESXCLI package to run remote execution functions against either the defined vCenter server or the ESXi host.

Whether or not the function runs against a vCenter Server or an ESXi host depends entirely upon the arguments passed into the function. Each function requires a host location, username, and password. If the credentials provided apply to a vCenter Server, then the function will be run against the vCenter Server. For example, when listing hosts using vCenter credentials, you'll get a list of hosts associated with that vCenter Server:

```
# salt my-minion vsphere.list_hosts <vcenter-ip> <vcenter-user> <vcenter-password>
my-minion:
   - esxi-1.example.com
   - esxi-2.example.com
```

However, some functions should be used against ESXi hosts, not vCenter Servers. Functionality such as getting a host's coredump network configuration should be performed against a host and not a vCenter server. If the authentication information you're using is against a vCenter server and not an ESXi host, you can provide the host name that is associated with the vCenter server in the command, as a list, using the `host_names` or `esxi_host` kwarg. For example:

```
# salt my-minion vsphere.get_coredump_network_config <vcenter-ip> <vcenter-user> <vcenter-password> esxi_hosts='[esxi-1.example.com, esxi-2.example.com]'
my-minion:
  esxi-1.example.com:
    ------------
    Coredump Config:
    ------------
    enabled: False
  esxi-2.example.com:
    ------------
    Coredump Config:
    ------------
    enabled: True
    host_vnic: vmk0
    ip: coredump-location.example.com
    port: 6500
```

You can also use these functions against an ESXi host directly by establishing a connection to an ESXi host using the host's location, username, and password. If ESXi connection credentials are used instead of vCenter credentials, the `host_names` and `esxi_host` arguments are not needed.

```
# salt my-minion vsphere.get_coredump_network_config esxi-1.example.com root <host-password>
local:
  10.4.28.150:
```
Coredump Config:

- enabled: True
- host_vnic: vmk0
- ip: coredump-location.example.com
- port: 6500

salt.modules.vsphere.add_host_to_dvs(host, username, password, vmknic_name, vmnic_name, dvs_name, portgroup_name, protocol=None, port=None, host_names=None)

Adds an ESXi host to a vSphere Distributed Virtual Switch DOES NOT migrate the ESXi’s physical and virtual NICs to the switch (yet) (please don’t remove the commented code)

salt.modules.vsphere.coredump_network_enable(host, username, password, enabled, protocol=None, port=None, esxi_hosts=None)

Enable or disable ESXi core dump collection. Returns True if coredump is enabled and returns False if core dump is not enabled. If there was an error, the error will be the value printed in the Error key dictionary for the given host.

- host The location of the host.
- username The username used to login to the host, such as root.
- password The password used to login to the host.
- enabled Python True or False to enable or disable coredumps.
- protocol Optionally set to alternate protocol if the host is not using the default protocol. Default protocol is https.
- port Optionally set to alternate port if the host is not using the default port. Default port is 443.
- esxi_hosts If host is a vCenter host, then use esxi_hosts to execute this function on a list of one or more ESXi machines.

CLI Example:

```
# Used for ESXi host connection information
salt '*' vsphere.coredump_network_enable my.esxi.host root bad-password True

# Used for connecting to a vCenter Server
salt '*' vsphere.coredump_network_enable my.vcenter.location root bad-password False
  esxi_hosts=['esxi-1.host.com, esxi-2.host.com']
```

salt.modules.vsphere.enable_firewall_ruleset(host, username, password, ruleset_enable, ruleset_name, protocol=None, port=None, esxi_hosts=None)

Enable or disable an ESXi firewall rule set.

- host The location of the host.
- username The username used to login to the host, such as root.
- password The password used to login to the host.
- ruleset_enable True to enable the ruleset, false to disable.
ruleset_name  Name of ruleset to target.

protocol  Optionally set to alternate protocol if the host is not using the default protocol. Default protocol is https.

port  Optionally set to alternate port if the host is not using the default port. Default port is 443.

esxi_hosts  If host is a vCenter host, then use esxi_hosts to execute this function on a list of one or more ESXi machines.

Returns  A standard cmd.run_all dictionary, per host.

CLI Example:

```
# Used for ESXi host connection information
salt '*' vsphere.enable_firewall_ruleset my.esxi.host root bad-password True
  →'syslog'

# Used for connecting to a vCenter Server
salt '*' vsphere.enable_firewall_ruleset my.vcenter.location root bad-password
  →True 'syslog' esxi_hosts='[esxi-1.host.com, esxi-2.host.com]'
```

salt.modules.vsphere.esxcli_cmd(host, username, password, cmd_str, protocol=None, port=None, esxi_hosts=None)

Run an ESXCLI command directly on the host or list of hosts.

host  The location of the host.

username  The username used to login to the host, such as root.

password  The password used to login to the host.

cmd_str  The ESXCLI command to run. Note: This should not include the -s, -u, -p, -h, --protocol, or --portnumber arguments that are frequently passed when using a bare ESXCLI command from the command line. Those arguments are handled by this function via the other args and kwargs.

protocol  Optionally set to alternate protocol if the host is not using the default protocol. Default protocol is https.

port  Optionally set to alternate port if the host is not using the default port. Default port is 443.

esxi_hosts  If host is a vCenter host, then use esxi_hosts to execute this function on a list of one or more ESXi machines.

CLI Example:

```
# Used for ESXi host connection information
salt '*' vsphere.esxcli_cmd my.esxi.host root bad-password
  →'system\ncoredump network get'

# Used for connecting to a vCenter Server
salt '*' vsphere.esxcli_cmd my.vcenter.location root bad-password
  →'system coredump network get' esxi_hosts='[esxi-1.host.com, esxi-2.host.com]'
```

salt.modules.vsphere.get_coredump_network_config(host, username, password, protocol=None, port=None, esxi_hosts=None)

Retrieve information on ESXi or vCenter network dump collection and format it into a dictionary.

host  The location of the host.
### vsphere.get_coredump_network_config

**username** The username used to login to the host, such as `root`.

**password** The password used to login to the host.

**protocol** Optionally set to alternate protocol if the host is not using the default protocol. Default protocol is `https`.

**port** Optionally set to alternate port if the host is not using the default port. Default port is 443.

**esxi_hosts** If `host` is a vCenter host, then use `esxi_hosts` to execute this function on a list of one or more ESXi machines.

**Returns** A dictionary with the network configuration, or, if getting the network config failed, a an error message retrieved from the standard cmd.run_all dictionary, per host.

**CLI Example:**

```bash
salt '*' vsphere.get_coredump_network_config my.esxi.host root bad-password

# Used for connecting to vCenter Server
salt '*' vsphere.get_coredump_network_config my.vcenter.location root bad-password

esxi_hosts='[esxi-1.host.com, esxi-2.host.com]'
```

### vsphere.get_firewall_status

**host** The location of the host.

**username** The username used to login to the host, such as `root`.

**password** The password used to login to the host.

**protocol** Optionally set to alternate protocol if the host is not using the default protocol. Default protocol is `https`.

**port** Optionally set to alternate port if the host is not using the default port. Default port is 443.

**esxi_hosts** If `host` is a vCenter host, then use `esxi_hosts` to execute this function on a list of one or more ESXi machines.

**Returns** Nested dictionary with two toplevel keys `rulesets` and `success` success will be True or False depending on query success. `rulesets` will list the rulesets and their statuses if `success` was true, per host.

**CLI Example:**

```bash
salt.modules.vsphere.get_firewall_status(host, username, password, protocol=None, port=None, esxi_hosts=None)

# Used for ESXi host connection information
salt '*' vsphere.get_firewall_status my.esxi.host root bad-password

# Used for connecting to vCenter Server
salt '*' vsphere.get_firewall_status my.vcenter.location root bad-password

esxi_hosts='[esxi-1.host.com, esxi-2.host.com]'
```

### vsphere.get_host_datetime

**host** The location of the host.

**username** The username used to login to the host, such as `root`.

**password** The password used to login to the host.

**protocol** Optionally set to alternate protocol if the host is not using the default protocol. Default protocol is `https`.

**port** Optionally set to alternate port if the host is not using the default port. Default port is 443.

**host_names** If `host` is a list of host names, then use `host_names` to execute this function on a list of one or more host names.

**Returns** The date/time information for a given host or list of host_names.

**CLI Example:**

```bash
salt.modules.vsphere.get_host_datetime(host, username, password, protocol=None, port=None, host_names=None)

# Used for ESXi host connection information
salt '*' vsphere.get_host_datetime my.esxi.host root bad-password

# Used for connecting to vCenter Server
salt '*' vsphere.get_host_datetime my.vcenter.location root bad-password

esxi_hosts='[esxi-1.host.com, esxi-2.host.com]'
```
password  The password used to login to the host.

protocol  Optionally set to alternate protocol if the host is not using the default protocol. Default protocol is https.

port  Optionally set to alternate port if the host is not using the default port. Default port is 443.

host_names  List of ESXi host names. When the host, username, and password credentials are provided for a vCenter Server, the host_names argument is required to tell vCenter the hosts for which to get date/time information.

If host_names is not provided, the date/time information will be retrieved for the host location instead. This is useful for when service instance connection information is used for a single ESXi host.

CLI Example:

```
# Used for single ESXi host connection information
salt '*' vsphere.get_host_datetime my.esxi.host root bad-password

# Used for connecting to a vCenter Server
salt '*' vsphere.get_host_datetime my.vcenter.location root bad-password
host_names='[esxi-1.host.com, esxi-2.host.com]'
```

salt.modules.vsphere.get_ntp_config(host, username, password, protocol=None, port=None, host_names=None)

Get the NTP configuration information for a given host or list of host_names.

host  The location of the host.

username  The username used to login to the host, such as root.

password  The password used to login to the host.

protocol  Optionally set to alternate protocol if the host is not using the default protocol. Default protocol is https.

port  Optionally set to alternate port if the host is not using the default port. Default port is 443.

host_names  List of ESXi host names. When the host, username, and password credentials are provided for a vCenter Server, the host_names argument is required to tell vCenter the hosts for which to get ntp configuration information.

If host_names is not provided, the NTP configuration will be retrieved for the host location instead. This is useful for when service instance connection information is used for a single ESXi host.

CLI Example:

```
# Used for single ESXi host connection information
salt '*' vsphere.get_ntp_config my.esxi.host root bad-password

# Used for connecting to a vCenter Server
salt '*' vsphere.get_ntp_config my.vcenter.location root bad-password
host_names='[esxi-1.host.com, esxi-2.host.com]'
```

salt.modules.vsphere.get_service_policy(host, username, password, service_name, protocol=None, port=None, host_names=None)

Get the service name's policy for a given host or list of hosts.

host  The location of the host.

username  The username used to login to the host, such as root.

password  The password used to login to the host.
service_name

The name of the service for which to retrieve the policy. Supported service names are:

- DCUI
- TSM
- SSH
- lbtd
- lsassd
- lwiod
- netlogond
- ntpd
- sfcbd-watchdog
- snmpd
- vprobed
- vpxa
- xorg

protocol

Optionally set to alternate protocol if the host is not using the default protocol. Default protocol is https.

port

Optionally set to alternate port if the host is not using the default port. Default port is 443.

host_names

List of ESXi host names. When the host, username, and password credentials are provided for a vCenter Server, the host_names argument is required to tell vCenter the hosts for which to get service policy information.

If host_names is not provided, the service policy information will be retrieved for the host location instead. This is useful for when service instance connection information is used for a single ESXi host.

CLI Example:

```bash
# Used for single ESXi host connection information
salt '*' vsphere.get_service_policy my.esxi.host root bad-password 'ssh'

# Used for connecting to a vCenter Server
salt '*' vsphere.get_service_policy my.vcenter.location root bad-password 'ntpd' &
    host_names='[esxi-1.host.com, esxi-2.host.com]'
```

Get the service name's running state for a given host or list of hosts.

salt.modules.vsphere.get_service_running(host, username, password, service_name, protocol=None, port=None, host_names=None)

host

The location of the host.

username

The username used to login to the host, such as root.

password

The password used to login to the host.

service_name

The name of the service for which to retrieve the policy. Supported service names are:

- DCUI
- TSM
• SSH
• lbtd
• Isassd
• lwiod
• netlogond
• ntpd
• sfcbd-watchdog
• snmpd
• vprobed
• vpxa
• xorg

**protocol** Optionally set to alternate protocol if the host is not using the default protocol. Default protocol is `https`.

**port** Optionally set to alternate port if the host is not using the default port. Default port is `443`.

**host_names** List of ESXi host names. When the host, username, and password credentials are provided for a vCenter Server, the host_names argument is required to tell vCenter the hosts for which to get the service's running state.

If host_names is not provided, the service's running state will be retrieved for the host location instead. This is useful for when service instance connection information is used for a single ESXi host.

**CLI Example:**

```
# Used for single ESXi host connection information
salt '*' vsphere.get_service_running my.esxi.host root bad-password 'ssh'

# Used for connecting to a vCenter Server
salt '*' vsphere.get_service_running my.vcenter.location root bad-password 'ntpd'
    host_names='[esxi-1.host.com, esxi-2.host.com]'
```

salt.modules.vsphere.get_ssh_key(*host*, *username*, *password*, *protocol=None*, *port=None*, *certificate_verify=False*)

Retrieve the authorized_keys entry for root. This function only works for ESXi, not vCenter.

**Parameters**

- **host** -- The location of the ESXi Host
- **username** -- Username to connect as
- **password** -- Password for the ESXi web endpoint
- **protocol** -- defaults to https, can be http if ssl is disabled on ESXi
- **port** -- defaults to 443 for https
- **certificate_verify** -- If true require that the SSL connection present a valid certificate

**Returns** True if upload is successful

**CLI Example:**
salt.modules.vsphere.get_ssh_key 'my.esxi.host' root bad-password certificate_verify=True

salt.modules.vsphere.get_syslog_config

Retrieve the syslog configuration.

- **host** The location of the host.
- **username** The username used to login to the host, such as *root*.
- **password** The password used to login to the host.
- **protocol** Optionally set to alternate protocol if the host is not using the default protocol. Default protocol is *https*.
- **port** Optionally set to alternate port if the host is not using the default port. Default port is *443*.
- **esxi_hosts** If **host** is a vCenter host, then use esxi_hosts to execute this function on a list of one or more ESXi machines.

**Returns** Dictionary with keys and values corresponding to the syslog configuration, per host.

**CLI Example:**

```bash
# Used for ESXi host connection information
salt '*' vsphere.get_syslog_config my.esxi.host root bad-password

# Used for connecting to a vCenter Server
salt '*' vsphere.get_syslog_config my.vcenter.location root bad-password
  # esxi_hosts='[esxi-1.host.com, esxi-2.host.com]'
```

salt.modules.vsphere.get_vmotion_enabled

Get the VMotion enabled status for a given host or a list of host_names. Returns *True* if VMotion is enabled, *False* if it is not enabled.

- **host** The location of the host.
- **username** The username used to login to the host, such as *root*.
- **password** The password used to login to the host.
- **protocol** Optionally set to alternate protocol if the host is not using the default protocol. Default protocol is *https*.
- **port** Optionally set to alternate port if the host is not using the default port. Default port is *443*.
- **host_names** List of ESXi host names. When the host, username, and password credentials are provided for a vCenter Server, the host_names argument is required to tell vCenter which hosts to check if VMotion is enabled.

  If host_names is not provided, the VMotion status will be retrieved for the host location instead. This is useful for when service instance connection information is used for a single ESXi host.

**CLI Example:**

```bash
# Used for single ESXi host connection information
salt '*' vsphere.get_vmotion_enabled my.esxi.host root bad-password

# Used for connecting to a vCenter Server
salt '*' vsphere.get_vmotion_enabled my.vcenter.location root bad-password
  # host_names='[esxi-1.host.com, esxi-2.host.com]'
```
salt.modules.vsphere.get_vsan_eligible_disks(host, username, password, protocol=None, port=None, host_names=None)

Returns a list of VSAN-eligible disks for a given host or list of host_names.

- **host**: The location of the host.
- **username**: The username used to login to the host, such as `root`.
- **password**: The password used to login to the host.
- **protocol**: Optionally set to alternate protocol if the host is not using the default protocol. Default protocol is `https`.
- **port**: Optionally set to alternate port if the host is not using the default port. Default port is `443`.
- **host_names**: List of ESXi host names. When the host, username, and password credentials are provided for a vCenter Server, the `host_names` argument is required to tell vCenter which hosts to check if any VSAN-eligible disks are available.

If `host_names` is not provided, the VSAN-eligible disks will be retrieved for the `host` location instead. This is useful for when service instance connection information is used for a single ESXi host.

CLI Example:

```
# Used for single ESXi host connection information
salt '*' vsphere.get_vsan_eligible_disks my.esxi.host root bad-password
# Used for connecting to a vCenter Server
salt '*' vsphere.get_vsan_eligible_disks my.vcenter.location root bad-password
```

salt.modules.vsphere.get_vsan_enabled(host, username, password, protocol=None, port=None, host_names=None)

Get the VSAN enabled status for a given host or a list of host_names. Returns `True` if VSAN is enabled, `False` if it is not enabled, and `None` if a VSAN Host Config is unset, per host.

- **host**: The location of the host.
- **username**: The username used to login to the host, such as `root`.
- **password**: The password used to login to the host.
- **protocol**: Optionally set to alternate protocol if the host is not using the default protocol. Default protocol is `https`.
- **port**: Optionally set to alternate port if the host is not using the default port. Default port is `443`.
- **host_names**: List of ESXi host names. When the host, username, and password credentials are provided for a vCenter Server, the `host_names` argument is required to tell vCenter which hosts to check if VSAN enabled.

If `host_names` is not provided, the VSAN status will be retrieved for the `host` location instead. This is useful for when service instance connection information is used for a single ESXi host.

CLI Example:

```
# Used for single ESXi host connection information
salt '*' vsphere.get_vsan_enabled my.esxi.host root bad-password
# Used for connecting to a vCenter Server
salt '*' vsphere.get_vsan_enabled my.vcenter.location root bad-password
```
salt.modules.vsphere.list_clusters(host, username, password, protocol=None, port=None)
Returns a list of clusters for the specified host.

- **host**: The location of the host.
- **username**: The username used to login to the host, such as root.
- **password**: The password used to login to the host.
- **protocol**: Optionally set to alternate protocol if the host is not using the default protocol. Default protocol is https.
- **port**: Optionally set to alternate port if the host is not using the default port. Default port is 443.

```
salt '*' vsphere.list_clusters 1.2.3.4 root bad-password
```

salt.modules.vsphere.list_datacenters(host, username, password, protocol=None, port=None)
Returns a list of datacenters for the specified host.

- **host**: The location of the host.
- **username**: The username used to login to the host, such as root.
- **password**: The password used to login to the host.
- **protocol**: Optionally set to alternate protocol if the host is not using the default protocol. Default protocol is https.
- **port**: Optionally set to alternate port if the host is not using the default port. Default port is 443.

```
salt '*' vsphere.list_datacenters 1.2.3.4 root bad-password
```

salt.modules.vsphere.list_datastore_clusters(host, username, password, protocol=None, port=None)
Returns a list of datastore clusters for the specified host.

- **host**: The location of the host.
- **username**: The username used to login to the host, such as root.
- **password**: The password used to login to the host.
- **protocol**: Optionally set to alternate protocol if the host is not using the default protocol. Default protocol is https.
- **port**: Optionally set to alternate port if the host is not using the default port. Default port is 443.

```
salt '*' vsphere.list_datastore_clusters 1.2.3.4 root bad-password
```

salt.modules.vsphere.list_datastores(host, username, password, protocol=None, port=None)
Returns a list of datastores for the specified host.

- **host**: The location of the host.
- **username**: The username used to login to the host, such as root.
- **password**: The password used to login to the host.
- **protocol**: Optionally set to alternate protocol if the host is not using the default protocol. Default protocol is https.
- **port**: Optionally set to alternate port if the host is not using the default port. Default port is 443.

```
salt '*' vsphere.list_datastores 1.2.3.4 root bad-password
```
salt.modules.vsphere.list_dvs(host, username, password, protocol=None, port=None)

Returns a list of distributed virtual switches for the specified host.

host The location of the host.
username The username used to login to the host, such as root.
password The password used to login to the host.
protocol Optionally set to alternate protocol if the host is not using the default protocol. Default protocol is https.
port Optionally set to alternate port if the host is not using the default port. Default port is 443.

```
salt '*' vsphere.list_dvs 1.2.3.4 root bad-password
```

salt.modules.vsphere.list_folders(host, username, password, protocol=None, port=None)

Returns a list of folders for the specified host.

host The location of the host.
username The username used to login to the host, such as root.
password The password used to login to the host.
protocol Optionally set to alternate protocol if the host is not using the default protocol. Default protocol is https.
port Optionally set to alternate port if the host is not using the default port. Default port is 443.

```
salt '*' vsphere.list_folders 1.2.3.4 root bad-password
```

salt.modules.vsphere.list_hosts(host, username, password, protocol=None, port=None)

Returns a list of hosts for the specified VMware environment.

host The location of the host.
username The username used to login to the host, such as root.
password The password used to login to the host.
protocol Optionally set to alternate protocol if the host is not using the default protocol. Default protocol is https.
port Optionally set to alternate port if the host is not using the default port. Default port is 443.

```
salt '*' vsphere.list_hosts 1.2.3.4 root bad-password
```

salt.modules.vsphere.list_networks(host, username, password, protocol=None, port=None)

Returns a list of networks for the specified host.

host The location of the host.
username The username used to login to the host, such as root.
password The password used to login to the host.
protocol Optionally set to alternate protocol if the host is not using the default protocol. Default protocol is https.
port Optionally set to alternate port if the host is not using the default port. Default port is 443.

```
salt '*' vsphere.list_networks 1.2.3.4 root bad-password
```
salt.modules.vsphere.list_non_ssds(host, username, password, protocol=None, port=None, host_names=None)

Returns a list of Non-SSD disks for the given host or list of host_names.

**Note:** In the pyVmomi StorageSystem, ScsiDisks may, or may not have an ssd attribute. This attribute indicates if the ScsiDisk is SSD backed. As this option is optional, if a relevant disk in the StorageSystem does not have \[ \text{ssd} \text{ = true} \], it will end up in the non_ssds list here.

- **host** The location of the host.
- **username** The username used to login to the host, such as `root`.
- **password** The password used to login to the host.
- **protocol** Optionally set to alternate protocol if the host is not using the default protocol. Default protocol is `https`.
- **port** Optionally set to alternate port if the host is not using the default port. Default port is `443`.
- **host_names** List of ESXi host names. When the host, username, and password credentials are provided for a vCenter Server, the host_names argument is required to tell vCenter the hosts for which to retrieve Non-SSD disks.

If host_names is not provided, Non-SSD disks will be retrieved for the host location instead. This is useful for when service instance connection information is used for a single ESXi host.

**CLI Example:**

```bash
# Used for single ESXi host connection information
salt '*' vsphere.list_non_ssds my.esxi.host root bad-password

# Used for connecting to a vCenter Server
salt '*' vsphere.list_non_ssds my.vcenter.location root bad-password host_names='[esxi-1.host.com, esxi-2.host.com]'
```

salt.modules.vsphere.list_resourcepools(host, username, password, protocol=None, port=None)

Returns a list of resource pools for the specified host.

- **host** The location of the host.
- **username** The username used to login to the host, such as `root`.
- **password** The password used to login to the host.
- **protocol** Optionally set to alternate protocol if the host is not using the default protocol. Default protocol is `https`.
- **port** Optionally set to alternate port if the host is not using the default port. Default port is `443`.

```
salt '*' vsphere.list_resourcepools 1.2.3.4 root bad-password
```

salt.modules.vsphere.list_ssds(host, username, password, protocol=None, port=None, host_names=None)

Returns a list of SSDs for the given host or list of host_names.

- **host** The location of the host.
- **username** The username used to login to the host, such as `root`.
- **password** The password used to login to the host.
**protocol** Optionally set to alternate protocol if the host is not using the default protocol. Default protocol is **https**.

**port** Optionally set to alternate port if the host is not using the default port. Default port is **443**.

**host_names** List of ESXi host names. When the host, username, and password credentials are provided for a vCenter Server, the host_names argument is required to tell vCenter the hosts for which to retrieve SSDs.

If host_names is not provided, SSDs will be retrieved for the host location instead. This is useful for when service instance connection information is used for a single ESXi host.

**CLI Example:**

```bash
# Used for single ESXi host connection information
salt '*' vsphere.list_ssds my.esxi.host root bad-password

# Used for connecting to a vCenter Server
salt '*' vsphere.list_ssds my.vcenter.location root bad-password
host_names='[esxi-1.host.com, esxi-2.host.com]'
```

**salt.modules.vsphere.list_vapps**(host, username, password, protocol=None, port=None)
Returns a list of vApps for the the specified host.

- **host** The location of the host.
- **username** The username used to login to the host, such as root.
- **password** The password used to login to the host.
- **protocol** Optionally set to alternate protocol if the host is not using the default protocol. Default protocol is https.
- **port** Optionally set to alternate port if the host is not using the default port. Default port is 443.

```bash
salt '*' vsphere.list_vapps 1.2.3.4 root bad-password
```

**salt.modules.vsphere.list_vms**(host, username, password, protocol=None, port=None)
Returns a list of VMs for the the specified host.

- **host** The location of the host.
- **username** The username used to login to the host, such as root.
- **password** The password used to login to the host.
- **protocol** Optionally set to alternate protocol if the host is not using the default protocol. Default protocol is https.
- **port** Optionally set to alternate port if the host is not using the default port. Default port is 443.

```bash
salt '*' vsphere.list_vms 1.2.3.4 root bad-password
```

**salt.modules.vsphere.reset_syslog_config**(host, username, password, protocol=None, port=None, syslog_config=None, esxi_hosts=None)

Reset the syslog service to its default settings.

- **Valid syslog_config values** are logdir, loghost, logdir-unique, default-rotate, default-size, default-timeout, or all for all of these.
- **host** The location of the host.
- **username** The username used to login to the host, such as root.
**password**  The password used to login to the host.

**protocol**  Optionally set to alternate protocol if the host is not using the default protocol. Default protocol is https.

**port**  Optionally set to alternate port if the host is not using the default port. Default port is 443.

**syslog_config**  List of parameters to reset, provided as a comma-delimited string, or 'all' to reset all syslog configuration parameters. Required.

**esxi_hosts**  If host is a vCenter host, then use esxi_hosts to execute this function on a list of one or more ESXi machines.

**Returns**  Dictionary with a top-level key of 'success' which indicates if all the parameters were reset, and individual keys for each parameter indicating which succeeded or failed, per host.

**CLI Example:**

```
# Used for ESXi host connection information
salt '*' vsphere.reset_syslog_config my.esxi.host root bad-password
    → syslog_config='logdir,loghost'

# Used for connecting to a vCenter Server
salt '*' vsphere.reset_syslog_config my.vcenter.location root bad-password
    → syslog_config='logdir,loghost' esxi_hosts='[esxi-1.host.com, esxi-2.host.com]'
```

salt.modules.vsphere.service_restart(host, username, password, service_name, protocol=None, port=None, host_names=None)

Restart the named service for the given host or list of hosts.

**host**  The location of the host.

**username**  The username used to login to the host, such as root.

**password**  The password used to login to the host.

**service_name**

The name of the service for which to set the policy. Supported service names are:

- DCUI
- TSM
- SSH
- lbtd
- lsassd
- lwiod
- netlogond
- ntpd
- sfcbd-watchdog
- snmpd
- vprobed
- vpxa
• xorg

**protocol**  Optionally set to alternate protocol if the host is not using the default protocol. Default protocol is https.

**port**  Optionally set to alternate port if the host is not using the default port. Default port is 443.

**host_names**  List of ESXi host names. When the host, username, and password credentials are provided for a vCenter Server, the host_names argument is required to tell vCenter the hosts for which to restart the service.

If host_names is not provided, the service will be restarted for the host location instead. This is useful for when service instance connection information is used for a single ESXi host.

CLI Example:

```bash
# Used for single ESXi host connection information
salt '*' vsphere.service_restart my.esxi.host root bad-password 'ntpd'

# Used for connecting to a vCenter Server
salt '*' vsphere.service_restart my.vcenter.location root bad-password 'ntpd' # host_names='[esxi-1.host.com, esxi-2.host.com]'
```

**salt.modules.vsphere.service_start**

Start the named service for the given host or list of hosts.

**host**  The location of the host.

**username**  The username used to login to the host, such as root.

**password**  The password used to login to the host.

**service_name**

The name of the service for which to set the policy. Supported service names are:

• DCUI
• TSM
• SSH
• lbtd
• lsassd
• lwiod
• netlogond
• ntpd
• sfcbd-watchdog
• snmpd
• vprobed
• vpxa
• xorg

**protocol**  Optionally set to alternate protocol if the host is not using the default protocol. Default protocol is https.

**port**  Optionally set to alternate port if the host is not using the default port. Default port is 443.
**host_names** List of ESXi host names. When the host, username, and password credentials are provided for a vCenter Server, the host_names argument is required to tell vCenter the hosts for which to start the service.

If host_names is not provided, the service will be started for the host location instead. This is useful for when service instance connection information is used for a single ESXi host.

**CLI Example:**

```bash
# Used for single ESXi host connection information
salt '*' vsphere.service_start my.esxi.host root bad-password 'ntpd'

# Used for connecting to a vCenter Server
salt '*' vsphere.service_start my.vcenter.location root bad-password 'ntpd' → host_names=[esxi-1.host.com, esxi-2.host.com]
```

salt.modules.vsphere.service_stop(host, username, password, service_name, protocol=None, port=None, host_names=None)

Stop the named service for the given host or list of hosts.

- **host** The location of the host.
- **username** The username used to login to the host, such as root.
- **password** The password used to login to the host.
- **service_name**
  The name of the service for which to set the policy. Supported service names are:
  - DCUI
  - TSM
  - SSH
  - lbtd
  - lsassd
  - lwiod
  - netlogond
  - ntpd
  - sfcbd-watchdog
  - snmpd
  - vprobed
  - vpxa
  - xorg

- **protocol** Optionally set to alternate protocol if the host is not using the default protocol. Default protocol is https.

- **port** Optionally set to alternate port if the host is not using the default port. Default port is 443.

**host_names** List of ESXi host names. When the host, username, and password credentials are provided for a vCenter Server, the host_names argument is required to tell vCenter the hosts for which to stop the service.

If host_names is not provided, the service will be stopped for the host location instead. This is useful for when service instance connection information is used for a single ESXi host.
CLI Example:

```bash
# Used for single ESXi host connection information
salt '*' vsphere.service_stop my.esxi.host root bad-password 'ssh'

# Used for connecting to a vCenter Server
salt '*' vsphere.service_stop my.vcenter.location root bad-password 'ssh'
```

salt.modules.vsphere.set_coredump_network_config(host, username, password, dump_ip, protocol=None, port=None, host_vnic='vmk0', dump_port=6500, esxi_hosts=None)

Set the network parameters for a network coredump collection. Note that ESXi requires that the dumps first be enabled (see coredump_network_enable) before these parameters may be set.

- **host** The location of the host.
- **username** The username used to login to the host, such as `root`.
- **password** The password used to login to the host.
- **dump_ip** IP address of host that will accept the dump.
- **protocol** Optionally set to alternate protocol if the host is not using the default protocol. Default protocol is `https`.
- **port** Optionally set to alternate port if the host is not using the default port. Default port is `443`.
- **esxi_hosts** If `host` is a vCenter host, then use `esxi_hosts` to execute this function on a list of one or more ESXi machines.
- **host_vnic** Host VNic port through which to communicate. Defaults to `vmk0`.
- **dump_port** TCP port to use for the dump, defaults to `6500`.

**Returns** A standard cmd.run_all dictionary with a `success` key added, per host. `success` will be True if the set succeeded, False otherwise.

CLI Example:

```bash
# Used for ESXi host connection information
salt '*' vsphere.set_coredump_network_config my.esxi.host root bad-password 'dump_ip.host.com'

# Used for connecting to a vCenter Server
salt '*' vsphere.set_coredump_network_config my.vcenter.location root bad-password 'dump_ip.host.com'
```

salt.modules.vsphere.set_ntp_config(host, username, password, ntp_servers, protocol=None, port=None, host_names=None)

Set NTP configuration for a given host of list of host_names.

- **host** The location of the host.
- **username** The username used to login to the host, such as `root`.
- **password** The password used to login to the host.
- **ntp_servers** A list of servers that should be added to and configured for the specified host's NTP configuration.
- **protocol** Optionally set to alternate protocol if the host is not using the default protocol. Default protocol is `https`.
**port** Optionally set to alternate port if the host is not using the default port. Default port is 443.

**host_names** List of ESXi host names. When the host, username, and password credentials are provided for a vCenter Server, the host_names argument is required to tell vCenter which hosts to configure ntp servers.

If host_names is not provided, the NTP servers will be configured for the host location instead. This is useful for when service instance connection information is used for a single ESXi host.

**CLI Example:**

```
# Used for single ESXi host connection information
salt '*' vsphere.ntp_configure my.esxi.host root bad-password '[192.174.1.100, 192.174.1.200]'

# Used for connecting to a vCenter Server
salt '*' vsphere.ntp_configure my.vcenter.location root bad-password '[192.174.1.100, 192.174.1.200]' host_names='[esxi-1.host.com, esxi-2.host.com]'
```

**salt.modules.vsphere.set_service_policy**

Set the service name’s policy for a given host or list of hosts.

- **host** The location of the host.
- **username** The username used to login to the host, such as `root`.
- **password** The password used to login to the host.
- **service_name** The name of the service for which to set the policy. Supported service names are:
  - DCUI
  - TSM
  - SSH
  - lbtd
  - lsassd
  - lwiod
  - netlogond
  - ntpd
  - sfcbd-watchdog
  - snmpd
  - vprobed
  - vpxa
  - xorg
- **service_policy** The policy to set for the service. For example, ‘automatic’.
- **protocol** Optionally set to alternate protocol if the host is not using the default protocol. Default protocol is `https`.
- **port** Optionally set to alternate port if the host is not using the default port. Default port is 443.
host_names  List of ESXi host names. When the host, username, and password credentials are provided for a vCenter Server, the host_names argument is required to tell vCenter the hosts for which to set the service policy.

If host_names is not provided, the service policy information will be retrieved for the host location instead. This is useful for when service instance connection information is used for a single ESXi host.

CLI Example:

```bash
# Used for single ESXi host connection information
salt '*' vsphere.set_service_policy my.esxi.host root bad-password 'ntpd' →'automatic'

# Used for connecting to a vCenter Server
salt '*' vsphere.set_service_policy my.vcenter.location root bad-password 'ntpd' →'automatic' host_names='[esxi-1.host.com, esxi-2.host.com]'
```

salt.modules.vsphere.set_syslog_config(host, username, password, syslog_config, config_value, protocol=None, port=None, firewall=True, reset_service=True, esxi_hosts=None)

Set the specified syslog configuration parameter. By default, this function will reset the syslog service after the configuration is set.

host  ESXi or vCenter host to connect to.

username  User to connect as, usually root.

password  Password to connect with.

d SOLD_CONFIG  Name of parameter to set (corresponds to the command line switch for esxcli without the double dashes (\=~))

Valid syslog_config values are logdir, loghost, default-rotate\, \~ default-size, default-timeout, and logdir-unique.

config_value  Value for the above parameter. For loghost, URLs or IP addresses to use for logging. Multiple log servers can be specified by listing them, comma-separated, but without spaces before or after commas.

protocol  Optionally set to alternate protocol if the host is not using the default protocol. Default protocol is https.

port  Optionally set to alternate port if the host is not using the default port. Default port is 443.

firewall  Enable the firewall rule set for syslog. Defaults to True.

reset_service  After a successful parameter set, reset the service. Defaults to True.

esxi_hosts  If host is a vCenter host, then use esxi_hosts to execute this function on a list of one or more ESXi machines.

Returns Dictionary with a top-level key of `success' which indicates if all the parameters were reset, and individual keys for each parameter indicating which succeeded or failed, per host.

CLI Example:

```bash
# Used for ESXi host connection information
salt '*' vsphere.set_syslog_config my.esxi.host root bad-password
 → loghost ssl://localhost:5432,tcp://10.1.0.1:1514
```

32.17. Full list of builtin execution modules 1499
# Used for connecting to a vCenter Server
salt '*' vsphere.set_syslog_config my.vcenter.location root bad-password
   → loghost ssl://localhost:5432,tcp://10.1.0.1:1514
   → '[esxi-1.host.com, esxi-2.host.com]'

salt.modules.vsphere.syslog_service_reload(host, username, password, protocol=None, port=None, esxi_hosts=None)

Reload the syslog service so it will pick up any changes.

host  The location of the host.
username  The username used to login to the host, such as root.
password  The password used to login to the host.
protocol  Optionally set to alternate protocol if the host is not using the default protocol. Default protocol is https.
port  Optionally set to alternate port if the host is not using the default port. Default port is 443.
esxi_hosts  If host is a vCenter host, then use esxi_hosts to execute this function on a list of one or more ESXi machines.

Returns  A standard cmd.run_all dictionary. This dictionary will at least have a retcode key. If retcode is 0 the command was successful.

CLI Example:

```
# Used for ESXi host connection information
salt '*' vsphere.syslog_service_reload my.esxi.host root bad-password

# Used for connecting to a vCenter Server
salt '*' vsphere.set_syslog_config my.vcenter.location root bad-password
   → loghost ssl://localhost:5432,tcp://10.1.0.1:1514
   → '[esxi-1.host.com, esxi-2.host.com]'
```

salt.modules.vsphere.system_info(host, username, password, protocol=None, port=None)

Return system information about a VMware environment.

host  The location of the host.
username  The username used to login to the host, such as root.
password  The password used to login to the host.
protocol  Optionally set to alternate protocol if the host is not using the default protocol. Default protocol is https.
port  Optionally set to alternate port if the host is not using the default port. Default port is 443.

CLI Example:

```
salt '*' vsphere.system_info 1.2.3.4 root bad-password
```

salt.modules.vsphere.update_host_datetime(host, username, password, protocol=None, port=None, host_names=None)

Update the date/time on the given host or list of host_names. This function should be used with caution since network delays and execution delays can result in time skews.

host  The location of the host.
username  The username used to login to the host, such as root.
password  The password used to login to the host.

protocol  Optionally set to alternate protocol if the host is not using the default protocol. Default protocol is https.

port  Optionally set to alternate port if the host is not using the default port. Default port is 443.

host_names  List of ESXi host names. When the host, username, and password credentials are provided for a vCenter Server, the host_names argument is required to tell vCenter which hosts should update their date/time.

If host_names is not provided, the date/time will be updated for the host location instead. This is useful for when service instance connection information is used for a single ESXi host.

CLI Example:

```bash
# Used for single ESXi host connection information
salt '*' vsphere.update_date_time my.esxi.host root bad-password

# Used for connecting to a vCenter Server
salt '*' vsphere.update_date_time my.vcenter.location root bad-password
  ←host_names='[esxi-1.host.com, esxi-2.host.com]'
```

salt.modules.vsphere.update_host_password  (host, username, password, new_password, protocol=None, port=None)

Update the password for a given host.

**Note:** Currently only works with connections to ESXi hosts. Does not work with vCenter servers.

**host**  The location of the ESXi host.

**username**  The username used to connect to the ESXi host, such as root.

**password**  The password used to login to the ESXi host.

**new_password**  The new password that will be updated for the provided username on the ESXi host.

**protocol**  Optionally set to alternate protocol if the host is not using the default protocol. Default protocol is https.

**port**  Optionally set to alternate port if the host is not using the default port. Default port is 443.

CLI Example:

```bash
salt '*' vsphere.update_host_password my.esxi.host root original-bad-password new-bad-password
```

salt.modules.vsphere.upload_ssh_key  (host, username, password, ssh_key=None, ssh_key_file=None, protocol=None, port=None, certificate_verify=False)

Upload an ssh key for root to an ESXi host via http PUT. This function only works for ESXi, not vCenter. Only one ssh key can be uploaded for root. Uploading a second key will replace any existing key.

**Parameters**

- **host** -- The location of the ESXi Host
- **username** -- Username to connect as
- **password** -- Password for the ESXi web endpoint
- **ssh_key** -- Public SSH key, will be added to authorized_keys on ESXi
- **ssh_key_file** -- File containing the SSH key. Use `ssh_key` or ssh_key_file, but not both.
- **protocol** -- defaults to https, can be http if ssl is disabled on ESXi
- **port** -- defaults to 443 for https
- **certificate_verify** -- If true require that the SSL connection present a valid certificate

**Returns** Dictionary with a `status` key, True if upload is successful. If upload is unsuccessful, `status` key will be False and an `Error` key will have an informative message.

CLI Example:

```
salt '*' vsphere.upload_ssh_key my.esxi.host root bad-password ssh_key_file='/etc/salt/my_keys/my_key.pub'
```

```python
salt.modules.vsphere.vmotion_disable
(host, username, password, protocol=protocol=None, port=None, host_names=None)
```

Enable vMotion for a given host or list of host_names.

- **host** The location of the host.
- **username** The username used to login to the host, such as root.
- **password** The password used to login to the host.
- **protocol** Optionally set to alternate protocol if the host is not using the default protocol. Default protocol is https.
- **port** Optionally set to alternate port if the host is not using the default port. Default port is 443.
- **host_names** List of ESXi host names. When the host, username, and password credentials are provided for a vCenter Server, the host_names argument is required to tell vCenter which hosts should disable VMotion.

If host_names is not provided, VMotion will be disabled for the host location instead. This is useful for when service instance connection information is used for a single ESXi host.

CLI Example:

```
# Used for single ESXi host connection information
salt '*' vsphere.vmotion_disable my.esxi.host root bad-password

# Used for connecting to a vCenter Server
salt '*' vsphere.vmotion_disable my.vcenter.location root bad-password

```

```
```

```python
salt.modules.vsphere.vmotion_enable
(host, username, password, protocol=protocol=None, port=None, host_names=None, device='vmk0')
```

Enable vMotion for a given host or list of host_names.

- **host** The location of the host.
- **username** The username used to login to the host, such as root.
- **password** The password used to login to the host.
- **protocol** Optionally set to alternate protocol if the host is not using the default protocol. Default protocol is https.
- **port** Optionally set to alternate port if the host is not using the default port. Default port is 443.
**host_names** List of ESXi host names. When the host, username, and password credentials are provided for a vCenter Server, the host_names argument is required to tell vCenter which hosts should enable VMotion.

If host_names is not provided, VMotion will be enabled for the host location instead. This is useful for when service instance connection information is used for a single ESXi host.

**device** The device that uniquely identifies the VirtualNic that will be used for VMotion for each host. Defaults to vmk0.

CLI Example:

```
# Used for single ESXi host connection information
salt '*' vsphere.vmotion_enable my.esxi.host root bad-password

# Used for connecting to a vCenter Server
salt '*' vsphere.vmotion_enable my.vcenter.location root bad-password host_names='[esxi-1.host.com, esxi-2.host.com]'
```

salt.modules.vsphere.vsan_add_disks(host, username, password, protocol=None, port=None, host_names=None)

Add any VSAN-eligible disks to the VSAN System for the given host or list of host_names.

**host** The location of the host.

**username** The username used to login to the host, such as root.

**password** The password used to login to the host.

**protocol** Optionally set to alternate protocol if the host is not using the default protocol. Default protocol is https.

**port** Optionally set to alternate port if the host is not using the default port. Default port is 443.

**host_names** List of ESXi host names. When the host, username, and password credentials are provided for a vCenter Server, the host_names argument is required to tell vCenter which hosts need to add any VSAN-eligible disks to the host's VSAN system.

If host_names is not provided, VSAN-eligible disks will be added to the host's VSAN system for the host location instead. This is useful for when service instance connection information is used for a single ESXi host.

CLI Example:

```
# Used for single ESXi host connection information
salt '*' vsphere.vsan_add_disks my.esxi.host root bad-password

# Used for connecting to a vCenter Server
salt '*' vsphere.vsan_add_disks my.vcenter.location root bad-password host_names='[esxi-1.host.com, esxi-2.host.com]'
```

salt.modules.vsphere.vsan_disable(host, username, password, protocol=None, port=None, host_names=None)

Disable VSAN for a given host or list of host_names.

**host** The location of the host.

**username** The username used to login to the host, such as root.

**password** The password used to login to the host.

**protocol** Optionally set to alternate protocol if the host is not using the default protocol. Default protocol is https.

**port** Optionally set to alternate port if the host is not using the default port. Default port is 443.
**host_names** List of ESXi host names. When the host, username, and password credentials are provided for a vCenter Server, the host_names argument is required to tell vCenter which hosts should disable VSAN.

If host_names is not provided, VSAN will be disabled for the host location instead. This is useful for when service instance connection information is used for a single ESXi host.

CLI Example:

```bash
# Used for single ESXi host connection information
salt '*' vsphere.vsan_disable my.esxi.host root bad-password

# Used for connecting to a vCenter Server
salt '*' vsphere.vsan_disable my.vcenter.location root bad-password --names='[esxi-1.host.com, esxi-2.host.com]'
```

salt.modules.vsphere.vsan_enable(**host**, **username**, **password**, **protocol=None**, **port=None**, **host_names=None**)

Enable VSAN for a given host or list of host_names.

**host** The location of the host.

**username** The username used to login to the host, such as root.

**password** The password used to login to the host.

**protocol** Optionally set to alternate protocol if the host is not using the default protocol. Default protocol is https.

**port** Optionally set to alternate port if the host is not using the default port. Default port is 443.

**host_names** List of ESXi host names. When the host, username, and password credentials are provided for a vCenter Server, the host_names argument is required to tell vCenter which hosts should enable VSAN.

If host_names is not provided, VSAN will be enabled for the host location instead. This is useful for when service instance connection information is used for a single ESXi host.

CLI Example:

```bash
# Used for single ESXi host connection information
salt '*' vsphere.vsan_enable my.esxi.host root bad-password

# Used for connecting to a vCenter Server
salt '*' vsphere.vsan_enable my.vcenter.location root bad-password --names='[esxi-1.host.com, esxi-2.host.com]'
```

32.17.297 salt.modules.win_autoruns

Module for listing programs that automatically run on startup (very alpha...not tested on anything but my Win 7x64)

salt.modules.win_autoruns.list()

Get a list of automatically running programs

CLI Example:

```bash
salt '*' autoruns.list
```
### 32.17.298 salt.modules.win_dacl

Manage DACLs on Windows

```python
depends

- winreg Python module

salt.modules.win_dacl.add_ace(path, objectType, user, permission, acetype, propagation)

add an ace to an object

path: path to the object (i.e. c:\temp\file, HKEY_LOCAL_MACHINE\SOFTWARE\KEY, etc) user: user to add permission: permissions for the user acetype: either allow/deny for each user/permission (ALLOW, DENY) propagation: how the ACE applies to children for Registry Keys and Directories (KEY, KEY&SUBKEYS, SUBKEYS)

CLI Example:

```python
allow domain\fakeuser full control on HKLM\SOFTWARE\somekey, propagate to this key and subkeys
salt 'myminion' win_dacl.add_ace 'HKEY_LOCAL_MACHINE\SOFTWARE\somekey' 'Registry' 'domain\fakeuser' 'FULLCONTROL' 'ALLOW' 'KEY&SUBKEYS'
```

salt.modules.win_dacl.check_ace(path, objectType, user=None, permission=None, acetype=None, propagation=None, exactPermissionMatch=False)

checks a path to verify the ACE (access control entry) specified exists returns `Exists' true if the ACE exists, false if it does not

path: path to the file/reg key user: user that the ACL is for permission: permission to test for (READ, FULLCONTROL, etc) acetype: the type of ACE (ALLOW or DENY) propagation: the propagation type of the ACE (FILES, FOLDERS, KEY, KEY&SUBKEYS, SUBKEYS, etc) exactPermissionMatch: the ACL must match exactly, IE if READ is specified, the user must have READ exactly and not FULLCONTROL (which also has the READ permission obviously)

salt.modules.win_dacl.check_inheritance(path, objectType, user=None)

check a specified path to verify if inheritance is enabled returns `Inheritance' of True/False

path: path of the registry key or file system object to check user: if provided, will consider only the ACEs for that user

class salt.modules.win_dacl.daclConstants
dacl constants used throughout the module

```python
getAceTypeBit(t)
returns the acetype bit of a text value

getAddressText(t)
returns the textual representation of a acetype bit

ggetObjectTypeBit(t)
returns the bit value of the string object type

getPermissionBit(t, m)
returns a permission bit of the string permission value for the specified object type

getAddressText(t, m)
returns the permission textual representation of a specified permission bit/object type

getPropagationBit(t, p)
returns the propagation bit of a text value

getAddressText(t, p)
returns the textual representation of a propagation bit
```
**getSecurityHkey**

returns the necessary string value for an HKEY for the win32security module

**processPath** *(path, objectType)*

processes a path/object type combo and returns: registry types with the correct HKEY text representation files/directories with environment variables expanded

**salt.modules.win_dacl.disable_inheritance** *(path, objectType, copy=True)*

disable inheritance on an object

copy = True will copy the Inherited ACEs to the DACL before disabling inheritance

**salt.modules.win_dacl.enable_inheritance** *(path, objectType, clear=False)*

enable/disable inheritance on an object

clear = True will remove non-Inherited ACEs from the ACL

**salt.modules.win_dacl.get** *(path, objectType, user=None)*

Get the acl of an object. Will filter by user if one is provided.

**salt.modules.win_dacl.rm_ace** *(path, objectType, user, permission=None, acetype=None, propagation=None)*

remove an ace to an object

path: path to the object (i.e. c:\temp\file, HKEY_LOCAL_MACHINE\SOFTWARE\KEY, etc) user: user to remove permission: permissions for the user acetypes: either allow/deny for each user/permission (ALLOW, DENY) propagation: how the ACE applies to children for Registry Keys and Directories(KEY, KEY&SUBKEYS, SUBKEYS)

If any of the optional parameters are omitted (or set to None) they act as wildcards.

**CLI Example:**

```
remove allow domain\fakeuser full control on HKLM\SOFTWARE\somekey propagated to this key and subkeys
salt 'myminion' win_dacl.rm_ace 'Registry' 'HKEY_LOCAL_MACHINE\SOFTWARE\somekey' 'domain\fakeuser' 'FULLCONTROL' 'ALLOW' 'KEY&SUBKEYS'
```

32.17.299 **salt.modules.win_disk**

Module for gathering disk information on Windows

depends

- win32api Python module

**salt.modules.win_disk.usage()**

Return usage information for volumes mounted on this minion

**CLI Example:**

```
salt '*' disk.usage
```

32.17.300 **salt.modules.win_dns_client**

Module for configuring DNS Client on Windows systems
salt.modules.win_dns_client.add_dns(ip, interface='Local Area Connection', index=1)
Add the DNS server to the network interface (index starts from 1)

Note: if the interface DNS is configured by DHCP, all the DNS servers will be removed from the interface and the requested DNS will be the only one

CLI Example:
```
salt '*' win_dns_client.add_dns <ip> <interface> <index>
```

salt.modules.win_dns_client.dns_dhcp(interface='Local Area Connection')
Configure the interface to get its DNS servers from the DHCP server

CLI Example:
```
salt '*' win_dns_client.dns_dhcp <interface>
```

salt.modules.win_dns_client.get_dns_config(interface='Local Area Connection')
Get the type of DNS configuration (dhcp / static)

CLI Example:
```
salt '*' win_dns_client.get_dns_config 'Local Area Connection'
```

salt.modules.win_dns_client.get_dns_servers(interface='Local Area Connection')
Return a list of the configured DNS servers of the specified interface

CLI Example:
```
salt '*' win_dns_client.get_dns_servers 'Local Area Connection'
```

salt.modules.win_dns_client.rm_dns(ip, interface='Local Area Connection')
Remove the DNS server from the network interface

CLI Example:
```
salt '*' win_dns_client.rm_dns <ip> <interface>
```

32.17.301 salt.modules.win_file
Manage information about files on the minion, set/read user, group data

    depends
    - win32api
    - win32file
    - win32security

salt.modules.win_file.chgrp(path, group)
Change the group of a file

Under Windows, this will do nothing.

While a file in Windows does have a `primary group', this rarely used attribute generally has no bearing on permissions unless intentionally configured and is only used to support Unix compatibility features (e.g. Services For Unix, NFS services).
Salt, therefore, remaps this function to do nothing while still being compatible with Unix behavior. When managing Windows systems, this function is superfluous and will generate an info level log entry if used directly.

If you do actually want to set the `primary group' of a file, use `file.chpgrp`.

CLI Example:
```bash
salt '*' file.chpgrp c:\temp\test.txt administrators
```

**salt.modules.win_file.chown**(path, user, group=None, pgroup=None, follow_symlinks=True)

Chown a file, pass the file the desired user and group.

Under Windows, the group parameter will be ignored.

This is because while files in Windows do have a `primary group' property, this is rarely used. It generally has no bearing on permissions unless intentionally configured and is most commonly used to provide Unix compatibility (e.g. Services For Unix, NFS services).

If you do want to change the `primary group' property and understand the implications, pass the Windows only parameter, pgroup, instead.

To set the primary group to `None', it must be specified in quotes. Otherwise Salt will interpret it as the Python value of None and no primary group changes will occur. See the example below.

CLI Example:
```bash
salt '*' file.chown c:\temp\test.txt myusername
salt '*' file.chown c:\temp\test.txt myusername pgroup=Administrators
salt '*' file.chown c:\temp\test.txt myusername "pgroup='None'"
```

**salt.modules.win_file.chpgrp**(path, group)

Change the group of a file

Under Windows, this will set the rarely used primary group of a file. This generally has no bearing on permissions unless intentionally configured and is most commonly used to provide Unix compatibility (e.g. Services For Unix, NFS services).

Ensure you know what you are doing before using this function.

To set the primary group to `None', it must be specified in quotes. Otherwise Salt will interpret it as the Python value of None and no primary group changes will occur. See the example below.

CLI Example:
```bash
salt '*' file.chpgrp c:\temp\test.txt Administrators
salt '*' file.chpgrp c:\temp\test.txt "'None'"
```

**salt.modules.win_file.get_attributes**(path)

Return a dictionary object with the Windows file attributes for a file.

CLI Example:
```bash
salt '*' file.get_attributes c:\temp\a.txt
```

**salt.modules.win_file.get_gid**(path, follow_symlinks=True)

Return the id of the group that owns a given file

Under Windows, this will return the uid of the file.

While a file in Windows does have a `primary group', this rarely used attribute generally has no bearing on permissions unless intentionally configured and is only used to support Unix compatibility features (e.g. Services For Unix, NFS services).
Salt, therefore, remaps this function to provide functionality that somewhat resembles Unix behavior for API compatibility reasons. When managing Windows systems, this function is superfluous and will generate an info level log entry if used directly.

If you do actually want to access the `primary group' of a file, use `file.get_pgid'.

CLI Example:

```bash
salt '*' file.get_gid c:\temp\test.txt
```

**salt.modules.win_file.get_group**(path, follow_symlinks=True)

Return the group that owns a given file

Under Windows, this will return the user (owner) of the file.

While a file in Windows does have a `primary group', this rarely used attribute generally has no bearing on permissions unless intentionally configured and is only used to support Unix compatibility features (e.g. Services For Unix, NFS services).

Salt, therefore, remaps this function to provide functionality that somewhat resembles Unix behavior for API compatibility reasons. When managing Windows systems, this function is superfluous and will generate an info level log entry if used directly.

If you do actually want to access the `primary group' of a file, use `file.get_pgroup'.

CLI Example:

```bash
salt '*' file.get_group c:\temp\test.txt
```

**salt.modules.win_file.get_mode**(path)

Return the mode of a file

Right now we're just returning None because Windows' doesn't have a mode like Linux

CLI Example:

```bash
salt '*' file.get_mode /etc/passwd
```

**salt.modules.win_file.get_pgid**(path, follow_symlinks=True)

Return the id of the primary group that owns a given file (Windows only)

This function will return the rarely used primary group of a file. This generally has no bearing on permissions unless intentionally configured and is most commonly used to provide Unix compatibility (e.g. Services For Unix, NFS services).

Ensure you know what you are doing before using this function.

CLI Example:

```bash
salt '*' file.get_pgid c:\temp\test.txt
```

**salt.modules.win_file.get_pgroup**(path, follow_symlinks=True)

Return the name of the primary group that owns a given file (Windows only)

This function will return the rarely used primary group of a file. This generally has no bearing on permissions unless intentionally configured and is most commonly used to provide Unix compatibility (e.g. Services For Unix, NFS services).

Ensure you know what you are doing before using this function.

The return value may be `None', e.g. if the user is not on a domain. This is a valid group - do not confuse this with the Salt/Python value of None which means no value was returned. To be certain, use the `get_pgid' function which will return the SID, including for the system `None' group.
CLI Example:
```
salt '*' file.get_pgroup c:\temp\test.txt
```

salt.modules.win_file.get_uid(path, follow_symlinks=True)

Return the id of the user that owns a given file

Symlinks are followed by default to mimic Unix behavior. Specify `follow_symlinks=False` to turn off this behavior.

CLI Example:
```
salt '*' file.get_uid c:\temp\test.txt
salt '*' file.get_uid c:\temp\test.txt follow_symlinks=False
```

salt.modules.win_file.get_user(path, follow_symlinks=True)

Return the user that owns a given file

Symlinks are followed by default to mimic Unix behavior. Specify `follow_symlinks=False` to turn off this behavior.

CLI Example:
```
salt '*' file.get_user c:\temp\test.txt
salt '*' file.get_user c:\temp\test.txt follow_symlinks=False
```

salt.modules.win_file.gid_to_group(gid)

Convert the group id to the group name on this system

Under Windows, because groups are just another ACL entity, this function behaves the same as `uid_to_user`.

For maintaining Windows systems, this function is superfluous and only exists for API compatibility with Unix. Use the `uid_to_user` function instead; an info level log entry will be generated if this function is used directly.

CLI Example:
```
salt '*' file.gid_to_group S-1-5-21-626487655-2533044672-482107328-1010
```

salt.modules.win_file.group_to_gid(group)

Convert the group to the gid on this system

Under Windows, because groups are just another ACL entity, this function behaves the same as `user_to_uid`, except if None is given, '' is returned.

For maintaining Windows systems, this function is superfluous and only exists for API compatibility with Unix. Use the `user_to_uid` function instead; an info level log entry will be generated if this function is used directly.

CLI Example:
```
salt '*' file.group_to_gid administrators
```

salt.modules.win_file.is_link(path)

Return the path that a symlink points to

This is only supported on Windows Vista or later.

Inline with Unix behavior, this function will raise an error if the path is not a symlink, however, the error raised will be a SaltInvocationError, not an OSError.

CLI Example:
salt.modules.win_file.lchown(*path*, *user*, *group=None*, *pgroup=None*)

Chown a file, pass the file the desired user and group without following any symlinks.

Under Windows, the group parameter will be ignored.

This is because while files in Windows do have a ‘primary group’ property, this is rarely used. It generally has no bearing on permissions unless intentionally configured and is most commonly used to provide Unix compatibility (e.g. Services For Unix, NFS services).

If you do want to change the ‘primary group’ property and understand the implications, pass the Windows only parameter, pgroup, instead.

To set the primary group to ‘None’, it must be specified in quotes. Otherwise Salt will interpret it as the Python value of None and no primary group changes will occur. See the example below.

CLI Example:

```
salt '*' file.lchown c:\temp\test.txt myusername
salt '*' file.lchown c:\temp\test.txt myusername pgroup=Administrators
salt '*' file.lchown c:\temp\test.txt myusername "pgroup='None'"
```

salt.modules.win_file.readlink(*path*)

Return the path that a symlink points to.

This is only supported on Windows Vista or later.

Inline with Unix behavior, this function will raise an error if the path is not a symlink, however, the error raised will be a SaltInvocationError, not an OSError.

CLI Example:

```
salt '*' file.readlink /path/to/link
```

salt.modules.win_file.remove(*path*, *force=False*)

Remove the named file or directory.

Parameters

- *path* (str) -- The path to the file or directory to remove.
- *force* (bool) -- Remove even if marked Read-Only

Returns True if successful, False if unsuccessful

Return type bool

CLI Example:

```
salt '*' file.remove C:\Temp
```

salt.modules.win_file.set_attributes(*path*, *archive=None*, *hidden=None*, *normal=None*, *notIndexed=None*, *readonly=None*, *system=None*, *temporary=None*)

Set file attributes for a file. Note that the normal attribute means that all others are false. So setting it will clear all others.

CLI Example:

```
salt '*' file.set_attributes c:\temp\a.txt normal=True
salt '*' file.set_attributes c:\temp\a.txt readonly=True hidden=True
```
salt.modules.win_file.set_mode(path, mode)
Set the mode of a file

This just calls get_mode, which returns None because we don’t use mode on Windows

CLI Example:

```
salt '*' file.set_mode /etc/passwd 0644
```

salt.modules.win_file.stats(path, hash_type='sha256', follow_symlinks=True)
Return a dict containing the stats for a given file

Under Windows, gid will equal uid and group will equal user.

While a file in Windows does have a ‘primary group’, this rarely used attribute generally has no bearing
on permissions unless intentionally configured and is only used to support Unix compatibility features (e.g.
Services For Unix, NFS services).

Salt, therefore, remaps these properties to keep some kind of compatibility with Unix behavior. If the ‘primary
group’ is required, it can be accessed in the pgroup and pgid properties.

CLI Example:

```
salt '*' file.stats /etc/passwd
```

salt.modules.win_file.symlink(src, link)
Create a symbolic link to a file

This is only supported with Windows Vista or later and must be executed by a user with the SeCreateSymbol-
icLink privilege.

The behavior of this function matches the Unix equivalent, with one exception - invalid symlinks cannot be
created. The source path must exist. If it doesn’t, an error will be raised.

CLI Example:

```
salt '*' file.symlink /path/to/file /path/to/link
```

salt.modules.win_file.uid_to_user(uid)
Convert a uid to a user name

CLI Example:

```
salt '*' file.uid_to_user S-1-5-21-626487655-2533044672-482107328-1010
```

salt.modules.win_file.user_to_uid(user)
Convert user name to a uid

CLI Example:

```
salt '*' file.user_to_uid myusername
```

32.17.302 salt.modules.win_firewall
Module for configuring Windows Firewall

salt.modules.win_firewall.add_rule(name, localport, protocol='tcp', action='allow', dir='in')
New in version 2015.5.0.

Add a new firewall rule
**CLI Example:**
```python
salt '*' firewall.add_rule 'test' '8080' 'tcp'
```

```python
salt.modules.win_firewall.delete_rule(name, localport, protocol='tcp', dir='in')
```

New in version 2015.8.0.
Delete an existing firewall rule

**CLI Example:**
```python
salt '*' firewall.delete_rule 'test' '8080' 'tcp' 'in'
```

```python
salt.modules.win_firewall.disable(profile='allprofiles')
```

Disable firewall profile

**CLI Example:**
```python
salt '*' firewall.disable
```

```python
salt.modules.win_firewall.enable(profile='allprofiles')
```

Enable firewall profile

New in version 2015.5.0.

**CLI Example:**
```python
salt '*' firewall.enable
```

```python
salt.modules.win_firewall.get_config()
```

Get the status of all the firewall profiles

**CLI Example:**
```python
salt '*' firewall.get_config
```

```python
salt.modules.win_firewall.get_rule(name='all')
```

New in version 2015.5.0.
Get firewall rule(s) info

**CLI Example:**
```python
salt '*' firewall.get_rule 'MyAppPort'
```

### 32.17.303 salt.modules.win_groupadd

Manage groups on Windows

**Important:** If you feel that Salt should be using this module to manage groups on a minion, and it is using a different module (or gives an error similar to `group.info` is not available), see [here](#).

```python
salt.modules.win_groupadd.add(name, gid=None, system=False)
```

Add the specified group

**CLI Example:**
salt '*' group.add foo

salt.modules.win_groupadd.adduser(name, username)
    add a user to a group
    CLI Example:
    salt '*' group.adduser foo username

salt.modules.win_groupadd.delete(name)
    Remove the named group
    CLI Example:
    salt '*' group.delete foo

salt.modules.win_groupadd.deluser(name, username)
    remove a user from a group
    CLI Example:
    salt '*' group.deluser foo username

salt.modules.win_groupadd.getent(refresh=False)
    Return info on all groups
    CLI Example:
    salt '*' group.getent

salt.modules.win_groupadd.info(name)
    Return information about a group
    CLI Example:
    salt '*' group.info foo

salt.modules.win_groupadd.members(name, members_list)
    remove a user from a group
    CLI Example:
    salt '*' group.members foo 'user1,user2,user3'

32.17.304 salt.modules.win_ip

The networking module for Windows based systems

salt.modules.win_ip.disable(iface)
    Disable an interface
    CLI Example:
    salt -G 'os_family:Windows' ip.disable 'Local Area Connection #2'

salt.modules.win_ip.enable(iface)
    Enable an interface
    CLI Example:
salt -G 'os_family:Windows' ip.enable 'Local Area Connection #2'

salt.modules.win_ip.get_all_interfaces()
Return configs for all interfaces

CLI Example:

salt -G 'os_family:Windows' ip.get_all_interfaces

salt.modules.win_ip.get_default_gateway()
Set DNS source to DHCP on Windows

CLI Example:

salt -G 'os_family:Windows' ip.get_default_gateway

salt.modules.win_ip.get_interface(iface)
Return the configuration of a network interface

CLI Example:

salt -G 'os_family:Windows' ip.get_interface 'Local Area Connection'

salt.modules.win_ip.get_subnet_length(mask)
Convenience function to convert the netmask to the CIDR subnet length

CLI Example:

salt -G 'os_family:Windows' ip.get_subnet_length 255.255.255.0

salt.modules.win_ip.is_disabled(iface)
Returns True if interface is disabled, otherwise False

CLI Example:

salt -G 'os_family:Windows' ip.is_disabled 'Local Area Connection #2'

salt.modules.win_ip.is_enabled(iface)
Returns True if interface is enabled, otherwise False

CLI Example:

salt -G 'os_family:Windows' ip.is_enabled 'Local Area Connection #2'

salt.modules.win_ip.raw_interface_configs()
Return raw configs for all interfaces

CLI Example:

salt -G 'os_family:Windows' ip.raw_interface_configs

salt.modules.win_ip.set_dhcp_all(iface)
Set both IP Address and DNS to DHCP

CLI Example:

salt -G 'os_family:Windows' ip.set_dhcp_all 'Local Area Connection'
salt.modules.win_ip.set_dhcp_dns(iface)
Set DNS source to DHCP on Windows

CLI Example:
```
salt -G 'os_family:Windows' ip.set_dhcp_dns 'Local Area Connection'
```

salt.modules.win_ip.set_dhcp_ip(iface)
Set Windows NIC to get IP from DHCP

CLI Example:
```
salt -G 'os_family:Windows' ip.set_dhcp_ip 'Local Area Connection'
```

salt.modules.win_ip.set_static_dns(iface, *addrs)
Set static DNS configuration on a Windows NIC

CLI Example:
```
salt -G 'os_family:Windows' ip.set_static_dns 'Local Area Connection' '192.168.1.1'
salt -G 'os_family:Windows' ip.set_static_dns 'Local Area Connection' '192.168.1.252' '192.168.1.253'
```

salt.modules.win_ip.set_static_ip(iface, addr, gateway=None, append=False)
Set static IP configuration on a Windows NIC

iface The name of the interface to manage
addr IP address with subnet length (ex. 10.1.2.3/24). The ip.get_subnet_length function can be
used to calculate the subnet length from a netmask.
gateway [None] If specified, the default gateway will be set to this value.
append [False] If True, this IP address will be added to the interface. Default is False, which overrides any
existing configuration for the interface and sets addr as the only address on the interface.

CLI Example:
```
salt -G 'os_family:Windows' ip.set_static_ip 'Local Area Connection' 10.1.2.3/24 --gateway=10.1.2.1
salt -G 'os_family:Windows' ip.set_static_ip 'Local Area Connection' 10.1.2.4/24 --append=True
```

32.17.305 salt.modules.win_network

Module for gathering and managing network information

salt.modules.win_network.dig(host)
Perform a DNS lookup with dig

Note: dig must be installed on the Windows minion

CLI Example:
```
salt '*' network.dig archlinux.org
```

salt.modules.win_network.hw_addr(iface)
Return the hardware address (a.k.a. MAC address) for a given interface

CLI Example:
salt.modules.win_network.hwaddr(iface)

This function is an alias of hw._addr.

Return the hardware address (a.k.a. MAC address) for a given interface

CLI Example:

```
salt '*' network.hw_addr 'Wireless Connection #1'
```

salt.modules.win_network.in_subnet(cidr)

Returns True if host is within specified subnet, otherwise False

CLI Example:

```
salt '*' network.in_subnet 10.0.0.0/16
```

salt.modules.win_network.interfaces()

Return a dictionary of information about all the interfaces on the minion

CLI Example:

```
salt '*' network.interfaces
```

salt.modules.win_network.interfaces_names()

Return a list of all the interfaces names

CLI Example:

```
salt '*' network.interfaces_names
```

salt.modules.win_network.ip_addrs(interface=None, include_loopback=False)

Returns a list of IPv4 addresses assigned to the host. 127.0.0.1 is ignored, unless `include_loopback=True` is indicated. If `interface` is provided, then only IP addresses from that interface will be returned.

CLI Example:

```
salt '*' network.ip_addrs
```

salt.modules.win_network.ip_addrs6(interface=None, include_loopback=False)

Returns a list of IPv6 addresses assigned to the host. ::1 is ignored, unless `include_loopback=True` is indicated. If `interface` is provided, then only IP addresses from that interface will be returned.

CLI Example:

```
salt '*' network.ip_addrs6
```

salt.modules.win_network.ipaddr(interface=None, include_loopback=False)

This function is an alias of ip_addrs.

Returns a list of IPv4 addresses assigned to the host. 127.0.0.1 is ignored, unless `include_loopback=True` is indicated. If `interface` is provided, then only IP addresses from that interface will be returned.

CLI Example:

```
salt '*' network.ipaddr
```
salt.modules.win_network.ipaddrs6(interface=None, include_loopback=False)

This function is an alias of ip_addrs6.

Returns a list of IPv6 addresses assigned to the host. ::1 is ignored, unless `include_loopback=True' is indicated. If `interface' is provided, then only IP addresses from that interface will be returned.

CLI Example:
```
salt '*' network.ip_addrs6
```

salt.modules.win_network.netstat()

Return information on open ports and states

CLI Example:
```
salt '*' network.netstat
```

salt.modules.win_network.nslookup(host)

Query DNS for information about a domain or ip address

CLI Example:
```
salt '*' network.nslookup archlinux.org
```

salt.modules.win_network.ping(host)

Performs a ping to a host

CLI Example:
```
salt '*' network.ping archlinux.org
```

salt.modules.win_network.subnets()

Returns a list of subnets to which the host belongs

CLI Example:
```
salt '*' network.subnets
```

salt.modules.win_network.traceroute(host)

Performs a traceroute to a 3rd party host

CLI Example:
```
salt '*' network.traceroute archlinux.org
```

32.17.306 salt.modules.win_ntp

Management of NTP servers on Windows

New in version 2014.1.0.

salt.modules.win_ntp.get_servers()

Get list of configured NTP servers

CLI Example:
```
salt '*' ntp.get_servers
```
salt.modules.win_ntp.set_servers('servers')
    Set Windows to use a list of NTP servers
    
    CLI Example:
    ```
salt '*' ntp.set_servers 'pool.ntp.org' 'us.pool.ntp.org'
    ```

32.17.307 salt.modules.win_path

Manage the Windows System PATH

Note that not all Windows applications will rehash the PATH environment variable, Only the ones that listen to the WM_SETTINGCHANGE message [http://support.microsoft.com/kb/104011](http://support.microsoft.com/kb/104011)

salt.modules.win_path.add(path, index=0)
    Add the directory to the SYSTEM path in the index location

    Returns: boolean True if successful, False if unsuccessful
    
    CLI Example:
    ```
    # Will add to the beginning of the path
    salt '*' win_path.add 'c:\python27' 0
    
    # Will add to the end of the path
    salt '*' win_path.add 'c:\python27' index='1'
    ```

salt.modules.win_path.exists(path)
    Check if the directory is configured in the SYSTEM path Case-insensitive and ignores trailing backslash

    Returns: boolean True if path exists, False if not
    
    CLI Example:
    ```
    salt '*' win_path.exists 'c:\python27'
    salt '*' win_path.exists 'c:\python27\'
    salt '*' win_path.exists 'C:\pyThon27'
    ```

salt.modules.win_path.get_path()
    Returns a list of items in the SYSTEM path
    
    CLI Example:
    ```
    salt '*' win_path.get_path
    ```

salt.modules.win_path.rehash()
    Send a WM_SETTINGCHANGE Broadcast to Windows to refresh the Environment variables
    
    CLI Example:
    ```
    ... code-block:: bash
    salt '*' win_path.rehash
    ```

salt.modules.win_path.remove(path)
    Remove the directory from the SYSTEM path

    Returns: boolean True if successful, False if unsuccessful
    
    CLI Example:
32.17.308 salt.modules.win_pkg

A module to manage software on Windows

**Important:** If you feel that Salt should be using this module to manage packages on a minion, and it is using a different module (or gives an error similar to `pkg.install' is not available), see [here](#).

**depends**

- win32com
- win32con
- win32api
- pywintypes

```python
salt.modules.win_pkg.compare_versions( ver1=''', oper='=='; ver2='''
```  
Compare software package versions

```python
salt.modules.win_pkg.genrepo(saltenv='base')
```  
Generate winrepo_cachefile based on sls files in the winrepo

CLI Example:

```bash
salt-run winrepo.genrepo
```

```python
salt.modules.win_pkg.get_name_map()
```  

```python
salt.modules.win_pkg.get_repo_data(saltenv='base')
```  
Returns the cached winrepo data

CLI Example:

```bash
salt '*' pkg.get_repo_data
```

```python
salt.modules.win_pkg.install(name=None, refresh=False, pkgs=None, saltenv='base', **kwargs)
```  
Install the passed package(s) on the system using winrepo

**Parameters**

- **name** *(str, list, or None)* -- The name of a single package, or a comma-separated list of packages to install. (no spaces after the commas)
- **version** *(str)* -- The specific version to install. If omitted, the latest version will be installed. If passed with multiple install, the version will apply to all packages. Recommended for single installation only.
- **refresh** *(bool)* -- Boolean value representing whether or not to refresh the winrepo db
- **pkgs** *(list or None)* -- A list of packages to install from a software repository. All packages listed under pkgs will be installed via a single command.
- **saltenv** *(str)* -- The salt environment to use. Default is `base`.
- **kwargs** *(dict)* -- Any additional argument that may be passed from the state module. If they don't apply, they are ignored.
**Returns** Return a dict containing the new package names and versions:

**Return type**

dict

If the package is installed by pkg.install:

```python
{'<package>': {'old': '<old-version>',
'new': '<new-version>'}}
```

If the package is already installed:

```python
{'<package>': {'current': '<current-version>'}}
```

The following example will refresh the winrepo and install a single package, 7zip.

**CLI Example:**

```shell
salt '*' pkg.install 7zip refresh=True
```

**CLI Example:**

```shell
salt '*' pkg.install 7zip
salt '*' pkg.install 7zip,filezilla
salt '*' pkg.install pkgs='["7zip","filezilla"]'
```

**salt.modules.win_pkg.latest_version('names', **kwargs)**

Return the latest version of the named package available for upgrade or installation. If more than one package name is specified, a dict of name/version pairs is returned.

If the latest version of a given package is already installed, an empty string will be returned for that package.

**CLI Example:**

```shell
salt '*' pkg.latest_version <package name>
salt '*' pkg.latest_version <package1> <package2> <package3> ...
```

**salt.modules.win_pkg.list_available('names)**

Return a list of available versions of the specified package.

**CLI Example:**

```shell
salt '*' pkg.list_available <package name>
salt '*' pkg.list_available <package name01> <package name02>
```

**salt.modules.win_pkg.list_pkgs(versions_as_list=False, **kwargs)**

List the packages currently installed in a dict:

```python
[{'<package_name>': '<version>'}
```

**CLI Example:**

```shell
salt '*' pkg.list_pkgs
salt '*' pkg.list_pkgs versions_as_list=True
```

**salt.modules.win_pkg.list_upgrades(refresh=True, **kwargs)**

List all available package upgrades on this system

**CLI Example:**

```shell
```
salt '*$' pkg.list_upgrades

salt.modules.win_pkg.purge(name=None, pkgs=None, version=None, **kwargs)

Package purges are not supported, this function is identical to remove().

name The name of the package to be deleted.

version The version of the package to be deleted. If this option is used in combination with the pkgs option below, then this version will be applied to all targeted packages.

Multiple Package Options:

pkgs A list of packages to delete. Must be passed as a python list. The name parameter will be ignored if this option is passed.

New in version 0.16.0.

Returns a dict containing the changes.

CLI Example:
salt '*$' pkg.purge <package name>
salt '*$' pkg.purge <package1>,<package2>,<package3>
salt '*$' pkg.purge pkgs=['"foo", "bar"]'

salt.modules.win_pkg.refresh_db(saltenv='base')

Just recheck the repository and return a dict:

{'<database name>': Bool}

CLI Example:
salt '*$' pkg.refresh_db

salt.modules.win_pkg.remove(name=None, pkgs=None, version=None, **kwargs)

Remove the passed package(s) from the system using winrepo

Parameters

- name (str, list, or None) -- The name of the package to be uninstalled.
  - version (str) -- The version of the package to be uninstalled. If this option is used to uninstall multiple packages, then this version will be applied to all targeted packages. Recommended using only when uninstalling a single package. If this parameter is omitted, the latest version will be uninstalled.

Multiple Package Options:

Parameters pkgs (list or None) -- A list of packages to delete. Must be passed as a python list. The name parameter will be ignored if this option is passed.

New in version 0.16.0.

Returns Returns a dict containing the changes.

Return type
dict

If the package is removed by pkg.remove:

{'<package>: {'old': '<old-version>', 'new': '<new-version>'}}

If the package is already uninstalled:
```
{'<package>': {'current': 'not installed'}}
```

CLI Example:

```
salt '*' pkg.remove <package name>
salt '*' pkg.remove <package1>,<package2>,<package3>
salt '*' pkg.remove pkgs=['"foo", "bar"']
```

**salt.modules.win_pkg.upgrade**(**refresh=True**)  
Run a full system upgrade  
Return a dict containing the new package names and versions:

```
{'<package>': {'old': '<old-version>', 'new': '<new-version>'}}
```

CLI Example:

```
salt '*' pkg.upgrade
```

**salt.modules.win_pkg.upgrade_available**(**name**)  
Check whether or not an upgrade is available for a given package  
CLI Example:

```
salt '*' pkg.upgrade_available <package name>
```

**salt.modules.win_pkg.version**(**names**, **kwargs**)  
Returns a version if the package is installed, else returns an empty string  
CLI Example:

```
salt '*' pkg.version <package name>
```

### salt.modules.win_powercfg

This module allows you to control the power settings of a windows minion via powercfg.

New in version 2015.8.0.

```
salt '*' powercfg.set_monitor_timeout 0 power=dc  
salt '*' powercfg.set_disk_timeout 120 power=ac
```

**salt.modules.win_powercfg.get_disk_timeout()**  
Get the current disk timeout of the current scheme  
CLI Example:

```
salt '*' powercfg.get_disk_timeout
```

**salt.modules.win_powercfg.get_hibernate_timeout()**  
Get the current hibernate timeout of the current scheme  
CLI Example:

```
salt '*' powercfg.get_hibernate_timeout
```
salt.modules.win_powercfg.get_monitor_timeout()
Get the current monitor timeout of the current scheme

CLI Example:
salt '*' powercfg.get_monitor_timeout

salt.modules.win_powercfg.get_standby_timeout()
Get the current standby timeout of the current scheme

CLI Example:
salt '*' powercfg.get_standby_timeout

salt.modules.win_powercfg.set_disk_timeout(timeout, power='ac')
Set the disk timeout in minutes for the current power scheme

CLI Example:
salt '*' powercfg.set_disk_timeout 30 power=dc

timeout The amount of time in minutes before the disk will timeout
power Should we set the value for AC or DC (battery)? Valid options ac,dc.

salt.modules.win_powercfg.set_hibernate_timeout(timeout, power='ac')
Set the hibernate timeout in minutes for the current power scheme

CLI Example:
salt '*' powercfg.set_hibernate_timeout 30 power=pc

timeout The amount of time in minutes before the computer hibernates
power Should we set the value for AC or DC (battery)? Valid options ac,dc.

salt.modules.win_powercfg.set_monitor_timeout(timeout, power='ac')
Set the monitor timeout in minutes for the current power scheme

CLI Example:
salt '*' powercfg.set_monitor_timeout 30 power=ac

timeout The amount of time in minutes before the monitor will timeout
power Should we set the value for AC or DC (battery)? Valid options ac,dc.

salt.modules.win_powercfg.set_standby_timeout(timeout, power='ac')
Set the standby timeout in minutes for the current power scheme

CLI Example:
salt '*' powercfg.set_standby_timeout 30 power=dc

timeout The amount of time in minutes before the computer sleeps
power Should we set the value for AC or DC (battery)? Valid options ac,dc.
32.17.310 salt.modules.win_repo

Module to manage Windows software repo on a Standalone Minion

**file_client:** local must be set in the minion config file.

For documentation on Salt's Windows Repo feature, see here.

**salt.modules.win_repo.genrepo()**

Generate winrepo_cachefile based on sls files in the winrepo_dir

CLI Example:

```python
salt-call winrepo.genrepo
```

**salt.modules.win_repo.show_sls(name, saltenv='base')**

New in version 2015.8.0.

Display the rendered software definition from a specific sls file in the local winrepo cache. This will parse all Jinja. Run pkg.refresh_db to pull the latest software definitions from the master.

**Note:** This function does not ask a master for an sls file to render. Instead it directly processes the file specified in `name`

**Args:**

- `name` str: The name/path of the package you want to view. This can be the full path to a file on the minion file system or a file on the local minion cache.
- `saltenv` str: The default environment is `base`

**Returns:**

- dict: Returns a dictionary containing the rendered data structure

**Note:** To use a file from the minion cache start from the local winrepo root (C:\salt\var\cache\salt\minion\files\base\win\repo-ng). If you have .sls files organized in subdirectories you'll have to denote them with .. For example, if you have a `test` directory in the winrepo root with a `gvim.sls` file inside, would target that file like so: `test.gvim`. Directories can be targeted as well as long as they contain an `init.sls` inside. For example, if you have a `node` directory with an `init.sls` inside, target that like so: `node`.

CLI Example:

```python
salt '*' winrepo.show_sls gvim
salt '*' winrepo.show_sls test.npp
salt '*' winrepo.show_sls C:\test\gvim.sls
```

**salt.modules.win_repo.update_git_repos(clean=False)**

Checkout git repos containing *Windows Software Package Definitions.*

**Important:** This function requires *Git for Windows* to be installed in order to work. When installing, make sure to select an installation option which permits the git executable to be run from the Command Prompt.

**clean** [False] Clean repo cachedirs which are not configured under `winrepo_remotes`. 
**Note:** This option only applies if either `pygit2` or `GitPython` is installed into Salt's bundled Python.

**Warning:** This argument should not be set to `True` if a mix of git and non-git repo definitions are being used, as it will result in the non-git repo definitions being removed.

New in version 2015.8.0.

CLI Example:

```
salt-call winrepo.update_git_repos
```

### 32.17.311 `salt.modules.win_servermanager`

Manage Windows features via the ServerManager powershell module

```python
salt.modules.win_servermanager.install(feature, recurse=False, source=None, restart=False, exclude=None)
```

Install a feature

**Note:** Some features require reboot after un/installation, if so until the server is restarted other features can not be installed!

**Note:** Some features take a long time to complete un/installation, set `-t` with a long timeout

**Parameters**

- `feature (str)` -- The name of the feature to install
- `recurse (bool)` -- Install all sub-features. Default is `False`
- `source (str)` -- Path to the source files if missing from the target system. None means that the system will use windows update services to find the required files. Default is `None`
- `restart (bool)` -- Restarts the computer when installation is complete, if required by the role/feature installed. Default is `False`
- `exclude (str)` -- The name of the feature to exclude when installing the named feature.

**Note:** As there is no exclude option for the `Add-WindowsFeature` command, the feature will be installed with other sub-features and will then be removed.

**Returns** A dictionary containing the results of the install

**Return type** `dict`

CLI Example:
salt '*' win_servermanager.install Telnet-Client
salt '*' win_servermanager.install SNMP-Service True
salt '*' win_servermanager.install TFTP-Client source=d:\side-by-side

salt.modules.win_servermanager.list_available()
List available features to install
  Returns  A list of available features
  Return type  list
  CLI Example:
  salt '*' win_servermanager.list_available

salt.modules.win_servermanager.list_installed()
List installed features. Supported on Windows Server 2008 and Windows 8 and newer.
  Returns  A list of installed features
  Return type  list
  CLI Example:
  salt '*' win_servermanager.list_installed

salt.modules.win_servermanager.remove(feature, remove_payload=False, restart=False)
Remove an installed feature

  Note: Some features require a reboot after installation/uninstallation. If one of these features are modified,
  then other features cannot be installed until the server is restarted. Additionally, some features take a while
  to complete installation/uninstallation, so it is a good idea to use the -t option to set a longer timeout.

  Parameters
  •  feature (str) -- The name of the feature to remove
  •  remove_payload (bool) -- True will cause the feature to be removed from the side-
    by-side store (%SystemDrive%: \Windows\WinSxS). Default is False
  •  restart (bool) -- Restarts the computer when uninstall is complete, if required by the
    role/feature removed. Default is False

  Returns  A dictionary containing the results of the uninstall
  Return type  dict
  CLI Example:
  salt -t 600 '*' win_servermanager.remove Telnet-Client

32.17.312  salt.modules.win_service

Windows Service module.

salt.modules.win_service.available(name)
  Returns True if the specified service is available, otherwise returns False.

32.17.  Full list of builtin execution modules
CLI Example:

```
salt '*' service.available <service name>
```

```
salt.modules.win_service.config(name, bin_path=None, display_name=None, svc_type=None, start_type=None, error=None, group=None, tag=None, depend=None, obj=None, password=None, **kwargs)
```

Modify the named service.

Required parameters:

**Parameters** `name (str)` -- Specifies the service name returned by the getkeyname operation

Optional parameters:

**Parameters** `bin_path (str)` -- Specifies the path to the service binary file, backslashes must be escaped - eg: C:\path\to\binary.exe

**Parameters** `display_name (str)` -- the name to be displayed in the service manager

Specifies a more descriptive name for identifying the service in user interface programs.

Parameters

- **svc_type (str)** -- Specifies the service type. Acceptable values are:  
  - own (default): Service runs in its own process  
  - share: Service runs as a shared process  
  - interact: Service can interact with the desktop  
  - kernel: Service is a driver  
  - filesys: Service is a system driver  
  - rec: Service is a file system-recognized driver that identifies filesystems on the computer  
  - adapt: Service is an adapter driver that identifies hardware such as keyboards, mice and disk drives

- **start_type (str)** -- Specifies the start type for the service.

Acceptable values are:

- boot: Device driver that is loaded by the boot loader  
- system: Device driver that is started during kernel initialization  
- auto: Service that automatically starts  
- demand (default): Service must be started manually  
- disabled: Service cannot be started  
- delayed-auto: Service starts automatically after other auto-services start

**Parameters** `error (str)` -- Specifies the severity of the error if the service fails to start. Acceptable values are:

- normal (default): Error is logged and a message box is displayed  
- severe: Error is logged and computer attempts a restart with last known good configuration  
- critical: Error is logged, computer attempts to restart with last known good configuration, system halts on failure
- ignore: Error is logged and startup continues, no notification is given to the user

Parameters **group**(str) -- Specifies the name of the group of which this service is a member. The list of groups is stored in the registry, in the HKLMSystemCurrentControlSetControlService-GroupOrder subkey. The default is null.

Parameters **tag**(str) -- Specifies whether or not to obtain a TagID from the CreateService call. For boot-start and system-start drivers only. Acceptable values are:

• yes/no

Parameters **depend**(str) -- Specifies the names of services or groups that must start before this service. The names are separated by forward slashes.

Parameters **obj**(str) -- Specifies the name of an account in which a service will run or specifies a name of the Windows driver object in which the driver will run. Default is LocalSystem

Parameters **password**(str) -- Specifies a password. Required if other than LocalSystem account is used.

Returns True if successful, False if not

Return type bool

CLI Example:

```
salt '*' service.config <service name> <path to exe> display_name='<display name>'
```

salt.modules.win_service.create(name, binpath, DisplayName=None, type='own', start='demand', error='normal', group=None, tag='no', depend=None, obj=None, password=None, **kwargs)

Create the named service.

New in version 2015.8.0.

Required parameters: name: Specifies the service name returned by the getkeyname operation binpath: Specifies the path to the service binary file, backslashes must be escaped

• eg: C:\path\to\binary.exe

Optional parameters: DisplayName: the name to be displayed in the service manager type: Specifies the service type, default is own

• own (default): Service runs in its own process
• share: Service runs as a shared process
• interact: Service can interact with the desktop
• kernel: Service is a driver
• filesys: Service is a system driver
• rec: Service is a file system-recognized driver that identifies filesystems on the computer

start: Specifies the start type for the service

• boot: Device driver that is loaded by the boot loader
• system: Device driver that is started during kernel initialization
- auto: Service that automatically starts
- demand (default): Service must be started manually
- disabled: Service cannot be started
- delayed-auto: Service starts automatically after other auto-services start

**error:** Specifies the severity of the error
- normal (default): Error is logged and a message box is displayed
- severe: Error is logged and computer attempts a restart with last known good configuration
- critical: Error is logged, computer attempts to restart with last known good configuration, system halts on failure
- ignore: Error is logged and startup continues, no notification is given to the user

group: Specifies the name of the group of which this service is a member
tag: Specifies whether or not to obtain a TagID from the CreateService call. For boot-start and system-start drivers
- yes/no

depend: Specifies the names of services or groups that must start before this service. The names are separated by forward slashes.
obj: Specifies the name of an account in which a service will run. Default is LocalSystem
password: Specifies a password. Required if other than LocalSystem account is used.

CLI Example:
```
salt '*' service.create <service name> <path to exe> display_name='<display name>'
```

**salt.modules.win_service.create_win_salt_restart_task()**
Create a task in Windows task scheduler to enable restarting the salt-minion

CLI Example:
```
salt '*' service.create_win_salt_restart_task()
```

**salt.modules.win_service.delete(name)**
delete the named service

CLI Example:
```
salt '*' service.delete <service name>
```

**salt.modules.win_service.disable(name,**kwargs**)**
Disable the named service to start at boot

CLI Example:
```
salt '*' service.disable <service name>
```

**salt.modules.win_service.disabled(name)**
Check to see if the named service is disabled to start on boot

CLI Example:
```
salt '*' service.disabled <service name>
```

**salt.modules.win_service.enable(name,**kwargs**)**
Enable the named service to start at boot

CLI Example:
```
salt '*' service.enable <service name>
```
CLI Example:

```
salt '*' service.enable <service name>
```

```
salt.modules.win_service.enabled(name, **kwargs)
Check to see if the named service is enabled to start on boot
```

CLI Example:

```
salt '*' service.enabled <service name>
```

```
salt.modules.win_service.execute_salt_restart_task()
Run the Windows Salt restart task
```

CLI Example:

```
salt '*' service.execute_salt_restart_task()
```

```
salt.modules.win_service.get_all()
Return all installed services
```

CLI Example:

```
salt '*' service.get_all
```

```
salt.modules.win_service.get_disabled()
Return the disabled services
```

CLI Example:

```
salt '*' service.get_disabled
```

```
salt.modules.win_service.get_enabled()
Return the enabled services
```

CLI Example:

```
salt '*' service.get_enabled
```

```
salt.modules.win_service.get_service_name(*args)
The Display Name is what is displayed in Windows when services.msc is executed. Each Display Name has an associated Service Name which is the actual name of the service. This function allows you to discover the Service Name by returning a dictionary of Display Names and Service Names, or filter by adding arguments of Display Names.
If no args are passed, return a dict of all services where the keys are the service Display Names and the values are the Service Names.
If arguments are passed, create a dict of Display Names and Service Names
```

CLI Example:

```
salt '*' service.get_service_name
salt '*' service.get_service_name 'Google Update Service (gupdate)' 'DHCP Client'
```

```
salt.modules.win_service.getsid(name)
Return the sid for this windows service
```

CLI Example:
salt.modules.win_service.missing(name)
The inverse of service.available. Returns True if the specified service is not available, otherwise returns False.

CLI Example:
salt '*' service.missing <service name>

salt.modules.win_service.restart(name)
Restart the named service

CLI Example:
salt '*' service.restart <service name>

salt.modules.win_service.start(name)
Start the specified service

CLI Example:
salt '*' service.start <service name>

salt.modules.win_service.status(name, sig=None)
Return the status for a service, returns the PID or an empty string if the service is running or not, pass a signature to use to find the service via ps

CLI Example:
salt '*' service.status <service name> [service signature]

salt.modules.win_service.stop(name)
Stop the specified service

CLI Example:
salt '*' service.stop <service name>

32.17.313 salt.modules.win_shadow

Manage the shadow file

Important: If you feel that Salt should be using this module to manage passwords on a minion, and it is using a different module (or gives an error similar to `shadow.info' is not available), see here.

salt.modules.win_shadow.info(name)
Return information for the specified user This is just returns dummy data so that salt states can work.

Parameters name (str) -- The name of the user account to show.

CLI Example:
salt '*' shadow.info root
salt.modules.win_shadow.require_password_change(name)
   Require the user to change their password the next time they log in.
   Parameters name -- The name of the user account to require a password change.
   Returns True if successful. False if unsuccessful.
   Return type bool

salt.modules.win_shadow.set_expire(name, expire)
   Set the expiration date for a user account.
   Parameters
   * name -- The name of the user account to edit.
   * expire -- The date the account will expire.
   Returns True if successful. False if unsuccessful.
   Return type bool

salt.modules.win_shadow.set_password(name, password)
   Set the password for a named user.
   Parameters
   * name (str) -- The name of the user account
   * password (str) -- The new password
   Returns True if successful. False if unsuccessful.
   Return type bool

CLI Example:

```
salt '*' shadow.set_password root mysecretpassword
```

salt.modules.win_shadow.unlock_account(name)
   Unlocks a user account.
   Parameters name -- The name of the user account to unlock.
   Returns True if successful. False if unsuccessful.
   Return type bool

32.17.314 salt.modules.win_status

Module for returning various status data about a minion. These data can be useful for compiling into stats later, or
for problem solving if your minion is having problems.

New in version 0.12.0.

depends
   * pythoncom
   * wmi

salt.modules.win_status.cpuload()
   New in version 2015.8.0.
   Return the processor load as a percentage
CLI Example:
```
salt '*' status.cpuload
```

```python
salt.modules.win_status.diskusage(human_readable=False, path=None)
```
New in version 2015.8.0.

Return the disk usage for this minion

human_readable [False] If True, usage will be in KB/MB/GB etc.

CLI Example:
```
salt '*' status.diskusage path=c:/salt
```

```python
salt.modules.win_status.master(master=None, connected=True)
```
New in version 2015.5.0.

Fire an event if the minion gets disconnected from its master. This function is meant to be run via a scheduled job from the minion. If master_ip is an FQDN/Hostname, must be resolvable to a valid IPv4 address.

CLI Example:
```
salt '*' status.master
```

```python
salt.modules.win_status.procs(count=False)
```
Return the process data

count [False] If True, this function will simply return the number of processes.

New in version 2015.8.0.

CLI Example:
```
salt '*' status.procs
salt '*' status.procs count
```

```python
salt.modules.win_status.saltmem(human_readable=False)
```
New in version 2015.8.0.

Returns the amount of memory that salt is using

human_readable [False] return the value in a nicely formatted number

CLI Example:
```
salt '*' status.saltmem
salt '*' status.saltmem human_readable=True
```

```python
salt.modules.win_status.uptime(human_readable=False)
```
New in version 2015.8.0.

Return the system uptime for this machine in seconds

human_readable [False] If True, then return uptime in years, days, and seconds.

CLI Example:
```
salt '*' status.uptime
salt '*' status.uptime human_readable=True
```
32.17.315 salt.modules.win_system

Module for managing windows systems.

depends

• win32net

Support for reboot, shutdown, etc

salt.modules.win_system.get_computer_desc()

Get the Windows computer description

Returns Returns the computer description if found. Otherwise returns False

CLI Example:

```
salt 'minion-id' system.get_computer_desc
```

salt.modules.win_system.get_computer_name()

Get the Windows computer name

Returns Returns the computer name if found. Otherwise returns False

CLI Example:

```
salt 'minion-id' system.get_computer_name
```

salt.modules.win_system.get_domain_workgroup()

Get the domain or workgroup the computer belongs to.

New in version 2015.5.7.

New in version 2015.8.2.

Returns The name of the domain or workgroup

Return type str

salt.modules.win_system.get_pending_computer_name()

Get a pending computer name. If the computer name has been changed, and the change is pending a system
reboot, this function will return the pending computer name. Otherwise, None will be returned. If there was
an error retrieving the pending computer name, False will be returned, and an error message will be logged
to the minion log.

Returns Returns the pending name if pending restart. Returns none if not pending restart.

CLI Example:

```
salt 'minion-id' system.get_pending_computer_name
```

salt.modules.win_system.get_system_date()

Get the Windows system date

Returns Returns the system date.

Return type str

CLI Example:

```
salt '*' system.get_system_date
```

salt.modules.win_system.get_system_info()

Get system information.
Returns: Returns a Dictionary containing information about the system to include name, description, version, etc...

Return type: dict

salt.modules.win_system.get_system_time()

Get the system time.

Returns: Returns the system time in HH:MM AM/PM format.

Return type: str

salt.modules.win_system.halt(timeout=5, in_seconds=False)

Halt a running system.

Parameters:
- **timeout (int)** -- Number of seconds before halting the system. Default is 5 seconds.
- **in_seconds** -- Whether to treat timeout as seconds or minutes.

Returns: True is successful.

Return type: bool

timeout: The wait time before the system will be shutdown.
in_seconds: Whether to treat timeout as seconds or minutes.

New in version 2015.8.0.

CLI Example:

```
salt '*' system.halt 5
```

salt.modules.win_system.init(runlevel)

Change the system runlevel on sysV compatible systems

CLI Example:

```
salt '*' system.init 3
```

salt.modules.win_system.join_domain(domain, username=None, password=None, account_ou=None, account_exists=False, restart=False)

Join a computer to an Active Directory domain. Requires reboot.

Parameters:

- **domain (str)** -- The domain to which the computer should be joined, e.g. example.com
- **username (str)** -- Username of an account which is authorized to join computers to the specified domain. Need to be either fully qualified like user@domain.tld or simply user
- **password (str)** -- Password of the specified user
- **account_ou (str)** -- The DN of the OU below which the account for this computer should be created when joining the domain, e.g. ou=computers,ou=department_432,dc=my-company,dc=com
- **account_exists (bool)** -- If set to True the computer will only join the domain if the account already exists. If set to False the computer account will be created if it does not exist, otherwise it will use the existing account. Default is False
- **restart (bool)** -- Restarts the computer after a successful join
New in version 2015.5.7.
New in version 2015.8.2.

Returns  Returns a dictionary if successful. False if unsuccessful.

Return type  dict, bool

CLI Example:

```py
salt 'minion-id' system.join_domain domain='domain.tld' "
    username='joinuser' password='joinpassword' "
    account_ou='ou=clients,ou=org,dc=domain,dc=tld' "
    account_exists=False, restart=True
```

salt.modules.win_system.lock()
Lock the workstation.

Returns  True if successful

Return type  bool

salt.modules.win_system.poweroff(timeout=5, in_seconds=False)
Power off a running system.

Parameters  timeout (int) -- Number of seconds before powering off the system. Default is 5 seconds.

Returns  True if successful

Return type  bool

timeout  The wait time before the system will be shutdown.
in_seconds  Whether to treat timeout as seconds or minutes.

New in version 2015.8.0.

CLI Example:

```py
salt '*' system.poweroff 5
```

salt.modules.win_system.reboot(timeout=5, in_seconds=False)
Reboot a running system.

Parameters

- timeout (int) -- Number of seconds before rebooting the system. Default is 5 minutes.
- in_seconds (bool) -- Whether to treat timeout as seconds or minutes.

New in version 2015.8.0.

Returns  True if successful

Return type  bool

CLI Example:

```py
salt '*' system.reboot 5
```

salt.modules.win_system.set_computer_desc(desc=None)
Set the Windows computer description

Parameters  desc (str) -- The computer description

32.17. Full list of builtin execution modules
Returns False if it fails. Description if successful.

CLI Example:

```
salt 'minion-id' system.set_computer_desc 'This computer belongs to Dave!'
```

salt.modules.win_system.set_computer_name(name)

Set the Windows computer name

Parameters name (str) -- The new name to give the computer. Requires a reboot to take effect.

Returns Returns a dictionary containing the old and new names if successful. False if not.

CLI Example:

```
salt 'minion-id' system.set_computer_name 'DavesComputer'
```

salt.modules.win_system.set_system_date(newdate)

Set the Windows system date. Use <mm-dd-yy> format for the date.

Parameters newdate (str) -- The date to set. Can be any of the following formats - YYYY-MM-DD - MM-DD-YYYY - MM-DD-YY - MM/DD/YYYY - MM/DD/YY - YYYY/MM/DD

CLI Example:

```
salt '*' system.set_system_date '03-28-13'
```

salt.modules.win_system.set_system_date_time(years=None, months=None, days=None, hours=None, minutes=None, seconds=None)

Set the system date and time. Each argument is an element of the date, but not required. If an element is not passed, the current system value for that element will be used. For example, if you don’t pass the year, the current system year will be used. (Used by set_system_date and set_system_time)

Parameters

• years (int) -- Years digit, ie: 2015
• months (int) -- Months digit: 1 - 12
• days (int) -- Days digit: 1 - 31
• hours (int) -- Hours digit: 0 - 23
• minutes (int) -- Minutes digit: 0 - 59
• seconds (int) -- Seconds digit: 0 - 59

Returns True if successful. Otherwise False.

Return type bool

CLI Example:

```
salt '*' system.set_system_date_ time 2015 5 12 11 37 53
```

salt.modules.win_system.set_system_time(newtime)

Set the system time.

Parameters newtime (str) -- The time to set. Can be any of the following formats. - HH:MM:SS AM/PM - HH:MM AM/PM - HH:MM:SS (24 hour) - HH:MM (24 hour)

Returns Returns True if successful. Otherwise False.

Return type bool
**salt.modules.win_system.shutdown** *(message=None, timeout=5, force_close=True, reboot=False, in_seconds=False)*

Shutdown a running system.

**Parameters**

- **message** *(str)* -- A message to display to the user before shutting down.
- **timeout** *(int)* -- The length of time that the shutdown dialog box should be displayed, in seconds. While this dialog box is displayed, the shutdown can be stopped by the shutdown_abort function.

If timeout is not zero, InitiateSystemShutdown displays a dialog box on the specified computer. The dialog box displays the name of the user who called the function, displays the message specified by the lpMessage parameter, and prompts the user to log off. The dialog box beeps when it is created and remains on top of other windows in the system. The dialog box can be moved but not closed. A timer counts down the remaining time before a forced shutdown.

If timeout is zero, the computer shuts down without displaying the dialog box, and the shutdown cannot be stopped by shutdown_abort.

Default is 5 minutes
- **in_seconds** *(bool)* -- Whether to treat timeout as seconds or minutes.

New in version 2015.8.0.
- **force_close** *(bool)* -- True to force close all open applications. False displays a dialog box instructing the user to close the applications.
- **reboot** *(bool)* -- True restarts the computer immediately after shutdown. False caches to disk and safely powers down the system.

**Returns** True if successful

**Return type** bool

**CLI Example:**

```
salt '*' system.shutdown 5
```

**salt.modules.win_system.shutdown_abort()**

Abort a shutdown. Only available while the dialog box is being displayed to the user. Once the shutdown has initiated, it cannot be aborted.

**Returns** True if successful

**Return type** bool

**salt.modules.win_system.shutdown_hard()**

Shutdown a running system with no timeout or warning.

**Returns** True if successful

**Return type** bool

**CLI Example:**

```
salt '*' system.shutdown_hard
```

**salt.modules.win_system.start_time_service()**

Start the Windows time service

**Returns** True if successful. Otherwise False
Return type: bool

CLI Example:
```bash
salt '*' system.start_time_service
```

```
salt.modules.win_system.stop_time_service()
```

Stop the Windows time service

Returns: True if successful. Otherwise False

Return type: bool

CLI Example:
```bash
salt '*' system.stop_time_service
```

```
salt.modules.win_system.unjoin_domain(username=None, password=None, domain=None, workgroup='WORKGROUP', disable=False, restart=False)
```

Unjoin a computer from an Active Directory Domain. Requires restart.

Parameters:
- **username** -- Username of an account which is authorized to manage computer accounts on the domain. Need to be fully qualified like `user@domain.tld` or `domain.tld\user`. If domain not specified, the passed domain will be used. If computer account doesn’t need to be disabled, can be None.
- **password (str)** -- Password of the specified user
- **domain (str)** -- The domain from which to unjoin the computer. Can be None
- **workgroup (str)** -- The workgroup to join the computer to. Default is WORKGROUP

New in version 2015.5.7.

New in version 2015.8.2.

Parameters:
- **disable (bool)** -- Disable the computer account in Active Directory. True to disable. Default is False
- **restart (bool)** -- Restart the computer after successful unjoin

New in version 2015.5.7.

New in version 2015.8.2.

Returns: Returns a dictionary if successful. False if unsuccessful.

Return type: dict, bool

CLI Example:
```bash
salt 'minion-id' system.unjoin_domain restart=True
salt 'minion-id' system.unjoin_domain username='unjoinuser' \ password='unjoinpassword' disable=True \ restart=True
```
32.17.316 salt.modules.win_timezone

Module for managing timezone on Windows systems.

salt.modules.win_timezone.get_hwclock()
Get current hardware clock setting (UTC or localtime)

CLI Example:
salt '*' timezone.get_hwclock

salt.modules.win_timezone.get_offset()
Get current numeric timezone offset from UCT (i.e. -0700)

CLI Example:
salt '*' timezone.get_offset

salt.modules.win_timezone.get_zone()
Get current timezone (i.e. America/Denver)

CLI Example:
salt '*' timezone.get_zone

salt.modules.win_timezone.get_zonecode()
Get current timezone (i.e. PST, MDT, etc)

CLI Example:
salt '*' timezone.get_zonecode

salt.modules.win_timezone.set_hwclock(clock)
Sets the hardware clock to be either UTC or localtime

CLI Example:
salt '*' timezone.set_hwclock UTC

salt.modules.win_timezone.set_zone(timezone)
Unlinks, then symlinks /etc/localtime to the set timezone.

The timezone is crucial to several system processes, each of which SHOULD be restarted (for instance, whatever you system uses as its cron and syslog daemons). This will not be magically done for you!

CLI Example:
salt '*' timezone.set_zone 'America/Denver'

salt.modules.win_timezone.zone_compare(timezone)
Checks the md5sum between the given timezone, and the one set in /etc/localtime. Returns True if they match, and False if not. Mostly useful for running state checks.

Example:
salt '*' timezone.zone_compare 'America/Denver'
32.17.317 salt.modules.win_update

Module for running windows updates.

   depends
   • win32com
   • win32con
   • win32api
   • pywintypes

New in version 2014.7.0.

Set windows updates to run by category. Default behavior is to install all updates that do not require user interaction to complete. Optionally set categories to a category of your choice to only install certain updates. Default is to set to install all available but driver updates. The following example will install all Security and Critical Updates, and download but not install standard updates.

```
salt '*' win_update.install_updates categories=
  "['Critical Updates', 'Security Updates']"
```

You can also specify a number of features about the update to have a fine grain approach to specific types of updates. These are the following features/states of updates available for configuring: .. code-block:: text

   'UI' - User interaction required, skipped by default `downloaded' - Already downloaded, included by
default `present' - Present on computer, included by default `installed' - Already installed, skipped by
default `reboot' - Reboot required, included by default `hidden' - Skip hidden updates, skipped by default
   `software' - Software updates, included by default `driver' - Driver updates, included by default

The following example installs all updates that don't require a reboot: .. code-block:: bash

```
salt '*' win_update.install_updates skips=['\{\'reboot\':True\}]"
```

Once installed Salt will return a similar output:

```
2 : Windows Server 2012 Update (KB123456)
4 : Internet Explorer Security Update (KB098765)
2 : Malware Definition Update (KB321456)
...
```

The number at the beginning of the line is an OperationResultCode from the Windows Update Agent, it's enumeration is described here: https://msdn.microsoft.com/en-us/library/windows/desktop/aa387095(v=vs.85).aspx. The result code is then followed by the update name and its KB identifier.

```
class salt.modules.win_update.PyWinUpdater(categories=None, skipUI=True, skip-
  Downloaded=False, skipInstalled=True, skipReboot=False, skipPresent=False, skipSoft-
  wareUpdates=False, skipDriverUpdates=False, skipHidden=True)
```

   AutoSearch()
   this function generates a search string. simplifying the search function while still providing as many
   features as possible.

   Download()

   GetAvailableCategories()

   GetCategories()
GetDownloadResults()
GetInstallationResults()
   this gets results of installation process.
GetInstallationResultsPretty()
   converts the installation results into a pretty print.
GetSearchResults()
GetSearchResultsPretty()
Install()
Search(searchString)
SetCategories(categories)
SetSkip(skip, state)
SetSkips(skips)
salt.modules.win_update.download_updates(skips=None, retries=5, categories=None)
Downloads all available updates, skipping those that require user interaction.
Various aspects of the updates can be included or excluded. This feature is still in development.
retries   Number of retries to make before giving up. This is total, not per step.
categories Specify the categories to update. Must be passed as a list.

    salt '*' win_update.download_updates categories='["Updates"]'

Categories include the following:
   • Updates
   • Windows 7
   • Critical Updates
   • Security Updates
   • Update Rollups

CLI Examples:

# Normal Usage
salt '*' win_update.download_updates

# Download critical updates only
salt '*' win_update.download_updates categories='["Critical Updates"]'

salt.modules.win_update.install_updates(skips=None, retries=5, categories=None)
Downloads and installs all available updates, skipping those that require user interaction.
Add cached to only install those updates which have already been downloaded.
you can set the maximum number of retries to n in the search process by adding: retries=n
various aspects of the updates can be included or excluded. This function is still under development.
retries   Number of retries to make before giving up. This is total, not per step.
categories Specify the categories to install. Must be passed as a list.
salt '*' win_update.install_updates categories="['Updates']"

Categories include the following:
- Updates
- Windows 7
- Critical Updates
- Security Updates
- Update Rollups

CLI Examples:

```
# Normal Usage
salt '*' win_update.install_updates

# Install all critical updates
salt '*' win_update.install_updates categories="['Critical Updates']"
```

salt.modules.win_update.list_updates(verbos=False, skips=None, retries=5, categories=None)

Returns a summary of available updates, grouped into their non-mutually exclusive categories.

**verbose**  Print results in greater detail

**retries**  Number of retries to make before giving up. This is total, not per step.

**categories**  Specify the categories to list. Must be passed as a list.

```
salt '*' win_update.list_updates categories="['Updates']"
```

Categories include the following:
- Updates
- Windows 7
- Critical Updates
- Security Updates
- Update Rollups

CLI Examples:

```
# Normal Usage
salt '*' win_update.list_updates

# List all critical updates list in verbose detail
salt '*' win_update.list_updates categories=['Critical Updates'] verbose=True
```

32.17.318 salt.modules.win_useradd

Module for managing Windows Users

**Important:**  If you feel that Salt should be using this module to manage users on a minion, and it is using a different module (or gives an error similar to `user.info` is not available), see here.
depends

- pywintypes
- win32api
- win32net
- win32netcon
- win32profile
- win32security
- win32ts

Note: This currently only works with local user accounts, not domain accounts

salt.modules.win_useradd.add(name, password=None, fullname=False, description=None, groups=None, home=None, homedrive=None, profile=None, logonscript=None)

Add a user to the minion.

Parameters

- **name** *(str)* -- User name
- **password** *(str)* -- User's password in plain text.
- **fullname** *(str)* -- The user's full name.
- **description** *(str)* -- A brief description of the user account.
- **groups** *(list)* -- A list of groups to add the user to.
- **home** *(str)* -- The path to the user's home directory.
- **homedrive** *(str)* -- The drive letter to assign to the home directory. Must be the Drive Letter followed by a colon. ie: U:
- **profile** *(str)* -- An explicit path to a profile. Can be a UNC or a folder on the system. If left blank, windows uses it's default profile directory.
- **logonscript** *(str)* -- Path to a login script to run when the user logs on.

Returns True if successful. False is unsuccessful.

Return type bool

CLI Example:

```
salt '*' user.add name password
```

salt.modules.win_useradd.addgroup(name, group)

Add user to a group

Parameters

- **name** *(str)* -- user name to add to the group
- **group** *(str)* -- name of the group to which to add the user

Returns True if successful. False is unsuccessful.

Return type bool
CLI Example:

```
salt '*' user.addgroup jsnuffy 'Power Users'
```

**salt.modules.win_useradd.chfullname(name, fullname)**

Change the full name of the user

**Parameters**

- **name**(str) -- user name for which to change the full name
- **fullname**(str) -- the new value for the full name

**Returns** True if successful. False is unsuccessful.

**Return type** bool

CLI Example:

```
salt '*' user.chfullname user 'First Last'
```

**salt.modules.win_useradd.chgroups(name, groups, append=True)**

Change the groups this user belongs to, add append=False to make the user a member of only the specified groups

**Parameters**

- **name**(str) -- user name for which to change groups
- **groups**(list, str) -- a single group or a list of groups to assign to the user
- **append**(bool) -- True adds the passed groups to the user's current groups False sets the user's groups to the passed groups only

**Returns** True if successful. False is unsuccessful.

**Return type** bool

CLI Example:

```
salt '*' user.chgroups jsnuffy Administrators,Users True
```

**salt.modules.win_useradd.chhome(name, home, persist=False)**

Change the home directory of the user, pass True for persist to move files to the new home directory if the old home directory exist.

**Parameters**

- **name**(str) -- name of the user whose home directory you wish to change
- **home**(str) -- new location of the home directory
- **persist**(bool) -- True to move the contents of the existing home directory to the new location

**Returns** True if successful. False is unsuccessful.

**Return type** bool

CLI Example:

```
salt '*' user.chhome foo \fileserver\home\foo True
```

**salt.modules.win_useradd.chprofile(name, profile)**

Change the profile directory of the user
Parameters

- **name** *(str)* -- name of the user whose profile you wish to change

- **profile** *(str)* -- new location of the profile

Returns

True if successful. False is unsuccessful. :rtype: bool

CLI Example:

```
salt '*' user.chprofile foo \\fileserv\profiles\foo
```

**salt.modules.win_useradd.current** *(sam=False)*

Get the username that salt-minion is running under. If salt-minion is running as a service it should return the Local System account. If salt is running from a command prompt it should return the username that started the command prompt.

New in version 2015.5.6.

**Parameters** sam *(bool)* -- False returns just the username without any domain notation. True returns the domain with the username in the SAM format. Ie:

```
domain\username
```

**Returns** Returns False if the username cannot be returned. Otherwise returns the username.

**Return type** bool str

CLI Example:

```
salt '*' user.current
```

**salt.modules.win_useradd.delete** *(name, purge=False, force=False)*

Remove a user from the minion

**Parameters**

- **name** *(str)* -- The name of the user to delete

- **purge** *(bool)* -- Boolean value indicating that the user profile should also be removed when the user account is deleted. If set to True the profile will be removed.

- **force** *(bool)* -- Boolean value indicating that the user account should be deleted even if the user is logged in. True will log the user out and delete user.

**Returns** True if successful

**Return type** bool

CLI Example:

```
salt '*' user.delete name
```

**salt.modules.win_useradd.getUserSid** *(username)*

Get the Security ID for the user

**Parameters** username *(str)* -- user name for which to look up the SID

**Returns** Returns the user SID

**Return type** str

CLI Example:
salt.modules.win_useradd.getent(refresh=False)
Return the list of all info for all users

Parameters
refresh (bool) -- Refresh the cached user information. Default is False. Useful when used from within a state function.

Returns
A dictionary containing information about all users on the system

Return type
dict

CLI Example:
salt '*' user.getent

salt.modules.win_useradd.info(name)
Return user information

Parameters
name (str) -- Username for which to display information

Returns
A dictionary containing user information

- fullname
- username
- SID
- passwd (will always return None)
- comment (same as description, left here for backwards compatibility)
- description
- active
- logonscript
- profile
- home
- homedrive
- groups
- password_changed
- successful_logon_attempts
- failed_logon_attempts
- last_logon
- account_disabled
- account_locked
- password_neverExpires
- disallow_change_password
- gid

Return type
dict
Salt Documentation, Release 2015.8.12

CLI Example:

```bash
salt '*' user.info jsnuffy
```

`salt.modules.win_useradd.list_groups(name)`
Return a list of groups the named user belongs to

- **Parameters** `name (str)` -- user name for which to list groups
- **Returns** list of groups to which the user belongs
- **Return type** `list`

CLI Example:

```bash
salt '*' user.list_groups foo
```

`salt.modules.win_useradd.list_users()`
Return a list of users on Windows

- **Returns** list of users on the system
- **Return type** `list`

CLI Example:

```bash
salt '*' user.list_users
```

`salt.modules.win_useradd.removegroup(name, group)`
Remove user from a group

- **Parameters**
  - `name (str)` -- user name to remove from the group
  - `group (str)` -- name of the group from which to remove the user
- **Returns** True if successful. False is unsuccessful.
- **Return type** `bool`

CLI Example:

```bash
salt '*' user.removegroup jsnuffy 'Power Users'
```

`salt.modules.win_useradd.rename(name, new_name)`
Change the username for a named user

- **Parameters**
  - `name (str)` -- user name to change
  - `new_name (str)` -- the new name for the current user
- **Returns** True if successful. False is unsuccessful.
- **Return type** `bool`

CLI Example:

```bash
salt '*' user.rename jsnuffy jshmoe
```

`salt.modules.win_useradd.setpassword(name, password)`
Set the user's password
Parameters

- name (str) -- user name for which to set the password
- password (str) -- the new password

Returns  True if successful. False is unsuccessful.

Return type  bool

CLI Example:
salt '*' user.setpassword jsnuffy sup3rs3cr3t

salt.modules.win_useradd.update(name, password=None, fullname=None, description=None, home=None, homedrive=None, logonscript=None, profile=None, expiration_date=None, expired=None, account_disabled=None, unlock_account=None, password_never_expires=None, disallow_change_password=None)

Updates settings for the windows user. Name is the only required parameter. Settings will only be changed if the parameter is passed a value.

New in version 2015.8.0.

Parameters

- name (str) -- The user name to update.
- password (str) -- New user password in plain text.
- fullname (str) -- The user’s full name.
- description (str) -- A brief description of the user account.
- home (str) -- The path to the user’s home directory.
- homedrive (str) -- The drive letter to assign to the home directory. Must be the Drive Letter followed by a colon. ie: U:
- logonscript (str) -- The path to the logon script.
- profile (str) -- The path to the user’s profile directory.
- expiration_date (date) -- The date and time when the account expires. Can be a valid date/time string. To set to never expire pass the string ‘Never’.

Parameters expired (bool) -- Pass True to expire the account. The user will be prompted to change their password at the next logon. Pass False to mark the account as ‘not expired’. You can’t use this to negate the expiration if the expiration was caused by the account expiring. You’ll have to change the expiration_date as well.

Parameters account_disabled (bool) -- True disables the account. False enables the account.

Parameters unlock_account (bool) -- True unlocks a locked user account. False is ignored.

Parameters password_never_expires (bool) -- True sets the password to never expire. False allows the password to expire.

Parameters disallow_change_password (bool) -- True blocks the user from changing the password. False allows the user to change the password.
Returns  True if successful. False is unsuccessful.
Return type  bool

CLI Example:
```
salt '*' user.update bob password=secret profile=C:\Users\Bob
    home=\server\homeshare\bob homedrive=U:
```

32.17.319  salt.modules.win_wua

Module for managing Windows Updates using the Windows Update Agent.
New in version 2015.8.0.

depends
  - win32com
  - pythoncom

salt.modules.win_wua.download_update(guid=None)
Downloads a single update

Parameters  guid  -- str A GUID for the update to be downloaded

Returns  A dictionary containing the status, a message, and a list of updates that were downloaded.

CLI Examples:
```
salt '*' win_wua.download_update 12345678-abcd-1234-abcd-1234567890ab
```

salt.modules.win_wua.download_updates(guid=None)
Downloads updates that match the list of passed GUIDs. It's easier to use this function by using list_updates and setting install=True.

Parameters  guid  -- A list of GUIDs to be downloaded

Returns  A dictionary containing the status, a message, and a list of updates that were downloaded.

CLI Examples:
```
# Normal Usage
salt '*' win_wua.download_updates guid=['12345678-abcd-1234-abcd-
    1234567890ab', '87654321-dcba-4321-dcba-ba0987654321']
```

salt.modules.win_wua.get_needs_reboot()
Determines if the system needs to be rebooted.

Returns  bool True if the system requires a reboot, False if not

CLI Examples:
```
salt '*' win_wua.get_needs_reboot
```

salt.modules.win_wua.get_wu_settings()
Get current Windows Update settings.

Returns
  - **Featured Updates**: Boolean value that indicates whether to display notifications for featured updates.
**Group Policy Required (Read-only):** Boolean value that indicates whether Group Policy requires the Automatic Updates service.

**Microsoft Update:** Boolean value that indicates whether to turn on Microsoft Update for other Microsoft Products

**Needs Reboot:** Boolean value that indicates whether the machine is in a reboot pending state.

**Non Admins Elevated:** Boolean value that indicates whether non-administrators can perform some update-related actions without administrator approval.

**Notification Level:**

Number 1 to 4 indicating the update level:
1. Never check for updates
2. Check for updates but let me choose whether to download and install them
3. Download updates but let me choose whether to install them
4. Install updates automatically

**Read Only (Read-only):** Boolean value that indicates whether the Automatic Update settings are read-only.

**Recommended Updates:** Boolean value that indicates whether to include optional or recommended updates when a search for updates and installation of updates is performed.

**Scheduled Day:** Days of the week on which Automatic Updates installs or uninstalls updates.

**Scheduled Time:** Time at which Automatic Updates installs or uninstalls updates.

CLI Examples:

```bash
salt '*' win_wua.get_wu_settings
```

salt.modules.win_wua.install_update(*guid=None*)
Installs a single update

**Parameters** guid -- str A GUID for the update to be installed

**Returns** dict A dictionary containing the details about the installed update

CLI Examples:

```bash
salt '*' win_wua.install_update 12345678-abcd-1234-abcd-1234567890ab
```

salt.modules.win_wua.install_updates(*guid=None*)
Installs updates that match the passed criteria. It may be easier to use the list_updates function and set install=True.

**Parameters** guid -- list A list of GUIDs to be installed

**Returns** dict A dictionary containing the details about the installed updates

CLI Examples:

```bash
# Normal Usage
salt '*' win_wua.install_updates
guid=['12345678-abcd-1234-abcd-1234567890ab', '87654321-dcba-4321-dcba-ba6987654321']
```

salt.modules.win_wua.list_update(*name=None, download=False, install=False*)
Returns details for all updates that match the search criteria
Parameters

- **name (str)** -- The name of the update you're searching for. This can be the GUID (preferred), a KB number, or the full name of the update. Run list_updates to get the GUID for the update you're looking for.

- **download (bool)** -- Download the update returned by this function. Run this function first to see if the update exists, then set download=True to download the update.

- **install (bool)** -- Install the update returned by this function. Run this function first to see if the update exists, then set install=True to install the update. This will override download=True

Returns

Returns a dict containing a list of updates that match the name if download and install are both set to False. Should usually be a single update, but can return multiple if a partial name is given. If download or install is set to true it will return the results of win_wua.download_updates:

```
List of Updates:
{'<GUID>': {'Title': <title>,
            'KB': <KB>,
            'GUID': <the globally unique identifier for the update>
            'Description': <description>,
            'Downloaded': <has the update been downloaded>,
            'Installed': <has the update been installed>,
            'Mandatory': <is the update mandatory>,
            'UserInput': <is user input required>,
            'EULAAccepted': <has the EULA been accepted>,
            'Severity': <update severity>,
            'NeedsReboot': <is the update installed and awaiting reboot>,
            'RebootBehavior': <will the update require a reboot>,
            'Categories': ['<category 1>',
                           '<category 2>',
                           ...
            ]
}
```

Return type  dict

CLI Examples:

```
# Recommended Usage using GUID without braces
# Use this to find the status of a specific update
salt '*' win_wua.list_updates 12345678-abcd-1234-abcd-1234567890ab

# Use the following if you don't know the GUID:

# Using a KB number (could possibly return multiple results)
# Not all updates have an associated KB
salt '*' win_wua.list_updates KB3030298

# Using part or all of the name of the update
# Could possibly return multiple results
# Not all updates have an associated KB
salt '*' win_wua.list_updates 'Microsoft Camera Codec Pack'

salt.modules.win_wua.list_updates(software=True, drivers=False, summary=False, installed=False, categories=None, severities=None, download=False, install=False)
```

32.17. Full list of builtin execution modules 1553
Returns a detailed list of available updates or a summary

Parameters

- `software (bool)` -- Include software updates in the results (default is True)
- `drivers (bool)` -- Include driver updates in the results (default is False)
- `summary (bool)` -- True: Return a summary of updates available for each category. False (default): Return a detailed list of available updates.
- `installed (bool)` -- Include installed updates in the results (default if False)
- `download (bool)` -- (Overrides reporting functionality) Download the list of updates returned by this function. Run this function first to see what will be installed, then set `download=True` to download the updates.
- `install (bool)` -- (Overrides reporting functionality) Install the list of updates returned by this function. Run this function first to see what will be installed, then set `install=True` to install the updates. This will override `download=True`
- `categories (list)` -- Specify the categories to list. Must be passed as a list. All categories returned by default.
  Categories include the following:
  - Critical Updates
  - Definition Updates
  - Drivers (make sure you set `drivers=True`)
  - Feature Packs
  - Security Updates
  - Update Rollups
  - Updates
  - Update Rollups
  - Windows 7
  - Windows 8.1
  - Windows 8.1 drivers
  - Windows 8.1 and later drivers
  - Windows Defender
- `severities (list)` -- Specify the severities to include. Must be passed as a list. All severities returned by default.
  Severities include the following:
  - Critical
  - Important

Returns

Returns a dict containing either a summary or a list of updates:
List of Updates:
{"<GUID>": {'Title': <title>,
  'KB': <KB>,
  'GUID': <the globally unique identifier for the update>,
  'Description': <description>,
  'Downloaded': <has the update been downloaded>,
  'Installed': <has the update been installed>,
  'Mandatory': <is the update mandatory>,
  'UserInput': <is user input required>,
  'EULAAccepted': <has the EULA been accepted>,
  'Severity': <update severity>,
  'NeedsReboot': <is the update installed and awaiting reboot>,
  'RebootBehavior': <will the update require a reboot>,
  'Categories': [ '<category 1>',
    '<category 2>',
    ...
  ]
}
}

Summary of Updates:
{"Total': <total number of updates returned>,
 'Available': <updates that are not downloaded or installed>,
 'Downloaded': <updates that are downloaded but not installed>,
 'Installed': <updates installed (usually 0 unless installed=True)>,
 'Categories': { '<category 1>': <total for that category>,
    '<category 2>': <total for category 2>,
    ...
  }
}

Return type  dict

CLI Examples:

# Normal Usage (list all software updates)
salt '*' win_wua.list_updates

# List all updates with categories of Critical Updates and Drivers
salt '*' win_wua.list_updates categories=['Critical Updates', 'Drivers']

# List all Critical Security Updates
salt '*' win_wua.list_updates categories=['Security Updates'] severities=['Critical']

# List all updates with a severity of Critical
salt '*' win_wua.list_updates severities=['Critical']

# A summary of all available updates
salt '*' win_wua.list_updates summary=True

# A summary of all Feature Packs and Windows 8.1 Updates
salt '*' win_wua.list_updates categories=['Feature Packs', 'Windows 8.1'] summary=True

salt.modules.win_wua.set_wu_settings(level=None, recommended=None, featured=None, elevated=None, msupdate=None, day=None, time=None)

Change Windows Update settings. If no parameters are passed, the current value will be returned.

Parameters
- **level** *(int)* --
  Number from 1 to 4 indicating the update level:
  1. Never check for updates
  2. Check for updates but let me choose whether to download and install them
  3. Download updates but let me choose whether to install them
  4. Install updates automatically

- **recommended** *(bool)* -- Boolean value that indicates whether to include optional or recommended updates when a search for updates and installation of updates is performed.

- **featured** *(bool)* -- Boolean value that indicates whether to display notifications for featured updates.

- **elevated** *(bool)* -- Boolean value that indicates whether non-administrators can perform some update-related actions without administrator approval.

- **msupdate** *(bool)* -- Boolean value that indicates whether to turn on Microsoft Update for other Microsoft products

- **day** *(str)* -- Days of the week on which Automatic Updates installs or uninstalls updates.
  Accepted values: - Everyday - Monday - Tuesday - Wednesday - Thursday - Friday - Saturday

- **time** *(str)* -- Time at which Automatic Updates installs or uninstalls updates. Must be in the #:### 24hr format, eg. 3:00 PM would be 15:00

**Returns**

Returns a dictionary containing the results.

**CLI Examples:**

```
salt '*' win_wua.set_wu_settings level=4 recommended=True featured=False
```

### 32.17.320 salt.modules.x509

Manage X509 certificates

New in version 2015.8.0.

salt.modules.x509.create_certificate(*path=None, text=False, ca_server=None, **kwargs*)

Create an X509 certificate.

**path:** Path to write the certificate to.

**text:** If True, return the PEM text without writing to a file. Default False.

**kwargs:** Any of the properties below can be included as additional keyword arguments.

**ca_server:** Request a remotely signed certificate from ca_server. For this to work, a signing_policy must be specified, and that same policy must be configured on the ca_server. See signing_policy for details. Also the salt master must permit peers to call the sign_remote_certificate function.

Example:

```
/etc/salt/master.d/peer.conf
```

1556 Chapter 32. Reference
subject properties: Any of the values below can be included to set subject properties. Any other subject properties supported by OpenSSL should also work.

- **C**: 2 letter Country code
- **CN**: Certificate common name, typically the FQDN.
- **Email**: Email address
- **GN**: Given Name
- **L**: Locality
- **O**: Organization
- **OU**: Organization Unit
- **SN**: Surname
- **ST**: State or Province

signing_private_key: A path or string of the private key in PEM format that will be used to sign this certificate. If neither signing_cert, public_key, or csr are included, it will be assumed that this is a self-signed certificate, and the public key matching signing_private_key will be used to create the certificate.

signing_cert: A certificate matching the private key that will be used to sign this certificate. This is used to populate the issuer values in the resulting certificate. Do not include this value for self-signed certificates.

public_key: The public key to be included in this certificate. This can be sourced from a public key, certificate, csr or private key. If a private key is used, the matching public key from the private key will be generated before any processing is done. This means you can request a certificate from a remote CA using a private key file as your public key and only the public key will be sent across the network to the CA. If neither public_key or csr are specified, it will be assumed that this is a self-signed certificate, and the public key derived from signing_private_key will be used. Specify either public_key or csr, not both. Because you can input a CSR as a public key or as a CSR, it is important to understand the difference. If you import a CSR as a public key, only the public key will be added to the certificate, subject or extension information in the CSR will be lost.

csr: A file or PEM string containing a certificate signing request. This will be used to supply the subject, extensions and public key of a certificate. Any subject or extensions specified explicitly will overwrite any in the CSR.

basicConstraints: X509v3 Basic Constraints extension.

extensions: The following arguments set X509v3 Extension values. If the value starts with `critical` the extension will be marked as critical.

Some special extensions are subjectKeyId and authorityKeyId.

subjectKeyId can be an explicit value or it can be the special string hash. hash will set the subjectKeyId equal to the SHA1 hash of the modulus of the public key in this certificate. Note that this is not the exact same hashing method used by OpenSSL when using the hash value.

authorityKeyId Use values acceptable to the openssl CLI tools. This will automatically populate authorityKeyId with the subjectKeyId of signing_cert. If this is a self-signed cert these values will be the same.

basicConstraints: X509v3 Basic Constraints

---

32.17. Full list of built-in execution modules
keyUsage: X509v3 Key Usage
extendedKeyUsage: X509v3 Extended Key Usage
subjectKeyIdentifier: X509v3 Subject Key Identifier
issuerAltName: X509v3 Issuer Alternative Name
subjectAltName: X509v3 Subject Alternative Name
crlDistributionPoints: X509v3 CRL distribution points
issuingDistributionPoint: X509v3 Issuing Distribution Point
certificatePolicies: X509v3 Certificate Policies
policyConstraints: X509v3 Policy Constraints
inhibitAnyPolicy: X509v3 Inhibit Any Policy
nameConstraints: X509v3 Name Constraints
noCheck: X509v3 OCSP No Check
nsComment: Netscape Comment
nsCertType: Netscape Certificate Type
days_valid: The number of days this certificate should be valid. This sets the notAfter property of the certificate. Defaults to 365.
version: The version of the X509 certificate. Defaults to 3. This is automatically converted to the version value, so version=3 sets the certificate version field to 0x2.
serial_number: The serial number to assign to this certificate. If omitted a random serial number of size serial_bits is generated.
serial_bits: The number of bits to use when randomly generating a serial number. Defaults to 64.
algorithm: The hashing algorithm to be used for signing this certificate. Defaults to sha256.
copypath: An additional path to copy the resulting certificate to. Can be used to maintain a copy of all certificates issued for revocation purposes.
signing_policy: A signing policy that should be used to create this certificate. Signing policies should be defined in the minion configuration, or in a minion pillar. It should be a yaml formatted list of arguments which will override any arguments passed to this function. If the minions key is included in the signing policy, only minions matching that pattern will be permitted to remotely request certificates from that policy.
Example:

```
x509_signing_policies:
  www:
    - minions: 'www*
    - signing_private_key: /etc/pki/ca.key
    - signing_cert: /etc/pki/ca.crt
    - C: US
    - ST: Utah
    - L: Salt Lake City
    - basicConstraints: "critical CA:false"
    - keyUsage: "critical cRLSign, keyCertSign"
    - subjectKeyIdentifier: hash
    - authorityKeyIdentifier: keyid,issuer:always
    - days_valid: 90
    - copypath: /etc/pki/issued_certs/
```
The above signing policy can be invoked with `signing_policy=www`

CLI Example:

```
salt '*' x509.create_certificate path=/etc/pki/myca.crt
  signing_private_key='/etc/pki/myca.key' csr='/etc/pki/myca.csr'}
```

```
salt.modules.x509.create_crl(path=None, text=False, signing_private_key=None, signing_cert=None, revoked=None, include_expired=False, days_valid=100)
```

Create a CRL

**Depends**
- PyOpenSSL Python module

**path**: Path to write the crl to.

**text**: If True, return the PEM text without writing to a file. Default False.

**signing_private_key**: A path or string of the private key in PEM format that will be used to sign this crl. This is required.

**signing_cert**: A certificate matching the private key that will be used to sign this crl. This is required.

**revoked**: A list of dicts containing all the certificates to revoke. Each dict represents one certificate. A dict must contain either the key `serial_number` with the value of the serial number to revoke, or `certificate` with either the PEM encoded text of the certificate, or a path to the certificate to revoke.

The dict can optionally contain the `revocation_date` key. If this key is omitted the revocation date will be set to now. If should be a string in the format ``%Y-%m-%d %H:%M:%S``.

The dict can also optionally contain the `not_after` key. This is redundant if the `certificate` key is included. If the `Certificate` key is not included, this can be used for the logic behind the `include_expired` parameter. If should be a string in the format ``%Y-%m-%d %H:%M:%S``.

The dict can also optionally contain the `reason` key. This is the reason code for the revocation. Available choices are unspecified, keyCompromise, CACompromise, affiliationChanged, superseded, cessationOfOperation and certificateHold.

**include_expired**: Include expired certificates in the CRL. Default is False.

**days_valid**: The number of days that the CRL should be valid. This sets the Next Update field in the CRL.

CLI Example:

```
salt '*' x509.create_crl path=/etc/pki/mykey.key
  signing_private_key=/etc/pki/ca.
  key
  signing_cert=/etc/pki/ca.crt
  revoked="{'compromized-web-key': {'certificate': '/etc/pki/certs/www1.crt
  
  , 'revocation_date': '2015-03-01 00:00:00'}}"
```

```
salt.modules.x509.create_csr(path=None, text=False, **kwargs)
```

Create a certificate signing request.

**path**: Path to write the certificate to.

**text**: If True, return the PEM text without writing to a file. Default False.

**kwargs**: The subject, extension and version arguments from `x509.create_certificate` can be used.
CLI Example:
```
salt '*' x509.create_csr path=/etc/pki/myca.csr public_key='/etc/pki/myca.key' CN="My Cert"
```

`salt.modules.x509.create_private_key(path=None, text=False, bits=2048)`  
Creates a private key in PEM format.
- path: The path to write the file to, either `path` or `text` are required.
- text: If `True`, return the PEM text without writing to a file. Default `False`.
- bits: Length of the private key in bits. Default 2048

CLI Example:
```
salt '*' x509.create_private_key path=/etc/pki/mykey.key
```

`salt.modules.x509.get_pem_entries(glob_path)`  
Returns a dict containing PEM entries in files matching a glob.
- `glob_path`: A path to certificates to be read and returned.

CLI Example:
```
salt '*' x509.read_pem_entries "/etc/pki/*.crt"
```

`salt.modules.x509.get_pem_entry(text, pem_type=None)`  
Returns a properly formatted PEM string from the input text fixing any whitespace or line-break issues.
- `text`: Text containing the X509 PEM entry to be returned or path to a file containing the text.
- `pem_type`: If specified, this function will only return a pem of a certain type, for example `CERTIFICATE` or `CERTIFICATE REQUEST`.

CLI Example:
```
salt '*' x509.get_pem_entry "-----BEGIN CERTIFICATE REQUEST-----MIICyzCC Ar8CAQI.. "-----END CERTIFICATE REQUEST"
```

`salt.modules.x509.get_private_key_size(private_key)`  
Returns the bit length of a private key in PEM format.
- `private_key`: A path or PEM encoded string containing a private key.

CLI Example:
```
salt '*' x509.get_private_key_size /etc/pki/mycert.key
```

`salt.modules.x509.get_public_key(key, asObj=False)`  
Returns a string containing the public key in PEM format.
- `key`: A path or PEM encoded string containing a CSR, Certificate or Private Key from which a public key can be retrieved.

CLI Example:
```
salt '*' x509.get_public_key /etc/pki/mycert.cer
```

`salt.modules.x509.get_signing_policy(signing_policy_name)`  
Returns the details of a names signing policy, including the text of the public key that will be used to sign it. Does not return the private key.
CLI Example:

```bash
salt '*' x509.get_signing_policy www
```

**salt.modules.x509.read_certificate**(`certificate`)

Returns a dict containing details of a certificate. Input can be a PEM string or file path.

- **certificate**: The certificate to be read. Can be a path to a certificate file, or a string containing the PEM formatted text of the certificate.

CLI Example:

```bash
salt '*' x509.read_certificate /etc/pki/mycert.crt
```

**salt.modules.x509.read_certificates**(`glob_path`)

Returns a dict containing details of a all certificates matching a glob

- **glob_path**: A path to certificates to be read and returned.

CLI Example:

```bash
salt '*' x509.read_certificates "/etc/pki/\.*\.crt"
```

**salt.modules.x509.read_crl**(`crl`)

Returns a dict containing details of a certificate revocation list. Input can be a PEM string or file path.

- **Depends**
  - OpenSSL command line tool

- **crl**: A path or PEM encoded string containing the CSL to read.

CLI Example:

```bash
salt '*' x509.read_crl /etc/pki/mycrl.crl
```

**salt.modules.x509.read_csr**(`csr`)

Returns a dict containing details of a certificate request.

- **Depends**
  - OpenSSL command line tool

- **csr**: A path or PEM encoded string containing the CSR to read.

CLI Example:

```bash
salt '*' x509.read_csr /etc/pki/mycert.csr
```

**salt.modules.x509.sign_remote_certificate**(`argdic`, **kwargs**)

Request a certificate to be remotely signed according to a signing policy.

- **argdic**: A dict containing all the arguments to be passed into the create_certificate function. This will become kwargs when passed to create_certificate.

- **kwargs**: kwargs delivered from publish.publish

CLI Example:

```bash
salt '*' x509.sign_remote_certificate argdic="{'public_key': '/etc/pki/www.key', \
'signing_policy': 'www'}" _pub_id='www1'
```
salt.modules.x509.verify_crl(crl, cert)
Validate a CRL against a certificate. Parses openssl command line output, this is a workaround for M2Crypto's inability to get them from CSR objects.

crl: The CRL to verify
cert: The certificate to verify the CRL against

CLI Example:
```
salt '*' x509.verify_crl crl=/etc/pki/myca.crl cert=/etc/pki/myca.crt
```

salt.modules.x509.verify_private_key(private_key, public_key)
Verify that `private_key' matches `public_key'

private_key: The private key to verify, can be a string or path to a private key in PEM format.
public_key: The public key to verify, can be a string or path to a PEM formatted certificate, csr, or another private key.

CLI Example:
```
salt '*' x509.verify_private_key private_key=/etc/pki/myca.key public_key=/etc/pki/myca.crt
```

salt.modules.x509.verify_signature(certificate, signing_pub_key=None)
Verify that `certificate' has been signed by `signing_pub_key'
certificate: The certificate to verify. Can be a path or string containing a PEM formatted certificate.
signing_pub_key: The public key to verify, can be a string or path to a PEM formatted certificate, csr, or another private key.

CLI Example:
```
salt '*' x509.verify_private_key private_key=/etc/pki/myca.key public_key=/etc/pki/myca.crt
```

salt.modules.x509.write_pem(text, path, pem_type=None)
Writes out a PEM string fixing any formatting or whitespace issues before writing.
text: PEM string input to be written out.
path: Path of the file to write the pem out to.
pem_type: The PEM type to be saved, for example CERTIFICATE or PUBLIC KEY. Adding this will allow the function to take input that may contain multiple pem types.

CLI Example:
```
salt '*' x509.write_pem "-----BEGIN CERTIFICATE-----MIIGMzCCBBugA...
```

### 32.17.321 salt.modules.xapi

This module (mostly) uses the XenAPI to manage Xen virtual machines.

Big fat warning: the XenAPI used in this file is the one bundled with Xen Source, NOT XenServer nor Xen Cloud Platform. As a matter of fact it will fail under those platforms. From what I've read, little work is needed to adapt this code to XS/XCP, mostly playing with XenAPI version, but as XCP is not taking precedence on Xen Source on many platforms, please keep compatibility in mind.
Useful documentation:
- http://docs.vmd.citrix.com/XenServer/6.0.0/1.0/en_gb/api/
- https://github.com/xapi-project/xen-api/tree/master/scripts/examples/python
- http://xenbits.xen.org/gitweb/?p=xen.git;a=tree;f=tools/python/xen/xm;hb=HEAD

```
salt.modules.xapi.create(config_)
    Start a defined domain
    CLI Example:
    ```shell
    salt '*' virt.create <path to Xen cfg file>
    ```

```
salt.modules.xapi.destroy(vm_)
    Hard power down the virtual machine, this is equivalent to pulling the power
    CLI Example:
    ```shell
    salt '*' virt.destroy <vm name>
    ```

```
salt.modules.xapi.freecpu()
    Return an int representing the number of unallocated cpus on this hypervisor
    CLI Example:
    ```shell
    salt '*' virt.freecpu
    ```

```
salt.modules.xapi.freemem()
    Return an int representing the amount of memory that has not been given to virtual machines on this node
    CLI Example:
    ```shell
    salt '*' virt.freemem
    ```

```
salt.modules.xapi.full_info()
    Return the node_info, vm_info and freemem
    CLI Example:
    ```shell
    salt '*' virt.full_info
    ```

```
salt.modules.xapi.get_disks(vm_)
    Return the disks of a named vm
    CLI Example:
    ```shell
    salt '*' virt.get_disks <vm name>
    ```

```
salt.modules.xapi.get_macs(vm_)
    Return a list off MAC addresses from the named vm
    CLI Example:
    ```shell
    salt '*' virt.get_macs <vm name>
    ```

```
salt.modules.xapi.get_nics(vm_)
    Return info about the network interfaces of a named vm
    CLI Example:
    ```shell
salt '*' virt.get_nics <vm name>

salt.modules.xapi.is_hyper()
Returns a bool whether or not this node is a hypervisor of any kind

CLI Example:
salt '*' virt.is_hyper

salt.modules.xapi.list_vms()
Return a list of virtual machine names on the minion

CLI Example:
salt '*' virt.list_vms

salt.modules.xapi.migrate(<vm name>, <target hypervisor>, live=1, port=0, node=-1, ssl=None, change_home_server=0)
Migrates the virtual machine to another hypervisor

CLI Example:
salt '*' virt.migrate <vm name> <target hypervisor> [live] [port] [node] [ssl] [change_home_server]

Optional values:
 live  Use live migration
 port  Use a specified port
 node  Use specified NUMA node on target
 ssl   use ssl connection for migration
 change_home_server  change home server for managed domains

salt.modules.xapi.node_info()
Return a dict with information about this node

CLI Example:
salt '*' virt.node_info

salt.modules.xapi.pause(<vm name>)
Pause the named vm

CLI Example:
salt '*' virt.pause <vm name>

salt.modules.xapi.reboot(<vm name>)
Reboot a domain via ACPI request

CLI Example:
salt '*' virt.reboot <vm name>

salt.modules.xapi.reset(<vm name>)
Reset a VM by emulating the reset button on a physical machine

CLI Example:
```python
salt 'vm' virt.reset <vm name>

salt.modules.xapi.resume(vm_)
Resume the named vm

CLI Example:
salt 'vm' virt.resume <vm name>

salt.modules.xapi.setmem(vm_, memory)
Changes the amount of memory allocated to VM.
Memory is to be specified in MB

CLI Example:
salt 'vm' virt.setmem myvm 768

salt.modules.xapi.setvcpus(vm_, vcpus)
Changes the amount of vcpus allocated to VM.
vcpus is an int representing the number to be assigned

CLI Example:
salt 'vm' virt.setvcpus myvm 2

salt.modules.xapi.shutdown(vm_)
Send a soft shutdown signal to the named vm

CLI Example:
salt 'vm' virt.shutdown <vm name>

salt.modules.xapi.start(config_)
Alias for the obscurely named `create' function

CLI Example:
salt 'vm' virt.start <path to Xen cfg file>

salt.modules.xapi.vcpu_pin(vm_, vcpu, cpus)
Set which CPUs a VCPU can use.

CLI Example:
salt 'foo' virt.vcpu_pin domU-id 2 1
salt 'foo' virt.vcpu_pin domU-id 2 2-6

salt.modules.xapi.vm_cputime(vm_=None)
Return cputime used by the vms on this hyper in a list of dicts:

```
If you pass a VM name in as an argument then it will return info for just the named VM, otherwise it will return all VMs.

CLI Example:
```
salt '*' virt.vm_cputime
```

```
salt.modules.xapi.vm_diskstats(vm_=None)
```

Return disk usage counters used by the vms on this hyper in a list of dicts:
```
[
    'your-vm': {
        'io_read_kbs' : 0,
        'io_write_kbs' : 0
    },
    ...
]
```

If you pass a VM name in as an argument then it will return info for just the named VM, otherwise it will return all VMs.

CLI Example:
```
salt '*' virt.vm_diskstats
```

```
salt.modules.xapi.vm_info(vm_=None)
```

Return detailed information about the vms.

If you pass a VM name in as an argument then it will return info for just the named VM, otherwise it will return all VMs.

CLI Example:
```
salt '*' virt.vm_info
```

```
salt.modules.xapi.vm_netstats(vm_=None)
```

Return combined network counters used by the vms on this hyper in a list of dicts:
```
[
    'your-vm': {
        'io_read_kbs' : 0,
        'io_total_read_kbs' : 0,
        'io_total_write_kbs' : 0,
        'io_write_kbs' : 0
    },
    ...
]
```

If you pass a VM name in as an argument then it will return info for just the named VM, otherwise it will return all VMs.

CLI Example:
```
salt '*' virt.vm_netstats
```

```
salt.modules.xapi.vm_state(vm_=None)
```

Return list of all the vms and their state.

If you pass a VM name in as an argument then it will return info for just the named VM, otherwise it will return all VMs.
32.17.322 salt.modules.xfs

Module for managing XFS file systems.

salt.modules.xfs.defragment(device)

Defragment mounted XFS filesystem. In order to mount a filesystem, device should be properly mounted and writable.

CLI Example:

```
salt '*' xfs.defragment /dev/sda1
```

salt.modules.xfs.devices()

Get known XFS formatted devices on the system.

CLI Example:

```
salt '*' xfs.devices
```

salt.modules.xfs.dump(device, destination, level=0, label=None, noerase=None)

Dump filesystem device to the media (file, tape etc).

Required parameters:

- device: XFS device, content of which to be dumped.
- destination: Specifies a dump destination.

Valid options are:

- label: Label of the dump. Otherwise automatically generated label is used.
- level: Specifies a dump level of 0 to 9.
- noerase: Pre-erase media.

Other options are not used in order to let xfsdump use its default values, as they are most optimal. See the xfsdump(8) manpage for a more complete description of these options.

CLI Example:

```
salt '*' xfs.dump /dev/sda1 /destination/on/the/client
salt '*' xfs.dump /dev/sda1 /destination/on/the/client label='Company accountancy'
salt '*' xfs.dump /dev/sda1 /destination/on/the/client noerase=True
```

salt.modules.xfs.estimate(path)

Estimate the space that an XFS filesystem will take. For each directory estimate the space that directory would take if it were copied to an XFS filesystem. Estimation does not cross mount points.

CLI Example:

```
salt '*' xfs.estimate /path/to/file
salt '*' xfs.estimate /path/to/dir/*
```

salt.modules.xfs.info(device)

Get filesystem geometry information.
CLI Example:

```
salt '*' xfs.info /dev/sda1
```

salt.modules.xfs.inventory()
Display XFS dump inventory without restoration.

CLI Example:

```
salt '*' xfs.inventory
```

salt.modules.xfs.mkfs(device, label=None, ssize=None, noforce=None, bso=None, gmo=None, dso=None, lso=None, nmo=None, rso=None, dso=None, noforce=None, bso=None, gmo=None, dso=None)
Create a file system on the specified device. By default wipes out with force.

General options:
- `label`: Specify volume label.
- `ssize`: Specify the fundamental sector size of the filesystem.
- `noforce`: Do not force create filesystem, if disk is already formatted.

Filesystem geometry options:
- `bso`: Block size options.
- `gmo`: Global metadata options.
- `dso`: Data section options. These options specify the location, size, and other parameters of the data section of the filesystem.
- `ino`: Inode options to specify the inode size of the filesystem, and other inode allocation parameters.
- `lso`: Log section options.
- `nmo`: Naming options.
- `rso`: Realtime section options.

See the `mkfs.xfs(8) manpage` for a more complete description of corresponding options description.

CLI Example:

```
salt '*' xfs.mkfs /dev/sda1
salt '*' xfs.mkfs /dev/sda1 dso='su=32k,sw=6' noforce=True
salt '*' xfs.mkfs /dev/sda1 dso='su=32k,sw=6' lso='logdev=/dev/sda2,size=10000b'
```

salt.modules.xfs.modify(device, label=None, lazy_counting=None, uuid=None)
Modify parameters of an XFS filesystem.

CLI Example:

```
salt '*' xfs.modify /dev/sda1 label='My backup' lazy_counting=False
salt '*' xfs.modify /dev/sda1 uuid=False
salt '*' xfs.modify /dev/sda1 uuid=True
```

salt.modules.xfs.prune_dump(sessionid)
Prunes the dump session identified by the given session id.

CLI Example:

```
salt '*' xfs.prune_dump b74a3586-e52e-4a4a-8775-c3334fa8ea2c
```
32.17.323 salt.modules.xmpp

Module for Sending Messages via XMPP (a.k.a. Jabber)

New in version 2014.1.0.

depends

• sleekxmpp>=1.3.1
• pyasn1
• pyasn1-modules
• dnspython

configuration This module can be used by either passing a jid and password directly to send_message, or by specifying the name of a configuration profile in the minion config, minion pillar, or master config.

For example:

```yaml
my-xmpp-login:
  xmpp.jid: myuser@jabber.example.org/resourcename
  xmpp.password: verybadpass
```

The resourcename refers to the resource that is using this account. It is user-definable, and optional. The following configurations are both valid:

```yaml
my-xmpp-login:
  xmpp.jid: myuser@jabber.example.org/salt
  xmpp.password: verybadpass

my-xmpp-login:
  xmpp.jid: myuser@jabber.example.org
  xmpp.password: verybadpass
```

class salt.modules.xmpp.SendMsgBot(jid, password, recipient, msg)

classmethod create_multi(jid, password, msg, recipients=None, rooms=None, nick='SaltStack Bot')
Alternate constructor that accept multiple recipients and rooms

start(event)

class salt.modules.xmpp.SleekXMPPMUC(name='')

filter(record)

salt.modules.xmpp.send_msg(recipient, message, jid=None, password=None, profile=None)
Send a message to an XMPP recipient. Designed for use in states.

CLI Examples:

```bash
xmpp.send_msg 'admins@xmpp.example.com' 'This is a salt module test'
```

salt.modules.xmpp.send_msg_multi(message, recipients=None, rooms=None, jid=None, password=None, nick='SaltStack Bot', profile=None)

Send a message to an XMPP recipient, support send message to multiple recipients or chat room.
CLI Examples:

```bash
xmpp.send_msg recipients=['admins@xmpp.example.com'] rooms=['secret@conference.xmpp.example.com'] 'This is a salt module test'

xmpp.send_msg recipients=['admins@xmpp.example.com'] rooms=['secret@conference.xmpp.example.com'] 'This is a salt module test'

jid='myuser@xmpp.example.com/salt' password='verybadpass'
```

### 32.17.324 salt.modules.yumpkg

Support for YUM/DNF

**Important:** If you feel that Salt should be using this module to manage packages on a minion, and it is using a different module (or gives an error similar to *pkg.install* is not available), see [here](#).

**Note:** This module makes use of the repoquery utility, from the yum-utils package. This package will be installed as a dependency if salt is installed via EPEL. However, if salt has been installed using pip, or a host is being managed using salt-ssh, then as of version 2014.7.0 yum-utils will be installed automatically to satisfy this dependency.

DNF is fully supported as of version 2015.5.10 and 2015.8.4 (partial support for DNF was initially added in 2015.8.0), and DNF is used automatically in place of YUM in Fedora 22 and newer. For these versions, repoquery is available from the dnf-plugins-core package.

**salt.modules.yumpkg.check_db(names, **kwargs)**

New in version 0.17.0.

Returns a dict containing the following information for each specified package:

1. A key `found`, which will be a boolean value denoting if a match was found in the package database.
2. If `found` is `False`, then a second key called `suggestions` will be present, which will contain a list of possible matches.

The `fromrepo`, `enablerepo` and `disablerepo` arguments are supported, as used in pkg states, and the `disableexcludes` option is also supported. However, in Fedora 22 and newer all of these but `fromrepo` is ignored.

New in version 2014.7.0: Support for the `disableexcludes` option

**CLI Examples:**

```bash
salt '*' pkg.check_db <package1> <package2> <package3>
salt '*' pkg.check_db <package1> <package2> <package3> fromrepo=epel-testing
salt '*' pkg.check_db <package1> <package2> <package3> disableexcludes=main
```

**salt.modules.yumpkg.clean_metadata(**kwargs)**

New in version 2014.1.0.

Cleans local yum metadata. Functionally identical to `refresh_db()`.

**CLI Example:**

```bash
salt '*' pkg.clean_metadata
```
salt.modules.yumpkg.del_repo(repo, basedir=None, **kwargs)
Delete a repo from <basedir> (default basedir: all dirs in reposdir yum option).

If the .repo file in which the repo exists does not contain any other repo configuration, the file itself will be deleted.

CLI Examples:

```
salt '*' pkg.del_repo myrepo
salt '*' pkg.del_repo myrepo basedir=/path/to/dir
salt '*' pkg.del_repo myrepo basedir=/path/to/dir,/path/to/another/dir
```

salt.modules.yumpkg.diff(paths)
Return a formatted diff between current files and original in a package. NOTE: this function includes all files (configuration and not), but does not work on binary content.

**Parameters**

- **path** -- Full path to the installed file

**Returns**

Difference string or raises and exception if examined file is binary.

CLI example:

```
salt '*' pkg.diff /etc/apache2/httpd.conf /etc/sudoers
```

salt.modules.yumpkg.download(*packages)
New in version 2015.5.0.
Download packages to the local disk. Requires yumdownloader from yum-utils package.

**Note:** yum-utils will already be installed on the minion if the package was installed from the Fedora / EPEL repositories.

CLI example:

```
salt '*' pkg.download httpd
salt '*' pkg.download httpd postfix
```

salt.modules.yumpkg.file_dict(*packages)
New in version 2014.1.0.
List the files that belong to a package, grouped by package. Not specifying any packages will return a list of every file on the system's rpm database (not generally recommended).

CLI Examples:

```
salt '*' pkg.file_list httpd
salt '*' pkg.file_list httpd postfix
salt '*' pkg.file_list
```

salt.modules.yumpkg.file_list(*packages)
New in version 2014.1.0.
List the files that belong to a package. Not specifying any packages will return a list of every file on the system's rpm database (not generally recommended).

CLI Examples:

```
salt '*' pkg.file_list httpd
salt '*' pkg.file_list httpd postfix
salt '*' pkg.file_list
```

32.17. Full list of builtin execution modules
salt.modules.yumpkg.get_repo(name, basedir=None, **kwargs)
    Display a repo from <basedir> (default basedir: all dirs in reposdir yum option).

    CLI Examples:
    
    salt '*' pkg.get_repo myrepo
    salt '*' pkg.get_repo myrepo basedir=/path/to/dir
    salt '*' pkg.get_repo myrepo basedir=/path/to/dir,/path/to/another/dir

salt.modules.yumpkg.group_diff(name)
    New in version 2014.1.0.

    Changed in version Boron,2015.8.4,2015.5.10: Environment groups are now supported. The key names have been renamed, similar to the changes made in pkg.group_info.

    Lists packages belonging to a certain group, and which are installed

    CLI Example:
    
    salt '*' pkg.group_diff 'Perl Support'

salt.modules.yumpkg.group_info(name, expand=False)
    New in version 2014.1.0.

    Changed in version Boron,2015.8.4,2015.5.10: The return data has changed. A new key type has been added to distinguish environment groups from package groups. Also, keys for the group name and group ID have been added. The mandatory packages, optional packages, and default packages keys have been renamed to mandatory, optional, and default for accuracy, as environment groups include other groups, and not packages. Finally, this function now properly identifies conditional packages.

    Lists packages belonging to a certain group

    CLI Example:
    
    salt '*' pkg.group_info 'Perl Support'

salt.modules.yumpkg.group_install(name, skip=(), include=(), **kwargs)
    New in version 2014.1.0.

    Install the passed package group(s). This is basically a wrapper around pkg.install, which performs package group resolution for the user. This function is currently considered experimental, and should be expected to undergo changes.

    name  Package group to install. To install more than one group, either use a comma-separated list or pass the value as a python list.

    CLI Examples:
    
    salt '*' pkg.group_install 'Group 1'
    salt '*' pkg.group_install 'Group 1,Group 2'
    salt '*' pkg.group_install ['"Group 1", "Group 2"]'

    skip  Packages that would normally be installed by the package group (``default'' packages), which should not be installed. Can be passed either as a comma-separated list or a python list.

    CLI Examples:
    
    salt '*' pkg.group_install 'My Group' skip='foo,bar'
    salt '*' pkg.group_install 'My Group' skip='["foo", "bar"]'
include Packages which are included in a group, which would not normally be installed by a `yum groupinstall` ("optional" packages). Note that this will not enforce group membership; if you include packages which are not members of the specified groups, they will still be installed. Can be passed either as a comma-separated list or a python list.

CLI Examples:

```shell
salt '*' pkg.group_install 'My Group' include='foo,bar'
salt '*' pkg.group_install 'My Group' include='["foo", "bar"]'
```

Note: Because this is essentially a wrapper around pkg.install, any argument which can be passed to pkg.install may also be included here, and it will be passed along wholesale.

---

**salt.modules.yumpkg.group_list()**

New in version 2014.1.0.

Lists all groups known by yum on this system

CLI Example:

```shell
salt '*' pkg.group_list
```

**salt.modules.yumpkg.hold(name=None, pkgs=None, sources=None, **kwargs)**

New in version 2014.7.0.

Version-lock packages

Note: Requires the appropriate versionlock plugin package to be installed:

- On RHEL 5: `yum-versionlock`
- On RHEL 6 & 7: `yum-plugin-versionlock`
- On Fedora: `python-dnf-plugins-extras-versionlock`

name The name of the package to be held.

Multiple Package Options:

pkgs A list of packages to hold. Must be passed as a python list. The name parameter will be ignored if this option is passed.

Returns a dict containing the changes.

CLI Example:

```shell
salt '*' pkg.hold <package name>
salt '*' pkg.hold pkgs='["foo", "bar"]'
```

**salt.modules.yumpkg.info_installed(**names**)**

Return the information of the named package(s), installed on the system.

CLI example:

```shell
salt '*' pkg.info_installed <package1>
salt '*' pkg.info_installed <package1> <package2> <package3> ...
```
salt.modules.yum_pkg.install(name=None, refresh=False, skip_verify=False, pkgs=None, sources=None, reinstall=False, normalize=True, **kwargs)

Changed in version 2015.8.12, 2016.3.3, Carbon: On minions running systemd>=205, systemctl-run(1) is now used to isolate commands which modify installed packages from the salt-minion daemon's control group. This is done to keep systemd from killing any yum/dnf commands spawned by Salt when the salt-minion service is restarted. (see KillMode in the systemctl.kill(5) manpage for more information). If desired, usage of systemctl-run(1) can be suppressed by setting a config option called systemctl.scope, with a value of False (no quotes).

Install the passed package(s), add refresh=True to clean the yum database before package is installed.

**name** The name of the package to be installed. Note that this parameter is ignored if either \``pkgs`` or \``sources`` is passed. Additionally, please note that this option can only be used to install packages from a software repository. To install a package file manually, use the \``sources`` option.

32-bit packages can be installed on 64-bit systems by appending the architecture designation (.i686, .i586, etc.) to the end of the package name.

CLI Example:

```bash
salt '*' pkg.install <package name>
```

**refresh** Whether or not to update the yum database before executing.

**reinstall** Specifying reinstall=True will use yum reinstall rather than yum install for requested packages that are already installed.

- If a version is specified with the requested package, then yum reinstall will only be used if the installed version matches the requested version.

- Works with sources when the package header of the source can be matched to the name and version of an installed package.

  New in version 2014.7.0.

**skip_verify** Skip the GPG verification check (e.g., --nogpgcheck)

**version** Install a specific version of the package, e.g. 1.2.3-4.el5. Ignored if \``pkgs`` or \``sources`` is passed.

Repository Options:

**fromrepo** Specify a package repository (or repositories) from which to install. (e.g., yum --disablerepo='*' --enablerepo='somerepo')

**enablerepo** (ignored if fromrepo is specified) Specify a disabled package repository (or repositories) to enable. (e.g., yum --enablerepo='somerepo')

**disablerepo** (ignored if fromrepo is specified) Specify an enabled package repository (or repositories) to disable. (e.g., yum --disablerepo='somerepo')

**disableexcludes** Disable exclude from main, for a repo or for everything. (e.g., yum --disableexcludes='main')

  New in version 2014.7.0.

Multiple Package Installation Options:

**pkgs** A list of packages to install from a software repository. Must be passed as a python list. A specific version number can be specified by using a single-element dict representing the package and its version.

CLI Examples:

```bash
salt '*' pkg.install pkgs='["foo", "bar"]'
salt '*' pkg.install pkgs='["foo", {"bar": "1.2.3-4.el5"}]'
```
sources  A list of RPM packages to install. Must be passed as a list of dicts, with the keys being package names, and the values being the source URI or local path to the package.

CLI Example:

```
salt '* pkg.install sources=[{"foo": "salt://foo.rpm"}, {"bar": "salt://bar.rpm"}]'
```

normalize  [True] Normalize the package name by removing the architecture. This is useful for poorly created packages which might include the architecture as an actual part of the name such as kernel modules which match a specific kernel version.

```
salt -G role:nsd pkg.install gpfs.gplbin-2.6.32-279.31.1.el6.x86_64
--normalize=False
```

New in version 2014.7.0.

Returns a dict containing the new package names and versions:

```
{ '<package>': { 'old': '<old-version>', 'new': '<new-version>' }}
```

salt.modules.yumpkg.latest_version(names, **kwargs)

Return the latest version of the named package available for upgrade or installation. If more than one package name is specified, a dict of name/version pairs is returned.

If the latest version of a given package is already installed, an empty string will be returned for that package.

A specific repo can be requested using the fromrepo keyword argument, and the disableexcludes option is also supported.

New in version 2014.7.0: Support for the disableexcludes option

CLI Example:

```
salt '*' pkg.latest_version <package name>
salt '*' pkg.latest_version <package name> fromrepo=epel-testing
salt '*' pkg.latest_version <package name> disableexcludes=main
salt '*' pkg.latest_version <package1> <package2> <package3> ...
```

salt.modules.yumpkg.list_holds(pattern='\w+(?:[-][^\^-]+)*', full=True)

Changed in version Boron,2015.8.4,2015.5.10: Function renamed from pkg.get_locked_pkgs to pkg.list_holds.

List information on locked packages

Note: Requires the appropriate versionlock plugin package to be installed:

- On RHEL 5: yum-versionlock
- On RHEL 6 & 7: yum-plugin-versionlock
- On Fedora: python-dnf-plugins-extras-versionlock

```
pattern '[\w+(?:[-][^\^-]+)]*' Regular expression used to match the package name
full [True] Show the full hold definition including version and epoch. Set to False to return just the name of the package(s) being held.
```
CLI Example:
```
salt '*' pkg.list_holds
salt '*' pkg.list_holds full=False
```

```
salt.modules.yumpkg.list_pkgs(versions_as_list=False, **kwargs)
```

List the packages currently installed in a dict:

```
{'<package_name>': '<version>'}
```

CLI Example:
```
salt '*' pkg.list_pkgs
```

```
salt.modules.yumpkg.list_repo_pkgs(*args, **kwargs)
```

New in version 2014.1.0.

Changed in version 2014.7.0: All available versions of each package are now returned. This required a slight modification to the structure of the return dict. The return data shown below reflects the updated return dict structure. Note that packages which are version-locked using `pkg.hold` will only show the currently-installed version, as locking a package will make other versions appear unavailable to yum/dnf.

Returns all available packages. Optionally, package names (and name globs) can be passed and the results will be filtered to packages matching those names. This is recommended as it speeds up the function considerably.

**Warning:** Running this function on RHEL/CentOS 6 and earlier will be more resource-intensive, as the version of yum that ships with older RHEL/CentOS has no yum subcommand for listing packages from a repository. Thus, a `yum list installed` and `yum list available` are run, which generates a lot of output, which must then be analyzed to determine which package information to include in the return data.

This function can be helpful in discovering the version or repo to specify in a `pkg.installed` state.

The return data is a dictionary of repo names, with each repo containing a dictionary in which the keys are package names, and the values are a list of version numbers. Here is an example of the return data:

```
{
    'base': {
        'bash': ['4.1.2-15.el6_4'],
        'kernel': ['2.6.32-431.el6']
    },
    'updates': {
        'bash': ['4.1.2-15.el6_5.2', '4.1.2-15.el6_5.1'],
        'kernel': ['2.6.32-431.29.2.el6',
                   '2.6.32-431.23.3.el6',
                   '2.6.32-431.20.5.el6',
                   '2.6.32-431.20.3.el6',
                   '2.6.32-431.17.1.el6',
                   '2.6.32-431.11.2.el6',
                   '2.6.32-431.5.1.el6',
                   '2.6.32-431.3.1.el6',
                   '2.6.32-431.1.2.0.1.el6']
    }
}
```

```
fromrepo [None] Only include results from the specified repo(s). Multiple repos can be specified, comma-separated.
```
**CLI Example:**

```
salt '*' pkg.list_repo_pkgs
salt '*' pkg.list_repo_pkgs foo bar baz
salt '*' pkg.list_repo_pkgs 'samba4*' fromrepo=base,updates
```

salt.modules.yumpkg.list_repos *(basedir=*

Lists all repos in <basedir> (default: all dirs in reposdir yum option).

**CLI Example:**

```
salt '*' pkg.list_repos
salt '*' pkg.list_repos basedir=/path/to/dir
salt '*' pkg.list_repos basedir=/path/to/dir,/path/to/another/dir
```

salt.modules.yumpkg.list_upgrades *(refresh=True, **kwargs)*

Check whether or not an upgrade is available for all packages

The fromrepo, enablerepo, and disablerepo arguments are supported, as used in pkg states, and the disableexcludes option is also supported. However, in Fedora 22 and newer all of these but fromrepo is ignored.

New in version 2014.7.0: Support for the disableexcludes option

**CLI Example:**

```
salt '*' pkg.list_upgrades
```

salt.modules.yumpkg.mod_repo *(repo, basedir=None, **kwargs)*

Modify one or more values for a repo. If the repo does not exist, it will be created, so long as the following values are specified:

- **repo** name by which the yum refers to the repo
- **name** a human-readable name for the repo
- **baseurl** the URL for yum to reference
- **mirrorlist** the URL for yum to reference

Key/Value pairs may also be removed from a repo's configuration by setting a key to a blank value. Bear in mind that a name cannot be deleted, and a baseurl can only be deleted if a mirrorlist is specified (or vice versa).

**CLI Examples:**

```
salt '*' pkg.mod_repo reponame enabled=1 gpgcheck=1
salt '*' pkg.mod_repo reponame basedir=/path/to/dir enabled=1
salt '*' pkg.mod_repo reponame basedir= mirrorlist=http://host.com/
```

salt.modules.yumpkg.modified *(packages, **flags)*

List the modified files that belong to a package. Not specifying any packages will return a list of _all_ modified files on the system's RPM database.

New in version 2015.5.0.

Filtering by flags (True or False):

- **size** Include only files where size changed.
- **mode** Include only files which file's mode has been changed.
- **checksum** Include only files which MD5 checksum has been changed.
- **device** Include only files which major and minor numbers has been changed.
symlink  Include only files which are symbolic link contents.
owner   Include only files where owner has been changed.
group   Include only files where group has been changed.
time    Include only files where modification time of the file has been changed.
capabilities Include only files where capabilities differ or not. Note: supported only on newer RPM versions.

CLI Examples:

```bash
salt '*' pkg.modified
salt '*' pkg.modified httpd
salt '*' pkg.modified httpd postfix
salt '*' pkg.modified httpd owner=True group=False
```
Salt Documentation, Release 2015.8.12

CLI Example:

```bash
salt '*' pkg.purge <package name>
salt '*' pkg.purge <package1>,<package2>,<package3>
salt '*' pkg.purge pkgs='["foo", "bar"]'
```

`salt.modules.yumpkg.refresh_db(**kwargs)`

Check the yum repos for updated packages

Returns:

- **True**: Updates are available
- **False**: An error occurred
- **None**: No updates are available

**repo** Refresh just the specified repo

**disablerrepo** Do not refresh the specified repo

**enablerrepo** Refesh a disabled repo using this option

**branch** Add the specified branch when refreshing

**disableexcludes** Disable the excludes defined in your config files. Takes one of three options: - **all** - disable all excludes - **main** - disable excludes defined in [main] in yum.conf - **repoid** - disable excludes defined for that repo

CLI Example:

```bash
salt '*' pkg.refresh_db
```

`salt.modules.yumpkg.remove(name=None, pkgs=None, **kwargs)`

Changed in version 2015.8.12,2016.3.3,Carbon: On minions running systemd>=205, systemd-run(1) is now used to isolate commands which modify installed packages from the salt-minion daemon's control group. This is done to keep systemd from killing any yum/dnf commands spawned by Salt when the salt-minion service is restarted. (see KillMode in the systemd.kill(5) manpage for more information). If desired, usage of systemd-run(1) can be suppressed by setting a config option called systemd.scope, with a value of False (no quotes).

Remove packages

**name** The name of the package to be removed

Multiple Package Options:

**pkgs** A list of packages to delete. Must be passed as a python list. The name parameter will be ignored if this option is passed.

New in version 0.16.0.

Returns a dict containing the changes.

CLI Example:

```bash
salt '*' pkg.remove <package name>
salt '*' pkg.remove <package1>,<package2>,<package3>
salt '*' pkg.remove pkgs='["foo", "bar"]'
```

`salt.modules.yumpkg.unhold(name=None, pkgs=None, sources=None, **kwargs)`

New in version 2014.7.0.
Remove version locks

**Note:** Requires the appropriate `versionlock` plugin package to be installed:

- On RHEL 5: `yum-versionlock`
- On RHEL 6 & 7: `yum-plugin-versionlock`
- On Fedora: `python-dnf-plugins-extras-versionlock`

**name**  The name of the package to be unheld

Multiple Package Options:

**pkgs**  A list of packages to unhold. Must be passed as a python list. The `name` parameter will be ignored if this option is passed.

Returns a dict containing the changes.

CLI Example:

```bash
salt '*' pkg.unhold <package name>
salt '*' pkg.unhold pkgs=['"foo", "bar"]
```

```python
salt.modules.yumpkg.upgrade(refresh=True, skip_verify=False, **kwargs)
```

Changed in version 2014.7.0.

Changed in version 2015.8.12, 2016.3.3, Carbon: On minions running systemd>=205, `systemd-run(1)` is now used to isolate commands which modify installed packages from the `salt-minion` daemon's control group.

This is done to keep systemd from killing any yum/dnf commands spawned by Salt when the `salt-minion` service is restarted. (see `KillMode` in the `systemd.kill(5)` manpage for more information).

If desired, usage of `systemd-run(1)` can be suppressed by setting a config option called `systemd.scope`, with a value of `False` (no quotes).

Run a full system upgrade, a yum upgrade

Return a dict containing the new package names and versions:

```json
{'<package>': {'old': '<old-version>', 'new': '<new-version>'}}
```

CLI Example:

```bash
salt '*' pkg.upgrade
```

Repository Options:

**fromrepo**  Specify a package repository (or repositories) from which to install. (e.g., `yum --disablerepo='*' --enablerepo='somerepo'`)

**enablerepo** (ignored if **fromrepo** is specified)  Specify a disabled package repository (or repositories) to enable. (e.g., `yum --enablerepo='somerepo'`)

**disablerepo** (ignored if **fromrepo** is specified)  Specify an enabled package repository (or repositories) to disable. (e.g., `yum --disablerepo='somerepo'`)

**disableexcludes**  Disable exclude from main, for a repo or for everything. (e.g., `yum --disableexcludes='main'`)
salt.modules.yumpkg.upgrade_available(name)
    Check whether or not an upgrade is available for a given package

    CLI Example:
    
    salt '*' pkg.upgrade_available <package name>

salt.modules.yumpkg.verify('names', **kwargs)
    New in version 2014.1.0.
    Runs an rpm -Va on a system, and returns the results in a dict
    Files with an attribute of config, doc, ghost, license or readme in the package header can be ignored using the
    ignore_types keyword argument

    CLI Example:
    
    salt '*' pkg.verify
    salt '*' pkg.verify httpd
    salt '*' pkg.verify 'httpd postfix'
    salt '*' pkg.verify 'httpd postfix' ignore_types=['config', 'doc']

salt.modules.yumpkg.version('names', **kwargs)
    Returns a string representing the package version or an empty string if not installed. If more than one package
    name is specified, a dict of name/version pairs is returned.

    CLI Example:
    
    salt '*' pkg.version <package name>
    salt '*' pkg.version <package1> <package2> <package3> ...

salt.modules.yumpkg.version_cmp(pkg1, pkg2, ignore_epoch=False)
    New in version 2015.5.4.
    Do a cmp-style comparison on two packages. Return -1 if pkg1 < pkg2, 0 if pkg1 == pkg2, and 1 if pkg1 > pkg2. Return None if there was a problem making the comparison.
    ignore_epoch [False] Set to True to ignore the epoch when comparing versions

    New in version 2015.8.10, 2016.3.2.

    CLI Example:
    
    salt '*' pkg.version_cmp '0.2-001' '0.2.0.1-002'

32.17.325 salt.modules.zcbuildout

Management of zc.buildout

New in version 2014.1.0.

This module is inspired by minitgage's buildout maker

Note: The zc.buildout integration is still in beta; the API is subject to change
General notes

You have those following methods:

- upgrade_bootstrap
- bootstrap
- run_buildout
- buildout

```python
salt.modules.zcbuildout.bootstrap(*a, **kw)
```

Run the buildout bootstrap dance (python bootstrap.py).

- `directory` directory to execute in
- `config` alternative buildout configuration file to use
- `runas` User used to run buildout as
- `env` environment variables to set when running
- `buildout_ver` force a specific buildout version (1 | 2)
- `test_release` buildout accept test release
- `offline` are we executing buildout in offline mode
- `distribute` Forcing use of distribute
- `new_st` Forcing use of setuptools >= 0.7
- `python` path to a python executable to use in place of default (salt one)
- `onlyif` Only execute cmd if statement on the host return 0
- `unless` Do not execute cmd if statement on the host return 0
- `use_vt` Use the new salt VT to stream output [experimental]

CLI Example:

```
salt '*' buildout.bootstrap /srv/mybuildout
```

```python
salt.modules.zcbuildout.buildout(*a, **kw)
```

Run buildout in a directory.

- `directory` directory to execute in
- `config` buildout config to use
- `parts` specific buildout parts to run
- `runas` user used to run buildout as
- `env` environment variables to set when running
- `buildout_ver` force a specific buildout version (1 | 2)
- `test_release` buildout accept test release
- `new_st` Forcing use of setuptools >= 0.7
- `distribute` use distribute over setuptools if possible
- `offline` does buildout run offline
- `python` python to use
debug run buildout with -D debug flag
onlyif Only execute cmd if statement on the host return 0
unless Do not execute cmd if statement on the host return 0
newest run buildout in newest mode
verbose run buildout in verbose mode (-vvvvv)
use_vt Use the new salt VT to stream output [experimental]

CLI Example:

```bash
salt '*' buildout.buildout /srv/mybuildout
```

```
salt.modules.zcbuildout.run_buildout(*a,**kw)
Run a buildout in a directory.

directory directory to execute in
config alternative buildout configuration file to use
offline are we executing buildout in offline mode
runas user used to run buildout as
env environment variables to set when running
onlyif Only execute cmd if statement on the host return 0
unless Do not execute cmd if statement on the host return 0
newest run buildout in newest mode
force run buildout unconditionally
verbose run buildout in verbose mode (-vvvvv)
use_vt Use the new salt VT to stream output [experimental]

CLI Example:

```bash
salt '*' buildout.run_buildout /srv/mybuildout
```

```
salt.modules.zcbuildout.upgrade_bootstrap(*a,**kw)
Upgrade current bootstrap.py with the last released one.

Indeed, when we first run a buildout, a common source of problem is to have a locally stale bootstrap, we just try to grab a new copy

directory directory to execute in
offline are we executing buildout in offline mode
buildout_ver forcing to use a specific buildout version (1 | 2)
onlyif Only execute cmd if statement on the host return 0
unless Do not execute cmd if statement on the host return 0

CLI Example:

```bash
salt '*' buildout.upgrade_bootstrap /srv/mybuildout
```
32.17.326 salt.modules.zfs

Salt interface to ZFS commands

codeauthor Nitin Madhok <nmadhok@clemson.edu>
salt.modules.zfs.create(name, **kwargs)
    New in version 2015.5.0.
    Create a ZFS File System.
    CLI Example:
    ```
salt '*' zfs.create myzpool/mydataset [create_parent=True|False]
```

Note: ZFS properties can be specified at the time of creation of the filesystem by passing an additional argument called ``properties'' and specifying the properties with their respective values in the form of a python dictionary:

```
properties={"property1": 'value1', 'property2': 'value2'}
```

Example:

```
salt '*' zfs.create myzpool/mydataset properties="{'mountpoint': '/export/zfs', 'sharenfs': 'on'}"
```

salt.modules.zfs.destroy(name, **kwargs)
    New in version 2015.5.0.
    Destroy a ZFS File System.
    CLI Example:
    ```
salt '*' zfs.destroy myzpool/mydataset [force=True|False]
```

salt.modules.zfs.exists(name)
    New in version 2015.5.0.
    Check if a ZFS filesystem or volume or snapshot exists.
    CLI Example:
    ```
salt '*' zfs.exists myzpool/mydataset
```

salt.modules.zfs.list(name='``', **kwargs)
    New in version 2015.5.0.
    Return a list of all datasets or a specified dataset on the system and the values of their used, available, referenced, and mountpoint properties.

Note: Information about the dataset and all of it's descendent datasets can be displayed by passing recursive=True on the CLI.

CLI Example:

```
salt '*' zfs.list [recursive=True|False]
salt '*' zfs.list /myzpool/mydataset [recursive=True|False]
```
Note: Dataset property value output can be customized by passing an additional argument called "properties" in the form of a python list:

```
properties="[property1, property2, property3]"
```

Example:

```
salt '*' zfs.list /myzpool/mydataset properties="[name, sharenfs, mountpoint]"
```

salt.modules.zfs.rename(name, new_name)

New in version 2015.5.0.

Rename or Relocate a ZFS File System.

CLI Example:

```
salt '*' zfs.rename myzpool/mydataset myzpool/renameddataset
```

32.17.327 salt.modules.zk_concurrency

Concurrency controls in zookeeper

This module allows you to acquire and release a slot. This is primarily useful for ensuring that no more than N hosts take a specific action at once. This can also be used to coordinate between masters.

salt.modules.zk_concurrency.lock(path, zk_hosts, identifier=None, max_concurrency=1, timeout=None, ephemeral_lease=False, force=False)

- Get lock (with optional timeout)
- **path** The path in zookeeper where the lock is
- **zk_hosts** zookeeper connect string
- **identifier** Name to identify this minion
- **max_concurrency** Maximum number of lock holders
- **timeout** timeout to wait for the lock. A None timeout will block forever
- **ephemeral_lease** Whether the locks in zookeeper should be ephemeral
- **force** Forcibly acquire the lock regardless of available slots

Example:

... code-block: bash

```
salt minion zk_concurrency.lock /lock/path host1:1234,host2:1234
```

salt.modules.zk_concurrency.lock_holders(path, zk_hosts, identifier=None, max_concurrency=1, timeout=None, ephemeral_lease=False)

- Return an un-ordered list of lock holders
- **path** The path in zookeeper where the lock is
- **zk_hosts** zookeeper connect string
- **identifier** Name to identify this minion
max_concurrency Maximum number of lock holders

timeout timeout to wait for the lock. A None timeout will block forever

ephemeral lease Whether the locks in zookeeper should be ephemeral

Example:
... code-block: bash
   salt minion zk_concurrency.lock_holders /lock/path host1:1234,host2:1234

salt.modules.zk_concurrency.party_members(path, zk_hosts)
Get the List of identifiers in a particular party

path The path in zookeeper where the lock is

zk_hosts zookeeper connect string

Example:
... code-block: bash
   salt minion zk_concurrency.party_members /lock/path host1:1234,host2:1234

salt.modules.zk_concurrency.unlock(path, zk_hosts=None, identifier=None, max_concurrency=1, ephemeral_lease=False)
Remove lease from semaphore

path The path in zookeeper where the lock is

zk_hosts zookeeper connect string

identifier Name to identify this minion

max_concurrency Maximum number of lock holders

timeout timeout to wait for the lock. A None timeout will block forever

ephemeral lease Whether the locks in zookeeper should be ephemeral

Example:
... code-block: bash
   salt minion zk_concurrency.unlock /lock/path host1:1234,host2:1234

32.17.328 salt.modules.znc

znc - An advanced IRC bouncer

New in version 2014.7.0.

Provides an interface to basic ZNC functionality

salt.modules.znc.buildmod(*modules)
Build module using znc-buildmod

   CLI Example:

   salt '*' znc.buildmod module.cpp [...]  

salt.modules.znc.dumpconf()
Write the active configuration state to config file

   CLI Example:
salt '*/' znc.dumpconf

salt.modules.znc.rehashconf()
    Rehash the active configuration state from config file
    CLI Example:
    salt '*' znc.rehashconf

salt.modules.znc.version()
    Return server version from znc --version
    CLI Example:
    salt '*' znc.version

32.17.329  salt.modules.zpool

Module for running ZFS zpool command

codeauthor Nitin Madhok <nmadhok@clemson.edu>

salt.modules.zpool.add(pool_name, *vdevs)
    Add the specified vdev's to the given pool
    CLI Example:
    salt '*' zpool.add myzpool /path/to/vdev1 /path/to/vdev2 [...]

salt.modules.zpool.create(pool_name, *vdevs, **kwargs)
    New in version 2015.5.0.
    Create a simple zpool, a mirrored zpool, a zpool having nested VDEVs, a hybrid zpool with cache, spare and log drives or a zpool with RAIDZ-1, RAIDZ-2 or RAIDZ-3
    CLI Example:
    salt '*' zpool.create myzpool /path/to/vdev1 [...]
    salt '*' zpool.create myzpool mirror /path/to/vdev1 /path/to/vdev2 [...]
    salt '*' zpool.create myzpool raidz1 /path/to/vdev1 /path/to/vdev2 raidz2 /path/to/vdev3 /path/to/vdev4 /path/to/vdev5 [...]
    salt '*' zpool.create myzpool mirror /path/to/vdev1 [...]
    mirror /path/to/vdev2 [...]
    salt '*' zpool.create myzybhopool mirror /tmp/file1 [...]
    log mirror /path/to/vdev1 [...]
    cache /path/to/vdev2 [...]
    spare /path/to/vdev3 [...]

Note:  Zpool properties can be specified at the time of creation of the pool by passing an additional argument called `properties` and specifying the properties with their respective values in the form of a python dictionary:

properties="{"property1": 'value1', 'property2': 'value2'}"

Example:
salt.modules.zpool.create myzpool /path/to/vdev1 [...] properties="{"property1": "value1", "property2": "value2"}"

**salt.modules.zpool.create_file_vdev(size, *vdevs)**

Creates file based virtual devices for a zpool

* *vdevs* is a list of full paths for mkfile to create

CLI Example:

```
salt '*' zpool.create_file_vdev 7g /path/to/vdev1 [/path/to/vdev2] [...]```

*Note:* Depending on file size, the above command may take a while to return.

**salt.modules.zpool.destroy(pool_name)**

Destroys a storage pool

CLI Example:

```
salt '*' zpool.destroy myzpool```

**salt.modules.zpool.exists(pool_name)**

Check if a ZFS storage pool is active

CLI Example:

```
salt '*' zpool.exists myzpool```

**salt.modules.zpool.export(*pools, **kwargs)**

New in version 2015.5.0.

Export storage pools

CLI Example:

```
salt '*' zpool.export myzpool ... [force=True|False]
salt '*' zpool.export myzpool2 myzpool2 ... [force=True|False]```

**salt.modules.zpool.import(pool_name='`, new_name='`, **kwargs)**

New in version 2015.5.0.

Import storage pools or list pools available for import

CLI Example:

```
salt '*' zpool.import [all=True|False]
salt '*' zpool.import myzpool [mynewzpool] [force=True|False]```

**salt.modules.zpool.iostat(name='*)**

Display I/O statistics for the given pools

CLI Example:

```
salt '*' zpool.iostat myzpool```

**salt.modules.zpool.list()**

New in version 2015.5.0.
Return a list of all pools in the system with health status and space usage

CLI Example:

```
salt '*' zpool.list
```

**salt.modules.zpool.offline** *(pool_name, *vdevs, **kwargs)*

New in version 2015.5.0.

Ensure that the specified devices are offline

**Warning:** By default, the OFFLINE state is persistent. The device remains offline when the system is rebooted. To temporarily take a device offline, use `temporary=True`.

CLI Example:

```
salt '*' zpool.offline myzpool /path/to/vdev1 [...] [temporary=True|False]
```

**salt.modules.zpool.online** *(pool_name, *vdevs, **kwargs)*

New in version 2015.5.0.

Ensure that the specified devices are online

CLI Example:

```
salt '*' zpool.online myzpool /path/to/vdev1 [...] 
```

**salt.modules.zpool.replace** *(pool_name, old, new)*

Replaces old device with new device.

CLI Example:

```
salt '*' zpool.replace myzpool /path/to/vdev1 /path/to/vdev2
```

**salt.modules.zpool.scrub** *(pool_name=None)*

Begin a scrub

CLI Example:

```
salt '*' zpool.scrub myzpool
```

**salt.modules.zpool.status** *(name='')*

Return the status of the named zpool

CLI Example:

```
salt '*' zpool.status myzpool
```

**salt.modules.zpool.zpool_list** *

Deprecated since version 2014.7.0: Use `list_()` instead.

Return a list of all pools in the system with health status and space usage

CLI Example:

```
salt '*' zpool.zpool_list
```
32.17.330  salt.modules.zypper

Package support for openSUSE via the zypper package manager

    depends

    • rpm Python module. Install with zypper install rpm-python

**Important:** If you feel that Salt should be using this module to manage packages on a minion, and it is using a different module (or gives an error similar to `pkg.install' is not available), see [here](#).

salt.modules.zypper.add_lock(packages, **kwargs)

Add a package lock. Specify packages to lock by exact name.

CLI Example:

```
salt '*' pkg.add_lock <package_name>
salt '*' pkg.add_lock <package1>,<package2>,<package3>
salt '*' pkg.add_lock pkgs=['"foo", "bar"']
```

salt.modules.zypper.clean_locks()

Remove unused locks that do not currently (with regard to repositories used) lock any package.

CLI Example:

```
salt '*' pkg.clean_locks
```

salt.modules.zypper.del_repo(repo)

Delete a repo.

CLI Examples:

```
salt '*' pkg.del_repo alias
```

salt.modules.zypper.diff(*paths)

Return a formatted diff between current files and original in a package. NOTE: this function includes all files (configuration and not), but does not work on binary content.

**Parameters** path -- Full path to the installed file

**Returns** Difference string or raises and exception if examined file is binary.

CLI example:

```
salt '*' pkg.diff /etc/apache2/httpd.conf /etc/sudoers
```

salt.modules.zypper.download(*packages, **kwargs)

Download packages to the local disk.

**refresh** force a refresh if set to True. If set to False (default) it depends on zypper if a refresh is executed.

CLI example:

```
salt '*' pkg.download httpd
salt '*' pkg.download httpd postfix
```

salt.modules.zypper.file_dict(*packages)

List the files that belong to a package, grouped by package. Not specifying any packages will return a list of every file on the system's rpm database (not generally recommended).
CLI Examples:

```shell
salt '*' pkg.file_list httpd
salt '*' pkg.file_list httpd postfix
salt '*' pkg.file_list
```

**salt.modules.zypper.file_list**(*packages*)
List the files that belong to a package. Not specifying any packages will return a list of every file on the system’s rpm database (not generally recommended).

CLI Examples:

```shell
salt '*' pkg.file_list httpd
salt '*' pkg.file_list httpd postfix
salt '*' pkg.file_list
```

**salt.modules.zypper.get_repo**(*repo, **kwargs*)
Display a repo.

CLI Example:

```shell
salt '*' pkg.get_repo alias
```

**salt.modules.zypper.info**(*names, **kwargs*)
Deprecated since version Nitrogen: Use info_available() instead.
Return the information of the named package available for the system.

CLI example:

```shell
salt '*' pkg.info <package1>
salt '*' pkg.info <package1> <package2> <package3> ...
```

**salt.modules.zypper.info_available**(*names, **kwargs*)
Return the information of the named package available for the system.

- **refresh** force a refresh if set to True (default). If set to False it depends on zypper if a refresh is executed or not.

CLI example:

```shell
salt '*' pkg.info_available <package1>
salt '*' pkg.info_available <package1> <package2> <package3> ...
```

**salt.modules.zypper.info_installed**(*names, **kwargs*)
Return the information of the named package(s), installed on the system.

**Parameters**

- **names** -- Names of the packages to get information about.
- **attr** -- Comma-separated package attributes. If no `attr` is specified, all available attributes returned.

Valid attributes are: version, vendor, release, build_date, build_date_time_t, install_date, install_date_time_t, build_host, group, source_rpm, arch, epoch, size, license, signature, packager, url, summary, description.

- **errors** -- Handle RPM field errors (true|false). By default, various mistakes in the textual fields are simply ignored and omitted from the data. Otherwise a field with a mistake is not returned, instead a `N/A (bad UTF-8)` (not available, broken) text is returned.
Valid attributes are: ignore, report

CLI example:

```bash
salt '*' pkg.info_installed <package1>
salt '*' pkg.info_installed <package1> <package2> <package3> ...
salt '*' pkg.info_installed <package1> attr=version,vendor
~attr=version,vendor
salt '*' pkg.info_installed <package1> <package2> <package3> ...
~attr=version,vendor errors=true
```

```
salt.modules.zypper.install(name=None, refresh=False, fromrepo=None, pkgs=None, sources=None, 
downloadonly=False, version=None, ignore_repo_failure=False, 
**kwargs)
```

Changed in version 2015.8.12,2016.3.3,Carbon: On minions running systemd>=205, `systemd-run(1)` is now used to isolate commands which modify installed packages from the `salt-minion` daemon's control group. This is done to keep systemd from killing any zypper commands spawned by Salt when the `salt-minion` service is restarted. (see `KillMode` in the `systemd.kill(5)` manpage for more information). If desired, usage of `systemd-run(1)` can be suppressed by setting a `config option` called `systemd.scope`, with a value of `False` (no quotes).

Install the passed package(s), add `refresh=True` to force a `zypper refresh` before package is installed.

**name**  The name of the package to be installed. Note that this parameter is ignored if either `pkgs` or `sources` is passed. Additionally, please note that this option can only be used to install packages from a software repository. To install a package file manually, use the `sources` option.

CLI Example:

```bash
salt '*' pkg.install <package name>
```

**refresh**  force a refresh if set to True. If set to False (default) it depends on zypper if a refresh is executed.

**fromrepo**  Specify a package repository to install from.

**downloadonly**  Only download the packages, do not install.

**version**  Can be either a version number, or the combination of a comparison operator (<, >, <=, >=, =) and a version number (ex. `>1.2.3-4`). This parameter is ignored if `pkgs` or `sources` is passed.

Multiple Package Installation Options:

**pkgs**  A list of packages to install from a software repository. Must be passed as a python list. A specific version number can be specified by using a single-element dict representing the package and its version. As with the `version` parameter above, comparison operators can be used to target a specific version of a package.

CLI Examples:

```bash
salt '*' pkg.install pkgs='["foo", "bar"]'
salt '*' pkg.install pkgs='["foo", {"bar": "1.2.3-4"}]'
salt '*' pkg.install pkgs='["foo", {"bar": "<1.2.3-4"}]'
```

**sources**  A list of RPM packages to install. Must be passed as a list of dicts, with the keys being package names, and the values being the source URI or local path to the package.

CLI Example:

```bash
salt '*' pkg.install sources='[{"foo": "salt://foo.rpm"},{"bar": "salt://bar.rpm"}]'
```
**ignore_repo_failure**  Zypper returns error code 106 if one of the repositories are not available for various reasons. In case to set strict check, this parameter needs to be set to True. Default: False.

Returns a dict containing the new package names and versions:

```python
{'<package>': {'old': '<old-version>', 'new': '<new-version>'}}
```

### `salt.modules.zypper.latest_version(*names, **kwargs)`

Return the latest version of the named package available for upgrade or installation. If more than one package name is specified, a dict of name/version pairs is returned.

If the latest version of a given package is already installed, an empty dict will be returned for that package.

**refresh** force a refresh if set to True (default). If set to False it depends on zypper if a refresh is executed or not.

CLI example:

```bash
salt '*' pkg.latest_version <package name>
salt '*' pkg.latest_version <package1> <package2> <package3> ...
```

### `salt.modules.zypper.list_installed_patterns()`

List installed patterns on the system.

CLI Examples:

```bash
salt '*' pkg.list_installed_patterns
```

### `salt.modules.zypper.list_locks()`

List current package locks.

Return a dict containing the locked package with attributes:

```python
{'<package>': {'case_sensitive': '<case_sensitive>', 'match_type': '<match_type>', 'type': '<type>'}}
```

CLI Example:

```bash
salt '*' pkg.list_locks
```

### `salt.modules.zypper.list_patterns(refresh=False)`

List all known patterns from available repos.

**refresh** force a refresh if set to True. If set to False (default) it depends on zypper if a refresh is executed.

CLI Examples:

```bash
salt '*' pkg.list_patterns
```

### `salt.modules.zypper.list_pkgs(versions_as_list=False, **kwargs)`

List the packages currently installed as a dict with versions as a comma separated string:

```python
{'<package_name>': '<version>[,<version>...]'}
```

**versions_as_list:** If set to true, the versions are provided as a list

```python
{'<package_name>': ['<version>', '<version>']}
```

**removed:** not supported
purge_desired: not supported

CLI Example:
salt '*' pkg.list_pkgs

```
salt.modules.zypper.list_products(all=False, refresh=False)
```

List all available or installed SUSE products.

all List all products available or only installed. Default is False.
refresh force a refresh if set to True. If set to False (default) it depends on zypper if a refresh is executed.

Includes handling for OEM products, which read the OEM productline file and overwrite the release value.

CLI Examples:
```
salt '*' pkg.list_products
salt '*' pkg.list_products all=True
```

```
salt.modules.zypper.list_repos()
```

Lists all repos.

CLI Example:
```
salt '*' pkg.list_repos
```

```
salt.modules.zypper.list_upgrades(refresh=True, **kwargs)
```

List all available package upgrades on this system

refresh force a refresh if set to True (default). If set to False it depends on zypper if a refresh is executed.

CLI Example:
```
salt '*' pkg.list_upgrades
```

```
salt.modules.zypper.mod_repo(repo, **kwargs)
```

Modify one or more values for a repo. If the repo does not exist, it will be created, so long as the following values are specified:

repo or alias alias by which the zypper refers to the repo
url, mirrorlist or baseurl the URL for zypper to reference
enabled enable or disable (True or False) repository, but do not remove if disabled.
refresh enable or disable (True or False) auto-refresh of the repository.
cache Enable or disable (True or False) RPM files caching.
gpgcheck Enable or disable (True or False) GOG check for this repository.
gpgautoimport Automatically trust and import new repository.

Key/Value pairs may also be removed from a repo's configuration by setting a key to a blank value. Bear in mind that a name cannot be deleted, and a url can only be deleted if a mirrorlist is specified (or vice versa).

CLI Examples:
```
salt '*' pkg.mod_repo alias alias=new_alias
salt '*' pkg.mod_repo alias url=mirrorlist=http://host.com/
```
salt.modules.zypper.modified(`packages`, `**flags`)  
List the modified files that belong to a package. Not specifying any packages will return a list of _all_ modified files on the system's RPM database.

New in version 2015.5.0.

Filtering by flags (True or False):

- **size** Include only files where size changed.
- **mode** Include only files which file's mode has been changed.
- **checksum** Include only files which MD5 checksum has been changed.
- **device** Include only files which major and minor numbers has been changed.
- **symlink** Include only files which are symbolic link contents.
- **owner** Include only files where owner has been changed.
- **group** Include only files where group has been changed.
- **time** Include only files where modification time of the file has been changed.
- **capabilities** Include only files where capabilities differ or not. Note: supported only on newer RPM versions.

CLI Examples:

```bash
salt '*' pkg.modified
salt '*' pkg.modified httpd
salt '*' pkg.modified httpd postfix
salt '*' pkg.modified httpd owner=True group=False
```

salt.modules.zypper.owner(`paths`)  
Return the name of the package that owns the file. Multiple file paths can be passed. If a single path is passed, a string will be returned, and if multiple paths are passed, a dictionary of file/package name pairs will be returned.

If the file is not owned by a package, or is not present on the minion, then an empty string will be returned for that path.

CLI Examples:

```bash
salt '*' pkg.owner /usr/bin/apachectl
salt '*' pkg.owner /usr/bin/apachectl /etc/httpd/conf/httpd.conf
```

salt.modules.zypper.purge(`name`=None, `pkgs`=None, `**kwargs`)  
Changed in version 2015.8.12, 2016.3.3, Carbon: On minions running systemd>=205, systemd-run(1) is now used to isolate commands which modify installed packages from the salt-minion daemon's control group. This is done to keep systemd from killing any zypper commands spawned by Salt when the salt-minion service is restarted. (see KillMode in the systemd.kill(5) manpage for more information). If desired, usage of systemd-run(1) can be suppressed by setting a config option called systemd.scope, with a value of False (no quotes).

Recursively remove a package and all dependencies which were installed with it, this will call a zypper -n remove -u

**name** The name of the package to be deleted.

Multiple Package Options:

**pkgs** A list of packages to delete. Must be passed as a python list. The `name` parameter will be ignored if this option is passed.
New in version 0.16.0.

Returns a dict containing the changes.

CLI Example:

```
salt '*' pkg.purge <package name>
salt '*' pkg.purge <package1>,<package2>,<package3>
salt '*' pkg.purge pkgs=['"foo", "bar"]'
```

```
salt.modules.zypper.refresh_db()
```

Force a repository refresh by calling zypper refresh --force, return a dict:

```
{
'<database name>': Bool
}
```

CLI Example:

```
salt '*' pkg.refresh_db
```

```
salt.modules.zypper.remove(name=None, pkgs=None, **kwargs)
```

Changed in version 2015.8.12,2016.3.3,Carbon: On minions running systemd>=205, systemd-run(1) is now used to isolate commands which modify installed packages from the salt-minion daemon's control group. This is done to keep systemd from killing any zypper commands spawned by Salt when the salt-minion service is restarted. (see KillMode in the systemd.kill(5) manpage for more information). If desired, usage of systemd-run(1) can be suppressed by setting a config option called systemd.scope, with a value of False (no quotes).

Remove packages with zypper -n remove

name The name of the package to be deleted.

Multiple Package Options:

pkgs A list of packages to delete. Must be passed as a python list. The name parameter will be ignored if this option is passed.

New in version 0.16.0.

Returns a dict containing the changes.

CLI Example:

```
salt '*' pkg.remove <package name>
salt '*' pkg.remove <package1>,<package2>,<package3>
salt '*' pkg.remove pkgs=['"foo", "bar"]'
```

```
salt.modules.zypper.remove_lock(packages, **kwargs)
```

Remove specified package lock.

CLI Example:

```
salt '*' pkg.remove_lock <package name>
salt '*' pkg.remove_lock <package1>,<package2>,<package3>
salt '*' pkg.remove_lock pkgs=['"foo", "bar"]'
```

```
salt.modules.zypper.search(criteria, refresh=False)
```

List known packages, available to the system.

refresh force a refresh if set to True. If set to False (default) it depends on zypper if a refresh is executed.

CLI Examples:
Salt Documentation, Release 2015.8.12

salt '*' pkg.search <criteria>

salt.modules.zypper.upgrade(refresh=True, dryrun=False, dist_upgrade=False, fromrepo=None, novendorchange=False, **kwargs)

Changed in version 2015.8.12, 2016.3.3, Carbon: On minions running systemd>=205, systemd-run(1) is now used to isolate commands which modify installed packages from the salt-minion daemon’s control group. This is done to keep systemd from killing any zypper commands spawned by Salt when the salt-minion service is restarted. (see KillMode in the systemd.kill(5) manpage for more information). If desired, usage of systemd-run() can be suppressed by setting a config option called systemd.scope, with a value of False (no quotes).

Run a full system upgrade, a zypper upgrade

refresh  force a refresh if set to True (default). If set to False it depends on zypper if a refresh is executed.

dryrun If set to True, it creates a debug solver log file and then perform a dry-run upgrade (no changes are made). Default: False

dist_upgrade  Perform a system dist-upgrade. Default: False

fromrepo  Specify a list of package repositories to upgrade from. Default: None

novendorchange  If set to True, no allow vendor changes. Default: False

Return a dict containing the new package names and versions:

{'<package>': {'old': '<old-version>', 'new': '<new-version>'}}

CLI Example:
salt '*' pkg.upgrade
salt '*' pkg.upgrade dist-upgrade=True fromrepo='["MyRepoName"]' novendorchange=True
dryrun=True

salt.modules.zypper.upgrade_available(name, **kwargs)

Check whether or not an upgrade is available for a given package

refresh  force a refresh if set to True (default). If set to False it depends on zypper if a refresh is executed or not.

CLI Example:
salt '*' pkg.upgrade_available <package name>

salt.modules.zypper.verify(*names, **kwargs)

Runs an rpm -Va on a system, and returns the results in a dict

Files with an attribute of config, doc, ghost, license or readme in the package header can be ignored using the ignore_types keyword argument

CLI Example:
salt '*' pkg.verify
salt '*' pkg.verify httpd
salt '*' pkg.verify 'httpd postfix'
salt '*' pkg.verify 'httpd postfix' ignore_types=['config', 'doc']
salt.modules.zypper.version(*names, **kwargs)

Returns a string representing the package version or an empty dict if not installed. If more than one package name is specified, a dict of name/version pairs is returned.

CLI Example:

```
salt '*' pkg.version <package name>
salt '*' pkg.version <package1> <package2> <package3> ...
```

salt.modules.zypper.version_cmp(ver1, ver2, ignore_epoch=False)

New in version 2015.5.4.

Do a cmp-style comparison on two packages. Return -1 if ver1 < ver2, 0 if ver1 == ver2, and 1 if ver1 > ver2. Return None if there was a problem making the comparison.

**ignore_epoch** [False] Set to True to ignore the epoch when comparing versions

New in version 2015.8.10,2016.3.2.

CLI Example:

```
salt '*' pkg.version_cmp '0.2-001' '0.2.0.1-002'
```

### 32.18 Full list of netapi modules

#### 32.18.1 rest_cherrypy

A REST API for Salt

New in version 2014.7.0.

**depends**

- CherryPy Python module. Version 3.2.3 is currently recommended when SSL is enabled, since this version worked the best with SSL in internal testing. Versions 3.2.3 - 4.x can be used if SSL is not enabled. Be aware that there is a known SSL error introduced in version 3.2.5. The issue was reportedly resolved with CherryPy milestone 3.3, but the patch was committed for version 3.6.1.

**optdepends**

- ws4py Python module for websockets support.

**client_libraries**

- Java: https://github.com/SUSE/saltstack-netapi-client-java
- Python: https://github.com/saltstack/pepper

**configuration** All authentication is done through Salt's external auth system which requires additional configuration not described here.

Example production-ready configuration; add to the Salt master config file and restart the salt-master and salt-api daemons:

```
rest_cherrypy:
    port: 8000
    ssl_crt: /etc/pki/tls/certs/localhost.crt
    ssl_key: /etc/pki/tls/certs/localhost.key
```
Using only a secure HTTPS connection is strongly recommended since Salt authentication credentials will be sent over the wire.

A self-signed certificate can be generated using the `create_self_signed_cert()` execution function. Running this function requires pyOpenSSL and the `salt-call` script is available in the `salt-minion` package.

```
salt-call --local tls.create_self_signed_cert
```

All available configuration options are detailed below. These settings configure the CherryPy HTTP server and do not apply when using an external server such as Apache or Nginx.

**port**  
Required  
The port for the webserver to listen on.

**host**  
`[0.0.0.0]`  
The socket interface for the HTTP server to listen on.

**debug**  
`[False]`  
Starts the web server in development mode. It will reload itself when the underlying code is changed and will output more debugging info.

**ssl_crt**  
The path to a SSL certificate. (See below)

**ssl_key**  
The path to the private key for your SSL certificate. (See below)

**disable_ssl**  
A flag to disable SSL. Warning: your Salt authentication credentials will be sent in the clear!

**webhook_disable_auth**  
`[False]`  
The Webhook URL requires authentication by default but external services cannot always be configured to send authentication. See the Webhook documentation for suggestions on securing this interface.

**webhook_url**  
`[/hook]`  
Configure the URL endpoint for the Webhook entry point.

**thread_pool**  
`[100]`  
The number of worker threads to start up in the pool.

**socket_queue_size**  
`[30]`  
Specify the maximum number of HTTP connections to queue.

**expire_responses**  
`[True]`  
Whether to check for and kill HTTP responses that have exceeded the default timeout.

**max_request_body_size**  
`[1048576]`  
Maximum size for the HTTP request body.

**collect_stats**  
`[False]`  
Collect and report statistics about the CherryPy server  
Reports are available via the Stats URL.

**static**  
A filesystem path to static HTML/JavaScript/CSS/image assets.

**static_path**  
`[/static]`  
The URL prefix to use when serving static assets out of the directory specified in the static setting.

**app**  
A filesystem path to an HTML file that will be served as a static file. This is useful for bootstrapping a single-page JavaScript app.

**app_path**  
`[/app]`  
The URL prefix to use for serving the HTML file specified in the app setting.  
This should be a simple name containing no slashes.

Any path information after the specified path is ignored; this is useful for apps that utilize the HTML5 history API.

**root_prefix**  
`[/]`  
A URL path to the main entry point for the application. This is useful for serving multiple applications from the same URL.
Authentication

Authentication is performed by passing a session token with each request. Tokens are generated via the Login URL.

The token may be sent in one of two ways:

- Include a custom header named X-Auth-Token.

  For example, using curl:

  ```bash
curl -sSk https://localhost:8000/login \
  -H 'Accept: application/x-yaml' \
  -d username=saltdev \
  -d password=saltdev \
  -d eauth=auto
  
  Copy the token value from the output and include it in subsequent requests:

  ```bash
curl -sSk https://localhost:8000 \
  -H 'Accept: application/x-yaml' \
  -H 'X-Auth-Token: 697adbdc8fe971d09ae4c2a3add7248859c87079' \
  -d client=local \
  -d tgt='*' \
  -d fun=test.ping
  ```

- Sent via a cookie. This option is a convenience for HTTP clients that automatically handle cookie support (such as browsers).

  For example, using curl:

  ```bash
  # Write the cookie file:
  curl -sSk https://localhost:8000/login \
  -c ~/cookies.txt \
  -H 'Accept: application/x-yaml' \
  -d username=saltdev \
  -d password=saltdev \
  -d eauth=auto

  # Read the cookie file:
  curl -sSk https://localhost:8000 \
  -b ~/cookies.txt \
  -H 'Accept: application/x-yaml' \
  -d client=local \
  -d tgt='*' \
  -d fun=test.ping
  ```

See also:

You can bypass the session handling via the Run URL.

Usage

Commands are sent to a running Salt master via this module by sending HTTP requests to the URLs detailed below.

Content negotiation
This REST interface is flexible in what data formats it will accept as well as what formats it will return (e.g., JSON, YAML, x-www-form-urlencoded).

- Specify the format of data in the request body by including the `Content-Type` header.
- Specify the desired data format for the response body with the `Accept` header.

Data sent in `POST` and `PUT` requests must be in the format of a list of lowstate dictionaries. This allows multiple commands to be executed in a single HTTP request. The order of commands in the request corresponds to the return for each command in the response.

Lowstate, broadly, is a dictionary of values that are mapped to a function call. This pattern is used pervasively throughout Salt. The functions called from netapi modules are described in Client Interfaces.

The following example (in JSON format) causes Salt to execute two commands, a command sent to minions as well as a runner function on the master:

```
[{
   "client": "local",
   "tgt": "*",
   "fun": "test.fib",
   "arg": ["10"]
},
{
   "client": "runner",
   "fun": "jobs.lookup_jid",
   "jid": "20130603122505459265"
}]
```

x-www-form-urlencoded

Sending JSON or YAML in the request body is simple and most flexible, however sending data in urlencoded format is also supported with the caveats below. It is the default format for HTML forms, many JavaScript libraries, and the `curl` command.

For example, the equivalent to running `salt '*' test.ping` is sending `fun=test.ping&arg&client=local&tgt=*` in the HTTP request body.

Caveats:

- Only a single command may be sent per HTTP request.
- Repeating the `arg` parameter multiple times will cause those parameters to be combined into a single list.

   Note, some popular frameworks and languages (notably jQuery, PHP, and Ruby on Rails) will automatically append empty brackets onto repeated parameters. E.g., `arg=one, arg=two` will be sent as `arg[]=one, arg[]=two`. This is not supported; send JSON or YAML instead.

Deployment

The `rest_cherrypy` netapi module is a standard Python WSGI app. It can be deployed one of two ways.

**salt-api using the CherryPy server**

The default configuration is to run this module using `salt-api` to start the Python-based CherryPy server. This server is lightweight, multi-threaded, encrypted with SSL, and should be considered production-ready.
Using a WSGI-compliant web server

This module may be deployed on any WSGI-compliant server such as Apache with mod_wsgi or Nginx with FastCGI, to name just two (there are many).

Note, external WSGI servers handle URLs, paths, and SSL certs directly. The `rest_cherrypy` configuration options are ignored and the `salt-api` daemon does not need to be running at all. Remember Salt authentication credentials are sent in the clear unless SSL is being enforced!

An example Apache virtual host configuration:

```xml
<VirtualHost *:80>
  ServerName example.com
  ServerAlias *.example.com

  ServerAdmin webmaster@example.com

  LogLevel warn
  ErrorLog /var/www/example.com/logs/error.log
  CustomLog /var/www/example.com/logs/access.log combined

  DocumentRoot /var/www/example.com/htdocs
  WSGIScriptAlias / /path/to/salt/netapi/rest_cherrypy/wsgi.py
</VirtualHost>
```

REST URI Reference

```
• /
  • /login
  • /logout
  • /minions
  • /jobs
  • /run
  • /events
  • /hook
  • /keys
  • /ws
  • /stats
```

```
/

class salt.netapi.rest_cherrypy.app.LowDataAdapter
    The primary entry point to Salt’s REST API

    GET()
        An explanation of the API with links of where to go next
```
GET /  
Request Headers  
- **Accept** -- the desired response format.  
Status Codes  
- **200** -- success  
- **401** -- authentication required  
- **406** -- requested Content-Type not available

Example request:
```bash
curl -i localhost:8000
```

GET / HTTP/1.1  
**Host**: localhost:8000  
**Accept**: application/json

Example response:
```
HTTP/1.1 200 OK  
Content-Type: application/json
```

**POST**  
Mock out specified imports  
This allows autodoc to do its thing without having oodles of req'd installed libs. This doesn't work with `import *` imports.  

**/login**  

class salt.netapi.rest_cherrypy.app.Login(*args, **kwargs)

Log in to receive a session token

*Authentication information.*

**GET()**  
Present the login interface  

**GET /login**  
An explanation of how to log in.  

Status Codes  
- **200** -- success  
- **401** -- authentication required  
- **406** -- requested Content-Type not available

Example request:
```bash
curl -i localhost:8000/login
```

GET /login HTTP/1.1  
**Host**: localhost:8000  
**Accept**: text/html

Example response:
POST (**kwargs)

Authenticate against Salt's eauth system

**POST /login**

Request Headers

- **X-Auth-Token** -- a session token from Login.
- **Accept** -- the desired response format.
- **Content-Type** -- the format of the request body.

Form Parameters

- **eauth** -- the eauth backend configured for the user
- **username** -- username
- **password** -- password

Status Codes

- **200** -- success
- **401** -- authentication required
- **406** -- requested Content-Type not available

Example request:

```
curl -si localhost:8000/login \\
-H "Accept: application/json" \\
-d username='saltuser' \\
-d password='saltpass' \\
-d eauth='pam'
```

Example response:

```
HTTP/1.1 200 OK
Content-Type: application/json
Content-Length: 206
X-Auth-Token: 6d1b722e
Set-Cookie: session_id=6d1b722e; expires=Sat, 17 Nov 2012 03:23:52 GMT; Path=/

{"return": {

```
/logout

class salt.netapi.rest_cherrypy.app.Logout
Class to remove or invalidate sessions

    POST()
    Destroy the currently active session and expire the session cookie

/minions

class salt.netapi.rest_cherrypy.app.Minions
Convenience URLs for working with minions

    GET(mid=None)
    A convenience URL for getting lists of minions or getting minion details

        GET /minions/(mid)
        Request Headers
        • X-Auth-Token -- a session token from Login.
        • Accept -- the desired response format.
        Status Codes
        • 200 -- success
        • 401 -- authentication required
        • 406 -- requested Content-Type not available

Example request:

    curl -i localhost:8000/minions/ms-3

Example response:

    HTTP/1.1 200 OK
    Content-Length: 129005
    Content-Type: application/x-yaml

    return:
    - ms-3:
      grains.items:
      ...

    POST(**kwargs)
    Start an execution command and immediately return the job id

    POST /minions
    Request Headers
    • X-Auth-Token -- a session token from Login.
    • Accept -- the desired response format.
    • Content-Type -- the format of the request body.
    Response Headers
    • Content-Type -- the format of the response body; depends on the Accept request header.
    Status Codes
lowstate data describing Salt commands must be sent in the request body. The client option will be set to local_async().

Example request:

```bash
curl -sSSI localhost:8000/minions \
   -H "Accept: application/x-yaml" \ 
   -d tgt='*' \ 
   -d fun='status.diskusage'
```

```
POST /minions HTTP/1.1
Host: localhost:8000
Accept: application/x-yaml
Content-Length: 26
Content-Type: application/x-www-form-urlencoded
tgt=*&fun=status.diskusage
```

Example response:

```
HTTP/1.1 202 Accepted
Content-Length: 86
Content-Type: application/x-yaml

return:
- jid: '20130603122505459265'
  minions: [ms-4, ms-3, ms-2, ms-1, ms-0]
  _links:
    jobs:
      - href: /jobs/20130603122505459265
```

/jobs

class salt.netapi.rest_cherrypy.app.Jobs

GET(jid=None, timeout='')

A convenience URL for getting lists of previously run jobs or getting the return from a single job

GET /jobs/(jid)

List jobs or show a single job from the job cache.

Request Headers
- X-Authorization -- a session token from Login.
- Accept -- the desired response format.

Status Codes
- 200 -- success
- 401 -- authentication required
- 406 -- requested Content-Type not available

Example request:

```bash
curl -i localhost:8000/jobs
```
GET /jobs HTTP/1.1
Host: localhost:8000
Accept: application/x-yaml

Example response:

HTTP/1.1 200 OK
Content-Length: 165
Content-Type: application/x-yaml

return:
- '20121130104633606931':
  Arguments:
  - '3'
  Function: test.fib
  Target: jerry
  Target-type: glob

Example request:
curl -i localhost:8000/jobs/20121130104633606931

GET /jobs/20121130104633606931 HTTP/1.1
Host: localhost:8000
Accept: application/x-yaml

Example response:

HTTP/1.1 200 OK
Content-Length: 73
Content-Type: application/x-yaml

info:
- Arguments:
  - '3'
  Function: test.fib
  Minions:
  - jerry
  Target: '*'
  Target-type: glob
  User: saltdev
  jid: '20121130104633606931'
return:
- jerry:
  - 0
  - 1
  - 1
  - 2
  - 6.9141387939453125e-06

/run

class salt.netapi.rest_cherrypy.app.Run
    Class to run commands without normal session handling

32.18. Full list of netapi modules
**POST (``**kwargs``)**

Run commands bypassing the normal session handling

**POST /run**

This entry point is primarily for "one-off" commands. Each request must pass full Salt authentication credentials. Otherwise this URL is identical to the root URL (`/`).

*lowstate* data describing Salt commands must be sent in the request body.

**Status Codes**

- **200** -- success
- **401** -- authentication required
- **406** -- requested Content-Type not available

Example request:

```
curl -sS localhost:8000/run \
   -H 'Accept: application/x-yaml' \
   -d client='local' \
   -d tgt='*' \
   -d fun='test.ping' \
   -d username='saltdev' \
   -d password='saltdev' \
   -d eauth='pam'
```

<table>
<thead>
<tr>
<th>POST /run HTTP/1.1</th>
<th>Host: localhost:8000</th>
<th>Accept: application/x-yaml</th>
<th>Content-Length: 75</th>
<th>Content-Type: application/x-www-form-urlencoded</th>
</tr>
</thead>
<tbody>
<tr>
<td>client=local&amp;tgt=*&amp;fun=test.ping&amp;username=saltdev&amp;password=saltdev&amp;eauth=pam</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Example response:

```
HTTP/1.1 200 OK
Content-Length: 73
Content-Type: application/x-yaml

return:
- ms-0: true
  ms-1: true
  ms-2: true
  ms-3: true
  ms-4: true
```

The /run endpoint can also be used to issue commands using the salt-ssh subsystem.

When using salt-ssh, eauth credentials should not be supplied. Instead, authentication should be handled by the SSH layer itself. The use of the salt-ssh client does not require a salt master to be running. Instead, only a roster file must be present in the salt configuration directory.

All SSH client requests are synchronous.

Example SSH client request:

```
curl -sS localhost:8000/run \
   -H 'Accept: application/x-yaml' \
   -d client='ssh' \
   -d tgt='*' \
   -d fun='test.ping'
```
POST /run HTTP/1.1
Host: localhost:8000
Accept: application/x-yaml
Content-Length: 75
Content-Type: application/x-www-form-urlencoded

client=ssh&tgt=&fun=test.ping

Example SSH response:

```
return:
  - silver:
      fun: test.ping
      fun_args: []
      id: silver
      jid: '20141203103525666185'
      retcode: 0
      return: true
      success: true
```

/events

class salt.netapi.rest_cherrypy.app.Events

Expose the Salt event bus

The event bus on the Salt master exposes a large variety of things, notably when executions are started on the master and also when minions ultimately return their results. This URL provides a real-time window into a running Salt infrastructure.

See also:

Salt Event System

GET (token=None, salt_token=None)

An HTTP stream of the Salt master event bus

This stream is formatted per the Server Sent Events (SSE) spec. Each event is formatted as JSON.

GET /events

Status Codes

- **200** -- success
- **401** -- authentication required
- **406** -- requested Content-Type not available

Query Parameters

- **token** -- optional parameter containing the token ordinarily supplied via the X-Auth-Token header in order to allow cross-domain requests in browsers that do not include CORS support in the EventSource API. E.g., curl -NsS localhost:8000/events?token=308650d
- **salt_token** -- optional parameter containing a raw Salt eauth token (not to be confused with the token returned from the /login URL). E.g., curl -NsS localhost:8000/events?salt_token=30742765

Example request:

curl -NsS localhost:8000/events
Example response:

Note, the `tag` field is not part of the spec. SSE compliant clients should ignore unknown fields. This addition allows non-compliant clients to only watch for certain tags without having to deserialize the JSON object each time.

```
HTTP/1.1 200 OK
Connection: keep-alive
Cache-Control: no-cache
Content-Type: text/event-stream;charset=utf-8
retry: 400

tag: salt/job/20130802115730568475/new
data: {'tag': 'salt/job/20130802115730568475/new', 'data': {'minions': ['ms-4', 'ms-3', 'ms-2', 'ms-1', 'ms-0']}}

tag: salt/job/20130802115730568475/ret/jerry
data: {'tag': 'salt/job/20130802115730568475/ret/jerry', 'data': {'jid': '20130802115730568475', 'return': True, 'retcode': 0, 'success': True, 'cmd': '_return', 'fun': 'test.ping', 'id': 'ms-1'}}
```

The event stream can be easily consumed via JavaScript:

```javascript
var source = new EventSource('/events');
source.onopen = function() { console.debug('opening') };
source.onerror = function(e) { console.debug('error!', e) };
source.onmessage = function(e) {
    console.debug('Tag: ', e.data.tag)
    console.debug('Data: ', e.data.data)
};
```

Or using CORS:

```javascript
var source = new EventSource('/events?token=ecd589e4e01912cf3c4835afad73426dbb8db75', {withCredentials: true});
```

It is also possible to consume the stream via the shell.

Records are separated by blank lines; the `data:` and `tag:` prefixes will need to be removed manually before attempting to unserialize the JSON.

curl's `-N` flag turns off input buffering which is required to process the stream incrementally.

Here is a basic example of printing each event as it comes in:

```bash
curl -NsS localhost:8000/events |
    while IFS= read -r line ; do
        echo "$line"
    done
```

Here is an example of using awk to filter events based on tag:

```bash
curl -NsS localhost:8000/events |
    awk '{ BEGIN { RS=""; FS="\n" } ...
```
tag: salt/job/20140112010149808995/new

data: ("tag": "salt/job/20140112010149808995/new", "data": {"tgt_type": "glob", "jid": "2014-01-12_01:01:49.809617", "user": "shouse", "arg": [], "fun": "test.ping", "minions": ["jerry"]})
tag: 20140112010149808995

data: ("tag": "20140112010149808995", "data": {"fun_args": [], "jid": "20140112010149808995", "return": true, "retcode": 0, "success": true, "cmd": ", "return": ", "stamp": "2014-01-12_01:01:49.819316", "fun": "test.ping", "id": "jerry"})

/hook

class salt.netapi.rest_cherrypy.app.Webhook
A generic web hook entry point that fires an event on Salt's event bus

External services can POST data to this URL to trigger an event in Salt. For example, Amazon SNS, Jenkins-CI or Travis-CI, or GitHub web hooks.

Note: Be mindful of security
Salt's Reactor can run any code. A Reactor SLS that responds to a hook event is responsible for validating that the event came from a trusted source and contains valid data.

This is a generic interface and securing it is up to you!

This URL requires authentication however not all external services can be configured to authenticate. For this reason authentication can be selectively disabled for this URL. Follow best practices -- always use SSL, pass a secret key, configure the firewall to only allow traffic from a known source, etc.

The event data is taken from the request body. The Content-Type header is respected for the payload.

The event tag is prefixed with salt/netapi/hook and the URL path is appended to the end. For example, a POST request sent to /hook/mycompany/myapp/mydata will produce a Salt event with the tag salt/netapi/hook/mycompany/myapp/mydata.

The following is an example .travis.yml file to send notifications to Salt of successful test runs:

```language: python
script: python -m unittest tests
after_success:
  - |
    curl -SSk https://saltapi-url.example.com:8000/hook/travis/build/success -d branch="${TRAVIS_BRANCH}" -d commit="${TRAVIS_COMMIT}"
```

See also:
Salt Event System, reactor

**POST**(*args, **kwargs*)
Fire an event in Salt with a custom event tag and data

**POST** /hook

Status Codes
Example request:

```bash
curl -sS localhost:8000/hook -d foo='Foo!' -d bar='Bar!'```

Example response:

```
HTTP/1.1 200 OK
Content-Length: 14
Content-Type: application/json

{"success": true}
```

As a practical example, an internal continuous-integration build server could send an HTTP POST request to the URL `https://localhost:8000/hook/mycompany/build/success` which contains the result of a build and the SHA of the version that was built as JSON. That would then produce the following event in Salt that could be used to kick off a deployment via Salt's Reactor:

```
Event fired at Fri Feb 14 17:40:11 2014
********************************************
Tag: salt/netapi/hook/mycompany/build/success
Data:
{ '_stamp': '2014-02-14_17:40:11.440996',
  'headers': {
    'X-My-Secret-Key': 'F0fAgoQjIT@W',
    'Content-Length': '37',
    'Content-Type': 'application/json',
    'Host': 'localhost:8000',
    'Remote-Addr': '127.0.0.1'},
  'post': { 'revision': 'aa22a3c4b2e7', 'result': True}}
```

Salt's Reactor could listen for the event:

```yaml
reactor:
  - 'salt/netapi/hook/mycompany/build/*':
    - /srv/reactor/react_ci_builds.sls
```

And finally deploy the new build:

```python
{% set secret_key = data.get('headers', {}).get('X-My-Secret-Key') %}
{% set build = data.get('post', {}) %}
{% if secret_key == 'F0fAgoQjIT@W' and build.result == True %}
    deploy_my_app:
        cmd.state.sls:
            - tgt: 'application*'
            - arg:
```
/keys

class salt.netapi.rest_cherrypy.app.Keys
    Convenience URLs for working with minion keys

    New in version 2014.7.0.
    These URLs wrap the functionality provided by the key wheel module functions.

    GET(/keys/mid=None)
    Show the list of minion keys or detail on a specific key

    New in version 2014.7.0.

    GET /keys/{mid}
    List all keys or show a specific key

    Status Codes
    • 200 -- success
    • 401 -- authentication required
    • 406 -- requested Content-Type not available

    Example request:
    curl -i localhost:8000/keys

    Example response:
    HTTP/1.1 200 OK
    Content-Length: 165
    Content-Type: application/x-yaml

    return:
    local:
    - master.pem
    - master.pub
    minions:
    - jerry
    minions_pre: []
    minions_rejected: []

    Example request:
    curl -i localhost:8000/keys/jerry

    GET /keys/jerry HTTP/1.1
    Host: localhost:8000
    Accept: application/x-yaml
Example response:

```
HTTP/1.1 200 OK
Content-Length: 73
Content-Type: application/x-yaml

return:
  minions:
```

**POST (**)kargs**

Easily generate keys for a minion and auto-accept the new key

Accepts all the same parameters as the `key.gen_accept`.

Example partial kickstart script to bootstrap a new minion:

```
%post
  mkdir -p /etc/salt/pki/minion
  curl -sSk https://localhost:8000/keys 
    -d mid=jerry 
    -d username=kickstart 
    -d password=kickstart 
    -d eauth=pam 
    | tar -C /etc/salt/pki/minion -xf -

  mkdir -p /etc/salt/minion.d
  printf 'master: 10.0.0.5
id: jerry' > /etc/salt/minion.d/id.conf
%end
```

**POST /keys**

Generate a public and private key and return both as a tarball

Authentication credentials must be passed in the request.

**Status Codes**

- **200** -- success
- **401** -- authentication required
- **406** -- requested Content-Type not available

Example request:

```
curl -sSk https://localhost:8000/keys 
  -d mid=jerry 
  -d username=kickstart 
  -d password=kickstart 
  -d eauth=pam 
  -o jerry-salt-keys.tar
```

Example response:

```
HTTP/1.1 200 OK
Content-Length: 10240
Content-Disposition: attachment; filename="saltkeys-jerry.tar"
Content-Type: application/x-tar

jerry.pub00006440000000000000000000000703000000000000010730 0ustar 6
...0000000000000
```
/ws

class salt.netapi.rest_cherrypy.app.WebsocketEndpoint

Open a WebSocket connection to Salt's event bus

The event bus on the Salt master exposes a large variety of things, notably when executions are started on the master and also when minions ultimately return their results. This URL provides a real-time window into a running Salt infrastructure. Uses websocket as the transport mechanism.

See also:
Salt Event System

GET (token=None, **kwargs)
Return a websocket connection of Salt's event stream

GET /ws/(token)

Query format_events The event stream will undergo server-side formatting if the format_events URL parameter is included in the request. This can be useful to avoid formatting on the client-side:

curl -NsS <...snip...> localhost:8000/ws?format_events

Reqheader X-Auth-Token an authentication token from Login.

Status 101 switching to the websockets protocol

Status 401 authentication required

Status 406 requested Content-Type not available

Example request:

curl -NsSk \
-H 'X-Auth-Token: ffedf49d' \
-H 'Host: localhost:8000' \
-H 'Connection: Upgrade' \
-H 'Upgrade: websocket' \
-H 'Origin: https://localhost:8000' \
-H 'Sec-WebSocket-Version: 13' \
-H 'Sec-WebSocket-Key: "$(echo -n $RANDOM | base64)"' \
localhost:8000/ws

GET /ws HTTP/1.1
Connection: Upgrade
Upgrade: websocket
Host: localhost:8000
Origin: https://localhost:8000
Sec-WebSocket-Version: 13
Sec-WebSocket-Key: s65VsgHigh7v/Jcf4nXHnA==
X-Auth-Token: ffedf49d

Example response:
HTTP/1.1 101 Switching Protocols
Upgrade: websocket
Connection: Upgrade
Sec-WebSocket-Accept: mWzjBV9FCglzn1rIKJAxrTFlnJE=
Sec-WebSocket-Version: 13

An authentication token may optionally be passed as part of the URL for browsers that cannot be configured to send the authentication header or cookie:

curl -NsS <...snip...> localhost:8000/ws/ffedf49d

The event stream can be easily consumed via JavaScript:

```
// Note, you must be authenticated!
var source = new Websocket('ws://localhost:8000/ws/d0ce6c1a');
source.onerror = function(e) { console.debug('error!', e); };
source.onmessage = function(e) { console.debug(e.data); };

source.send('websocket client ready')
source.close();
```

Or via Python, using the Python module websocket-client for example.

```
# Note, you must be authenticated!
from websocket import create_connection

ws = create_connection('ws://localhost:8000/ws/d0ce6c1a')
ws.send('websocket client ready')

# Look at https://pypi.python.org/pypi/websocket-client/ for more
# examples.
while listening_to_events:
    print ws.recv()
ws.close()
```

Above examples show how to establish a websocket connection to Salt and activating real time updates from Salt's event stream by signaling websocket client ready.

/stats

class salt.netapi.rest_cherrypy.app.Stats
    Expose statistics on the running CherryPy server

GET()
    Return a dump of statistics collected from the CherryPy server

GET /stats
    Request Headers
    • X-Auth-Token -- a session token from Login.
    • Accept -- the desired response format.
    Response Headers
    • Content-Type -- the format of the response body; depends on the Accept request header.
Status Codes
- 200 -- success
- 401 -- authentication required
- 406 -- requested Content-Type not available

32.18.2 rest_tornado

A non-blocking REST API for Salt

depends
- tornado Python module

configuration All authentication is done through Salt’s external auth system which requires additional configuration not described here.

In order to run rest_tornado with the salt-master add the following to the Salt master config file.

```yaml
rest_tornado:
  # can be any port
  port: 8000
  # address to bind to (defaults to 0.0.0.0)
  address: 0.0.0.0
  # socket backlog
  backlog: 128
  ssl_crt: /etc/pki/api/certs/server.crt
  # no need to specify ssl_key if cert and key are in one single file
  ssl_key: /etc/pki/api/certs/server.key
  debug: False
  disable_ssl: False
  webhook_disable_auth: False
```

Authentication

Authentication is performed by passing a session token with each request. Tokens are generated via the `SaltAuthHandler` URL.

The token may be sent in one of two ways:
- Include a custom header named `X-Auth-Token`.
- Sent via a cookie. This option is a convenience for HTTP clients that automatically handle cookie support (such as browsers).

See also:
You can bypass the session handling via the `RunSaltAPITHandler` URL.

Usage

Commands are sent to a running Salt master via this module by sending HTTP requests to the URLs detailed below.
This REST interface is flexible in what data formats it will accept as well as what formats it will return (e.g., JSON, YAML, x-www-form-urlencoded).

- Specify the format of data in the request body by including the `Content-Type` header.
- Specify the desired data format for the response body with the `Accept` header.

Data sent in POST and PUT requests must be in the format of a list of lowstate dictionaries. This allows multiple commands to be executed in a single HTTP request.

**lowstate**  A dictionary containing various keys that instruct Salt which command to run, where that command lives, any parameters for that command, any authentication credentials, what returner to use, etc.

Salt uses the lowstate data format internally in many places to pass command data between functions. Salt also uses lowstate for the `LocalClient()` Python API interface.

The following example (in JSON format) causes Salt to execute two commands:

```json
[
  {
    "client": "local",
    "tgt": "+",
    "fun": "test.fib",
    "arg": ["10"]
  },
  {
    "client": "runner",
    "fun": "jobs.lookup_jid",
    "jid": "20130603122505459265"
  }
]
```

Multiple commands in a Salt API request will be executed in serial and makes no guarantees that all commands will run. Meaning that if test.fib (from the example above) had an exception, the API would still execute `jobs.lookup_jid`.

Responses to these lowstates are an in-order list of dicts containing the return data, a yaml response could look like:

```
- ms-1: true
  ms-2: true
- ms-1: foo
  ms-2: bar
```

In the event of an exception while executing a command the return for that lowstate will be a string, for example if no minions matched the first lowstate we would get a return like:

```
- No minions matched the target. No command was sent, no jid was assigned.
  - ms-1: true
    ms-2: true
```

**x-www-form-urlencoded**

Sending JSON or YAML in the request body is simple and most flexible, however sending data in urlencoded format is also supported with the caveats below. It is the default format for HTML forms, many JavaScript libraries, and the `curl` command.

For example, the equivalent to running `salt '*' test.ping` is sending `fun=test.ping&arg&client=local&tgt=*/ in the HTTP request body.

Caveats:

- Only a single command may be sent per HTTP request.
• Repeating the arg parameter multiple times will cause those parameters to be combined into a single list.

Note, some popular frameworks and languages (notably jQery, PHP, and Ruby on Rails) will automatically append empty brackets onto repeated parameters. E.g., arg=one, arg=two will be sent as arg[]=one, arg[]=two. This is not supported; send JSON or YAML instead.

A Websockets add-on to saltnado

depends

• tornado Python module

In order to enable saltnado_websockets you must add websockets: True to your saltnado config block.

```
rest_tornado:
    # can be any port
    port: 8000
    ssl_crt: /etc/pki/api/certs/server.crt
    # no need to specify ssl_key if cert and key
    # are in one single file
    ssl_key: /etc/pki/api/certs/server.key
    debug: False
    disable_ssl: False
    websockets: True
```

All Events

Exposes all `"real-time"` events from Salt's event bus on a websocket connection. It should be noted that `"Real-time"` here means these events are made available to the server as soon as any salt related action (changes to minions, new jobs etc) happens. Clients are however assumed to be able to tolerate any network transport related latencies. Functionality provided by this endpoint is similar to the /events end point.

The event bus on the Salt master exposes a large variety of things, notably when executions are started on the master and also when minions ultimately return their results. This URL provides a real-time window into a running Salt infrastructure. Uses websocket as the transport mechanism.

Exposes GET method to return websocket connections. All requests should include an auth token. A way to obtain authentication tokens is shown below.

```
% curl -si localhost:8000/login \
   -H "Accept: application/json" \
   -d username='salt' \
   -d password='salt' \
   -d eauth='pam'
```

Which results in the response

```
{
   "return": [{
      "perms": [".", "+", "+runner", "+wheel"],
      "start": 1400556492.277421,
      "token": "d0ce6c1a37e99d9cc0374392f272fe19c0090cda7",
      "expire": 1400599692.277422,
      "user": "salt",
      "eauth": "pam"
   }
}
```
In this example the token returned is `d0ce6c1a37e99d0c374392f272fe19c0090cca7` and can be included in subsequent websocket requests (as part of the URL).

The event stream can be easily consumed via JavaScript:

```javascript
// Note, you must be authenticated!
// Get the Websocket connection to Salt
var source = new WebSocket('wss://localhost:8000/all_events/
                        →d0ce6c1a37e99d0c374392f272fe19c0090cca7');

// Get Salt's "real time" event stream.
source.onopen = function() { source.send('websocket client ready'); };;

// Other handlers
source.onerror = function(e) { console.debug('error!', e); };;

// e.data represents Salt's "real time" event data as serialized JSON.
source.onmessage = function(e) { console.debug(e.data); };;

// Terminates websocket connection and Salt's "real time" event stream on the server.
source.close();
```

Or via Python, using the Python module `websocket-client` for example. Or the `tornado` client.

```python
# Note, you must be authenticated!

from websocket import create_connection

# Get the Websocket connection to Salt
ws = create_connection('wss://localhost:8000/all_events/
                        →d0ce6c1a37e99d0c374392f272fe19c0090cca7')

# Get Salt's "real time" event stream.
ws.send('websocket client ready')

# Simple listener to print results of Salt's "real time" event stream.
# Look at https://pypi.python.org/pypi/websocket-client/ for more examples.
while listening_to_events:
    print ws.recv()            # Salt's "real time" event data as serialized JSON.

# Terminates websocket connection and Salt's "real time" event stream on the server.
ws.close()

# Please refer to https://github.com/liris/websocket-client/issues/81 when using a self signed cert
```

Above examples show how to establish a websocket connection to Salt and activating real time updates from Salt's event stream by signaling `websocket client ready`. 
Formatted Events

Exposes formatted ``real-time`` events from Salt’s event bus on a websocket connection. It should be noted that ``Real-time`` here means these events are made available to the server as soon as any salt related action (changes to minions, new jobs etc) happens. Clients are however assumed to be able to tolerate any network transport related latencies. Functionality provided by this endpoint is similar to the /events end point.

The event bus on the Salt master exposes a large variety of things, notably when executions are started on the master and also when minions ultimately return their results. This URL provides a real-time window into a running Salt infrastructure. Uses websocket as the transport mechanism.

Formatted events parses the raw `’real time’` event stream and maintains a current view of the following:

- minions
- jobs

A change to the minions (such as addition, removal of keys or connection drops) or jobs is processed and clients are updated. Since we use salt’s presence events to track minions, please enable presence_events and set a small value for the loop_interval in the salt master config file.

Exposes GET method to return websocket connections. All requests should include an auth token. A way to obtain obtain authentication tokens is shown below.

```bash
% curl -si localhost:8000/login \
   -H "Accept: application/json" \
   -d username='salt' \ 
   -d password='salt' \ 
   -d eauth='pam'
```

Which results in the response

```json
{
   "return": [{
      "perms": [".*", "@runner", "@wheel"],
      "start": 1400556492.277421,
      "token": "d0ce6c1a37e99dcc0374392f272fe19c0090cca7",
      "expire": 1400599692.277422,
      "user": "salt",
      "eauth": "pam"
    }
}
```

In this example the token returned is d0ce6c1a37e99dcc0374392f272fe19c0090cca7 and can be included in subsequent websocket requests (as part of the URL).

The event stream can be easily consumed via JavaScript:

```javascript
// Note, you must be authenticated!

// Get the Websocket connection to Salt
var source = new WebSocket('wss://localhost:8000/formatted_events/
   -d0ce6c1a37e99dcc0374392f272fe19c0090cca7');

// Get Salt's "real time" event stream.
source.onopen = function() { source.send('websocket client ready'); };

// Other handlers
source.onerror = function(e) { console.debug('error!', e); };
```
// e.data represents Salt's "real time" event data as serialized JSON.
source.onmessage = function(e) { console.debug(e.data); };

// Terminates websocket connection and Salt's "real time" event stream on the server.
source.close();

Or via Python, using the Python module websocket-client for example. Or the tornado client.

```python
# Note, you must be authenticated!

from websocket import create_connection

# Get the Websocket connection to Salt
ws = create_connection('wss://localhost:8000/formatted_events/'
                       +d0ce6c1a37e99dcc0374392f272fe19c0090cca7)

# Get Salt's "real time" event stream.
ws.send('websocket client ready')

# Simple listener to print results of Salt's "real time" event stream.
# Look at https://pypi.python.org/pypi/websocket-client/ for more examples.
while listening_to_events:
    print ws.recv() # Salt's "real time" event data as serialized JSON.

# Terminates websocket connection and Salt's "real time" event stream on the server.
ws.close()

# Please refer to https://github.com/liris/websocket-client/issues/81 when using a
# self signed cert
```

Above examples show how to establish a websocket connection to Salt and activating real time updates from Salt's event stream by signaling websocket client ready.

**Example responses**

Minion information is a dictionary keyed by each connected minion's id (mid), grains information for each minion is also included.

Minion information is sent in response to the following minion events:

- connection drops
  - requires running manage.present periodically every loop_interval seconds
- minion addition
- minion removal

```json
# Not all grains are shown
data: {
    "minions": {
        "minion1": {
            "id": "minion1",
            "grains": {
                "kernel": "Darwin",
                "domain": "local",
                "zmqversion": "4.0.3",
            }
        }
    }
}
```
Job information is also tracked and delivered.

Job information is also a dictionary in which each job's information is keyed by salt's jid.

```json

data: {
  "jobs": {
    "20140609153646699137": {
      "tgt_type": "glob",
      "jid": "20140609153646699137",
      "tgt": "*",
      "start_time": "2014-06-09T15:36:46.700315",
      "state": "complete",
      "fun": "test.ping",
      "minions": {
        "minion1": {
          "return": true,
          "retcode": 0,
          "success": true
        }
      }
    }
  }
}

```

```

32.18. Full list of netapi modules
A minimalist REST API for Salt

This `rest_wsgi` module provides a no-frills REST interface for sending commands to the Salt master. There are no dependencies.

Extra care must be taken when deploying this module into production. Please read this documentation in entirety.

All authentication is done through Salt’s `external auth` system.

**Usage**

- All requests must be sent to the root URL (`/`).
- All requests must be sent as a POST request with JSON content in the request body.
- All responses are in JSON.
See also:

`rest_cherrypy`

The `rest_cherrypy` module is more full-featured, production-ready, and has built-in security features.

**Deployment**

The `rest_wsgi` netapi module is a standard Python WSGI app. It can be deployed one of two ways.

**Using a WSGI-compliant web server**

This module may be run via any WSGI-compliant production server such as Apache with mod_wsgi or Nginx with FastCGI.

It is strongly recommended that this app be used with a server that supports HTTPS encryption since raw Salt authentication credentials must be sent with every request. Any apps that access Salt through this interface will need to manually manage authentication credentials (either username and password or a Salt token). Tread carefully.

**salt-api using a development-only server**

If run directly via the salt-api daemon it uses the `wsgiref.simple_server()` that ships in the Python standard library. This is a single-threaded server that is intended for testing and development. **This server does not use encryption; please note that raw Salt authentication credentials must be sent with every HTTP request.**

Running this module via salt-api is not recommended!

In order to start this module via the `salt-api` daemon the following must be put into the Salt master config:

```plaintext
rest_wsgi:
  port: 8001
```

**Usage examples**

**POST /**

Example request for a basic `test.ping`:

```bash
% curl -sS -i -H 'Content-Type: application/json' -d '{"eauth":"pam","username":"saltdev","password":"saltdev","client":"local","tgt":"*","fun":"test.ping"}' localhost:8001
```

Example response:

```plaintext
HTTP/1.0 200 OK
Content-Length: 89
Content-Type: application/json

{"return": [{"ms--4": true, "ms--3": true, "ms--2": true, "ms--1": true, "ms--0":true}]

Example request for an asynchronous `test.ping`:

```
% curl -sS -i "  
-H 'Content-Type: application/json'  
-d '{{"eauth":"pam","username":"saltdev","password":"saltdev","client":  
"local_async","tgt":"*","fun":"test.ping"}}' localhost:8001

Example response:

HTTP/1.0 200 OK  
Content-Length: 103  
Content-Type: application/json

{"return": [{"jid": "20130412192112593739", "minions": ["ms--4", "ms--3", "ms--2", "ms--1", "ms--0"]}]

Example request for looking up a job ID:

% curl -sS -i "  
-H 'Content-Type: application/json'  
-d '{{"eauth":"pam","username":"saltdev","password":"saltdev","client":  
"runner","fun":"jobs.lookup_jid","jid":"20130412192112593739"}}' localhost:8001

Example response:

HTTP/1.0 200 OK  
Content-Length: 89  
Content-Type: application/json

{"return": [{"ms--4": true, "ms--3": true, "ms--2": true, "ms--1": true, "ms--0":[true]}]}

form lowstate  A list of lowstate data appropriate for the client interface you are calling.

status 200 success

status 401 authentication required

32.19.1 salt.output.compact

Display compact output data structure

Example output: `saltdev': {`test_|-always-passes_|-foo_|-succeed_without_changes': {`comment': `Success!', `name': `foo', `start_time': `05:16:26.111814', `result': True, `duration': 1, `__run_num__': 0, `changes': {}}, `test_|-my-custom-combo_|-foo_|-configurable_test_state': {`comment': `bar.baz', `name': `foo', `start_time': `05:16:26.117177', `result': False, `duration': 1, `__run_num__': 4, `changes': {`testing': {`new': `Something pretended to change', `old': `Unchanged'}}}, `test_|-always-fails_|-foo_|-fail_without_changes': {`comment': `Failure!', `name': `foo', `start_time': `05:16:26.111324', `result': False, `duration': 1, `__run_num__': 1, `changes': {}}, `test_|-always-changes-and-succeeds_|-foo_|-succeed_with_changes': {`comment': `Success!', `name': `foo', `start_time': `05:16:26.114570', `result': True, `duration': 0, `__run_num__': 2, `changes': {`testing': {`new': `Something pretended to change', `old': `Unchanged'}}}, `test_|-always-changes-and-fails_|-foo_|-fail_with_changes': {`comment': `Failure!', `name': `foo', `start_time': `05:16:26.115561', `result': False, `duration': 1, `__run_num__': 3, `changes': {`testing': {`new': `Something pretended to change', `old': `Unchanged'}}}}}

salt.output.compact.output(data)
   Rather basic.

32.19.2 salt.output.highstate

Outpuṭter for displaying results of state runs

The return data from the Highstate command is a standard data structure which is parsed by the highstate outpuṭter to deliver a clean and readable set of information about the HighState run on minions.

Two configurations can be set to modify the highstate outpuṭter. These values can be set in the master config to change the output of the salt command or set in the minion config to change the output of the salt-call command.

state_verbose: By default state_verbose is set to True, setting this to False will instruct the highstate outpuṭter to omit displaying anything in green, this means that nothing with a result of True and no changes will not be printed

state_output: The highstate outpuṭter has five output modes, full, terse, mixed, changes and filter.
   • The default is set to full, which will display many lines of detailed information for each executed chunk.
   • If terse is used, then the output is greatly simplified and shown in only one line.
   • If mixed is used, then terse output will be used unless a state failed, in which case full output will be used.
   • If changes is used, then terse output will be used if there was no error and no changes, otherwise full output will be used.
   • If filter is used, then either or both of two different filters can be used: exclude or terse. * for exclude, state.highstate expects a list of states to be excluded (or None) followed by True for terse output or False for regular output. Because of parsing nuances, if only one of these is used, it must still contain a comma. For instance: exclude=True,
- for terse, state.highstate expects simply True or False.
  
  These can be set as such from the command line, or in the Salt config as state_output_exclude or state_output_terse, respectively.

state_tabular: If state_output uses the terse output, set this to True for an aligned output format. If you wish to use a custom format, this can be set to a string.

Example usage:

If state_output: filter is set in the configuration file:

```python
salt 'x' state.highstate exclude=None,True
```

means to exclude no states from the highstate and turn on terse output.

```python
salt twd state.highstate exclude=problemstate1,problemstate2,False
```

means to exclude states problemstate1 and problemstate2 from the highstate, and use regular output.

Example output for the above highstate call when top.sls defines only one other state to apply to minion twd:

```
twd:
Summary for twd
----------
Succeeded: 1 (changed=1)
Failed: 0
----------
Total states run: 1
```

Example output with no special settings in configuration files:

```
myminion:
----------
   ID: test.ping
     Function: module.run
        Result: True
     Comment: Module function test.ping executed
    Changes:
       --
       ret:
            True

Summary for myminion
----------
Succeeded: 1
Failed: 0
----------
Total: 0
```

salt.output.highstate.output(data)

The HighState Outpouter is only meant to be used with the state.highstate function, or a function that returns highstate return data.
32.19.3 salt.output.json_out

Display return data in JSON format

configuration
The output format can be configured in two ways: Using the `--out-indent` CLI flag and specifying a positive integer or a negative integer to group JSON from each minion to a single line.

Or setting the `output_indent` setting in the Master or Minion configuration file with one of the following values:

- **Null**: put each minion return on a single line.
- **Pretty**: use four-space indents and sort the keys.
- An integer: specify the indentation level.

Salt's outputters operate on a per-minion basis. Each minion return will be output as a single JSON object once it comes in to the master.

Some JSON parsers can guess when an object ends and a new one begins but many can not. A good way to differentiate between each minion return is to use the single-line output format and to parse each line individually. Example output (truncated):

```json
{"dave": {"en0": {"hwaddr": "02:b0:26:32:4c:69", ...}}}
{"jerry": {"en0": {"hwaddr": "02:26:ab:0d:b9:0d", ...}}}
{"kevin": {"en0": {"hwaddr": "02:6d:7f:ce:9f:ee", ...}}}
{"mike": {"en0": {"hwaddr": "02:48:a2:4b:70:a0", ...}}}
{"phill": {"en0": {"hwaddr": "02:1d:cc:a2:33:55", ...}}}
{"stuart": {"en0": {"hwaddr": "02:9a:e0:ea:9e:3c", ...}}}
```

salt.output.json_out.output(data)
Print the output data in JSON

32.19.4 salt.output.key

Display salt-key output

The `salt-key` command makes use of this outputter to format its output.

salt.output.key.output(data)
Read in the dict structure generated by the salt key API methods and print the structure.

32.19.5 salt.output.nested

Recursively display nested data

This is the default outputter for most execution functions.

Example output:

```
myminion:
  
  foo:
    
    bar:
      baz
```
dictionary:
- abc: 123
- def: 456
- list:
  - Hello
  - World

class salt.output.nested.NestDisplay
Manage the nested display contents

    display(ret, indent, prefix, out)
    Recursively iterate down through data structures to determine output

    ustring(indent, color, msg, prefix='', suffix='', endc=None)

salt.output.nested.output(ret)
Display ret data

32.19.6 salt.output.newline_values_only

Display values only, separated by newlines

New in version 2015.5.0.

This outputer is designed for Salt CLI return data. It will do the following to the return dict:

1. Get just the values (ignoring the minion IDs).
2. Each value, if it is iterable, is split a separate line.
3. Each minion's values are separated by newlines.

This results in a single string of return data containing all the values from the various minions.

Warning: As noted above, this outputer will discard the minion ID. If the minion ID is important, then an outputer that returns the full return dictionary in a parsable format (such as json, pprint, or yaml) may be more suitable.

Example 1

Input

```python
{
    'myminion': ['127.0.0.1', '10.0.0.1'],
    'second-minion': ['127.0.0.1', '10.0.0.2']
}
```
Output

```
127.0.0.1
10.0.0.1
127.0.0.1
10.0.0.2
```

Example 2

Input

```
{
    'myminion': 8,
    'second-minion': 10
}
```

Output

```
8
10
```

```
salt.output.newline_values_only.output(data)
    Display modified ret data
```

### 32.19.7 salt.output.no_out

Display no output

No output is produced when this outpuverter is selected

```
salt.output.no_out.output(ret)
    Don't display data. Used when you only are interested in the return.
```

### 32.19.8 salt.output.no_return

Display output for minions that did not return

This outpuverter is used to display notices about which minions failed to return when a salt function is run with -v or --verbose. It should not be called directly from the CLI.

Example output:

```
virtucentos:
    Minion did **not return**
```

class salt.output.no_return.NestDisplay
    Create generator for nested output
    
    **display**(ret, indent, prefix, out)
    
    Recursively iterate down through data structures to determine output

32.19. Full list of builtin output modules
32.19.9  salt.output.overstatestage

Display clean output of an overstate stage

This outputer is used to display OverState stages, and should not be called directly.

salt.output.overstatestage.output(data)
Format the data for printing stage information from the overstate system

32.19.10 salt.output.pprint_out

Python pretty-print (pprint)

The python pretty-print system was once the default outputer. It simply passes the return data through to pprint.pformat and prints the results.

Example output:

```python
{'saltmine': {'foo': {'bar': 'baz',
    'dictionary': {'abc': 123, 'def': 456},
    'list': ['Hello', 'World']}}}
```

salt.output.pprint_out.output(data)
Print out via pretty print

32.19.11 salt.output.progress

Display return data as a progress bar

salt.output.progress.output(ret, bar)
Update the progress bar

salt.output.progress.progress_iter(progress)
Initialize and return a progress bar iter

32.19.12 salt.output.raw

Display raw output data structure

This outputer simply displays the output as a python data structure, by printing a string representation of it. It is similar to the pprint outputer, only the data is not nicely formatted/indented.

This was the original outputer used by Salt before the outputer system was developed.

Example output:

```python
{'myminion': {'foo': {'list': ['Hello', 'World'], 'bar': 'baz', 'dictionary': {'abc': 123, 'def': 456}}}}
```

salt.output.raw.output(data)
Rather basic...
32.19.13 salt.output.txt

Simple text outputter

The txt outputter has been developed to make the output from shell commands on minions appear as they do when the command is executed on the minion.

```python
salt.output.txt.output(data)
```
Output the data in lines, very nice for running commands

32.19.14 salt.output.virt_query

virt.query outputter

Used to display the output from the `virt.query` runner.

```python
salt.output.virt_query.output(data)
```
Display output for the salt-run virt.query function

32.19.15 salt.output.yaml_out

Display return data in YAML format

This outputter defaults to printing in YAML block mode for better readability.

Example output:

```yaml
saltmine:
  foo:
    bar: baz
  dictionary:
    abc: 123
    def: 456
  list:
    - Hello
    - World
```

```python
salt.output.yaml_out.output(data)
```
Print out YAML using the block mode

32.20 Peer Communication

Salt 0.9.0 introduced the capability for Salt minions to publish commands. The intent of this feature is not for Salt minions to act as independent brokers one with another, but to allow Salt minions to pass commands to each other.

In Salt 0.10.0 the ability to execute runners from the master was added. This allows for the master to return collective data from runners back to the minions via the peer interface.

The peer interface is configured through two options in the master configuration file. For minions to send commands from the master the `peer` configuration is used. To allow for minions to execute runners from the master the `peer_run` configuration is used.
Since this presents a viable security risk by allowing minions access to the master publisher the capability is turned off by default. The minions can be allowed access to the master publisher on a per minion basis based on regular expressions. Minions with specific ids can be allowed access to certain Salt modules and functions.

### 32.20.1 Peer Configuration

The configuration is done under the `peer` setting in the Salt master configuration file, here are a number of configuration possibilities.

The simplest approach is to enable all communication for all minions, this is only recommended for very secure environments.

```yaml
peer:
  .*:
    - .*
```

This configuration will allow minions with IDs ending in example.com access to the test, ps, and pkg module functions.

```yaml
peer:
  .*example.com:
    - test.*
    - ps.*
    - pkg.*
```

The configuration logic is simple, a regular expression is passed for matching minion ids, and then a list of expressions matching minion functions is associated with the named minion. For instance, this configuration will also allow minions ending with foo.org access to the publisher.

```yaml
peer:
  .*example.com:
    - test.*
    - ps.*
    - pkg.*
  .*foo.org:
    - test.*
    - ps.*
    - pkg.*
```

**Note:** Functions are matched using regular expressions.

### 32.20.2 Peer Runner Communication

Configuration to allow minions to execute runners from the master is done via the `peer_run` option on the master. The `peer_run` configuration follows the same logic as the `peer` option. The only difference is that access is granted to runner modules.

To open up access to all minions to all runners:

```yaml
peer_run:
  .*:
    - .*
```
This configuration will allow minions with IDs ending in example.com access to the manage and jobs runner functions.

```
peer_run:
  .*example.com:
    - manage.*
    - jobs.*
```

**Note:** Functions are matched using regular expressions.

### 32.20.3 Using Peer Communication

The publish module was created to manage peer communication. The publish module comes with a number of functions to execute peer communication in different ways. Currently there are three functions in the publish module. These examples will show how to test the peer system via the salt-call command.

To execute test.ping on all minions:

```
# salt-call publish.publish \* test.ping
```

To execute the manage.up runner:

```
# salt-call publish.runner manage.up
```

To match minions using other matchers, use `expr_form`:

```
# salt-call publish.publish 'webserv* and not G@os:Ubuntu' test.ping expr_form=
  !'compound'
```

### 32.21 Pillars

Salt includes a number of built-in external pillars, listed at [Full list of builtin pillar modules](#). You may also wish to look at the standard pillar documentation, at [Pillar Configuration](#)

The source for the built-in Salt pillars can be found here: https://github.com/saltstack/salt/blob/develop/salt/pillar

### 32.22.1 `salt.pillar.cmd_json`

Execute a command and read the output as JSON. The JSON data is then directly overlaid onto the minion’s Pillar data.

```
salt.pillar.cmd_json.ext_pillar(minion_id, pillar, command)
```

Execute a command and read the output as JSON

### 32.22.2 `salt.pillar.cmd_yaml`

Execute a command and read the output as YAML. The YAML data is then directly overlaid onto the minion’s Pillar data

```
salt.pillar.cmd_yaml.ext_pillar(minion_id, pillar, command)
```

Execute a command and read the output as YAML

### 32.22.3 `salt.pillar.cmd_yamlex`

Execute a command and read the output as YAMLEX. The YAMLEX data is then directly overlaid onto the minion’s Pillar data

```
salt.pillar.cmd_yamlex.ext_pillar(minion_id, pillar, command)
```

Execute a command and read the output as YAMLEX
32.22.4 salt.pillar.cobbler

A module to pull data from Cobbler via its API into the Pillar dictionary

Configuring the Cobbler ext_pillar

The same cobbler.* parameters are used for both the Cobbler tops and Cobbler pillar modules.

```
ext_pillar:
- cobbler:
    key: cobbler  # Nest results within this key. By default, values are not nested.
    only: [parameters]  # Add only these keys to pillar.

cobbler.url: https://example.com/cobbler_api  #default is http://localhost/cobbler_api

cobbler.user: username  # default is no username

cobbler.password: password  # default is no password
```

Module Documentation

`salt.pillar.cobbler.ext_pillar`(
  `minion_id`,
  `pillar`,
  `key=None`,
  `only=()`)

Read pillar data from Cobbler via its API.

32.22.5 salt.pillar.consul_pillar module

Use consul data as a Pillar source

```
depends
  • python-consul
```

In order to use an consul server, a profile must be created in the master configuration file:

```
my_consul_config:
  consul.host: 127.0.0.1
  consul.port: 8500
```

After the profile is created, configure the external pillar system to use it. Optionally, a root may be specified.

```
ext_pillar:
- consul: my_consul_config

ext_pillar:
- consul: my_consul_config root=/salt
```

Using these configuration profiles, multiple consul sources may also be used:

```
ext_pillar:
- consul: my_consul_config
- consul: my_other_consul_config
```

The `minion_id` may be used in the `root` path to expose minion-specific information stored in consul.

```
ext_pillar:
- consul: my_consul_config root=/salt/%(minion_id)s
```

32.22. Full list of builtin pillar modules

1637
Minion-specific values may override shared values when the minion-specific root appears after the shared root:

```yaml
ext_pillar:
  - consul: my_consul_config root=/salt-shared
  - consul: my_other_consul_config root=/salt-private/%(minion_id)s
```

salt.pillar.consul_pillar.consul_fetch(client, path)
Query consul for all keys/values within base path

salt.pillar.consul_pillar.ext_pillar(minion_id, pillar, conf)
Check consul for all data

salt.pillar.consul_pillar.fetch_tree(client, path)
Grab data from consul, trim base path and remove any keys which are folders. Take the remaining data and send it to be formatted in such a way as to be used as pillar data.

salt.pillar.consul_pillar.get_conn(opts, profile)
Return a client object for accessing consul

salt.pillar.consul_pillar.pillar_format(ret, keys, value)
Perform data formatting to be used as pillar data and merge it with the current pillar data

### 32.22.6 salt.pillar.django_orm

Generate Pillar data from Django models through the Django ORM

**Maintainer** Micah Hausler <micah.hausler@gmail.com>

**Maturity** new

#### Configuring the django_orm ext_pillar

To use this module, your Django project must be on the salt master server with database access. This assumes you are using virtualenv with all the project's requirements installed.

```yaml
ext_pillar:
  - django_orm:
      pillar_name: my_application
      project_path: /path/to/project/
      settings_module: my_application.settings
      env_file: /path/to/env/file.sh
      # Optional: If your project is not using the system python,
      # add your virtualenv path below.
      env: /path/to/virtualenv/
      
      django_app:
        # Required: the app that is included in INSTALLED_APPS
        my_application.clients:
          # Required: the model name
          Client:
            # Required: model field to use as the key in the rendered
            # Pillar. Must be unique; must also be included in the
            # `fields` list below.
            name: shortname
```
# Optional:
# See Django's QuerySet documentation for how to use .filter()
filter: {'kw': 'args'}

# Required: a list of field names
# List items will be used as arguments to the .values() method.
# See Django's QuerySet documentation for how to use .values()
fields:
  - field_1
  - field_2

This would return pillar data that would look like

```
my_application:
  my_application.clients:
    Client:
      client_1:
        field_1: data_from_field_1
        field_2: data_from_field_2
      client_2:
        field_1: data_from_field_1
        field_2: data_from_field_2
```

As another example, data from multiple database tables can be fetched using Django's regular lookup syntax. Note, using ManyToManyFields will not currently work since the return from values() changes if a ManyToMany is present.

```
ext_pillar:
  - django_orm:
    pillar_name: djangotutorial
    project_path: /path/to/mysite
    settings_module: mysite.settings

    django_app:
      mysite.polls:
        Choices:
          name: poll__question
          fields:
            - poll__question
            - poll__id
            - choice_text
            - votes
```

Module Documentation

salt.pillar.django_orm.ext_pillar(minion_id, pillar, pillar_name, project_path, settings_module, django_app, env=None, env_file=None, **kwargs)

Connect to a Django database through the ORM and retrieve model fields

Parameters

- pillar_name (str) -- The name of the pillar to be returned
- project_path (str) -- The full path to your Django project (the directory manage.py is in)
- settings_module (str) -- The settings module for your project. This can be found in your manage.py file
• **django_app** *(str)* -- A dictionary containing your apps, models, and fields

• **env** *(str)* -- The full path to the virtualenv for your Django project

• **env_file** *(str)* -- An optional bash file that sets up your environment. The file is run in a subprocess and the changed variables are then added

### 32.22.7 salt.pillar.ec2_pillar

Retrieve EC2 instance data for minions.

The minion id must be the instance-id retrieved from AWS. As an option, use_grain can be set to True. This allows the use of an instance-id grain instead of the minion-id. Since this is a potential security risk, the configuration can be further expanded to include a list of minions that are trusted to only allow the alternate id of the instances to specific hosts. There is no glob matching at this time.

```yaml
ext_pillar:
  - ec2_pillar:
    use_grain: True
    minion_ids:
      - trusted-minion-1
      - trusted-minion-2
      - trusted-minion-3
```

This is a very simple pillar that simply retrieves the instance data from AWS. Currently the only portion implemented are EC2 tags, which returns a list of key/value pairs for all of the EC2 tags assigned to the instance.

```python
salt.pillar.ec2_pillar.ext_pillar(minion_id, pillar, use_grain=False, minion_ids=None)
```

Execute a command and read the output as YAML

### 32.22.8 salt.pillar.etcd_pillar

Use etcd data as a Pillar source

New in version 2014.7.0.

```yaml
depends
  - python-etcd
```

In order to use an etcd server, a profile must be created in the master configuration file:

```yaml
my_etcd_config:
etcd.host: 127.0.0.1
etcd.port: 4001
```

After the profile is created, configure the external pillar system to use it. Optionally, a root may be specified.

```yaml
ext_pillar:
  - etcd: my_etcd_config
ext_pillar:
  - etcd: my_etcd_config root=/salt
```

Using these configuration profiles, multiple etcd sources may also be used.
ext_pillar:
  - etcd: my_etcd_config
  - etcd: my_other_etcd_config

The minion_id may be used in the root path to expose minion-specific information stored in etcd.

ext_pillar:
  - etcd: my_etcd_config root=/salt/%(minion_id)s

Minion-specific values may override shared values when the minion-specific root appears after the shared root:

ext_pillar:
  - etcd: my_etcd_config root=/salt-shared
  - etcd: my_other_etcd_config root=/salt-private/%(minion_id)s

Using the configuration above, the following commands could be used to share a key with all minions but override its value for a specific minion:

etcdctl set /salt-shared/mykey my_value
etcdctl set /salt-private/special_minion_id/mykey my_other_value

salt.pillar.etcd_pillar.ext_pillar(minion_id, pillar, conf)
  Check etcd for all data

### 32.22.9 salt.pillar.file_tree

Recursively iterate over directories and add all files as Pillar data

New in version 2015.5.0.

**Example Configuration**

```python
ext_pillar:
  - file_tree:
      root_dir: /path/to/root/directory
      follow_dir_links: False
      keep_newline: True
```

The root_dir parameter is required and points to the directory where files for each host are stored. The follow_dir_links parameter is optional and defaults to False. If follow_dir_links is set to True, this external pillar will follow symbolic links to other directories.

**Warning:** Be careful when using follow_dir_links, as a recursive symlink chain will result in unexpected results.

If keep_newline is set to True, then the pillar values for files ending in newlines will keep that newline. The default behavior is to remove the end-of-file newline. keep_newline should be turned on if the pillar data is intended to be used to deploy a file using contents_pillar with a file.managed state.

Changed in version 2015.8.4: The raw_data parameter has been renamed to keep_newline. In earlier releases, raw_data must be used. Also, this parameter can now be a list of globs, allowing for more granular control over which pillar values keep their end-of-file newline. The globs match paths relative to the directories named for minion IDs and nodegroups underneath the root_dir (see the layout examples in the below sections).
ext_pillar:
  - file_tree:
      root_dir: /path/to/root/directory
      keep_newline:
        - files/testdir/*

Note: In earlier releases, this documentation incorrectly stated that binary files would not be affected by the `keep_newline` configuration. However, this module does not actually distinguish between binary and text files.

Assigning Pillar Data to Individual Hosts

To configure pillar data for each host, this external pillar will recursively iterate over `root_dir/hosts/id` (where `id` is a minion ID), and compile pillar data with each subdirectory as a dictionary key and each file as a value.

For example, the following `root_dir` tree:

```
./hosts/
./hosts/test-host/
./hosts/test-host/files/
./hosts/test-host/files/testdir/
./hosts/test-host/files/testdir/file1.txt
./hosts/test-host/files/testdir/file2.txt
./hosts/test-host/files/another-testdir/
./hosts/test-host/files/another-testdir/symlink-to-file1.txt
```

will result in the following pillar tree for minion with ID `test-host`:

```
test-host:
  --------
  files:
    --------
    another-testdir:
      --------
      symlink-to-file1.txt:
        Contents of file #1.
    testdir:
      --------
      file1.txt:
        Contents of file #1.
      file2.txt:
        Contents of file #2.
```

Note: Subdirectories underneath `root_dir/hosts/id` become nested dictionaries, as shown above.

Assigning Pillar Data to Entire Nodegroups

To assign Pillar data to all minions in a given nodegroup, this external pillar recursively iterates over `root_dir/nodegroups/nodegroup` (where `nodegroup` is the name of a nodegroup), and like for individual hosts, compiles pillar data with each subdirectory as a dictionary key and each file as a value.
**Important:** If the same Pillar key is set for a minion both by nodegroup and by individual host, then the value set for the individual host will take precedence.

For example, the following root_dir tree:

```plaintext
./nodegroups/
./nodegroups/test-group/
./nodegroups/test-group/files/
./nodegroups/test-group/files/testdir/
./nodegroups/test-group/files/testdir/file1.txt
./nodegroups/test-group/files/testdir/file2.txt
./nodegroups/test-group/files/another-testdir/
./nodegroups/test-group/files/another-testdir/symlink-to-file1.txt
```

will result in the following pillar data for minions in the node group test-group:

```plaintext
test-host:
    ---------
    files:
    ---------
    another-testdir:
    ---------
    symlink-to-file1.txt:
        Contents of file #1.
    testdir:
    ---------
    file1.txt:
        Contents of file #1.
    file2.txt:
        Contents of file #2.
```

---

**salt.pillar.file_tree.ext_pillar** *(minion_id, pillar, root_dir=None, follow_dir_links=False, debug=False, raw_data=None, keep_newline=False)*

Compile pillar data for the specified minion ID

---

### 32.22.10 salt.pillar.foreman

A module to pull data from Foreman via its API into the Pillar dictionary

**Configuring the Foreman ext_pillar**

Set the following Salt config to setup Foreman as external pillar source:

```plaintext
ext_pillar:
    - foreman:
        key: foreman # Nest results within this key
        only: ['hostgroup_name', 'parameters'] # Add only these keys to pillar
foreman.url: https://example.com/foreman_api
foreman.user: username # default is admin
foreman.password: password # default is changeme
```
The following options are optional:

```python
foreman.api: apiversion # default is 2 (1 is not supported yet)
foreman.verifyssl: False # default is True
foreman.certfile: /etc/ssl/certs/mycert.pem # default is None
foreman.keyfile: /etc/ssl/private/mykey.pem # default is None
foreman.cafile: /etc/ssl/certs/mycert.ca.pem # default is None
foreman.lookup_parameters: True # default is True
```

An alternative would be to use the Foreman modules integrating Salt features in the Smart Proxy and the webinterface.

Further information can be found on GitHub.

**Module Documentation**

```python
salt.pillar.foreman.ext_pillar(minion_id, pillar, key=None, only=())
```

Read pillar data from Foreman via its API.

### 32.22.11 salt.pillar.git_pillar

Use a git repository as a Pillar source

**Note:** This external pillar has been rewritten for the 2015.8.0 release. The old method of configuring this external pillar will be maintained for a couple releases, allowing time for configurations to be updated to reflect the new usage.

This external pillar allows for a Pillar top file and Pillar SLS files to be sourced from a git repository.

However, since git_pillar does not have an equivalent to the `pillar_roots` parameter, configuration is slightly different. The Pillar top file must still contain the relevant environment, like so:

```python
base:
  '*':
    - foo
```

The branch/tag which maps to that environment must then be specified along with the repo's URL. Configuration details can be found below.

**Important:** Each branch/tag used for git_pillar must have its own top file. This is different from how the top file works when configuring States. The reason for this is that each git_pillar branch/tag is processed separately from the rest. Therefore, if the qa branch is to be used for git_pillar, it would need to have its own top file, with the qa environment defined within it, like this:

```python
qa:
  'dev-*':
    - bar
```

Additionally, while git_pillar allows for the branch/tag to be overridden (see here, or here for Salt releases before 2015.8.0), keep in mind that the top file must reference the actual environment name. It is common practice to make the environment in a git_pillar top file match the branch/tag name, but when remapping, the environment of course no longer matches the branch/tag, and the top file needs to be adjusted accordingly. When expected Pillar values
configured in git_pillar are missing, this is a common misconfiguration that may be to blame, and is a good first step in troubleshooting.

**Configuring git_pillar for Salt releases before 2015.8.0**

For Salt releases earlier than 2015.8.0, GitPython is the only supported provider for git_pillar. Individual repositories can be configured under the `ext_pillar` configuration parameter like so:

```yaml
ext_pillar:
- git: master https://gitserver/git-pillar.git root=subdirectory
```

The repository is specified in the format `<branch> <repo_url>`, with an optional `root` parameter (added in the 2014.7.0 release) which allows the pillar SLS files to be served up from a subdirectory (similar to `gitfs_root` in gitfs).

To use more than one branch from the same repo, multiple lines must be specified under `ext_pillar`:

```yaml
ext_pillar:
- git: master https://gitserver/git-pillar.git
- git: dev https://gitserver/git-pillar.git
```

To remap a specific branch to a specific Pillar environment, use the format `<branch>:<env>`:

```yaml
ext_pillar:
- git: develop:dev https://gitserver/git-pillar.git
- git: master:prod https://gitserver/git-pillar.git
```

In this case, the `develop` branch would need its own `top.sls` with a `dev` section in it, like this:

```yaml
dev:
  '*':
    - bar
```

The `master` branch would need its own `top.sls` with a `prod` section in it:

```yaml
prod:
  '*':
    - bar
```

If `__env__` is specified as the branch name, then git_pillar will use the branch specified by `gitfs_base`:

```yaml
ext_pillar:
- git: __env__ https://gitserver/git-pillar.git root=pillar
```

The corresponding Pillar top file would look like this:

```yaml
{{env}}:
  '*':
    - bar
```

**Configuring git_pillar for Salt releases 2015.8.0 and later**
Note: In version 2015.8.0, the method of configuring git external pillars has changed, and now more closely resembles that of the Git Filesserver Backend. If Salt detects the old configuration schema, it will use the pre-2015.8.0 code to compile the external pillar. A warning will also be logged.

Beginning with Salt version 2015.8.0, pygit2 is now supported in addition to GitPython (Dulwich will not be supported for the foreseeable future). The requirements for GitPython and pygit2 are the same as for gitfs, as described here.

Important: git_pillar has its own set of global configuration parameters. While it may seem intuitive to use the global gitfs configuration parameters (gitfs_base, etc.) to manage git_pillar, this will not work. The main difference for this is the fact that the different components which use Salt’s git backend code do not all function identically. For instance, in git_pillar it is necessary to specify which branch/tag to be used for git_pillar remotes. This is the reverse behavior from gitfs, where branches/tags make up your environments.

See here for documentation on the git_pillar configuration options and their usage.

Here is an example git_pillar configuration:

```
ext_pillar:
  - git:
    # Use 'prod' instead of the branch name 'production' as the environment
    - production https://gitserver/git-pillar.git:
      - env: prod
    # Use 'dev' instead of the branch name 'develop' as the environment
    - develop https://gitserver/git-pillar.git:
      - env: dev
    # No per-remote config parameters (and no trailing colon), 'qa' will # be used as the environment
    - qa https://gitserver/git-pillar.git
    # SSH key authentication
    - master git@other-git-server:pillardata-ssh.git:
      # Pillar SLS files will be read from the 'pillar' subdirectory in # this repository
      - root: pillar
      - privkey: /path/to/key
      - pubkey: /path/to/key.pub
      - passphrase: CorrectHorseBatteryStaple
    # HTTPS authentication
    - master https://other-git-server/pillardata-https.git:
      - user: git
      - password: CorrectHorseBatteryStaple
```

The main difference between this and the old way of configuring git_pillar is that multiple remotes can be configured under one git section under **ext_pillar**. More than one git section can be used, but it is not necessary. Remotes will be evaluated sequentially.

Per-remote configuration parameters are supported (similar to gitfs), and global versions of the git_pillar configuration parameters can also be set. To remap a specific branch to a specific Pillar environment, use the **env** per-remote parameter:

```
ext_pillar:
  - git:
    - production https://gitserver/git-pillar.git:
      - env: prod
```
With the addition of `pygit2` support, `git_pillar` can now interact with authenticated remotes. Authentication works just like in `gitfs` (as outlined in the `Git Fileserver Backend Walkthrough`), only with the global authentication parameter names prefixed with `git_pillar` instead of `gitfs` (e.g. `git_pillar_pubkey`, `git_pillar_privkey`, `git_pillar_passphrase`, etc.).

**Note:** The `name` parameter can be used to further differentiate between two remotes with the same URL and branch. When using two remotes with the same URL, the `name` option is required.

```python
salt.pillar.git_pillar.ext_pillar(minion_id, repo, pillar_dirs)
```

Checkout the `ext_pillar` sources and compile the resulting pillar SLS

### 32.22.12 salt.pillar.hg_pillar

Use remote Mercurial repository as a Pillar source.

New in version 2015.8.0.

The module depends on the `hglib` python module being available. This is the same requirement as for `hgfs`, so should not pose any extra hurdles.

This external Pillar source can be configured in the master config file as such:

```yaml
ext_pillar:
  - hg: ssh://hg@example.co/user/repo
```

```python
class salt.pillar.hg_pillar.Repo(repo_uri)
    Deal with remote hg (mercurial) repository for Pillar
        close()
            Cleanup mercurial command server
        pull()
        update(branch='default')
            Ensure we are using the latest revision in the hg repository
```

```python
salt.pillar.hg_pillar.ext_pillar(minion_id, pillar, repo, branch='default', root=None)
    Extract pillar from an hg repository
```

```python
salt.pillar.hg_pillar.update(repo_uri)
    Execute an hg pull on all the repos
```

### 32.22.13 salt.pillar.hiera

Use hiera data as a Pillar source

```python
salt.pillar.hiera.ext_pillar(minion_id, pillar, conf)
    Execute hiera and return the data
```

### 32.22.14 salt.pillar.libvirt

Load up the libvirt keys into Pillar for a given minion if said keys have been generated using the libvirt key runner

```python
salt.pillar.libvirt.ext_pillar(minion_id, pillar, command)
    Read in the generated libvirt keys
```
salt.pillar.libvirt.gen_hyper_keys(minion_id, country='US', state='Utah', locality='Salt Lake City', organization='Salted')

Generate the keys to be used by libvirt hypervisors, this routine gens the keys and applies them to the pillar for the hypervisor minions

32.22.15 salt.pillar.mongo

Read Pillar data from a mongodb collection

depends pymongo (for salt-master)

This module will load a node-specific pillar dictionary from a mongo collection. It uses the node's id for lookups and can load either the whole document, or just a specific field from that document as the pillar dictionary.

Salt Master Mongo Configuration

The module shares the same base mongo connection variables as salt.returners.mongo_return. These variables go in your master config file.

- mongo.db - The mongo database to connect to. Defaults to 'salt'.
- mongo.host - The mongo host to connect to. Supports replica sets by specifying all hosts in the set, comma-delimited. Defaults to 'salt'.
- mongo.port - The port that the mongo database is running on. Defaults to 27017.
- mongo.user - The username for connecting to mongo. Only required if you are using mongo authentication. Defaults to ''. 
- mongo.password - The password for connecting to mongo. Only required if you are using mongo authentication. Defaults to ''. 

Configuring the Mongo ext_pillar

The Mongo ext_pillar takes advantage of the fact that the Salt Master configuration file is yaml. It uses a sub-dictionary of values to adjust specific features of the pillar. This is the explicit single-line dictionary notation for yaml. One may be able to get the easier-to-read multi-line dict to work correctly with some experimentation.

```yaml
ext_pillar:
  - mongo: {collection: 'vm', id_field: 'name', re_pattern: '\.example\..com', fields:[
      customer_id, software, apache_vhosts]}
```

In the example above, we've decided to use the vm collection in the database to store the data. Minion ids are stored in the name field on documents in that collection. And, since minion ids are FQDNs in most cases, we'll need to trim the domain name in order to find the minion by hostname in the collection. When we find a minion, return only the customer_id, software, and apache_vhosts fields, as that will contain the data we want for a given node. They will be available directly inside the pillar dict in your SLS templates.

Module Documentation

salt.pillar.mongo.ext_pillar(minion_id, pillar, collection='pillar', id_field='_id', re_pattern=None, re_replace=':', fields=None)

Connect to a mongo database and read per-node pillar information.

Parameters:
• **collection**: The mongodb collection to read data from. Defaults to 'pillar'.

• **id_field**: The field in the collection that represents an individual minion id. Defaults to '_id'.

• **re_pattern**: If your naming convention in the collection is shorter than the minion id, you can use this to trim the name. `re_pattern` will be used to match the name, and `re_replace` will be used to replace it. Backrefs are supported as they are in the Python standard library. If `None`, no mangling of the name will be performed - the collection will be searched with the entire minion id. Defaults to `None`.

• **re_replace**: Use as the replacement value in node ids matched with `re_pattern`. Defaults to `''`. Feel free to use backreferences here.

• **fields**: The specific fields in the document to use for the pillar data. If `None`, will use the entire document. If using the entire document, the `_id` field will be converted to string. Be careful with other fields in the document as they must be string serializable. Defaults to `None`.

### 32.22.16 salt.pillar.mysql

Retrieve Pillar data by doing a MySQL query

MariaDB provides Python support through the MySQL Python package. Therefore, you may use this module with both MySQL or MariaDB.

This module is a concrete implementation of the sql_base ext_pillar for MySQL.

```plaintext
maturity   new
depends    python-mysqldb
platform   all
```

**Legacy compatibility**

This module has an extra addition for backward compatibility.

If there's a keyword arg of mysql_query, that'll go first before other args. This legacy compatibility translates to depth 1.

We do this so that it's backward compatible with older configs. This is deprecated and slated to be removed in Boron.

**Configuring the mysql ext_pillar**

Use the `mysql` key under ext_pillar for configuration of queries.

MySQL configuration of the MySQL returner is being used (mysql.db, mysql.user, mysql.pass, mysql.port, mysql.host) for database connection info.

Required python modules: MySQLdb

**Complete example**

```plaintext
mysql:
  user: 'salt'
  pass: 'super_secret_password'
  db: 'salt_db'
```
class salt.pillar.mysql.MySQLExtPillar
    This class receives and processes the database rows from MySQL.

    extract_queries(args, kwargs)
        This function normalizes the config block into a set of queries we can use. The return is a list of consistently laid out dicts.

salt.pillar.mysql.ext_pillar(minion_id, pillar, *args, **kwargs)
    Execute queries against MySQL, merge and return as a dict

32.22.17 salt.pillar.neutron module

Use Openstack Neutron data as a Pillar source. Will list all networks listed inside of Neutron, to all minions.
New in version 2015.5.1.

depends
    - python-neutronclient

A keystone profile must be used for the pillar to work (no generic keystone configuration here). For example:

my_openstack_config:
    keystone.user: 'admin'
    keystone.password: 'password'
    keystone.tenant: 'admin'
    keystone.auth_url: 'http://127.0.0.1:5000/v2.0/'
    keystone.region_name: 'RegionOne'
    keystone.service_type: 'network'

After the profile is created, configure the external pillar system to use it.

ext_pillar:
    - neutron: my_openstack_conf

Using these configuration profiles, multiple neutron sources may also be used:

ext_pillar:
    - neutron: my_openstack_config
    - neutron: my_other_openstack_config

By default, these networks will be returned as a pillar item called networks. In order to have them returned under a different name, add the name after the Keystone profile name:

ext_pillar:
    - neutron: my_openstack_config neutron_networks

salt.pillar.neutron.ext_pillar(minion_id, pillar, conf)
    Check neutron for all data
32.22.18  salt.pillar.pepa

Pepa

Configuration templating for SaltStack using Hierarchical substitution and Jinja.

Configuring Pepa

```
extension_modules: /srv/salt/ext

ext_pillar:
  - pepa:
      resource: host  # Name of resource directory and sub-key in pillars
      sequence:
        - hostname:
          name: input
          base_only: True  # Only use templates from Base environment, i.e. no
      subkey: True  # Create a sub-key in pillars, named after the resource in this case [host]
      subkey_only: True  # Only create a sub-key, and leave the top level untouched

  → staging
        - default:
          - environment:
            - location..region:
              name: region
            - location..country:
              name: country
            - location..datacenter:
              name: datacenter
            - roles:
              - osfinger:
                name: os
              - hostname:
                name: override
                base_only: True
                subkey: True
        → resource in this case [host]
        → subkey: True
        → subkey_only: True

  → resource in this case [host]

pepa_roots:
  base: /srv/pepa/base  # Base directory for each environment
  dev: /srv/pepa/base  # Path for base environment
  qa: /srv/pepa/qa  # Associate dev with base
  prod: /srv/pepa/prod

# Use a different delimiter for nested dictionaries, defaults to '..' since some keys may use '.' in the name
#pepa_delimiter: ..

# Supply Grains for Pepa, this should **ONLY** be used for testing or validation
#pepa_grains:
# environment: dev

# Supply Pillar for Pepa, this should **ONLY** be used for testing or validation
#pepa_pillars:
# saltversion: 0.17.4

# Enable debug for Pepa, and keep Salt on warning
#log_level: debug

```
Pepa can also be used in Master-less SaltStack setup.

**Command line**

```

positional arguments:
hostname          Hostname

optional arguments:
-h, --help        show this help message and exit
-c CONFIG, --config CONFIG  Configuration file
-d, --debug       Print debug info
-g GRAINS, --grains GRAINS Input Grains as YAML
-p PILLAR, --pillar PILLAR Input Pillar as YAML
-n, --no-color    No color output
-v, --validate    Validate output
```

**Templates**

Templates is configuration for a host or software, that can use information from Grains or Pillars. These can then be used for hierarchically substitution.

**Example File**: `host/input/test_example_com.yaml`

```yaml
location..region: emea
location..country: nl
location..datacenter: foobar
environment: dev
roles:
  - salt.master
network..gateway: 10.0.0.254
network..interfaces..eth0..hwaddr: 00:20:26:a1:12:12
network..interfaces..eth0..ipv4: 10.0.0.3
network..interfaces..eth0..netmask: 255.255.255.0
network..interfaces..eth0..fqdn: {{ hostname }}
cobbler..profile: fedora-19-x86_64
```

As you see in this example you can use Jinja directly inside the template.

**Example File**: `host/region/amer.yaml`

```yaml
network..dns..servers:
  - 10.0.0.1
  - 10.0.0.2
```
time..ntp..servers:
- ntp1.amer.example.com
- ntp2.amer.example.com
- ntp3.amer.example.com
time..timezone: America/Chihuahua
yum..mirror: yum.amer.example.com

Each template is named after the value of the key using lowercase and all extended characters are replaced with underscore.

Example:

osfinger: Fedora-19

Would become:

fedora_19.yaml

**Nested dictionaries**

In order to create nested dictionaries as output you can use double dot ""."" as a delimiter. You can change this using `pepa_delimiter` we choose double dot since single dot is already used by key names in some modules, and using ":" requires quoting in the YAML.

Example:

```
network..dns..servers:
  - 10.0.0.1
  - 10.0.0.2
network..dns..options:
  - timeout:2
  - attempts:1
  - ndots:1
network..dns..search:
  - example.com
```

Would become:

```
network:
  dns:
    servers:
      - 10.0.0.1
      - 10.0.0.2
    options:
      - timeout:2
      - attempts:1
      - ndots:1
    search:
      - example.com
```

**Operators**

Operators can be used to merge/unset a list/hash or set the key as immutable, so it can't be changed.
<table>
<thead>
<tr>
<th>Operator</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>merge()</td>
<td>Merge list or hash</td>
</tr>
<tr>
<td>unset()</td>
<td>Unset key</td>
</tr>
<tr>
<td>immutable()</td>
<td>Set the key as immutable, so it can’t be changed</td>
</tr>
<tr>
<td>immerge()</td>
<td>Set immutable and merge</td>
</tr>
<tr>
<td>iunset()</td>
<td>Set immutable and unset</td>
</tr>
</tbody>
</table>

**Example:**

```yaml
network..dns..search..merge():
- foobar.com
- dummy.nl
owner..immutable(): Operations
host..printers..unset():
```

**Validation**

Since it’s very hard to test Jinja as is, the best approach is to run all the permutations of input and validate the output, i.e. Unit Testing.

To facilitate this in Pea we use YAML, Jinja and Cerberus [https://github.com/nicolaiarocci/cerberus].

**Schema**

So this is a validation schema for network configuration, as you see it can be customized with Jinja just as Pea templates.

This was designed to be run as a build job in Jenkins or similar tool. You can provide Grains/Pillar input using either the config file or command line arguments.

**File Example: host/validation/network.yaml**

```yaml
network..dns..search:
  type: list
  allowed:
    - example.com

network..dns..options:
  type: list
  allowed: ['timeout:2', 'attempts:1', 'ndots:1']

network..dns..servers:
  type: list
  regex: ^([0-9]{1,3}\.){3}[0-9]{1,3}$

network..gateway:
  type: string
  regex: ^([0-9]{1,3}\.){3}[0-9]{1,3}$

{% if network.interfaces is defined %}
{% for interface in network.interfaces %}

network..interfaces..{{ interface }}..dhcp:
  type: boolean

network..interfaces..{{ interface }}..fqdn:
```

Links

salt.pillar.pepa.ext_pillar(minion_id, pillar, resource, sequence, subkey=False, subkey_only=False)
Evaluate Pea templates

salt.pillar.pepa.key_value_to_tree(data)
Convert key/value to tree

salt.pillar.pepa.validate(output, resource)
Validate Pea templates

32.22.19 salt.pillar.pillar_ldap

Use LDAP data as a Pillar source

This pillar module executes a series of LDAP searches. Data returned by these searches are aggregated, whereby
data returned by later searches override data by previous searches with the same key.

The final result is merged with existing pillar data.

The configuration of this external pillar module is done via an external file which provides the actual configuration
for the LDAP searches.

Configuring the LDAP ext_pillar

The basic configuration is part of the master configuration.

```
ext_pillar:
  - pillar_ldap: /etc/salt/master.d/pillar_ldap.yaml
```

Note: When placing the file in the master.d directory, make sure its name doesn't end in .conf, otherwise the
salt-master process will attempt to parse its content.
Warning:  Make sure this file has very restrictive permissions, as it will contain possibly sensitive LDAP credentials!

The only required key in the master configuration is pillar_ldap pointing to a file containing the actual configuration.

Configuring the LDAP searches

The file is processed using Salt’s Renderers <renderers> which makes it possible to reference grains within the configuration.

Warning: When using Jinja in this file, make sure to do it in a way which prevents leaking sensitive information. A rogue minion could send arbitrary grains to trick the master into returning secret data. Use only the `id' grain which is verified through the minion's key/cert.

Map Mode

The it-admins configuration below returns the Pillar it-admins by:

- filtering for:
  - members of the group it-admins
  - objects with objectclass=user
- returning the data of users (mode: map), where each user is a dictionary containing the configured string or list attributes.

Configuration:

```yaml
salt-users:
  server: ldap.company.tld
  port: 389
  tls: true
  dn: 'dc=company,dc=tld'
  binddn: 'cn=salt-pillars,ou=users,dc=company,dc=tld'
  bindpw: bi7ieBai5Ano
  referrals: false
  anonymous: false
  mode: map
  dn: 'ou=users,dc=company,dc=tld'
  filter: '(&(memberof=cn=it-admins,ou=groups,dc=company,dc=tld)(objectclass=user))'
  attrs:
    - cn
    - displayName
    - givenName
    - sn
  lists:
    - memberOf
```

**Result:**

1656 Chapter 32. Reference
List Mode

TODO: see also `_result_to_dict()` documentation

```python
salt.pillar.pillar_ldap.ext_pillar(minion_id, pillar, config_file)
```

Execute LDAP searches and return the aggregated data

### 32.22.20 salt.pillar.puppet

Execute an unmodified puppet_node_classifier and read the output as YAML. The YAML data is then directly overlaid onto the minion’s Pillar data.

```python
salt.pillar.puppet.ext_pillar(minion_id, pillar, command)
```

Execute an unmodified puppet_node_classifier and read the output as YAML

### 32.22.21 salt.pillar.reclass_adapter

Use the `reclass` database as a Pillar source

This `ext_pillar` plugin provides access to the `reclass` database, such that Pillar data for a specific minion are fetched using reclass.

You can find more information about reclass at [http://reclass.pantsfullofunix.net](http://reclass.pantsfullofunix.net).

To use the plugin, add it to the `ext_pillar` list in the Salt master config and tell reclass by way of a few options how and where to find the inventory:

```python
ext_pillar:
  - reclass:
      storage_type: yaml_fs
      inventory_base_uri: /srv/salt
```

This would cause reclass to read the inventory from YAML files in `/srv/salt/nodes` and `/srv/salt/classes`.

If you are also using reclass as master_tops plugin, and you want to avoid having to specify the same information for both, use YAML anchors (take note of the differing data types for `ext_pillar` and `master_tops`):

```python
salt-users:
  - cn: cn=johndoe,ou=users,dc=company,dc=tld
    displayName: John Doe
    givenName: John
    sn: Doe
    memberOf:
      - cn=it-admins,ou=groups,dc=company,dc=tld
      - cn=team01,ou=groups,dc=company
  - cn: cn=janedoe,ou=users,dc=company,dc=tld
    displayName: Jane Doe
    givenName: Jane
    sn: Doe
    memberOf:
      - cn=it-admins,ou=groups,dc=company,dc=tld
      - cn=team02,ou=groups,dc=company
```
If you want to run reclass from source, rather than installing it, you can either let the master know via the PYTHONPATH environment variable, or by setting the configuration option, like in the example above.

```python
salt.pillar.reclass_adapter.ext_pillar(minion_id, pillar, **kwargs)
```

Obtain the Pillar data from reclass for the given minion_id.

### 32.22.22 salt.pillar.redismod

**Read pillar data from a Redis backend**

New in version 2014.7.0.

```python
depends
    * redis Python module (on master)
```

**Salt Master Redis Configuration**

The module shares the same base Redis connection variables as `salt.returners.redis_return`. These variables go in your master config file.

- `redis.db` - The Redis database to use. Defaults to 0.
- `redis.host` - The Redis host to connect to. Defaults to 'salt'.
- `redis.port` - The port that the Redis database is listening on. Defaults to 6379.
- `redis.password` - The password for authenticating with Redis. Only required if you are using master auth. Defaults to None.

**Configuring the Redis ext_pillar**

```python
ext_pillar:
    - redis: {function: key_value}
```

```python
code
salt.pillar.redismod.ext_pillar(minion_id, pillar, function, **kwargs)
```

Grabs external pillar data based on configured function.

```python
code
salt.pillar.redismod.key_json(minion_id, pillar, pillar_key=None)
```

Pulls a string from redis and deserializes it from json. Deserialized dictionary data loaded directly into top level if pillar_key is not set.

- `pillar_key` - Pillar key to return data into
salt.pillar.redismod.key_value(minion_id, pillar, pillar_key='redis_pillar')

Looks for key in redis matching minion_id, returns a structure based on the data type of the redis key. String for string type, dict for hash type and lists for lists, sets and sorted sets.

pillar_key Pillar key to return data into

32.22.23  salt.pillar.s3

Copy pillar data from a bucket in Amazon S3

The S3 pillar can be configured in the master config file with the following options:

```python
ext_pillar:
  - s3:
      bucket: my.fancy.pillar.bucket
      keyid: KASKFJWAKJASJKDAJKSD
      key: ksladfDLKDALSFKSD93q032sdasdfsadflsadkf
      multiple_env: False
      environment: base
      prefix: somewhere/overthere
      verify_ssl: True
      service_url: s3.amazonaws.com
      s3_cache_expire: 30
      s3_sync_on_update: True
```

The `bucket` parameter specifies the target S3 bucket. It is required.

The `keyid` parameter specifies the key id to use when access the S3 bucket. If it is not provided, an attempt to fetch it from EC2 instance meta-data will be made.

The `key` parameter specifies the key to use when access the S3 bucket. If it is not provided, an attempt to fetch it from EC2 instance meta-data will be made.

The `multiple_env` defaults to False. It specifies whether the pillar should interpret top level folders as pillar environments (see mode section below).

The `environment` defaults to `base`. It specifies which environment the bucket represents when in single environments mode (see mode section below). It is ignored if `multiple_env` is True.

The `prefix` defaults to `. It specifies a key prefix to use when searching for data in the bucket for the pillar. It works when `multiple_env` is True or False. Essentially it tells ext_pillar to look for your pillar data in a 'subdirectory' of your S3 bucket

The `verify_ssl` parameter defaults to True. It specifies whether to check for valid S3 SSL certificates. NOTE If you use bucket names with periods, this must be set to False else an invalid certificate error will be thrown (issue #12200).

The `service_url` parameter defaults to `s3.amazonaws.com`. It specifies the base url to use for accessing S3.

The `s3_cache_expire` parameter defaults to 30s. It specifies expiration time of S3 metadata cache file.

The `s3_sync_on_update` parameter defaults to True. It specifies if cache is synced on update rather than jit.

This pillar can operate in two modes, single environment per bucket or multiple environments per bucket.

Single environment mode must have this bucket structure:

```
s3://<bucket name>/<prefix>/<files>
```

Multiple environment mode must have this bucket structure:

32.22. Full list of builtin pillar modules
If you wish to define your pillar data entirely within S3 it's recommended that you use the `prefix=` parameter and specify one entry in ext_pillar for each environment rather than specifying multiple_env. This is due to issue #22471 (https://github.com/saltstack/salt/issues/22471)

```python
class salt.pillar.s3.S3Credentials
    key, keyid, bucket, service_url, verify_ssl, location

salt.pillar.s3.ext_pillar
    minion_id, pillar, bucket, key=None, keyid=None, verify_ssl=True, location=None, multiple_env=False, environment='base', prefix='', service_url=None, s3_cache_expire=30, s3_sync_on_update=True)
```

Execute a command and read the output as YAML

### 32.22.24 salt.pillar.sql_base module

Retrieve Pillar data by doing a SQL query

This module is not meant to be used directly as an ext_pillar. It is a place to put code common to PEP 249 compliant SQL database adapters. It exposes a python ABC that can be subclassed for new database providers.

```yaml
maturity new
platform all
```

**Theory of sql_base ext_pillar**

Ok, here's the theory for how this works...

- First, any non-keyword args are processed in order.
- Then, remaining keywords are processed.

We do this so that it's backward compatible with older configs. Keyword arguments are sorted before being appended, so that they're predictable, but they will always be applied last so overall it's moot.

For each of those items we process, it depends on the object type:

- Strings are executed as is and the pillar depth is determined by the number of fields returned.
- A list has the first entry used as the query, the second as the pillar depth.
- A mapping uses the keys `query` and `depth` as the tuple

You can retrieve as many fields as you like, how they get used depends on the exact settings.

**Configuring a sql_base ext_pillar**

The sql_base ext_pillar cannot be used directly, but shares query configuration with its implementations. These examples use a fake 'sql_base' adapter, which should be replaced with the name of the adapter you are using.

A list of queries can be passed in

```yaml
ext_pillar:
    - sql_base:
      "SELECT pillar, value FROM pillars WHERE minion_id = %s"
      "SELECT pillar, value FROM more_pillars WHERE minion_id = %s"
```

Or you can pass in a mapping
The query can be provided as a string as we have just shown, but they can be provided as lists

```
ext_pillar:
  - sql_base:
    main: "SELECT pillar,value FROM pillars WHERE minion_id = %s"
    extras: "SELECT pillar,value FROM more_pillars WHERE minion_id = %s"
```

Or as a mapping

```
ext_pillar:
  - sql_base:
    - query: "SELECT pillar,value FROM pillars WHERE minion_id = %s"
depth: 2
```

The depth defines how the dicts are constructed. Essentially if you query for fields a,b,c,d for each row you’ll get:

- With depth 1: `{a: {`b`: b, `c`: c, `d`: d}}`
- With depth 2: `{a: {`c`: c, `d`: d}}`
- With depth 3: `{a: {c: d}}`

Depth greater than 3 wouldn’t be different from 3 itself. Depth of 0 translates to the largest depth needed, so 3 in this case. (max depth == key count - 1)

Then they are merged in a similar way to plain pillar data, in the order returned by the SQL database.

Thus subsequent results overwrite previous ones when they collide.

The ignore_null option can be used to change the overwrite behavior so that only non-NULL values in subsequent results will overwrite. This can be used to selectively overwrite default values.

```
ext_pillar:
  - sql_base:
    - query: "SELECT pillar,value FROM pillars WHERE minion_id = %s and minion_id != %s"
depth: 2
    - query: "SELECT pillar,value FROM pillars WHERE minion_id = %s"
depth: 2
    ignore_null: True
```

If you specify `as_list: True` in the mapping expression it will convert collisions to lists.

If you specify `with_lists: `...` in the mapping expression it will convert the specified depths to list. The string provided is a sequence numbers that are comma separated. The string `1,3` will result in:

```
a,b,c,d,e,1  # field 1 same, field 3 differs
a,b,c,f,g,2  # ^^^^  ^
a,z,h,y,j,3  # field 1 same, field 3 same
a,z,h,y,k,4  # ^^^^  ^
```

These columns define list grouping
The range for with_lists is 1 to number_of_fields, inclusive. Numbers outside this range are ignored.

Finally, if you pass the queries in via a mapping, the key will be the first level name where as passing them in as a list will place them in the root. This isolates the query results into their own subtrees. This may be a help or hindrance to your aims and can be used as such.

You can basically use any SELECT query that gets you the information, you could even do joins or subqueries in case your minion_id is stored elsewhere. It is capable of handling single rows or multiple rows per minion.

Configuration of the connection depends on the adapter in use.

More complete example for MySQL (to also show configuration)

```yaml
mysql:
  user: 'salt'
  pass: 'super_secret_password'
  db: 'salt_db'

ext_pillar:
  - mysql:
      fromdb:
        query: '
          SELECT col1,col2,col3,col4,col5,col6,col7
          FROM some_random_table
          WHERE minion_pattern LIKE %s'
      depth: 5
      as_list: True
      with_lists: [1,3]
```

**class salt.pillar.sql_base.SqlBaseExtPillar**

This class receives and processes the database rows in a database agnostic way.

- `as_list` = False
- `depth` = 0
- `enter_root(root)`
  
  Set self.focus for kwargs queries
- `extract_queries(args, kwargs)`
  
  This function normalizes the config block into a set of queries we can use. The return is a list of consistently laid out dicts.
- `fetch(minion_id, pillar, *args, **kwargs)`
  
  Execute queries, merge and return as a dict.
- `field_names = None`
The primary purpose of this function is to store the SQL field list and the depth to which we process.

This function takes a list of database results and iterates over, merging them into a dict form.

This class receives and processes the database rows from SQLite3.
salt.pillar.sqlite3.ext_pillar(minion_id, pillar, *args, **kwargs)
   Execute queries against SQLite3, merge and return as a dict

32.22.26 salt.pillar.svn_pillar

Clone a remote SVN repository and use the filesystem as a Pillar source
This external Pillar source can be configured in the master config file like so:

```yaml
ext_pillar:
  - svn: trunk svn://svnserver/repo root=subdirectory
```

The root= parameter is optional and used to set the subdirectory from where to look for Pillar files (such as top.sls).
Changed in version 2014.7.0: The optional root parameter will be added.

Note that this is not the same thing as configuring pillar data using the pillar_roots parameter. The branch referenced in the ext_pillar entry above (master), would evaluate to the base environment, so this branch needs to contain a top.sls with a base section in it, like this:

```yaml
base:
  '*':
    - foo
```

To use other environments from the same SVN repo as svn_pillar sources, just add additional lines, like so:

```yaml
ext_pillar:
  - svn: trunk svn://svnserver/repo
  - svn: dev svn://svnserver/repo
```

In this case, the dev branch would need its own top.sls with a dev section in it, like this:

```yaml
dev:
  '*':
    - bar
```

class salt.pillar.svn_pillar.SvnPillar(branch, repo_location, root, opts)
   Deal with the remote SVN repository for Pillar

   pillar_dir()
      Returns the directory of the pillars (repo cache + branch + root)

   update()

salt.pillar.svn_pillar.ext_pillar(minion_id, pillar, repo_string)
   Execute a command and read the output as YAML

32.22.27 salt.pillar.varstack_pillar

Use Varstack data as a Pillar source

Configuring Varstack

Using varstack in Salt is fairly simple. Just put the following into the config file of your master:
ext_pillar:
  - varstack: /etc/varstack.yaml

Varstack will then use /etc/varstack.yaml to determine which configuration data to return as pillar information. From there you can take a look at the README of varstack on how this file is evaluated.

salt.pillar.varstack_pillar.ext_pillar(minion_id, pillar, conf)
  Parse varstack data and return the result

32.22.28 salt.pillar.virtkey

Accept a key from a hypervisor if the virt runner has already submitted an authorization request

salt.pillar.virtkey.ext_pillar(hyper_id, pillar, name, key)
  Accept the key for the VM on the hyper, if authorized.

32.23.1 salt.proxy.esxi

Proxy Minion interface module for managing VMWare ESXi hosts.

New in version 2015.8.4.

**Special Note:** SaltStack thanks Adobe Corporation for their support in creating this Proxy Minion integration.

This proxy minion enables VMware ESXi (hereafter referred to as simply `ESXi') hosts to be treated individually like a Salt Minion.

Since the ESXi host may not necessarily run on an OS capable of hosting a Python stack, the ESXi host can't run a Salt Minion directly. Salt's "Proxy Minion" functionality enables you to designate another machine to host a minion process that `proxies` communication from the Salt Master. The master does not know nor care that the target is not a "real" Salt Minion.

More in-depth conceptual reading on Proxy Minions can be found in the Proxy Minion section of Salt's documentation.

**Dependencies**

- pyVmomi Python Module
- ESXCLI
**pyVmomi**

PyVmomi can be installed via pip:

```
pip install pyVmomi
```

---

**Note:** Version 6.0 of pyVmomi has some problems with SSL error handling on certain versions of Python. If using version 6.0 of pyVmomi, Python 2.6, Python 2.7.9, or newer must be present. This is due to an upstream dependency in pyVmomi 6.0 that is not supported in Python versions 2.7 to 2.7.8. If the version of Python is not in the supported range, you will need to install an earlier version of pyVmomi. See Issue #29537 for more information.

Based on the note above, to install an earlier version of pyVmomi than the version currently listed in PyPi, run the following:

```
pip install pyVmomi==5.5.0.2014.1.1
```

The 5.5.0.2014.1.1 is a known stable version that this original ESXi State Module was developed against.

**ESXCLI**

Currently, about a third of the functions used in the vSphere Execution Module require the ESXCLI package be installed on the machine running the Proxy Minion process.

The ESXCLI package is also referred to as the VMware vSphere CLI, or vCLI. VMware provides vCLI package installation instructions for vSphere 5.5 and vSphere 6.0.

Once all of the required dependencies are in place and the vCLI package is installed, you can check to see if you can connect to your ESXi host or vCenter server by running the following command:

```
esxcli -s <host-location> -u <username> -p <password> system syslog config get
```

If the connection was successful, ESXCLI was successfully installed on your system. You should see output related to the ESXi host's syslog configuration.

**Configuration**

To use this integration proxy module, please configure the following:

**Pillar**

Proxy minions get their configuration from Salt's Pillar. Every proxy must have a stanza in Pillar and a reference in the Pillar top-file that matches the ID. At a minimum for communication with the ESXi host, the pillar should look like this:

```
proxy:
    proxytype: esxi
    host: <ip or dns name of esxi host>
    username: <ESXi username>
    passwords:
        - first_password
        - second_password
        - third_password
```
proxytype

The proxytype key and value pair is critical, as it tells Salt which interface to load from the proxy directory in Salt's install hierarchy, or from /srv/salt/_proxy on the Salt Master (if you have created your own proxy module, for example). To use this ESXi Proxy Module, set this to esxi.

host

The location, or ip/dns, of the ESXi host. Required.

username

The username used to login to the ESXi host, such as root. Required.

passwords

A list of passwords to be used to try and login to the ESXi host. At least one password in this list is required. The proxy integration will try the passwords listed in order. It is configured this way so you can have a regular password and the password you may be updating for an ESXi host either via the vsphere.update_host_password execution module function or via the esxi.password_present state function. This way, after the password is changed, you should not need to restart the proxy minion—it should just pick up the new password provided in the list. You can then change pillar at will to move that password to the front and retire the unused ones.

This also allows you to use any number of potential fallback passwords.

Note: When a password is changed on the host to one in the list of possible passwords, the further down on the list the password is, the longer individual commands will take to return. This is due to the nature of pyVmomi's login system. We have to wait for the first attempt to fail before trying the next password on the list.

This scenario is especially true, and even slower, when the proxy minion first starts. If the correct password is not the first password on the list, it may take up to a minute for test.ping to respond with a True result. Once the initial authorization is complete, the responses for commands will be a little faster.

To avoid these longer waiting periods, SaltStack recommends moving the correct password to the top of the list and restarting the proxy minion at your earliest convenience.

protocol

If the ESXi host is not using the default protocol, set this value to an alternate protocol. Default is https.

port

If the ESXi host is not using the default port, set this value to an alternate port. Default is 443.
Salt Proxy

After your pillar is in place, you can test the proxy. The proxy can run on any machine that has network connectivity to your Salt Master and to the ESXi host in question. SaltStack recommends that the machine running the salt-proxy process also run a regular minion, though it is not strictly necessary.

On the machine that will run the proxy, make sure there is an `/etc/salt/proxy` file with at least the following in it:

```
master: <ip or hostname of salt-master>
```

You can then start the salt-proxy process with:

```
salt-proxy --proxyid <id you want to give the host>
```

You may want to add `-l debug` to run the above in the foreground in debug mode just to make sure everything is OK.

Next, accept the key for the proxy on your salt-master, just like you would for a regular minion:

```
salt-key -a <id you gave the esxi host>
```

You can confirm that the pillar data is in place for the proxy:

```
salt <id> pillar.items
```

And now you should be able to ping the ESXi host to make sure it is responding:

```
salt <id> test.ping
```

At this point you can execute one-off commands against the host. For example, you can get the ESXi host’s system information:

```
salt <id> esxi.cmd system_info
```

Note that you don't need to provide credentials or an ip/hostname. Salt knows to use the credentials you stored in Pillar.

It’s important to understand how this particular proxy works. `Salt.modules.vsphere` is a standard Salt execution module. If you pull up the docs for it you’ll see that almost every function in the module takes credentials and a target host. When credentials and a host aren’t passed, Salt runs commands through `pyVmomi` against the local machine. If you wanted, you could run functions from this module on any host where an appropriate version of `pyVmomi` is installed, and that host would reach out over the network and communicate with the ESXi host.

`esxi.cmd` acts as a “shim” between the execution module and the proxy. Its first parameter is always the function from `salt.modules.vsphere`. If the function takes more positional or keyword arguments you can append them to the call. It’s this shim that speaks to the ESXi host through the proxy, arranging for the credentials and hostname to be pulled from the Pillar section for this Proxy Minion.

Because of the presence of the shim, to lookup documentation for what functions you can use to interface with the ESXi host, you’ll want to look in `salt.modules.vsphere` instead of `salt.modules.esxi`.

**States**

Associated states are thoroughly documented in `salt.states.esxi`. Look there to find an example structure for Pillar as well as an example `.sls` file for standing up an ESXi host from scratch.
salt.proxy.esxi.ch_config(cmd, *args, **kwargs)
This function is called by the salt.modules.esxi.cmd shim. It then calls whatever is passed in cmd inside the
salt.modules.vsphere module. Passes the return through from the vsphere module.

- **cmd** The command to call inside salt.modules.vsphere
- **args** Arguments that need to be passed to that command.
- **kwargs** Keyword arguments that need to be passed to that command.

salt.proxy.esxi.find_credentials(host)
Cycle through all the possible credentials and return the first one that works.

salt.proxy.esxi.grains()
Get the grains from the proxy device.

salt.proxy.esxi.grains_refresh()
Refresh the grains from the proxy device.

salt.proxy.esxi.init(opts)
This function gets called when the proxy starts up. For ESXi devices, the host, login credentials, and, if con-
figured, the protocol and port are cached.

salt.proxy.esxi.ping()
Check to see if the host is responding. Returns False if the host didn't respond, True otherwise.

CLI Example:
salt esxi-host test.ping

salt.proxy.esxi.shutdown()
 Shutdown the connection to the proxy device. For this proxy, shutdown is a no-op.

32.23.2 salt.proxy.fx2

Dell FX2 chassis

New in version 2015.8.2.

Proxy minion interface module for managing Dell FX2 chassis (Dell Chassis Management Controller version 1.2 and
above, iDRAC8 version 2.00 and above)

Dependencies

- iDRAC Remote execution module (salt.modules.dracr)
- Chassis command shim (salt.modules.chassis)
- Dell Chassis States (salt.states.dellchassis)
- Dell's racadm command line interface to CMC and iDRAC devices.

Special Note: SaltStack thanks Adobe Corporation for their support in creating this proxy minion integration.

This proxy minion enables Dell FX2 and FX2s (hereafter referred to as simply `"chassis", "CMC", or "FX2") chassis
to be treated individually like a salt-minion.

Since the CMC embedded in the chassis does not run an OS capable of hosting a Python stack, the chassis can’t run
a minion directly. Salt’s "Proxy Minion" functionality enables you to designate another machine to host a minion
process that "proxies" communication from the salt-master. The master does not know nor care that the target is not a real minion.

More in-depth conceptual reading on Proxy Minions can be found in the Proxy Minion section of Salt's documentation.

To configure this integration, follow these steps:

Pillar

Proxy minions get their configuration from Salt's Pillar. Every proxy must have a stanza in Pillar, and a reference in the Pillar topfile that matches the ID. At a minimum for communication with the chassis the pillar should look like this:

```
proxy:
  host: <ip or dns name of chassis controller>
  admin_username: <iDRAC username for the CMC, usually 'root'>
  fallback_admin_username: <username to try if the first fails>
  passwords:
    - first_password
    - second_password
    - third_password
  proxytype: fx2
```

The `proxytype` line above is critical, it tells Salt which interface to load from the `proxy` directory in Salt's install hierarchy, or from `/srv/salt/_proxy` on the salt-master (if you have created your own proxy module, for example).

The proxy integration will try the passwords listed in order. It is configured this way so you can have a regular password, a potential fallback password, and the third password can be the one you intend to change the chassis to use. This way, after it is changed, you should not need to restart the proxy minion--it should just pick up the third password in the list. You can then change pillar at will to move that password to the front and retire the unused ones.

Beware, many Dell CMC and iDRAC units are configured to lockout IP addresses or users after too many failed password attempts. This can generate user panic in the form of "I no longer know what the password is!!!". To mitigate panic try the web interface from a different IP, or setup a emergency administrator user in the CMC before doing a wholesale password rotation.

The automatic lockout can be disabled via Salt with the following:

```
salt <cmc> chassis.cmd set_general cfgRacTuning cfgRacTuneIpBlkEnable 0
```

and then verified with

```
salt <cmc> chassis.cmd get_general cfgRacTuning cfgRacTuneIpBlkEnable
```

salt-proxy

After your pillar is in place, you can test the proxy. The proxy can run on any machine that has network connectivity to your salt-master and to the chassis in question. SaltStack recommends that this machine also run a regular minion, though it is not strictly necessary.

On the machine that will run the proxy, make sure there is an `/etc/salt/proxy` file with at least the following in it:
You can start the proxy with

```
salt-proxy --proxyid <id you want to give the chassis>
```

You may want to add `-l debug` to run the above in the foreground in debug mode just to make sure everything is OK.

Next, accept the key for the proxy on your salt-master, just like you would for a regular minion:

```
salt-key -a <id you want to give the chassis>
```

You can confirm that the pillar data is in place for the proxy:

```
salt <id> pillar.items
```

And now you should be able to ping the chassis to make sure it is responding:

```
salt <id> test.ping
```

At this point you can execute one-off commands against the chassis. For example, you can get the chassis inventory:

```
salt <id> chassis.cmd inventory
```

Note that you don't need to provide credentials or an ip/hostname. Salt knows to use the credentials you stored in Pillar.

It's important to understand how this particular proxy works. `salt.modules.dracr` is a standard Salt execution module. If you pull up the docs for it you'll see that almost every function in the module takes credentials and a target host. When credentials and a host aren't passed, Salt runs `racadm` against the local machine. If you wanted you could run functions from this module on any host where an appropriate version of `racadm` is installed, and that host would reach out over the network and communicate with the chassis.

`Chassis.cmd` acts as a `shim` between the execution module and the proxy. It's first parameter is always the function from `salt.modules.dracr` to execute. If the function takes more positional or keyword arguments you can append them to the call. It's this shim that speaks to the chassis through the proxy, arranging for the credentials and hostname to be pulled from the pillar section for this proxy minion.

Because of the presence of the shim, to lookup documentation for what functions you can use to interface with the chassis, you'll want to look in `salt.modules.dracr` instead of `salt.modules.chassis`.

**States**

Associated states are thoroughly documented in `salt.states.dellchassis`. Look there to find an example structure for pillar as well as an example `.sls` file for standing up a Dell Chassis from scratch.

salt.proxy.fx2.admin_password()

Return the admin_password in the DETAILS dictionary, or `calvin` (the Dell default) if there is none present

salt.proxy.fx2.admin_username()

Return the admin_username in the DETAILS dictionary, or root if there is none present

salt.proxy.fx2.chconfig(cmd, *args, **kwargs)

This function is called by the `salt.modules.chassis.cmd` shim. It then calls whatever is passed in `cmd` inside the `salt.modules.dracr` module.

**Parameters**
• **cmd** -- The command to call inside salt.modules.dracr
• **args** -- Arguments that need to be passed to that command
• **kwargs** -- Keyword arguments that need to be passed to that command

**Returns**  Passthrough the return from the dracr module.
salt.proxy.fx2.find_credentials()
Cycle through all the possible credentials and return the first one that works
salt.proxy.fx2.grains()
Get the grains from the proxied device
salt.proxy.fx2.grains_refresh()
Refresh the grains from the proxied device
salt.proxy.fx2.host()
salt.proxy.fx2.init(opts)
This function gets called when the proxy starts up. We check opts to see if a fallback user and password are supplied. If they are present, and the primary credentials don’t work, then we try the backup before failing.

Whichever set of credentials works is placed in the persistent DETAILS dictionary and will be used for further communication with the chassis.
salt.proxy.fx2.ping()
Is the chassis responding?

**Returns**  Returns False if the chassis didn’t respond, True otherwise.
salt.proxy.fx2.shutdown(opts)
Shutdown the connection to the proxied device. For this proxy shutdown is a no-op.

### 32.23.3 salt.proxy.junos

Interface with a Junos device via proxy-minion.
salt.proxy.junos.conn()
salt.proxy.junos.facts()
salt.proxy.junos.id(opts)
Returns a unique ID for this proxy minion
salt.proxy.junos.init(opts)
Open the connection to the Junos device, login, and bind to the Resource class
salt.proxy.junos.ping()
Ping? Pong!
salt.proxy.junos.proxytype()
Returns the name of this proxy
salt.proxy.junos.refresh()
salt.proxy.junos.rpc()
salt.proxy.junos.shutdown(opts)
This is called when the proxy-minion is exiting to make sure the connection to the device is closed cleanly.
32.23.4 salt.proxy.rest_sample

This is a simple proxy-minion designed to connect to and communicate with the bottle-based web service contained in https://github.com/saltstack/salt-contrib/tree/master/proxyminion_rest_example

salt.proxy.rest_sample.grains()
   Get the grains from the proxied device

salt.proxy.rest_sample.grains_refresh()
   Refresh the grains from the proxied device

salt.proxy.rest_sample.id(opts)
   Return a unique ID for this proxy minion. This ID MUST NOT CHANGE. If it changes while the proxy is running the salt-master will get really confused and may stop talking to this minion

salt.proxy.rest_sample.init(opts)

salt.proxy.rest_sample.package_install(name, **kwargs)
   Install a ``package`` on the REST server

salt.proxy.rest_sample.package_list()
   List ``packages`` installed on the REST server

salt.proxy.rest_sample.package_remove(name)
   Remove a ``package`` on the REST server

salt.proxy.rest_sample.package_status(name)
   Check the installation status of a package on the REST server

salt.proxy.rest_sample.ping()
   Is the REST server up?

salt.proxy.rest_sample.service_list()
   List ``services`` on the REST server

salt.proxy.rest_sample.service_restart(name)
   Restart a ``service`` on the REST server

salt.proxy.rest_sample.service_start(name)
   Start a ``service`` on the REST server

salt.proxy.rest_sample.service_status(name)
   Check if a service is running on the REST server

salt.proxy.rest_sample.service_stop(name)
   Stop a ``service`` on the REST server

salt.proxy.rest_sample.shutdown(opts)
   For this proxy shutdown is a no-op

32.23.5 salt.proxy.ssh_sample

This is a simple proxy-minion designed to connect to and communicate with a server that exposes functionality via SSH. This can be used as an option when the device does not provide an api over HTTP and doesn't have the python stack to run a minion.

salt.proxy.ssh_sample.init(opts)
   Required. Can be used to initialize the server connection.

salt.proxy.ssh_sample.package_install(name, **kwargs)
   Install a ``package`` on the ssh server
SLS files are translated from whatever data templating format they are written in back into Python data types to be consumed by Salt.

By default SLS files are rendered as Jinja templates and then parsed as YAML documents. But since the only thing the state system cares about is raw data, the SLS files can be any structured format that can be dreamed up.

Currently there is support for Jinja + YAML, Mako + YAML, Wempy + YAML, Jinja + json, Mako + json and Wempy + json.

Renderers can be written to support any template type. This means that the Salt states could be managed by XML files, HTML files, Puppet files, or any format that can be translated into the Pythonic data structure used by the state system.

32.24.1 Multiple Renderers

A default renderer is selected in the master configuration file by providing a value to the renderer key.
When evaluating an SLS, more than one renderer can be used. When rendering SLS files, Salt checks for the presence of a Salt-specific shebang line. The shebang line directly calls the name of the renderer as it is specified within Salt. One of the most common reasons to use multiple renderers is to use the Python or `py` renderer.

Below, the first line is a shebang that references the `py` renderer.

```python
#!py

def run():
    """Install the python-mako package"
    """  return {'include': ['python'],
              'python-mako': {'pkg': ['installed']}}
```

### 32.24.2 Composing Renderers

A renderer can be composed from other renderers by connecting them in a series of pipes (`|`). In fact, the default `Jinja + YAML` renderer is implemented by connecting a YAML renderer to a Jinja renderer. Such renderer configuration is specified as: `jinja | yaml`.

Other renderer combinations are possible:

- `yaml` i.e, just YAML, no templating.
- `mako | yaml` pass the input to the mako renderer, whose output is then fed into the yaml renderer.
- `jinja | mako | yaml` This one allows you to use both Jinja and Mako templating syntax in the input and then parse the final rendered output as YAML.

The following is a contrived example SLS file using the `jinja | mako | yaml` renderer:

```bash
#!/jinjal/mako/yaml

An_Example:
  cmd.run:
    - name: |
        echo "Using Salt ${grains['saltversion']}" \ 
          "from path {{grains['saltpath']}}."
    - cwd: /

<%doc> $(...) is Mako's notation, and so is this comment. </%doc>
{# Similarly, {{...}} is Jinja's notation, and so is this comment. #}
```

For backward compatibility, `jinja | yaml` can also be written as `yaml_jinja`, and similarly, the `yaml_mako`, `yaml_wempy`, `json_jinja`, `json_mako`, and `json_wempy` renderers are all supported.

Keep in mind that not all renderers can be used alone or with any other renderers. For example, the template renderers shouldn't be used alone as their outputs are just strings, which still need to be parsed by another renderer to turn them into highstate data structures.

For example, it doesn't make sense to specify `yaml | jinja` because the output of the YAML renderer is a highstate data structure (a dict in Python), which cannot be used as the input to a template renderer. Therefore, when combining renderers, you should know what each renderer accepts as input and what it returns as output.
32.24.3 Writing Renderers

A custom renderer must be a Python module placed in the renderers directory and the module implement the `render` function.

The `render` function will be passed the path of the SLS file as an argument.

The purpose of the `render` function is to parse the passed file and to return the Python data structure derived from the file.

Custom renderers must be placed in a `_renderers` directory within the `file_roots` specified by the master config file.

Custom renderers are distributed when any of the following are run:

- `state.apply`
- `saltutil.sync_renderers`
- `saltutil.sync_all`

Any custom renderers which have been synced to a minion, that are named the same as one of Salt’s default set of renderers, will take the place of the default renderer with the same name.

32.24.4 Examples

The best place to find examples of renderers is in the Salt source code.

Documentation for renderers included with Salt can be found here:

https://github.com/saltstack/salt/blob/develop/salt/renderers

Here is a simple YAML renderer example:

```python
import yaml

def render(yaml_data, env='', sls='', **kws):
    if not isinstance(yaml_data, basestring):
        yaml_data = yaml_data.read()  # Read the YAML data
    data = yaml.load(yaml_data)  # Parse the YAML data
    return data if data else {}  # Return the data or an empty dictionary
```

32.24.5 Full List of Renderers

**salt.renderers.cheetah**

Cheetah Renderer for Salt

```python
salt.renderers.cheetah.render(cheetah_data, saltenv='base', sls='`, method='xml', **kws)
```

Render a Cheetah template.

**Return type** A Python data structure

**salt.renderers.genshi**

Genshi Renderer for Salt

```python
salt.renderers.genshi.render(genshi_data, saltenv='base', sls='`, method='xml', **kws)
```

Render a Genshi template. A method should be passed in as part of the kwargs. If no method is passed in, xml is assumed. Valid methods are:

- **Note that the text method will call NewTextTemplate. If oldtext is desired, it must be called explicitly**

**Return type** A Python data structure

**salt.renderers.gpg**

Renderer that will decrypt GPG ciphers

Any key in the SLS file can be a GPG cipher, and this renderer will decrypt it before passing it off to Salt. This allows you to safely store secrets in source control, in such a way that only your Salt master can decrypt them and distribute them only to the minions that need them.

The typical use-case would be to use ciphers in your pillar data, and keep a secret key on your master. You can put the public key in source control so that developers can add new secrets quickly and easily.

This renderer requires the gpg binary.

**No python libraries are required as of the 2015.8.3 release.**

To set things up, you will first need to generate a keypair. On your master, run:

```bash
# mkdir -p /etc/salt/gpgkeys
# chmod 0700 /etc/salt/gpgkeys
# gpg --gen-key --homedir /etc/salt/gpgkeys
```

Do not supply a password for your keypair, and use a name that makes sense for your application. Be sure to back up your gpg directory someplace safe!

**Note:** Unfortunately, there are some scenarios - for example, on virtual machines which don’t have real hardware - where insufficient entropy causes key generation to be extremely slow. If you come across this problem, you should
investigate means of increasing the system entropy. On virtualised Linux systems, this can often be achieved by installing the rng-tools package.

To retrieve the public key:

```
# gpg --homedir /etc/salt/gpgkeys --armor --export <KEY-NAME> > exported_pubkey.gpg
```

Now, to encrypt secrets, copy the public key to your local machine and run:

```
$ gpg --import exported_pubkey.gpg
```

To generate a cipher from a secret:

```
$ echo -n "supersecret" | gpg --armor --encrypt -r <KEY-name>
```

To apply the renderer on a file-by-file basis add the following line to the top of any pillar with gpg data in it:

```
#yaml|gpg
```

Now with your renderer configured, you can include your ciphers in your pillar data like so:

```
#yaml|gpg
a-secret: |
-----BEGIN PGP MESSAGE-----

hQEMAwuRHkAFCfNvQf9GLTN16hCfXAbPwU6BnK80unOc7i9/etGuVc5CyU9Q6umQuetdVQVLFO/Hkrc41geNQdM6D9E8PKonMlgJPcYyCggxJ9/IFPFEKmrsa5vk6+cnEfVexSto/U1V0VjouyUeliMCJLaz/3ORxaME49Cpi6No2+vKD8a4q4nZ11UZCGRhkh0S2zXN0XQ38TBkmtdJcqxnxq76YWkTusjVubW3bVCtu2HGqJHt79wmuwnZtzm4wBkfcAf3Eyo2jEnWcMC4TcXf01XPL424g1/9AAxh+Q4d8RRP4fbw7ct4nCjGr9v2DTF7HNigIMl4vMIn9fp+EZurJNiQskLgNbktJGAeEKYqX5iCuB1b693hjFKLwHi3t5ya8X2dIff8/PhJ1x2TwG5+L6j1zaNq3R1xuAZZzZMvZDe5+i3RJskqMFTb0iA==
=Eqsm
-----END PGP MESSAGE-----
```

salt.renderers.gpg.render(gpg_data, saltenv='base', sls='`, argline='`, **kwargs)
Create a gpg object given a gpg_keydir, and then use it to try to decrypt the data to be rendered.

salt.renderers.hjson

Hjson Renderer for Salt http://laktak.github.io/hjson/
salt.renderers.hjson.render(hjson_data, saltenv='base', sls='`, **kws)
Accepts HJSON as a string or as a file object and runs it through the HJSON parser.

Return type  A Python data structure

salt.renderers.jinja

Jinja loading utils to enable a more powerful backend for jinja templates
Jinja in States

The most basic usage of Jinja in state files is using control structures to wrap conditional or redundant state elements:

```salt
{% if grains['os'] != 'FreeBSD' %}
tcsh:
    pkg:
        - installed
{% endif %}

motd:
    file.managed:
        {% if grains['os'] == 'FreeBSD' %}
            name: /etc/motd
        {% elif grains['os'] == 'Debian' %}
            name: /etc/motd.tail
        {% endif %}
        - source: salt://motd
```

In this example, the first if block will only be evaluated on minions that aren't running FreeBSD, and the second block changes the file name based on the `os` grain.

Writing if-else blocks can lead to very redundant state files however. In this case, using `pillars`, or using a previously defined variable might be easier:

```salt
{% set motd = ['/etc/motd'] %}
{% if grains['os'] == 'Debian' %}
    {% set motd = ['/etc/motd.tail', '/var/run/motd'] %}
{% endif %}

{% for motdfile in motd %}
    {{ motdfile }}:
        file.managed:
            - source: salt://motd
{% endfor %}
```

Using a variable set by the template, the `for` loop will iterate over the list of MOTD files to update, adding a state block for each file.

Include and Import

Includes and imports can be used to share common, reusable state configuration between state files and between files.

```salt
{% from 'lib.sls' import test %}
```

This would import the `test` template variable or macro, not the `test` state element, from the file `lib.sls`. In the case that the included file performs checks again grains, or something else that requires context, passing the context into the included file is required:

```salt
{% from 'lib.sls' import test with context %}
```
Macros

Macros are helpful for eliminating redundant code, however stripping whitespace from the template block, as well as contained blocks, may be necessary to emulate a variable return from the macro.

```
# init.sls
{% from 'lib.sls' import pythonpkg with context %}

python-virtualenv:
  pkg.installed:
    - name: {{ pythonpkg('virtualenv') }}

python-fabric:
  pkg.installed:
    - name: {{ pythonpkg('fabric') }}
```

```
# lib.sls
{% macro pythonpkg(pkg) %}
{%- if grains['os'] == 'FreeBSD' %}
py27-{{ pkg }}
{%- elif grains['os'] == 'Debian' %}
python-{{ pkg }}
{%- endif %}
{%- endmacro %}
```

This would define a macro that would return a string of the full package name, depending on the packaging system's naming convention. The whitespace of the macro was eliminated, so that the macro would return a string without line breaks, using whitespace control.

Template Inheritance

Template inheritance works fine from state files and files. The search path starts at the root of the state tree or pillar.

Filters

Saltstack extends builtin filters with these custom filters:

* strftime* Converts any time related object into a time based string. It requires a valid strftime directives. An exhaustive list can be found in the official Python documentation.

```
{%- set curtime = None | strftime() %}
```

Fuzzy dates require the timelib Python module is installed.

```
{{ "2002/12/25"|strftime("%y") }}
{{ "1040814000"|strftime("%Y-%m-%d") }}
{{ datetime|strftime("%w") }}
{{ "tomorrow"|strftime }}
```

* sequence* Ensure that parsed data is a sequence.

* yaml_encode* Serializes a single object into a YAML scalar with any necessary handling for escaping special characters. This will work for any scalar YAML data type: ints, floats, timestamps, booleans, strings, unicode. It will not work for multi-objects such as sequences or maps.
In the above case {{ bar }} and {{ foo.bar }} should be identical and {{ baz }} and {{ foo.baz }} should be identical.

yaml_dquote Serializes a string into a properly-escaped YAML double-quoted string. This is useful when the contents of a string are unknown and may contain quotes or unicode that needs to be preserved. The resulting string will be emitted with opening and closing double quotes.

In the above case {{ bar }} and {{ foo.bar }} should be identical and {{ baz }} and {{ foo.baz }} should be identical. If variable contents are not guaranteed to be a string then it is better to use yaml_encode which handles all YAML scalar types.

yaml_squote Similar to the yaml_dquote filter but with single quotes. Note that YAML only allows special escapes inside double quotes so yaml_squote is not nearly as useful (viz. you likely want to use yaml_encode or yaml_dquote).

Jinja in Files

Jinja can be used in the same way in managed files:

```
# redis.sls
/etc/redis/redis.conf:
  file.managed:
    - source: salt://redis.conf
    - template: jinja
    - context:
      bind: 127.0.0.1

# lib.sls
{% set port = 6379 %}

# redis.conf
{% from 'lib.sls' import port with context %}
port {{ port }}
bind {{ bind }}
```

As an example, configuration was pulled from the file context and from an external template file.
Escaping Jinja

Occasionally, it may be necessary to escape Jinja syntax. There are two ways to do this in Jinja. One is escaping individual variables or strings and the other is to escape entire blocks.

To escape a string commonly used in Jinja syntax such as {{, you can use the following syntax:

```plaintext
{{ '{{' }}
```

For larger blocks that contain Jinja syntax that needs to be escaped, you can use raw blocks:

```plaintext
{% raw %}
    some text that contains jinja characters that need to be escaped
{% endraw %}
```

See the Escaping section of Jinja's documentation to learn more.

A real-word example of needing to use raw tags to escape a larger block of code is when using `file.managed` with the `contents_pillar` option to manage files that contain something like consul-template, which shares a syntax subset with Jinja. Raw blocks are necessary here because the Jinja in the pillar would be rendered before the `file.managed` is ever called, so the Jinja syntax must be escaped:

```plaintext
{% raw %}
- contents_pillar: |
    job "example-job" {
        <snipped>
    task "example" {
        driver = "docker"
        config {
            image = "docker-registry.service.consul:5000/example-job:{key "nomad/jobs/example-job/version"}"
        }
    }
{% endraw %}
```

Calling Salt Functions

The Jinja renderer provides a shorthand lookup syntax for the `salt` dictionary of execution function.

New in version 2014.7.0.

```plaintext
# The following two function calls are equivalent.
{{ salt['cmd.run']('whoami') }}
{{ salt.cmd.run('whoami') }}
```

Debugging

The `show_full_context` function can be used to output all variables present in the current Jinja context.
New in version 2014.7.0.

salt.renderers.jinja.render(
    template_file, saltenv='base', sls='`, argline='`, context=None, tm-
    path=None, **kws)

    Render the template_file, passing the functions and grains into the Jinja rendering system.

    Return type string

class salt.utils.jinja.SerializerExtension(environment)

    Yaml and Json manipulation.

    Format filters

    Allows jsonifying or yamlifying any data structure. For example, this dataset:

        data = {
            'foo': True,
            'bar': 42,
            'baz': [1, 2, 3],
            'qux': 2.0
        }

    yaml = {{ data|yaml }}
    json = {{ data|json }}
    python = {{ data|python }}

    will be rendered as:

        yaml = {bar: 42, baz: [1, 2, 3], foo: true, qux: 2.0}
        json = {"baz": [1, 2, 3], "foo": true, "bar": 42, "qux": 2.0}
        python = {'bar': 42, 'baz': [1, 2, 3], 'foo': True, 'qux': 2.0}

    The yaml filter takes an optional flow_style parameter to control the default-flow-style parameter of the YAML dumper.

        {{ data|yaml(False) }}

    will be rendered as:

        bar: 42
        baz:
            - 1
            - 2
            - 3
        foo: true
        qux: 2.0

    Load filters

    Strings and variables can be deserialized with load_yaml and load_json tags and filters. It allows one to manipulate data directly in templates, easily:

        {% set yaml_src = "{foo: it works}"|load_yaml %}
        {% set json_src = '{"bar": 'for real!"}'|load_json %}
        Dude, {{ yaml_src.foo }} {{ json_src.bar }}!

    will be rendered as:
Dude, it works for real!

Load tags
Salt implements import_yaml and import_json tags. They work like the import tag, except that the document is also deserialized.

Syntaxes are {% load_yaml as [VARIABLE] %}[YOUR DATA]{% endload %} and {% load_json as [VARIABLE] %}[YOUR DATA]{% endload %}

For example:

{% load_yaml as yaml_src %}
   foo: it works
{% endload %}
{% load_json as json_src %}
   
   "bar": "for real"
{% endload %}

Dude, {{ yaml_src.foo }} {{ json_src.bar }}!

will be rendered as:

Dude, it works for real!

Import tags
External files can be imported and made available as a Jinja variable.

{% import_yaml "myfile.yml" as myfile %}
{% import_json "defaults.json" as defaults %}
{% import_text "completeworksofshakespeare.txt" as poems %}

Catalog
import_* and load_* tags will automatically expose their target variable to import. This feature makes catalog of data to handle.

for example:

# doc1.sls
{% load_yaml as var1 %}
   foo: it works
{% endload %}
{% load_yaml as var2 %}
   bar: for real
{% endload %}

# doc2.sls
{% from "doc1.sls" import var1, var2 as local2 %}
   {{ var1.foo }} {{ local2.bar }}

salt.renderers.json
JSON Renderer for Salt
salt.renderers.json.

-salt.renderers.json.render(json_data, saltenv='base', sls='`, `**kws)
    Accepts JSON as a string or as a file object and runs it through the JSON parser.

    Return type  A Python data structure

salt.renderers.mako

Mako Renderer for Salt

-salt.renderers.mako.render(template_file, saltenv='base', sls='`, context=None, tmplpath=None, `**kws)
    Render the template_file, passing the functions and grains into the Mako rendering system.

    Return type  string

salt.renderers.msgpack

salt.renderers.msgpack.render(msgpack_data, saltenv='base', sls='`, `**kws)
    Accepts a message pack string or a file object, renders said data back to a python dict.

    Return type  A Python data structure

salt.renderers.py

Pure python state renderer

The SLS file should contain a function called run which returns high state data.

In this module, a few objects are defined for you, giving access to Salt’s execution functions, grains, pillar, etc. They are:

- __salt__ - Execution functions (i.e. __salt__['test.echo']('foo'))
- __grains__ - Grains (i.e. __grains__['os'])
- __pillar__ - Pillar data (i.e. __pillar__['foo'])
- __opts__ - Minion configuration options
- __env__ - The effective salt fileserver environment (i.e. base). Also referred to as a `saltenv`. __env__ should not be modified in a pure python SLS file. To use a different environment, the environment should be set when executing the state. This can be done in a couple different ways:
  - Using the saltenv argument on the salt CLI (i.e. salt 'state.sls foo.bar.baz saltenv=env_name).
  - By adding a saltenv argument to an individual state within the SLS file. In other words, adding a line like this to the state's data structure: {'saltenv': 'env_name'}
- __sls__ - The SLS path of the file. For example, if the root of the base environment is /srv/salt, and the SLS file is /srv/salt/foo/bar/baz.sls, then __sls__ in that file will be foo.bar.baz.

```python
![code]
```
```python
group = 'ubuntu'
home = '/home/{0}'.format(user)

else:
    user = 'root'
group = 'root'
home = '/root/'

config['s3cmd'] = {
    'pkg': [
        'installed',
        {'name': 's3cmd'},
    ],
}

config[home + '/.s3cfg'] = {
    'file.managed': [
        {'source': 'salt://s3cfg/templates/s3cfg'},
        {'template': 'jinja'},
        {'user': user},
        {'group': group},
        {'mode': 600},
        {'context': {
            'aws_key': __pillar__['AWS_ACCESS_KEY_ID'],
            'aws_secret_key': __pillar__['AWS_SECRET_ACCESS_KEY'],
        }},
    ],
}

return config
```

```
salt.renderers.py
render(template, saltenv='base', sls='-', tmplpath=None, **kws)

    Render the python module's components

    Return type  string
```

**salt.renderers.pydsl**

A Python-based DSL

- **maintainer** Jack Kuan <kjkuan@gmail.com>
- **maturity** new
- **platform** all

The `pydsl` renderer allows one to author salt formulas (sls files) in pure Python using a DSL that's easy to write and easy to read. Here's an example:

```python
#!/pydsl
apache = state('apache')
apache.pkg.installed()
apache.service.running()
state('/var/www/index.html') \
    .file('managed',
        source='salt://webserver/index.html') \
    .require(pkg='apache')
```
Notice that any Python code is allow in the file as it's really a Python module, so you have the full power of Python at your disposal. In this module, a few objects are defined for you, including the usual (with __ added) __salt__ dictionary, __grains__, __pillar__, __opts__, __env__, and __sls__. plus a few more:

```
__file__
local file system path to the sls module.
__pydsl__
Salt PyDSL object, useful for configuring DSL behavior per sls rendering.
include
Salt PyDSL function for creating Include declaration's.
extend
Salt PyDSL function for creating Extend declaration's.
state
Salt PyDSL function for creating ID declaration's.
```

A state **ID declaration** is created with a state(id) function call. Subsequent state(id) call with the same id returns the same object. This singleton access pattern applies to all declaration objects created with the DSL.

```
state('example')
assert state('example') is state('example')
assert state('example').cmd is state('example').cmd
assert state('example').cmd.running is state('example').cmd.running
```

The *id* argument is optional. If omitted, an UUID will be generated and used as the *id*.

```
state('example')
state('example').file
state('example').pkg
... 
```

Then, a **Function declaration** object can be created from a **State declaration** object by one of the following two ways:

1. by calling a method named after the state function on the **State declaration** object.
```
state('example').file.managed(...)
```

2. by directly calling the attribute named for the **State declaration**, and supplying the state function name as the first argument.
```
state('example').file('managed', ...)
```

With either way of creating a **Function declaration** object, any **Function arg declaration**'s can be passed as keyword arguments to the call. Subsequent calls of a **Function declaration** will update the arg declarations.

```
state('example').file('managed', source='salt://webserver/index.html')
state('example').file.managed(source='salt://webserver/index.html')
```

As a shortcut, the special *name* argument can also be passed as the first or second positional argument depending on the first or second way of calling the **State declaration** object. In the following two examples *ls -la* is the *name* argument.
Finally, a `Requisite declaration` object with its `Requisite reference`'s can be created by invoking one of the requisite methods (see `State Requisites`) on either a `Function declaration` object or a `State declaration` object. The return value of a requisite call is also a `Function declaration` object, so you can chain several requisite calls together.

Arguments to a requisite call can be a list of `State declaration` objects and/or a set of keyword arguments whose names are state modules and values are IDs of `ID declaration`'s or names of `Name declaration`'s.

```python
apache2 = state('apache2')
apache2.pkg.installed()

state('libapache2-mod-wsgi').pkg.installed()

# you can call requisites on function declaration
apache2.service.running()  
  .require(apache2.pkg,  
    pkg='libapache2-mod-wsgi')  
  .watch(file='/etc/apache2/httpd.conf')

# or you can call requisites on state declaration.
# this actually creates an anonymous function declaration object
# to add the requisites.
apache2.service.require(state('libapache2-mod-wsgi').pkg,  
    pkg='apache2')  
  .watch(file='/etc/apache2/httpd.conf')

# we still need to set the name of the function declaration.
apache2.service.running()
```

`Include declaration` objects can be created with the `include` function, while `Extend declaration` objects can be created with the `extend` function, whose arguments are just `Function declaration` objects.

```python
include('edit.vim', 'http.server')
extend(state('apache2').service.watch(file='/etc/httpd/httpd.conf')
```

The `include` function, by default, causes the included sls file to be rendered as soon as the `include` function is called. It returns a list of rendered module objects; sls files not rendered with the pydsl renderer return `None`'s. This behavior creates no `Include declaration`'s in the resulting high state data structure.

```python
import types

# including multiple sls returns a list.
_, mod = include('a-non-pydsl-sls', 'a-pydsl-sls')

assert _ is None
assert isinstance(slsmods[1], types.ModuleType)

# including a single sls returns a single object
mod = include('a-pydsl-sls')

# myfunc is a function that calls state(...) to create more states.
mod.myfunc(1, 2, "three")
```

Notice how you can define a reusable function in your pydsl sls module and then call it via the module returned by `include`.

It's still possible to do late includes by passing the `delayed=True` keyword argument to `include`.

```python
state('example').cmd.run('ls -la', cwd='/')
state('example').cmd('run', 'ls -la', cwd='/')
```
Above will just create a Include declaration in the rendered result, and such call always returns None.

Special integration with the cmd state

Taking advantage of rendering a Python module, PyDSL allows you to declare a state that calls a pre-defined Python function when the state is executed.

```
greeting = "hello world"
def helper(something, *args, **kws):
    print greeting # hello world
    print something, args, kws  # test123 ['a', 'b', 'c'] {'x': 1, 'y': 2}
state().cmd.call(helper, "test123", 'a', 'b', 'c', x=1, y=2)
```

The cmd.call state function takes care of calling our helper function with the arguments we specified in the states, and translates the return value of our function into a structure expected by the state system. See salt.states.cmd.call() for more information.

Implicit ordering of states

Salt states are explicitly ordered via Requisite declaration’s. However, with pydsl it’s possible to let the renderer track the order of creation for Function declaration objects, and implicitly add require requisites for your states to enforce the ordering. This feature is enabled by setting the ordered option on __pydsl__.

Note: this feature is only available if your minions are using Python >= 2.7.

```
include('some.sls.file')
A = state('A').cmd.run(cwd='/var/tmp')
extend(A)
__pydsl__.set(ordered=True)

for i in range(10):
    i = str(i)
    state(i).cmd.run('echo '+i, cwd='/')
state('1').cmd.run('echo one')
state('2').cmd.run(name='echo two')
```

Notice that the ordered option needs to be set after any extend calls. This is to prevent pydsl from tracking the creation of a state function that’s passed to an extend call.

Above example should create states from 0 to 9 that will output 0, one, two, 3, ... 9, in that order.

It’s important to know that pydsl tracks the creations of Function declaration objects, and automatically adds a require requisite to a Function declaration object that requires the last Function declaration object created before it in the sls file.

This means later calls (perhaps to update the function’s Function arg declaration) to a previously created function declaration will not change the order.
Render time state execution

When Salt processes a salt formula file, the file is rendered to Salt's high state data representation by a renderer before the states can be executed. In the case of the pydsl renderer, the .sls file is executed as a python module as it is being rendered which makes it easy to execute a state at render time. In pydsl, executing one or more states at render time can be done by calling a configured ID declaration object.

```#!pydsl
s = state()  # save for later invocation
# configure it
s.cmd.run('echo at render time', cwd='/')
s.file.managed('target.txt', source='salt://source.txt')
```

Once an ID declaration is called at render time it is detached from the sls module as if it was never defined.

Note: If implicit ordering is enabled (i.e., via __pydsl__.set(ordered=True)) then the first invocation of a ID declaration object must be done before a new Function declaration is created.

Integration with the stateconf renderer

The salt.renderers.stateconf renderer offers a few interesting features that can be leveraged by the pydsl renderer. In particular, when using with the pydsl renderer, we are interested in stateconf's sls namespacing feature (via dot-prefixed id declarations), as well as, the automatic start and goal states generation.

Now you can use pydsl with stateconf like this:

```#!pydsl|stateconf -ps
include('xxx', 'yyy')
# ensure that states in xxx run BEFORE states in this file.
extend(state('.start').stateconf.require(stateconf='xxx::goal'))
# ensure that states in yyy run AFTER states in this file.
extend(state('.goal').stateconf.require_in(stateconf='yyy::start'))
__pydsl__.set(ordered=True)
...
```

-s enables the generation of a stateconf start state, and -p lets us pipe high state data rendered by pydsl to stateconf. This example shows that by require-ing or require_in-ing the included sls' start or goal states, it’s possible to ensure that the included sls files can be made to execute before or after a state in the including sls file.

Importing custom Python modules

To use a custom Python module inside a PyDSL state, place the module somewhere that it can be loaded by the Salt loader, such as _modules in the /srv/salt directory.
Then, copy it to any minions as necessary by using `saltutil.sync_modules`.

To import into a PyDSL SLS, one must bypass the Python importer and insert it manually by getting a reference from Python’s `sys.modules` dictionary.

For example:

```python
#!pydsl|stateconf -ps
def main():
    my_mod = sys.modules['salt.loaded.ext.module.my_mod']
salt.renderers.pydsl.render(template, saltenv='base', sls='`, tmplpath=None, rendered_sls=None, **kws)
```

**salt.renderers.pyobjects**

Python renderer that includes a Pythonic Object based interface

**maintainer** Evan Borgstrom <evan@borgstrom.ca>

Let’s take a look at how you use pyobjects in a state file. Here’s a quick example that ensures the `/tmp` directory is in the correct state.

```python
#!pyobjects
File.managed("/tmp", user='root', group='root', mode='1777')
```

Nice and Pythonic!

By using the `shebang` syntax to switch to the pyobjects renderer we can now write our state data using an object based interface that should feel at home to python developers. You can import any module and do anything that you’d like (with caution, importing sqlalchemy, django or other large frameworks has not been tested yet). Using the pyobjects renderer is exactly the same as using the built-in Python renderer with the exception that pyobjects provides you with an object based interface for generating state data.

**Creating state data**

Pyobjects takes care of creating an object for each of the available states on the minion. Each state is represented by an object that is the CamelCase version of its name (i.e. `File`, `Service`, `User`, etc), and these objects expose all of their available state functions (i.e. `File.managed`, `Service.running`, etc).

The name of the state is split based upon underscores (_), then each part is capitalized and finally the parts are joined back together.

Some examples:

- `postgres_user` becomes `PostgresUser`
- `ssh_known_hosts` becomes `SshKnownHosts`

**Context Managers and requisites**

How about something a little more complex. Here we're going to get into the core of how to use pyobjects to write states.
The objects that are returned from each of the magic method calls are setup to be used as Python context managers (with) and when you use them as such all declarations made within the scope will automatically use the enclosing state as a requisite!

The above could have also been written use direct requisite statements as.

You can use the direct requisite statement for referencing states that are generated outside of the current file.

The last thing that direct requisites provide is the ability to select which of the SaltStack requisites you want to use (require, require_in, watch, watch_in, use & use_in) when using the requisite as a context manager.

The above example would cause all declarations inside the scope of the context manager to automatically have their watch_in set to Service("my-service").

### Including and Extending

To include other states use the include() function. It takes one name per state to include.

To extend another state use the extend() function on the name when creating a state.
Importing from other state files

Like any Python project that grows you will likely reach a point where you want to create reusability in your state tree and share objects between state files, Map Data (described below) is a perfect example of this.

To facilitate this Python's `import` statement has been augmented to allow for a special case when working with a Salt state tree. If you specify a Salt url (`salt://...`) as the target for importing from then the pyobjects renderer will take care of fetching the file for you, parsing it with all of the pyobjects features available and then place the requested objects in the global scope of the template being rendered.

This works for all types of import statements; `import X`, `from X import Y`, and `from X import Y as Z`.

```python
#!pyobjects
import salt://myfile.sls
from salt://something/data.sls import Object
from salt://something/data.sls import Object as Other
```

See the Map Data section for a more practical use.

Caveats:

- Imported objects are ALWAYS put into the global scope of your template, regardless of where your import statement is.

Salt object

In the spirit of the object interface for creating state data pyobjects also provides a simple object interface to the `__salt__` object.

A function named `salt` exists in scope for your sls files and will dispatch its attributes to the `__salt__` dictionary.

The following lines are functionally equivalent:

```python
#!pyobjects
ret = salt.cmd.run(bar)
ret = __salt__['cmd.run'](bar)
```

Pillar, grain, mine & config data

Pyobjects provides shortcut functions for calling `pillar.get`, `grains.get`, `mine.get` & `config.get` on the `__salt__` object. This helps maintain the readability of your state files.

Each type of data can be access by a function of the same name: `pillar()`, `grains()`, `mine()` and `config()`.

The following pairs of lines are functionally equivalent:

```python
#!pyobjects
value = pillar('foo:bar:baz', 'qux')
value = __salt__['pillar.get']('foo:bar:baz', 'qux')

value = grains('pkg:apache')
value = __salt__['grains.get']('pkg:apache')

value = mine('os:Fedora', 'network.interfaces', 'grain')
```
Map Data

When building complex states or formulas you often need a way of building up a map of data based on grain data. The most common use of this is tracking the package and service name differences between distributions.

To build map data using pyobjects we provide a class named Map that you use to build your own classes with inner classes for each set of values for the different grain matches.

```python
#!pyobjects

from salt:samba/map.sls import Samba

with Pkg.installed("samba", names=[Samba.server, Samba.client]):
    Service.running("samba", name=Samba.service)
```

TODO

- Interface for working with reactor files

```python
class salt.renderers.pyobjects.PyobjectsModule(name, attrs)

    This provides a wrapper for bare imports.

class salt.renderers.pyobjects.load_states()

    This loads our states into the salt __context__

class salt.renderers.pyobjects.render(template, saltenv='base', sls=' ', salt_data=True, **kwargs)
```
This module provides a custom renderer that processes a salt file with a specified templating engine (e.g. Jinja) and a chosen data renderer (e.g. YAML), extracts arguments for any `stateconf.set` state, and provides the extracted arguments (including Salt-specific args, such as `require`, etc) as template context. The goal is to make writing reusable/configurable/parameterized salt files easier and cleaner.

To use this renderer, either set it as the default renderer via the `renderer` option in master/minion's config, or use the shebang line in each individual sls file, like so: `#!stateconf`. Note, due to the way this renderer works, it must be specified as the first renderer in a render pipeline. That is, you cannot specify `#!mako|yaml|stateconf`, for example. Instead, you specify them as renderer arguments: `#!stateconf mako . yaml`.

Here's a list of features enabled by this renderer.

- Prefixes any state id (declaration or reference) that starts with a dot (.) to avoid duplicated state ids when the salt file is included by other salt files.

For example, in the `salt://some/file.sls`, a state id such as `.sls_params` will be turned into `some.file::sls_params`. Example:

```
#!stateconf yaml . jinja
.vim:
  pkg.installed
```

Above will be translated into:

```
some.file::vim:
  pkg.installed:
    - name: vim
```

Notice how that if a state under a dot-prefixed state id has no `name` argument then one will be added automatically by using the state id with the leading dot stripped off.

The leading dot trick can be used with extending state ids as well, so you can include relatively and extend relatively. For example, when extending a state in `salt://some/other_file.sls`, e.g.:

```
#!stateconf yaml . jinja
include:
  - .file
extend:
  .file::sls_params:
    stateconf.set:
      - name1: something
```

Above will be pre-processed into:

```
include:
  - some.file
extend:
  some.file::sls_params:
```
* Adds a `sls_dir` context variable that expands to the directory containing the rendering salt file. So, you can write `salt:///{{sls_dir}}/...` to reference templates files used by your salt file.

* Recognizes the special state function, `stateconf.set`, that configures a default list of named arguments usable within the template context of the salt file. Example:

```yaml
#!stateconf yaml . jinja
.sls_params:
  stateconf.set:
    - name1: value1
    - name2: value2
    - name3:
      - value1
      - value2
      - value3
    - require_in:
    - cmd: output

# --- end of state config ---
```

This even works with `include + extend` so that you can override the default configured arguments by including the salt file and then extend the `stateconf.set` states that come from the included salt file. *(IMPORTANT: Both the included and the extending sls files must use the stateconf renderer for this `extend` to work!)*

Notice that the end of configuration marker (`# ---end of state config --`) is needed to separate the use of `stateconf.set` form the rest of your salt file. The regex that matches such marker can be configured via the `stateconf_end_marker` option in your master or minion config file.

Sometimes, it is desirable to set a default argument value that’s based on earlier arguments in the same `stateconf.set`. For example, it may be tempting to do something like this:

```yaml
#!stateconf yaml . jinja
.apache:
  stateconf.set:
    - host: localhost
    - port: 1234
    - url: 'http://{{host}}:{{port}}/

# --- end of state config ---
```

```yaml
test:
  cmd.run:
    - name: echo '{{apache.url}}
```
However, this won’t work. It can however be worked around like so:

```
#!stateconf yaml . jinja

.apache:
  stateconf.set:
    - host: localhost
    - port: 1234
    # - url: 'http://{{host}}:{{port}}/'

# --- end of state config ---
# {{ apache.setdefault('url', "http://%(host)s:%(port)s/" % apache) }}

.test:
  cmd.run:
    - name: echo '{{apache.url}}'
    - cwd: /
```

• Adds support for relative include and exclude of .sls files. Example:

```
#!stateconf yaml . jinja

include:
  - .apache
  - .db.mysql
  - ..app.django

exclude:
  - sls: .users
```

If the above is written in a salt file at `salt://some/where.sls` then it will include `salt://some/apache.sls`, `salt://some/db/mysql.sls` and `salt://app/django.sls`, and exclude `salt://some/users.sls`. Actually, it does that by rewriting the above `include` and `exclude` into:

```
include:
  - some.apache
  - some.db.mysql
  - app.django

exclude:
  - sls: some.users
```

• Optionally (enabled by default, `disable` via the `-G` renderer option, e.g. in the shebang line: `#!stateconf -G`), generates a `stateconf.set` goal state (state id named as `.goal` by default, configurable via the master/minion config option, `stateconf_goal_state`) that requires all other states in the salt file. Note, the `.goal` state id is subject to dot-prefix rename rule mentioned earlier.

Such goal state is intended to be required by some state in an including salt file. For example, in your webapp salt file, if you include a sls file that is supposed to setup Tomcat, you might want to make sure that all states in the Tomcat sls file will be executed before some state in the webapp sls file.

• Optionally (enable via the `-o` renderer option, e.g. in the shebang line: `#!stateconf -o`), orders the states in a sls file by adding a `require` requisite to each state such that every state requires the state defined just before it. The order of the states here is the order they are defined in the sls file. (Note: this feature is only available if your minions are using Python >= 2.7. For Python2.6, it should also work if you install the `ordereddict` module from PyPI)

By enabling this feature, you are basically agreeing to author your sls files in a way that gives up the explicit (or implicit?) ordering imposed by the use of `require`, `watch`, `require_in` or `watch_in` requisites,
and instead, you rely on the order of states you define in the sls files. This may or may not be a better way for you. However, if there are many states defined in a sls file, then it tends to be easier to see the order they will be executed with this feature.

You are still allowed to use all the requisites, with a few restrictions. You cannot require or watch a state defined after the current state. Similarly, in a state, you cannot require_in or watch_in a state defined before it. Breaking any of the two restrictions above will result in a state loop. The renderer will check for such incorrect uses if this feature is enabled.

Additionally, names declarations cannot be used with this feature because the way they are compiled into low states make it impossible to guarantee the order in which they will be executed. This is also checked by the renderer. As a workaround for not being able to use names, you can achieve the same effect, by generate your states with the template engine available within your sls file.

Finally, with the use of this feature, it becomes possible to easily make an included sls file execute all its states after some state (say, with id X) in the including sls file. All you have to do is to make state, X, require_in the first state defined in the included sls file.

When writing sls files with this renderer, one should avoid using what can be defined in a name argument of a state as the state's id. That is, avoid writing states like this:

```
/path/to/some/file:
  file.managed:
    - source: salt://some/file

cp /path/to/some/file file2:
  cmd.run:
    - cwd: /
    - require:
      - file: /path/to/some/file
```

Instead, define the state id and the name argument separately for each state. Also, the ID should be something meaningful and easy to reference within a requisite (which is a good habit anyway, and such extra indirection would also makes the sls file easier to modify later). Thus, the above states should be written like this:

```
add-some-file:
  file.managed:
    - name: /path/to/some/file
      - source: salt://some/file

copy-files:
  cmd.run:
    - name: cp /path/to/some/file file2
      - cwd: /
      - require:
        - file: add-some-file
```

Moreover, when referencing a state from a requisite, you should reference the state's id plus the state name rather than the state name plus its name argument. (Yes, in the above example, you can actually require the file: /path/to/some/file, instead of the file: add-some-file). The reason is that this renderer will re-write or rename state id's and their references for state id's prefixed with .. So, if you reference name then there's no way to reliably rewrite such reference.

```python
salt.renderers.wempy

salt.renderers.wempy.render(template_file, saltenv='base', sls='''', argline='''', context=None, **kws)
```

Render the data passing the functions and grains into the rendering system
Return type \textit{string}

\texttt{salt.renderers.yamlex}

YAMLEX renderer is a replacement of the YAML renderer. It's 100\% YAML with a pinch of Salt magic:
- All mappings are automatically \texttt{OrderedDict}
- All strings are automatically \texttt{str} obj
- data aggregation with \texttt{!aggregation} yaml tag, based on the \texttt{salt.utils.aggregation} module.
- data aggregation over documents for pillar

Instructed aggregation within the \texttt{!aggregation} and the \texttt{!reset} tags:

\begin{verbatim}
#!yamlex
foo: !aggregate first
foo: !aggregate second
bar: !aggregate {first: foo}
bar: !aggregate {second: bar}
baz: !aggregate 42
qux: !aggregate default
!reset qux: !aggregate my custom data
\end{verbatim}

is roughly equivalent to

\begin{verbatim}
foo: [first, second]
bar: {first: foo, second: bar}
baz: [42]
qux: [my custom data]
\end{verbatim}

Reference

\texttt{salt.renderers.yamlex.render(sls\_data, saltenv='base', sls='\', **kws)}

Accepts YAML\_EX as a string or as a file object and runs it through the YAML\_EX parser.

Return type A Python data structure

\section{32.25 Returners}

By default the return values of the commands sent to the Salt minions are returned to the Salt master, however anything at all can be done with the results data.

By using a Salt returner, results data can be redirected to external data-stores for analysis and archival.

Returners pull their configuration values from the Salt minions. Returners are only configured once, which is generally at load time.

The returner interface allows the return data to be sent to any system that can receive data. This means that return data can be sent to a Redis server, a MongoDB server, a MySQL server, or any system.

See also:

\textit{Full list of builtin returners}
32.25.1 Using Returners

All Salt commands will return the command data back to the master. Specifying returners will ensure that the data is _also_ sent to the specified returner interfaces.

Specifying what returners to use is done when the command is invoked:

```
salt '*' test.ping --return redis_return
```

This command will ensure that the redis_return returner is used.

It is also possible to specify multiple returners:

```
salt '*' test.ping --return mongo_return,redis_return,cassandra_return
```

In this scenario all three returners will be called and the data from the test.ping command will be sent out to the three named returners.

32.25.2 Writing a Returner

A returner is a Python module containing at minimum a `returner` function. Other optional functions can be included to add support for `master_job_cache`, `external_job_cache`, and `Event Returners`. Salt’s `master_job_cache` allows returners to be used as a pluggable replacement for the `Default Job Cache`. In order to do so, a returner must implement the following functions:

**Note:** The code samples contained in this section were taken from the cassandra_cql returner.
**prep_jid** Ensures that job ids (jid) don't collide, unless passed_jid is provided.

    nochache is an optional boolean that indicates if return data should be cached. passed_jid is a caller provided jid which should be returned unconditionally.

```python
def prep_jid(nocache, passed_jid=None):  # pylint: disable=unused-argument
    '''
    Do any work necessary to prepare a JID, including sending a custom id
    '''
    return passed_jid if passed_jid is not None else salt.utils.jid.gen_jid()
```

**save_load** Save job information. The jid is generated by prep_jid and should be considered a unique identifier for the job. The jid, for example, could be used as the primary/unique key in a database. The load is what is returned to a Salt master by a minion. The following code example stores the load as a JSON string in the salt.jids table.

```python
def save_load(jid, load):
    '''
    Save the load to the specified jid id
    '''
    query = '''INSERT INTO salt.jids (
        jid, load
    ) VALUES (  
        '{0}', '{1}'
    );'''.format(jid, json.dumps(load))

    # cassandra_cql.cql_query may raise a CommandExecutionError
    try:
        __salt__['cassandra_cql.cql_query'](query)
    except CommandExecutionError:
        log.critical('Could not save load in jids table.
    raise
    except Exception as e:
        log.critical('Unexpected error while inserting into jids: {0}'.format(str(e)))
    raise
```

**get_load** must accept a job id (jid) and return the job load stored by save_load, or an empty dictionary when not found.

```python
def get_load(jid):
    '''
    Return the load data that marks a specified jid
    '''
    query = '''SELECT load FROM salt.jids WHERE jid = '{0}';'''.format(jid)
    ret = {}

    # cassandra_cql.cql_query may raise a CommandExecutionError
    try:
        data = __salt__['cassandra_cql.cql_query'](query)
        if data:
            load = data[0].get('load')
            if load:
                ret = json.loads(load)
        except CommandExecutionError:
            log.critical('Could not get load from jids table.')
        raise
    except Exception as e:
External Job Cache Support

Salt’s external_job_cache extends the master_job_cache. External Job Cache support requires the following functions in addition to what is required for Master Job Cache support:

**get_jid** Return a dictionary containing the information (load) returned by each minion when the specified job id was executed.

Sample:
```
{  
    "local": {  
        "master_minion": {  
            "fun_args": [],  
            "jid": "20150330121011408195",  
            "return": true,  
            "retcode": 0,  
            "success": true,  
            "cmd": "_return",  
            "_stamp": "2015-03-30T12:10:12.708663",  
            "fun": "test.ping",  
            "id": "master_minion"  
        },  
        "id": "master_minion"  
    }  
}
```

**get_fun** Return a dictionary of minions that called a given Salt function as their last function call.

Sample:
```
{  
    "local": {  
        "minion1": "test.ping",  
        "minion3": "test.ping",  
        "minion2": "test.ping"  
    }  
}
```

**get_jids** Return a list of all job ids.

Sample:
```
{  
    "local": [  
        "20150330121011408195",  
        "20150330195922139916"  
    ]  
}
```

**get_minions** Returns a list of minions

Sample:
Please refer to one or more of the existing returners (i.e. mysql, cassandra_cql) if you need further clarification.

**Event Support**

An event_return function must be added to the returner module to allow events to be logged from a master via the returner. A list of events are passed to the function by the master.

The following example was taken from the MySQL returner. In this example, each event is inserted into the salt_events table keyed on the event tag. The tag contains the jid and therefore is guaranteed to be unique.

```python
def event_return(events):
    '''
    Return event to mysql server

    Requires that configuration be enabled via 'event_return'
    option in master config.
    '''
    with _get_serv(events, commit=True) as cur:
        for event in events:
            tag = event.get('tag', '')
            data = event.get('data', '')
            sql = '''INSERT INTO `salt_events` (`tag`, `data`, `master_id`)
                    VALUES (%s, %s, %s)'''
            cur.execute(sql, (tag, json.dumps(data), __opts__['id']))
```

**Custom Returners**

Place custom returners in a _returners directory within the file_roots specified by the master config file. Custom returners are distributed when any of the following are called:

- state.apply
- saltutil.sync_returners
- saltutil.sync_all

Any custom returners which have been synced to a minion that are named the same as one of Salt’s default set of returners will take the place of the default returner with the same name.

**Naming the Returner**

Note that a returner’s default name is its filename (i.e. foo.py becomes returner foo), but that its name can be overridden by using a __virtual__ function. A good example of this can be found in the redis returner, which is named redis_return.py but is loaded as simply redis:
try:
    import redis
    HAS_REDIS = True
except ImportError:
    HAS_REDIS = False
__virtualname__ = 'redis'

def __virtual__():
    if not HAS_REDIS:
        return False
    return __virtualname__

Testing the Returner

The returner, prep_jid, save_load, get_load, and event_return functions can be tested by configuring the master_job_cache and Event Returners in the master config file and submitting a job to test.ping each minion from the master.

Once you have successfully exercised the Master Job Cache functions, test the External Job Cache functions using the ret execution module.

    salt-call ret.get_jids cassandra_cql --output=json
    salt-call ret.get_fun cassandra_cql test.ping --output=json
    salt-call ret.get_minions cassandra_cql --output=json
    salt-call ret.get_jid cassandra_cql 20150330121011408195 --output=json

32.25.3 Event Returners

For maximum visibility into the history of events across a Salt infrastructure, all events seen by a salt master may be logged to a returner.

To enable event logging, set the event_return configuration option in the master config to returner which should be designated as the handler for event returns.

Note: Not all returners support event returns. Verify a returner has an event_return() function before using.

Note: On larger installations, many hundreds of events may be generated on a busy master every second. Be certain to closely monitor the storage of a given returner as Salt can easily overwhelm an underpowered server with thousands of returns.

</tbody>
</table>

**salt.returners.carbon_return**

Take data from salt and "return" it into a carbon receiver

Add the following configuration to the minion configuration file:

```yaml
carbon.host: <server ip address>
carbon.port: 2003
```

Errors when trying to convert data to numbers may be ignored by setting `carbon.skip_on_error` to True:

```yaml
carbon.skip_on_error: True
```

By default, data will be sent to carbon using the plaintext protocol. To use the pickle protocol, set `carbon.mode` to pickle:

```yaml
carbon.mode: pickle
```

32.25. Returners
You can also specify the pattern used for the metric base path (except for virt modules metrics):
  carbon.metric_base_pattern: carbon.[minion_id].[module].[function]

These tokens can used: [module]: salt module [function]: salt function [minion_id]: minion id

Default is: carbon.metric_base_pattern: [module].[function].[minion_id]

Carbon settings may also be configured as:

```yaml
carbon:
  host: <server IP or hostname>
  port: <carbon port>
  skip_on_error: True
  mode: (pickle|text)
  metric_base_pattern: <pattern> | [module].[function].[minion_id]
```

Alternative configuration values can be used by prefacing the configuration. Any values not found in the alternative configuration will be pulled from the default location:

```yaml
alternative.carbon:
  host: <server IP or hostname>
  port: <carbon port>
  skip_on_error: True
  mode: (pickle|text)
```

To use the carbon returner, append `--return carbon` to the salt command.

```shell
salt '*' test.ping --return carbon
```

To use the alternative configuration, append `--return_config alternative` to the salt command.

New in version 2015.5.0.

```shell
salt '*' test.ping --return carbon --return_config alternative
```

```python
salt.returners.carbon_return.event_return(events)
    Return event data to remote carbon server
    Provide a list of events to be stored in carbon

salt.returners.carbon_return.prep_jid(nocache=False, passed_jid=None)
    Do any work necessary to prepare a JID, including sending a custom id

salt.returners.carbon_return.returner(ret)
    Return data to a remote carbon server using the text metric protocol
    Each metric will look like:

    [module].[function].[minion_id].[metric path [...]].[metric name]
```

```python
salt.returners.cassandra_cql_return
```

Return data to a cassandra server

New in version 2015.5.0.

- maintainer Corin Kochenower<ckochenower@saltstack.com>
- maturity new as of 2015.2
- depends salt.modules.cassandra_cql
depends DataStax Python Driver for Apache Cassandra [https://github.com/datastax/python-driver]
install cassandra-driver

platform all

configuration To enable this returner, the minion will need the DataStax Python Driver for Apache
Cassandra ([https://github.com/datastax/python-driver]) installed and the following values configured in
the minion or master config. The list of cluster IPs must include at least one cassandra node
IP address. No assumption or default will be used for the cluster IPs. The cluster IPs will be tried
in the order listed. The port, username, and password values shown below will be the assumed
defaults if you do not provide values:

cassandra:
  cluster:
    - 192.168.50.11
    - 192.168.50.12
    - 192.168.50.13
  port: 9042
  username: salt
  password: salt

Use the following cassandra database schema:

```
CREATE KEYSPACE IF NOT EXISTS salt
  WITH replication = {'class': 'SimpleStrategy', 'replication_factor': 1};

CREATE USER IF NOT EXISTS salt WITH PASSWORD 'salt' NOSUPERUSER;
GRANT ALL ON KEYSPACE salt TO salt;
USE salt;

CREATE TABLE IF NOT EXISTS salt.salt_returns (
  jid text,
  minion_id text,
  fun text,
  alter_time timestamp,
  full_ret text,
  return text,
  success boolean,
  PRIMARY KEY (jid, minion_id, fun)
) WITH CLUSTERING ORDER BY (minion_id ASC, fun ASC);
CREATE INDEX IF NOT EXISTS salt_returns_minion_id ON salt.salt_returns(minion_id);
CREATE INDEX IF NOT EXISTS salt_returns_fun ON salt.salt_returns(fun);

CREATE TABLE IF NOT EXISTS salt.jids (
  jid text PRIMARY KEY,
  load text
);

CREATE TABLE IF NOT EXISTS salt.minions (
  minion_id text PRIMARY KEY,
  last_fun text
);
CREATE INDEX IF NOT EXISTS minions_last_fun ON salt.minions(last_fun);

CREATE TABLE IF NOT EXISTS salt.salt_events (}

32.25. Returners
id timeuuid,
tag text,
alter_time timestamp,
data text,
master_id text,
) PRIMARY KEY (id, tag)
) WITH CLUSTERING ORDER BY (tag ASC);
CREATE INDEX tag ON salt.salt_events (tag);

Required python modules: cassandra-driver

To use the cassandra returner, append `--return cassandra' to the salt command. ex:
salt '*' test.ping --return cassandra

salt.returners.cassandra_cql_return.event_return(events)
    Return event to one of potentially many clustered cassandra nodes
    Requires that configuration be enabled via 'event_return' option in master config.
    Cassandra does not support an auto-increment feature due to the highly inefficient nature of creating a mono-
    tonically increasing number across all nodes in a distributed database. Each event will be assigned a uuid by
    the connecting client.

salt.returners.cassandra_cql_return.get_fun(fun)
    Return a dict of the last function called for all minions

salt.returners.cassandra_cql_return.get_jid(jid)
    Return the information returned when the specified job id was executed

salt.returners.cassandra_cql_return.get_jids()
    Return a list of all job ids

salt.returners.cassandra_cql_return.get_load(jid)
    Return the load data that marks a specified jid

salt.returners.cassandra_cql_return.get_minions()
    Return a list of minions

salt.returners.cassandra_cql_return.prep_jid(nocache, passed_jid=None)
    Do any work necessary to prepare a JID, including sending a custom id

salt.returners.cassandra_cql_return.returner(ret)
    Return data to one of potentially many clustered cassandra nodes
    Save the load to the specified jid id

salt.returners.cassandra_cql_return.returner(ret)
    Return data to one of potentially many clustered cassandra nodes

Here's an example Keyspace / ColumnFamily setup that works with this returner:

create keyspace salt;
use salt;
create column family returns
    with key_validation_class='UTF8Type'
    and comparator='UTF8Type'
    and default_validation_class='UTF8Type';
Required python modules: pycassa

To use the cassandra returner, append `--return cassandra' to the salt command. ex:
salt '*' test.ping --return cassandra

```
salt.returners.cassandra_return.prep_jid(nocache=False, passed_jid=None)
```
Do any work necessary to prepare a JID, including sending a custom id

```
salt.returners.cassandra_return.returner(ret)
```
Return data to a Cassandra ColumnFamily

**salt.returners.couchbase_return**

Simple returner for Couchbase. Optional configuration settings are listed below, along with sane defaults.

couchbase.host: `salt' couchbase.port: 8091 couchbase.bucket: `salt' couchbase.skip_verify_views: False

To use the couchbase returner, append `--return couchbase' to the salt command. ex:
salt '*' test.ping --return couchbase

All of the return data will be stored in documents as follows:

**JID**

load: load obj tgt_minions: list of minions targeted nocache: should we not cache the return data

**JID/MINION_ID**

return: return_data out: out_data

```
salt.returners.couchbase_return.get_jid(jid)
```
Return the information returned when the specified job id was executed

```
salt.returners.couchbase_return.get_jids()
```
Return a list of all job ids

```
salt.returners.couchbase_return.get_load(jid)
```
Return the load data that marks a specified jid

```
salt.returners.couchbase_return.prep_jid(nocache=False, passed_jid=None)
```
Return a job id and prepare the job id directory This is the function responsible for making sure jids don’t collide (unless its passed a jid) So do what you have to do to make sure that stays the case

```
salt.returners.couchbase_return.returner(load)
```
Return data to the local job cache

```
salt.returners.couchbase_return.save_load(jid, clear_load, minion=None)
```
Save the load to the specified jid

```
salt.returners.couchbase_return.save_minions(jid, minions, syndic_id=None)
```
Save/update the minion list for a given jid. The syndic_id argument is included for API compatibility only.
Simple returner for CouchDB. Optional configuration settings are listed below, along with sane defaults:

```
couchdb.db: 'salt'
couchdb.url: 'http://salt:5984/
```

Alternative configuration values can be used by prefacing the configuration. Any values not found in the alternative configuration will be pulled from the default location:

```
alternative.couchdb.db: 'salt'
alternative.couchdb.url: 'http://salt:5984/
```

To use the couchdb returner, append `--return couchdb` to the salt command. Example:

```
salt '*' test.ping --return couchdb
```

To use the alternative configuration, append `--return_config alternative` to the salt command. New in version 2015.5.0.

```
salt '*' test.ping --return couchdb --return_config alternative
```

### On concurrent database access

As this returner creates a couchdb document with the salt job id as document id and as only one document with a given id can exist in a given couchdb database, it is advised for most setups that every minion be configured to write to its own database (the value of `couchdb.db` may be suffixed with the minion id), otherwise multi-minion targeting can lead to losing output:

- the first returning minion is able to create a document in the database
- other minions fail with `{ 'error': 'HTTP Error 409: Conflict' }`

- `salt.returners.couchdb_return.ensure_views()`
  This function makes sure that all the views that should exist in the design document do exist.

- `salt.returners.couchdb_return.get_fun(fun)`
  Return a dict with key being minion and value being the job details of the last run of function `fun`.

- `salt.returners.couchdb_return.get_jid(jid)`
  Get the document with a given JID.

- `salt.returners.couchdb_return.get_jids()`
  List all the jobs that we have..

- `salt.returners.couchdb_return.get_minions()`
  Return a list of minion identifiers from a request of the view.

- `salt.returners.couchdb_return.get_valid_salt_views()`
  Returns a dict object of views that should be part of the salt design document.

- `salt.returners.couchdb_return.prep_jid(nocache=False, passed_jid=None)`
  Do any work necessary to prepare a JID, including sending a custom id

- `salt.returners.couchdb_return.returner(ret)`
  Take in the return and shove it into the couchdb database.

- `salt.returners.couchdb_return.set_salt_view()`
  Helper function that sets the salt design document. Uses `get_valid_salt_views` and some hardcoded values.
salt.returners.django_return

A returner that will inform a Django system that returns are available using Django's signal system.

https://docs.djangoproject.com/en/dev/topics/signals/

It is up to the Django developer to register necessary handlers with the signals provided by this returner and process returns as necessary.

The easiest way to use signals is to import them from this returner directly and then use a decorator to register them. An example Django module that registers a function called `returner_callback` with this module's `returner` function:

```python
import salt.returners.django_return
from django.dispatch import receiver

@receiver(salt.returners.django_return, sender=returner)
def returner_callback(sender, ret):
    print('I received {0} from {1}'.format(ret, sender))
```

salt.returners.django_return.prep_jid(nocache=False, passed_jid=None)

Do any work necessary to prepare a JID, including sending a custom ID

salt.returners.django_return.returner(ret)

Signal a Django server that a return is available

salt.returners.django_return.save_load(jid, load, minions=None)

Save the load to the specified JID

salt.returners.elasticsearch_return

Return data to an elasticsearch server for indexing.

maintainer Jurnell Cockhren <jurnell.cockhren@sophicware.com>, Arnold Bechtoldt <mail@arnoldbechtoldt.com>

maturity New

depends elasticsearch-py

platform all

To enable this returner the elasticsearch python client must be installed on the desired minions (all or some subset).

Please see documentation of elasticsearch execution module for a valid connection configuration.

**Warning:** The index that you wish to store documents will be created by Elasticsearch automatically if it doesn't exist yet. It is highly recommended to create predefined index templates with appropriate mapping(s) that will be used by Elasticsearch upon index creation. Otherwise you will have problems as described in #20826.

To use the returner per salt call:

```sh
salt '*' test.ping --return elasticsearch
```

In order to have the returner apply to all minions:

```sh
salt '*' test.ping --return elasticsearch
```

In order to have the returner apply to all minions:

```sh
ext_job_cache: elasticsearch
```
salt.returners.elasticsearch_return.

salt.returners.elasticsearch_return.get_load(jid)
Return the load data that marks a specified jid

salt.returners.elasticsearch_return.prep_jid(nocache=False, passed_jid=None)
Do any work necessary to prepare a JID, including sending a custom id

salt.returners.elasticsearch_return.returner(ret)
Process the return from Salt

salt.returners.elasticsearch_return.save_load(jid, load, minions=None)
Save the load to the specified jid id

salt.returners.etcd_return

Return data to an etcd server or cluster

deps
- python-etc
depends

In order to return to an etcd server, a profile should be created in the master configuration file:

```python
my_etcd_config:
  etcd.host: 127.0.0.1
  etcd.port: 4001
```

It is technically possible to configure etcd without using a profile, but this is not considered to be a best practice, especially when multiple etcd servers or clusters are available.

```python
etcd.host: 127.0.0.1
etcd.port: 4001
```

Additionally, two more options must be specified in the top-level configuration in order to use the etcd returner:

```python
etcd.returner: my_etcd_config
etcd.returner_root: /salt/return
```

The `etcd.returner` option specifies which configuration profile to use. The `etcd.returner_root` option specifies the path inside etcd to use as the root of the returner system.

Once the etcd options are configured, the returner may be used:

CLI Example:

```
salt '*' test.ping --return etcd
```

salt.returners.etcd_return.

salt.returners.etcd_return.get_fun()
Return a dict of the last function called for all minions

salt.returners.etcd_return.get_jid(jid)
Return the information returned when the specified job id was executed

salt.returners.etcd_return.get_jids()
Return a list of all job ids

salt.returners.etcd_return.get_load(jid)
Return the load data that marks a specified jid
Salt Documentation, Release 2015.8.12

salt.returners.etcd_return.get_minions()
Return a list of minions

salt.returners.etcd_return.prep_jid(nocache=False, passed_jid=None)
Do any work necessary to prepare a JID, including sending a custom id

salt.returners.etcd_return.returner(ret)
Return data to an etcd server or cluster

salt.returners.etcd_return.save_load(jid, load, minions=None)
Save the load to the specified jid

salt.returners.hipchat_return

Return salt data via hipchat.
New in version 2015.5.0.
The following fields can be set in the minion conf file:

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>hipchat.room_id</td>
<td>(required)</td>
</tr>
<tr>
<td>hipchat.api_key</td>
<td>(required)</td>
</tr>
<tr>
<td>hipchat.api_version</td>
<td>(required)</td>
</tr>
<tr>
<td>hipchat.from_name</td>
<td>(required)</td>
</tr>
<tr>
<td>hipchat.color</td>
<td>(optional)</td>
</tr>
<tr>
<td>hipchat.notify</td>
<td>(optional)</td>
</tr>
<tr>
<td>hipchat.profile</td>
<td>(optional)</td>
</tr>
</tbody>
</table>

Note: When using Hipchat's API v2, api_key needs to be assigned to the room with the `Label` set to what you would have been set in the hipchat.from_name field. The v2 API disregards the from_name in the data sent for the room notification and uses the Label assigned through the Hipchat control panel.

Alternative configuration values can be used by prefacing the configuration. Any values not found in the alternative configuration will be pulled from the default location:

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>hipchat.room_id</td>
<td></td>
</tr>
<tr>
<td>hipchat.api_key</td>
<td></td>
</tr>
<tr>
<td>hipchat.api_version</td>
<td></td>
</tr>
<tr>
<td>hipchat.from_name</td>
<td></td>
</tr>
</tbody>
</table>

Hipchat settings may also be configured as:

```
hipchat:
  room_id: RoomName
  api_key: xxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx
  api_version: v1
  from_name: user@email.com

alternative.hipchat:
  room_id: RoomName
  api_key: xxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx
  api_version: v1
  from_name: user@email.com

hipchat_profile:
  api_key: xxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx
```
api_version: v1
from_name: user@email.com

hipchat:
  profile: hipchat_profile
  room_id: RoomName

alternative.hipchat:
  profile: hipchat_profile
  room_id: RoomName

To use the HipChat returner, append `--return hipchat' to the salt command.

```bash
salt '*' test.ping --return hipchat
```

To use the alternative configuration, append `--return_config alternative' to the salt command.

New in version 2015.5.0.

```bash
salt '*' test.ping --return hipchat --return_config alternative
```

salt.returners.hipchat_return.

- **event_return(events)**: Return event data to hipchat
- **returner(ret)**: Send an hipchat message with the return data from a job

**salt.returners.influxdb_return**

Return data to an influxdb server.

New in version 2015.8.0.

To enable this returner the minion will need the python client for influxdb installed and the following values configured in the minion or master config, these are the defaults:

```plaintext
influxdb.db: 'salt'
influxdb.user: 'salt'
influxdb.password: 'salt'
influxdb.host: 'localhost'
influxdb.port: 8086
```

Alternative configuration values can be used by prefacing the configuration. Any values not found in the alternative configuration will be pulled from the default location:

```plaintext
alternative.influxdb.db: 'salt'
alternative.influxdb.user: 'salt'
alternative.influxdb.password: 'salt'
alternative.influxdb.host: 'localhost'
alternative.influxdb.port: 6379
```

To use the influxdb returner, append `--return influxdb' to the salt command.

```bash
salt '*' test.ping --return influxdb
```

To use the alternative configuration, append `--return_config alternative' to the salt command.
Return a dict of the last function called for all minions

salt.returners.influxdb_return.get_jid(jid)
Return the information returned when the specified job id was executed

salt.returners.influxdb_return.get_jids()
Return a list of all job ids

salt.returners.influxdb_return.get_load(jid)
Return the load data that marks a specified jid

salt.returners.influxdb_return.get_minions()
Return a list of minions

salt.returners.influxdb_return.prep_jid(nocache=False, passed_jid=None)
Do any work necessary to prepare a JID, including sending a custom id

salt.returners.influxdb_return.returner(ret)
Return data to a influxdb data store

salt.returners.influxdb_return.save_load(jid, load, minions=None)
Save the load to the specified jid

salt.returners.kafka_return

Return data to a Kafka topic

maintainer  Christer Edwards (christer.edwards@gmail.com)
maturity  0.1
depends  kafka-python
platform  all

To enable this returner install kafka-python and enable the following settings in the minion config:

   returner.kafka.hostnames:
   • `server1`
   • `server2`
   • `server3`

   returner.kafka.topic: 'topic'

To use the kafka returner, append `--return kafka` to the Salt command, eg:

   salt '*' test.ping --return kafka

salt.returners.kafka_return.returner(ret)
Return information to a Kafka server

salt.returners.local

The local returner is used to test the returner interface, it just prints the return data to the console to verify that it is being passed properly
To use the local returner, append `--return local' to the salt command. ex:

    salt `*' test.ping --return local

salt.returners.local.event_return(event)
    Print event return data to the terminal to verify functionality

salt.returners.local.returner(ret)
    Print the return data to the terminal to verify functionality

salt.returners.local_cache

Return data to local job cache

salt.returners.local_cache.clean_old_jobs()
    Clean out the old jobs from the job cache

salt.returners.local_cache.get_endtime(jid)
    Retrieve the stored endtime for a given job
    Returns False if no endtime is present

salt.returners.local_cache.get_jid(jid)
    Return the information returned when the specified job id was executed

salt.returners.local_cache.get_jids()
    Return a dict mapping all job ids to job information

salt.returners.local_cache.get_jids_filter(count, filter_find_job=True)
    Return a list of all jobs information filtered by the given criteria.
    :param int count: show not more than the count of most recent jobs
    :param bool filter_find_jobs: filter out `saltutil.find_job' jobs

salt.returners.local_cache.get_load(jid)
    Return the load data that marks a specified jid

salt.returners.local_cache.prep_jid(nocache=False, passed_jid=None, recurse_count=0)
    Return a job id and prepare the job id directory.
    This is the function responsible for making sure jids don't collide (unless it is passed a jid). So do what you have to do to make sure that stays the case

salt.returners.local_cache.returner(load)
    Return data to the local job cache

salt.returners.local_cache.save_load(jid, clear_load, minions=None, recurse_count=0)
    Save the load to the specified jid

    minions argument is to provide a pre-computed list of matched minions for the job, for cases when this function can't compute that list itself (such as for salt-ssh)

salt.returners.local_cache.save_minions(jid, minions, syndic_id=None)
    Save/update the serialized list of minions for a given job

salt.returners.local_cache.update_endtime(jid, time)
    Update (or store) the end time for a given job

    Endtime is stored as a plain text string
Salt Documentation, Release 2015.8.12

salt.returners.memcache_return

Return data to a memcache server

To enable this returner the minion will need the python client for memcache installed and the following values configured in the minion or master config, these are the defaults.

```python
memcache.host: 'localhost'
memcache.port: '11211'
```

Alternative configuration values can be used by prefacing the configuration. Any values not found in the alternative configuration will be pulled from the default location.

```python
alternative.memcache.host: 'localhost'
alternative.memcache.port: '11211'
```

python2-memcache uses `localhost` and `11211` as syntax on connection.

To use the memcache returner, append `--return memcache` to the salt command.

```bash
salt '*' test.ping --return memcache
```

To use the alternative configuration, append `--return_config alternative` to the salt command.

New in version 2015.5.0.

```bash
salt '*' test.ping --return memcache --return_config alternative
```

salt.returners.memcache_return.

- **get_fun** *(fun)*
  Return a dict of the last function called for all minions

- **get_jid** *(jid)*
  Return the information returned when the specified job id was executed

- **get_jids** *
  Return a list of all job ids

- **get_load** *(jid)*
  Return the load data that marks a specified jid

- **get_minions** *
  Return a list of minions

- **prep_jid** *(nocache=False, passed_jid=None)*
  Do any work necessary to prepare a JID, including sending a custom id

- **returner** *(ret)*
  Return data to a memcache data store

- **save_load** *(jid, load, minions=None)*
  Save the load to the specified jid

salt.returners.mongo_future_return

Return data to a mongodb server

Required python modules: pymongo

This returner will send data from the minions to a MongoDB server. To configure the settings for your MongoDB server, add the following lines to the minion config files:
You can also ask for indexes creation on the most common used fields, which should greatly improve performance. Indexes are not created by default.

```
mongo.indexes: true
```

Alternative configuration values can be used by prefacing the configuration. Any values not found in the alternative configuration will be pulled from the default location:

```
alternative.mongo.db: <database name>
alternative.mongo.host: <server ip address>
alternative.mongo.user: <MongoDB username>
alternative.mongo.password: <MongoDB user password>
alternative.mongo.port: 27017
```

This mongo returner is being developed to replace the default mongodb returner in the future and should not be considered API stable yet.

To use the mongo returner, append `--return mongo` to the salt command.

```
salt '*' test.ping --return mongo
```

To use the alternative configuration, append `--return_config alternative` to the salt command.

New in version 2015.5.0.

```
salt '*' test.ping --return mongo --return_config alternative
```

- `salt.returners.mongo_future_return.get_fun(fun)`
  
  Return the most recent jobs that have executed the named function

- `salt.returners.mongo_future_return.get_jid(jid)`
  
  Return the return information associated with a jid

- `salt.returners.mongo_future_return.get_jids()`
  
  Return a list of job ids

- `salt.returners.mongo_future_return.get_load(jid)`
  
  Return the load associated with a given job id

- `salt.returners.mongo_future_return.get_minions()`
  
  Return a list of minions

- `salt.returners.mongo_future_return.prep_jid(nocache=False, passed_jid=None)`
  
  Do any work necessary to prepare a JID, including sending a custom id

- `salt.returners.mongo_future_return.returner(ret)`
  
  Return data to a mongodb server

- `salt.returners.mongo_future_return.save_load(jid, load, minions=None)`
  
  Save the load for a given job id
salt.returners.mongo_return

Return data to a mongodb server

Required python modules: pymongo

This returner will send data from the minions to a MongoDB server. To configure the settings for your MongoDB server, add the following lines to the minion config files.

```
mongo.db: <database name>
mongo.host: <server ip address>
mongo.user: <MongoDB username>
mongo.password: <MongoDB user password>
mongo.port: 27017
```

Alternative configuration values can be used by prefacing the configuration. Any values not found in the alternative configuration will be pulled from the default location.

```
alternative.mongo.db: <database name>
alternative.mongo.host: <server ip address>
alternative.mongo.user: <MongoDB username>
alternative.mongo.password: <MongoDB user password>
alternative.mongo.port: 27017
```

To use the mongo returner, append `--return mongo` to the salt command.

```
salt '*' test.ping --return mongo_return
```

To use the alternative configuration, append `--return_config alternative` to the salt command.

New in version 2015.5.0.

```
salt '*' test.ping --return mongo_return --return_config alternative
```

salt.returners.mongo_return.get_fun(fun)

Return the most recent jobs that have executed the named function

salt.returners.mongo_return.get_jid(jid)

Return the return information associated with a jid

salt.returners.mongo_return.prep_jid(nocache=False, passed_jid=None)

Do any work necessary to prepare a JID, including sending a custom id

salt.returners.mongo_return.returner(ret)

Return data to a mongodb server

salt.returners.multi_returner

Read/Write multiple returners

salt.returners.multi_returner.clean_old_jobs()

Clean out the old jobs from all returners (if you have it)

salt.returners.multi_returner.get_jid(jid)

Merge the return data from all returners

salt.returners.multi_returner.get_jids()

Return all job data from all returners
salt.returners.multi_returner.get_load(jid)
    Merge the load data from all returners

salt.returners.multi_returner.prep_jid(nocache=False, passed_jid=None)
    Call both with prep_jid on all returners in multi_returner

    TODO: finish this, what do do when you get different jids from 2 returners... since our jids are time based, this
    make this problem hard, because they aren't unique, meaning that we have to make sure that no one else got
    the jid and if they did we spin to get a new one, which means "locking" the jid in 2 returners is non-trivial

salt.returners.multi_returner.returner(load)
    Write return to all returners in multi_returner

salt.returners.multi_returner.save_load(jid, clear_load, minions=None)
    Write load to all returners in multi_returner

salt.returners.mysql

Return data to a mysql server

    maintainer  Dave Boucha <dave@saltstack.com>, Seth House <shouse@saltstack.com>
    maturity    new
    depends     python-mysql
    platform    all

To enable this returner, the minion will need the python client for mysql installed and the following values configured
in the minion or master config. These are the defaults:

```
mysql.host: 'salt'
m.mysql.user: 'salt'
m.mysql.pass: 'salt'
m.mysql.db: 'salt'
m.mysql.port: 3306
```

SSL is optional. The defaults are set to None. If you do not want to use SSL, either exclude these options or set them
to None.

```
mysql.ssl_ca: None
mysql.ssl_cert: None
mysql.ssl_key: None
```

Alternative configuration values can be used by prefacing the configuration with `alternative`. Any values not found in
the alternative configuration will be pulled from the default location. As stated above, SSL configuration is optional.
The following ssl options are simply for illustration purposes:

```
alternative.mysql.host: 'salt'
alternative.mysql.user: 'salt'
alternative.mysql.pass: 'salt'
alternative.mysql.db: 'salt'
alternative.mysql.port: 3306
alternative.mysql.ssl_ca: '/etc/pki/mysql/certs/localhost.pem'
alternative.mysql.ssl_cert: '/etc/pki/mysql/certs/localhost.crt'
alternative.mysql.ssl_key: '/etc/pki/mysql/certs/localhost.key'
```

Use the following mysql database schema:
CREATE DATABASE `salt`
  DEFAULT CHARACTER SET utf8
  DEFAULT COLLATE utf8_general_ci;

USE `salt`;

-- Table structure for table `jids`

DROP TABLE IF EXISTS `jids`;
CREATE TABLE `jids`(
  `jid` varchar(255) NOT NULL,
  `load` mediumtext NOT NULL,
  UNIQUE KEY `jid` (`jid`)
) ENGINE=InnoDB DEFAULT CHARSET=utf8;
CREATE INDEX jid ON jids(jid) USING BTREE;

-- Table structure for table `salt_returns`

DROP TABLE IF EXISTS `salt_returns`;
CREATE TABLE `salt_returns`(
  `fun` varchar(50) NOT NULL,
  `jid` varchar(255) NOT NULL,
  `return` mediumtext NOT NULL,
  `id` varchar(255) NOT NULL,
  `success` varchar(10) NOT NULL,
  `full_ret` mediumtext NOT NULL,
  `alter_time` TIMESTAMP DEFAULT CURRENT_TIMESTAMP,
  KEY `id` (`id`),
  KEY `jid` (`jid`),
  KEY `fun` (`fun`)
) ENGINE=InnoDB DEFAULT CHARSET=utf8;

-- Table structure for table `salt_events`

DROP TABLE IF EXISTS `salt_events`;
CREATE TABLE `salt_events`(
  `id` BIGINT NOT NULL AUTO_INCREMENT,
  `tag` varchar(255) NOT NULL,
  `data` mediumtext NOT NULL,
  `alter_time` TIMESTAMP DEFAULT CURRENT_TIMESTAMP,
  `master_id` varchar(255) NOT NULL,
  PRIMARY KEY (`id`),
  KEY `tag` (`tag`)
) ENGINE=InnoDB DEFAULT CHARSET=utf8;

Required python modules: MySQLdb

To use the mysql returner, append `--return mysql` to the salt command.

```
salt '*' test.ping --return mysql
```

To use the alternative configuration, append `--return_config alternative` to the salt command.
New in version 2015.5.0.

```bash
salt '*' test.ping --return mysql --return_config alternative
```

salt.returners.mysql.event_return(events)

Return event to mysql server

Requires that configuration be enabled via `event_return' option in master config.

salt.returners.mysql.get_fun(fun)

Return a dict of the last function called for all minions

salt.returners.mysql.get_jid(jid)

Return the information returned when the specified job id was executed

salt.returners.mysql.get_jids()

Return a list of all job ids

salt.returners.mysql.get_jids_filter(count, filter_find_job=True)

Return a list of all job ids :param int count: show not more than the count of most recent jobs :param bool filter_find_jobs: filter out `saltutil.find_job' jobs

salt.returners.mysql.get_load(jid)

Return the load data that marks a specified jid

salt.returners.mysql.get_minions()

Return a list of minions

salt.returners.mysql.prep_jid(nocache=False, passed_jid=None)

Do any work necessary to prepare a JID, including sending a custom id

salt.returners.mysql.returner(ret)

Return data to a mysql server

salt.returners.mysql.save_load(jid, load, minions=None)

Save the load to the specified jid id

salt.returners.nagios_return

Return salt data to Nagios

The following fields can be set in the minion conf file:

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>nagios.url</td>
<td>(required)</td>
</tr>
<tr>
<td>nagios.token</td>
<td>(required)</td>
</tr>
<tr>
<td>nagios.service</td>
<td>(optional)</td>
</tr>
<tr>
<td>nagios.check_type</td>
<td>(optional)</td>
</tr>
</tbody>
</table>

Alternative configuration values can be used by prefacing the configuration. Any values not found in the alternative configuration will be pulled from the default location:

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>nagios.url</td>
<td></td>
</tr>
<tr>
<td>nagios.token</td>
<td></td>
</tr>
<tr>
<td>nagios.service</td>
<td></td>
</tr>
</tbody>
</table>

Nagios settings may also be configured as:

```yaml
nagios:
  url: http://localhost/nrdp
  token: r4nd0mt0k3n
```
service: service-check

alternative.nagios:
  url: http://localhost/nrdp
  token: r4nd0mt0k3n
  service: another-service-check

To use the Nagios returner, append '--return nagios' to the salt command.

ex:

```bash
code-block:: bash
salt '*' test.ping --return nagios
```

To use the alternative configuration, append '--return_config alternative' to the salt command.

ex:

```bash
code-block:: bash
salt '*' test.ping --return nagios --return_config alternative
```

salt.returners.nagios_return

Send a message to Nagios with the data

salt.returners.odbc

Return data to an ODBC compliant server. This driver was developed with Microsoft SQL Server in mind, but theoretically could be used to return data to any compliant ODBC database as long as there is a working ODBC driver for it on your minion platform.

maintainer

3. (a) Oldham (cr@saltstack.com)

maturity New

depends unixodbc, pyodbc, freetds (for SQL Server)

platform all

To enable this returner the minion will need

On Linux:

unixodbc (http://www.unixodbc.org) pyodbc (pip install pyodbc) The FreeTDS ODBC driver for SQL Server (http://www.freetds.org) or another compatible ODBC driver

On Windows:

TBD

unixODBC and FreeTDS need to be configured via /etc/odbcinst.ini and /etc/odbc.ini.

/etc/odbcinst.ini:

```
[TDSS]
Description=TDS
Driver=/usr/lib/x86_64-linux-gnu/odbc/libtdsodbc.so
```

(Note the above Driver line needs to point to the location of the FreeTDS shared library. This example is for Ubuntu 14.04.)

/etc/odbc.ini:
Description = "Salt Returner"
Driver = TDS
Server = <your server ip or fqdn>
Port = 1433
Database = salt
Trace = No

Also you need the following values configured in the minion or master config. Configure as you see fit:

returner.odbc.dsn: 'TS'
returner.odbc.user: 'salt'
returner.odbc.passwd: 'salt'

Alternative configuration values can be used by prefacing the configuration. Any values not found in the alternative configuration will be pulled from the default location:

alternative.returner.odbc.dsn: 'TS'
alternative.returner.odbc.user: 'salt'
alternative.returner.odbc.passwd: 'salt'

Running the following commands against Microsoft SQL Server in the desired database as the appropriate user should create the database tables correctly. Replace with equivalent SQL for other ODBC-compliant servers:

```sql
--
-- Table structure for table 'jids'
--

IF OBJECT_ID('dbo.jids', 'U') IS NOT NULL
    DROP TABLE dbo.jids

CREATE TABLE dbo.jids (
    jid varchar(255) PRIMARY KEY,
    load varchar(MAX) NOT NULL
);

--
-- Table structure for table 'salt_returns'
--

IF OBJECT_ID('dbo.salt_returns', 'U') IS NOT NULL
    DROP TABLE dbo.salt_returns;

CREATE TABLE dbo.salt_returns (
    added datetime not null default (getdate()),
    fun varchar(100) NOT NULL,
    jid varchar(255) NOT NULL,
    retval varchar(MAX) NOT NULL,
    id varchar(255) NOT NULL,
    success bit default(0) NOT NULL,
    full_ret varchar(MAX)
);)

CREATE INDEX salt_returns_added on dbo.salt_returns(added);
CREATE INDEX salt_returns_id on dbo.salt_returns(id);
CREATE INDEX salt_returns_jid on dbo.salt_returns(jid);
CREATE INDEX salt_returns_fun on dbo.salt_returns(fun);

To use this returner, append '--return odbc' to the salt command.
To use the alternative configuration, append 'return_config alternative' to the salt command.

.. versionadded:: 2015.5.0

salt 'x' status.diskusage --return odbc

To use the alternative configuration, append '--return_config alternative' to the salt command.

.. versionadded:: 2015.5.0

salt 'x' test.ping --return odbc --return_config alternative

salt.returners.odbc.get_fun(fun)
    Return a dict of the last function called for all minions

salt.returners.odbc.get_jid(jid)
    Return the information returned when the specified job id was executed

salt.returners.odbc.get_jids()
    Return a list of all job ids

salt.returners.odbc.get_load(jid)
    Return the load data that marks a specified jid

salt.returners.odbc.get_minions()
    Return a list of minions

salt.returners.odbc.prep_jid(nocache=False, passed_jid=None)
    Do any work necessary to prepare a JID, including sending a custom id

salt.returners.odbc.returner(ret)
    Return data to an odbc server

salt.returners.odbc.save_load(jid, load, minions=None)
    Save the load to the specified jid id

salt.returners.pgjsonb

Return data to a PostgreSQL server with json data stored in Pg's jsonb data type

    maintainer Dave Boucha <dave@saltstack.com>, Seth House <shouse@saltstack.com>, C. R. Oldham <cr@saltstack.com>

    maturity new

    depends python-psycopg2

    platform all

To enable this returner, the minion will need the python client for PostgreSQL installed and the following values configured in the minion or master config. These are the defaults:

    returner.pgjsonb.host: 'salt'
    returner.pgjsonb.user: 'salt'
    returner.pgjsonb.pass: 'salt'
    returner.pgjsonb.db: 'salt'
    returner.pgjsonb.port: 5432
SSL is optional. The defaults are set to None. If you do not want to use SSL, either exclude these options or set them to None.

```
returner.pgjsonb.ssl_ca: None
returner.pgjsonb.ssl_cert: None
returner.pgjsonb.ssl_key: None
```

Alternative configuration values can be used by prefacing the configuration with `alternative`. Any values not found in the alternative configuration will be pulled from the default location. As stated above, SSL configuration is optional. The following ssl options are simply for illustration purposes:

```
alternative.pgjsonb.host: 'salt'
alternative.pgjsonb.user: 'salt'
alternative.pgjsonb.pass: 'salt'
alternative.pgjsonb.db: 'salt'
alternative.pgjsonb.port: 5432
alternative.pgjsonb.ssl_ca: '/etc/pki/mysql/certs/localhost.pem'
alternative.pgjsonb.ssl_cert: '/etc/pki/mysql/certs/localhost.crt'
alternative.pgjsonb.ssl_key: '/etc/pki/mysql/certs/localhost.key'
```

Use the following Pg database schema:

```
CREATE DATABASE salt
    WITH CODING 'utf-8';

-- Table structure for table `jids`
--
DROP TABLE IF EXISTS jids;
CREATE OR REPLACE TABLE jids (
    jid varchar(255) NOT NULL primary key
    load jsonb NOT NULL
);
CREATE INDEX idx_jids_jsonb on jids
    USING gin (load)
    WITH (fastupdate=on);

-- Table structure for table `salt_returns`
--
DROP TABLE IF EXISTS salt_returns;
CREATE TABLE salt_returns (
    fun varchar(50) NOT NULL,
    jid varchar(255) NOT NULL,
    return jsonb NOT NULL,
    id varchar(255) NOT NULL,
    success varchar(10) NOT NULL,
    full_ret jsonb NOT NULL,
    alter_time TIMESTAMP WITH TIME ZONE DEFAULT NOW());

CREATE INDEX idx_salt_returns_id ON salt_returns (id);
CREATE INDEX idx_salt_returns_jid ON salt_returns (jid);
CREATE INDEX idx_salt_returns_fun ON salt_returns (fun);
CREATE INDEX idx_salt_returns_return ON salt_returns
    USING gin (return) with (fastupdate=on);
CREATE INDEX idx_salt_returns_full_ret ON salt_returns
    USING gin (full_ret) with (fastupdate=on);
```
### Table structure for table `salt_events`

```sql
DROP TABLE IF EXISTS salt_events;
DROP SEQUENCE IF EXISTS seq_salt_events_id;
CREATE SEQUENCE seq_salt_events_id;
CREATE TABLE salt_events (  
id BIGINT NOT NULL UNIQUE DEFAULT nextval('seq_salt_events_id'),
tag varchar(255) NOT NULL,
data jsonb NOT NULL,
alter_time TIMESTAMP WITH TIME ZONE DEFAULT NOW(),
master_id varchar(255) NOT NULL);

CREATE INDEX idx_salt_events_tag on salt_events (tag);
CREATE INDEX idx_salt_events_data ON salt_events  
USING gin (data) with (fastupdate=on);
```

**Required python modules:** Psycopg2

To use this returner, append `--return pgjsonb` to the salt command.

```bash
salt '*' test.ping --return pgjsonb
```

To use the alternative configuration, append `--return_config alternative` to the salt command.

New in version 2015.5.0.

```bash
salt '*' test.ping --return pgjsonb --return_config alternative
```

- `salt.returners.pgjsonb.event_return(events)`
  - Return event to Pg server
    - Requires that configuration be enabled via `event_return` option in master config.
- `salt.returners.pgjsonb.get_fun(fun)`
  - Return a dict of the last function called for all minions
- `salt.returners.pgjsonb.get_jid(jid)`
  - Return the information returned when the specified job id was executed
- `salt.returners.pgjsonb.get_jids()`
  - Return a list of all job ids
- `salt.returners.pgjsonb.get_load(jid)`
  - Return the load data that marks a specified jid
- `salt.returners.pgjsonb.get_minions()`
  - Return a list of minions
- `salt.returners.pgjsonb.prep_jid(nocache=False, passed_jid=None)`
  - Do any work necessary to prepare a JID, including sending a custom id
- `salt.returners.pgjsonb.returner(ret)`
  - Return data to a Pg server
- `salt.returners.pgjsonb.save_load(jid, load, minions=None)`
  - Save the load to the specified jid id
salt.returners.postgres

Return data to a postgresql server

maintainer None
maturity New
depends psycopg2
platform all

To enable this returner the minion will need the psycopg2 installed and the following values configured in the minion or master config:

```
returner.postgres.host: 'salt'
returner.postgres.user: 'salt'
returner.postgres.passwd: 'salt'
returner.postgres.db: 'salt'
returner.postgres.port: 5432
```

Alternative configuration values can be used by prefacing the configuration. Any values not found in the alternative configuration will be pulled from the default location:

```
alternative.returner.postgres.host: 'salt'
alternative.returner.postgres.user: 'salt'
alternative.returner.postgres.passwd: 'salt'
alternative.returner.postgres.db: 'salt'
alternative.returner.postgres.port: 5432
```

Running the following commands as the postgres user should create the database correctly:

```
psql << EOF
CREATE ROLE salt WITH PASSWORD 'salt';
CREATE DATABASE salt WITH OWNER salt;
EOF

psql -h localhost -U salt << EOF
--
-- Table structure for table 'jids'
--
DROP TABLE IF EXISTS jids;
CREATE TABLE jids (jid varchar(20) PRIMARY KEY,
                    load text NOT NULL);
--
-- Table structure for table 'salt_returns'
--
DROP TABLE IF EXISTS salt_returns;
CREATE TABLE salt_returns (added TIMESTAMP WITH TIME ZONE DEFAULT now(),
                           fun text NOT NULL,
                           jid varchar(20) NOT NULL,
                           return text NOT NULL,
                           id text NOT NULL,
                           success boolean)
```

Required python modules: psycopg2

To use the postgres returner, append `--return postgres` to the salt command.

```bash
salt '*' test.ping --return postgres
```

To use the alternative configuration, append `--return_config alternative` to the salt command.

New in version 2015.5.0.

```bash
salt '*' test.ping --return postgres --return_config alternative
```

```python
salt.returners.postgres.get_fun(fun)
    Return a dict of the last function called for all minions

salt.returners.postgres.get_jid(jid)
    Return the information returned when the specified job id was executed

salt.returners.postgres.get_jids()
    Return a list of all job ids

salt.returners.postgres.get_load(jid)
    Return the load data that marks a specified jid

salt.returners.postgres.get_minions()
    Return a list of minions

salt.returners.postgres.prep_jid(nocache=False, passed_jid=None)
    Do any work necessary to prepare a JID, including sending a custom id

salt.returners.postgres.returner(ret)
    Return data to a postgres server

salt.returners.postgres.save_load(jid, load, minions=None)
    Save the load to the specified jid id
```

**salt.returners.postgres_local_cache**

Use a postgresql server for the master job cache. This helps the job cache to cope with scale.

- maintainer gjredelinghuys@gmail.com
- maturity New
- depends psycopg2
- platform all

To enable this returner the minion will need the psycopg2 installed and the following values configured in the master config:

```yaml
master_job_cache: postgres_local_cache
master_job_cache.postgres.host: 'salt'
master_job_cache.postgres.user: 'salt'
```
Running the following command as the postgres user should create the database correctly:

```
psql << EOF
CREATE ROLE salt WITH PASSWORD 'salt';
CREATE DATABASE salt WITH OWNER salt;
EOF
```

and then:

```
psql -h localhost -U salt << EOF
-- Table structure for table 'jids'
--
DROP TABLE IF EXISTS jids;
CREATE TABLE jids (
  jid  varchar(20) PRIMARY KEY,
  started  TIMESTAMP WITH TIME ZONE DEFAULT now(),
  tgt_type  text NOT NULL,
  cmd  text NOT NULL,
  tgt  text NOT NULL,
  kwargs  text NOT NULL,
  username  text NOT NULL,
  arg  text NOT NULL,
  fun  text NOT NULL
);
--
-- Table structure for table 'salt_returns'
--
-- note that 'success' must not have NOT NULL constraint, since
-- some functions don't provide it.
--
DROP TABLE IF EXISTS salt_returns;
CREATE TABLE salt_returns (
  added  TIMESTAMP WITH TIME ZONE DEFAULT now(),
  fun  text NOT NULL,
  jid  varchar(20) NOT NULL,
  return  text NOT NULL,
  id  text NOT NULL,
  success  boolean
);
CREATE INDEX ON salt_returns (added);
CREATE INDEX ON salt_returns (id);
CREATE INDEX ON salt_returns (jid);
CREATE INDEX ON salt_returns (fun);
EOF
```

Required python modules: psycopg2

salt.returners.postgres_local_cache.clean_old_jobs()
Clean out the old jobs from the job cache

salt.returners.postgres_local_cache.get_jid(jid)
Return the information returned when the specified job id was executed

```python
salt.returners.postgres_local_cache.get_jids()
```
Return a list of all job ids For master job cache this also formats the output and returns a string

```python
salt.returners.postgres_local_cache.get_load(jid)
```
Return the load data that marks a specified jid

```python
salt.returners.postgres_local_cache.prep_jid(nocache=False, passed_jid=None)
```
Return a job id and prepare the job id directory This is the function responsible for making sure jids don’t collide (unless its passed a jid). So do what you have to do to make sure that stays the case

```python
salt.returners.postgres_local_cache.returner(load)
```
Return data to a postgres server

```python
salt.returners.postgres_local_cache.save_load(jid, clear_load, minions=None)
```
Save the load to the specified jid id

### salt.returners.pushover_returner

Return salt data via pushover (http://www.pushover.net)

New in version Boron.

The following fields can be set in the minion conf file:

- `pushover.user` (required)
- `pushover.token` (required)
- `pushover.title` (optional)
- `pushover.device` (optional)
- `pushover.priority` (optional)
- `pushover.expire` (optional)
- `pushover.retry` (optional)
- `pushover.profile` (optional)

Alternative configuration values can be used by prefacing the configuration. Any values not found in the alternative configuration will be pulled from the default location:

- `alternative.pushover.user`
- `alternative.pushover.token`
- `alternative.pushover.title`
- `alternative.pushover.device`
- `alternative.pushover.priority`
- `alternative.pushover.expire`
- `alternative.pushover.retry`

PushOver settings may also be configured as:

```python
pushover:
    user: xxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx
    token: xxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx
    title: Salt Returner
    device: phone
    priority: -1
    expire: 3600
    retry: 5

alternative.pushover:
    user: xxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx
```
To use the PushOver returner, append `--return pushover` to the salt command. ex:

```bash
salt '*' test.ping --return pushover
```

To use the alternative configuration, append `--return_config alternative` to the salt command. ex:

```bash
salt '*' test.ping --return pushover --return_config alternative
```

salt.returners.pushover_returner

Send an PushOver message with the data

salt.returners.redis_return

Return data to a redis server

To enable this returner the minion will need the python client for redis installed and the following values configured in the minion or master config, these are the defaults:

```
redis.db: '0'
redis.host: 'salt'
redis.port: 6379
```

Alternative configuration values can be used by prefacing the configuration. Any values not found in the alternative configuration will be pulled from the default location:

```
alternative.redis.db: '0'
alternative.redis.host: 'salt'
alternative.redis.port: 6379
```

To use the redis returner, append `--return redis` to the salt command.

```bash
salt '*' test.ping --return redis
```

To use the alternative configuration, append `--return_config alternative` to the salt command.

New in version 2015.5.0.
Salth Documentation, Release 2015.8.12

salt '*' test.ping --return redis --return_config alternative

salt returns redis return.get_fun(fun)
Return a dict of the last function called for all minions

salt returns redis return.get_jid(jid)
Return the information returned when the specified job id was executed

salt returns redis return.get_jids()
Return a list of all job ids

salt returns redis return.get_load(jid)
Return the load data that marks a specified jid

salt returns redis return.get_minions()
Return a list of minions

salt returns redis return.prep_jid(nocache=False, passed_jid=None)
Do any work necessary to prepare a JID, including sending a custom id

salt returns redis return.returner(ret)
Return data to a redis data store

salt returns redis return.save_load(jid, load, minions=None)
Save the load to the specified jid

salt returns sentry return

Salt returner that report execution results back to sentry. The returner will inspect the payload to identify errors and flag them as such.

Pillar needs something like:

raven:
    servers:
        - http://192.168.1.1
        - https://sentry.example.com
    public_key: deadbeefdeadbeefdeadbeefdeadbeef
nen_key: beefdeadbeefdeadbeefdeadbeefdeadbeef
tags:
    - os
    - master
    - saltversion
    - cpuarch

and https://pypi.python.org/pypi/raven installed

The tags list (optional) specifies grains items that will be used as sentry tags, allowing tagging of events in the sentry ui.

salt returns sentry return.prep_jid(nocache=False, passed_jid=None)
Do any work necessary to prepare a JID, including sending a custom id

salt returns sentry return.returner(ret)
Log outcome to sentry. The returner tries to identify errors and report them as such. All other messages will be reported at info level.

32.25. Returns
**salt.returners.slack_returner**

Return salt data via slack

New in version 2015.5.0.

The following fields can be set in the minion conf file:

```
slack.channel (required)
slack.api_key (required)
slack.username (required)
slack.as_user (required to see the profile picture of your bot)
slack.profile (optional)
```

Alternative configuration values can be used by prefacing the configuration. Any values not found in the alternative configuration will be pulled from the default location:

```
slack.channel
slack.api_key
slack.username
slack.as_user
```

Slack settings may also be configured as:

```
slack:
  channel: RoomName
  api_key: xxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx
  username: user
  as_user: true

alternative.slack:
  room_id: RoomName
  api_key: xxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx
  from_name: user@email.com

slack_profile:
  api_key: xxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx
  from_name: user@email.com

slack:
  profile: slack_profile
  channel: RoomName

alternative.slack:
  profile: slack_profile
  channel: RoomName
```

To use the Slack returner, append `--return slack` to the salt command.

```
salt '*' test.ping --return slack
```

To use the alternative configuration, append `--return_config alternative` to the salt command.

```
salt '*' test.ping --return slack --return_config alternative
```

`salt.returners.slack_returner.returner(ret)`

Send an slack message with the data
salt.returners.sms_return

Return data by SMS.

New in version 2015.5.0.

maintainer  Damian Myerscough  
maturity  new  
depends  twilio  
platform  all  

To enable this returner the minion will need the python twilio library installed and the following values configured in the minion or master config:

<table>
<thead>
<tr>
<th>Variable</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>twilio.sid</td>
<td>'XXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXX'</td>
</tr>
<tr>
<td>twilio.token</td>
<td>'XXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXX'</td>
</tr>
<tr>
<td>twilio.to</td>
<td>'+1415XXXXXXXXX'</td>
</tr>
<tr>
<td>twilio.from</td>
<td>'+1650XXXXXXXXX'</td>
</tr>
</tbody>
</table>

To use the sms returner, append `--return sms` to the salt command.

```
salt '*' test.ping --return sms
```

salt.returners.sms_return.returner(ret)

Return a response in an SMS message

salt.returners.smtp_return

Return salt data via email

The following fields can be set in the minion conf file. Fields are optional unless noted otherwise.

- **from** (required) The name/address of the email sender.
- **to** (required) The name/address of the email recipient.
- **host** (required) The SMTP server hostname or address.
- **port** The SMTP server port; defaults to 25.
- **username** The username used to authenticate to the server. If specified a password is also required. It is recommended but not required to also use TLS with this option.
- **password** The password used to authenticate to the server.
- **tls** Whether to secure the connection using TLS; defaults to False
- **subject** The email subject line.
- **fields** Which fields from the returned data to include in the subject line of the email; comma-delimited. For example: `id, fun`. Please note, the subject line is not encrypted.
- **gpgowner** A user's `~/.gpg` directory. This must contain a gpg public key matching the address the mail is sent to. If left unset, no encryption will be used. Requires `python-gnupg` to be installed.
- **template** The path to a file to be used as a template for the email body.
- **renderer** A Salt renderer, or render-pipe, to use to render the email template. Default `jinja`.

Below is an example of the above settings in a Salt Minion configuration file:
smtp.from: me@example.net
smtp.to: you@example.com
smtp.host: localhost
smtp.port: 1025

Alternative configuration values can be used by prefacing the configuration. Any values not found in the alternative configuration will be pulled from the default location. For example:

```python
alternative.smtp.username: saltdev
alternative.smtp.password: saltdev
alternative.smtp.tls: True
```

To use the SMTP returner, append `--return smtp` to the salt command.

```bash
salt '*' test.ping --return smtp
```

To use the alternative configuration, append `--return_config alternative` to the salt command.

New in version 2015.5.0.

```bash
salt '*' test.ping --return smtp --return_config alternative
```

An easy way to test the SMTP returner is to use the development SMTP server built into Python. The command below will start a single-threaded SMTP server that prints any email it receives to the console.

```bash
python -m smtpd -n -c DebuggingServer localhost:1025
```

**salt.returners.smtp_return**

- **prep_jid**(nocache=False, passed_jid=None)
  - Do any work necessary to prepare a JID, including sending a custom id
- **returner**(ret)
  - Send an email with the data

**salt.returners.sqlite3**

Insert minion return data into a sqlite3 database

- **maintainer** Mickey Malone <mickey.malone@gmail.com>
- **maturity** New
- **depends** None
- **platform** All

SQLite is a serverless database that lives in a single file. In order to use this returner the database file must exist, have the appropriate schema defined, and be accessible to the user whom the minion process is running as. This returner requires the following values configured in the master or minion config:

```python
returner.sqlite3.database: /usr/lib/salt/salt.db
returner.sqlite3.timeout: 5.0
```

Alternative configuration values can be used by prefacing the configuration. Any values not found in the alternative configuration will be pulled from the default location:

```python
alternative.returner.sqlite3.database: /usr/lib/salt/salt.db
alternative.returner.sqlite3.timeout: 5.0
```
Use the commands to create the sqlite3 database and tables:

```sql
sqlite3 /usr/lib/salt/salt.db << EOF
--
-- Table structure for table 'jids'
--

CREATE TABLE jids (  
jid TEXT PRIMARY KEY,  
load TEXT NOT NULL  
);

--
-- Table structure for table 'salt_returns'
--

CREATE TABLE salt_returns (  
fun TEXT KEY,  
jid TEXT KEY,  
id TEXT KEY,  
fun_args TEXT,  
date TEXT NOT NULL,  
full_ret TEXT NOT NULL,  
success TEXT NOT NULL  
);
EOF
```

To use the sqlite returner, append `--return sqlite3' to the salt command.

```
salt '*' test.ping --return sqlite3
```

To use the alternative configuration, append `--return_config alternative' to the salt command.

New in version 2015.5.0.

```
salt '*' test.ping --return sqlite3 --return_config alternative
```

salt.returners.sqlite3_return.get_fun(fun)

Return a dict of the last function called for all minions

salt.returners.sqlite3_return.get_jid(jid)

Return the information returned from a specified jid

salt.returners.sqlite3_return.get_jids()

Return a list of all job ids

salt.returners.sqlite3_return.get_load(jid)

Return the load from a specified jid

salt.returners.sqlite3_return.get_minions()

Return a list of minions

salt.returners.sqlite3_return.prep_jid(nocache=False, passed_jid=None)

Do any work necessary to prepare a JID, including sending a custom id

salt.returners.sqlite3_return.returner(ret)

Insert minion return data into the sqlite3 database

salt.returners.sqlite3_return.save_load(jid, load, minions=None)

Save the load to the specified jid
salt.returners.syslog_return

Return data to the host operating system's syslog facility

Required python modules: syslog, json

The syslog returner simply reuses the operating system's syslog facility to log return data

To use the syslog returner, append `--return syslog` to the salt command.

```
salt '*' test.ping --return syslog
```

Note: Syslog server implementations may have limits on the maximum record size received by the client. This may lead to job return data being truncated in the syslog server's logs. For example, for rsyslog on RHEL-based systems, the default maximum record size is approximately 2KB (which return data can easily exceed). This is configurable in rsyslog.conf via the $MaxMessageSize config parameter. Please consult your syslog implementation's documentation to determine how to adjust this limit.

salt.returners.syslog_return.prep_jid(nocache=False, passed_jid=None)

Do any work necessary to prepare a JID, including sending a custom id

salt.returners.syslog_return.returner(ret)

Return data to the local syslog

salt.returners.xmpp_return

Return salt data via xmpp

The following fields can be set in the minion conf file:

```
xmpp.jid (required)
xmpp.password (required)
xmpp.recipient (required)
xmpp.profile (optional)
```

Alternative configuration values can be used by prefacing the configuration. Any values not found in the alternative configuration will be pulled from the default location:

```
xmpp.jid
xmpp.password
xmpp.recipient
xmpp.profile
```

XMPP settings may also be configured as:

```
xmpp:
    jid: user@xmpp.domain.com/resource
    password: password
    recipient: user@xmpp.example.com

alternative.xmpp:
    jid: user@xmpp.domain.com/resource
    password: password
    recipient: someone@xmpp.example.com

xmpp_profile:
```
To use the XMPP returner, append `--return xmpp' to the salt command.

```bash
salt '*' test.ping --return xmpp
```

To use the alternative configuration, append `--return_config alternative' to the salt command.

New in version 2015.5.0.

```bash
salt '*' test.ping --return xmpp --return_config alternative
```

class `salt.returners.xmpp_return.SendMsgBot(jid, password, recipient, msg)`

```python
start(event)
```

```python
salt.returners.xmpp_return.returner(ret)
```

Send an xmpp message with the data

### 32.26 Full list of builtin roster modules

<table>
<thead>
<tr>
<th>Module</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ansible</td>
<td>Read in an Ansible inventory file or script</td>
</tr>
<tr>
<td>cache</td>
<td>Use the minion cache on the master to derive IP addresses based on minion ID.</td>
</tr>
<tr>
<td>cloud</td>
<td>Use the cloud cache on the master to derive IPv4 addresses based on minion ID.</td>
</tr>
<tr>
<td>clustershell</td>
<td>This roster resolves hostname in a pdsh/clustershell style.</td>
</tr>
<tr>
<td>flat</td>
<td>Read in the roster from a flat file using the renderer system</td>
</tr>
<tr>
<td>scan</td>
<td>Scan a netmask or ipaddr for open ssh ports</td>
</tr>
</tbody>
</table>

#### 32.26.1 salt.roster.ansible

Read in an Ansible inventory file or script

Flat inventory files should be in the regular ansible inventory format.

```ini
[servers]
salt.gtmanfred.com ansible_ssh_user=gtmanfred ansible_ssh_host=127.0.0.1 ansible_ssh_port=22 ansible_ssh_pass='password'

[desktop]
home ansible_ssh_user=gtmanfred ansible_ssh_host=12.34.56.78 ansible_ssh_port=23 ansible_ssh_pass='password'
```
then salt-ssh can be used to hit any of them

```
[~]# salt-ssh all test.ping
salt.gtmanfred.com:
   True
home:
   True
[~]# salt-ssh desktop test.ping
home:
   True
[~]# salt-ssh computers test.ping
salt.gtmanfred.com:
   True
home:
   True
[~]# salt-ssh salt.gtmanfred.com test.ping
salt.gtmanfred.com:
   True
```

There is also the option of specifying a dynamic inventory, and generating it on the fly

```
#!/bin/bash
echo '{
   "servers": {
      "hosts": [
      "salt.gtmanfred.com"
   ],
   "desktop": {
      "hosts": [
      "home"
   ],
   "computers": {
      "hosts":{},
      "children": [
      "desktop",
      "servers"
   ],
   "_meta": {
      "hostvars": {
      "salt.gtmanfred.com": {
         "ansible_ssh_user": "gtmanfred",
         "ansible_ssh_host": "127.0.0.1",
         "ansible_sudo_pass": "password",
         "ansible_ssh_port": 22
      },
      "home": {
         "ansible_ssh_user": "gtmanfred",
         "ansible_ssh_host": "12.34.56.78",
```
"ansible_sudo_pass": "password",
"ansible_ssh_port": 23
}
]
}
}

This is the format that an inventory script needs to output to work with ansible, and thus here.

```
[~]# salt-ssh --roster-file /etc/salt/hosts salt.gtmanfred.com test.ping
salt.gtmanfred.com: True
```

Any of the [groups] or direct hostnames will return. The `all' is special, and returns everything.

class salt.roster.ansible.Inventory(tgt, tgt_type='glob', inventory_file='/etc/salt/roster')
    Matcher for static inventory files

class salt.roster.ansible.Script(tgt, tgt_type='glob', inventory_file='/etc/salt/roster')
    Matcher for Inventory scripts

class salt.roster.ansible.Target

    get_glob()
    Return minions that match via glob

    targets()
    Execute the correct tgt_type routine and return

salt.roster.ansible.targets(tgt, tgt_type='glob', **kwargs)
    Return the targets from the ansible inventory_file Default: /etc/salt/roster

### 32.26.2 salt.roster.cache

Use the minion cache on the master to derive IP addresses based on minion ID.

Currently only contains logic to return an IPv4 address; does not handle IPv6, or authentication (passwords, keys, etc).

It is possible to configure this roster to prefer a particular type of IP over another. To configure the order, set the roster_order in the master config file. The default for this is:

```
roster_order:
  - public
  - private
  - local
```

salt.roster.cache.extract_ipv4(roster_order, ipv4)
    Extract the preferred IP address from the ipv4 grain

salt.roster.cache.targets(tgt, tgt_type='glob', **kwargs)
    Return the targets from the flat yaml file, checks opts for location but defaults to /etc/salt/roster

### 32.26.3 salt.roster.cloud

Use the cloud cache on the master to derive IPv4 addresses based on minion ID.
This roster requires that the minion in question was created using at least the 2015.5.0 version of Salt Cloud. Starting with the 2015.5.0 release, Salt Cloud maintains an index of minions that it creates and deletes. This index tracks the provider and profile configuration used to provision the minion, including authentication information. So long as this configuration remains current, it can be used by Salt SSH to log into any minion in the index.

To connect as a user other than root, modify the cloud configuration file usually located at /etc/salt/cloud. For example, add the following:

```yaml
ssh_username: my_user
sudo: True
```

```
salt.roster.cloud.extract_ipv4(roster_order, ipv4)
    Extract the preferred IP address from the ipv4 grain
salt.roster.cloud.targets(tgt, tgt_type='glob', **kwargs)
    Return the targets from the flat yaml file, checks opts for location but defaults to /etc/salt/roster
```

### 32.26.4 `salt.roster.clustershell`

This roster resolves hostname in a pdsh/clustershell style.

```
depends clustershell, https://github.com/cea-hpc/clustershell
```

When you want to use host globs for target matching, use `--roster clustershell`. For example:

```
salt-ssh --roster clustershell 'server_[1-10,21-30],test_server[5,7,9]' test.ping
```

```
salt.roster.clustershell.targets(tgt, tgt_type='glob', **kwargs)
    Return the targets
```

### 32.26.5 `salt.roster.flat`

Read in the roster from a flat file using the renderer system.

```
class salt.roster.flat.RosterMatcher (raw, tgt, tgt_type, ipv='ipv4')
    Matcher for the roster data structure
    get_data(minion)
        Return the configured ip
    ret_glob_minions()
        Return minions that match via glob
    ret_list_minions()
        Return minions that match via list
    ret_nodegroup_minions()
        Return minions which match the special list-only groups defined by ssh_list_nodegroups
    ret_pcre_minions()
        Return minions that match via pcre
    ret_range_minions()
        Return minions that are returned by a range query
    targets()
        Execute the correct tgt_type routine and return
```

salt.roster.flat.targets(tgt, tgt_type='glob', **kwargs)
    Return the targets from the flat yaml file, checks opts for location but defaults to /etc/salt/roster

32.26.6 salt.roster.scan

Scan a netmask or ipaddr for open ssh ports
class salt.roster.scan.RosterMatcher(tgt, tgt_type)
    Matcher for the roster data structure
    targets()
        Return ip addr based on netmask, sitting in the `glob` spot because it is the default
salt.roster.scan.targets(tgt, tgt_type='glob', **kwargs)
    Return the targets from the flat yaml file, checks opts for location but defaults to /etc/salt/roster

32.27 Salt Runners

Salt runners are convenience applications executed with the salt-run command.
Salt runners work similarly to Salt execution modules however they execute on the Salt master itself instead of remote Salt minions.
A Salt runner can be a simple client call or a complex application.

</tbody>
</table>

**salt.runners.cache**

Return cached data from minions

```python
salt.runners.cache.clear_all(tgt=None, expr_form='glob')
```

Clear the cached pillar, grains, and mine data of the targeted minions

CLI Example:

```
salt-run cache.clear_all
```

```python
salt.runners.cache.clear_git_lock(role, remote=None, **kwargs)
```

New in version 2015.8.2.

Remove the update locks for Salt components (gitfs, git_pillar, winrepo) which use gitfs backend code from salt.utils.gitfs.

**Note:** Running `cache.clear_all` will not include this function as it does for pillar, grains, and mine. Additionally, executing this function with a `role` of `gitfs` is equivalent to running `salt-run file-server.clear_lock backend=git`.

**role** Which type of lock to remove (gitfs, git_pillar, or winrepo)

**remote** If specified, then any remotes which contain the passed string will have their lock cleared. For example, a remote value of `github` will remove the lock from all github.com remotes.

**type** [update,checkout] The types of lock to clear. Can be update, checkout, or both of

CLI Example:
salt-run cache.clear_git_lock git_pillar

```python
salt.runners.cache.clear_grains(tgt=None, expr_form='glob')
Clear the cached grains data of the targeted minions
CLI Example:
salt-run cache.clear_grains
```

```python
salt.runners.cache.clear_mine(tgt=None, expr_form='glob')
Clear the cached mine data of the targeted minions
CLI Example:
salt-run cache.clear_mine
```

```python
salt.runners.cache.clear_mine_func(tgt=None, expr_form='glob', clear_mine_func_flag=None)
Clear the cached mine function data of the targeted minions
CLI Example:
salt-run cache.clear_mine_func tgt='*' clear_mine_func_flag='network.interfaces'
```

```python
salt.runners.cache.clear_pillar(tgt=None, expr_form='glob')
Clear the cached pillar data of the targeted minions
CLI Example:
salt-run cache.clear_pillar
```

```python
salt.runners.cache.grains(tgt=None, expr_form='glob', outputter=None, **kwargs)
Return cached grains of the targeted minions
CLI Example:
salt-run cache.grains
```

```python
salt.runners.cache.mine(tgt=None, expr_form='glob', outputter=None, **kwargs)
Return cached mine data of the targeted minions
CLI Example:
salt-run cache.mine
```

```python
salt.runners.cache.pillar(tgt=None, expr_form='glob', outputter=None, **kwargs)
Return cached pillars of the targeted minions
CLI Example:
salt-run cache.pillar
```

salt.runners.cloud

**The Salt Cloud Runner**

This runner wraps the functionality of salt cloud making salt cloud routines available to all internal apis via the runner system
salt.runners.cloud.action(func=None, cloudmap=None, instances=None, provider=None, instance=None, **kwargs)

Execute a single action on the given map/provider-instance

CLI Example:
```
salt-run cloud.actions start my-salt-vm
```

salt.runners.cloud.create(provider, instances, **kwargs)

Create an instance using Salt Cloud

CLI Example:
```
salt-run cloud.create my-ec2-config myinstance
```

<table>
<thead>
<tr>
<th>provider</th>
<th>instances</th>
<th>image=ami-1624987f</th>
<th>size=t1.micro</th>
<th>ssh_username=ec2-user</th>
<th>securitygroup=default</th>
<th>delvol_on_destroy=True</th>
</tr>
</thead>
</table>

salt.runners.cloud.destroy(instances)

Destroy the named vm(s)

salt.runners.cloud.full_query(query_type='list_nodes_full')

List all available cloud provider data

salt.runners.cloud.list_images(provider='all')

List cloud provider images for the given providers

salt.runners.cloud.list_locations(provider='all')

List cloud provider sizes for the given providers

salt.runners.cloud.list_sizes(provider='all')

List cloud provider sizes for the given providers

salt.runners.cloud.map_run(path, **kwargs)

Execute a salt cloud map file

salt.runners.cloud.profile(prof=None, instances=None, **kwargs)

Create a cloud vm with the given profile and instances, instances can be a list or comma-delimited string

CLI Example:
```
salt-run cloud.profile prof=my-ec2 instances=node1,node2,node3
```

salt.runners.cloud.query(query_type='list_nodes')

List cloud provider data for all providers

salt.runners.cloud.select_query(query_type='list_nodes_select')

List selected nodes

salt.runners.doc

A runner module to collect and display the inline documentation from the various module types

salt.runners.doc.execution()

Collect all the sys.doc output from each minion and return the aggregate

CLI Example:
```
salt-run doc.execution
```
salt.runners.doc.runner()
    Return all inline documentation for runner modules
    CLI Example:
    ```
salt-run doc.runner
    ```

salt.runners.doc.wheel()
    Return all inline documentation for wheel modules
    CLI Example:
    ```
salt-run doc.wheel
    ```

salt.runners.drac

Manage Dell DRAC from the Master

The login credentials need to be configured in the Salt master configuration file.

salt.runners.drac.poweroff(hostname, timeout=20)
    Power server off
    CLI Example:
    ```
salt-run drac.poweroff example.com
    ```

salt.runners.drac.poweron(hostname, timeout=20)
    Power server on
    CLI Example:
    ```
salt-run drac.poweron example.com
    ```

salt.runners.drac.pxe(hostname, timeout=20)
    Connect to the Dell DRAC and have the boot order set to PXE and power cycle the system to PXE boot
    CLI Example:
    ```
salt-run drac.pxe example.com
    ```

salt.runners.drac.reboot(hostname, timeout=20)
    Reboot a server using the Dell DRAC
    CLI Example:
    ```
salt-run drac.reboot example.com
    ```

salt.runners.drac.version(hostname, timeout=20)
    Display the version of DRAC
    CLI Example:
    ```
salt-run drac.version example.com
    ```
salt.runners.error

Error generator to enable integration testing of salt runner error handling

```
salt.runners.error.error(name=None, message='')
```
If name is None Then return empty dict
Otherwise raise an exception with __name__ from name, message from message

CLI Example:

```
salt-run error
salt-run error.error name="Exception" message="This is an error."
```

salt.runners.f5

Runner to provide F5 Load Balancer functionality

**depends**

- pycontrol Python module

**configuration** In order to connect to a F5 Load Balancer, you must specify in the Salt master configuration the currently available load balancers

```
load_balancers:
  bigip1.example.com
    username: admin
    password: secret
  bigip2.example.com:
    username: admin
    password: secret
```

class salt.runners.f5.F5Mgmt(lb, username, password)

```
add_pool_member(name, port, pool_name)
    Add a node to a pool

check_member_pool(member, pool_name)
    Check a pool member exists in a specific pool

check_pool(name)
    Check to see if a pool exists

check_virtualserver(name)
    Check to see if a virtual server exists

create_pool(name, method='ROUND_ROBIN')
    Create a pool on the F5 load balancer

create_vs(name, ip, port, protocol, profile, pool_name)
    Create a virtual server

lbmethods()
    List all the load balancer methods
```

salt.runners.f5.add_pool_member(lb, name, port, pool_name)
Add a node to a pool

CLI Examples:
```bash
salt-run f5.add_pool_member load_balancer 10.0.0.1 80 my_pool
```

salt.runners.f5.check_member_pool(lb, member, pool_name)
Check a pool member exists in a specific pool

CLI Examples:
```
salt-run f5.check_member_pool load_balancer 10.0.0.1 my_pool
```

salt.runners.f5.check_pool(lb, name)
Check to see if a pool exists

CLI Examples:
```
salt-run f5.check_pool load_balancer pool_name
```

salt.runners.f5.check_virtualserver(lb, name)
Check to see if a virtual server exists

CLI Examples:
```
salt-run f5.check_virtualserver load_balancer virtual_server
```

salt.runners.f5.create_pool(lb, name, method='ROUND_ROBIN')
Create a pool on the F5 load balancer

CLI Examples:
```
salt-run f5.create_pool load_balancer pool_name loadbalance_method
salt-run f5.create_pool load_balancer my_pool ROUND_ROBIN
```

salt.runners.f5.create_vs(lb, name, ip, port, protocol, profile, pool_name)
Create a virtual server

CLI Examples:
```
salt-run f5.create_vs lbalancer vs_name 10.0.0.1 80 tcp http poolname
```

salt.runners.fileserver

Directly manage the Salt fileserver plugins

salt.runners.fileserver.clear_cache(backend=None)
New in version 2015.5.0.

Clear the fileserver cache from VCS fileserver backends (git, hg, svn). Executing this runner with no arguments will clear the cache for all enabled VCS fileserver backends, but this can be narrowed using the backend argument.

**backend** Only clear the update lock for the specified backend(s). If all passed backends start with a minus sign (-), then these backends will be excluded from the enabled backends. However, if there is a mix of backends with and without a minus sign (ex: backend=-roots,git) then the ones starting with a minus sign will be disregarded.

CLI Example:
salt-run fileserver.clear_cache
salt-run fileserver.clear_cache backend=git,hg
salt-run fileserver.clear_cache hg
salt-run fileserver.clear_cache -roots

salt.runners.fileserver.clear_lock(backend=None, remote=None)
New in version 2015.5.0.

Clear the fileserver update lock from VCS fileserver backends (git, hg, svn). This should only need to be done if a fileserver update was interrupted and a remote is not updating (generating a warning in the Master's log file). Executing this runner with no arguments will remove all update locks from all enabled VCS fileserver backends, but this can be narrowed by using the following arguments:

backend Only clear the update lock for the specified backend(s).

remote If specified, then any remotes which contain the passed string will have their lock cleared. For example, a remote value of github will remove the lock from all github.com remotes.

CLI Example:
salt-run fileserver.clear_lock
salt-run fileserver.clear_lock backend=git,hg
salt-run fileserver.clear_lock backend=git remote=github
salt-run fileserver.clear_lock remote=bitbucket

salt.runners.fileserver.dir_list(saltenv='base', backend=None, outputter=None)
Return a list of directories in the given environment

saltenv [base] The salt fileserver environment to be listed

backend Narrow fileserver backends to a subset of the enabled ones. If all passed backends start with a minus sign (−), then these backends will be excluded from the enabled backends. However, if there is a mix of backends with and without a minus sign (ex: backend=-roots,git) then the ones starting with a minus sign will be disregarded.

New in version 2015.5.0.

CLI Example:
salt-run fileserver.dir_list
class-run fileserver.dir_list saltenv=prod
class-run fileserver.dir_list saltenv=dev backend=git
class-run fileserver.dir_list base hg,roots
class-run fileserver.dir_list -git

salt.runners.fileserver.empty_dir_list(saltenv='base', backend=None, outputter=None)
New in version 2015.5.0.

Return a list of empty directories in the given environment

saltenv [base] The salt fileserver environment to be listed

backend Narrow fileserver backends to a subset of the enabled ones. If all passed backends start with a minus sign (−), then these backends will be excluded from the enabled backends. However, if there is a mix of backends with and without a minus sign (ex: backend=-roots,git) then the ones starting with a minus sign will be disregarded.

Note: Some backends (such as git and hg) do not support empty directories. So, passing backend=git or backend=hg will result in an empty list being returned.
CLI Example:

```bash
salt-run fileserver.empty_dir_list
salt-run fileserver.empty_dir_list saltenv=prod
salt-run fileserver.empty_dir_list backend=roots
```

**salt.runners.fileserver.envs** (backend=None, sources=False, outputter=None)

Return the available fileserver environments. If no backend is provided, then the environments for all configured backends will be returned.

**backend** Narrow fileserver backends to a subset of the enabled ones.

Changed in version 2015.5.0: If all passed backends start with a minus sign (-), then these backends will be excluded from the enabled backends. However, if there is a mix of backends with and without a minus sign (ex: `backend=-roots,git`) then the ones starting with a minus sign will be disregarded.

Additionally, fileserver backends can now be passed as a comma-separated list. In earlier versions, they needed to be passed as a python list (ex: `backend="['roots','git']"`)

CLI Example:

```bash
salt-run fileserver.envs
salt-run fileserver.envs backend=roots,git
salt-run fileserver.envs git
```

**salt.runners.fileserver.file_list** (saltenv='base', backend=None, outputter=None)

Return a list of files from the salt fileserver

**saltenv** [base] The salt fileserver environment to be listed

**backend** Narrow fileserver backends to a subset of the enabled ones. If all passed backends start with a minus sign (-), then these backends will be excluded from the enabled backends. However, if there is a mix of backends with and without a minus sign (ex: `backend=-roots,git`) then the ones starting with a minus sign will be disregarded.

New in version 2015.5.0.

CLI Examples:

```bash
salt-run fileserver.file_list
salt-run fileserver.file_list saltenv=prod
salt-run fileserver.file_list saltenv=dev backend=git
salt-run fileserver.file_list base hg,roots
salt-run fileserver.file_list -git
```

**salt.runners.fileserver.lock** (backend=None, remote=None)

New in version 2015.5.0.

Set a fileserver update lock for VCS fileserver backends (`git`, `hg`, `svn`).

**Note:** This will only operate on enabled backends (those configured in `fileserver_backend`).

**backend** Only set the update lock for the specified backend(s).

**remote** If not None, then any remotes which contain the passed string will have their lock cleared. For example, a `remote` value of `*github.com*` will remove the lock from all github.com remotes.

CLI Example:
### salt.runners.fileserver.symlink_list

*salt.runners.fileserver.symlink_list*(**saltenv**='base', **backend**=None, **outputter**=None)

Return a list of symlinked files and dirs

**saltenv** [base] The salt fileserver environment to be listed

**backend** Narrow fileserver backends to a subset of the enabled ones. If all passed backends start with a minus sign (-), then these backends will be excluded from the enabled backends. However, if there is a mix of backends with and without a minus sign (ex: backend=-roots,git) then the ones starting with a minus sign will be disregarded.

New in version 2015.5.0.

**CLI Example:**

```
salt-run fileserver.symlink_list
salt-run fileserver.symlink_list saltenv=prod
salt-run fileserver.symlink_list saltenv=dev backend=git
salt-run fileserver.symlink_list base hg,roots
salt-run fileserver.symlink_list -git
```

### salt.runners.fileserver.update

*salt.runners.fileserver.update*(**backend**=None)

Update the fileserver cache. If no backend is provided, then the cache for all configured backends will be updated.

**backend** Narrow fileserver backends to a subset of the enabled ones.

Changed in version 2015.5.0: If all passed backends start with a minus sign (-), then these backends will be excluded from the enabled backends. However, if there is a mix of backends with and without a minus sign (ex: backend=-roots,git) then the ones starting with a minus sign will be disregarded.

Additionally, fileserver backends can now be passed as a comma-separated list. In earlier versions, they needed to be passed as a python list (ex: backend="[roots', 'git']")

**CLI Example:**

```
salt-run fileserver.update
salt-run fileserver.update backend=roots,git
```

### salt.runners.git_pillar

Runner module to directly manage the git external pillar

*salt.runners.git_pillar.update*(**branch**=None, **repo**=None)

New in version 2014.1.0.

Changed in version 2015.8.4: This runner function now supports the new git_pillar configuration schema introduced in 2015.8.0. Additionally, the branch and repo can now be omitted to update all git_pillar remotes. The return data has also changed. For releases 2015.8.3 and earlier, there is no value returned. Starting with 2015.8.4, the return data is a dictionary. If using the old git_pillar configuration schema, then the dictionary values will be True if the update completed without error, and False if an error occurred. If using the new git_pillar configuration schema, the values will be True only if new commits were fetched, and False if there were errors or no new commits were fetched.

Update one or all configured git_pillar remotes.
CLI Example:

```
# Update specific branch and repo
salt-run git_pillar.update branch='branch' repo='https://foo.com/bar.git'
# Update all repos (2015.8.4 and later)
salt-run git_pillar.update
# Run with debug logging
salt-run git_pillar.update -l debug
```

**salt.runners.http**

Module for making various web calls. Primarily designed for webhooks and the like, but also useful for basic http testing.

New in version 2015.5.0.

**salt.runners.http.query(url, output=True, **kwargs)**

Query a resource, and decode the return data

New in version 2015.5.0.

CLI Example:

```
salt-run http.query http://somelink.com/
salt-run http.query http://somelink.com/ method=POST
   -key1=val1&
   -key2=val2'
salt-run http.query http://somelink.com/ method=POST
   data='<xml>
   <somecontent></xml>'
```

**salt.runners.http.update_ca_bundle(target=None, source=None, merge_files=None)**

Update the local CA bundle file from a URL

New in version 2015.5.0.

CLI Example:

```
salt-run http.update_ca_bundle
salt-run http.update_ca_bundle target=/path/to/cacerts.pem
salt-run http.update_ca_bundle source=https://example.com/cacerts.pem
```

If the `target` is not specified, it will be pulled from the `ca_cert` configuration variable available to the master. If it cannot be found there, it will be placed at `<FILE_ROOTS>/cacerts.pem`.

If the `source` is not specified, it will be pulled from the `ca_cert_url` configuration variable available to the master. If it cannot be found, it will be downloaded from the cURL website, using an http (not https) URL. USING THE DEFAULT URL SHOULD BE AVOIDED!

`merge_files` may also be specified, which includes a string or list of strings representing a file or files to be appended to the end of the CA bundle, once it is downloaded.

CLI Example:

```
salt-run http.update_ca_bundle merge_files=/path/to/mycert.pem
```

**salt.runners.jobs**

A convenience system to manage jobs, both active and already run
salt.runners.jobs.active(outputter=None, display_progress=False)

Return a report on all actively running jobs from a job id centric perspective

CLI Example:

```
salt-run jobs.active
```

salt.runners.jobs.exit_success(jid, ext_source=None)

Check if a job has been executed and exit successfully

jid The jid to look up.

ext_source The external job cache to use. Default: None.

CLI Example: .. code-block:: bash

```
salt-run jobs.exit_success 20160520145827701627
```

salt.runners.jobs.last_run(ext_source=None, outputter=None, metadata=None, function=None, target=None, display_progress=False)

New in version 2015.8.0.

List all detectable jobs and associated functions

CLI Example:

```
salt-run jobs.last_run
salt-run jobs.last_run target=nodename
salt-run jobs.last_run function='cmd.run'
salt-run jobs.last_run metadata="{'foo': 'bar'}"
```

salt.runners.jobs.list_job(jid, ext_source=None, outputter=None, display_progress=False)

List a specific job given by its jid

ext_source If provided, specifies which external job cache to use.

display_progress [False] If True, fire progress events.

CLI Example:

```
salt-run jobs.list_job 20130916125524463507
salt-run jobs.list_job 20130916125524463507 --out=pprint
```

salt.runners.jobs.list_jobs(ext_source=None, outputter=None, search_metadata=None, search_function=None, search_target=None, start_time=None, end_time=None, display_progress=False)

List all detectable jobs and associated functions

ext_source If provided, specifies which external job cache to use.

FILTER OPTIONS

Note: If more than one of the below options are used, only jobs which match all of the filters will be returned.

search_metadata Specify a dictionary to match to the job's metadata. If any of the key-value pairs in this dictionary match, the job will be returned. Example:

```
salt-run jobs.list_jobs search_metadata='{"foo": "bar", "baz": "qux"}''
```
**search_function** Can be passed as a string or a list. Returns jobs which match the specified function. Globbing is allowed. Example:

```
salt-run jobs.list_jobs search_function='test.*'
salt-run jobs.list_jobs search_function='["test.*", "pkg.install"]'
```

Changed in version 2015.8.8: Multiple targets can now also be passed as a comma-separated list. For example:

```
salt-run jobs.list_jobs search_function='test.*,pkg.install'
```

**search_target** Can be passed as a string or a list. Returns jobs which match the specified minion name. Globbing is allowed. Example:

```
salt-run jobs.list_jobs search_target='*.mydomain.tld'
salt-run jobs.list_jobs search_target='["db", "myminion"]'
```

Changed in version 2015.8.8: Multiple targets can now also be passed as a comma-separated list. For example:

```
salt-run jobs.list_jobs search_target='db*,myminion'
```

**start_time** Accepts any timestamp supported by the `dateutil` Python module (if this module is not installed, this argument will be ignored). Returns jobs which started after this timestamp.

**end_time** Accepts any timestamp supported by the `dateutil` Python module (if this module is not installed, this argument will be ignored). Returns jobs which started before this timestamp.

CLI Example:

```
salt-run jobs.list_jobs
salt-run jobs.list_jobs search_function='test.*' search_target='localhost' search_metadata='{"bar": "foo"}'
salt-run jobs.list_jobs start_time='2015, Mar 16 19:00' end_time='2015, Mar 18 22:00'
```

salt.runners.jobs.list_jobs_filter(count, filter_find_job=True, ext_source=None, outputter=None, display_progress=False)

List all detectable jobs and associated functions

CLI Example:

```
salt-run jobs.list_jobs_filter 50
salt-run jobs.list_jobs_filter 100 filter_find_job=False
```

salt.runners.jobs.lookup_jid(jid, ext_source=None, returned=True, missing=False, outputter=None, display_progress=False)

Return the printout from a previously executed job

**jid** The jid to look up.

**ext_source** The external job cache to use. Default: *None*.

**returned** [True] If True, include the minions that did return from the command.

New in version 2015.8.0.

**missing** [False] If True, include the minions that did not return from the command.
display_progress  [False] If True, fire progress events.

   New in version 2015.5.0.

CLI Example:

```bash
salt-run jobs.lookup_jid 20130916125524463507
salt-run jobs.lookup_jid 20130916125524463507 --out=highstate
```

**salt.runners.jobs.print_job** (*jid, ext_source=None, outpuer=None*)

Print a specific job's detail given by it's jid, including the return data.

CLI Example:

```bash
salt-run jobs.print_job 20130916125524463507
```

**salt.runners.launchd**

Manage launchd plist files

**salt.runners.launchd.write_launchd_plist** (*program*)

Write a launchd plist for managing salt-master or salt-minion

CLI Example:

```bash
salt-run launchd.write_launchd_plist salt-master
```

**salt.runners.lxc**

Control Linux Containers via Salt

**depends** lxc execution module

**salt.runners.lxc.cloud_init** (*names, host=None, quiet=False, **kwargs*)

Wrapper for using lxc.init in saltcloud compatibility mode

   names  Name of the containers, supports a single name or a comma delimited list of names.
   host  Minion to start the container on. Required.
   path  path to the container parent default: /var/lib/lxc (system default)

   New in version 2015.8.0.

   saltcloud_mode  init the container with the saltcloud opts format instead

**salt.runners.lxc.find_guest** (*name, quiet=False, path=None*)

Returns the host for a container.

   path  path to the container parent default: /var/lib/lxc (system default)

   New in version 2015.8.0.

```bash
salt-run lxc.find_guest name
```

**salt.runners.lxc.find_guests** (*names, path=None*)

Return a dict of hosts and named guests

   path  path to the container parent default: /var/lib/lxc (system default)

   New in version 2015.8.0.
**Salt Documentation, Release 2015.8.12**

**salt.runners.lxc.freeze** *(name, quiet=False, path=None)*

Freeze the named container

**path** path to the container parent default: /var/lib/lxc (system default)

New in version 2015.8.0.

```bash
salt-run lxc.freeze name
```

**salt.runners.lxc.info** *(name, quiet=False, path=None)*

Returns information about a container.

**path** path to the container parent default: /var/lib/lxc (system default)

New in version 2015.8.0.

```bash
classic.lxc.lxc.info name
```

**salt.runners.lxc.init** *(names, host=None, saltcloud_mode=False, quiet=False, **kwargs)*

Initialize a new container

```bash
classic.lxc.lxc.init name host=minion_id [cpuset=cgroups_cpuset] \
    [cpushare=cgroups_cpushare] [memory=cgroups_memory] \
    [template=lxc_template_name] [clone=original name] \
    [profile=lxc_profile] [network_profile=network_profile] \
    [nic=network_profile] [nic_opts=nic_opts] \
    [start=(true|false)] [seed=(true|false)] \
    [install=(true|false)] [config=minion_config] \
    [snapshot=(true|false)]
```

**names** Name of the containers, supports a single name or a comma delimited list of names.

**host** Minion on which to initialize the container *(required)*

**path** path to the container parent default: /var/lib/lxc (system default)

New in version 2015.8.0.

**saltcloud_mode** init the container with the saltcloud opts format instead See lxc.init_interface module documentation

**cpuset** cgroups cpuset.

**cpushare** cgroups cpu shares.

**memory** cgroups memory limit, in MB

Changed in version 2015.5.0: If no value is passed, no limit is set. In earlier Salt versions, not passing this value causes a 1024MB memory limit to be set, and it was necessary to pass memory=0 to set no limit.

**template** Name of LXC template on which to base this container

**clone** Clone this container from an existing container

**profile** A LXC profile (defined in config or pillar).

**network_profile** Network profile to use for the container

New in version 2015.5.2.

**nic** Deprecated since version 2015.5.0: Use network_profile instead
nic_opts Extra options for network interfaces. E.g.:
   {"eth0": {"mac": "aa:bb:cc:dd:ee:ff","ipv4": "10.1.1.1","ipv6": "2001:db8::ff00:42:8329"}}

start Start the newly created container.

seed Seed the container with the minion config and autosign its key. Default: true

install If salt-minion is not already installed, install it. Default: true

config Optional config parameters. By default, the id is set to the name of the container.

salt.runners.lxc.list(host=host, quiet=False, path=None)
List defined containers (running, stopped, and frozen) for the named (or all) host(s).

path path to the container parent default: /var/lib/lxc (system default)

New in version 2015.8.0.

```
salt-run lxc.list [host=minion_id]
```

salt.runners.lxc.purge(name, delete_key=True, quiet=False, path=None)
Purge the named container and delete its minion key if present. WARNING: Destroys all data associated with
the container.

path path to the container parent default: /var/lib/lxc (system default)

New in version 2015.8.0.

```
salt-run lxc.purge name
```

salt.runners.lxc.start(name, quiet=False, path=None)
Start the named container.

path path to the container parent default: /var/lib/lxc (system default)

New in version 2015.8.0.

```
salt-run lxc.start name
```

salt.runners.lxc.stop(name, quiet=False, path=None)
Stop the named container.

path path to the container parent default: /var/lib/lxc (system default)

New in version 2015.8.0.

```
salt-run lxc.stop name
```

salt.runners.lxc.unfreeze(name, quiet=False, path=None)
Unfreeze the named container

path path to the container parent default: /var/lib/lxc (system default)

New in version 2015.8.0.

```
salt-run lxc.unfreeze name
```
salt.runners.manage

General management functions for salt, tools like seeing what hosts are up and what hosts are down

salt.runners.manage.alived(subset=\texttt{None}, show_ipv4=\texttt{False})

New in version 2015.8.0.

Print a list of all minions that are up according to Salt’s presence detection (no commands will be sent to minions)

\texttt{subset} [\texttt{None}] Pass in a CIDR range to filter minions by IP address.

\texttt{show_ipv4} [\texttt{False}] Also show the IP address each minion is connecting from.

CLI Example:

\begin{verbatim}
salt-run manage.alived
\end{verbatim}

salt.runners.manage.allowed(subset=\texttt{None}, show_ipv4=\texttt{False})

New in version 2015.8.0.

Print a list of all minions that are up according to Salt’s presence detection (no commands will be sent to minions)

\texttt{subset} [\texttt{None}] Pass in a CIDR range to filter minions by IP address.

\texttt{show_ipv4} [\texttt{False}] Also show the IP address each minion is connecting from.

CLI Example:

\begin{verbatim}
salt-run manage.allowed
\end{verbatim}

salt.runners.manage.bootstrap(version=\texttt{develop}, script=\texttt{None}, hosts=\texttt{``}, root_user=\texttt{True})

Bootstrap minions with salt-bootstrap

\texttt{version} [\texttt{develop}] Git tag of version to install

\texttt{script} [\texttt{\url{https://bootstrap.saltstack.com}}] Script to execute

\texttt{hosts} Comma-separated hosts [example: \texttt{hosts=`host1.local,host2.local\'}}

\texttt{root_user} [\texttt{True}] Prepend root@ to each host.

CLI Example:

\begin{verbatim}
salt-run manage.bootstrap hosts='host1,host2' version=v0.17'
salt-run manage.bootstrap hosts='host1,host2' version=v0.17' script='\url{https://
  __bootstrap.saltstack.com/develop}'
salt-run manage.bootstrap hosts='ec2-user@host1,ec2-user@host2' root_user=\texttt{False}
\end{verbatim}

salt.runners.manage.bootstrap_psexec(hosts=\texttt{``}, master=\texttt{None}, version=\texttt{None}, arch=\texttt{`win32'}, installer_url=\texttt{None}, username=\texttt{None}, password=\texttt{None})

Bootstrap Windows minions via PsExec.

\texttt{hosts} Comma separated list of hosts to deploy the Windows Salt minion.

\texttt{master} Address of the Salt master passed as an argument to the installer.

\texttt{version} Point release of installer to download. Defaults to the most recent.

\texttt{arch} Architecture of installer to download. Defaults to win32.

\texttt{installer_url} URL of minion installer executable. Defaults to the latest version from \url{https://repo.saltstack.com/windows/}
username  Optional user name for login on remote computer.
password  Password for optional username. If omitted, PsExec will prompt for one to be entered for each host.

CLI Example:

```bash
salt-run manage.bootstrap_psexec hosts='host1,host2'
salt-run manage.bootstrap_psexec hosts='host1,host2' version='0.17' username='\DOMAIN\Administrator'
salt-run manage.bootstrap_psexec hosts='host1,host2' installer_url='http://exampledomain/salt-installer.exe'
```

salt.runners.manage.down(removekeys=False)
Print a list of all the down or unresponsive salt minions Optionally remove keys of down minions

CLI Example:

```bash
salt-run manage.down
salt-run manage.down removekeys=True
```

salt.runners.manage.get_stats(estate=None, stack='road')
Print the stack stats

estate  [None] The name of the target estate. Master stats would be requested by default
stack  ['road'] Show stats on either road or lane stack Allowed values are `road` or `lane`.

CLI Example:

```bash
salt-run manage.get_stats [estate=alpha_minion] [stack=lane]
```

salt.runners.manage.joined(subset=None, show_ipv4=False)
New in version 2015.8.0.
Print a list of all minions that are up according to Salt's presence detection (no commands will be sent to minions)

subset  [None] Pass in a CIDR range to filter minions by IP address.
show_ipv4  [False] Also show the IP address each minion is connecting from.

CLI Example:

```bash
salt-run manage.joined
```

salt.runners.manage.key_regen()
This routine is used to regenerate all keys in an environment. This is invasive! ALL KEYS IN THE SALT ENVIRONMENT WILL BE REGENERATED!!

The key_regen routine sends a command out to minions to revoke the master key and remove all minion keys, it then removes all keys from the master and prompts the user to restart the master. The minions will all reconnect and keys will be placed in pending.

After the master is restarted and minion keys are in the pending directory execute a salt-key -A command to accept the regenerated minion keys.

The master must be restarted within 60 seconds of running this command or the minions will think there is something wrong with the keys and abort.

Only Execute this runner after upgrading minions and master to 0.15.1 or higher!

CLI Example:
salt-run manage.key_regen

salt.runners.manage.lane_stats(estate=None)
   Print the estate manor lane stack stats
   
   estate [None] The name of the target estate. Master stats would be requested by default
   
   CLI Example:
   
   salt-run manage.lane_stats [estate=alpha_minion]

salt.runners.manage.list_not_state(subset=None, show_ipv4=False, state=None)
   New in version 2015.8.0.
   Print a list of all minions that are NOT up according to Salt’s presence detection (no commands will be sent to
   minions)
   
   subset [None] Pass in a CIDR range to filter minions by IP address.
   
   show_ipv4 [False] Also show the IP address each minion is connecting from.
   
   state [’available’] Show minions being in specific state that is one of ’available’, ’joined’, ’allowed’, ’alived’ or
   ’reaped’.
   
   CLI Example:
   
   salt-run manage.list_not_state

salt.runners.manage.list_state(subset=None, show_ipv4=False, state=None)
   New in version 2015.8.0.
   Print a list of all minions that are up according to Salt’s presence detection (no commands will be sent to
   minions)
   
   subset [None] Pass in a CIDR range to filter minions by IP address.
   
   show_ipv4 [False] Also show the IP address each minion is connecting from.
   
   state [’available’] Show minions being in specific state that is one of ’available’, ’joined’, ’allowed’, ’alived’ or
   ’reaped’.
   
   CLI Example:
   
   salt-run manage.list_state

salt.runners.manage.not_alived(subset=None, show_ipv4=False)
   New in version 2015.8.0.
   Print a list of all minions that are NOT up according to Salt’s presence detection (no commands will be sent)
   
   subset [None] Pass in a CIDR range to filter minions by IP address.
   
   show_ipv4 [False] Also show the IP address each minion is connecting from.
   
   CLI Example:
   
   salt-run manage.not_alived

salt.runners.manage.not_allowed(subset=None, show_ipv4=False)
   New in version 2015.8.0.
   Print a list of all minions that are NOT up according to Salt’s presence detection (no commands will be sent)
   
   subset [None] Pass in a CIDR range to filter minions by IP address.
show_ipv4 [False] Also show the IP address each minion is connecting from.

CLI Example:
```
salt-run manage.not_allowed
```

salt.runners.manage.notJoined(subset=None, show_ipv4=False)
New in version 2015.8.0.
Print a list of all minions that are NOT up according to Salt's presence detection (no commands will be sent)

subset [None] Pass in a CIDR range to filter minions by IP address.

show_ipv4 [False] Also show the IP address each minion is connecting from.

CLI Example:
```
salt-run manage.notJoined
```

salt.runners.manage.notPresent(subset=None, show_ipv4=False)
New in version 2015.5.0.
Print a list of all minions that are NOT up according to Salt's presence detection (no commands will be sent)

subset [None] Pass in a CIDR range to filter minions by IP address.

show_ipv4 [False] Also show the IP address each minion is connecting from.

CLI Example:
```
salt-run manage.notPresent
```

salt.runners.manage.notReaped(subset=None, show_ipv4=False)
New in version 2015.8.0.
Print a list of all minions that are NOT up according to Salt's presence detection (no commands will be sent)

subset [None] Pass in a CIDR range to filter minions by IP address.

show_ipv4 [False] Also show the IP address each minion is connecting from.

CLI Example:
```
salt-run manage.notReaped
```

salt.runners.manage.present(subset=None, show_ipv4=False)
Print a list of all minions that are up according to Salt's presence detection (no commands will be sent to minions)

subset [None] Pass in a CIDR range to filter minions by IP address.

show_ipv4 [False] Also show the IP address each minion is connecting from.

CLI Example:
```
salt-run manage.present
```

salt.runners.manage.reaped(subset=None, show_ipv4=False)
New in version 2015.8.0.
Print a list of all minions that are up according to Salt's presence detection (no commands will be sent to minions)

subset [None] Pass in a CIDR range to filter minions by IP address.
**show_ipv4** [False] Also show the IP address each minion is connecting from.

CLI Example:

```
salt-run manage.reaped
```

**salt.runners.manage.road_stats** *(estate=None)*

Print the estate road stack stats

**estate** [None] The name of the target estate. Master stats would be requested by default

CLI Example:

```
salt-run manage.road_stats [estate=alpha_minion]
```

**salt.runners.manage.safe_accept** *(target, expr_form='glob')*

Accept a minion's public key after checking the fingerprint over salt-ssh

CLI Example:

```
salt-run manage.safe_accept my_minion
salt-run manage.safe_accept minion1,minion2 expr_form=list
```

**salt.runners.manage.status** *(output=True)*

Print the status of all known salt minions

CLI Example:

```
salt-run manage.status
```

**salt.runners.manage.up()**

Print a list of all of the minions that are up

CLI Example:

```
salt-run manage.up
```

**salt.runners.manage.versions()**

Check the version of active minions

CLI Example:

```
salt-run manage.versions
```

**salt.runners.mine**

A runner to access data from the salt mine

**salt.runners.mine.get**(tgt, fun, tgt_type='glob')

Gathers the data from the specified minions' mine, pass in the target, function to look up and the target type

CLI Example:

```
salt-run mine.get '*' network.interfaces
```

**salt.runners.nacl**

This runner helps create encrypted passwords that can be included in pillars.
depends libnacl, https://github.com/saltstack/libnacl

This is often useful if you wish to store your pillars in source control or share your pillar data with others that you trust. I don’t advise making your pillars public regardless if they are encrypted or not.

The following configurations can be defined in the master config so your users can create encrypted passwords using the runner nacl:

```bash
cat /etc/salt/master.d/nacl.conf
nacl.config:
  key: 'cKEzd4kXsbeCE7/nLTIqXwnUiD1ulg4NoeeYcCFpd9k='
  keyfile: /root/.nacl
```

Now with the config in the master you can use the runner nacl like:

```bash
git-run nacl.enc 'data'
```

```python
salt.runners.nacl.dec(data, **kwargs)
Takes a key generated from nacl.keygen and decrypt some data.

CLI Examples:
```
salt-run nacl.dec pEXHQM6cuaF7A=
salt-run nacl.dec data='pEXHQM6cuaF7A=' keyfile=/root/.nacl
salt-run nacl.dec data='pEXHQM6cuaF7A=' key='cKEzd4kXsbeCE7/nLTIqXwnUiD1ulg4NoeeYcCFpd9k='
```

salt.runners.nacl.enc(data, **kwargs)
Takes a key generated from nacl.keygen and encrypt some data.

CLI Examples:

```bash
salt-run nacl.enc datatoenc
salt-run nacl.enc datatoenc keyfile=/root/.nacl
salt-run nacl.enc datatoenc key='cKEzd4kXsbeCE7/nLTIqXwnUiD1ulg4NoeeYcCFpd9k='
```

salt.runners.nacl.keygen(keyfile=None)
Use libnacl to generate a private key

CLI Examples:

```bash
salt-run nacl.keygen
salt-run nacl.keygen keyfile=/root/.nacl
salt-run --out=newline_values_only nacl.keygen > /root/.nacl
```

salt.runners.network

Network tools to run from the Master

salt.runners.network.wol(mac, bcast='255.255.255.255', destport=9)
Send a "Magic Packet" to wake up a Minion

CLI Example:

```bash
salt-run network.wol 08-00-27-13-69-77
salt-run network.wol 080027136977 255.255.255.255 7
salt-run network.wol 08:00:27:13:69:77 255.255.255.255 7
```
salt.runners.network.wollist(*maclist*, *bcast=’255.255.255.255’, *destport=9*)

Send a "Magic Packet" to wake up a list of Minions. This list must contain one MAC hardware address per line.

CLI Example:

```
salt-run network.wollist '/path/to/maclist'
salt-run network.wollist '/path/to/maclist' 255.255.255.255 7
salt-run network.wollist '/path/to/maclist' 255.255.255.255 7
```

salt.runners.pagerduty

Runner Module for Firing Events via PagerDuty

New in version 2014.1.0.

configuration This module can be used by specifying the name of a configuration profile in the master config. For example:

```
my-pagerduty-account:
pagerduty.api_key: F3Rbyjbye43rfFWf2214
pagerduty.subdomain: mysubdomain
```

salt.runners.pagerduty.create_event(*service_key=None, description=None, details=None, incident_key=None, profile=None*)

Create an event in PagerDuty. Designed for use in states.

CLI Example:

```
salt-run pagerduty.create_event <service_key> <description> <details> !

<profile=my-pagerduty-account>
```

The following parameters are required:

- **service_key** This key can be found by using pagerduty.list_services.
- **description** This is a short description of the event.
- **details** This can be a more detailed description of the event.
- **profile** This refers to the configuration profile to use to connect to the PagerDuty service.

salt.runners.pagerduty.list_escalation_policies(*profile=None, api_key=None*)

This function is an alias of list_policies.

List escalation policies belonging to this account

CLI Example:

```
salt-run pagerduty.list_policies my-pagerduty-account salt-run pagerduty.list_escalation_policies my-pagerduty-account
```

salt.runners.pagerduty.list_incidents(*profile=None, api_key=None*)

List incidents belonging to this account

CLI Example:

```
salt-run pagerduty.list_incidents my-pagerduty-account
```

salt.runners.pagerduty.list_maintenance_windows(*profile=None, api_key=None*)

This function is an alias of list_windows.
List maintenance windows belonging to this account

CLI Example:

```
salt-run pagerduty.list_windows my-pagerduty-account
salt-run pagerduty.list_maintenance_windows my-pagerduty-account
```

**salt.runners.pagerduty.list_policies***(profile=\*None, api\_key=\*None)***
List escalation policies belonging to this account

CLI Example:

```
salt-run pagerduty.list_policies my-pagerduty-account
salt-run pagerduty.list_escalation_policies my-pagerduty-account
```

**salt.runners.pagerduty.list_schedules***(profile=\*None, api\_key=\*None)***
List schedules belonging to this account

CLI Example:

```
salt-run pagerduty.list_schedules my-pagerduty-account
```

**salt.runners.pagerduty.list_services***(profile=\*None, api\_key=\*None)***
List services belonging to this account

CLI Example:

```
salt-run pagerduty.list_services my-pagerduty-account
```

**salt.runners.pagerduty.list_users***(profile=\*None, api\_key=\*None)***
List users belonging to this account

CLI Example:

```
salt-run pagerduty.list_users my-pagerduty-account
```

**salt.runners.pagerduty.list_windows***(profile=\*None, api\_key=\*None)***
List maintenance windows belonging to this account

CLI Example:

```
salt-run pagerduty.list_windows my-pagerduty-account
salt-run pagerduty.list_maintenance_windows my-pagerduty-account
```

**salt.runners.pillar**

Functions to interact with the pillar compiler on the master

**salt.runners.pillar.show_pillar***(minion=\*", **kwargs)***
Returns the compiled pillar either of a specific minion or just the global available pillars. This function assumes that no minion has the id *.

CLI Example:

```
salt-run pillar.show_pillar 'www.example.com'
salt-run pillar.show_pillar
```

shows global pillar for `dev` pillar environment:
salt-run pillar.show_pillar 'saltenv=dev'

API Example:

```python
import salt.config
import salt.runner

opts = salt.config.master_config('/etc/salt/master')
runner = salt.runner.RunnerClient(opts)
pillar = runner.cmd('pillar.show_pillar', [])
print(pillar)
```

salt.runners.pillar.show_top(minion=None, saltenv='base')

Returns the compiled top data for pillar for a specific minion. If no minion is specified, we use the first minion we find.

CLI Example:

```
salt-run pillar.show_top
```

salt.runners.pkg

Package helper functions using salt.modules.pkg

New in version 2015.8.0.

salt.runners.pkg.list_upgrades(jid, style='group', outpu terra='nested', ext_source=None)

Show list of available pkg upgrades using a specified format style

CLI Example:

```
salt-run pkg.list_upgrades jid=2014112011441719 style=group
```

salt.runners.queue

General management and processing of queues.

This runner facilitates interacting with various queue backends such as the included sqlite3 queue or the planned AWS SQS and Redis queues.

The queue functions such as insert, delete, and pop can be used for typical management of the queue.

The process_queue function pops the requested number of items from the queue and creates a Salt Event that can then be processed by a Reactor. The process_queue function can be called manually, or can be configured to run on a schedule with the Salt Scheduler or regular system cron. It is also possible to use the peer system to allow a minion to call the runner.

This runner, as well as the Queues system, is not api stable at this time.

There are many things that could potentially be done with queues within Salt. For the time being the focus will be on queueing infrastructure actions on specific minions. The queues generally will be populated with minion IDs. When the process_queue runner function is called events are created on the Salt Event bus that indicate the queue and a list of one or more minion IDs. The reactor is set up to match on event tags for a specific queue and then take infrastructure actions on those minion IDs. These actions might be to delete the minion’s key from the master, use salt-cloud to destroy the vm, or some other custom action.

salt.runners.queue.delete(queue, items, backend='sqlite')

Delete an item or items from a queue
salt Documentation, Release 2015.8.12

CLI Example:

```
salt-run queue.delete myqueue myitem
salt-run queue.delete myqueue myitem backend=sqite
salt-run queue.delete myqueue "["item1", "item2", "item3"]"
```

**salt.runners.queue.insert**(queue, items, backend='sqlite')

Add an item or items to a queue

CLI Example:

```
salt-run queue.insert myqueue myitem
salt-run queue.insert myqueue "["item1", "item2", "item3"]"
```

salt.runners.queue.list_items**(queue, backend='sqlite')**

List contents of a queue

CLI Example:

```
salt-run queue.list_items myqueue
salt-run queue.list_items myqueue backend=sqite
```

salt.runners.queue.list_length**(queue, backend='sqlite')**

Provide the number of items in a queue

CLI Example:

```
salt-run queue.list_length myqueue
salt-run queue.list_length myqueue backend=sqite
```

salt.runners.queue.list_queues**(backend='sqlite')**

Return a list of Salt Queues on the backend

CLI Example:

```
salt-run queue.list_queues
salt-run queue.list_queues backend=sqite
```

salt.runners.queue.pop**(queue, quantity=1, backend='sqlite')**

Pop one or more or all items from a queue

CLI Example:

```
salt-run queue.pop myqueue
salt-run queue.pop myqueue 6
salt-run queue.pop myqueue all
salt-run queue.pop myqueue 6 backend=sqite
salt-run queue.pop myqueue all backend=sqite
```

salt.runners.queue.process_queue**(queue, quantity=1, backend='sqlite')**

Pop items off a queue and create an event on the Salt event bus to be processed by a Reactor.

CLI Example:

```
salt-run queue.process_queue myqueue
salt-run queue.process_queue myqueue 6
salt-run queue.process_queue myqueue all backend=sqite
```
salt.runners.sdb

Runner for setting and querying data via the sdb API on the master

salt.runners.sdb.get(uri)
Get a value from a db, using a uri in the form of sdb://<profile>/<key>. If the uri provided does not start with sdb://, then it will be returned as-is.

CLI Example:
```
salt '*' sdb.get sdb://mymemcached/foo
```

salt.runners.sdb.set(uri, value)
Set a value in a db, using a uri in the form of sdb://<profile>/<key>. If the uri provided does not start with sdb:// or the value is not successfully set, return False.

CLI Example:
```
salt '*' sdb.set sdb://mymemcached/foo bar
```

salt.runners.ssh

A Runner module interface on top of the salt-ssh Python API.

This allows for programmatic use from salt-api, the Reactor, Orchestrate, etc.

salt.runners.ssh.cmd(tgt, fun, arg=(), timeout=None, expr_form='glob', kwarg=None)
Execute a single command via the salt-ssh subsystem and return all routines at once

New in version 2015.5.0.

A wrapper around the `SSHClient.cmd` method.

salt.runners.search

Runner frontend to search system

salt.runners.search.query(term)
Query the search system

CLI Example:
```
salt-run search.query foo
```

salt.runners.state

Execute orchestration functions

salt.runners.state.event(tagmatch='*', count=-1, quiet=False, sock_dir=None, pretty=False)
Watch Salt’s event bus and block until the given tag is matched

New in version 2014.7.0.

This is useful for utilizing Salt’s event bus from shell scripts or for taking simple actions directly from the CLI.

Enable debug logging to see ignored events.

Parameters
- **tagmatch** -- the event is written to stdout for each tag that matches this pattern; uses the same matching semantics as Salt's Reactor.
- **count** -- this number is decremented for each event that matches the tagmatch parameter; pass -1 to listen forever.
- **quiet** -- do not print to stdout; just block
- **sock_dir** -- path to the Salt master's event socket file.
- **pretty** -- Output the JSON all on a single line if False (useful for shell tools); pretty-print the JSON output if True.

CLI Examples:

```bash
# Reboot a minion and run highstate when it comes back online
salt 'jerry' system.reboot && \
  salt-run state.event 'salt/minion/jerry/start' count=1 quiet=True && \
  salt 'jerry' state.highstate

# Reboot multiple minions and run highstate when all are back online
salt -L 'kevin,stewart,dave' system.reboot && \
  salt-run state.event 'salt/minion/*/start' count=3 quiet=True && \
  salt -L 'kevin,stewart,dave' state.highstate

# Watch the event bus forever in a shell while-loop.
salt-run state.event | while read -r tag data; do 
  echo $tag
  echo $data | jq -colour-output .
done
```

See also:

See https://github.com/saltstack/salt/blob/develop/tests/eventlisten.sh for an example of usage within a shell script.

salt.runners.state.orchestrate (mods, saltenv='base', test=None, exclude=None, pillar=None)
New in version 0.17.0.

Execute a state run from the master, used as a powerful orchestration system.

See also:

More Orchestrate documentation

- Full Orchestrate Tutorial
- Docs for the master-side state module

CLI Examples:

```bash
salt-run state.orchestrate webserver
salt-run state.orchestrate webserver saltenv=dev test=True
```

Changed in version 2014.1.1: Runner renamed from state.sls to state.orchestrate

Changed in version 2014.7.0: Runner uses the pillar variable

salt.runners.state.orchestrate_high (data, test=None, queue=False, pillar=None, **kwargs)
New in version 2015.5.0.

CLI Example:
salt-run state.orchestrate_high '{
    stage_one:
    {salt.state: [{tgt: "db*"}, {sls: postgres_setup}]},
    stage_two:
    {salt.state: [{tgt: "web*"}, {sls: apache_setup}, {
        require: [{salt: stage_one}],
    }],}
}'

**salt.runners.state.orchestrate_single**(fun, name, test=None, queue=False, pillar=None, **kwargs)

Execute a single state orchestration routine

New in version 2015.5.0.

CLI Example:

```
salt-run state.orchestrate_single fun=salt.wheel name=key.list_all
```

**salt.runners.survey**

A general map/reduce style salt runner for aggregating results returned by several different minions.

New in version 2014.7.0.

Aggregated results are sorted by the size of the minion pools which returned matching results.

Useful for playing the game: "some of these things are not like the others..." when identifying discrepancies in a large infrastructure managed by salt.

**salt.runners.survey.diff**(args, **kwargs)

Return the DIFFERENCE of the result sets returned by each matching minion pool

New in version 2014.7.0.

These pools are determined from the aggregated and sorted results of a salt command. This command displays the "difs" as a series of 2-way differences-- namely the difference between the FIRST displayed minion pool (according to sort order) and EACH SUBSEQUENT minion pool result set. Differences are displayed according to the Python `difflib.unified_diff()` as in the case of the salt execution module `file.get_diff`.

This command is submitted via a salt runner using the general form:

```
salt-run survey.diff [survey_sort=up/down] <target> <salt-execution-module> <salt-execution-module parameters>
```

Optionally accept a `survey_sort=` parameter. Default: `survey_sort=down`

CLI Example #1: (Example to display the "differences of files")

```
salt-run survey.diff survey_sort=up "*" cp.get_file_str file:///etc/hosts
```

**salt.runners.survey.hash**(args, **kwargs)

Return the MATCHING minion pools from the aggregated and sorted results of a salt command

New in version 2014.7.0.

This command is submitted via a salt runner using the general form:

```
salt-run survey.hash [survey_sort=up/down] <target> <salt-execution-module> <salt-execution-module parameters>
```

32.27. Salt Runners
Optionally accept a `survey_sort=` parameter. Default: `survey_sort=down`

CLI Example #1: (functionally equivalent to `salt-run manage.up`)

```bash
salt-run survey.hash "*" test.ping
```

CLI Example #2: (find an `outlier` minion config file)

```bash
salt-run survey.hash "*" file.get_hash /etc/salt/minion survey_sort=up
```

**salt.runners.test**

This runner is used only for test purposes and servers no production purpose

```python
salt.runners.test.arg(*args, **kwargs)
```

Output the given args and kwargs

Kwargs will be filtered for `private` keynames.

```python
salt.runners.test.raw_arg(*args, **kwargs)
```

Output the given args and kwargs

```python
salt.runners.test.sleep(s_time=10)
```

Sleep `s_time` seconds, then return `True`

```python
salt.runners.test.stdout_print()
```

Print `foo` and return `bar`

```python
salt.runners.test.stream()
```

Return `True`

**salt.runners.thin**

The thin runner is used to manage the salt thin systems.

Salt Thin is a transport-less version of Salt that can be used to run routines in a standalone way. This runner has tools which generate the standalone salt system for easy consumption.

```python
salt.runners.thin.generate(extra_mods='`, overwrite=False, so_mods='`)
```

Generate the salt-thin tarball and print the location of the tarball Optional additional mods to include (e.g. mako) can be supplied as a comma delimited string. Permits forcing an overwrite of the output file as well.

CLI Example:

```bash
salt-run thin.generate
salt-run thin.generate mako
salt-run thin.generate mako,wempy 1
salt-run thin.generate overwrite=1
```

**salt.runners.virt**

Control virtual machines via Salt

```python
salt.runners.virt.force_off(name)
```

Force power down the named virtual machine

```python
salt.runners.virt.host_info(host=None)
```

Return information about the host connected to this master
salt.runners.virt.hyper_info(hyper=None)

Return information about the host connected to this master

salt.runners.virt.init(name, cpu, mem, image, hyper=None, hypervisor='kvm', host=None, seed=True, nic='default', install=True, start=True, disk='default', saltenv='base')

This routine is used to create a new virtual machine. This routine takes a number of options to determine what the newly created virtual machine will look like.

- **name**: The mandatory name of the new virtual machine. The name option is also the minion id, all minions must have an id.
- **cpu**: The number of cpus to allocate to this new virtual machine.
- **mem**: The amount of memory to allocate to this virtual machine. The number is interpreted in megabytes.
- **image**: The network location of the virtual machine image, commonly a location on the salt fileserver, but http, https and ftp can also be used.
- **hypervisor**: The hypervisor to use for the new virtual machine. Default is `kvm`.
- **host**: The host to use for the new virtual machine, if this is omitted Salt will automatically detect what host to use.
- **seed**: Set to False to prevent Salt from seeding the new virtual machine.
- **nic**: The nic profile to use, defaults to the `default` nic profile which assumes a single network interface per VM associated with the `br0` bridge on the master.
- **install**: Set to False to prevent Salt from installing a minion on the new VM before it spins up.
- **disk**: The disk profile to use
- **saltenv**: The Salt environment to use

salt.runners.virt.list(host=None, quiet=False, hyper=None)

List the virtual machines on each host, this is a simplified query, showing only the virtual machine names belonging to each host. A single host can be passed in to specify an individual host to list.

salt.runners.virt.migrate(name, target='')

Migrate a VM from one host to another. This routine will just start the migration and display information on how to look up the progress.

salt.runners.virt.next_host()

Return the host to use for the next autodeployed VM. This queries the available host and executes some math to determine the most `available` next host.

salt.runners.virt.next_hyper()

Return the host to use for the next autodeployed VM. This queries the available host and executes some math to determine the most `available` next host.

salt.runners.virt.pause(name)

Pause the named VM

salt.runners.virt.purge(name, delete_key=True)

Destroy the named VM

salt.runners.virt.query(host=None, quiet=False, hyper=None)

Query the virtual machines. When called without options all hosts are detected and a full query is returned. A single host can be passed in to specify an individual host to query.

salt.runners.virt.reset(name)

Force power down and restart an existing VM
salt.runners.virt.resume(name)
   Resume a paused VM
salt.runners.virt.start(name)
   Start a named virtual machine
salt.runners.virt.vm_info(name, quiet=False)
   Return the information on the named VM

salt.runners.winrepo

Runner to manage Windows software repo
salt.runners.winrepo.genrepo(opts=None, fire_event=True)
   Generate winrepo_cachefile based on sls files in the winrepo_dir
      opts  Specify an alternate opts dict. Should not be used unless this function is imported into an execution module.
      fire_event  [True] Fire an event on failure. Only supported on the master.
   CLI Example:
      salt-run winrepo.genrepo
salt.runners.winrepo.update_git_repos(opts=None, clean=False, masterless=False)
   Checkout git repos containing Windows Software Package Definitions
      opts  Specify an alternate opts dict. Should not be used unless this function is imported into an execution module.
      clean  [False] Clean repo cachedirs which are not configured under winrepo_remotes.

      Warning: This argument should not be set to True if a mix of git and non-git repo definitions are being used, as it will result in the non-git repo definitions being removed.

   New in version 2015.8.0.
   CLI Examples:
      salt-run winrepo.update_git_repos
      salt-run winrepo.update_git_repos clean=True

32.27.2 Writing Salt Runners

A Salt runner is written in a similar manner to a Salt execution module. Both are Python modules which contain functions and each public function is a runner which may be executed via the salt-run command.

For example, if a Python module named test.py is created in the runners directory and contains a function called foo, the test runner could be invoked with the following command:

      # salt-run test.foo

Runners have several options for controlling output.
Any print statement in a runner is automatically also fired onto the master event bus where. For example:
```python
def a_runner(outputter=None, display_progress=False):
    print('Hello world')
```

The above would result in an event fired as follows:

```
Event fired at Tue Jan 13 15:26:45 2015
*************************
Tag: salt/run/20150113152644070246/print
Data:
{'_stamp': '2015-01-13T15:26:45.078707',
 'data': 'hello',
 'outputter': 'pprint'}
```

A runner may also send a progress event, which is displayed to the user during runner execution and is also passed across the event bus if the `display_progress` argument to a runner is set to True.

A custom runner may send its own progress event by using the `__jid_event__.fire_event()` method as shown here:

```python
if display_progress:
    __jid_event__.fire_event({'message': 'A progress message', 'progress'})
```

The above would produce output on the console reading: A progress message as well as an event on the event similar to:

```
Event fired at Tue Jan 13 15:21:20 2015
*************************
Tag: salt/run/20150113152118341421/progress
Data:
 'message': 'A progress message'}
```

A runner could use the same approach to send an event with a customized tag onto the event bus by replacing the second argument (progress) with whatever tag is desired. However, this will not be shown on the command-line and will only be fired onto the event bus.

### 32.27.3 Synchronous vs. Asynchronous

A runner may be fired asynchronously which will immediately return control. In this case, no output will be displayed to the user if `salt-run` is being used from the command-line. If used programatically, no results will be returned. If results are desired, they must be gathered either by firing events on the bus from the runner and then watching for them or by some other means.

---

**Note:** When running a runner in asynchronous mode, the `--progress` flag will not deliver output to the salt-run CLI. However, progress events will still be fired on the bus.

In synchronous mode, which is the default, control will not be returned until the runner has finished executing. To add custom runners, put them in a directory and add it to `runner_dirs` in the master configuration file.

### 32.27.4 Examples

Examples of runners can be found in the Salt distribution:
A simple runner that returns a well-formatted list of the minions that are responding to Salt calls could look like this:

```python
# Import salt modules
import salt.client

def up():
    '''
    Print a list of all of the minions that are up
    '''
    client = salt.client.LocalClient(__opts__['conf_file'])
    minions = client.cmd('*', 'test.ping', timeout=1)
    for minion in sorted(minions):
        print minion
```

### 32.28 State Enforcement

Salt offers an optional interface to manage the configuration or ``state`` of the Salt minions. This interface is a fully capable mechanism used to enforce the state of systems from a central manager.

#### 32.28.1 Mod Aggregate State Runtime Modifications

New in version 2014.7.0.

The mod_aggregate system was added in the 2014.7.0 release of Salt and allows for runtime modification of the executing state data. Simply put, it allows for the data used by Salt’s state system to be changed on the fly at runtime, kind of like a configuration management JIT compiler or a runtime import system. All in all, it makes Salt much more dynamic.

**How it Works**

The best example is the `pkg` state. One of the major requests in Salt has long been adding the ability to install all packages defined at the same time. The mod_aggregate system makes this a reality. While executing Salt’s state system, when a `pkg` state is reached the `mod_aggregate` function in the state module is called. For `pkg` this function scans all of the other states that are slated to run, and picks up the references to `name` and `pkgs`, then adds them to `pkgs` in the first state. The result is a single call to yum, apt-get, pacman, etc as part of the first package install.

**How to Use it**

---

**Note:** Since this option changes the basic behavior of the state runtime, after it is enabled states should be executed using `test=True` to ensure that the desired behavior is preserved.

---

**In config files**

The first way to enable aggregation is with a configuration option in either the master or minion configuration files. Salt will invoke `mod_aggregate` the first time it encounters a state module that has aggregate support.
If this option is set in the master config it will apply to all state runs on all minions, if set in the minion config it will only apply to said minion.

Enable for all states:

```
state_aggregate: True
```

Enable for only specific state modules:

```
state_aggregate:
  - pkg
```

**In states**

The second way to enable aggregation is with the state-level `aggregate` keyword. In this configuration, Salt will invoke the `mod_aggregate` function the first time it encounters this keyword. Any additional occurrences of the keyword will be ignored as the aggregation has already taken place.

The following example will trigger `mod_aggregate` when the `lamp_stack` state is processed resulting in a single call to the underlying package manager.

```
lamp_stack:
  pkg.installed:
    - pkgs:
        - php
        - mysql-client
    - aggregate: True

memcached:
  pkg.installed:
    - name: memcached
```

**Adding mod_aggregate to a State Module**

Adding a `mod_aggregate` routine to an existing state module only requires adding an additional function to the state module called `mod_aggregate`.

The `mod_aggregate` function just needs to accept three parameters and return the low data to use. Since `mod_aggregate` is working on the state runtime level it does need to manipulate low data.

The three parameters are `low`, `chunks`, and `running`. The `low` option is the low data for the state execution which is about to be called. The `chunks` is the list of all of the low data dictionaries which are being executed by the runtime and the `running` dictionary is the return data from all of the state executions which have already be executed.

This example, simplified from the `pkg` state, shows how to create `mod_aggregate` functions:

```
def mod_aggregate(low, chunks, running):
    '''
    The mod_aggregate function which looks up all packages in the available
    low chunks and merges them into a single pkgs ref in the present low data
    '''
    pkgs = []
    # What functions should we aggregate?
    agg_enabled = [u'
        'installed',
        'latest',
```
'removed',
'purged',
]
# The 'low' data is just a dict with the state, function (fun) and
# arguments passed in from the sls
if low.get('fun') not in agg_enabled:
    return low
# Now look into what other things are set to execute
for chunk in chunks:
    # The state runtime uses "tags" to track completed jobs, it may
    # look familiar with the _|-
tag = salt.utils.gen_state_tag(chunk)
    if tag in running:
        # Already ran the pkg state, skip aggregation
        continue
    if chunk.get('state') == 'pkg':
        if '__agg__' in chunk:
            continue
        # Check for the same function
        if chunk.get('fun') != low.get('fun'):
            continue
    # Pull out the pkg names!
    if 'pkgs' in chunk:
        pkgs.extend(chunk['pkgs'])
        chunk['__agg__'] = True
    elif 'name' in chunk:
        pkgs.append(chunk['name'])
        chunk['__agg__'] = True
    if pkgs:
        if 'pkgs' in low:
            low['pkgs'].extend(pkgs)
    else:
        low['pkgs'] = pkgs
    # The low has been modified and needs to be returned to the state
    # runtime for execution
return low

32.28.2 Altering States

Note: This documentation has been moved here.

32.28.3 File State Backups

In 0.10.2 a new feature was added for backing up files that are replaced by the file.managed and file.recurse states. The new feature is called the backup mode. Setting the backup mode is easy, but it can be set in a number of places.

The backup_mode can be set in the minion config file:

```
backup_mode: minion
```

Or it can be set for each file:
Backed-up Files

The files will be saved in the minion cachedir under the directory named file_backup. The files will be in the location relative to where they were under the root filesystem and be appended with a timestamp. This should make them easy to browse.

Interacting with Backups

Starting with version 0.17.0, it will be possible to list, restore, and delete previously-created backups.

Listing

The backups for a given file can be listed using `file.list_backups`:

```bash
# salt foo.bar.com file.list_backups /tmp/foo.txt
foo.bar.com:
   -----------
   0:  -----------
     Backup Time:  Sat Jul 27 2013 17:48:41.738027
     Location:  /var/cache/salt/minion/file_backup/tmp/foo.txt_Sat Jul 27 17:48:41_738027_2013
     Size:  13
   1:  -----------
     Backup Time:  Sat Jul 27 2013 17:48:28.369804
     Size:  35
```

Restoring

Restoring is easy using `file.restore_backup`, just pass the path and the numeric id found with `file.list_backups`:

```bash
# salt foo.bar.com file.restore_backup /tmp/foo.txt 1
foo.bar.com:
   -----------
   comment:  Successfully restored /var/cache/salt/minion/file_backup/tmp/foo.txt_Sat Jul_27_17:48:28_369804_2013 to /tmp/foo.txt
```
The existing file will be backed up, just in case, as can be seen if `file.list_backups` is run again:

```bash
# salt foo.bar.com file.list_backups /tmp/foo.txt
```

```
foo.bar.com:
    0:
        Backup Time: Sat Jul 27 2013 18:00:19.822550
        Location: /var/cache/salt/minion/file_backup/tmp/foo.txt_Sat_Jul_27_18:00:19_822550_
        Size: 53
    1:
        Backup Time: Sat Jul 27 2013 17:48:41.738027
        Location: /var/cache/salt/minion/file_backup/tmp/foo.txt_Sat_Jul_27_17:48:41_738027_
        Size: 13
    2:
        Backup Time: Sat Jul 27 2013 17:48:28.369804
        Location: /var/cache/salt/minion/file_backup/tmp/foo.txt_Sat_Jul_27_17:48:28_369804_
        Size: 35
```

**Note:** Since no state is being run, restoring a file will not trigger any watches for the file. So, if you are restoring a config file for a service, it will likely still be necessary to run a `service.restart`.

### Deleting

Deleting backups can be done using `file.delete_backup`:

```bash
# salt foo.bar.com file.delete_backup /tmp/foo.txt 0
```

```
foo.bar.com:
    comment:
        Successfully removed /var/cache/salt/minion/file_backup/tmp/foo.txt_Sat_Jul_27_18:00:19_822550_2013
    result:
        True
```
32.28.4 Understanding State Compiler Ordering

**Note:** This tutorial is an intermediate level tutorial. Some basic understanding of the state system and writing Salt Formulas is assumed.

Salt’s state system is built to deliver all of the power of configuration management systems without sacrificing simplicity. This tutorial is made to help users understand in detail just how the order is defined for state executions in Salt.

This tutorial is written to represent the behavior of Salt as of version 0.17.0.

**Compiler Basics**

To understand ordering in depth some very basic knowledge about the state compiler is very helpful. No need to worry though, this is very high level!

**High Data and Low Data**

When defining Salt Formulas in YAML the data that is being represented is referred to by the compiler as High Data. When the data is initially loaded into the compiler it is a single large python dictionary, this dictionary can be viewed raw by running:

```bash
salt '*' state.show_highstate
```

This ``High Data`` structure is then compiled down to ```Low Data```. The Low Data is what is matched up to create individual executions in Salt’s configuration management system. The low data is an ordered list of single state calls to execute. Once the low data is compiled the evaluation order can be seen.

The low data can be viewed by running:

```bash
salt '*' state.show_lowstate
```

**Note:** The state execution module contains MANY functions for evaluating the state system and is well worth a read! These routines can be very useful when debugging states or to help deepen one’s understanding of Salt’s state system.

As an example, a state written thusly:

```yaml
apache:
  pkg.installed:
    - name: httpd
  service.running:
    - name: httpd
    - watch:
      - file: apache_conf
      - pkg: apache

apache_conf:
  file.managed:
    - name: /etc/httpd/conf.d/httpd.conf
    - source: salt://apache/httpd.conf
```
Will have High Data which looks like this represented in json:

```json
{
    "apache": {
        "pkg": [
            {
                "name": "httpd",
                "installed",
                "order": 10000
            }
        ],
        "service": [
            {
                "name": "httpd",
                "watch": [
                    {
                        "file": "apache_conf",
                        "pkg": "apache"
                    }
                ],
                "running",
                "order": 10001
            }
        ],
        "__sls__": "blah",
        "__env__": "base"
    },
    "apache_conf": {
        "file": [
            {
                "name": "/etc/httpd/conf.d/httpd.conf",
                "source": "salt://apache/httpd.conf",
                "managed",
                "order": 10002
            }
        ],
        "__sls__": "blah",
        "__env__": "base"
    }
}
```

The subsequent Low Data will look like this:

```
[
    {
        "name": "httpd",
        "state": "pkg",
        "order": 10001
    }
]
```
This tutorial discusses the Low Data evaluation and the state runtime.

Ordering Layers

Salt defines 2 order interfaces which are evaluated in the state runtime and defines these orders in a number of passes.

Definition Order

Note: The Definition Order system can be disabled by turning the option state_auto_order to False in the master configuration file.

The top level of ordering is the Definition Order. The Definition Order is the order in which states are defined in salt formulas. This is very straightforward on basic states which do not contain include statements or a top file, as the states are just ordered from the top of the file, but the include system starts to bring in some simple rules for how the Definition Order is defined.

Looking back at the `Low Data` and `High Data` shown above, the order key has been transparently added to the data to enable the Definition Order.
The Include Statement

Basically, if there is an include statement in a formula, then the formulas which are included will be run BEFORE the contents of the formula which is including them. Also, the include statement is a list, so they will be loaded in the order in which they are included.

In the following case:

```
foo.sls

include:
  - bar
  - baz
```

```
bar.sls

include:
  - quo
```

```
baz.sls

include:
  - qux
```

In the above case if `state.apply foo` were called then the formulas will be loaded in the following order:

1. quo
2. bar
3. qux
4. baz
5. foo

The order Flag

The Definition Order happens transparently in the background, but the ordering can be explicitly overridden using the order flag in states:

```
apache:
  pkg.installed:
    - name: httpd
    - order: 1
```

This order flag will over ride the definition order, this makes it very simple to create states that are always executed first, last or in specific stages, a great example is defining a number of package repositories that need to be set up before anything else, or final checks that need to be run at the end of a state run by using `order: last` or `order: -1`.

When the order flag is explicitly set the Definition Order system will omit setting an order for that state and directly use the order flag defined.

Lexicographical Fall-back

Salt states were written to ALWAYS execute in the same order. Before the introduction of Definition Order in version 0.17.0 everything was ordered lexicographically according to the name of the state, then function then id.
This is the way Salt has always ensured that states always run in the same order regardless of where they are deployed, the addition of the Definition Order method mealy makes this finite ordering easier to follow.

The lexicographical ordering is still applied but it only has any effect when two order statements collide. This means that if multiple states are assigned the same order number that they will fall back to lexicographical ordering to ensure that every execution still happens in a finite order.

Note: If running with state_auto_order: False the order key is not set automatically, since the Lexicographical order can be derived from other keys.

Requisite Ordering

Salt states are fully declarative, in that they are written to declare the state in which a system should be. This means that components can require that other components have been set up successfully. Unlike the other ordering systems, the Requisite system in Salt is evaluated at runtime.

The requisite system is also built to ensure that the ordering of execution never changes, but is always the same for a given set of states. This is accomplished by using a runtime that processes states in a completely predictable order instead of using an event loop based system like other declarative configuration management systems.

Runtime Requisite Evaluation

The requisite system is evaluated as the components are found, and the requisites are always evaluated in the same order. This explanation will be followed by an example, as the raw explanation may be a little dizzying at first as it creates a linear dependency evaluation sequence.

The `Low Data` is an ordered list or dictionaries, the state runtime evaluates each dictionary in the order in which they are arranged in the list. When evaluating a single dictionary it is checked for requisites, requisites are evaluated in order, require then watch then prereq.

Note: If using requisite in statements like require_in and watch_in these will be compiled down to require and watch statements before runtime evaluation.

Each requisite contains an ordered list of requisites, these requisites are looked up in the list of dictionaries and then executed. Once all requisites have been evaluated and executed then the requiring state can safely be run (or not run if requisites have not been met).

This means that the requisites are always evaluated in the same order, again ensuring one of the core design principals of Salt’s State system to ensure that execution is always finite is intact.

Simple Runtime Evaluation Example

Given the above `Low Data` the states will be evaluated in the following order:

1. The pkg.installed is executed ensuring that the apache package is installed, it contains no requisites and is therefore the first defined state to execute.
2. The service.running state is evaluated but NOT executed, a watch requisite is found, therefore they are read in order, the runtime first checks for the file, sees that it has not been executed and calls for the file state to be evaluated.
3. The file state is evaluated AND executed, since it, like the pkg state does not contain any requisites.
4. The evaluation of the service state continues, it next checks the pkg requisite and sees that it is met, with all requisites met the service state is now executed.

**Best Practice**

The best practice in Salt is to choose a method and stick with it, official states are written using requisites for all associations since requisites create clean, traceable dependency trails and make for the most portable formulas. To accomplish something similar to how classical imperative systems function all requisites can be omitted and the `failhard` option then set to `True` in the master configuration, this will stop all state runs at the first instance of a failure.

In the end, using requisites creates very tight and fine grained states, not using requisites makes full sequence runs and while slightly easier to write, and gives much less control over the executions.

### 32.28.5 Extending External SLS Data

Sometimes a state defined in one SLS file will need to be modified from a separate SLS file. A good example of this is when an argument needs to be overwritten or when a service needs to watch an additional state.

**The Extend Declaration**

The standard way to extend is via the extend declaration. The extend declaration is a top level declaration like `include` and encapsulates ID declaration data included from other SLS files. A standard extend looks like this:

```yaml
include:
- http
- ssh
extend:
apache:
  file:
    - name: /etc/httpd/conf/httpd.conf
    - source: salt://http/httpd2.conf
sshd-server:
service:
  watch:
    - file: /etc/ssh/banner
/etc/ssh/banner:
  file.managed:
    - source: salt://ssh/banner
```

A few critical things happened here, first off the SLS files that are going to be extended are included, then the extend dec is defined. Under the extend dec 2 IDs are extended, the apache ID's file state is overwritten with a new name and source. Than the ssh server is extended to watch the banner file in addition to anything it is already watching.

**Extend is a Top Level Declaration**

This means that `extend` can only be called once in an sls, if if is used twice then only one of the extend blocks will be read. So this is WRONG:
include:
- http
- ssh

extend:
  apache:
    file:
      - name: /etc/httpd/conf/httpd.conf
      - source: salt://http/httpd2.conf
    # Second extend will overwrite the first!! Only make one
  ssh-server:
    service:
      - watch:
        - file: /etc/ssh/banner

The Requisite `in` Statement

Since one of the most common things to do when extending another SLS is to add states for a service to watch, or anything for a watcher to watch, the requisite in statement was added to 0.9.8 to make extending the watch and require lists easier. The ssh-server extend statement above could be more cleanly defined like so:

include:
- ssh

/etc/ssh/banner:
  file.managed:
    - source: salt://ssh/banner
    - watch_in:
      - service: ssh-server

Rules to Extend By

There are a few rules to remember when extending states:

1. Always include the SLS being extended with an include declaration
2. Requisites (watch and require) are appended to, everything else is overwritten
3. extend is a top level declaration, like an ID declaration, cannot be declared twice in a single SLS
4. Many IDs can be extended under the extend declaration

32.28.6 Failhard Global Option

Normally, when a state fails Salt continues to execute the remainder of the defined states and will only refuse to execute states that require the failed state.

But the situation may exist, where you would want all state execution to stop if a single state execution fails. The capability to do this is called failing hard.
State Level Failhard

A single state can have a failhard set, this means that if this individual state fails that all state execution will immediately stop. This is a great thing to do if there is a state that sets up a critical config file and setting a require for each state that reads the config would be cumbersome. A good example of this would be setting up a package manager early on:

```
/etc/yum.repos.d/company.repo:
  file.managed:
    - source: salt://company/yumrepo.conf
    - user: root
    - group: root
    - mode: 644
    - order: 1
    - failhard: True
```

In this situation, the yum repo is going to be configured before other states, and if it fails to lay down the config file, than no other states will be executed.

Global Failhard

It may be desired to have failhard be applied to every state that is executed, if this is the case, then failhard can be set in the master configuration file. Setting failhard in the master configuration file will result in failing hard when any minion gathering states from the master have a state fail.

This is NOT the default behavior, normally Salt will only fail states that require a failed state.

Using the global failhard is generally not recommended, since it can result in states not being executed or even checked. It can also be confusing to see states failhard if an admin is not actively aware that the failhard has been set.

To use the global failhard set failhard: True in the master configuration file.

32.28.7 Global State Arguments

Note: This documentation has been moved here.

32.28.8 Highstate data structure definitions

The Salt State Tree

A state tree is a collection of SLS files and directories that live under the directory specified in file_roots.

Note: Directory names or filenames in the state tree cannot contain a period, with the exception of the period in the .sls file suffix.

Top file

The main state file that instructs minions what environment and modules to use during state execution.
Configurable via `state_top`.

See also:

*A detailed description of the top file*

**Include declaration**

Defines a list of *Module reference* strings to include in this SLS.

Occurs only in the top level of the SLS data structure.

Example:

```
include:
  - edit.vim
  - http.server
```

**Module reference**

The name of a SLS module defined by a separate SLS file and residing on the Salt Master. A module named `edit.vim` is a reference to the SLS file `salt://edit/vim.sls`.

**ID declaration**

Defines an individual *highstate* component. Always references a value of a dictionary containing keys referencing *State declaration* and *Requisite declaration*. Can be overridden by a *Name declaration* or a *Names declaration*.

Occurs on the top level or under the *Extend declaration*.

Must be unique across entire state tree. If the same ID declaration is used twice, only the first one matched will be used. All subsequent ID declarations with the same name will be ignored.

---

**Note:** Naming gotchas

In Salt versions earlier than 0.9.7, ID declarations containing dots would result in unpredictable output.

---

**Extend declaration**

Extends a *Name declaration* from an included SLS module. The keys of the extend declaration always refer to an existing *ID declaration* which have been defined in included SLS modules.

Occurs only in the top level and defines a dictionary.

States cannot be extended more than once in a single state run.

Extend declarations are useful for adding-to or overriding parts of a *State declaration* that is defined in another SLS file. In the following contrived example, the shown `mywebsite.sls` file is include -ing and extend -ing the apache.sls module in order to add a watch declaration that will restart Apache whenever the Apache configuration file, `mywebsite` changes.
include:
  - apache

extend:
  apache:
    service:
      - watch:
        - file: mywebsite

mywebsite:
  file.managed:
    - name: /var/www/mysite

See also:
watch_in and require_in
Sometimes it is more convenient to use the watch_in or require_in syntax instead of extending another SLS file.

State Requisites

State declaration

A list which contains one string defining the Function declaration and any number of Function arg declaration dictionaries.

Can, optionally, contain a number of additional components like the name override components — name and names. Can also contain requisite declarations.

Occurs under an ID declaration.

Requisite declaration

A list containing requisite references.

Used to build the action dependency tree. While Salt states are made to execute in a deterministic order, this order is managed by requiring and watching other Salt states.

Occurs as a list component under a State declaration or as a key under an ID declaration.

Requisite reference

A single key dictionary. The key is the name of the referenced State declaration and the value is the ID of the referenced ID declaration.

Occurs as a single index in a Requisite declaration list.

Function declaration

The name of the function to call within the state. A state declaration can contain only a single function declaration.

For example, the following state declaration calls the installed function in the pkg state module:
The function can be declared inline with the state as a shortcut. The actual data structure is compiled to this form:

```yaml
httpd:
  pkg:
    - installed
```

Where the function is a string in the body of the state declaration. Technically when the function is declared in dot notation the compiler converts it to be a string in the state declaration list. Note that the use of the first example more than once in an ID declaration is invalid yaml.

**INVALID:**

```yaml
httpd:
  pkg.installed
  service.running
```

When passing a function without arguments and another state declaration within a single ID declaration, then the long or "standard" format needs to be used since otherwise it does not represent a valid data structure.

**VALID:**

```yaml
httpd:
  pkg.installed: []
  service.running: []
```

Occurs as the only index in the *State declaration* list.

**Function arg declaration**

A single key dictionary referencing a Python type which is to be passed to the named *Function declaration* as a parameter. The type must be the data type expected by the function.

Occurs under a *Function declaration*.

For example in the following state declaration `user`, `group`, and `mode` are passed as arguments to the `managed` function in the `file` state module:

```yaml
/etc/http/conf/http.conf:
  file.managed:
    user: root
    group: root
    mode: 644
```

**Name declaration**

Overrides the `name` argument of a *State declaration*. If `name` is not specified the *ID declaration* satisfies the `name` argument.

The name is always a single key dictionary referencing a string.

Overriding name is useful for a variety of scenarios.

For example, avoiding clashing ID declarations. The following two state declarations cannot both have `/etc/motd` as the ID declaration:
motd_perms:
    file.managed:
    - name: /etc/motd
    - mode: 644

motd_quote:
    file.append:
    - name: /etc/motd
    - text: "Of all smells, bread; of all tastes, salt."

Another common reason to override name is if the ID declaration is long and needs to be referenced in multiple places. In the example below it is much easier to specify mywebsite than to specify /etc/apache2/sites-available/mywebsite.com multiple times:

mywebsite:
    file.managed:
    - name: /etc/apache2/sites-available/mywebsite.com
    - source: salt://mywebsite.com

a2ensite mywebsite.com:
    cmd.wait:
    - unless: test -L /etc/apache2/sites-enabled/mywebsite.com
    - watch:
      - file: mywebsite

apache2:
    service.running:
    - watch:
      - file: mywebsite

**Names declaration**

Expands the contents of the containing *State declaration* into multiple state declarations, each with its own name. For example, given the following state declaration:

```
python-pkgs:
    pkg.installed:
    - names:
      - python-django
      - python-crypto
      - python-yaml
```

Once converted into the lowstate data structure the above state declaration will be expanded into the following three state declarations:

```
python-django:
    pkg.installed

python-crypto:
    pkg.installed

python-yaml:
    pkg.installed
```

Other values can be overridden during the expansion by providing an additional dictionary level.
New in version 2014.7.0.

```yaml
ius:
  pkgrepo.managed:
    - humanname: IUS Community Packages for Enterprise Linux 6 - $basearch
    - gpgcheck: 1
    - gpgkey: http://dl.iuscommunity.org/pub/ius/IUS-COMMUNITY-GPG-KEY
    - names:
        - ius
        - ius-devel:
            - baseurl: http://mirror.rackspace.com/ius/development/CentOS/6/$basearch
```

**Large example**

Here is the layout in yaml using the names of the highdata structure components.

```yaml
<Include Declaration>:
  - <Module Reference>
  - <Module Reference>

<Extend Declaration>:
<ID Declaration>:
  [overrides]

# standard declaration

<ID Declaration>:
  <State Module>:
    - <Function>
    - <Function Arg>
    - <Function Arg>
    - <Function Arg>
    - <Name>: <name>
    - <Requisite Declaration>:
        - <Requisite Reference>
        - <Requisite Reference>

# inline function and names

<ID Declaration>:
  <State Module>.<Function>:
    - <Function Arg>
    - <Function Arg>
    - <Function Arg>
    - <Names>:
        - <name>
        - <name>
        - <name>
        - <Requisite Declaration>:
            - <Requisite Reference>
            - <Requisite Reference>

# multiple states for single id

32.28. State Enforcement
32.28.9 Include and Exclude

Salt SLS files can include other SLS files and exclude SLS files that have been otherwise included. This allows for an SLS file to easily extend or manipulate other SLS files.

Include

When other SLS files are included, everything defined in the included SLS file will be added to the state run. When including define a list of SLS formulas to include:

```include:
   - http
   - libvirt```

The include statement will include SLS formulas from the same environment that the including SLS formula is in. But the environment can be explicitly defined in the configuration to override the running environment, therefore if an SLS formula needs to be included from an external environment named `dev` the following syntax is used:

```include:
   - dev: http```

NOTE: `include` does not simply inject the states where you place it in the SLS file. If you need to guarantee order of execution, consider using requisites.

Do not use dots in SLS file names or their directories

The initial implementation of `top.sls` and `Include declaration` followed the python import model where a slash is represented as a period. This means that a SLS file with a period in the name (besides the suffix period) cannot be referenced. For example, `webserver_1.0.sls` is not referenceable because `webserver_1.0` would refer to the directory/file `webserver_1/0.sls`

The same applies for any subdirectories, this is especially `tricky` when git repos are created. Another command that typically can’t render it’s output is `state.show_sls` of a file in a path that contains a dot.
Relative Include

In Salt 0.16.0, the capability to include SLS formulas which are relative to the running SLS formula was added. Simply precede the formula name with a .:

```
include:
  - .virt
  - .virt.hyper
```

In Salt 2015.8, the ability to include SLS formulas which are relative to the parents of the running SLS formula was added. In order to achieve this, precede the formula name with more than one . (dot). Much like Python’s relative import abilities, two or more leading dots represent a relative include of the parent or parents of the current package, with each . representing one level after the first.

The following SLS configuration, if placed within `example.dev.virtual`, would result in `example.http` and `base` being included respectively:

```
include:
  - ..http
  - ...base
```

Exclude

The exclude statement, added in Salt 0.10.3, allows an SLS to hard exclude another SLS file or a specific id. The component is excluded after the high data has been compiled, so nothing should be able to override an exclude.

Since the exclude can remove an id or an sls the type of component to exclude needs to be defined. An exclude statement that verifies that the running `highstate` does not contain the `http` sls and the `/etc/vimrc` id would look like this:

```
exclude:
  - sls: http
  - id: /etc/vimrc
```

Note: The current state processing flow checks for duplicate IDs before processing excludes. An error occurs if duplicate IDs are present even if one of the IDs is targeted by an `exclude`.

32.28.10 State System Layers

The Salt state system is comprised of multiple layers. While using Salt does not require an understanding of the state layers, a deeper understanding of how Salt compiles and manages states can be very beneficial.

Function Call

The lowest layer of functionality in the state system is the direct state function call. State executions are executions of single state functions at the core. These individual functions are defined in state modules and can be called directly via the `state.single` command.

```
salt '*' state.single pkg.installed name='vim'
```
Low Chunk

The low chunk is the bottom of the Salt state compiler. This is a data representation of a single function call. The low chunk is sent to the state caller and used to execute a single state function.

A single low chunk can be executed manually via the `state.low` command.

```bash
salt '*' state.low '{name: vim, state: pkg, fun: installed}'
```

The passed data reflects what the state execution system gets after compiling the data down from sls formulas.

Low State

The `Low State` layer is the list of low chunks "evaluated" in order. To see what the low state looks like for a `highstate`, run:

```bash
salt '*' state.show_lowstate
```

This will display the raw lowstate in the order which each low chunk will be evaluated. The order of evaluation is not necessarily the order of execution, since requisites are evaluated at runtime. Requisite execution and evaluation is finite; this means that the order of execution can be ascertained with 100% certainty based on the order of the low state.

High Data

High data is the data structure represented in YAML via SLS files. The High data structure is created by merging the data components rendered inside sls files (or other render systems). The High data can be easily viewed by executing the `state.show_highstate` or `state.show_sls` functions. Since this data is a somewhat complex data structure, it may be easier to read using the json, yaml, or pprint outputters:

```bash
salt '*' state.show_highstate --out yaml
salt '*' state.show_sls edit.vim --out pprint
```

SLS

Above "High Data", the logical layers are no longer technically required to be executed, or to be executed in a hierarchy. This means that how the High data is generated is optional and very flexible. The SLS layer allows for many mechanisms to be used to render sls data from files or to use the fileserver backend to generate sls and file data from external systems.

The SLS layer can be called directly to execute individual sls formulas.

Note: SLS Formulas have historically been called "SLS files". This is because a single SLS was only constituted in a single file. Now the term "SLS Formula" better expresses how a compartmentalized SLS can be expressed in a much more dynamic way by combining pillar and other sources, and the SLS can be dynamically generated.

To call a single SLS formula named `edit.vim`, execute `state.apply` and pass `edit.vim` as an argument:

```bash
salt '*' state.apply edit.vim
```
**HighState**

Calling SLS directly logically assigns what states should be executed from the context of the calling minion. The Highstate layer is used to allow for full contextual assignment of what is executed where to be tied to groups of, or individual, minions entirely from the master. This means that the environment of a minion, and all associated execution data pertinent to said minion, can be assigned from the master without needing to execute or configure anything on the target minion. This also means that the minion can independently retrieve information about its complete configuration from the master.

To execute the `highstate` use `state.apply`:

```
salt '*' state.apply
```

**Orchestrate**

The orchestrate layer expresses the highest functional layer of Salt’s automated logic systems. The Overstate allows for stateful and functional orchestration of routines from the master. The orchestrate defines in data execution stages which minions should execute states, or functions, and in what order using requisite logic.

### 32.28.11 The Orchestrate Runner

**Note:** This documentation has been moved [here](#).

### 32.28.12 Ordering States

The way in which configuration management systems are executed is a hotly debated topic in the configuration management world. Two major philosophies exist on the subject, to either execute in an imperative fashion where things are executed in the order in which they are defined, or in a declarative fashion where dependencies need to be mapped between objects.

Imperative ordering is finite and generally considered easier to write, but declarative ordering is much more powerful and flexible but generally considered more difficult to create.

Salt has been created to get the best of both worlds. States are evaluated in a finite order, which guarantees that states are always executed in the same order, and the states runtime is declarative, making Salt fully aware of dependencies via the `requisite` system.

**State Auto Ordering**

Salt always executes states in a finite manner, meaning that they will always execute in the same order regardless of the system that is executing them. But in Salt 0.17.0, the `state_auto_order` option was added. This option makes states get evaluated in the order in which they are defined in sls files, including the top.sls file.

The evaluation order makes it easy to know what order the states will be executed in, but it is important to note that the requisite system will override the ordering defined in the files, and the `order` option described below will also override the order in which states are defined in sls files.

If the classic ordering is preferred (lexicographic), then set `state_auto_order` to `False` in the master configuration file. Otherwise, `state_auto_order` defaults to `True`. 
Requisite Statements

Note: The behavior of requisites changed in version 0.9.7 of Salt. This documentation applies to requisites in version 0.9.7 and later.

Often when setting up states any single action will require or depend on another action. Salt allows for the building of relationships between states with requisite statements. A requisite statement ensures that the named state is evaluated before the state requiring it. There are three types of requisite statements in Salt, require, watch, and prereq.

These requisite statements are applied to a specific state declaration:

```
httpd:
    pkg.installed: []
    file.managed:
        - name: /etc/httpd/conf/httpd.conf
        - source: salt://httpd/httpd.conf
        - require:
            - pkg: httpd
```

In this example, the `require` requisite is used to declare that the file `/etc/httpd/conf/httpd.conf` should only be set up if the pkg state executes successfully.

The requisite system works by finding the states that are required and executing them before the state that requires them. Then the required states can be evaluated to see if they have executed correctly.

Require statements can refer to any state defined in Salt. The basic examples are `pkg`, `service`, and `file`, but any used state can be referenced.

In addition to state declarations such as pkg, file, etc., sls type requisites are also recognized, and essentially allow ‘chaining’ of states. This provides a mechanism to ensure the proper sequence for complex state formulas, especially when the discrete states are split or groups into separate sls files:

```
include:
    - network

httpd:
    pkg.installed: []
    service.running:
        - require:
            - pkg: httpd
            - sls: network
```

In this example, the httpd service running state will not be applied (i.e., the httpd service will not be started) unless both the httpd package is installed AND the network state is satisfied.

Note: Requisite matching

Requisites match on both the ID Declaration and the name parameter. Therefore, if using the pkgs or sources argument to install a list of packages in a pkg state, it’s important to note that it is impossible to match an individual package in the list, since all packages are installed as a single state.
Multiple Requisites

The requisite statement is passed as a list, allowing for the easy addition of more requisites. Both requisite types can also be separately declared:

```
httpd:
  pkg.installed: []
  service.running:
    - enable: True
    - watch:
      - file: /etc/httpd/conf/httpd.conf
    - require:
      - pkg: httpd
      - user: httpd
      - group: httpd
  file.managed:
    - name: /etc/httpd/conf/httpd.conf
    - source: salt://httpd/httpd.conf
    - require:
      - pkg: httpd
  user.present: []
  group.present: []
```

In this example, the httpd service is only going to be started if the package, user, group, and file are executed successfully.

Requisite Documentation

For detailed information on each of the individual requisites, please look here.

The Order Option

Before using the `order` option, remember that the majority of state ordering should be done with a Requisite declaration, and that a requisite declaration will override an `order` option, so a state with order option should not require or required by other states.

The order option is used by adding an order number to a state declaration with the option `order`:

```
vim:
  pkg.installed:
    - order: 1
```

By adding the order option to 1 this ensures that the vim package will be installed in tandem with any other state declaration set to the order 1.

Any state declared without an order option will be executed after all states with order options are executed.

But this construct can only handle ordering states from the beginning. Certain circumstances will present a situation where it is desirable to send a state to the end of the line. To do this, set the order to `last`:

```
vim:
  pkg.installed:
    - order: last
```
32.28.13 State Providers

New in version 0.9.8.

Salt predetermines what modules should be mapped to what uses based on the properties of a system. These determinations are generally made for modules that provide things like package and service management.

Sometimes in states, it may be necessary to use an alternative module to provide the needed functionality. For instance, an very old Arch Linux system may not be running systemd, so instead of using the systemd service module, you can revert to the default service module:

```yaml
httpd:
  service.running:
    - enable: True
    - provider: service
```

In this instance, the basic `service` module (which manages `sysvinit`-based services) will replace the `systemd` module which is used by default on Arch Linux.

This change only affects this one state though. If it is necessary to make this override for most or every service, it is better to just override the provider in the minion config file, as described [here](#).

Also, keep in mind that this only works for states with an identically-named virtual module (`pkg`, `service`, etc.).

Arbitrary Module Redirects

The provider statement can also be used for more powerful means, instead of overwriting or extending the module used for the named service an arbitrary module can be used to provide certain functionality.

```yaml
emacs:
  pkg.installed:
    - provider:
      - cmd: customcmd
```

In this example, the state is being instructed to use a custom module to invoke commands.

Arbitrary module redirects can be used to dramatically change the behavior of a given state.

32.28.14 Requisites and Other Global State Arguments

Requisites

The Salt requisite system is used to create relationships between states. The core idea being that, when one state is dependent somehow on another, that inter-dependency can be easily defined. These dependencies are expressed by declaring the relationships using state names and ID’s or names. The generalized form of a requisite target is `<state name> : <ID or name>`. The specific form is defined as a Requisite Reference.

Requisites come in two types: Direct requisites (such as `require`), and requisite_ins (such as `require_in`). The relationships are directional: a direct requisite requires something from another state. However, a requisite_in inserts a requisite into the targeted state pointing to the targeting state. The following example demonstrates a direct requisite:

```yaml
vim:
  pkg.installed: []

/etc/vimrc:
  file.managed:
```
In the example above, the file /etc/vimrc depends on the vim package.

Requisite_in statements are the opposite. Instead of saying "I depend on something", requisite_ins say "Someone depends on me":

```yaml
vim:
  pkg.installed:
    - require_in:
      - file: /etc/vimrc

/etc/vimrc:
  file.managed:
    - source: salt://edit/vimrc
```

So here, with a requisite_in, the same thing is accomplished as in the first example, but the other way around. The vim package is saying "/etc/vimrc depends on me". This will result in a require being inserted into the /etc/vimrc state which targets the vim state.

In the end, a single dependency map is created and everything is executed in a finite and predictable order.

**Note:** Requisite matching

Requisites match on both the ID Declaration and the name parameter. This means that, in the example above, the require_in requisite would also have been matched if the /etc/vimrc state was written as follows:

```yaml
vimrc:
  file.managed:
    - name: /etc/vimrc
    - source: salt://edit/vimrc
```

**Direct Requisite and Requisite_in types**

There are several direct requisite statements that can be used in Salt:

- `require`
- `watch`
- `prereq`
- `use`
- `onchanges`
- `onfail`

Each direct requisite also has a corresponding requisite_in:

- `require_in`
- `watch_in`
- `prereq_in`
- `use_in`
- onchanges_in
- onfail_in

All of the requisites define specific relationships and always work with the dependency logic defined above.

**require**

The use of `require` demands that the dependent state executes before the depending state. The state containing the `require` requisite is defined as the depending state. The state specified in the `require` statement is defined as the dependent state. If the dependent state's execution succeeds, the depending state will then execute. If the dependent state's execution fails, the depending state will not execute. In the first example above, the file `/etc/vimrc` will only execute after the vim package is installed successfully.

**Require an entire sls file**

As of Salt 0.16.0, it is possible to require an entire sls file. Do this first by including the sls file and then setting a state to `require` the included sls file:

```yaml
include:
 - foo

bar:
 pkg.installed:
   - require:
     - sls: foo
```

**watch**

**Watch statements** are used to add additional behavior when there are changes in other states.

**Note:** If a state should only execute when another state has changes, and otherwise do nothing, the new `on-changes` requisite should be used instead of `watch`. `watch` is designed to add additional behavior when there are changes, but otherwise execute normally.

The state containing the `watch` requisite is defined as the watching state. The state specified in the `watch` statement is defined as the watched state. When the watched state executes, it will return a dictionary containing a key named `'changes'`. Here are two examples of state return dictionaries, shown in json for clarity:

```json
"local": {
   "file_|-/tmp/foo_|-/tmp/foo_|-directory": {
      "comment": "Directory /tmp/foo updated",
      "__run_num__": 0,
      "changes": {
         "user": "bar"
      },
      "name": "/tmp/foo",
      "result": true
   }
}
"local": {

```
If the "result" of the watched state is True, the watching state will execute normally. This part of watch mirrors the functionality of the require requisite. If the "result" of the watched state is False, the watching state will never run, nor will the watching state's mod_watch function execute.

However, if the "result" of the watched state is True, and the "changes" key contains a populated dictionary (changes occurred in the watched state), then the watch requisite can add additional behavior. This additional behavior is defined by the mod_watch function within the watching state module. If the mod_watch function exists in the watching state module, it will be called in addition to the normal watching state. The return data from the mod_watch function is what will be returned to the master in this case; the return data from the main watching function is discarded.

If the "changes" key contains an empty dictionary, the watch requisite acts exactly like the require requisite (the watching state will execute if "result" is True, and fail if "result" is False in the watched state).

Note: Not all state modules contain mod_watch. If mod_watch is absent from the watching state module, the watch requisite behaves exactly like a require requisite.

A good example of using watch is with a service.running state. When a service watches a state, then the service is reloaded/restarted when the watched state changes, in addition to Salt ensuring that the service is running.

```
ntpd:
  service.running:
    - watch:
      - file: /etc/ntp.conf
  file.managed:
    - name: /etc/ntp.conf
    - source: salt://ntp/files/ntp.conf
```

prereq

New in version 0.16.0.

prereq allows for actions to be taken based on the expected results of a state that has not yet been executed. The state containing the prereq requisite is defined as the pre-requiring state. The state specified in the prereq statement is defined as the pre-required state.

When a prereq requisite is evaluated, the pre-required state reports if it expects to have any changes. It does this by running the pre-required single state as a test-run by enabling test=True. This test-run will return a dictionary containing a key named "changes". (See the watch section above for examples of "changes" dictionaries.)

If the "changes" key contains a populated dictionary, it means that the pre-required state expects changes to occur when the state is actually executed, as opposed to the test-run. The pre-requiring state will now actually run. If the pre-requiring state executes successfully, the pre-required state will then execute. If the pre-requiring state fails, the pre-required state will not execute.
If the "changes" key contains an empty dictionary, this means that changes are not expected by the pre-required state. Neither the pre-required state nor the pre-requiring state will run.

The best way to define how `prereq` operates is displayed in the following practical example: When a service should be shut down because underlying code is going to change, the service should be off-line while the update occurs. In this example, `graceful-down` is the pre-requiring state and `site-code` is the pre-required state.

```yaml
graceful-down:
  cmd.run:
    - name: service apache graceful
    - prereq:
      - file: site-code

site-code:
  file.recurse:
    - name: /opt/site_code
    - source: salt://site/code
```

In this case the apache server will only be shutdown if the site-code state expects to deploy fresh code via the file.recurse call. The site-code deployment will only be executed if the graceful-down run completes successfully.

### onfail

New in version 2014.7.0.

The `onfail` requisite allows for reactions to happen strictly as a response to the failure of another state. This can be used in a number of ways, such as executing a second attempt to set up a service or begin to execute a separate thread of states because of a failure.

The `onfail` requisite is applied in the same way as `require` as `watch`:

```yaml
primary_mount:
  mount.mounted:
    - name: /mnt/share
    - device: 10.0.0.45:/share
    - fstype: nfs

backup_mount:
  mount.mounted:
    - name: /mnt/share
    - device: 192.168.40.34:/share
    - fstype: nfs
    - onfail:
      - mount: primary_mount
```

### onchanges

New in version 2014.7.0.

The `onchanges` requisite makes a state only apply if the required states generate changes, and if the watched state's "result" is True. This can be a useful way to execute a post hook after changing aspects of a system.

If a state has multiple `onchanges` requisites then the state will trigger if any of the watched states changes.

**Note:** One easy-to-make mistake is to use `onchanges_in` when `onchanges` is supposed to be used. For example, the below configuration is not correct:
myservice:
  pkg.installed:
    - name: myservice
  file.managed:
    - name: /etc/myservice/myservice.conf
    - source: salt://myservice/files/myservice.conf
    - mode: 600
  cmd.run:
    - name: /usr/libexec/myservice/post-changes-hook.sh
    - onchanges_in:
      - file: /etc/myservice/myservice.conf

This will set up a requisite relationship in which the cmd.run state always executes, and the file.managed state only executes if the cmd.run state has changes (which it always will, since the cmd.run state includes the command results as changes).

It may semantically seem like the the cmd.run state should only run when there are changes in the file state, but remember that requisite relationships involve one state watching another state, and a requisite_in does the opposite: it forces the specified state to watch the state with the requisite_in.

The correct usage would be:

myservice:
  pkg.installed:
    - name: myservice
  file.managed:
    - name: /etc/myservice/myservice.conf
    - source: salt://myservice/files/myservice.conf
    - mode: 600
  cmd.run:
    - name: /usr/libexec/myservice/post-changes-hook.sh
    - onchanges:
      - file: /etc/myservice/myservice.conf

use

The use requisite is used to inherit the arguments passed in another id declaration. This is useful when many files need to have the same defaults.

/etc/foo.conf:
  file.managed:
    - source: salt://foo.conf
    - template: jinja
    - mkdirs: True
    - user: apache
    - group: apache
    - mode: 755

/etc/bar.conf
  file.managed:
    - source: salt://bar.conf
    - use:
      - file: /etc/foo.conf
The `use` statement was developed primarily for the networking states but can be used on any states in Salt. This makes sense for the networking state because it can define a long list of options that need to be applied to multiple network interfaces.

The `use` statement does not inherit the requisites arguments of the targeted state. This means also a chain of `use` requisites would not inherit inherited options.

**The _in versions of requisites**

All of the requisites also have corresponding requisite_in versions, which do the reverse of their normal counterparts. The examples below all use `require_in` as the example, but note that all of the `_in` requisites work the same way: They result in a normal requisite in the targeted state, which targets the state which has defines the requisite_in. Thus, a `require_in` causes the target state to `require` the targeting state. Similarly, a `watch_in` causes the target state to `watch` the targeting state. This pattern continues for the rest of the requisites.

If a state declaration needs to be required by another state declaration then `require_in` can accommodate it. Therefore, these two sls files would be the same in the end:

Using `require`

```
httpd:
  pkg.installed: [ ]
  service.running:
    - require:
      - pkg: httpd
```

Using `require_in`

```
httpd:
  pkg.installed:
    - require_in:
      - service: httpd

service.running: [ ]
```

The `require_in` statement is particularly useful when assigning a require in a separate sls file. For instance it may be common for `httpd` to require components used to set up PHP or mod_python, but the HTTP state does not need to be aware of the additional components that require it when it is set up:

```
http.sls

httpd:
  pkg.installed: [ ]
  service.running:
    - require:
      - pkg: httpd
```

```
php.sls

include:
  - http

php:
  pkg.installed:
    - require_in:
      - service: httpd
```

```
mod_python.sls
```
Now the httpd server will only start if php or mod_python are first verified to be installed. Thus allowing for a requisite to be defined `after the fact`.

**Fire Event Notifications**

New in version 2015.8.0.

The `fire_event` option in a state will cause the minion to send an event to the Salt Master upon completion of that individual state.

The following example will cause the minion to send an event to the Salt Master with a tag of `salt/state_result/201505051215176431/dasalt/nano` and the result of the state will be the data field of the event. Notice that the `name` of the state gets added to the tag.

```
nano_stuff:
  pkg.installed:
    - name: nano
    - fire_event: True
```

In the following example instead of setting `fire_event` to `True`, `fire_event` is set to an arbitrary string, which will cause the event to be sent with this tag: `salt/state_result/20150505121725642845/dasalt/custom/tag/nano/finished`

```
nano_stuff:
  pkg.installed:
    - name: nano
    - fire_event: custom/tag/nano/finished
```

**Altering States**

The state altering system is used to make sure that states are evaluated exactly as the user expects. It can be used to double check that a state preformed exactly how it was expected to, or to make 100% sure that a state only runs under certain conditions. The use of unless or onlyif options help make states even more stateful. The check_cmds option helps ensure that the result of a state is evaluated correctly.

**Reload**

`reload_modules` is a boolean option that forces salt to reload its modules after a state finishes. `reload_pillar` and `reload_grains` can also be set. See *Reloading Modules*.

**Unless**

New in version 2014.7.0.
The `unless` requisite specifies that a state should only run when any of the specified commands return `False`. The `unless` requisite operates as NAND and is useful in giving more granular control over when a state should execute.

**NOTE:** Under the hood `unless` calls `cmd.retcode` with `python_shell=True`. This means the commands referenced by `unless` will be parsed by a shell, so beware of side-effects as this shell will be run with the same privileges as the salt-minion. Also be aware that the boolean value is determined by the shell's concept of `True` and `False`, rather than Python's concept of `True` and `False`.

```yaml
vim:
  pkg.installed:
    - unless:
      - rpm -q vim-enhanced
      - ls /usr/bin/vim
```

In the example above, the state will only run if either the vim-enhanced package is not installed (returns `False`) or if `/usr/bin/vim` does not exist (returns `False`). The state will run if both commands return `False`.

However, the state will not run if both commands return `True`.

Unless checks are resolved for each name to which they are associated.

For example:

```yaml
deploy_app:
  cmd.run:
    - names:
      - first_deploy_cmd
      - second_deploy_cmd
    - unless: ls /usr/bin/vim
```

In the above case, `some_check` will be run prior to _each_ name -- once for `first_deploy_cmd` and a second time for `second_deploy_cmd`.

### Onlyif

**New in version 2014.7.0.**

The `onlyif` requisite specifies that if each command listed in `onlyif` returns `True`, then the state is run. If any of the specified commands return `False`, the state will not run.

**NOTE:** Under the hood `onlyif` calls `cmd.retcode` with `python_shell=True`. This means the commands referenced by `onlyif` will be parsed by a shell, so beware of side-effects as this shell will be run with the same privileges as the salt-minion. Also be aware that the boolean value is determined by the shell's concept of `True` and `False`, rather than Python's concept of `True` and `False`.

```yaml
stop-volume:
  module.run:
    - name: glusterfs.stop_volume
    - m_name: work
    - onlyif:
      - gluster volume status work
      - order: 1

remove-volume:
  module.run:
    - name: glusterfs.delete
    - m_name: work
```
The above example ensures that the stop_volume and delete modules only run if the gluster commands return a 0 ret value.

Listen/Listen_in

New in version 2014.7.0.

listen and its counterpart listen_in trigger mod_wait functions for states, when those states succeed and result in changes, similar to how watch its counterpart watch_in. Unlike watch and watch_in, listen, and listen_in will not modify the order of states and can be used to ensure your states are executed in the order they are defined. All listen/listen_in actions will occur at the end of a state run, after all states have completed.

```
restart-apache2:
    - service.running:
      - name: apache2
      - listen:
        - file: /etc/apache2/apache2.conf

configure-apache2:
    - file.managed:
      - name: /etc/apache2/apache2.conf
      - source: salt://apache2/apache2.conf
```

This example will cause apache2 to be restarted when the apache2.conf file is changed, but the apache2 restart will happen at the end of the state run.

```
restart-apache2:
    - service.running:
      - name: apache2

configure-apache2:
    - file.managed:
      - name: /etc/apache2/apache2.conf
      - source: salt://apache2/apache2.conf
      - listen_in:
        - service: apache2
```

This example does the same as the above example, but puts the state argument on the file resource, rather than the service resource.

check_cmd

New in version 2014.7.0.

Check Command is used for determining that a state did or did not run as expected.

NOTE: Under the hood check_cmd calls cmd.retcode with python_shell=True. This means the commands referenced by unless will be parsed by a shell, so beware of side-effects as this shell will be run with the same privileges as the salt-minion.
comment-repo:
  file.replace:
    - name: /etc/yum.repos.d/fedora.repo
    - pattern: ^enabled=0
    - repl: enabled=1
    - check_cmd:
      - grep 'enabled=0' /etc/yum.repos.d/fedora.repo && return 1 || return 0

This will attempt to do a replace on all enabled=0 in the .repo file, and replace them with enabled=1. The check_cmd is just a bash command. It will do a grep for enabled=0 in the file, and if it finds any, it will return a 0, which will prompt the && portion of the command to return a 1, causing check_cmd to set the state as failed. If it returns a 1, meaning it didn't find any `enabled=0' it will hit the || portion of the command, returning a 0, and declaring the function succeeded.

Overriding Checks

There are two commands used for the above checks.

mod_run_check is used to check for onlyif and unless. If the goal is to override the global check for these to variables, include a mod_run_check in the salt/states/ file.

mod_run_check_cmd is used to check for the check_cmd options. To override this one, include a mod_run_check_cmd in the states file for the state.

32.28.15 Startup States

Sometimes it may be desired that the salt minion execute a state run when it is started. This alleviates the need for the master to initiate a state run on a new minion and can make provisioning much easier.

As of Salt 0.10.3 the minion config reads options that allow for states to be executed at startup. The options are startup_states, sls_list, and top_file.

The startup_states option can be passed one of a number of arguments to define how to execute states. The available options are:

    highstate Execute state.apply
    sls Read in the sls_list option and execute the named sls files
    top Read in the top_file option and execute states based on that top file on the Salt Master

Examples:

Execute state.apply to run the highstate when starting the minion:

startup_states: highstate

Execute the sls files edit.vim and hyper:

startup_states: sls

sls_list:
    - edit.vim
    - hyper
32.28.16 State Testing

Executing a Salt state run can potentially change many aspects of a system and it may be desirable to first see what a state run is going to change before applying the run.

Salt has a test interface to report on exactly what will be changed, this interface can be invoked on any of the major state run functions:

```
salt '*' state.apply test=True
salt '*' state.apply mysls test=True
salt '*' state.single test=True
```

The test run is mandated by adding the test=True option to the states. The return information will show states that will be applied in yellow and the result is reported as None.

Default Test

If the value test is set to True in the minion configuration file then states will default to being executed in test mode. If this value is set then states can still be run by calling test=False:

```
salt '*' state.apply test=False
salt '*' state.apply mysls test=False
salt '*' state.single test=False
```

32.28.17 The Top File

Introduction

Most infrastructures are made up of groups of machines, each machine in the group performing a role similar to others. Those groups of machines work in concert with each other to create an application stack.

To effectively manage those groups of machines, an administrator needs to be able to create roles for those groups. For example, a group of machines that serve front-end web traffic might have roles which indicate that those machines should all have the Apache webserver package installed and that the Apache service should always be running.

In Salt, the file which contains a mapping between groups of machines on a network and the configuration roles that should be applied to them is called a top file.

Top files are named top.sls by default and they are so-named because they always exist in the ```top``` of a directory hierarchy that contains state files. That directory hierarchy is called a state tree.

A Basic Example

Top files have three components:

- Environment: A state tree directory containing a set of state files to configure systems.
- Target: A grouping of machines which will have a set of states applied to them.
- State files: A list of state files to apply to a target. Each state file describes one or more states to be configured and enforced on the targeted machines.

The relationship between these three components is nested as follows:

- Environments contain targets
- Targets contain states
Putting these concepts together, we can describe a scenario in which all minions with an ID that begins with web have an apache state applied to them:

```
base:          # Apply SLS files from the directory root for the 'base' environment
  'web*':      # All minions with a minion_id that begins with 'web'
    - apache   # Apply the state file named 'apache.sls'
```

## Environments

Environments are directory hierarchies which contain a top files and a set of state files.

Environments can be used in many ways, however there is no requirement that they be used at all. In fact, the most common way to deploy Salt is with a single environment, called base. It is recommended that users only create multiple environments if they have a use case which specifically calls for multiple versions of state trees.

### Getting Started with Top Files

Each environment is defined inside a salt master configuration variable called, `file_roots`.

In the most common single-environment setup, only the base environment is defined in `file_roots` along with only one directory path for the state tree.

```
file_roots:
  base:
    - /srv/salt
```

In the above example, the top file will only have a single environment to pull from.

Next is a simple single-environment top file placed in `/srv/salt/top.sls`, illustrating that for the environment called base, all minions will have the state files named core.sls and edit.sls applied to them.

```
base:
  '*':
    - core
    - edit
```

Assuming the `file_roots` configuration from above, Salt will look in the `/srv/salt` directory for core.sls and edit.sls.

### Multiple Environments

In some cases, teams may wish to create versioned state trees which can be used to test Salt configurations in isolated sets of systems such as a staging environment before deploying states into production.

For this case, multiple environments can be used to accomplish this task.

To create multiple environments, the `file_roots` option can be expanded:

```
file_roots:
  dev:
    - /srv/salt/dev
  qa:
    - /srv/salt/qa
  prod:
    - /srv/salt/prod
```
In the above, we declare three environments: dev, qa and prod. Each environment has a single directory assigned to it.

Our top file references the environments:

```plaintext
dev:
  'webserver*':
    - webserver
  'db*':
    - db
qa:
  'webserver*':
    - webserver
  'db*':
    - db
prod:
  'webserver*':
    - webserver
  'db*':
    - db
```

As seen above, the top file now declares the three environments and for each, targets are defined to map globs of minion IDs to state files. For example, all minions which have an ID beginning with the string webserver will have the webserver state from the requested environment assigned to it.

In this manner, a proposed change to a state could first be made in a state file in `/srv/salt/dev` and then be applied to development webservers before moving the state into QA by copying the state file into `/srv/salt/qa`.

Choosing an Environment to Target

The top file is used to assign a minion to an environment unless overridden using the methods described below. The environment in the top file must match valid fileserver environment (a.k.a. saltenv) in order for any states to be applied to that minion. When using the default fileserver backend, environments are defined in `file_roots`.

The states that will be applied to a minion in a given environment can be viewed using the `state.show_top` function.

Minions may be pinned to a particular environment by setting the `environment` value in the minion configuration file. In doing so, a minion will only request files from the environment to which it is assigned.

The environment may also be dynamically selected at runtime by passing it to the `salt`, `salt-call` or `salt-ssh` command. This is most commonly done with functions in the `state` module by using the `saltenv` argument. For example, to run a `highstate` on all minions, using only the top file and SLS files in the `prod` environment, run: `salt '*' state.highstate saltenv=prod`.

Note: Not all functions accept `saltenv` as an argument, see the documentation for an individual function documentation to verify.

Shorthand

If you assign only one SLS to a system, as in this example, a shorthand is also available:

```plaintext
base:
  '*': global
dev:
```

32.28. State Enforcement
Advanced Minion Targeting

In addition to globs, minions can be specified in top files a few other ways. Some common ones are **compound matches** and **node groups**.

Below is a slightly more complex top file example, showing the different types of matches you can perform:

```bash
# All files will be taken from the file path specified in the base
# environment in the ```file_roots``` configuration value.

base:
  # All minions get the following three state files applied
  '*':
    - ldap-client
    - networking
    - salt.minion

  # All minions which have an ID that begins with the phrase
  # 'salt-master' will have an SLS file applied that is named
  # 'master.sls' and is in the 'salt' directory, underneath
  # the root specified in the ```base``` environment in the
  # configuration value for ```file_roots```
  'salt-master*':
    - salt.master

  # Minions that have an ID matching the following regular
  # expression will have the state file called 'web.sls' in the
  # nagios/mon directory applied. Additionally, minions matching
  # the regular expression will also have the 'server.sls' file
  # in the apache/ directory applied.
  # NOTE!
  #
  # Take note of the 'match' directive here, which tells Salt
  # to treat the target string as a regex to be matched!
  #^\(memcache|web\).(qa|prod).loc$':
    - match: pcre
    - nagios.mon.web
    - apache.server

  # Minions that have a grain set indicating that they are running
  # the Ubuntu operating system will have the state file called
  # 'ubuntu.sls' in the 'repos' directory applied.
  #
  # Again take note of the 'match' directive here which tells
```
# Salt to match against a grain instead of a minion ID.

'os:Ubuntu':
  - match: grain
  - repos.ubuntu

# Minions that are either RedHat or CentOS should have the 'epel.sls' state applied, from the 'repos/' directory.

'os:(RedHat|CentOS)'
  - match: grain_pcre
  - repos.epel

# The three minions with the IDs of 'foo', 'bar' and 'baz' should have 'database.sls' applied.

'foo,bar,baz':
  - match: list
  - database

# Any minion for which the pillar key 'somekey' is set and has a value of that key matching 'abc' will have the 'xyz.sls' state applied.

'somekey:abc':
  - match: pillar
  - xyz

# All minions which begin with the strings 'nag1' or any minion with a grain set called 'role' with the value of 'monitoring' will have the 'server.sls' state file applied from the 'nagios/' directory.

'nag1*' or G@role:monitoring':
  - match: compound
  - nagios.server

How Top Files Are Compiled

When a highstate is executed and an environment is specified (either using the environment config option or by passing the saltenv when executing the highstate), then that environment's top file is the only top file used to assign states to minions, and only states from the specified environment will be run.

The remainder of this section applies to cases in which a highstate is executed without an environment specified.

With no environment specified, the minion will look for a top file in each environment, and each top file will be processed to determine the SLS files to run on the minions. By default, the top files from each environment will be merged together. In configurations with many environments, such as with GitFS where each branch and tag is treated as a distinct environment, this may cause unexpected results as SLS files from older tags cause defunct SLS files to be included in the highstate. In cases like this, it can be helpful to set top_file_merging_strategy to same to force each environment to use its own top file.

top_file_merging_strategy: same

Another option would be to set state_top_saltenv to a specific environment, to ensure that any top files in other environments are disregarded:
state_top_saltenv: base

With GitFS, it can also be helpful to simply manage each environment's top file separately, and/or manually specify the environment when executing the highstate to avoid any complicated merging scenarios. `gitfs_env_whitelist` and `gitfs_env_blacklist` can also be used to hide unneeded branches and tags from GitFS to reduce the number of top files in play.

When using multiple environments, it is not necessary to create a top file for each environment. The easiest-to-maintain approach is to use a single top file placed in the base environment. This is often infeasible with GitFS though, since branching/tagging can easily result in extra top files. However, when only the default (roots) file-server backend is used, a single top file in the base environment is the most common way of configuring a highstate.

The following minion configuration options affect how top files are compiled when no environment is specified:

- `state_top_saltenv`
- `top_file_merging_strategy`
- `env_order`
- `default_top`

**Top File Compilation Examples**

For the scenarios below, assume the following configuration:

/etc/salt/master:

```yaml
file_roots:
  base:
    - /srv/salt/base
  dev:
    - /srv/salt/dev
  qa:
    - /srv/salt/qa
```

/srv/salt/base/top.sls:

```yaml
base:
  '*':
    - base1
dev:
  '*':
    - dev1
qa:
  '*':
    - qa1
```

/srv/salt/dev/top.sls:

```yaml
base:
  'minion1':
    - base2
dev:
  'minion2':
    - dev2
qa:
  '*':
    - qa2
```
Note: For the purposes of these examples, there is no top file in the qa environment.

Scenario 1 - dev Environment Specified

In this scenario, the highstate was either invoked with saltenv=dev or the minion has environment: dev set in the minion config file. The result will be that only the dev2 SLS from the dev environment will be part of the highstate, and it will be applied to minion2, while minion1 will have no states applied to it.

If the base environment were specified, the result would be that only the base1 SLS from the base environment would be part of the highstate, and it would be applied to all minions.

If the qa environment were specified, the highstate would exit with an error.

Scenario 2 - No Environment Specified, top_file_merging_strategy is `merge`

In this scenario, assuming that the base environment's top file was evaluated first, the base1, dev1, and qa1 states would be applied to all minions. If, for instance, the qa environment is not defined in /srv/salt/base/top.sls, then because there is no top file for the qa environment, no states from the qa environment would be applied.

Scenario 3 - No Environment Specified, top_file_merging_strategy is `same`

Changed in version Carbon: In prior versions, `same` did not quite work as described below (see here). This has now been corrected. It was decided that changing something like top file handling in a point release had the potential to unexpectedly impact users’ top files too much, and it would be better to make this correction in a feature release.

In this scenario, base1 from the base environment is applied to all minions. Additionally, dev2 from the dev environment is applied to minion2.

If default_top is unset (or set to base, which happens to be the default), then qa1 from the qa environment will be applied to all minions. If default_top were set to dev, then qa2 from the qa environment would be applied to all minions.

32.28.18 SLS Template Variable Reference

The template engines available to sls files and file templates come loaded with a number of context variables. These variables contain information and functions to assist in the generation of templates. See each variable below for its availability -- not all variables are available in all templating contexts.

Salt

The salt variable is available to abstract the salt library functions. This variable is a python dictionary containing all of the functions available to the running salt minion. It is available in all salt templates.

```
{% for file in salt["cmd.run"]("ls -1 /opt/to_remove").splitlines() %}
  /opt/to_remove/{{ file }}:
    file.absent
{% endfor %}
```
Opts

The *opts* variable abstracts the contents of the minion's configuration file directly to the template. The *opts* variable is a dictionary. It is available in all templates.

```python
{{ opts['cachedir'] }}
```

The `config.get` function also searches for values in the *opts* dictionary.

Pillar

The *pillar* dictionary can be referenced directly, and is available in all templates:

```python
{{ pillar['key'] }}
```

Using the `pillar.get` function via the *salt* variable is generally recommended since a default can be safely set in the event that the value is not available in pillar and dictionaries can be traversed directly:

```python
{{ salt['pillar.get']('key', 'failover_value') }}
{{ salt['pillar.get']('stuff:more:deeper') }}
```

Grains

The *grains* dictionary makes the minion's grains directly available, and is available in all templates:

```python
{{ grains['os'] }}
```

The `grains.get` function can be used to traverse deeper grains and set defaults:

```python
{{ salt['grains.get']('os') }}
```

saltenv

The *saltenv* variable is available in only in sls files when gathering the sls from an environment.

```python
{{ saltenv }}
```

sls

The *sls* variable contains the sls reference value, and is only available in the actual SLS file (not in any files referenced in that SLS). The sls reference value is the value used to include the sls in top files or via the include option.

```python
{{ sls }}
```

slspath

The *slspath* variable contains the path to the current sls file. The value of *slspath* in files referenced in the current sls depends on the reference method. For jinja includes *slspath* is the path to the current file. For salt includes *slspath* is the path to the included file.
32.28.19 State Modules

State Modules are the components that map to actual enforcement and management of Salt states.

States are Easy to Write!

State Modules should be easy to write and straightforward. The information passed to the SLS data structures will map directly to the states modules.

Mapping the information from the SLS data is simple, this example should illustrate:

```
/etc/salt/master:  # maps to "name"
file.managed:    # maps to <filename>..<function> - e.g. "managed" in https://github.com/saltstack/salt/tree/develop/salt/states/file.py
  - user: root  # one of many options passed to the manage function
  - group: root
  - mode: 644
  - source: salt://salt/master
```

Therefore this SLS data can be directly linked to a module, function, and arguments passed to that function.

This does issue the burden, that function names, state names and function arguments should be very human readable inside state modules, since they directly define the user interface.

Keyword Arguments

Salt passes a number of keyword arguments to states when rendering them, including the environment, a unique identifier for the state, and more. Additionally, keep in mind that the requisites for a state are part of the keyword arguments. Therefore, if you need to iterate through the keyword arguments in a state, these must be considered and handled appropriately. One such example is in the `pkgrepo.managed` state, which needs to be able to handle arbitrary keyword arguments and pass them to module execution functions. An example of how these keyword arguments can be handled can be found here.

Using Custom State Modules

Place your custom state modules inside a `_states` directory within the `file_roots` specified by the master config file. These custom state modules can then be distributed in a number of ways. Custom state modules are distributed when `state.apply` is run, or by executing the `saltutil.sync_states` or `saltutil.sync_all` functions.

Any custom states which have been synced to a minion, that are named the same as one of Salt's default set of states, will take the place of the default state with the same name. Note that a state's default name is its filename (i.e. `foo.py` becomes state `foo`), but that its name can be overridden by using a `__virtual__` function.

Cross Calling Execution Modules from States

As with Execution Modules, State Modules can also make use of the `__salt__` and `__grains__` data. See `cross calling execution modules`.
It is important to note that the real work of state management should not be done in the state module unless it is needed. A good example is the pkg state module. This module does not do any package management work, it just calls the pkg execution module. This makes the pkg state module completely generic, which is why there is only one pkg state module and many backend pkg execution modules.

On the other hand some modules will require that the logic be placed in the state module, a good example of this is the file module. But in the vast majority of cases this is not the best approach, and writing specific execution modules to do the backend work will be the optimal solution.

Cross Calling State Modules

All of the Salt state modules are available to each other and state modules can call functions available in other state modules.

The variable __states__ is packed into the modules after they are loaded into the Salt minion.

The __states__ variable is a Python dictionary containing all of the state modules. Dictionary keys are strings representing the names of the modules and the values are the functions themselves.

Salt state modules can be cross-called by accessing the value in the __states__ dict:

```
ret = __states__['file.managed']('name=/tmp/myfile', source='salt://myfile')
```

This code will call the managed function in the file state module and pass the arguments name and source to it.

Return Data

A State Module must return a dict containing the following keys/values:

- **name**: The same value passed to the state as ```name```.
- **changes**: A dict describing the changes made. Each thing changed should be a key, with its value being another dict with keys called ```old``` and ```new``` containing the old/new values. For example, the pkg state's changes dict has one key for each package changed, with the ```old``` and ```new``` keys in its sub-dict containing the old and new versions of the package. For example, the final changes dictionary for this scenario would look something like this:

  ```
  ret['changes'].update({'my_pkg_name': {'old': '', 'new': 'my_pkg_name-1.0'}})
  ```

- **result**: A tristate value. True if the action was successful, False if it was not, or None if the state was run in test mode, ```test=True```, and changes would have been made if the state was not run in test mode.

<table>
<thead>
<tr>
<th></th>
<th>live mode</th>
<th>test mode</th>
</tr>
</thead>
<tbody>
<tr>
<td>no changes</td>
<td>True</td>
<td>True</td>
</tr>
<tr>
<td>successful changes</td>
<td>True</td>
<td>None</td>
</tr>
<tr>
<td>failed changes</td>
<td>False</td>
<td>None</td>
</tr>
</tbody>
</table>

**Note**: Test mode does not predict if the changes will be successful or not.

- **comment**: A string containing a summary of the result.

Test State

All states should check for and support ```test``` being passed in the options. This will return data about what changes would occur if the state were actually run. An example of such a check could look like this:
# Return comment of changes if test.

```python
if __opts__['test']:
    ret['result'] = None
    ret['comment'] = 'State Foo will execute with param {0}'.format(bar)
    return ret
```

Make sure to test and return before performing any real actions on the minion.

**Note:** Be sure to refer to the `result` table listed above and displaying any possible changes when writing support for `test`. Looking for changes in a state is essential to `test=true` functionality. If a state is predicted to have no changes when `test=true` (or `test: true` in a config file) is used, then the result of the final state **should not** be `None`.

**Watcher Function**

If the state being written should support the watch requisite then a watcher function needs to be declared. The watcher function is called whenever the watch requisite is invoked and should be generic to the behavior of the state itself.

The watcher function should accept all of the options that the normal state functions accept (as they will be passed into the watcher function).

A watcher function typically is used to execute state specific reactive behavior, for instance, the watcher for the service module restarts the named service and makes it useful for the watcher to make the service react to changes in the environment.

The watcher function also needs to return the same data that a normal state function returns.

**Mod_init Interface**

Some states need to execute something only once to ensure that an environment has been set up, or certain conditions global to the state behavior can be predefined. This is the realm of the mod_init interface.

A state module can have a function called `mod_init` which executes when the first state of this type is called. This interface was created primarily to improve the pkg state. When packages are installed the package metadata needs to be refreshed, but refreshing the package metadata every time a package is installed is wasteful. The mod_init function for the pkg state sets a flag down so that the first, and only the first, package installation attempt will refresh the package database (the package database can of course be manually called to refresh via the `refresh` option in the pkg state).

The mod_init function must accept the Low State Data for the given executing state as an argument. The low state data is a dict and can be seen by executing the state.show_lowstate function. Then the mod_init function must return a bool. If the return value is True, then the mod_init function will not be executed again, meaning that the needed behavior has been set up. Otherwise, if the mod_init function returns False, then the function will be called the next time.

A good example of the mod_init function is found in the pkg state module:

```python
def mod_init(low):
    '''
    Refresh the package database here so that it only needs to happen once
    '''
    if low['fun'] == 'installed' or low['fun'] == 'latest':
        rtag = __gen_rtag()
```
The `mod_init` function in the pkg state accepts the low state data as `low` and then checks to see if the function being called is going to install packages, if the function is not going to install packages then there is no need to refresh the package database. Therefore if the package database is prepared to refresh, then return `True` and the `mod_init` will not be called the next time a pkg state is evaluated, otherwise return `False` and the `mod_init` will be called next time a pkg state is evaluated.

Log Output

You can call the logger from custom modules to write messages to the minion logs. The following code snippet demonstrates writing log messages:

```python
import logging

log = logging.getLogger(__name__)

log.info('Here is Some Information')
log.warning('You Should Not Do That')
log.error('It Is Busted')
```

Full State Module Example

The following is a simplistic example of a full state module and function. Remember to call out to execution modules to perform all the real work. The state module should only perform "before" and "after" checks.

1. Make a custom state module by putting the code into a file at the following path: `/srv/salt/_states/my_custom_state.py`.
2. Distribute the custom state module to the minions: `salt '*' saltutil.sync_states`
3. Write a new state to use the custom state by making a new state file, for instance `/srv/salt/my_custom_state.sls`.
4. Add the following SLS configuration to the file created in Step 3:

```yaml
human_friendly_state_id: # An arbitrary state ID declaration.
  my_custom_state: # The custom state module name.
    - enforce_custom_thing # The function in the custom state module.
      - name: a_value # Maps to the "name" parameter in the custom function.
      - foo: Foo # Specify the required "foo" parameter.
      - bar: False # Override the default value for the "bar" parameter.
```

Example state module

```python
import salt.exceptions

def enforce_custom_thing(name, foo, bar=True):
    '''
    Enforce the state of a custom thing

    This state module does a custom thing. It calls out to the execution module
    `my_custom_module` in order to check the current system and perform any
    needed changes.

    name
    The thing to do something to

    foo
    A required argument

    bar : True
    An argument with a default value

    '''
    ret = {'name': name, 'changes': {}, 'result': False, 'comment': ''}

    # Start with basic error-checking. Do all the passed parameters make sense
    # and agree with each-other?
    if bar == True and foo.startswith('Foo'):
        raise salt.exceptions.SaltInvocationError(
            'Argument "foo" cannot start with "Foo" if argument "bar" is True.')

    # Check the current state of the system. Does anything need to change?
    current_state = __salt__['my_custom_module.current_state'](name)

    if current_state == foo:
        ret['result'] = True
        ret['comment'] = 'System already in the correct state'
        return ret

    # The state of the system does need to be changed. Check if we're running
    # in `test=true` mode.
    if __opts__['test'] == True:
        ret['comment'] = 'The state of "{}" will be changed.'.format(name)
        ret['changes'] = {
            'old': current_state,
            'new': 'Description, diff, whatever of the new state',
        }

        # Return `None` when running with `test=true`.
        ret['result'] = None
        return ret

    # Finally, make the actual change and return the result.
    new_state = __salt__['my_custom_module.change_state'](name, foo)

    ret['comment'] = 'The state of "{}" was changed!'.format(name)
    ret['changes'] = {
        'old': current_state,
        'new': new_state,
    }
```

Salt Documentation, Release 2015.8.12

32.28.20 State Management

State management, also frequently called Software Configuration Management (SCM), is a program that puts and keeps a system into a predetermined state. It installs software packages, starts or restarts services or puts configuration files in place and watches them for changes.

Having a state management system in place allows one to easily and reliably configure and manage a few servers or a few thousand servers. It allows configurations to be kept under version control.

Salt States is an extension of the Salt Modules that we discussed in the previous remote execution tutorial. Instead of calling one-off executions the state of a system can be easily defined and then enforced.

32.28.21 Understanding the Salt State System Components

The Salt state system is comprised of a number of components. As a user, an understanding of the SLS and renderer systems are needed. But as a developer, an understanding of Salt states and how to write the states is needed as well.

Note: States are compiled and executed only on minions that have been targeted. To execute functions directly on masters, see runners.

Salt SLS System

The primary system used by the Salt state system is the SLS system. SLS stands for Salt State.

The Salt States are files which contain the information about how to configure Salt minions. The states are laid out in a directory tree and can be written in many different formats.

The contents of the files and they way they are laid out is intended to be as simple as possible while allowing for maximum flexibility. The files are laid out in states and contains information about how the minion needs to be configured.

SLS File Layout

SLS files are laid out in the Salt file server.

A simple layout can look like this:

```bash
top.sls
ssh.sls
sshd_config
users/init.sls
users/admin.sls
salt/master.sls
web/init.sls
```
The **top.sls** file is a key component. The **top.sls** files is used to determine which SLS files should be applied to which minions.

The rest of the files with the **.sls** extension in the above example are state files. Files without a **.sls** extensions are seen by the Salt master as files that can be downloaded to a Salt minion.

States are translated into dot notation. For example, the **ssh.sls** file is seen as the **ssh** state and the **users/admin.sls** file is seen as the **users.admin** state.

Files named **init.sls** are translated to be the state name of the parent directory, so the **web/init.sls** file translates to the **web** state.

In Salt, everything is a file; there is no "magic translation" of files and file types. This means that a state file can be distributed to minions just like a plain text or binary file.

### SLS Files

The Salt state files are simple sets of data. Since SLS files are just data they can be represented in a number of different ways.

The default format is YAML generated from a Jinja template. This allows for the states files to have all the language constructs of Python and the simplicity of YAML.

State files can then be complicated Jinja templates that translate down to YAML, or just plain and simple YAML files.

The State files are simply common data structures such as dictionaries and lists, constructed using a templating language such as YAML.

Here is an example of a Salt State:

```yaml
vim:
  pkg.installed: []

salt:
  pkg.latest:
    - name: salt
  service.running:
    - names:
      - salt-master
      - salt-minion
    - require:
      - pkg: salt
    - watch:
      - file: /etc/salt/minion

/etc/salt/minion:
  file.managed:
    - source: salt://salt/minion
    - user: root
    - group: root
    - mode: 644
    - require:
      - pkg: salt
```

This short stanza will ensure that vim is installed, Salt is installed and up to date, the salt-master and salt-minion daemons are running and the Salt minion configuration file is in place. It will also ensure everything is deployed in the right order and that the Salt services are restarted when the watched file updated.
The Top File

The top file controls the mapping between minions and the states which should be applied to them. The top file specifies which minions should have which SLS files applied and which environments they should draw those SLS files from.

The top file works by specifying environments on the top-level. Each environment contains globs to match minions. Finally, each glob contains a list of lists of Salt states to apply to matching minions:

```
base:
  'x*':
    - salt
    - users
    - users.admin
  'saltmaster.*':
    - match: pcre
    - salt.master
```

This above example uses the base environment which is built into the default Salt setup. The base environment has two globs. First, the `'*'` glob contains a list of SLS files to apply to all minions. The second glob contains a regular expression that will match all minions with an ID matching saltmaster.* and specifies that for those minions, the salt.master state should be applied.

Reloading Modules

Some Salt states require that specific packages be installed in order for the module to load. As an example the pip state module requires the pip package for proper name and version parsing.

In most of the common cases, Salt is clever enough to transparently reload the modules. For example, if you install a package, Salt reloads modules because some other module or state might require just that package which was installed.

On some edge-cases salt might need to be told to reload the modules. Consider the following state file which we'll call pep8.sls:

```
python-pip:
  cmd.run:
    - name: |
      easy_install --script-dir=/usr/bin -U pip
    - cwd: /

pep8:
  pip.installed:
    - require:
      - cmd: python-pip
```

The above example installs pip using easy_install from setuptools and installs pep8 using pip, which, as told earlier, requires pip to be installed system-wide. Let's execute this state:

```
salt-call state.apply pep8
```

The execution output would be something like:
If we executed the state again the output would be:

```yaml
----------
State: - pip
Name:   pep8
Function: installed
Result: True
Comment: Package was successfully installed
Changes: pep8==1.4.6: Installed
----------
Succeeded: 2
Failed: 0
----------
Total: 2
```

Since we installed pip using cmd, Salt has no way to know that a system-wide package was installed. On the second execution, since the required pip package was installed, the state executed correctly.

**Note:** Salt does not reload modules on every state run because doing so would greatly slow down state execution.

So how do we solve this *edge-case*? `reload_modules`!

`reload_modules` is a boolean option recognized by salt on all available states which forces salt to reload its modules once a given state finishes.

The modified state file would now be:

```yaml
python-pip:
  cmd.run:
    - name: |
      easy_install --script-dir=/usr/bin -U pip
    - cwd: /
    - reload_modules: true

pep8:
  pip.installed:
    - require:
    - cmd: python-pip
```
Let's run it, once:

```
salt-call state.apply pep8
```

The output is:

```
---------
  State: - pip
    Name:  pep8
  Function:  installed
   Result: True
   Comment: Package was successfully installed
    Changes: pep8==1.4.6: Installed

Summary
---------
Succeeded: 2
  Failed: 0
---------
  Total: 2
```

### 32.29 Full list of builtin state modules

32.29.1 salt.states.alias

Configuration of email aliases

The mail aliases file can be managed to contain definitions for specific email aliases:

```yaml
username:
  alias.present:
    - target: user@example.com

thomas:
  alias.present:
    - target: thomas@example.com
```

The default alias file is set to `/etc/aliases`, as defined in Salt's `config execution module`. To change the alias file from the default location, set the following in your minion config:

```yaml
aliases.file: /my/alias/file
```

salt.states.alias.absent(name)

Ensure that the named alias is absent

- **name**: The alias to remove

salt.states.alias.present(name, target)

Ensures that the named alias is present with the given target or list of targets. If the alias exists but the target differs from the previous entry, the target(s) will be overwritten. If the alias does not exist, the alias will be created.

- **name**: The local user/address to assign an alias to
- **target**: The forwarding address

32.29.2 salt.states.alternatives

Configuration of the alternatives system
Control the alternatives system

```{% set my_hadoop_conf = '/opt/hadoop/conf' %}

{{ my_hadoop_conf }}:
  file.directory

hadoop-0.20-conf:
  alternatives.install:
    - name: hadoop-0.20-conf
    - link: /etc/hadoop-0.20/conf
    - path: {{ my_hadoop_conf }}
    - priority: 30
    - require:
      - file: {{ my_hadoop_conf }}

hadoop-0.20-conf:
  alternatives.remove:
    - name: hadoop-0.20-conf
    - path: {{ my_hadoop_conf }}

salt.states.alternatives.auto(name)
New in version 0.17.0.
Instruct alternatives to use the highest priority path for <name>

  name is the master name for this link group (e.g. pager)

salt.states.alternatives.install(name, link, path, priority)
Install new alternative for defined <name>

  name is the master name for this link group (e.g. pager)

  link is the symlink pointing to /etc/alternatives/<name>. (e.g. /usr/bin/pager)

  path is the location of the new alternative target. NB: This file / directory must already exist. (e.g. /usr/bin/less)

  priority is an integer; options with higher numbers have higher priority in automatic mode.

salt.states.alternatives.remove(name, path)
Removes installed alternative for defined <name> and <path> or fallback to default alternative, if some defined before.

  name is the master name for this link group (e.g. pager)

  path is the location of one of the alternative target files. (e.g. /usr/bin/less)

salt.states.alternatives.set(name, path)
New in version 0.17.0.
Sets alternative for <name> to <path>, if <path> is defined as an alternative for <name>.

  name is the master name for this link group (e.g. pager)

  path is the location of one of the alternative target files. (e.g. /usr/bin/less)

32.29.3 salt.states.apache

Apache state
New in version 2014.7.0.
Allows for inputting a yaml dictionary into a file for apache configuration files.

The variable this is special and signifies what should be included with the above word between angle brackets (<>).

```bash
/etc/httpd/conf.d/website.com.conf:
  apache.configfile:
    - config:
      - VirtualHost:
        this: '*:80'
        ServerName:
          - website.com
        ServerAlias:
          - www.website.com
          - dev.website.com
      ErrorLog: logs/website.com-error_log
      CustomLog: logs/website.com-access_log combined
      DocumentRoot: /var/www/vhosts/website.com
      Directory:
        this: /var/www/vhosts/website.com
        Order: Deny,Allow
        Deny from: all
        Allow from:
          - 127.0.0.1
          - 192.168.100.0/24
      Options:
        - +Indexes
        - FollowSymlinks
      AllowOverride: All

salt.states.apache.configfile(name, config)

32.29.4 salt.states.apache_module

Manage Apache Modules

New in version 2014.7.0.

Enable and disable apache modules.

Enable cgi module:
  apache_module.enable:
    - name: cgi

Disable cgi module:
  apache_module.disable:
    - name: cgi

salt.states.apache_module.disable(name)
  Ensure an Apache module is disabled.
  name Name of the Apache module

salt.states.apache_module.enable(name)
  Ensure an Apache module is enabled.
  name Name of the Apache module
32.29.5 salt.states.aptpkg

Package management operations specific to APT- and DEB-based systems

salt.states.aptpkg.held(name)
  Set package in 'hold' state, meaning it will not be upgraded.
  
  name The name of the package, e.g., 'tmux'

32.29.6 salt.states.archive

Extract an archive

New in version 2014.1.0.

salt.states.archive.extracted(name, source, archive_format, archive_user=None, user=None, 
group=None, tar_options=None, source_hash=None, if_missing=None, keep=False)

New in version 2014.1.0.

State that make sure an archive is extracted in a directory. The downloaded archive is erased if successfully extracted. The archive is downloaded only if necessary.

Note: If if_missing is not defined, this state will check for name instead. If name exists, it will assume the archive was previously extracted successfully and will not extract it again.

Example, tar with flag for lmza compression:

```
graylog2-server:
  archive.extracted:
    - name: /opt/
    - source: https://github.com/downloads/Graylog2/graylog2-server/graylog2-
               server-0.9.6p1.tar.lzma
    - source_hash: md5=499ae16dcaee71eeb7c3a30c75ea7a1a6
    - tar_options: J
    - archive_format: tar
    - if_missing: /opt/graylog2-server-0.9.6p1/
```

Example, tar with flag for verbose output:

```
graylog2-server:
  archive.extracted:
    - name: /opt/
    - source: https://github.com/downloads/Graylog2/graylog2-server/graylog2-
               server-0.9.6p1.tar.gz
    - source_hash: md5=499ae16dcaee71eeb7c3a30c75ea7a1a6
    - archive_format: tar
    - tar_options: v
    - user: root
    - group: root
    - if_missing: /opt/graylog2-server-0.9.6p1/
```

name Location where archive should be extracted

source Archive source, same syntax as file.managed source argument.
source_hash Hash of source file, or file with list of hash-to-file mappings. It uses the same syntax as the file.managed source_hash argument.

archive_format tar, zip or rar

archive_user The user to own each extracted file.

Deprecated since version 2014.7.2: Replaced by user parameter

user The user to own each extracted file.

New in version 2015.8.0.

group The group to own each extracted file.

New in version 2015.8.0.

if_missing If specified, this path will be checked, and if it exists then the archive will not be extracted. This can be helpful if the archive extracts all files into a subfolder. This path can be either a directory or a file, so this option can also be used to check for a semaphore file and conditionally skip extraction.

tar_options If archive_format is set to tar, this option can be used to specify a string of additional arguments to pass to the tar command. If archive_format is set to tar and this option is not used, then the minion will attempt to use Python's native tarfile support to extract it. Python's native tarfile support can only handle gzip and bzip2 compression, however.

Changed in version 2015.8.11, 2016.3.2: XZ-compressed archives no longer require J to manually be set in the tar_options, they are now detected automatically and Salt will extract them using xz-utils. This is a more platform-independent solution, as not all tar implementations support the J argument for extracting archives.

Note: Main operators like -x, --extract, --get, -c and -f/--file should not be used here.

Using this option means that the tar command will be used, which is less platform-independent, so keep this in mind when using this option; the options must be valid options for the tar implementation on the minion's OS.

keep Keep the archive in the minion's cache

32.29.7 salt.states.artifactory

This state downloads artifacts from artifactory.

salt.states.artifactory.downloaded(name, artifact, target_dir='/tmp', target_file=None)

Ensures that the artifact from artifactory exists at given location. If it doesn’t exist, then it will be downloaded. If it already exists then the checksum of existing file is checked against checksum in artifactory. If it is different then the step will fail.

artifact Details of the artifact to be downloaded from artifactory. Various options are:

- artifact_url: URL of the artifactory instance
- repository: Repository in artifactory
- artifact_id: Artifact ID
- group_id: Group ID
- packaging: Packaging
- classifier: Classifier .. versionadded:: 2015.8.0
• version: Version
• username: Artifactory username .. versionadded:: 2015.8.0
• password: Artifactory password .. versionadded:: 2015.8.0

target_dir Directory where the artifact should be downloaded. By default it is downloaded to /tmp directory.

target_file Target file to download artifact to. By default file name is resolved by artifactory.

An example to download an artifact to a specific file:

```
jboss_module_downloaded:
  artifactory.downloaded:
  - artifact:
      artifactory_url: http://artifactory.intranet.example.com/artifactory
      repository: 'libs-release-local'
      artifact_id: 'module'
      group_id: 'com.company.module'
      packaging: 'jar'
      classifier: 'sources'
      version: '1.0'
      target_file: /opt/jboss7/modules/com/company/lib/module.jar
```

Download artifact to the folder (automatically resolves file name):

```
jboss_module_downloaded:
  artifactory.downloaded:
  - artifact:
      artifactory_url: http://artifactory.intranet.example.com/artifactory
      repository: 'libs-release-local'
      artifact_id: 'module'
      group_id: 'com.company.module'
      packaging: 'jar'
      classifier: 'sources'
      version: '1.0'
      target_dir: /opt/jboss7/modules/com/company/lib
```

### 32.29.8 salt.states.at

**Configuration disposable regularly scheduled tasks for at.**

The at state can be add disposable regularly scheduled tasks for your system.

**salt.states.at.absent**(name, jobid=None, **kwargs)

Remove a job from queue The `kwargs` can include hour. minute. day. month. year

- limit Target range
- tag Job's tag
- runas Runs user-specified jobs

```
example1:
  at.absent:
  - limit: all

example2:
  at.absent:
```

32.29. Full list of builtin state modules
example3:
  at.absent:
    - limit: all
    - tag: rose
    - runas: jim

example4:
  at.absent:
    - limit: all
    - tag: rose
    - day: 13
    - hour: 16

salt.states.at.present(name, timespec, tag=None, user=None, job=None)
Add a job to queue.

  job  Command to run.

  timespec  The `timespec' follows the format documented in the at(1) manpage.

  tag  Make a tag for the job.

  user  The user to run the at job

    New in version 2014.1.4.

rose:
  at.present:
    - job: 'echo "I love saltstack" > love'
    - timespec: '9:09 11/09/13'
    - tag: love
    - user: jam

32.29.9 salt.states.augeas

Configuration management using Augeas

New in version 0.17.0.

This state requires the augeas Python module.

Augeas can be used to manage configuration files.

**Warning:** Minimal installations of Debian and Ubuntu have been seen to have packaging bugs with python-augeas, causing the augeas module to fail to import. If the minion has the augeas module installed, and the state fails with a comment saying that the state is unavailable, first restart the salt-minion service. If the problem persists past that, the following command can be run from the master to determine what is causing the import to fail:

```
salt minion-id cmd.run 'python -c "from augeas import Augeas"'
```

For affected Debian/Ubuntu hosts, installing libpython2.7 has been known to resolve the issue.
salt.states.augeas.change

New in version 2014.7.0.

This state replaces setvalue().

Issue changes to Augeas, optionally for a specific context, with a specific lens.

name State name

context A file path, prefixed by /files. Should resolve to an actual file (not an arbitrary augeas path). This is used to avoid duplicating the file name for each item in the changes list (for example, set bind 0.0.0.0 in the example below operates on the file specified by context). If context is not specified, a file path prefixed by /files should be included with the set command.

The file path is examined to determine if the specified changes are already present.

changes List of changes that are issued to Augeas. Available commands are set, setm, mv/move, ins/insert, and rm/remove.

lens The lens to use, needs to be suffixed with .lns, e.g.: Nginx.lns. See the list of stock lenses shipped with Augeas.

Usage examples:

Set the bind parameter in /etc/redis/redis.conf:

```
redis-conf:
augeas.change:
  - context: /files/etc/redis/redis.conf
  - changes:
    - set bind 0.0.0.0
    - set maxmemory 1G
```

Note: Use the context parameter to specify the file you want to manipulate. This way you don’t have to include this in the changes every time:

```
redis-conf:
augeas.change:
  - context: /files/etc/redis/redis.conf
  - changes:
    - set bind 0.0.0.0
    - set databases 4
    - set maxmemory 1G
```

Augeas is aware of a lot of common configuration files and their syntax. It knows the difference between for example ini and yaml files, but also files with very specific syntax, like the hosts file. This is done with lenses, which provide mappings between the Augeas tree and the file.

There are many preconfigured lenses that come with Augeas by default, and they specify the common locations for configuration files. So most of the time Augeas will know how to manipulate a file. In the event that you need to manipulate a file that Augeas doesn’t know about, you can specify the lens to use like this:
redis-conf:
    augeas.change:
    - lens: redis
    - context: /files/etc/redis/redis.conf
    - changes:
      - set bind 0.0.0.0

Note: Even though Augeas knows that /etc/redis/redis.conf is a Redis configuration file and knows how to parse it, it is recommended to specify the lens anyway. This is because by default, Augeas loads all known lenses and their associated file paths. All these files are parsed when Augeas is loaded, which can take some time. When specifying a lens, Augeas is loaded with only that lens, which speeds things up quite a bit.

A more complex example, this adds an entry to the services file for Zabbix, and removes an obsolete service:

zabbix-service:
    augeas.change:
    - lens: services
    - context: /files/etc/services
    - changes:
      - ins service-name after service-name[last()]
      - set service-name[last()]/zabbix-agent
      - set service-name[. = 'zabbix-agent']/#comment "Zabbix Agent service"
      - set service-name[. = 'zabbix-agent']/port 10050
      - set service-name[. = 'zabbix-agent']/protocol tcp
      - rm service-name[. = 'im-obsolete']
      - unless: grep "zabbix-agent" /etc/services

Warning: Don't forget the unless here, otherwise a new entry will be added every time this state is run.

32.29.10 salt.states.aws_sqs

Manage SQS Queues

Create and destroy SQS queues. Be aware that this interacts with Amazon's services, and so may incur charges.

This module uses the awscli tool provided by Amazon. This can be downloaded from pip. Also check the documentation for awscli for configuration information.

myqueue:
    aws_sqs.exists:
        - region: eu-west-1

salt.states.aws_sqs.absent(name, region=None, user=None, opts=False)
Remove the named SQS queue if it exists.

name  Name of the SQS queue.
region Region to remove the queue from
user  Name of the user performing the SQS operations
opts  Include additional arguments and options to the aws command line

salt.states.aws_sqs.exists(name, region=None, user=None, opts=False)
Ensure the SQS queue exists.
name  Name of the SQS queue.
region  Region to create the queue
user  Name of the user performing the SQS operations
opts  Include additional arguments and options to the aws command line

32.29.11 salt.states.beacon

Management of the Salt beacons

New in version 2015.8.0.

```yaml
ps:
  beacon.present:
    enable: False
    salt-master: running
    apache2: stopped

sh:
  beacon.present:

load:
  beacon.present:
    1m:
      - 0.0
      - 2.0
    5m:
      - 0.0
      - 1.5
    15m:
      - 0.1
      - 1.0
```

salt.states.beacon.absent(name, **kwargs)
Ensure beacon is absent.

name  The name of the beacon ensured absent.

class name

salt.states.beacon.disabled(name, **kwargs)
Disable a beacon.

name  The name of the beacon to enable.

class name

class

salt.states.beacon.enabled(name, **kwargs)
Enable a beacon.

name  The name of the beacon to enable.

class name

salt.states.beacon.present(name, **kwargs)
Ensure beacon is configured with the included beacon data.

name  The name of the beacon ensure is configured.

class name

32.29.12 salt.states.bigip

A state module designed to enforce load-balancing configurations for F5 Big-IP entities.
salt.states.bigip.add_pool_member

A function to connect to a bigip device and add a new member to an existing pool.

- **hostname**: The host/address of the bigip device
- **username**: The iControl REST username
- **password**: The iControl REST password
- **name**: The name of the pool to modify
- **member**: The member to add to the pool

salt.states.bigip.create_monitor

A function to connect to a bigip device and create a monitor.

- **hostname**: The host/address of the bigip device
- **username**: The iControl REST username
- **password**: The iControl REST password
- **monitor_type**: The type of monitor to create
- **name**: The name of the monitor to create
- **kwargs**: [ arg=val ] ...

Consult F5 BIGIP user guide for specific options for each monitor type. Typically, tmsh arg names are used.

salt.states.bigip.create_node

Create a new node if it does not already exist.

- **hostname**: The host/address of the bigip device
- **username**: The iControl REST username
- **password**: The iControl REST password
- **name**: The name of the node to create
- **address**: The address of the node

salt.states.bigip.create_pool

Create a new node if it does not already exist.

- **hostname**: The host/address of the bigip device
- **username**: The iControl REST username
- **password**: The iControl REST password
name  The name of the pool to create

members  List of members to be added to the pool

allow_nat  [yes | no]
allow_snat  [yes | no]

description  [string]

service_down_action  [drop | none | reselect | reset]
slow_ramp_time  [integer]

salt.states.bigip.create_profile( hostname, username, password, profile_type, name, **kwargs)
A function to connect to a bigip device and create a profile.

hostname  The host/address of the bigip device

username  The iControl REST username

password  The iControl REST password

profile_type  The type of profile to create

name  The name of the profile to create

kwargs  [ arg=val ] ...
Consult F5 BIGIP user guide for specific options for each profile type. Typically, tmsh arg names are used.
Special Characters |, , and : must be escaped using \ when used within strings.

```
salt.states.bigip.create_virtual(hostname, username, password, name, destination, pool=None, address_status=None, auto_lasthop=None, bwc_policy=None, cmp_enabled=None, connection_limit=None, dhcp_relay=None, description=None, fallback_persistence=None, flow_eviction_policy=None, gtm_score=None, ip_forward=None, ip_protocol=None, internal=None, twelve_forward=None, last_hop_pool=None, mask=None, mirror=None, nat64=None, persist=None, profiles=None, policies=None, rate_class=None, rate_limit=None, rate_limit_mode=None, rate_limit_dst=None, rate_limit_src=None, rules=None, related_rules=None, reject=None, source=None, source_address_translation=None, source_port=None, virtual_state=None, traffic_classes=None, translate_address=None, translate_port=None, vlans=None)
```

A function to connect to a bigip device and create a virtual server if it does not already exists.

- **hostname** The host/address of the bigip device
- **username** The iControl REST username
- **password** The iControl REST password
- **name** The name of the virtual to create
- **destination** ([virtual_address_name:port] | [ipv4:port] | [ipv6:port])
- **pool** ([pool_name] | none)

salt.states.bigip.delete_monitor ( hostname, username, password, monitor_type, name )
Modify an existing monitor. If it does exists, only the parameters specified will be enforced.

hostname The host/address of the bigip device
username The iControl REST username
password The iControl REST password
monitor_type The type of monitor to create
name The name of the monitor to create
kwargs [ arg=val ] ...

Consult F5 BIGIP user guide for specific options for each monitor type. Typically, tmsh arg names are used.

salt.states.bigip.delete_node ( hostname, username, password, name )
Delete an existing node.

hostname The host/address of the bigip device
username The iControl REST username
password The iControl REST password
name  The name of the node which will be deleted.

`salt.states.bigip.delete_pool(hostname, username, password, name)`
Delete an existing pool.

- hostname  The host/address of the bigip device
- username  The iControl REST username
- password  The iControl REST password
- name  The name of the pool which will be deleted

`salt.states.bigip.delete_pool_member(hostname, username, password, name, member)`
Delete an existing pool member.

- hostname  The host/address of the bigip device
- username  The iControl REST username
- password  The iControl REST password
- name  The name of the pool to be modified
- member  The name of the member to delete from the pool

`salt.states.bigip.delete_profile(hostname, username, password, profile_type, name)`
Modify an existing profile. If it does exists, only the parameters specified will be enforced.

- hostname  The host/address of the bigip device
- username  The iControl REST username
- password  The iControl REST password
- profile_type  The type of profile to create
- name  The name of the profile to create
- kwargs  [ arg=val ] ...

  Consult F5 BIGIP user guide for specific options for each profile type. Typically, tmsh arg names are used.

`salt.states.bigip.delete_virtual(hostname, username, password, name)`
Delete an existing virtual.

- hostname  The host/address of the bigip device
- username  The iControl REST username
- password  The iControl REST password
- name  The name of the virtual which will be deleted

`salt.states.bigip.list_monitor(hostname, username, password, monitor_type, name)`
A function to list an existing monitor.

- hostname  The host/address of the bigip device
- username  The iControl REST username
- password  The iControl REST password
- monitor_type  The type of monitor to list
- name  The name of the monitor to list
salt.states.bigip.list_node(hostname, username, password, name)
    A function to connect to a bigip device and list a specific node.
    hostname  The host/address of the bigip device
    username  The iControl REST username
    password  The iControl REST password
    name  The name of the node to list.

salt.states.bigip.list_pool(hostname, username, password, name)
    A function to connect to a bigip device and list a specific pool.
    hostname  The host/address of the bigip device
    username  The iControl REST username
    password  The iControl REST password
    name  The name of the pool to list.

salt.states.bigip.list_profile(hostname, username, password, profile_type, name)
    A function to list an existing profile.
    hostname  The host/address of the bigip device
    username  The iControl REST username
    password  The iControl REST password
    profile_type  The type of profile to list
    name  The name of the profile to list

salt.states.bigip.list_virtual(hostname, username, password, name)
    A function to list a specific virtual.
    hostname  The host/address of the bigip device
    username  The iControl REST username
    password  The iControl REST password
    name  The name of the virtual to list

salt.states.bigip.manage_monitor(hostname, username, password, monitor_type, name, **kwargs)
    Create a new monitor if a monitor of this type and name does not already exists. If it does exists, only the parameters specified will be enforced.
    hostname  The host/address of the bigip device
    username  The iControl REST username
    password  The iControl REST password
    monitor_type  The type of monitor to create
    name  The name of the monitor to create
    kwargs [ arg=val ] ...

        Consult F5 BIGIP user guide for specific options for each monitor type. Typically, tmsh arg names are used.

32.29. Full list of builtin state modules 1847
**salt.states.bigip.manage_node**

Manages a node of a given bigip device. If the node does not exist it will be created, otherwise, only the properties which are different than the existing will be updated.

- **hostname** The host/address of the bigip device
- **username** The iControl REST username
- **password** The iControl REST password
- **name** The name of the node to manage.
- **address** The address of the node
- **connection_limit** [integer]
- **description** [string]
- **dynamic_ratio** [integer]
- **logging** [enabled | disabled]
- **monitor** [(name) | none | default]
- **rate_limit** [integer]
- **ratio** [integer]
- **session** [user-enabled | user-disabled]
- **node_state (state)** [user-down | user-up]

**salt.states.bigip.manage_pool**

Create a new pool if it does not already exist. Pool members are managed separately. Only the parameters specified are enforced.

- **hostname** The host/address of the bigip device
- **username** The iControl REST username
- **password** The iControl REST password
- **name** The name of the pool to create
- **allow_nat** [yes | no]
- **allow_snat** [yes | no]
- **description** [string]
- **gateway_failsafe_device** [string]
- **ignore_persisted_weight** [enabled | disabled]
- **ip_tos_to_client** [string]
- **ip_tos_to_server** [string]
- **load_balancing_mode** [string]
- **min_active_members** [string]
- **min_up_members** [string]
- **min_up_members_checking** [string]
- **min_up_members_action** [string]
- **min_up_members_checking** [string]
- **monitor** [string]
- **profiles** [string]
- **queue_depth_limit** [string]
- **queue_on_connection_limit** [string]
- **queue_time_limit** [string]
- **reselect_tries** [string]
- **service_down_action** [string]
- **slow_ramp_time** [string]
salt.states.bigip.manage_pool_members(hostname, username, password, name, members)
Manage the members of an existing pool. This function replaces all current pool members. Only the parameters specified are enforced.

hostname  The host/address of the bigip device
username  The iControl REST username
password  The iControl REST password
name  The name of the pool to modify
members  list of pool members to manage.

salt.states.bigip.manage_profile(hostname, username, password, profile_type, name, **kwargs)
Create a new profile if a monitor of this type and name does not already exists. If it does exists, only the parameters specified will be enforced.

hostname  The host/address of the bigip device
username  The iControl REST username
password  The iControl REST password
profile_type  The type of profile to create
name  The name of the profile to create
kwargs [ arg=val ] ...

Consult F5 BIGIP user guide for specific options for each profile type. Typically, tmsh arg names are used.

salt.states.bigip.managenet_virtual(hostname, username, password, name, destination, pool=None, address_status=None, auto_lasthop=None, bwc_policy=None, cmp_enabled=None, connection_limit=None, dhcp_relay=None, description=None, fallback_persistence=None, flow_eviction_policy=None, gtm_score=None, ip_forward=None, ip_protocol=None, internal=None, twelve_forward=None, last_hop_pool=None, mask=None, mirror=None, nat64=None, persist=None, profiles=None, policies=None, rate_class=None, rate_limit=None, rate_limit_mode=None, rate_limit_dst=None, rate_limit_src=None, rules=None, related_rules=None, reject=None, source=None, source_address_translation=None, source_port=None, virtual_state=None, traffic_classes=None, translate_address=None, translate_port=None, vlans=None)

Manage a virtual server. If a virtual does not exists it will be created, otherwise only the parameters specified will be enforced.

hostname  The host/address of the bigip device
username  The iControl REST username
password  The iControl REST password
name  The name of the virtual to create

salt.states.bigip.modify_monitor(hostname, username, password, monitor_type, name, **kwargs)

Modify an existing monitor. If it does exists, only the parameters specified will be enforced.

hostname The host/address of the bigip device

username The iControl REST username

password The iControl REST password

monitor_type The type of monitor to create

name The name of the monitor to create

kwargs [ arg=val ] ...

Consult F5 BIGIP user guide for specific options for each monitor type. Typically, tmsh arg names are used.
salt.states.bigip.modify_node(hostname, username, password, name, connection_limit=None, description=None, dynamic_ratio=None, logging=None, monitor=None, rate_limit=None, ratio=None, session=None, node_state=None)

Modify an existing node. Only a node which already exists will be modified and only the parameters specified will be enforced.

hostname The host/address of the bigip device
username The iControl REST username
password The iControl REST password
name The name of the node to modify
connection_limit [integer]
description [string]
dynamic_ratio [integer]
logging [enabled | disabled]
monitor [[name] | none | default]
rate_limit [integer]
ratio [integer]
session [user-enabled | user-disabled]
node_state (state) [user-down | user-up ]

salt.states.bigip.modify_pool(hostname, username, password, name, allow_nat=None, allow_snat=None, description=None, gateway_failsafe_device=None, ignore_persisted_weight=None, ip_tos_to_client=None, ip_tos_to_server=None, link_qos_to_client=None, link_qos_to_server=None, load_balancing_mode=None, min_active_members=None, min_up_members=None, min_up_members_action=None, min_up_members_checking=None, monitor=None, profiles=None, queue_depth_limit=None, queue_on_connection_limit=None, queue_time_limit=None, reselect_tries=None, service_down_action=None, slow_ramp_time=None)

Modify an existing pool. Pool members are managed separately. Only the parameters specified are enforced.

hostname The host/address of the bigip device
username The iControl REST username
password The iControl REST password
name The name of the pool to create
allow_nat [yes | no]
allow_snat [yes | no]
description [string]
gateway_failsafe_device [string]
ignore_persisted_weight [enabled | disabled]
ip_tos_to_client [pass-through | [integer]]
ip_tos_to_server [pass-through | [integer]]

**rate_limit** [integer]
ratio  [integer]

session  [user-enabled | user-disabled]

member_state (state)  [ user-up | user-down ]

`salt.states.bigip.modify_profile` *(hostname, username, password, profile_type, name, **kwargs)*
Modify an existing profile. If it does exists, only the parameters specified will be enforced.

hostname  The host/address of the bigip device

username  The iControl REST username

password  The iControl REST password

profile_type  The type of profile to create

name  The name of the profile to create

kwargs  [ arg=val ] …

Consult F5 BIGIP user guide for specific options for each monitor type. Typically, tmsh arg names are used.

`salt.states.bigip.modify_virtual` *(hostname, username, password, name, destination, pool=None, address_status=None, auto_lasthop=None, bwc_policy=None, cmp_enabled=None, connection_limit=None, dhcp_relay=None, description=None, fallback_persistence=None, flow_eviction_policy=None, gtmscore=None, ip_forward=None, ip_protocol=None, internal=None, twelve_forward=None, lasthoppool=None, mask=None, mirror=None, nat64=None, persist=None, profiles=None, policies=None, rate_class=None, rate_limit=None, rate_limit_mode=None, rate_limit_dst=None, rate_limit Src=None, reject=None, source=None, source_address_translation=None, source_port=None, virtual_state=None, traffic_classes=None, translate_address=None, translate_port=None, vlans=None)*

Modify an virtual server. modify an existing virtual. Only parameters specified will be enforced.

hostname  The host/address of the bigip device

username  The iControl REST username

password  The iControl REST password

name  The name of the virtual to create

destination  [ [virtual_address_name:port] | [ipv4:port] | [ipv6:port] ]

32.29.13 salt.states.blockdev

Management of Block Devices

A state module to manage blockdevices

```
/dev/sda:
    blockdev.tuned:
    - read-only: True

master-data:
    blockdev.tuned:
    - name: /dev/vg/master-data
    - read-only: True
    - read-ahead: 1024
```

New in version 2014.7.0.

salt.states.blockdev.formatted(name, fs_type='ext4', **kwargs)

Manage filesystems of partitions.

- **name** The name of the block device
- **fs_type** The filesystem it should be formatted as

salt.states.blockdev.tuned(name, **kwargs)

Manage options of block device

- **name** The name of the block device
- **opts**
  - **read-ahead** Read-ahead buffer size
  - **filesystem-read-ahead** Filesystem Read-ahead buffer size
  - **read-only** Set Read-Only
  - **read-write** Set Read-Write

32.29.14 salt.states.boto_asg

Manage Autoscale Groups

New in version 2014.7.0.

Create and destroy autoscale groups. Be aware that this interacts with Amazon’s services, and so may incur charges.

This module uses boto, which can be installed via package, or pip.

This module accepts explicit autoscale credentials but can also utilize IAM roles assigned to the instance through Instance Profiles. Dynamic credentials are then automatically obtained from AWS API and no further configuration is necessary. More Information available at:

If IAM roles are not used you need to specify them either in a pillar or in the minion’s config file:

```
asg.keyid: GKTADJGHEIQSXMKKRBJ08H
asg.key: askdjghsdfjkgWupUjasdflkdfklgjsdfjajkghs
```
It's also possible to specify key, keyid and region via a profile, either as a passed in dict, or as a string to pull from pillars or minion config:

```
myprofile:
    keyid: GKTADJGHEIQSXMKKRBJ08H
    key: askdjghsdfjkghWupUjasdflkdfklgjsdfajkghs
    region: us-east-1
```

Ensure myasg exists:
```
boto_asg.present:
    - name: myasg
      launch_config_name: mylc
      availability_zones:
        - us-east-1a
        - us-east-1b
      min_size: 1
      max_size: 1
      desired_capacity: 1
      load_balancers:
        - myelb
      suspended_processes:
        - AddToLoadBalancer
        - AlarmNotification
      scaling_policies:
        - adjustment_type: ChangeInCapacity
          as_name: api-production-iad
          cooldown: 1800
          min_adjustment_step: None
          name: ScaleDown
          scaling_adjustment: -1
        region: us-east-1
      keyid: GKTADJGHEIQSXMKKRBJ08H
      key: askdjghsdfjkghWupUjasdflkdfklgjsdfajkghs
```

# Using a profile from pillars.
Ensure myasg exists:
```
boto_asg.present:
    - name: myasg
      launch_config_name: mylc
      availability_zones:
        - us-east-1a
        - us-east-1b
      min_size: 1
      max_size: 1
      desired_capacity: 1
      load_balancers:
        - myelb
      profile: myprofile
```

# Passing in a profile.
Ensure myasg exists:
```
boto_asg.present:
    - name: myasg
      launch_config_name: mylc
      availability_zones:
        - us-east-1a
        - us-east-1b
      min_size: 1
      max_size: 1
      desired_capacity: 1
      load_balancers:
        - myelb
      region: us-east-1
      keyid: GKTADJGHEIQSXMKKRBJ08H
      key: askdjghsdfjkghWupUjasdflkdfklgjsdfajkghs
```

32.29. Full list of builtin state modules 1857
- max_size: 1
- desired_capacity: 1
- load_balancers:
  - myelb
- profile:
  keyid: GKTADJGHEIQSXMKKRBJ08H
  key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
  region: us-east-1

# Deleting an autoscale group with running instances.
Ensure myasg is deleted:
  boto_asg.absent:
    - name: myasg
  # If instances exist, we must force the deletion of the asg.
    - force: True

It's possible to specify cloudwatch alarms that will be setup along with the ASG. Note the alarm name will be the name attribute defined, plus the ASG resource name.

Ensure myasg exists:
  boto_asg.present:
    - name: myasg
    - launch_config_name: mylc
    - availability_zones:
      - us-east-1a

          unit: null
          description: 'ASG CPU'
        alarm_actions: [ 'arn:aws:sns:us-east-1:12345:myalarm' ]
        insufficient_data_actions: []
        ok_actions: [ 'arn:aws:sns:us-east-1:12345:myalarm' ]

You can also use alarms from pillars, and override values from the pillar alarms by setting overrides on the resource. Note that `boto_asg_alarms` will be used as a default value for all resources, if defined and can be used to ensure alarms are always set for an ASG resource.

Setting the alarms in a pillar:

my_asg_alarm:
  CPU:
    name: 'ASG CPU **MANAGED BY SALT**'
attributes:
  metric: CPUUtilization
  namespace: AWS/EC2
  statistic: Average
  comparison: '>='
  threshold: 65.0
  period: 60
  evaluation_periods: 30
  unit: null
  description: 'ASG CPU'
  insufficient_data_actions: []
  ok_actions: ['arn:aws:sns:us-east-1:12345:myalarm']

Overriding the alarm values on the resource:

Ensure myasg exists:

```yaml
boto_asg.present:
  - name: myasg
  - launch_config_name: mylc
  - availability_zones:
    - us-east-1a
    - us-east-1b
  - min_size: 1
  - max_size: 1
  - desired_capacity: 1
  - load_balancers:
    - myelb
  - profile: myprofile
  - alarms_from_pillar: my_asg_alarm
  # override CPU:attributes:threshold
  - alarms:
    - CPU:
      attributes:
        threshold: 50.0
```

salt.states.boto_asg.absent(name, force=False, region=None, key=None, keyid=None, profile=None)

Ensure the named autoscale group is deleted.

name Name of the autoscale group.
force Force deletion of autoscale group.
region The region to connect to.
key Secret key to be used.
keyid Access key to be used.
profile A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

32.29. Full list of builtin state modules
salt.states.boto_asg.present(name, launch_config_name, availability_zones, min_size, max_size, launch_config=None, desired_capacity=None, load_balancers=None, default_cooldown=None, health_check_type=None, health_check_period=None, placement_group=None, vpc_zone_identifier=None, tags=None, termination_policies=None, suspended_processes=None, scaling_policies=None, scaling_policies_from_pillar='boto_asg_scaling_policies', alarms=None, alarms_from_pillar='boto_asg_alarms', region=None, key=None, keyid=None, profile=None, notification_arn=None, notification_arn_from_pillar='boto_asg_notification_arn', notification_types=None, notification_types_from_pillar='boto_asg_notification_types')

Ensure the autoscale group exists.

name Name of the autoscale group.

launch_config_name Name of the launch config to use for the group. Or, if launch_config is specified, this will be the launch config name's prefix. (see below)

launch_config A dictionary of launch config attributes. If specified, a launch config will be used or created, matching this set of attributes, and the autoscale group will be set to use that launch config. The launch config name will be the launch_config_name followed by a hyphen followed by a hash of the launch_config dict contents.

availability_zones List of availability zones for the group.

min_size Minimum size of the group.

max_size Maximum size of the group.

desired_capacity The desired capacity of the group.

load_balancers List of load balancers for the group. Once set this can not be updated (Amazon restriction).

default_cooldown Number of seconds after a Scaling Activity completes before any further scaling activities can start.

health_check_type The service you want the health status from, Amazon EC2 or Elastic Load Balancer (EC2 or ELB).

health_check_period Length of time in seconds after a new EC2 instance comes into service that Auto Scaling starts checking its health.

placement_group Physical location of your cluster placement group created in Amazon EC2. Once set this can not be updated (Amazon restriction).

vpc_zone_identifier A list of the subnet identifiers of the Virtual Private Cloud.

tags A list of tags. Example:

```
- key: 'key'
  value: 'value'
  propagate_at_launch: true
```

termination_policies A list of termination policies. Valid values are:

- OldestInstance
- NewestInstance
- OldestLaunchConfiguration
- ClosestToNextInstanceHour
- **Default**
  If no value is specified, the Default value is used.

**scaling_policies_from_pillar** name of pillar dict that contains scaling policy settings. Scaling policies defined for this specific state will override those from pillar.

**alarms** a dictionary of name->boto_cloudwatch_alarm sections to be associated with this ASG. All attributes should be specified except for dimension which will be automatically set to this ASG.

See the **salt.states.boto_cloudwatch_alarm** state for information about these attributes.

**alarms_from_pillar** name of pillar dict that contains alarm settings. Alarms defined for this specific state will override those from pillar.

**region** The region to connect to.

**key** Secret key to be used.

**keyid** Access key to be used.

**profile** A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

**notification_arn** The AWS arn that notifications will be sent to

**notification_arn_from_pillar** name of the pillar dict that contains notification_arn settings. A notification_arn defined for this specific state will override the one from pillar.

**notification_types** A list of event names that will trigger a notification. The list of valid notification types is:

- **autoscaling:**EC2_INSTANCE_LAUNCH
- **autoscaling:**EC2_INSTANCE_LAUNCH_ERROR
- **autoscaling:**EC2_INSTANCE_TERMINATE
- **autoscaling:**EC2_INSTANCE_TERMINATE_ERROR
- **autoscaling:**TEST_NOTIFICATION

**notification_types_from_pillar** name of the pillar dict that contains notification_types settings. notification_types defined for this specific state will override those from the pillar.

### 32.29.15 salt.states.boto_cfn

Connection module for Amazon Cloud Formation

New in version 2015.8.0.

**depends** boto

**configuration** This module accepts explicit AWS credentials but can also utilize IAM roles assigned to the instance through Instance Profiles. Dynamic credentials are then automatically obtained from AWS API and no further configuration is necessary. More Information available at [http://docs.aws.amazon.com/AWSEC2/latest/UserGuide/iam-roles-for-amazon-ec2.html](http://docs.aws.amazon.com/AWSEC2/latest/UserGuide/iam-roles-for-amazon-ec2.html)

If IAM roles are not used you need to specify them either in a pillar or in the minion's config file:
keyid: GKTADJGHEIQXSXMKRRBJ08H
key: askdjghsdfjdkgWupUjasdflkdflgsdfjajkghs

stack-present:
  boto_cfn.present:
  - name: mystack
  - template_body: salt://base/mytemplate.json
  - disable_rollback: true
  - region: eu-west-1
  - keyid: 'AKIAJHTMIQ2ASDFLASDF'
  - key: 'fdkjsafkljsASSADFalkfjasdf'

stack-absent:
  boto_cfn.absent:
  - name: mystack

salt.states.boto_cfn.absent(name, region=None, key=None, keyid=None, profile=None)
Ensure cloud formation stack is absent.

name (string) – The name of the stack to delete.
region (string) - Region to connect to.
key (string) - Secret key to be used.
keyid (string) - Access key to be used.
profile (dict) - A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

salt.states.boto_cfn.present(name, template_body=None, template_url=None, parameters=None, notification_arns=None, disable_rollback=None, timeout_in_minutes=None, capabilities=None, tags=None, on_failure=None, stack_policy_body=None, stack_policy_url=None, use_previous_template=None, stack_policy_during_update_body=None, stack_policy_during_update_url=None, region=None, key=None, keyid=None, profile=None)
Ensure cloud formation stack is present.

name (string) - Name of the stack.

template_body (string) – Structure containing the template body. Can also be loaded from a file by using salt://.
template_url (string) – Location of file containing the template body. The URL must point to a template located in an S3 bucket in the same region as the stack.

parameters (list) – A list of key/value tuples that specify input parameters for the stack. A 3-tuple (key, value, bool) may be used to specify the UsePreviousValue option.
notification_arns (list) – The Simple Notification Service (SNS) topic ARNs to publish stack related events. You can find your SNS topic ARNs using the `SNS console`_ or your Command Line Interface (CLI).

disable_rollback (bool) – Indicates whether or not to rollback on failure.
timeout_in_minutes (integer) – The amount of time that can pass before the stack status becomes CREATE_FAILED; if DisableRollback is not set or is set to False, the stack will be rolled back.
capabilities (list) – The list of capabilities you want to allow in the stack. Currently, the only valid capability is 'CAPABILITY_IAM'.
tags (dict) – A set of user-defined Tags to associate with this stack, represented by key/value pairs. Tags defined for the stack are propagated to EC2 resources that are created as part of the stack. A maximum number of 10 tags can be specified.

on_failure (string) – Determines what action will be taken if stack creation fails. This must be one of: DO NOTHING, ROLLBACK, or DELETE. You can specify either OnFailure or DisableRollback, but not both.

stack_policy_body (string) – Structure containing the stack policy body. Can also be loaded from a file by using salt://.

stack_policy_url (string) – Location of a file containing the stack policy. The URL must point to a policy (max size: 16KB) located in an S3 bucket in the same region as the stack. If you pass StackPolicyBody and StackPolicyURL, only StackPolicyBody is used.

use_previous_template (boolean) – Used only when templates are not the same. Set to True to use the previous template instead of uploading a new one via TemplateBody or TemplateURL.

stack_policy_during_update_body (string) – Used only when templates are not the same. Structure containing the temporary overriding stack policy body. If you pass StackPolicyDuringUpdateBody and StackPolicyDuringUpdateURL, only StackPolicyDuringUpdateBody is used. Can also be loaded from a file by using salt://.

stack_policy_during_update_url (string) – Used only when templates are not the same. Location of a file containing the temporary overriding stack policy. The URL must point to a policy (max size: 16KB) located in an S3 bucket in the same region as the stack. If you pass StackPolicyDuringUpdateBody and StackPolicyDuringUpdateURL, only StackPolicyDuringUpdateBody is used.

region (string) - Region to connect to.
key (string) - Secret key to be used.
keyid (string) - Access key to be used.
profile (dict) - A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

32.29.16 salt.states.boto_cloudwatch_alarm

Manage Cloudwatch alarms

New in version 2014.7.0.

Create and destroy cloudwatch alarms. Be aware that this interacts with Amazon's services, and so may incur charges.

This module uses boto, which can be installed via package, or pip.

This module accepts explicit credentials but can also utilize IAM roles assigned to the instance through Instance Profiles. Dynamic credentials are then automatically obtained from AWS API and no further configuration is necessary. More Information available at:

If IAM roles are not used you need to specify them either in a pillar or in the minion's config file:

```
cloudwatch.keyid: GKTADJGHEIQSXMKKRBJ08H
cloudwatch.key: askdjghsdfjkghWuwujasdfklkflgjdsfjajkghs
```

It's also possible to specify key, keyid and region via a profile, either as a passed in dict, or as a string to pull from pillars or minion config:

32.29. Full list of builtin state modules 1863
myprofile:
  keyid: GKTADJGHEIQXSXMKKRBJ08H
  key: askdjghsdfjkgwupUjasdlfkdfklgjsdfjajkgjh
  region: us-east-1

my test alarm:
boto_cloudwatch_alarm.present:
  - name: my test alarm
  - attributes:
    metric: ApproximateNumberOfMessagesVisible
    namespace: AWS/SQS
    statistic: Average
    comparison: "\geq"
    threshold: 20000.0
    period: 60
    evaluation_periods: 1
    description: test alarm via salt
    dimensions:
      QueueName:
        - the-sqs-queue-name
    alarm_actions:

salt.states.boto_cloudwatch_alarm.absent(name, region=None, key=None, keyid=None, profile=None)

Ensure the named cloudwatch alarm is deleted.

name Name of the alarm.
region Region to connect to.
key Secret key to be used.
keyid Access key to be used.
profile A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

salt.states.boto_cloudwatch_alarm.present(name, attributes, region=None, key=None, keyid=None, profile=None)

Ensure the cloudwatch alarm exists.

name Name of the alarm
attributes A dict of key/value cloudwatch alarm attributes.
region Region to connect to.
key Secret key to be used.
keyid Access key to be used.
profile A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

32.29.17 salt.states.boto_dynamodb

Manage DynamoDB Tables

New in version 2015.5.0.
Create and destroy DynamoDB tables. Be aware that this interacts with Amazon's services, and so may incur charges.

This module uses boto, which can be installed via package, or pip.

This module accepts explicit DynamoDB credentials but can also utilize IAM roles assigned to the instance through Instance Profiles. Dynamic credentials are then automatically obtained from AWS API and no further configuration is necessary. More information available here.

If IAM roles are not used you need to specify them either in a pillar file or in the minion's config file:

```yaml
keyid: GKTADJGHEIQSXMKKRBJ08H
key: askdjghsdfjkgwupujasdklfjgklgjhsdfajkg
region: us-east-1
```

It's also possible to specify key, keyid and region via a profile, either passed in as a dict, or as a string to pull from pillars or minion config:

```yaml
myprofile:
  keyid: GKTADJGHEIQSXMKKRBJ08H
  key: askdjghsdfjkgwupujasdklfjgklgjhsdfajkg
  region: us-east-1
```

Ensure DynamoDB table does not exist:

```yaml
boto_dynamodb.absent:
  - table_name: new_table
  - keyid: GKTADJGHEIQSXMKKRBJ08H
  - key: askdjghsdfjkgwupujasdklfjgklgjhsdfajkg
  - region: us-east-1
```

Ensure DynamoDB table exists:

```yaml
boto_dynamodb.present:
  - table_name: new_table
  - read_capacity_units: 1
  - write_capacity_units: 2
  - hash_key: primary_id
  - hash_key_data_type: N
  - range_key: start_timestamp
  - range_key_data_type: N
  - keyid: GKTADJGHEIQSXMKKRBJ08H
  - key: askdjghsdfjkgwupujasdklfjgklgjhsdfajkg
  - region: us-east-1
  - local_indexes:
    - index:
      - name: "primary_id_end_timestamp_index"
      - hash_key: primary_id
      - hash_key_data_type: N
      - range_key: end_timestamp
      - range_key_data_type: N
    - global_indexes:
      - index:
        - name: "name_end_timestamp_index"
        - hash_key: name
        - hash_key_data_type: S
        - range_key: end_timestamp
        - range_key_data_type: N
        - read_capacity_units: 3
        - write_capacity_units: 4
```
salt.states.boto_dynamodb.absent(table_name, region=None, key=None, keyid=None, profile=None)

Ensure the DynamoDB table does not exist.

- **table_name**: Name of the DynamoDB table.
- **region**: Region to connect to.
- **key**: Secret key to be used.
- **keyid**: Access key to be used.
- **profile**: A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

salt.states.boto_dynamodb.present(table_name, region=None, key=None, keyid=None, profile=None, read_capacity_units=None, write_capacity_units=None, hash_key=None, hash_key_data_type=None, range_key=None, range_key_data_type=None, local_indexes=None, global_indexes=None)

Ensure the DynamoDB table exists. Note: all properties of the table can only be set during table creation. Adding or changing indexes or key schema cannot be done after table creation.

- **table_name**: Name of the DynamoDB table
- **region**: Region to connect to.
- **key**: Secret key to be used.
- **keyid**: Access key to be used.
- **profile**: A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.
- **read_capacity_units**: The read throughput for this table
- **write_capacity_units**: The write throughput for this table
- **hash_key**: The name of the attribute that will be used as the hash key for this table
- **hash_key_data_type**: The DynamoDB datatype of the hash key
- **range_key**: The name of the attribute that will be used as the range key for this table
- **range_key_data_type**: The DynamoDB datatype of the range key
- **local_indexes**: The local indexes you would like to create
- **global_indexes**: The local indexes you would like to create

32.29.18 salt.states.boto_ec2

Manage EC2

New in version 2015.8.0.

This module provides an interface to the Elastic Compute Cloud (EC2) service from AWS.

The below code creates a key pair:

```yaml
create-key-pair:
  boto_ec2.key_present:
    - name: mykeypair
    - save_private: /root/
```
You can also use salt:// in order to define the public key.

```python
import-key-pair:
  boto_ec2.key_present:
    - name: mykeypair
    - upload_public: salt://mybase/public_key.pub
    - keyid: GKTADJGHEIQSXMKKRBJ08H
    - key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
```

The below code deletes a key pair:

```python
delete-key-pair:
  boto_ec2.key_absent:
    - name: mykeypair
    - region: eu-west-1
    - keyid: GKTADJGHEIQSXMKKRBJ08H
    - key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
```

32.29.19 salt.states.boto_elasticache

Manage Elasticache

New in version 2014.7.0.

Create, destroy and update Elasticache clusters. Be aware that this interacts with Amazon's services, and so may incur charges.

Note: This module currently only supports creation and deletion of elasticache resources and will not modify clusters when their configuration changes in your state files.

This module uses boto, which can be installed via package, or pip.

This module accepts explicit elasticache credentials but can also utilize IAM roles assigned to the instance through Instance Profiles. Dynamic credentials are then automatically obtained from AWS API and no further configuration is necessary. More information available here.

If IAM roles are not used you need to specify them either in a pillar file or in the minion's config file:
elasticache.keyid: GKTADJGHEIQSXMKKRBJ08H
elasticache.key: askdjghsdfjkgWupUjasdflkdfklgjsdfjajkghs

It’s also possible to specify key, keyid and region via a profile, either passed in as a dict, or as a string to pull from pillars or minion config:

myprofile:
  keyid: GKTADJGHEIQSXMKKRBJ08H
  key: askdjghsdfjkgWupUjasdflkdfklgjsdfjajkghs
  region: us-east-1

Ensure myelasticache exists:
  boto_elasticache.present:
    - name: myelasticache
    - engine: redis
    - cache_node_type: cache.t1.micro
    - num_cache_nodes: 1
    - region: us-east-1
    - keyid: GKTADJGHEIQSXMKKRBJ08H
    - key: askdjghsdfjkgWupUjasdflkdfklgjsdfjajkghs

# Using a profile from pillars
Ensure myelasticache exists:
  boto_elasticache.present:
    - name: myelasticache
    - engine: redis
    - cache_node_type: cache.t1.micro
    - num_cache_nodes: 1
    - region: us-east-1
    - profile: myprofile

# Passing in a profile
Ensure myelasticache exists:
  boto_elasticache.present:
    - name: myelasticache
    - engine: redis
    - cache_node_type: cache.t1.micro
    - num_cache_nodes: 1
    - region: us-east-1
    - profile:
      keyid: GKTADJGHEIQSXMKKRBJ08H
      key: askdjghsdfjkgWupUjasdflkdfklgjsdfjajkghs

salt.states.boto_elasticache.absent(name, wait=True, region=None, key=None, keyid=None, profile=None)

Ensure the named elasticache cluster is deleted.

name Name of the cache cluster.

wait Boolean. Wait for confirmation from boto that the cluster is in the deleting state.

region Region to connect to.

key Secret key to be used.

keyid Access key to be used.
profile  A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

salt.states.boto_elasticache.creategroup(name, primary_cluster_id, replication_group_description, wait=None, region=None, key=None, keyid=None, profile=None)

Ensure the a replication group is create.

name  Name of replication group

wait  Waits for the group to be available

primary_cluster_id  Name of the master cache node

replication_group_description  Description for the group

region  Region to connect to.

key  Secret key to be used.

keyid  Access key to be used.

profile  A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

salt.states.boto_elasticache.present(name, engine=None, cache_node_type=None, num_cache_nodes=None, preferred_availability_zone=None, port=None, cache_parameter_group_name=None, cache_security_group_names=None, replication_group_id=None, auto_minor_version_upgrade=True, security_group_ids=None, cache_subnet_group_name=None, engine_version=None, notification_topic_arn=None, preferred_maintenance_window=None, wait=None, region=None, key=None, keyid=None, profile=None)

Ensure the cache cluster exists.

name  Name of the cache cluster (cache cluster id).

engine  The name of the cache engine to be used for this cache cluster. Valid values are memcached or redis.

cache_node_type  The compute and memory capacity of the nodes in the cache cluster. cache.t1.micro, cache.m1.small, etc. See: http://boto.readthedocs.org/en/latest/ref/elasticache.html#boto.elasticache.layer1.ElastiCacheConnection.create_cache_cluster

num_cache_nodes  The number of cache nodes that the cache cluster will have.

preferred_availability_zone  The EC2 Availability Zone in which the cache cluster will be created. All cache nodes belonging to a cache cluster are placed in the preferred availability zone.

port  The port number on which each of the cache nodes will accept connections.

cache_parameter_group_name  The name of the cache parameter group to associate with this cache cluster. If this argument is omitted, the default cache parameter group for the specified engine will be used.

cache_security_group_names  A list of cache security group names to associate with this cache cluster. Use this parameter only when you are creating a cluster outside of a VPC.

replication_group_id  The replication group to which this cache cluster should belong. If this parameter is specified, the cache cluster will be added to the specified replication group as a read replica; otherwise, the cache cluster will be a standalone primary that is not part of any replication group.
**auto_minor_version_upgrade** Determines whether minor engine upgrades will be applied automatically to the cache cluster during the maintenance window. A value of True allows these upgrades to occur; False disables automatic upgrades.

**security_group_ids** One or more VPC security groups associated with the cache cluster. Use this parameter only when you are creating a cluster in a VPC.

**cache_subnet_group_name** The name of the cache subnet group to be used for the cache cluster. Use this parameter only when you are creating a cluster in a VPC.

**engine_version** The version number of the cache engine to be used for this cluster.

**notification_topic_arn** The Amazon Resource Name (ARN) of the Amazon Simple Notification Service (SNS) topic to which notifications will be sent. The Amazon SNS topic owner must be the same as the cache cluster owner.

**preferred_maintenance_window** The weekly time range (in UTC) during which system maintenance can occur. Example: sun:05:00-sun:09:00

**wait** Boolean. Wait for confirmation from boto that the cluster is in the available state.

**region** Region to connect to.

**key** Secret key to be used.

**keyid** Access key to be used.

**profile** A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

salt.states.boto_elasticache.subnet_group_absent(name, tags=None, region=None, key=None, keyid=None, profile=None)

salt.states.boto_elasticache.subnet_group_present(name, subnet_ids, description, tags=None, region=None, key=None, keyid=None, profile=None)

Ensure ElastiCache subnet group exists.

New in version 2015.8.0.

**name** The name for the ElastiCache subnet group. This value is stored as a lowercase string.

**subnet_ids** A list of VPC subnet IDs for the cache subnet group.

**description** Subnet group description.

**tags** A list of tags.

**region** Region to connect to.

**key** Secret key to be used.

**keyid** Access key to be used.

**profile** A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

32.29.20 salt.states.boto_elb

Manage ELBs

New in version 2014.7.0.

Create and destroy ELBs. Be aware that this interacts with Amazon’s services, and so may incur charges.
This module uses `boto`, which can be installed via package, or `pip`.

This module accepts explicit elb credentials but can also utilize IAM roles assigned to the instance through Instance Profiles. Dynamic credentials are then automatically obtained from AWS API and no further configuration is necessary. More information available [here](#).

If IAM roles are not used you need to specify them either in a pillar file or in the minion's config file:

```yaml
elb.keyid: GKTADJGHEIQSXMKKRBJ08H
elb.key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
```

It's also possible to specify `key`, `keyid` and `region` via a profile, either passed in as a dict, or as a string to pull from pillars or minion config:

```yaml
myprofile:
  keyid: GKTADJGHEIQSXMKKRBJ08H
  key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
  region: us-east-1
```

Ensure `myelb` ELB exists:

```yaml
boto_elb.present:
  - name: myelb
  - region: us-east-1
  - availability_zones:
    - us-east-1a
    - us-east-1c
    - us-east-1d
  - keyid: GKTADJGHEIQSXMKKRBJ08H
  - key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
  - listeners:
    - elb_port: 443
      instance_port: 80
      elb_protocol: HTTPS
      instance_protocol: HTTP
      certificate: 'arn:aws:iam::11111111:server-certificate/mycert'
    - elb_port: 8210
      instance_port: 8210
      elb_protocol: TCP

32.29. Full list of built-in state modules

1871
# Using a profile from pillars
Ensure myelb ELB exists:
```yaml
boto_elb.present:
  - name: myelb
  - region: us-east-1
  - profile: myelbprofile
```

# Passing in a profile
Ensure myelb ELB exists:
```yaml
boto_elb.present:
  - name: myelb
  - region: us-east-1
  - profile:
    keyid: GKTADJGHEIQXSXMKKRB08H
    key: askdjghsdfjkgWupUjasdfklkdfklgjsdfjajkghs
```

It’s possible to specify attributes from pillars by specifying a pillar. You can override the values defined in the pillar by setting the attributes on the resource. The module will use the default pillar key `boto_elb_attributes', which allows you to set default attributes for all ELB resources.

Setting the attributes pillar:
```yaml
my_elb_attributes:
  cross_zone_load_balancing:
    enabled: true
  connection_draining:
    enabled: true
  timeout: 20
  access_log:
    enabled: true
  s3_bucket_name: 'mybucket'
  s3_bucket_prefix: 'my-logs'
  emit_interval: 5
```

Overriding the attribute values on the resource:
```yaml
boto_elb.present:
  - name: myelb
  - region: us-east-1
  - attributes_from_pillar: my_elb_attributes
    # override cross_zone_load_balancing:enabled
    attributes:
      cross_zone_load_balancing:
        enabled: false
    - profile: myelbprofile
```

It’s possible to specify cloudwatch alarms that will be setup along with the ELB. Note the alarm name will be defined by the name attribute provided, plus the ELB resource name.

```yaml
myelb ELB exists:
  boto_elb.present:
    - name: myelb
    - region: us-east-1
    - profile: myelbprofile
    - alarms:
      UnHealthyHostCount:
        name: 'ELB UnHealthyHostCount **MANAGED BY SALT**'
```
You can also use alarms from pillars, and override values from the pillar alarms by setting overrides on the resource. Note that `boto_elb_alarms` will be used as a default value for all resources, if defined and can be used to ensure alarms are always set for a resource.

Setting the alarms in a pillar:

```yaml
my_elb_alarm:
  UnHealthyHostCount:
    name: 'ELB UnHealthyHostCount **MANAGED BY SALT**'
    attributes:
      metric: UnHealthyHostCount
      namespace: AWS/ELB
      statistic: Average
      comparison: '>='
      threshold: 1.0
      period: 600
      evaluation_periods: 6
      unit: null
      description: ELB UnHealthyHostCount
      insufficient_data_actions: []
      ok_actions: ['arn:aws:sns:us-east-1:12345:myalarm']
```

Overriding the alarm values on the resource:

```python
Ensure myelb ELB exists:
  boto_elb.present:
    - name: myelb
    - region: us-east-1
    - profile: myelbprofile
    - alarms_from_pillar: my_elb_alarm
      # override UnHealthyHostCount:attributes:threshold
    - alarms:
      UnHealthyHostCount:
        attributes:
          threshold: 2.0

salt.states.boto_elb.absent(name, region=None, key=None, keyid=None, profile=None)
```
salt.states.boto_elb.present(name, listeners, availability_zones=None, subnets=None, security_groups=None, scheme='internet-facing', health_check=None, attributes=None, attributes_from_pillar='boto_elb_attributes', cnames=None, alarms=None, alarms_from_pillar='boto_elb_alarms', region=None, key=None, keyid=None, profile=None, wait_for_sync=True)

Ensure the ELB exists.

name Name of the ELB.

availability_zones A list of availability zones for this ELB.

listeners A list of listener lists; example:

```
[ ['443', 'HTTPS', 'arn:aws:iam::11111111:server-certificate/mycert'],
  ['8443', '80', 'HTTPS', 'HTTP', 'arn:aws:iam::11111111:server-certificate/mycert']
]
```

subnets A list of subnet IDs in your VPC to attach to your LoadBalancer.

security_groups The security groups assigned to your LoadBalancer within your VPC. Must be passed either as a list or a comma-separated string.

For example, a list:

```
- security_groups:
  - secgroup-one
  - secgroup-two
```

Or as a comma-separated string:

```
- security_groups: secgroup-one,secgroup-two
```

scheme The type of a LoadBalancer, internet-facing or internal. Once set, can not be modified.

health_check A dict defining the health check for this ELB.

attributes A dict defining the attributes to set on this ELB. Unknown keys will be silently ignored.

See the salt.modules.boto_elb.set_attributes function for recognized attributes.

attributes_from_pillar name of pillar dict that contains attributes. Attributes defined for this specific state will override those from pillar.

cnames An optional list of cname dicts with attributes: name, zone, ttl, and identifier. If specified, a CNAME record will be created referencing this ELB’s public FQDN.

See the salt.states.boto_route53 state for information about these attributes.

alarms: a dictionary of name->boto_cloudwatch_alarm sections to be associated with this ELB. All attributes should be specified except for dimension which will be automatically set to this ELB.

See the salt.states.boto_cloudwatch_alarm state for information about these attributes.

alarms_from_pillar: name of pillar dict that contains alarm settings. Alarms defined for this specific state will override those from pillar.

region Region to connect to.

key Secret key to be used.

keyid Access key to be used.
profile A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

wait_for_sync Wait for an INSYNC change status from Route53.

salt.states.boto_elb.register_instances(name, instances, region=None, key=None, keyid=None, profile=None)

Add EC2 instance(s) to an Elastic Load Balancer. Removing an instance from the instances list does not remove it from the ELB.

name The name of the Elastic Load Balancer to add EC2 instances to.

instances A list of EC2 instance IDs that this Elastic Load Balancer should distribute traffic to. This state will only ever append new instances to the ELB. EC2 instances already associated with this ELB will not be removed if they are not in the instances list.

New in version 2015.8.0.

```
add-instances:
  boto_elb.register_instances:
    - name: myloadbalancer
      instances:
        - instance-id1
        - instance-id2
```

32.29.21 salt.states.boto_iam

Manage IAM objects

New in version 2015.8.0.

This module uses boto, which can be installed via package, or pip.

This module accepts explicit IAM credentials but can also utilize IAM roles assigned to the instance through Instance Profiles. Dynamic credentials are then automatically obtained from AWS API and no further configuration is necessary. More information available here.

It's also possible to specify key, keyid and region via a profile, either passed in as a dict, or as a string to pull from pillars or minion config:

```
delete-user:
  boto_iam.user_absent:
    - name: myuser
    - delete_keys: true

delete-keys:
  boto_iam.keys_absent:
    - access_keys:
      - 'AKIAJHTMQ2ASDFLASDF'
      - 'PQIAJHTMQ2ASRTLASFR'
    - user_name: myuser

create-user:
  boto_iam.user_present:
    - name: myuser
    - policies:
      mypolicy: |
```

32.29. Full list of builtin state modules
create-group:
boto_iam.group_present:
  - name: mygroup
  - users:
    - myuser
    - myuser1
  - policies:
    mypolicy: |
      {
        "Version": "2012-10-17",
        "Statement": [{
            "Effect": "Allow",
            "Action": "*",
            "Resource": "*"}
      ]
    }
  - region: eu-west-1
  - keyid: 'AKIAJHTMIQ2ASDFLASDF'
  - key: 'fdkjsafkljsASSADFalkfjasdf'

change-policy:
boto_iam.account_policy:
  - change_password: True
  - region: eu-west-1
  - keyid: 'AKIAJHTMIQ2ASDFLASDF'
  - key: 'safsdfsalsdfkjsafkljsASSADFalkfjasdf'

create server certificate:
boto_iam.server_cert_present:
  - name: mycert
  - public_key: salt://base/mycert.crt
  - private_key: salt://base/mycert.key
  - cert_chain: salt://base/mycert_chain.crt
  - region: eu-west-1
  - keyid: 'AKIAJHTMIQ2ASDFLASDF'
  - key: 'fdkjsafkljsASSADFalkfjasdf'

delete server certificate:
boto_iam.server_cert_absent:
  - name: mycert

create keys for user:
boto_iam.keys_present:
  - name: myusername
  - number: 2
  - save_dir: /root
salt.states.boto_iam.account_policy(allow_users_to_change_password=None,  
hard_expiry=None, max_password_age=None,  
minimum_password_length=None,  
password_reuse_prevention=None,  
require_lowercase_characters=None,  
require_numbers=None, require_symbols=None,  
require_uppercase_characters=None, region=None,  
key=None, keyid=None, profile=None)

Change account policy.

allow_users_to_change_password (bool) Allows all IAM users in your account to use the AWS Management Console to change their own passwords.

hard_expiry (bool) Prevents IAM users from setting a new password after their password has expired.

max_password_age (int) The number of days that an IAM user password is valid.

minimum_password_length (int) The minimum number of characters allowed in an IAM user password.

password_reuse_prevention (int) Specifies the number of previous passwords that IAM users are prevented from reusing.

require_lowercase_characters (bool) Specifies whether IAM user passwords must contain at least one lowercase character from the ISO basic Latin alphabet (a to z).

require_numbers (bool) Specifies whether IAM user passwords must contain at least one numeric character (0 to 9).

require_symbols (bool) Specifies whether IAM user passwords must contain at least one of the following non-alphanumeric characters: ! @ # $ % ^ & * ( ) _ + - = [ ] { } |`

require_uppercase_characters (bool) Specifies whether IAM user passwords must contain at least one uppercase character from the ISO basic Latin alphabet (A to Z).

region (string) Region to connect to.

key (string) Secret key to be used.

keyid (string) Access key to be used.

profile (dict) A dict with region, key and keyid, or a pillar key (string)

salt.states.boto_iam.group_present(name, policies=None, policies_from_pillars=None,  
users=None, region=None, key=None, keyid=None, profile=None, path='/')

Ensure the IAM group is present

name (string) The name of the new group.

path (string) The path for the group, defaults to `/`

policies (dict) A dict of IAM group policy documents.

policies_from_pillars (list) A list of pillars that contain role policy dicts. Policies in the pillars will be merged in the order defined in the list and key conflicts will be handled by later defined keys overriding earlier defined keys. The policies defined here will be merged with the policies defined in the policies argument. If keys conflict, the keys in the policies argument will override the keys defined in policies_from_pillars.

users (list) A list of users to be added to the group.
region (string)  Region to connect to.
key (string)  Secret key to be used.
keyid (string)  Access key to be used.
profile (dict)  A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

salt.states.boto_iam.keys_absent(access_keys, user_name, region=None, key=None, keyid=None, profile=None)
Ensure the IAM user access_key_id is absent.
access_key_id (list)  A list of access key ids
user_name (string)  The username of the user
region (string)  Region to connect to.
key (string)  Secret key to be used.
keyid (string)  Access key to be used.
profile (dict)  A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

salt.states.boto_iam.keys_present(name, number, save_dir, region=None, key=None, keyid=None, profile=None)
Ensure the IAM access keys are present.
name (string)  The name of the new user.
number (int)  Number of keys that user should have.
save_dir (string)  The directory that the key/keys will be saved. Keys are saved to a file named according to the username provided.
region (string)  Region to connect to.
key (string)  Secret key to be used.
keyid (string)  Access key to be used.
profile (dict)  A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

salt.states.boto_iam.server_cert_absent(name, region=None, key=None, keyid=None, profile=None)
Deletes a server certificate.
name (string)  The name for the server certificate. Do not include the path in this value.
region (string)  The name of the region to connect to.
key (string)  The key to be used in order to connect
keyid (string)  The keyid to be used in order to connect
profile (string)  The profile that contains a dict of region, key, keyid

salt.states.boto_iam.server_cert_present(name, public_key, private_key, cert_chain=None, path=None, region=None, key=None, keyid=None, profile=None)
Create server certificate.
name (string)  The name for the server certificate. Do not include the path in this value.
public_key (string)  The contents of the public key certificate in PEM-encoded format.
private_key (string)  The contents of the private key in PEM-encoded format.

cert_chain (string)  The contents of the certificate chain. This is typically a concatenation of the PEM-encoded
public key certificates of the chain.

path (string)  The path for the server certificate.

region (string)  The name of the region to connect to.

key (string)  The key to be used in order to connect

keyid (string)  The keyid to be used in order to connect

profile (string)  The profile that contains a dict of region, key, keyid

salt.states.boto_iam.user_absent(name, delete_keys=None, region=None, key=None, keyid=None, profile=None)
Ensure the IAM user is absent. User cannot be deleted if it has keys.

name (string)  The name of the new user.

delete_keys (bool)  Delete all keys from user.

region (string)  Region to connect to.

key (string)  Secret key to be used.

keyid (string)  Access key to be used.

profile (dict)  A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key
and keyid.

salt.states.boto_iam.user_present(name, policies=None, policies_from_pillars=None, password=None, path=None, region=None, key=None, keyid=None, profile=None)
Ensure the IAM user is present

name (string)  The name of the new user.

policies (dict)  A dict of IAM group policy documents.

policies_from_pillars (list)  A list of pillars that contain role policy dicts. Policies in the pillars will be merged
in the order defined in the list and key conflicts will be handled by later defined keys overriding earlier
defined keys. The policies defined here will be merged with the policies defined in the policies argument.
If keys conflict, the keys in the policies argument will override the keys defined in policies_from_pillars.

password (string)  The password for the new user. Must comply with account policy.

path (string)  The path of the user. Default is ‘/’.

    New in version 2015.8.2.

region (string)  Region to connect to.

key (string)  Secret key to be used.

keyid (string)  Access key to be used.

profile (dict)  A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key
and keyid.
32.29.22 salt.states.boto_iam_role

Manage IAM roles

New in version 2014.7.0.

This module uses boto, which can be installed via package, or pip.

This module accepts explicit IAM credentials but can also utilize IAM roles assigned to the instance through Instance Profiles. Dynamic credentials are then automatically obtained from AWS API and no further configuration is necessary. More information available here.

If IAM roles are not used you need to specify them either in a pillar file or in the minion's config file:

```yaml
iam.keyid: GKTADJGHEIQSXMKKRBJ08H
iam.key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
```

It's also possible to specify key, keyid and region via a profile, either passed in as a dict, or as a string to pull from pillars or minion config:

```yaml
myprofile:
  keyid: GKTADJGHEIQSXMKKRBJ08H
  key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
  region: us-east-1
```

Creating a role will automatically create an instance profile and associate it with the role. This is the default behavior of the AWS console.

```yaml
myrole:
  boto_iam_role.present:
    - region: us-east-1
    - key: GKTADJGHEIQSXMKKRBJ08H
    - keyid: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
    - policies_from_pillars:
      - shared_iam_bootstrap_policy
    - policies:
      MySQSPolicy:
        Statement:
        - Action:
          - sqs:*
        Effect: Allow
        Resource:
          - arn:aws:sqs:***:***
        Sid: MyPolicySQS1
      MyS3Policy:
        Statement:
        - Action:
          - s3:GetObject
        Effect: Allow
        Resource:
          - arn:aws:s3:***:***:mybucket/*
```

# Using a credentials profile from pillars

```yaml
myrole:
  boto_iam_role.present:
    - profile: myiamprofile
```

# Passing in a credentials profile

```yaml
myrole:
```
boto_iam_role.present:
- profile:
  key: GKTADJGHEIQXSXMKRBJ08H
  keyid: askdjghsdfjkgshWupUjasdfklqmgjsdfjajkghs
  region: us-east-1

If delete_policies: False is specified, existing policies that are not in the given list of policies will not be deleted. This allows manual modifications on the IAM role to be persistent. This functionality was added in 2015.8.0.

Note: When using the profile parameter and region is set outside of the profile group, region is ignored and a default region will be used.

If region is missing from the profile data set, us-east-1 will be used as the default region.

salt.states.boto_iam_role.absent(name, region=None, key=None, keyid=None, profile=None)
Ensure the IAM role is deleted.
name Name of the IAM role.
region Region to connect to.
key Secret key to be used.
keyid Access key to be used.
profile A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

salt.states.boto_iam_role.present(name, policy_document=None, path=None, policies=None, policies_from_pillars=None, create_instance_profile=True, region=None, key=None, keyid=None, profile=None, delete_policies=True)
Ensure the IAM role exists.
name Name of the IAM role.
policy_document The policy that grants an entity permission to assume the role. (See http://boto.readthedocs.org/en/latest/ref/iam.html#boto.iam.connection.IAMConnection.create_role)
path The path to the role/instance profile. (See http://boto.readthedocs.org/en/latest/ref/iam.html#boto.iam.connection.IAMConnection.create_role)
policies A dict of IAM role policies.
policies_from_pillars A list of pillars that contain role policy dicts. Policies in the pillars will be merged in the order defined in the list and key conflicts will be handled by later defined keys overriding earlier defined keys. The policies defined here will be merged with the policies defined in the policies argument. If keys conflict, the keys in the policies argument will override the keys defined in policies_from_pillars.
create_instance_profile A boolean of whether or not to create an instance profile and associate it with this role.
region Region to connect to.
key Secret key to be used.
keyid Access key to be used.
profile A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.
**delete_policies** Deletes existing policies that are not in the given list of policies. Default value is `True`. If `False` is specified, existing policies will not be deleted allowing manual modifications on the IAM role to be persistent.

New in version 2015.8.0.

### 32.29.23 `salt.states.boto_kms`

Manage KMS keys, key policies and grants.

New in version 2015.8.0.

Be aware that this interacts with Amazon's services, and so may incur charges.

This module uses `boto`, which can be installed via package, or `pip`.

This module accepts explicit `kms` credentials but can also utilize IAM roles assigned to the instance through Instance Profiles. Dynamic credentials are then automatically obtained from AWS API and no further configuration is necessary. More information available [here](#).

If IAM roles are not used you need to specify them either in a pillar file or in the minion's config file:

```yaml
elb.keyid: GKTADJGHEIQSXMKKRBJ08H
elb.key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
```

It's also possible to specify `key`, `keyid` and `region` via a profile, either passed in as a dict, or as a string to pull from pillars or minion config:

```yaml
myprofile:
  keyid: GKTADJGHEIQSXMKKRBJ08H
  key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
  region: us-east-1
```

Ensure mykey key exists:

```yaml
salt.states.boto_kms.key_present:
  - name: mykey
  - region: us-east-1
```

# Using a profile from pillars

Ensure mykey key exists:

```yaml
salt.states.boto_kms.key_present:
  - name: mykey
  - region: us-east-1
  - profile: myprofile
```

# Passing in a profile

Ensure mykey key exists:

```yaml
salt.states.boto_kms.key_present:
  - name: mykey
  - region: us-east-1
  - profile:
    keyid: GKTADJGHEIQSXMKKRBJ08H
    key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
```

- `name`: Name of the KMS key.
  - `policy`: Policy to apply to the KMS key.
  - `description`: Description of the KMS key.
  - `key_usage`: Key usage patterns.
  - `grants`: Grants for the KMS key.
  - `manage_grants`: Whether to manage grants.
  - `key_rotation`: Whether to enable key rotation.
  - `enabled`: Whether the KMS key is enabled.
  - `region`: Region of the KMS key.
  - `keyid`: Key ID of the KMS key.
  - `profile`: Profile to use for credentials.

salt.states.boto_kms.key_present(name, policy, description=None, key_usage=None, grants=None, manage_grants=False, key_rotation=False, enabled=True, region=None, key=None, keyid=None, profile=None)
Ensure the KMS key exists. KMS keys can not be deleted, so this function must be used to ensure the key is enabled or disabled.

**name**  Name of the key.

**policy**  Key usage policy.

**description**  Description of the key.

**key_usage**  Specifies the intended use of the key. Can only be set on creation, defaults to ENCRYPT_DECRYPT, which is also the only supported option.

**grants**  A list of grants to apply to the key. Not currently implemented.

**manage_grants**  Whether or not to manage grants. False by default, which will not manage any grants.

**key_rotation**  Whether or not key rotation is enabled for the key. False by default.

**enabled**  Whether or not the key is enabled. True by default.

**region**  Region to connect to.

**key**  Secret key to be used.

**keyid**  Access key to be used.

**profile**  A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

### 32.29.24 salt.states.boto_lc

Manage Launch Configurations

New in version 2014.7.0.

Create and destroy Launch Configurations. Be aware that this interacts with Amazon's services, and so may incur charges.

A limitation of this module is that you can not modify launch configurations once they have been created. If a launch configuration with the specified name exists, this module will always report success, even if the specified configuration doesn't match. This is due to a limitation in Amazon's launch configuration API, as it only allows launch configurations to be created and deleted.

Also note that a launch configuration that's in use by an autoscale group can not be deleted until the autoscale group is no longer using it. This may affect the way in which you want to order your states.

This module uses boto, which can be installed via package, or pip.

This module accepts explicit autoscale credentials but can also utilize IAM roles assigned to the instance through Instance Profiles. Dynamic credentials are then automatically obtained from AWS API and no further configuration is necessary. More information available [here](#). If IAM roles are not used you need to specify them either in a pillar file or in the minion's config file:

```yaml
asg.keyid: GKTADJGHEIQSXMKKRBJ08H
asg.key: askdjghsdfjkghWuPujasfdkflkjsdfjajkghs
```

It's also possible to specify key, keyid and region via a profile, either passed in as a dict, or as a string to pull from pillars or minion config:

```yaml
myprofile:
  keyid: GKTADJGHEIQSXMKKRBJ08H
```

---

32.29. Full list of builtin state modules
Credential information is shared with autoscale groups as launch configurations and autoscale groups are completely dependent on each other.

Ensure mylc exists:
```
    boto_lc.present:
        - name: mylc
        - image_id: ami-0b9c9f62
        - key_name: mykey
        - security_groups:
            - mygroup
        - instance_type: m1.small
        - instance_monitoring: true
        - block_device_mappings:
            - '/dev/sda1':
              size: 20
        - cloud_init:
            scripts:
                'run_salt.sh': |
                    #!/bin/bash
                    add-apt-repository -y ppa:saltstack/salt
                    apt-get update
                    apt-get install -y salt-minion
                    salt-call state.highstate
            region: us-east-1
        - keyid: GKTADJGHEIQSXMKKRBJ08H
        - key: askdjghsdfjkghWupUjasdlfkjgjsdfajkghs
```

# Using a profile from pillars.
Ensure mylc exists:
```
    boto_lc.present:
        - name: mylc
        - image_id: ami-0b9c9f62
        - profile: myprofile
```

# Passing in a profile.
Ensure mylc exists:
```
    boto_lc.present:
        - name: mylc
        - image_id: ami-0b9c9f62
        - profile:
            keyid: GKTADJGHEIQSXMKKRBJ08H
            key: askdjghsdfjkghWupUjasdlfkjgjsdfajkghs
            region: us-east-1
```

salt.states.boto_lc.absent(name, region=None, key=None, keyid=None, profile=None)

Ensure the named launch configuration is deleted.

name Name of the launch configuration.
region The region to connect to.
key Secret key to be used.
keyid Access key to be used.
profile A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

```python
salt.states.boto_lc.present(name, image_id, key_name=None, security_groups=None, user_data=None, cloud_init=None, instance_type='m1.small', kernel_id=None, ramdisk_id=None, block_device_mappings=None, instance_monitoring=False, spot_price=None, instance_profile_name=None, spot_price=None, associate_public_ip_address=None, volume_type=None, delete_on_termination=True, iops=None, use_block_device_types=False, region=None, key=None, keyid=None, profile=None)
```

Ensure the launch configuration exists.

name Name of the launch configuration.

image_id AMI to use for instances. AMI must exist or creation of the launch configuration will fail.

key_name Name of the EC2 key pair to use for instances. Key must exist or creation of the launch configuration will fail.

security_groups List of Names or security group id’s of the security groups with which to associate the EC2 instances or VPC instances, respectively. Security groups must exist, or creation of the launch configuration will fail.

user_data The user data available to launched EC2 instances.

cloud_init A dict of cloud_init configuration. Currently supported values: scripts, cloud-config. Mutually exclusive with user_data.

instance_type The instance type. ex: m1.small.

kernel_id The kernel id for the instance.

ramdisk_id The RAM disk ID for the instance.

block_device_mappings A dict of block device mappings.

instance_monitoring Whether instances in group are launched with detailed monitoring.

spot_price The spot price you are bidding. Only applies if you are building an autoscaling group with spot instances.

instance_profile_name The name or the Amazon Resource Name (ARN) of the instance profile associated with the IAM role for the instance. Instance profile must exist or the creation of the launch configuration will fail.

ebs_optimized Specifies whether the instance is optimized for EBS I/O (true) or not (false).

associate_public_ip_address Used for Auto Scaling groups that launch instances into an Amazon Virtual Private Cloud. Specifies whether to assign a public IP address to each instance launched in a Amazon VPC.

volume_type Undocumented in boto.

delete_on_termination Undocumented in boto.

iops Undocumented in boto.

use_block_device_types Undocumented in boto.

region The region to connect to.

key Secret key to be used.

keyid Access key to be used.
**profile**  A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

### 32.29.25 salt.states.boto_rds

**Manage RDSs**

New in version 2015.8.0.

Create and destroy RDS instances. Be aware that this interacts with Amazon's services, and so may incur charges.

This module uses boto, which can be installed via package, or pip.

This module accepts explicit rds credentials but can also utilize IAM roles assigned to the instance through Instance Profiles. Dynamic credentials are then automatically obtained from AWS API and no further configuration is necessary. More information available [here](#).

If IAM roles are not used you need to specify them either in a pillar file or in the minion's config file:

```python
rds.keyid: GKTADJGHEIQSXMKKRBJ08H
rds.key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
```

It's also possible to specify `key`, `keyid` and `region` via a profile, either passed in as a dict, or as a string to pull from pillars or minion config:

```yaml
myprofile:
    keyid: GKTADJGHEIQSXMKKRBJ08H
    key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
    region: us-east-1
```

Ensure `myrds` RDS exists:

```yaml
boto_rds.present:
    - name: myrds
    - allocated_storage: 5
    - db_instance_class: db.t2.micro
    - engine: MySQL
    - master_username: myuser
    - master_user_password: mypass
    - region: us-east-1
    - keyid: GKTADJGHEIQSXMKKRBJ08H
    - key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
    - tags:
      - key1
      - value1
      - key2
      - value2
```

Note: This state module uses `boto.rds2`, which requires a different tagging syntax than some of the other boto states. The `tags` key and value set noted in the example above is the required yaml notation that `rds2` depends upon to function properly. For more information, please see Issue #28715.

```python
salt.states.boto_rds.absent(name, skip_final_snapshot=None, final_db_snapshot_identifier=None, tags=None, region=None, key=None, keyid=None, profile=None)
```
salt.states.boto_rds.present(name, allocated_storage, db_instance_class, engine, master_username, master_user_password, db_name=None, db_security_groups=None, vpc_security_group_ids=None, availability_zone=None, db_subnet_group_name=None, preferred_maintenance_window=None, db_parameter_group_name=None, backup_retention_period=None, preferred_backup_window=None, port=None, multi_az=None, engine_version=None, auto_minor_version_upgrade=None, license_model=None, iops=None, option_group_name=None, character_set_name=None, publicly_accessible=None, wait_status=None, tags=None, region=None, key=None, keyid=None, profile=None)

Ensure RDS instance exists.

- **name** Name of the RDS instance.
- **allocated_storage** The amount of storage (in gigabytes) to be initially allocated for the database instance.
- **db_instance_class** The compute and memory capacity of the Amazon RDS DB instance.
- **engine** The name of the database engine to be used for this instance. Supported engine types are: MySQL, oracle-se1, oracle-se, oracle-ee, sqlserver-ee, sqlserver-se, sqlserver-ex, sqlserver-web, and postgres. For more information, please see the `engine` argument in the boto_rds create_dbinstance documentation.
- **master_username** The name of master user for the client DB instance.
- **master_user_password** The password for the master database user. Can be any printable ASCII character except `/`, `"`, or `@`.
- **db_name** The database name for the restored DB instance.
- **db_security_groups** A list of DB security groups to associate with this DB instance.
- **vpc_security_group_ids** A list of EC2 VPC security groups to associate with this DB instance.
- **availability_zone** The EC2 Availability Zone that the database instance will be created in.
- **db_subnet_group_name** A DB subnet group to associate with this DB instance.
- **preferred_maintenance_window** The weekly time range (in UTC) during which system maintenance can occur.
- **backup_retention_period** The number of days for which automated backups are retained.
- **preferred_backup_window** The daily time range during which automated backups are created if automated backups are enabled.
- **port** The port number on which the database accepts connections.
- **multi_az** Specifies if the DB instance is a Multi-AZ deployment. You cannot set the AvailabilityZone parameter if the MultiAZ parameter is set to true.
- **engine_version** The version number of the database engine to use.
- **autoMinorVersionUpgrade** Indicates that minor engine upgrades will be applied automatically to the DB instance during the maintenance window.
- **license_model** License model information for this DB instance.
- **iops** The amount of Provisioned IOPS (input/output operations per second) to be initially allocated for the DB instance.
- **option_group_name** Indicates that the DB instance should be associated with the specified option group.
- **character_set_name** For supported engines, indicates that the DB instance should be associated with the specified CharacterSet.
publicly_accessible Specifies the accessibility options for the DB instance. A value of true specifies an Internet-facing instance with a publicly resolvable DNS name, which resolves to a public IP address. A value of false specifies an internal instance with a DNS name that resolves to a private IP address.

wait_status Wait for the RDS instance to reach a desired status before finishing the state. Available states: available, modifying, backing-up

tags A list of tags.

region Region to connect to.

key Secret key to be used.

keyid Access key to be used.

profile A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

```python
salt.states.boto_rds.replica_present(name, source, db_instance_class=None, availability_zone=None, port=None, auto_minor_version_upgrade=None, iops=None, option_group_name=None, publicly_accessible=None, tags=None, region=None, key=None, keyid=None, profile=None)
```

Ensure RDS replica exists.

```
Ensure myrds replica RDS exists:
  boto_rds.create_replica:
    - name: myreplica
    - source: mydb
```

```python
salt.states.boto_rds.subnet_group_absent(name, tags=None, region=None, key=None, keyid=None, profile=None)
```

```python
salt.states.boto_rds.subnet_group_present(name, subnet_ids, description, tags=None, region=None, key=None, keyid=None, profile=None)
```

Ensure DB subnet group exists.

name The name for the DB subnet group. This value is stored as a lowercase string.

subnet_ids The EC2 Subnet IDs for the DB subnet group.

description Subnet group description.

tags A list of tags.

region Region to connect to.

key Secret key to be used.

keyid Access key to be used.

profile A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

32.29.26 salt.states.boto_route53

Manage Route53 records

New in version 2014.7.0.

Create and delete Route53 records. Be aware that this interacts with Amazon's services, and so may incur charges.
This module uses boto, which can be installed via package, or pip.

This module accepts explicit route53 credentials but can also utilize IAM roles assigned to the instance through Instance Profiles. Dynamic credentials are then automatically obtained from AWS API and no further configuration is necessary. More information available here.

If IAM roles are not used you need to specify them either in a pillar file or in the minion's config file:

```
route53.keyid: GKTADJGHEIQSXMKKRBJ08H
route53.key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
```

It’s also possible to specify key, keyid and region via a profile, either passed in as a dict, or as a string to pull from pillars or minion config:

```
myprofile:
  keyid: GKTADJGHEIQSXMKKRBJ08H
  key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
  region: us-east-1
```

```
mycnamerecord:
  boto_route53.present:
    - name: test.example.com.
    - zone: example.com.
    - ttl: 60
    - record_type: CNAME
    - region: us-east-1
    - keyid: GKTADJGHEIQSXMKKRBJ08H
    - key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
```

```
# Using a profile from pillars
myarecord:
  boto_route53.present:
    - name: test.example.com.
    - value: 1.1.1.1
    - zone: example.com.
    - ttl: 60
    - record_type: A
    - region: us-east-1
    - profile: myprofile
```

```
# Passing in a profile
myarecord:
  boto_route53.present:
    - name: test.example.com.
    - value: 1.1.1.1
    - zone: example.com.
    - ttl: 60
    - record_type: A
    - region: us-east-1
    - profile:
      keyid: GKTADJGHEIQSXMKKRBJ08H
      key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
```

```
salt.states.boto_route53.absent(name, zone, record_type, identifier=None, region=None, key=None, keyid=None, profile=None, wait_for_sync=True, split_dns=False, private_zone=False)
```

Ensure the Route53 record is deleted.
name  Name of the record.
zone  The zone to delete the record from.
record_type  The record type (A, NS, MX, TXT, etc.)
identifier  An identifier to match for deletion.
region  The region to connect to.
key  Secret key to be used.
keyid  Access key to be used.
profile  A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.
wait_for_sync  Wait for an INSYNC change status from Route53.
split_dns  Route53 supports a public and private DNS zone with the same names.
private_zone  If using split_dns, specify if this is the private zone.
salt.states.boto_route53.present(name, value, zone, record_type, ttl=None, identifier=None, region=None, key=None, keyid=None, profile=None, wait_for_sync=True, split_dns=False, private_zone=False)

Ensure the Route53 record is present.
name  Name of the record.
value  Value of the record.
zone  The zone to create the record in.
record_type  The record type (A, NS, MX, TXT, etc.)
ttl  The time to live for the record.
identifier  The unique identifier to use for this record.
region  The region to connect to.
key  Secret key to be used.
keyid  Access key to be used.
profile  A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.
wait_for_sync  Wait for an INSYNC change status from Route53.
split_dns  Route53 supports a public and private DNS zone with the same names.
private_zone  If using split_dns, specify if this is the private zone.

32.29.27  salt.states.boto_secgroup

Manage Security Groups

New in version 2014.7.0.
Create and destroy Security Groups. Be aware that this interacts with Amazon's services, and so may incur charges.
This module uses boto, which can be installed via package, or pip.
This module accepts explicit EC2 credentials but can also utilize IAM roles assigned to the instance through Instance Profiles. Dynamic credentials are then automatically obtained from AWS API and no further configuration is necessary. More information available [here](#).

If IAM roles are not used you need to specify them either in a pillar file or in the minion's config file:

```yaml
secgroup.keyid: GKTADJGHEIQXSXMCRJBD8H
secgroup.key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
```

It's also possible to specify `key`, `keyid` and `region` via a profile, either passed in as a dict, or as a string to pull from pillars or minion config:

```yaml
myprofile:
  keyid: GKTADJGHEIQXSXMCRJBD8H
  key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
  region: us-east-1
```

Ensure `mysecgroup` exists:

```yaml
boto_secgroup.present:
  - name: mysecgroup
  - description: My security group
  - rules:
    - ip_protocol: tcp
      from_port: 80
      to_port: 80
      cidr_ip:
        - 10.0.0.0/0
        - 192.168.0.0/0
    - ip_protocol: icmp
      from_port: -1
      to_port: -1
      source_group_name: mysecgroup
  - rules_egress:
    - ip_protocol: all
      from_port: -1
      to_port: -1
      cidr_ip:
        - 10.0.0.0/0
        - 192.168.0.0/0
    - region: us-east-1
    - keyid: GKTADJGHEIQXSXMCRJBD8H
    - key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
```

# Using a profile from pillars
Ensure `mysecgroup` exists:

```yaml
boto_secgroup.present:
  - name: mysecgroup
  - description: My security group
  - profile: myprofile
```

# Passing in a profile
Ensure `mysecgroup` exists:

```yaml
boto_secgroup.present:
  - name: mysecgroup
  - description: My security group
  - profile:
    keyid: GKTADJGHEIQXSXMCRJBD8H
    key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
```

32.29. Full list of builtin state modules 1891
Note: When using the `profile` parameter and `region` is set outside of the profile group, `region` is ignored and a default region will be used.

If `region` is missing from the `profile` data set, `us-east-1` will be used as the default region.

```python
salt.states.boto_secgroup.absent(name, vpc_id=None, vpc_name=None, region=None, key=None, keyid=None, profile=None)
```

Ensure a security group with the specified name does not exist.

- **name**: Name of the security group.
- **vpc_id**: The ID of the VPC to remove the security group from, if any. Exclusive with `vpc_name`.
- **vpc_name**: The name of the VPC wherefrom to delete the security group, if any. Exclusive with `vpc_id`.
- **region**: Region to connect to.
- **key**: Secret key to be used.
- **keyid**: Access key to be used.
- **profile**: A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

```python
salt.states.boto_secgroup.present(name, description, vpc_id=None, vpc_name=None, rules=None, rules_egress=None, region=None, key=None, keyid=None, profile=None)
```

Ensure the security group exists with the specified rules.

- **name**: Name of the security group.
- **description**: A description of this security group.
- **vpc_id**: The ID of the VPC to create the security group in, if any. Exclusive with `vpc_name`.
- **vpc_name**: The name of the VPC wherein to create the security group, if any. Exclusive with `vpc_id`.

  New in version 2015.8.2.

- **rules**: A list of ingress rule dicts. If not specified, `rules=None`, the ingress rules will be unmanaged. If set to an empty list, `[]`, then all ingress rules will be removed.

- **rules_egress**: A list of egress rule dicts. If not specified, `rules_egress=None`, the egress rules will be unmanaged. If set to an empty list, `[]`, then all egress rules will be removed.

- **region**: Region to connect to.
- **key**: Secret key to be used.
- **keyid**: Access key to be used.
- **profile**: A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key, and keyid.

### 32.29.28 salt.states.boto_sns

Manage SNS Topics

Create and destroy SNS topics. Be aware that this interacts with Amazon's services, and so may incur charges.
This module uses boto, which can be installed via package, or pip.

This module accepts explicit AWS credentials but can also utilize IAM roles assigned to the instance through Instance Profiles. Dynamic credentials are then automatically obtained from AWS API and no further configuration is necessary. More information available [here](#).

If IAM roles are not used you need to specify them either in a pillar file or in the minion's config file:

```
sns.keyid: GKTADJGHEIQSXMKKRBJ08H
sns.key: askdjghsdfjkgWupUjasdlfkjgjsdfjakghs
```

It's also possible to specify `key`, `keyid` and `region` via a profile, either passed in as a dict, or as a string to pull from pillars or minion config:

```
myprofile:
    keyid: GKTADJGHEIQSXMKKRBJ08H
    key: askdjghsdfjkgWupUjasdlfkjgjsdfjakghs
    region: us-east-1

mytopic:
    boto_sns.present:
        - region: us-east-1
        - keyid: GKTADJGHEIQSXMKKRBJ08H
        - key: askdjghsdfjkgWupUjasdlfkjgjsdfjakghs

    # Using a profile from pillars
    mytopic:
        boto_sns.present:
            - region: us-east-1
            - profile: mysnsprofile

    # Passing in a profile
    mytopic:
        boto_sns.present:
            - region: us-east-1
            - profile:
                keyid: GKTADJGHEIQSXMKKRBJ08H
                key: askdjghsdfjkgWupUjasdlfkjgjsdfjakghs
```

**salt.states.boto_sns.absent**(name, region=None, key=None, keyid=None, profile=None)

Ensure the named sns topic is deleted.

- **name** Name of the SNS topic.
- **region** Region to connect to.
- **key** Secret key to be used.
- **keyid** Access key to be used.
- **profile** A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

**salt.states.boto_sns.present**(name, subscriptions=None, region=None, key=None, keyid=None, profile=None)

Ensure the SNS topic exists.

- **name** Name of the SNS topic.
- **subscriptions** List of SNS subscriptions.

Each subscription is a dictionary with a protocol and endpoint key:
[{
    'protocol': 'https', 'endpoint': 'https://www.example.com/sns-endpoint'},
{
    'protocol': 'sqs', 'endpoint': 'arn:aws:sqs:us-west-2:123456789012:MyQueue'
}]

region Region to connect to.
key Secret key to be used.
keyid Access key to be used.
profile A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and
     keyid.

32.29.29 salt.states.boto_sqs

Manage SQS Queues
New in version 2014.7.0.
Create and destroy SQS queues. Be aware that this interacts with Amazon’s services, and so may incur charges.
This module uses boto, which can be installed via package, or pip.
This module accepts explicit SQS credentials but can also utilize IAM roles assigned to the instance through In-
stance Profiles. Dynamic credentials are then automatically obtained from AWS API and no further configuration is
necessary. More information available here.
If IAM roles are not used you need to specify them either in a pillar file or in the minion's config file:
sqs.keyid: GKTADJGHEIQSXMKKRBJ08H
sqs.key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs

It's also possible to specify key, keyid and region via a profile, either passed in as a dict, or as a string to pull
from pillars or minion config:
myprofile:
    keyid: GKTADJGHEIQSXMKKRBJ08H
    key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
    region: us-east-1

myqueue:
    boto_sqs.present:
        - region: us-east-1
        - keyid: GKTADJGHEIQSXMKKRBJ08H
        - key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
        - attributes:
            ReceiveMessageWaitTimeSeconds: 20

# Using a profile from pillars
myqueue:
    boto_sqs.present:
        - region: us-east-1
        - profile: mysqsprofile

# Passing in a profile
myqueue:
    boto_sqs.present:
        - region: us-east-1
salt.states.boto_sqs.absent(name, region=None, key=None, keyid=None, profile=None)
Ensure the named sqs queue is deleted.

name  Name of the SQS queue.
region Region to connect to.
key   Secret key to be used.
keyid Access key to be used.
profile A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

salt.states.boto_sqs.present(name, attributes=None, region=None, key=None, keyid=None, profile=None)
Ensure the SQS queue exists.

name  Name of the SQS queue.
attributes A dict of key/value SQS attributes.
region Region to connect to.
key   Secret key to be used.
keyid Access key to be used.
profile A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

32.29.30 salt.states.boto_vpc

Manage VPCs

New in version 2015.8.0.

Create and destroy VPCs. Be aware that this interacts with Amazon's services, and so may incur charges.

This module uses boto, which can be installed via package, or pip.

This module accepts explicit vpc credentials but can also utilize IAM roles assigned to the instance through Instance Profiles. Dynamic credentials are then automatically obtained from AWS API and no further configuration is necessary. More information available here.

If IAM roles are not used you need to specify them either in a pillar file or in the minion's config file:

```
vpc.keyid: GKTADJGHEIQSXMKKRBJ08H
vpc.key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
```

It's also possible to specify key, keyid and region via a profile, either passed in as a dict, or as a string to pull from pillars or minion config:

```
myprofile:
  keyid: GKTADJGHEIQSXMKKRBJ08H
  key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
  region: us-east-1
```
Ensure VPC exists:
```yaml
boto_vpc.present:
  - name: myvpc
  - cidr_block: 10.10.11.0/24
  - dns_hostnames: True
  - region: us-east-1
  - keyid: GKTADJGHEIQSXMKKRBJ08H
  - key: askdjghsdfjkghWupUjasdflkdfklgjsdfajkghs
```

Ensure subnet exists:
```yaml
boto_vpc.subnet_present:
  - name: mysubnet
  - vpc_id: vpc-123456
  - cidr_block: 10.0.0.0/16
  - region: us-east-1
  - keyid: GKTADJGHEIQSXMKKRBJ08H
  - key: askdjghsdfjkghWupUjasdflkdfklgjsdfajkghs
```

Ensure internet gateway exists:
```yaml
boto_vpc.internet_gateway_present:
  - name: myigw
  - vpc_name: myvpc
  - region: us-east-1
  - keyid: GKTADJGHEIQSXMKKRBJ08H
  - key: askdjghsdfjkghWupUjasdflkdfklgjsdfajkghs
```

Ensure route table exists:
```yaml
boto_vpc.route_table_present:
  - name: my_route_table
  - vpc_id: vpc-123456
  - routes:
    - destination_cidr_block: 0.0.0.0/0
      instance_id: i-123456
      interface_id: eni-123456
    - subnet_names:
      - subnet1
      - subnet2
      - region: us-east-1
      - keyid: GKTADJGHEIQSXMKKRBJ08H
      - key: askdjghsdfjkghWupUjasdflkdfklgjsdfajkghs
```

```python
salt.states.boto_vpc.absent(name, tags=None, region=None, key=None, keyid=None, profile=None)
```

Ensure VPC with passed properties is absent.

- **name**: Name of the VPC.
- **tags**: A list of tags. All tags must match.
- **region**: Region to connect to.
- **key**: Secret key to be used.
- **keyid**: Access key to be used.
- **profile**: A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

```python
salt.states.boto_vpc.internet_gateway_absent(name, detach=False, region=None, key=None, keyid=None, profile=None)
```
Ensure the named internet gateway is absent.

**name**  Name of the internet gateway.

**detach**  First detach the internet gateway from a VPC, if attached.

**region**  Region to connect to.

**key**  Secret key to be used.

**keyid**  Access key to be used.

**profile**  A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

```python
salt.states.boto_vpc.internet_gateway_present(name, vpc_name=None, vpc_id=None, tags=None, region=None, key=None, keyid=None, profile=None)
```

Ensure an internet gateway exists.

**name**  Name of the internet gateway.

**vpc_name**  Name of the VPC to which the internet gateway should be attached.

**vpc_id**  Id of the VPC to which the internet_gateway should be attached. Only one of vpc_name or vpc_id may be provided.

**tags**  A list of tags.

**region**  Region to connect to.

**key**  Secret key to be used.

**keyid**  Access key to be used.

**profile**  A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

```python
salt.states.boto_vpc.present(name, cidr_block, instance_tenancy=None, dns_support=None, dns_hostnames=None, tags=None, region=None, key=None, keyid=None, profile=None)
```

Ensure VPC exists.

**name**  Name of the VPC.

**cidr_block**  The range of IPs in CIDR format, for example: 10.0.0.0/24. Block size must be between /16 and /28 netmask.

**instance_tenancy**  Instances launched in this VPC will be single-tenant or dedicated hardware.

**dns_support**  Indicates whether the DNS resolution is supported for the VPC.

**dns_hostnames**  Indicates whether the instances launched in the VPC get DNS hostnames.

**tags**  A list of tags.

**region**  Region to connect to.

**key**  Secret key to be used.

**keyid**  Access key to be used.

**profile**  A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

```python
salt.states.boto_vpc.route_table_absent(name, region=None, key=None, keyid=None, profile=None)
```

Ensure the named route table is absent.
name Name of the route table.
region Region to connect to.
key Secret key to be used.
keyid Access key to be used.
profile A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

```yaml
boto_vpc.route_table_present:
  - name: my_route_table
  - vpc_id: vpc-123456
  - routes:
    - destination_cidr_block: 0.0.0.0/0
      instance_id: i-123456
      interface_id: eni-123456
    - subnet_names: subnet1 - subnet2

name Name of the route table.
vpc_name Name of the VPC with which the route table should be associated.
vpc_id Id of the VPC with which the route table should be associated. Either vpc_name or vpc_id must be provided.
routes A list of routes.
subnet_ids A list of subnet ids to associate
subnet_names A list of subnet names to associate
tags A list of tags.
region Region to connect to.
key Secret key to be used.
keyid Access key to be used.
profile A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

salt.states.boto_vpc.subnet_absent(name=None, subnet_id=None, region=None, key=None, keyid=None, profile=None)

Ensure subnet with passed properties is absent.
name Name of the subnet.
region Region to connect to.
key Secret key to be used.
keyid  Access key to be used.

profile  A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

salt.states.boto_vpc.subnet_present(name, cidr_block, vpc_name=None, vpc_id=None, availability_zone=None, tags=None, region=None, key=None, keyid=None, profile=None)

Ensure a subnet exists.

name  Name of the subnet.

cidr_block  The range if IPs for the subnet, in CIDR format. For example: 10.0.0.0/24. Block size must be between /16 and /28 netmask.

vpc_name  Name of the VPC in which the subnet should be placed. Either vpc_name or vpc_id must be provided.

vpc_id  Id of the VPC in which the subnet should be placed. Either vpc_name or vpc_id must be provided.

availability_zone  AZ in which the subnet should be placed.

tags  A list of tags.

region  Region to connect to.

key  Secret key to be used.

keyid  Access key to be used.

profile  A dict with region, key and keyid, or a pillar key (string) that contains a dict with region, key and keyid.

32.29.31  salt.states.bower

Installation of Bower Packages

These states manage the installed packages using Bower. Note that npm, git and bower must be installed for these states to be available, so bower states should include requisites to pkg.installed states for the packages which provide npm and git (simply npm and git in most cases), and npm.installed state for the package which provides bower.

Example:

```python
npm:
    pkg.installed

git:
    pkg.installed

bower:
    npm.installed
    require:
        - pkg: npm
        - pkg: git

underscore:
    bower.installed:
        - dir: /path/to/project
        - require:
            - npm: bower
```

salt.states.bower.bootstrap(name, user=None)

Bootstraps a frontend distribution.

32.29.  Full list of builtin state modules
Will execute `bower install` on the specified directory.

**user** The user to run Bower with

**salt.states.bower.installed**

Verify that the given package is installed and is at the correct version (if specified).

```yaml
underscore:
  bower.installed:
    - dir: /path/to/project
    - user: someuser

jquery#2.0:
  bower.installed:
    - dir: /path/to/project
```

**name** The package to install  
**dir** The target directory in which to install the package  
**pkgs** A list of packages to install with a single Bower invocation; specifying this argument will ignore the **name** argument  
**user** The user to run Bower with  
**env** A list of environment variables to be set prior to execution. The format is the same as the `cmd.run` state function.

**salt.states.bower.removed**

Verify that the given package is not installed.

**dir** The target directory in which to install the package  
**user** The user to run Bower with

## 32.29.32 salt.states.cabal

### Installation of Cabal Packages

New in version 2015.8.0.

These states manage the installed packages for Haskell using cabal. Note that cabal-install must be installed for these states to be available, so cabal states should include a requisite to a pkg.installed state for the package which provides cabal (`cabal-install` in case of Debian based distributions). Example:

```yaml
shellcheck:
  cabal.installed:
    - require: - pkg: cabal-install

salt.states.cabal.installed
```

Verify that the given package is installed and is at the correct version (if specified).
ShellCheck-0.3.5:
cabal:
  - installed:

name  The package to install
user  The user to run cabal install with
install_global  Install package globally instead of locally
env  A list of environment variables to be set prior to execution. The format is the same as the `cmd.run` state function.

`salt.states.cabal.removed(name, user=None, env=None)`
Verify that given package is not installed.

### 32.29.33 `salt.states.chef`

**Execute Chef client runs**

Run chef-client or chef-solo

```python
chef.client:
  - override-runlist: 'demo1,demo2'
  - server: 'https://chef.domain.com'

default-chef-run:
  chef.client: []

my-solo-run:
  chef.solo:
    - environment: dev
```

`salt.states.chef.client(name, **kwargs)`

- name  Unique identifier for the state. Does not affect the Chef run.
- server  The chef server URL
- client_key  Set the client key file location
- config  The configuration file to use
- config-file-jail  Directory under which config files are allowed to be loaded (no client.rb or knife.rb outside this path will be loaded).
- environment  Set the Chef Environment on the node
- group  Group to set privilege to
- json-attributes  Load attributes from a JSON file or URL
- localmode  Point chef-client at local repository if True
- log_level  Set the log level (debug, info, warn, error, fatal)
- logfile  Set the log file location
- node-name  The node name for this client

32.29. Full list of builtin state modules
override-runlist  Replace current run list with specified items for a single run

pid  Set the PID file location, defaults to /tmp/chef-client.pid

run-lock-timeout  Set maximum duration to wait for another client run to finish, default is indefinitely.

runlist  Permanently replace current run list with specified items

user  User to set privilege to

validation_key  Set the validation key file location, used for registering new clients

salt.states.chef.solo(name, **kwargs)

name  Unique identifier for the state. Does not affect the Chef run.

config  The configuration file to use

environment  Set the Chef Environment on the node

group  Group to set privilege to

json-attributes  Load attributes from a JSON file or URL

log_level  Set the log level (debug, info, warn, error, fatal)

logfile  Set the log file location

node-name  The node name for this client

override-runlist  Replace current run list with specified items for a single run

recipe-url  Pull down a remote gzipped tarball of recipes and untar it to the cookbook cache

run-lock-timeout  Set maximum duration to wait for another client run to finish, default is indefinitely.

user  User to set privilege to

32.29.34 salt.states.cloud

Using states instead of maps to deploy clouds

New in version 2014.1.0.

Use this minion to spin up a cloud instance:

```
my-ec2-instance:
  cloud.profile:
    my-ec2-config
```

salt.states.cloud.absent(name, onlyif=None, unless=None)

Ensure that no instances with the specified names exist.

CAUTION: This is a destructive state, which will search all configured cloud providers for the named instance, and destroy it.

name  The name of the instance to destroy

onlyif  Do run the state only if is unless succeed

unless  Do not run the state at least unless succeed

salt.states.cloud.present(name, cloud_provider, onlyif=None, unless=None, **kwargs)

Spin up a single instance on a cloud provider, using salt-cloud. This state does not take a profile argument; rather, it takes the arguments that would normally be configured as part of the state.
Note that while this function does take any configuration argument that would normally be used to create an instance, it will not verify the state of any of those arguments on an existing instance. Stateful properties of an instance should be configured using their own individual state (i.e., cloud.tagged, cloud.untagged, etc).

- **name**: The name of the instance to create
- **cloud_provider**: The name of the cloud provider to use
- **onlyif**: Do run the state only if is unless succeed
- **unless**: Do not run the state at least unless succeed

```python
def salt.states.cloud.profile(name, profile, onlyif=None, unless=None, **kwargs):
    # Create a single instance on a cloud provider, using a salt-cloud profile.
    # Note that while profiles used this function do take any configuration argument that would normally be used to create an instance using a profile, this state will not verify the state of any of those arguments on an existing instance. Stateful properties of an instance should be configured using their own individual state (i.e., cloud.tagged, cloud.untagged, etc).
    # **name**: The name of the instance to create
    # **profile**: The name of the cloud profile to use
    # **onlyif**: Do run the state only if is unless succeed
    # **unless**: Do not run the state at least unless succeed
    # **kwargs**: Any profile override or addition
```

- **salt.states.cloud.volume_absent(name, provider=None, **kwargs)**: Check that a block volume exists.
- **salt.states.cloud.volume_attached(name, server_name=None, provider=None, **kwargs)**: Check if a block volume is attached.
- **salt.states.cloud.volume_detached(name, server_name=None, provider=None, **kwargs)**: Check if a block volume is detached.
- **salt.states.cloud.volume_present(name, provider=None, **kwargs)**: Check that a block volume exists.

### 32.29.35 salt.states.cmd

#### Execution of arbitrary commands

The cmd state module manages the enforcement of executed commands, this state can tell a command to run under certain circumstances.

A simple example to execute a command:

```bash
date > /tmp/salt-run:
    cmd.run
```

Only run if another execution failed, in this case truncate syslog if there is no disk space:

```bash
> /var/log/messages:
    cmd.run:
        - unless: echo 'foo' > /tmp/.test && rm -f /tmp/.test
```
Only run if the file specified by `creates` does not exist, in this case touch /tmp/foo if it does not exist.

```bash
touch /tmp/foo:
  cmd.run:
    - creates: /tmp/foo
```

**Note:** The `creates` option was added to version 2014.7.0

Salt determines whether the `cmd` state is successfully enforced based on the exit code returned by the command. If the command returns a zero exit code, then salt determines that the state was successfully enforced. If the script returns a non-zero exit code, then salt determines that it failed to successfully enforce the state. If a command returns a non-zero exit code but you wish to treat this as a success, then you must place the command in a script and explicitly set the exit code of the script to zero.

Please note that the success or failure of the state is not affected by whether a state change occurred nor the stateful argument.

When executing a command or script, the state (i.e., changed or not) of the command is unknown to Salt's state system. Therefore, by default, the `cmd` state assumes that any command execution results in a changed state.

This means that if a `cmd` state is watched by another state then the state that's watching will always be executed due to the `changed` state in the `cmd` state.

### Using the `Stateful` Argument

Many state functions in this module now also accept a `stateful` argument. If `stateful` is specified to be true then it is assumed that the command or script will determine its own state and communicate it back by following a simple protocol described below:

1. **If there's nothing in the stdout of the command, then assume no changes.** Otherwise, the stdout must be either in JSON or its last non-empty line must be a string of key=value pairs delimited by spaces (no spaces on either side of `=`).

2. **If it's JSON then it must be a JSON object (e.g., `{}`).** If it's key=value pairs then quoting may be used to include spaces. (Python's shlex module is used to parse the key=value string)

   Two special keys or attributes are recognized in the output:

   ```
   changed: bool (i.e., 'yes', 'no', 'true', 'false', case-insensitive)
   comment: str (i.e., any string)
   ```

   So, only if `changed` is `True` then assume the command execution has changed the state, and any other key values or attributes in the output will be set as part of the changes.

3. **If there's a comment then it will be used as the comment of the state.**

   Here's an example of how one might write a shell script for use with a stateful command:

   ```bash
   #!/bin/bash
   
   # working hard...
   echo "Working hard...

   # writing the state line
   echo # an empty line here so the next line will be the last.
   echo "changed=yes comment='something has changed' whatever=123"
   ```

   And an example SLS file using this module:
Run myscript:
  cmd.run:
    - name: /path/to/myscript
    - cwd: /
    - stateful: True

Run only if myscript changed something:
  cmd.wait:
    - name: echo hello
    - cwd: /
    - watch:
      - cmd: Run myscript

Note that if the cmd.wait state also specifies stateful: True it can then be watched by some other states as well.

4. The stateful argument can optionally include a test_name parameter.

This is used to specify a command to run in test mode. This command should return stateful data for changes that would be made by the command in the name parameter.

New in version 2015.2.0.

Run myscript:
  cmd.run:
    - name: /path/to/myscript
    - cwd: /
    - stateful:
      - test_name: /path/to/myscript test

Run masterscript:
  cmd.script:
    - name: masterscript
    - source: salt://path/to/masterscript
    - cwd: /
    - stateful:
      - test_name: masterscript test

cmd.wait is not restricted to watching only cmd states. For example it can also watch a git state for changes.

# Watch for changes to a git repo and rebuild the project on updates
my-project:
  git.latest:
    - name: git@github.com/repo/foo
    - target: /opt/foo
    - rev: master
  cmd.wait:
    - name: make install
    - cwd: /opt/foo
    - watch:
      - git: my-project

Should I use cmd.run or cmd.wait?

These two states are often confused. The important thing to remember about them is that cmd.run states are run each time the SLS file that contains them is applied. If it is more desirable to have a command that only runs after
some other state changes, then `cmd.wait` does just that. `cmd.wait` is designed to watch other states, and is executed when the state it is watching changes. Example:

```
/usr/local/bin/postinstall.sh:
  cmd.wait:
    - watch:
      - pkg: mycustompkg
  file.managed:
    - source: salt://utils/scripts/postinstall.sh

mycustompkg:
  pkg.installed:
    - require:
      - file: /usr/local/bin/postinstall.sh
```

How do I create an environment from a pillar map?

The map that comes from a pillar cannot be directly consumed by the env option. To use it one must convert it to a list. Example:

```
printenv:
  cmd.run:
    - env:
      {% for key, value in pillar['keys'].iteritems() %}
        - '{% key %}': '{% value %}'
      {% endfor %}
```

```python
salt.states.cmd.call(name, func, args=(), kws=None, onlyif=None, unless=None, creates=None, output_loglevel='debug', use_vt=False, **kwargs)
```

Invoke a pre-defined Python function with arguments specified in the state declaration. This function is mainly used by the `salt.renderers.pydsl` renderer.

The interpretation of onlyif and unless arguments are identical to those of `cmd.run`, and all other arguments(cwd, runas, ...) allowed by `cmd.run` are allowed here, except that their effects apply only to the commands specified in onlyif and unless rather than to the function to be invoked.

In addition, the stateful argument has no effects here.

The return value of the invoked function will be interpreted as follows.

If it’s a dictionary then it will be passed through to the state system, which expects it to have the usual structure returned by any salt state function.

Otherwise, the return value (denoted as `result` in the code below) is expected to be a JSON serializable object, and this dictionary is returned:

```
{
  'name': name,
  'changes': {'retval': result},
  'result': True if result is None else bool(result),
  'comment': result if isinstance(result, string_types) else ''
}
```

```python
salt.states.cmd.mod_run_check(cmd_kwargs, onlyif, unless, group, creates)
```

Execute the onlyif and unless logic. Return a result dict if:

- group is not available
- onlyif failed (onlyif != 0)
- unless succeeded (unless == 0) else return True
salt.states.cmd.mod_watch(name, **kwargs)
    Execute a cmd function based on a watch call

salt.states.cmd.run(name, onlyif=None, unless=None, creates=None, cwd=None, user=None, group=None, shell=None, env=None, stateful=False, umask=None, output_loglevel='debug', quiet=False, timeout=None, ignore_timeout=False, use_vt=False, **kwargs)
    Run a command if certain circumstances are met. Use cmd.wait if you want to use the watch requisite.

name The command to execute, remember that the command will execute with the path and permissions of the salt-minion.

onlyif A command to run as a check, run the named command only if the command passed to the onlyif option returns true

unless A command to run as a check, only run the named command if the command passed to the unless option returns false

cwd The current working directory to execute the command in, defaults to /root

user The user name to run the command as

group The group context to run the command as

shell The shell to use for execution, defaults to the shell grain

env A list of environment variables to be set prior to execution. Example:

```
script-foo:
    cmd.run:
        - env:
            - BATCH: 'yes'
```

Warning: The above illustrates a common PyYAML pitfall, that yes, no, on, off, true, and false are all loaded as boolean True and False values, and must be enclosed in quotes to be used as strings. More info on this (and other) PyYAML idiosyncrasies can be found here.

Variables as values are not evaluated. So $PATH in the following example is a literal `$PATH`:

```
script-bar:
    cmd.run:
        - env: "PATH=/some/path:$PATH"
```

One can still use the existing $PATH by using a bit of Jinja:

```
{% set current_path = salt['environ.get']('PATH', '/bin:/usr/bin') %}
mycommand:
    cmd.run:
        - name: ls -l /
        - env:
            - PATH: {{ [current_path, '/my/special/bin']|join(':') }}
```

stateful The command being executed is expected to return data about executing a state. For more information, see the Using the `Stateful` Argument section.

umask The umask (in octal) to use when running the command.

output_loglevel Control the loglevel at which the output from the command is logged. Note that the command being run will still be logged (loglevel: DEBUG) regardless, unless quiet is used for this value.
quiet The command will be executed quietly, meaning no log entries of the actual command or its return data. This is deprecated as of the 2014.1.0 release, and is being replaced with output_loglevel: quiet.

timeout If the command has not terminated after timeout seconds, send the subprocess sigterm, and if sigterm is ignored, follow up with sigkill

ignore_timeout Ignore the timeout of commands, which is useful for running nohup processes.

New in version 2015.8.0.

creates Only run if the file specified by creates does not exist.

New in version 2014.7.0.

use_vt Use VT utils (saltstack) to stream the command output more interactively to the console and the logs. This is experimental.

Note: cmd.run supports the usage of reload_modules. This functionality allows you to force Salt to reload all modules. You should only use reload_modules if your cmd.run does some sort of installation (such as pip), if you do not reload the modules future items in your state which rely on the software being installed will fail.

getpip:
  cmd.run:
  - name: /usr/bin/python /usr/local/sbin/get-pip.py
  - unless: which pip
  - require:
    - pkg: python
  - file: /usr/local/sbin/get-pip.py
  - reload_modules: True

salt.states.cmd.script(name, source=None, template=None, onlyif=None, unless=None, creates=None, cwd=None, user=None, group=None, shell=None, env=None, stateful=False, umask=None, timeout=None, use_vt=False, output_loglevel='debug', **kwargs)

Download a script and execute it with specified arguments.

source The location of the script to download. If the file is located on the master in the directory named spam, and is called eggs, the source string is salt://spam/eggs

template If this setting is applied then the named templating engine will be used to render the downloaded file. Currently jinja, mako, and wempy are supported

name Either `cmd arg1 arg2 arg3...` (cmd is not used) or a source `salt://...`

onlyif Run the named command only if the command passed to the onlyif option returns true

unless Run the named command only if the command passed to the unless option returns false

cwd The current working directory to execute the command in, defaults to /root

user The name of the user to run the command as

group The group context to run the command as

shell The shell to use for execution. The default is set in grains['shell']

env A list of environment variables to be set prior to execution. Example:
Warning: The above illustrates a common PyYAML pitfall, that yes, no, on, off, true, and false are all loaded as boolean True and False values, and must be enclosed in quotes to be used as strings. More info on this (and other) PyYAML idiosyncrasies can be found here.

Variables as values are not evaluated. So $PATH in the following example is a literal `$PATH`:

```yaml
salt://scripts/bar.sh:
  cmd.script:
    - env: "PATH=/some/path:$PATH"
```

One can still use the existing $PATH by using a bit of Jinja:

```jinja
{% set current_path = salt['environ.get']('PATH', '/bin:/usr/bin') %}

mycommand:
  cmd.run:
    - name: ls -l /
    - env:
      - PATH: {{ [current_path, '/my/special/bin']|join(':') }}
```

**saltenv**  [base] The Salt environment to use

**umask** The umask (in octal) to use when running the command.

**stateful** The command being executed is expected to return data about executing a state. For more information, see the Using the ``Stateful`` Argument section.

**timeout** If the command has not terminated after timeout seconds, send the subprocess sigterm, and if sigterm is ignored, follow up with sigkill

**args** String of command line args to pass to the script. Only used if no args are specified as part of the name argument. To pass a string containing spaces in YAML, you will need to doubly-quote it: `"arg1 `arg two' arg3"

**creates** Only run if the file specified by creates does not exist.

New in version 2014.7.0.

**use_vt** Use VT utils (saltstack) to stream the command output more interactively to the console and the logs. This is experimental.

**output_loglevel** Control the loglevel at which the output from the command is logged. Note that the command being run will still be logged (loglevel: DEBUG) regardless, unless quiet is used for this value.

```python
salt.states.cmd.wait(name, onlyif=None, unless=None, creates=None, cwd=None, user=None, group=None, shell=None, env=(), stateful=False, umask=None, output_loglevel='debug', use_vt=False, **kwargs)
```

Run the given command only if the watch statement calls it

**name** The command to execute, remember that the command will execute with the path and permissions of the salt-minion.

**onlyif** A command to run as a check, run the named command only if the command passed to the onlyif option returns true
unless A command to run as a check, only run the named command if the command passed to the unless option returns false

cwd The current working directory to execute the command in, defaults to /root

user The user name to run the command as

group The group context to run the command as

shell The shell to use for execution, defaults to /bin/sh

e A list of environment variables to be set prior to execution. Example:

```
script-foo:
  cmd.wait:
    - env:
      - BATCH: 'yes'
```

**Warning:** The above illustrates a common PyYAML pitfall, that yes, no, on, off, true, and false are all loaded as boolean True and False values, and must be enclosed in quotes to be used as strings. More info on this (and other) PyYAML idiosyncrasies can be found [here](#).

Variables as values are not evaluated. So $PATH in the following example is a literal `\$PATH`:

```
script-bar:
  cmd.wait:
    - env: "PATH=/some/path:$PATH"
```

One can still use the existing $PATH by using a bit of Jinja:

```
{% set current_path = salt['environ.get']('PATH', '/bin:/usr/bin') %}

mycommand:
  cmd.run:
    - name: ls -l /
    - env:
      - PATH: {{ current_path, '/my/special/bin' }}
```

umask The umask (in octal) to use when running the command.

stateful The command being executed is expected to return data about executing a state. For more information, see the Using the Stateful Argument section.

creates Only run if the file specified by creates does not exist.

New in version 2014.7.0.

output_loglevel Control the loglevel at which the output from the command is logged. Note that the command being run will still be logged (loglevel: DEBUG) regardless, unless quiet is used for this value.

use_vt Use VT utils (saltstack) to stream the command output more interactively to the console and the logs.

This is experimental.

salt.states.cmd.wait_call(name, func, args=(), kws=None, onlyif=None, unless=None, creates=None, stateful=False, use_vt=False, output_loglevel='debug', **kwargs)

salt.states.cmd.wait_script(name, source=None, template=None, onlyif=None, unless=None, cwd=None, user=None, group=None, shell=None, env=None, stateful=False, umask=None, use_vt=False, output_loglevel='debug', **kwargs)
Download a script from a remote source and execute it only if a watch statement calls it.

**source** The source script being downloaded to the minion, this source script is hosted on the salt master server. If the file is located on the master in the directory named spam, and is called eggs, the source string is `salt://spam/eggs`.

**template** If this setting is applied then the named templating engine will be used to render the downloaded file, currently jinja, mako, and wempy are supported.

**name** The command to execute, remember that the command will execute with the path and permissions of the salt-minion.

**onlyif** A command to run as a check, run the named command only if the command passed to the `onlyif` option returns true.

**unless** A command to run as a check, only run the named command if the command passed to the `unless` option returns false.

**cwd** The current working directory to execute the command in, defaults to `/root`.

**user** The user name to run the command as.

**group** The group context to run the command as.

**shell** The shell to use for execution, defaults to the shell grain.

**env** A list of environment variables to be set prior to execution. Example:

```yaml
salt://scripts/foo.sh:
  cmd.wait_script:
  - env:
    - BATCH: 'yes'
```

**Warning:** The above illustrates a common PyYAML pitfall, that `yes, no, on, off, true, and false` are all loaded as boolean `True` and `False` values, and must be enclosed in quotes to be used as strings. More info on this (and other) PyYAML idiosyncrasies can be found [here](#).

Variables as values are not evaluated. So `$PATH` in the following example is a literal `$PATH`:

```yaml
salt://scripts/bar.sh:
  cmd.wait_script:
  - env: "PATH=/some/path:$PATH"
```

One can still use the existing `PATH` by using a bit of Jinja:

```yaml
{% set current_path = salt['environ.get']('PATH', '/bin:/usr/bin') %}
mycommand:
  cmd.run:
  - name: ls -l /
  - env:
    - PATH: {{ [current_path, '/my/special/bin']|join(':') }}
```

**umask** The umask (in octal) to use when running the command.

**stateful** The command being executed is expected to return data about executing a state. For more information, see the Using the `Stateful` Argument section.

**use_vt**
Use VT utils (saltstack) to stream the command output more interactively to the console and the logs. This is experimental.

**output_loglevel** Control the loglevel at which the output from the command is logged. Note that the command being run will still be logged (loglevel: DEBUG) regardless, unless `quiet` is used for this value.

### 32.29.36 salt.states.composer

**Installation of Composer Packages**

These states manage the installed packages for composer for PHP. Note that either composer is installed and accessible via a bin directory or you can pass the location of composer in the state.

```python
get-composer:
  cmd.run:
    - name: '{CURL=`which curl`; $CURL -sS https://getcomposer.org/installer | php'
    - unless: test -f /usr/local/bin/composer
    - cwd: /root/

install-composer:
  cmd.wait:
    - name: mv /root/composer.phar /usr/local/bin/composer
    - cwd: /root/
    - watch:
      - cmd: get-composer

/path/to/project:
  composer.installed:
    - no_dev: true
    - require:
      - cmd: install-composer

# Without composer installed in your PATH
# Note: composer.phar must be executable for state to work properly
/path/to/project:
  composer.installed:
    - composer: /path/to/composer.phar
    - php: /usr/local/bin/php
    - no_dev: true

salt.states.composer.installed(name, composer=None, php=None, user=None, prefer_source=None, prefer_dist=None, no_scripts=None, no_plugins=None, optimize=None, no_dev=None, quiet=False, composer_home='/root', always_check=True)

Verify that the correct versions of composer dependencies are present.

**dir** Directory location of the composer.json file.

**composer** Location of the composer.phar file. If not set composer will just execute `composer` as if it is installed globally. (i.e. /path/to/composer.phar)

**php** Location of the php executable to use with composer. (i.e. /usr/bin/php)

**user** Which system user to run composer as.

New in version 2014.1.4.
prefer_source --prefer-source option of composer.
prefer_dist --prefer-dist option of composer.
no_scripts --no-scripts option of composer.
no_plugins --no-plugins option of composer.
optimize --optimize-autoloader option of composer. Recommended for production.
no_dev --no-dev option for composer. Recommended for production.
quiet --quiet option for composer. Whether or not to return output from composer.

composer_home $COMPOSER_HOME environment variable

always_check If True, _always_ run composer install in the directory. This is the default behavior. If False, only run composer install if there is no vendor directory present.

salt.states.composer.update(name, composer=None, php=None, user=None, prefer_source=None,
prefer_dist=None, no_scripts=None, no_plugins=None, optimize=None,
no_dev=None, quiet=False, composer_home='/root')

Composer update the directory to ensure we have the latest versions of all project dependencies.

dir Directory location of the composer.json file.

composer Location of the composer.phar file. If not set composer will just execute `composer` as if it is installed globally. (i.e. /path/to/composer.phar)

php Location of the php executable to use with composer. (i.e. /usr/bin/php)

user Which system user to run composer as.

New in version 2014.1.4.

prefer_source --prefer-source option of composer.
prefer_dist --prefer-dist option of composer.
no_scripts --no-scripts option of composer.
no_plugins --no-plugins option of composer.
optimize --optimize-autoloader option of composer. Recommended for production.
no_dev --no-dev option for composer. Recommended for production.
quiet --quiet option for composer. Whether or not to return output from composer.

composer_home $COMPOSER_HOME environment variable

32.29.37 salt.states.cron

Management of cron, the Unix command scheduler

Cron declarations require a number of parameters. The following are the parameters used by Salt to define the various timing values for a cron job:

- minute
- hour
- daymonth
- month
• dayweek (0 to 6 are Sunday through Saturday, 7 can also be used for Sunday)

**Warning:** Any timing arguments not specified take a value of *. This means that setting `hour` to 5, while not defining the `minute` param, will result in Salt adding a job that will execute every minute between 5 and 6 A.M.!

Additionally, the default user for these states is `root`. Therefore, if the cron job is for another user, it is necessary to specify that user with the `user` parameter.

A long time ago (before 2014.2), when making changes to an existing cron job, the name declaration is the parameter used to uniquely identify the job, so if an existing cron that looks like this:

```plaintext
date > /tmp/crontest:
cron.present:
- user: root
- minute: 5
```

Is changed to this:

```plaintext
date > /tmp/crontest:
cron.present:
- user: root
- minute: 7
- hour: 2
```

Then the existing cron will be updated, but if the cron command is changed, then a new cron job will be added to the user's crontab.

The current behavior is still relying on that mechanism, but you can also specify an identifier to identify your crontabs:

```plaintext
date > /tmp/crontest:
cron.present:
- identifier: SUPERCRON
- user: root
- minute: 7
- hour: 2
```

New in version 2014.1.2.

And, some months later, you modify it:

```plaintext
superscript > /tmp/crontest:
cron.present:
- identifier: SUPERCRON
- user: root
- minute: 3
- hour: 4
```

New in version 2014.1.2.

The old `date > /tmp/crontest` will be replaced by `superscript > /tmp/crontest`.

Additionally, Salt also supports running a cron every `x` minutes very similarly to the Unix convention of using `*/5` to have a job run every five minutes. In Salt, this looks like:

```plaintext
date > /tmp/crontest:
cron.present:
```
The job will now run every 5 minutes.

Additionally, the temporal parameters (minute, hour, etc.) can be randomized by using `random` instead of using a specific value. For example, by using the `random` keyword in the `minute` parameter of a cron state, the same cron job can be pushed to hundreds or thousands of hosts, and they would each use a randomly-generated minute. This can be helpful when the cron job accesses a network resource, and it is not desirable for all hosts to run the job concurrently.

```bash
/path/to/cron/script:
cron.present:
  - user: root
  - minute: random
  - hour: 2
```

New in version 0.16.0.

Since Salt assumes a value of `*` for unspecified temporal parameters, adding a parameter to the state and setting it to `random` will change that value from `*` to a randomized numeric value. However, if that field in the cron entry on the minion already contains a numeric value, then using the `random` keyword will not modify it.

```python
salt.states.cron.absent(name, user='root', identifier=False, **kwargs)
Verifies that the specified cron job is absent for the specified user; only the name is matched when removing a cron job.

name  The command that should be absent in the user crontab.
user  The name of the user whose crontab needs to be modified, defaults to the root user
identifier  Custom-defined identifier for tracking the cron line for future crontab edits. This defaults to the state id
```

```python
salt.states.cron.env_absent(name, user='root')
Verifies that the specified environment variable is absent from the crontab for the specified user

name  The name of the environment variable to remove from the user crontab
user  The name of the user whose crontab needs to be modified, defaults to the root user
```

```python
salt.states.cron.env_present(name, value=None, user='root')
Verifies that the specified environment variable is present in the crontab for the specified user.

name  The name of the environment variable to set in the user crontab
user  The name of the user whose crontab needs to be modified, defaults to the root user
value  The value to set for the given environment variable
```

```python
salt.states.cron.file(name, source_hash=' ', user='root', template=None, context=None, replace=True, defaults=None, env=None, backup='', **kwargs)
Provides file.managed-like functionality (templating, etc.) for a pre-made crontab file, to be assigned to a given user.

name  The source file to be used as the crontab. This source file can be hosted on either the salt master server, or on an HTTP or FTP server. For files hosted on the salt file server, if the file is located on the master in the directory named spam, and is called eggs, the source string is `salt://spam/eggs`

If the file is hosted on a HTTP or FTP server then the source_hash argument is also required
```
**source_hash** This can be either a file which contains a source hash string for the source, or a source hash string. The source hash string is the hash algorithm followed by the hash of the file:

```
md5=e138491e9d5b97023cea823fe17bac22
```

**user** The user to whom the crontab should be assigned. This defaults to root.

**template** If this setting is applied then the named templating engine will be used to render the downloaded file. Currently, jinja and mako are supported.

**context** Overrides default context variables passed to the template.

**replace** If the crontab should be replaced, if False then this command will be ignored if a crontab exists for the specified user. Default is True.

**defaults** Default context passed to the template.

**backup** Overrides the default backup mode for the user's crontab.

```python
salt.states.cron.present(name, user='root', minute='*', hour='*', daymonth='*', month='*', dayweek='*', comment=None, identifier=False)
```

Verifies that the specified cron job is present for the specified user. For more advanced information about what exactly can be set in the cron timing parameters, check your cron system's documentation. Most Unix-like systems' cron documentation can be found via the `crontab` man page: `man 5 crontab`.

**name** The command that should be executed by the cron job.

**user** The name of the user whose crontab needs to be modified, defaults to the root user

**minute** The information to be set into the minute section, this can be any string supported by your cron system's the minute field. Default is *

**hour** The information to be set in the hour section. Default is *

**daymonth** The information to be set in the day of month section. Default is *

**month** The information to be set in the month section. Default is *

**dayweek** The information to be set in the day of week section. Default is *

**comment** User comment to be added on line previous the cron job

**identifier** Custom-defined identifier for tracking the cron line for future crontab edits. This defaults to the state id

---

## 32.29.38 salt.states.cyg

Installation of Cygwin packages.

A state module to manage cygwin packages. Packages can be installed or removed.

```bash
dos2unix:
  cyg.installed
```

class salt.states.cyg.DictDiffer(current_dict, past_dict)

Calculate the difference between two dictionaries.

1. items added
2. items removed
3. keys same in both but changed values
4. keys same in both and unchanged values

---
**added()**
Return a set of additions to past_dict.

**changed()**
Return a set of the keys with changed values.

**removed()**
Return a set of things removed from past_dict.

**same()**
True if the two dicts are the same.

**unchanged()**
Return a set of the keys with unchanged values.

```python
salt.states.cyg.installed(name, cyg_arch='x86_64', mirrors=None)
```
Make sure that a package is installed.

- **name** The name of the package to install
- **cyg_arch** [x86_64] The cygwin architecture to install the package into. Current options are x86 and x86_64
- **mirrors** [None] List of mirrors to check. None will use a default mirror (kernel.org)

```bash
titin:
  cyg.installed:
    - mirrors:
      - http://mirror/without/public/key: ""
```

```python
salt.states.cyg.removed(name, cyg_arch='x86_64', mirrors=None)
```
Make sure that a package is not installed.

- **name** The name of the package to uninstall
- **cyg_arch** [x86_64] The cygwin architecture to remove the package from. Current options are x86 and x86_64
- **mirrors** [None] List of mirrors to check. None will use a default mirror (kernel.org)

```bash
titin:
  cyg.removed:
    - mirrors:
      - http://mirror/without/public/key: ""
```

```python
salt.states.cyg.updated(name=None, cyg_arch='x86_64', mirrors=None)
```
Make sure all packages are up to date.

- **name** [None] No affect, salt fails poorly without the arg available
- **cyg_arch** [x86_64] The cygwin architecture to update. Current options are x86 and x86_64
- **mirrors** [None] List of mirrors to check. None will use a default mirror (kernel.org)

```bash
titin:
  cyg.updated:
    - mirrors:
```
Dynamic DNS updates

Ensure a DNS record is present or absent utilizing RFC 2136 type dynamic updates.

depends
  - dnspython

Note: The dnspython module is required when managing DDNS using a TSIG key. If you are not using a TSIG key, DDNS is allowed by ACLs based on IP address and the dnspython module is not required.

Example:

```yaml
webserver:
  ddns.present:
    - zone: example.com
    - ttl: 60
    - data: 111.222.333.444
    - nameserver: 123.234.345.456
    - keyfile: /srv/salt/dnspy_tsig_key.txt
```

salt.states.ddns.absent(name, zone, data=None, rdtype=None, **kwargs)

Ensures that the named DNS record is absent.

- **name** The host portion of the DNS record, e.g., `webserver`. Name and zone are concatenated when the entry is created, so make sure that information is not duplicated in these two arguments.
- **zone** The zone to check
- **data** Data for the DNS record. E.g., the IP address for an A record. If omitted, all records matching name (and rdtype, if provided) will be purged.
- **rdtype** DNS resource type. If omitted, all types will be purged.
- **kwargs** Additional arguments the ddns.update function may need (e.g. nameserver, keyfile, keyname).

Note that the nsupdate key file can’t be reused by this function, the keyfile and other arguments must follow the dnspython spec.

salt.states.ddns.present(name, zone, ttl, data, rdtype='A', **kwargs)

Ensures that the named DNS record is present with the given ttl.

- **name** The host portion of the DNS record, e.g., `webserver`. Name and zone are concatenated when the entry is created, so make sure that information is not duplicated in these two arguments.
- **zone** The zone to check/update
- **ttl** TTL for the record
- **data** Data for the DNS record. E.g., the IP address for an A record.
- **rdtype** DNS resource type. Default `A`.
**kwargs Additional arguments the ddns.update function may need (e.g. nameserver, keyfile, keyname). Not that the nsupdate key file can’t be reused by this function, the keyfile and other arguments must follow the dnspython spec.

32.29.40 salt.states.debconfmod

Management of debconf selections

depends

- debconf-utils package

The debconfmod state module manages the enforcement of debconf selections, this state can set those selections prior to package installation.

Available Functions

The debconfmod state has two functions, the set and set_file functions

set Set debconf selections from the state itself

set_file Set debconf selections from a file

```yaml
nullmailer-debconf:
  debconf.set:
    - name: nullmailer
    - data:
      'shared/mailname': {'type': 'string', 'value': 'server.domain.tld'}
      'nullmailer/relayhost': {'type': 'string', 'value': 'mail.domain.tld'}

ferm-debconf:
  debconf.set:
    - name: ferm
    - data:
      'ferm/enable': {'type': 'boolean', 'value': True}
```

Note: Due to how PyYAML imports nested dicts (see here), the values in the data dict must be indented four spaces instead of two.

```yaml
salt.states.debconfmod.set(name, data, **kwargs)

Set debconf selections

```

```yaml
<state_id>:
  debconf.set:
    - name: <name>
    - data:
      <question>: {'type': <type>, 'value': <value>}
      <question>: {'type': <type>, 'value': <value>}

<state_id>:
  debconf.set:
    - name: <name>
    - data:
      <question>: {'type': <type>, 'value': <value>}
      <question>: {'type': <type>, 'value': <value>}
```
name: The package name to set answers for.

data: A set of questions/answers for debconf. Note that everything under this must be indented twice.

question: The question the is being pre-answered

type: The type of question that is being asked (string, boolean, select, etc.)

value: The answer to the question

salt.states.debconfmod.set_file(name, source, template=None, context=None, defaults=None, **kwargs)

Set debconf selections from a file or a template

```yaml
<state_id>:
  debconf.set_file:
    - source: salt://path/to/pkg.selections

<state_id>:
  debconf.set_file:
    - source: salt://path/to/pkg.selections?saltenv=myenvironment

<state_id>:
  debconf.set_file:
    - source: salt://path/to/pkg.selections.jinja2
      template: jinja
      context:
        some_value: "false"
```

source: The location of the file containing the package selections

template If this setting is applied then the named templating engine will be used to render the package selections file, currently jinja, mako, and wempy are supported

context Overrides default context variables passed to the template.

defaults Default context passed to the template.

32.29.41 salt.states.dellchassis

Manage chassis via Salt Proxies.

New in version 2015.8.2.

Below is an example state that sets basic parameters:

```yaml
my-dell-chassis:
  dellchassis.chassis:
    - chassis_name: my-dell-chassis
    - datacenter: dc-1-us
    - location: my-location
    - mode: 2
    - idrac_launch: 1
    - slot_names:
        - server-1: my-slot-name
        - server-2: my-other-slot-name
    - blade_power_states:
        - server-1: on
        - server-2: off
        - server-3: powercycle
```
However, it is possible to place the entire set of chassis configuration data in pillar. Here's an example pillar structure:

```yaml
proxy:
  host: 10.27.20.18
  admin_username: root
  fallback_admin_username: root
  passwords:
    - super-secret
    - old-secret
  proxytype: fx2

chassis:
  name: fx2-1
  username: root
  password: saltstack1
  datacenter: london
  location: rack-1-shelf-3
  management_mode: 2
  idrac_launch: 0
  slot_names:
    - 'server-1': blade1
    - 'server-2': blade2

servers:
  server-1:
    idrac_password: saltstack1
    ipmi_over_lan: True
    ip: 172.17.17.132
    netmask: 255.255.0.0
    gateway: 172.17.17.1
  server-2:
    idrac_password: saltstack1
    ipmi_over_lan: True
    ip: 172.17.17.2
    netmask: 255.255.0.0
    gateway: 172.17.17.1
  server-3:
    idrac_password: saltstack1
    ipmi_over_lan: True
    ip: 172.17.17.20
    netmask: 255.255.0.0
    gateway: 172.17.17.1
  server-4:
    idrac_password: saltstack1
    ipmi_over_lan: True
    ip: 172.17.17.2
    netmask: 255.255.0.0
    gateway: 172.17.17.1

switches:
  switch-1:
    ip: 192.168.1.2
    netmask: 255.255.255.0
    gateway: 192.168.1.1
    snmp: nonpublic
    password: saltstack1
  switch-2:
    ip: 192.168.1.3
    netmask: 255.255.255.0
```

32.29. Full list of built-in state modules
And to go with it, here's an example state that pulls the data from the pillar stated above:

```python
{% set details = pillar.get('proxy:chassis', {}) %}
standup-step1:
  dellchassis.chassis:
   - name: {{ details['name'] }}
   - location: {{ details['location'] }}
   - mode: {{ details['management_mode'] }}
   - idrac_launch: {{ details['idrac_launch'] }}
   - slot_names:
     {% for entry in details['slot_names'] %}
     - {{ entry.keys()[0] }}: {{ entry[entry.keys()[0]] }}
     {% endfor %}

blade_powercycle:
  dellchassis.chassis:
   - blade_power_states:
     - server-1: powercycle
     - server-2: powercycle
     - server-3: powercycle
     - server-4: powercycle

# Set idrac_passwords for blades. racadm needs them to be called 'server-x'
{% for k, v in details['servers'].iteritems() %}
  {{ k }}:
  dellchassis.blade_idrac:
   - idrac_password: {{ v['idrac_password'] }}
{% endfor %}

# Set management ip addresses, passwords, and snmp strings for switches
{% for k, v in details['switches'].iteritems() %}
  {{ k }}-switch-setup:
  dellchassis.switch:
   - name: {{ k }}
   - ip: {{ v['ip'] }}
   - netmask: {{ v['netmask'] }}
   - gateway: {{ v['gateway'] }}
   - password: {{ v['password'] }}
   - snmp: {{ v['snmp'] }}
{% endfor %}
```

Note: This state module relies on the dracr.py execution module, which runs racadm commands on the chassis, blades, etc. The racadm command runs very slowly and, depending on your state, the proxy minion return might timeout before the racadm commands have completed. If you are repeatedly seeing minions timeout after state calls, please use the -t CLI argument to increase the timeout variable.

For example:

```
salt '* state.sls my-dell-chasis-state-name -t 60
```

Note: The Dell CMC units perform adequately but many iDRACs are excruciatingly slow. Some functions can take
minutes to execute.

```

salt.states.dellchassis.blade_idrac(name, idrac_password=None, idrac_ipmi=None, idrac_ip=None, idrac_netmask=None, idrac_gateway=None, idrac_dnsname=None, idrac_dhcp=None)
```

Set parameters for iDRAC in a blade.

**Parameters**

- `idrac_password` -- Password to use to connect to the iDRACs directly (idrac_ipmi and idrac_dnsname must be set directly on the iDRAC. They can't be set through the CMC. If this password is present, use it instead of the CMC password)
- `idrac_ipmi` -- Enable/Disable IPMI over LAN
- `idrac_ip` -- Set IP address for iDRAC
- `idrac_netmask` -- Set netmask for iDRAC
- `idrac_gateway` -- Set gateway for iDRAC
- `idrac_dhcp` -- Turn on DHCP for iDRAC (True turns on, False because setting a static IP will disable DHCP).

**Returns**

A standard Salt changes dictionary

NOTE: If any of the IP address settings is configured, all of ip, netmask, and gateway must be present

```

salt.states.dellchassis.chassis(name, chassis_name=None, password=None, datacenter=None, location=None, mode=None, idrac_launch=None, slot_names=None, blade_power_states=None)
```

Manage a Dell Chassis.

- `chassis_name` -- The name of the chassis.
- `datacenter` -- The datacenter in which the chassis is located
- `location` -- The location of the chassis.
- `password` -- Password for the chassis. Note: If this password is set for the chassis, the current implementation of this state will set this password both on the chassis and the iDrac passwords on any configured blades. If the password for the blades should be distinct, they should be set separately with the blade_idrac function.
- `mode` -- The management mode of the chassis. Viable options are:
  - 0: None
  - 1: Monitor
  - 2: Manage and Monitor
- `idrac_launch` -- The iDRAC launch method of the chassis. Viable options are:
  - 0: Disabled (launch iDRAC using IP address)
  - 1: Enabled (launch iDRAC using DNS name)
- `slot_names` -- The names of the slots, provided as a list identified by their slot numbers.
- `blade_power_states` -- The power states of a blade server, provided as a list and identified by their server numbers. Viable options are:
  - on: Ensure the blade server is powered on.
  - off: Ensure the blade server is powered off.
  - powercycle: Power cycle the blade server.

Example:
my-dell-chassis:
  dellchassis.chassis:
    - chassis_name: my-dell-chassis
    - location: my-location
    - datacenter: london
    - mode: 2
    - idrac_launch: 1
    - slot_names:
        - 1: my-slot-name
        - 2: my-other-slot-name
    - blade_power_states:
        - server-1: on
        - server-2: off
        - server-3: powercycle

salt.states.dellchassis.firmware_update(hosts=None, directory='')

State to update the firmware on host using the racadm command

firmwarefile filename (string) starting with salt://

host string representing the hostname supplied to the racadm command

directory Directory name where firmwarefile will be downloaded

dell-chassis-firmware-update:
  dellchassis.firmware_update:
    hosts:
      cmc:
        salt://firmware_cmc.exe
      server-1:
        salt://firmware.exe
      directory: /opt/firmwares

salt.states.dellchassis.switch(name=None, ip=None, netmask=None, gateway=None, dhcp=None, password=None, snmp=None)

Manage switches in a Dell Chassis.

name The switch designation (e.g. switch-1, switch-2)
ip The Static IP Address of the switch
netmask The netmask for the static IP
gateway The gateway for the static IP
dhcp True: Enable DHCP False: Do not change DHCP setup (disabling DHCP is automatic when a static IP is set)
password The access (root) password for the switch
snmp The SNMP community string for the switch

Example:

my-dell-chassis:
  dellchassis.switch:
    - switch: switch-1
    - ip: 192.168.1.1
    - netmask: 255.255.255.0
    - gateway: 192.168.1.254
    - dhcp: True
32.29.42 salt.states.disk

Disk monitoring state

Monitor the state of disk resources.

The `disk.status` function can be used to report that the used space of a filesystem is within the specified limits.

```python
used_space:
    disk.status:
      - name: /dev/xdal
      - maximum: 79%
      - minimum: 11%
```

It can be used with an `onfail` requisite, for example, to take additional action in response to or in preparation for other states.

```python
storage_threshold:
    disk.status:
      - name: /dev/xdal
      - maximum: 97%

clear_cache:
    cmd.run:
      - name: rm -r /var/cache/app
      - onfail:
        - disk: storage_threshold
```

`salt.states.disk.status(name, maximum=None, minimum=None)`

Return the current disk usage stats for the named mount point

- **name**  Filesystem with which to check used space
- **minimum**  The required minimum amount of used space in percent
- **maximum**  The required maximum amount of used space in percent

32.29.43 salt.states.dockerio

Manage Docker containers

Deprecated since version 2015.8.0: Future feature development will be done only in `dockerng`. See the documentation for this module for information on the deprecation path.

Docker is a lightweight, portable, self-sufficient software container wrapper. The base supported wrapper type is `LXC`, `cgroups`, and the `Linux Kernel`.

**Note:** This state module requires `docker-py` version >= 0.6.0 which supports Docker Remote API version 1.12.
Available Functions

- **built**

  ```
  corp/mysuperdocker_image:
  docker.built:
    - path: /path/to/dir/container
  ```

- **pulled**

  ```
  ubuntu:
  docker.pulled:
    - tag: latest
  ```

- **pushed**

  ```
  corp/mysuperdocker_image:
  docker.pushed
  ```

- **installed**

  ```
  mysuperdocker-container:
  docker.installed:
    - name: mysuperdocker
    - hostname: superdocker
    - image: corp/mysuperdocker_image
  ```

- **loaded**

  ```
  mysuperdocker-file:
  docker.loaded:
    - name: mysuperdocker
    - source: salt://_files/tmp/docker_image.tar
  ```

- **running**

  ```
  my_service:
  docker.running:
    - container: mysuperdocker
    - image: corp/mysuperdocker_image
    - ports:
      - "5000/tcp":
        HostIp: ""
        HostPort: "5000"
  ```

**Note**: The `ports` argument above is a dictionary. The double indentation is required for PyYAML to load the data structure properly as a python dictionary. More information can be found [here](#).

- **absent**

  ```
  my_olduperdocker:
  docker.absent
  ```

- **run**
Use Cases

Ensures the container is running with the latest image available

```yaml
my-service-image:
  docker.pulled:
    - name: registry/my-service:latest
    - force: true

my-service-container:
  docker.installed:
    - image: registry/my-service:latest
    - watch:
      - docker: my-service-image

my-service:
  docker.running:
    - container: my-service-container
    - watch:
      - docker: my-service-container
```

**Note:** The docker modules are named `dockerio` because the name 'docker' would conflict with the underlying docker-py library.

salt.states.dockerio.absent(name)

Ensure that the container is absent; if not, it will be killed and destroyed. *(docker inspect)*

**name:** Either the container name or id

salt.states.dockerio.built(name, tag='latest', path=None, quiet=False, nocache=False, rm=True, force=False, timeout=None, **kwargs)

Build a docker image from a path or URL to a dockerfile. *(docker build)*

**name** Name of the image

**tag** tag of the image (defaults to 'latest')

**path** URL (e.g. url/branch/docker_dir/dockerfile) or filesystem path to the dockerfile

salt.states.dockerio.installed(name, image, command=None, hostname=None, user=None, detach=True, stdin_open=False, tty=False, mem_limit=None, ports=None, environment=None, dns=None, volumes=None, volumes_from=None, cpu_shares=None, cpuset=None, **kwargs)

Ensure that a container with the given name exists; if not, build a new container from the specified image. *(docker run)*

**name** Name for the container

**image** Image from which to build this container
tag  tag of the image (defaults to 'latest')

environment

Environment variables for the container, either

• a mapping of key, values
• a list of mappings of key, values

ports

List of ports definitions, either:

• a port to map
• a mapping of mapping portInHost : PortInContainer

volumes List of volumes (see notes for the running function)

For other parameters, see absolutely first the salt.modules.dockerio execution module and the docker-py python bindings for docker documentation for docker.create_container.

Note: This command does not verify that the named container is running the specified image.

salt.states.dockerio.loaded(name, tag='latest', source=None, source_hash='`', force=False)
Load an image into the local docker registry (docker load)

name  Name of the docker image

tag  tag of the image (defaults to 'latest')

source  The source .tar file to download to the minion, created by docker save this source file can be hosted on either the salt master server, or on an HTTP or FTP server.

   If the file is hosted on a HTTP or FTP server then the source_hash argument is also required

Note: See first the documentation for Salt file.managed

source_hash

This can be one of the following:

1. a source hash string
2. the URI of a file that contains source hash strings

force  Load even if the image exists

salt.states.dockerio.mod_watch(name, sfun=None, *args, **kw)

salt.states.dockerio.present(name, image=None, tag='latest', is_latest=False)
If a container with the given name is not present, this state will fail. Supports optionally checking for specific image/tag (docker inspect)

name: container id

image: image the container should be running (defaults to any)

tag: tag of the image (defaults to 'latest')

is_latest: also check if the container runs the latest version of the image (latest defined as the latest pulled onto the local machine)
salt.states.dockerio.pulled(name, tag='latest', force=False, insecure_registry=False, *args, **kwargs)
Pull an image from a docker registry. (docker pull)

**Note:** See first the documentation for docker login, docker pull, docker push, and docker.import_image (docker import). NOTE that we added in SaltStack a way to authenticate yourself with the Docker Hub Registry by supplying your credentials (username, email & password) using pillars. For more information, see salt.modules.dockerio execution module.

- **name** Name of the image
- **tag** Tag of the image
- **force** Pull even if the image is already pulled
- **insecure_registry** Set to True to allow connections to non-HTTPS registries. Default False.

salt.states.dockerio.pushed(name, tag='latest', insecure_registry=False)
Push an image from a docker registry. (docker push)

**Note:** See first the documentation for docker login, docker pull, docker push, and docker.import_image (docker import). NOTE that we added in SaltStack a way to authenticate yourself with the Docker Hub Registry by supplying your credentials (username, email & password) using pillars. For more information, see salt.modules.dockerio execution module.

- **name** Name of the image
- **insecure_registry** Set to True to allow connections to non-HTTPS registries. Default False.

salt.states.dockerio.run(name, cid=None, hostname=None, onlyif=None, unless=None, docked_onlyif=None, docked_unless=None, *args, **kwargs)
Run a command in a specific container
You can match by either name or hostname

- **name** command to run in the container
- **cid** Container id or name
- **state_id** state_id
- **onlyif** Only execute cmd if statement on the host returns 0
- **unless** Do not execute cmd if statement on the host returns 0
- **docked_onlyif** Only execute cmd if statement in the container returns 0
- **docked_unless** Do not execute cmd if statement in the container returns 0
salt.states.dockerio.running(name, image, tag='latest', container=None, command=None, hostname=None, user=None, detach=True, stdin_open=False, tty=False, mem_limit=None, ports=None, environment=None, dns=None, volumes=None, volumes_from=None, start=True, cap_add=None, cap_drop=None, privileged=None, lxc_conf=None, network_mode=None, check_is_running=True, publish_all_ports=False, links=None, restart_policy=None, cpu_shares=None, cpuset=None, kill_signal=None, *args, **kwargs)

Ensure that a container is running. If the container does not exist, it will be created from the specified image.

*(docker run)*

**name / container** Name for the container

**image** Image from which to build this container

**tag** tag of the image (defaults to 'latest')

**environment**

Environment variables for the container, either

- a mapping of key, values
- a list of mappings of key, values

**ports**

List of ports definitions, either:

- a port to map
- a mapping of mapping portInHost : PortInContainer

```
- ports:
  - "5000/tcp":
    HostIp: ""
    HostPort: "5000"
```

**publish_all_ports** Publish all ports from the port list (default is false, only meaningful if port does not contain portInHost:portInContainer mapping)

**volumes** List of volumes to mount or create in the container (like -v of docker run command), mapping host directory to container directory.

To specify a volume in the container in terse list format:

```
- volumes:
  - "/var/log/service" # container-only volume
  - "/srv/zone/etc/timezone" # bound volume
  - "/usr/local/etc/passwd:/etc/passwd:ro" # read-only bound volume
```

You can also use the short dictionary form (note that the notion of source:target from docker is preserved):

```
- volumes:
  - /var/log/service: /var/log/service # mandatory read-write implied
```

Or, alternatively, to specify read-only mounting, use the extended form:

```
- volumes:
  - /home/user1:
    bind: /mnt/vol2
    ro: True
```
- /var/www:
  bind: /mnt/vol1
  ro: False

Or (for backwards compatibility) another dict style:

- volumes:
  /home/user1:
    bind: /mnt/vol2
    ro: True
  /var/www:
    bind: /mnt/vol1
    ro: False

volumes_from List of containers to share volumes with
dns List of DNS servers.

- dns:
  - 127.0.0.1

network_mode
- `bridge`: creates a new network stack for the container on the docker bridge
- `none`: no networking for this container
- `container:[name|id]`: reuses another container network stack
- `host`: use the host network stack inside the container

- network_mode: host

restart_policy Restart policy to apply when a container exits (no, on-failure[:max-retry], always)

- restart_policy:
  MaximumRetryCount: 5
  Name: on-failure

cap_add List of capabilities to add in a container.
cap_drop List of capabilities to drop in a container.
check_is_running Enable checking if a container should run or not. Useful for data-only containers that must be linked to another one. e.g. nginx <-> static-files

cpu_shares CPU shares (relative weight)

- cpu_shares: 2

cpuset CPUs in which to allow execution (`0-3` or `0,1`)

- cpuset: '0-3'

kill_signal If defined, its value will be sent as a kill signal to the running container. i.e. It will use client.kill(signal=kill_signal) instead of client.restart(), when the state is triggered by a watcher requisite.
  possible use case: Soft reload of nginx
This state will ask nginx to reload (instead of restart) each time the /etc/nginx/nginx.conf is modified.

New in version 2015.8.0.

For other parameters, see salt.modules.dockerio execution module and the docker-py python bindings for docker documentation `<https://github.com/dotcloud/docker-py#api>`_ for `docker.create_container`.

---

**Note:** This command does not verify that the named container is running the specified image.

---

**32.29.44 salt.states.dockerng**

Management of Docker containers

New in version 2015.8.0.

This is the state module to accompany the `dockerng` execution module.

**Why Make a Second Docker State Module?**

We have received a lot of feedback on our Docker support. In the process of implementing recommended improvements, it became obvious that major changes needed to be made to the functions and return data. In the end, a complete rewrite was done.

The changes being too significant, it was decided that making a separate execution module and state module (called `dockerng`) would be the best option. This will give users a couple release cycles to modify their scripts, SLS files, etc. to use the new functionality, rather than forcing users to change everything immediately.

In the Nitrogen release of Salt (due in 2017), this execution module will take the place of the default Docker execution module, and backwards-compatible naming will be maintained for a couple releases after that to allow users time to replace references to `dockerng` with `docker`.

---

**Note:** To pull from a Docker registry, authentication must be configured. See here for more information on how to configure access to docker registries in Pillar data.

---

**salt.states.dockerng.absent**(name, force=False)

Ensure that a container is absent

name  Name of the container
force [False] Set to True to remove the container even if it is running

Usage Examples:

<table>
<thead>
<tr>
<th>usage_example</th>
</tr>
</thead>
<tbody>
<tr>
<td>mycontainer:</td>
</tr>
<tr>
<td>- dockerng.absent</td>
</tr>
<tr>
<td>multiple_containers:</td>
</tr>
<tr>
<td>- names:</td>
</tr>
<tr>
<td>- foo</td>
</tr>
<tr>
<td>- bar</td>
</tr>
<tr>
<td>- baz</td>
</tr>
</tbody>
</table>

salt.states.dockerng.image_absent(name=None, images=None, force=False)

Ensure that an image is absent from the Minion. Image names can be specified either using repo:tag notation, or just the repo name (in which case a tag of latest is assumed).

images Run this state on more than one image at a time. The following two examples accomplish the same thing:

<table>
<thead>
<tr>
<th>usage_example</th>
</tr>
</thead>
<tbody>
<tr>
<td>remove_images:</td>
</tr>
<tr>
<td>- dockerng.image_absent:</td>
</tr>
<tr>
<td>- names:</td>
</tr>
<tr>
<td>- busybox</td>
</tr>
<tr>
<td>- centos:6</td>
</tr>
<tr>
<td>- nginx</td>
</tr>
<tr>
<td>remove_images:</td>
</tr>
<tr>
<td>- dockerng.image_absent:</td>
</tr>
<tr>
<td>- images:</td>
</tr>
<tr>
<td>- busybox</td>
</tr>
<tr>
<td>- centos:6</td>
</tr>
<tr>
<td>- nginx</td>
</tr>
</tbody>
</table>

However, the second example will be a bit quicker since Salt will do all the deletions in a single run, rather than executing the state separately on each image (as it would in the first example).

force [False] Salt will fail to remove any images currently in use by a container. Set this option to true to remove the image even if it is already present.

Note: This option can also be overridden by Pillar data. If the Minion has a pillar variable named dockerng.running.force which is set to True, it will turn on this option. This pillar variable can even be set at runtime. For example:

```
salt myminion state.sls docker_stuff pillar="{dockerng.force: True}"```

If this pillar variable is present and set to False, then it will turn off this option.

For more granular control, setting a pillar variable named dockerng.force.image_name will affect only the named image.

salt.states.dockerng.image_present(name, build=None, load=None, force=False, insecure_registry=False, client_timeout=60, **kwargs)

Ensure that an image is present. The image can either be pulled from a Docker registry, built from a Dockerfile, or loaded from a saved image. Image names can be specified either using repo:tag notation, or just the repo name (in which case a tag of latest is assumed).
If neither of the build or load arguments are used, then Salt will pull from the configured registries. If the specified image already exists, it will not be pulled unless force is set to True. Here is an example of a state that will pull an image from the Docker Hub:

```
myuser/myimage:mytag:
  dockerng.image_present
```

**build** Path to directory on the Minion containing a Dockerfile

```
myuser/myimage:mytag:
  dockerng.image_present:
    - build: /home/myuser/docker/myimage
```

The image will be built using `dockerng.build` and the specified image name and tag will be applied to it.

**load** Loads a tar archive created with `dockerng.load` (or the `docker load` Docker CLI command), and assigns it the specified repo and tag.

```
myuser/myimage:mytag:
  dockerng.image_present:
    - load: salt://path/to/image.tar
```

**force** [False] Set this parameter to True to force Salt to pull/build/load the image even if it is already present.

**client_timeout** Timeout in seconds for the Docker client. This is not a timeout for the state, but for receiving a response from the API.

```
salt.states.dockerng.mod_watch(name, sfun=None, **kwargs)
salt.states.dockerng.network_absent(name, driver=None)
  Ensure that a network is absent.
  name  Name of the network
  Usage Examples:
  network_foo:
    dockerng.network_absent
```

```
salt.states.dockerng.network_present(name, driver=None, containers=None)
  Ensure that a network is present.
  name  Name of the network
  driver  Type of driver for that network.
  containers:  List of container names that should be part of this network
  Usage Examples:
  network_foo:
    dockerng.network_present
```

```
network_bar:
  dockerng.network_present
    - name: bar
    - containers:
      - cont1
      - cont2
```
salt.states.dockerng.running(name, image=None, force=False, stop_timeout=10, validate_ip_addrs=True, watch_action='force', client_timeout=60, start=True, **kwargs)

Ensure that a container with a specific configuration is present and running

name  Name of the container

image  Image to use for the container. Image names can be specified either using repo:tag notation, or just the repo name (in which case a tag of latest is assumed).

Note: This state will pull the image if it is not present. However, if the image needs to be built from a Dockerfile or loaded from a saved image, or if you would like to use requisites to trigger a replacement of the container when the image is updated, then the dockerng.image_present should be used to manage the image.

force  [False] Set this parameter to True to force Salt to re-create the container irrespective of whether or not it is configured as desired.

stop_timeout  [10] If the container needs to be replaced, the container will be stopped using dockerng.stop. The value of this parameter will be passed to dockerng.stop as the timeout value, telling Docker how long to wait for a graceful shutdown before killing the container.

validate_ip_addrs  [True] For parameters which accept IP addresses as input, IP address validation will be performed. To disable, set this to False

watch_action  [force] Control what type of action is taken when this state watches another state that has changes. The default action is force, which runs the state with force set to True, triggering a rebuild of the container.

If any other value is passed, it will be assumed to be a kill signal. If the container matches the specified configuration, and is running, then the action will be to send that signal to the container. Kill signals can be either strings or numbers, and are defined in the Standard Signals section of the signal(7) manpage. Run man 7 signal on a Linux host to browse this manpage. For example:

```
mycontainer:
  dockerng.running:
    - image: busybox
    - watch_action: SIGHUP
    - watch:
      - file: some_file
```

Note: If the container differs from the specified configuration, or is not running, then instead of sending a signal to the container, the container will be re-created/started and no signal will be sent.

client_timeout  Timeout in seconds for the Docker client. This is not a timeout for this function, but for receiving a response from the API.

Note: This is only used if Salt needs to pull the requested image.

CONTAINER CONFIGURATION PARAMETERS

command or cmd  Command to run in the container
```yaml
- image: bar/baz:latest
- command: bash

OR

```yaml
def

```yaml
dockerng.running:
- image: bar/baz:latest
- cmd: bash

```

Changed in version 2015.8.1: `cmd` is now also accepted

**hostname** Hostname of the container. If not provided, and if a `name` has been provided, the `hostname` will default to the `name` that was passed.

```yaml
def

dockerng.running:
- image: bar/baz:latest
- hostname: web1

```

**Warning:** `hostname` cannot be set if `network_mode` is set to `host`. The below example will result in an error:

```yaml
def

dockerng.running:
- image: bar/baz:latest
- hostname: web1
- network_mode: host

```

domainname Domain name of the container

```yaml
def

dockerng.running:
- image: bar/baz:latest
- hostname: domain.tld

```

**interactive** [False] Leave stdin open

```yaml
def

dockerng.running:
- image: bar/baz:latest
- interactive: True

```

**tty** [False] Attach TTYs

```yaml
def

dockerng.running:
- image: bar/baz:latest
- tty: True

```

**detach** [True] If True, run the container's command in the background (daemon mode)

```yaml
def

dockerng.running:
- image: bar/baz:latest
- detach: False
```
user  User under which to run docker

```yaml
foo:
  dockerng.running:
  - image: bar/baz:latest
  - user: foo
```

memory  [0] Memory limit. Can be specified in bytes or using single-letter units (i.e. 512M, 2G, etc.). A value of 0 (the default) means no memory limit.

```yaml
foo:
  dockerng.running:
  - image: bar/baz:latest
  - memory: 512M
```

memory_swap  [-1] Total memory limit (memory plus swap). Set to -1 to disable swap. A value of 0 means no swap limit.

```yaml
foo:
  dockerng.running:
  - image: bar/baz:latest
  - memory_swap: 1G
```

mac_address  MAC address to use for the container. If not specified, a random MAC address will be used.

```yaml
foo:
  dockerng.running:
  - image: bar/baz:latest
  - mac_address: 01:23:45:67:89:0a
```

network_disabled  [False] If True, networking will be disabled within the container

```yaml
foo:
  dockerng.running:
  - image: bar/baz:latest
  - network_disabled: True
```

working_dir  Working directory inside the container

```yaml
foo:
  dockerng.running:
  - image: bar/baz:latest
  - working_dir: /var/log/nginx
```

entrypoint  Entrypoint for the container

```yaml
foo:
  dockerng.running:
  - image: bar/baz:latest
  - entrypoint: "mycmd --arg1 --arg2"
```

The entrypoint can also be specified as a list of arguments:

```yaml
foo:
  dockerng.running:
  - image: bar/baz:latest
  - entrypoint:
    - mycmd
```
environment  Either a list of variable/value mappings, or a list of strings in the format \texttt{VARNAME=value}. The below two examples are equivalent:

```yaml
foo:
  dockerNG.running:
    - image: bar/baz:latest
    - environment:
      - VAR1: value
      - VAR2: value
```

```yaml
foo:
  dockerNG.running:
    - image: bar/baz:latest
    - environment:
      - VAR1=value
      - VAR2=value
```

Note: Values must be strings. Otherwise it will be considered as an error.

ports  A list of ports to expose on the container. Can either be a comma-separated list or a YAML list. If the protocol is omitted, the port will be assumed to be a TCP port. The below two examples are equivalent:

```yaml
foo:
  dockerNG.running:
    - image: bar/baz:latest
    - ports: 1111,2222/udp
```

```yaml
foo:
  dockerNG.running:
    - image: bar/baz:latest
    - ports:
      - 1111
      - 2222/udp
```

volumes  [None] List of directories to expose as volumes. Can either be a comma-separated list or a YAML list. The below two examples are equivalent:

```yaml
foo:
  dockerNG.running:
    - image: bar/baz:latest
    - volumes: /mnt/vol1,/mnt/vol2
```

```yaml
foo:
  dockerNG.running:
    - image: bar/baz:latest
    - volumes:
      - /mnt/vol1
      - /mnt/vol2
```

cpu_shares  CPU shares (relative weight)
foo:
  dockerng.running:
  - image: bar/baz:latest
  - cpu_shares: 0.5

**cpuset** CPUs on which to allow execution, specified as a string containing a range (e.g. 0-3) or a comma-separated list of CPUs (e.g. 0,1).

```
foo:
  dockerng.running:
  - image: bar/baz:latest
  - cpuset: "0,1"
```

**binds** Files/directories to bind mount. Each bind mount should be passed in the format `<host_path>:<container_path>:<read_only>`, where `<read_only>` is one of **rw** (for read-write access) or **ro** (for read-only access).

```
foo:
  dockerng.running:
  - image: bar/baz:latest
  - binds: /srv/www:/var/www:ro,/etc/foo.conf:/usr/local/etc/foo.conf:rw
```

Binds can be passed as a YAML list instead of a comma-separated list:

```
foo:
  dockerng.running:
  - image: bar/baz:latest
  - binds:
    - /srv/www:/var/www:ro
    - /home/myuser/conf/foo.conf:/etc/foo.conf:rw
```

Optionally, the read-only information can be left off the end and the bind mount will be assumed to be read-write. The example below is equivalent to the one above:

```
foo:
  dockerng.running:
  - image: bar/baz:latest
  - binds:
    - /srv/www:/var/www:ro
    - /home/myuser/conf/foo.conf:/etc/foo.conf
```

**port_bindings** Bind exposed ports. Port bindings should be passed in the same way as the `--publish` argument to the `docker run` CLI command:

- **ip:port/containerPort** - Bind a specific IP and port on the host to a specific port within the container.
- **ip::containerPort** - Bind a specific IP and an ephemeral port to a specific port within the container.
- **hostPort/containerPort** - Bind a specific port on all of the host’s interfaces to a specific port within the container.
- **containerPort** - Bind an ephemeral port on all of the host’s interfaces to a specific port within the container.

Multiple bindings can be separated by commas, or passed as a Python list. The below two examples are equivalent:
foo:
dockerng.running:
  - image: bar/baz:latest
  - port_bindings: "5000:5000,2123:2123/udp,8080"

foo:
dockerng.running:
  - image: bar/baz:latest
  - port_bindings:
    - 5000:5000
    - 2123:2123/udp
    - "8080"

Note: When configuring bindings for UDP ports, the protocol must be passed in the containerPort value, as seen in the examples above.

lxc_conf Additional LXC configuration parameters to set before starting the container.

foo:
dockerng.running:
  - image: bar/baz:latest
  - lxc_conf:
    - lxc.utsname: docker

Note: These LXC configuration parameters will only have the desired effect if the container is using the LXC execution driver, which has not been the default for some time.

publish_all_ports [False] Allocates a random host port for each port exposed using the ports parameter

foo:
dockerng.running:
  - image: bar/baz:latest
  - ports: 8080
  - publish_all_ports: True

links Link this container to another. Links should be specified in the format <container_name_or_id>:<link_alias>. Multiple links can be passed, either as a comma separated list or a YAML list. The below two examples are equivalent:

foo:
dockerng.running:
  - image: bar/baz:latest
  - links: web1:link1,web2:link2

foo:
dockerng.running:
  - image: bar/baz:latest
  - links:
    - web1:link1
    - web2:link2

dns List of DNS nameservers. Can be passed as a comma-separated list or a YAML list. The below two examples are equivalent:
foo:
dockerng.running:
  - image: bar/baz:latest
  - dns: 8.8.8.8,8.8.4.4

foo:
dockerng.running:
  - image: bar/baz:latest
  - dns:
    - 8.8.8.8
    - 8.8.4.4

**Note:** To skip IP address validation, use `validate_ip_addrs=False`

dns_search List of DNS search domains. Can be passed as a comma-separated list or a YAML list. The below two examples are equivalent:

foo:
dockerng.running:
  - image: bar/baz:latest
  - dns_search: foo1.domain.tld,foo2.domain.tld

foo:
dockerng.running:
  - image: bar/baz:latest
  - dns_search:
    - foo1.domain.tld
    - foo2.domain.tld

volumes_from Container names or IDs from which the container will get volumes. Can be passed as a comma-separated list or a YAML list. The below two examples are equivalent:

foo:
dockerng.running:
  - image: bar/baz:latest
  - volumes_from: foo

foo:
dockerng.running:
  - image: bar/baz:latest
  - volumes_from:
    - foo

network_mode [bridge] One of the following:

- **bridge** - Creates a new network stack for the container on the docker bridge
- **null** - No networking (equivalent of the Docker CLI argument `--net=none`)
- **container:<name_or_id>** - Reuses another container's network stack
- **host** - Use the host's network stack inside the container
- Any name that identifies an existing network that might be created with `dockerng.network_present`. 
Warning: Using host mode gives the container full access to the host's system's services (such as D-bus), and is therefore considered insecure.

```yaml
foo:
  docker NG.running:
    - image: bar/baz:latest
    - network_mode: null
```

**restart_policy** Set a restart policy for the container. Must be passed as a string in the format policy[:retry_count] where policy is one of always or on-failure, and retry_count is an optional limit to the number of retries. The retry count is ignored when using the always restart policy.

```yaml
foo:
  docker NG.running:
    - image: bar/baz:latest
    - restart_policy: on-failure:5
bar:
  docker NG.running:
    - image: bar/baz:latest
    - restart_policy: always
```

**cap_add** List of capabilities to add within the container. Can be passed as a comma-separated list or a Python list. The below two examples are equivalent:

```yaml
foo:
  docker NG.running:
    - image: bar/baz:latest
    - cap_add: SYS_ADMIN,MKNOD
```

```yaml
foo:
  docker NG.running:
    - image: bar/baz:latest
    - cap_add:
        - SYS_ADMIN
        - MKNOD
```

**Note:** This option requires Docker 1.2.0 or newer.

**cap_drop** List of capabilities to drop within the container. Can be passed as a comma-separated list or a Python list. The below two examples are equivalent:

```yaml
foo:
  docker NG.running:
    - image: bar/baz:latest
    - cap_drop: SYS_ADMIN,MKNOD
```

```yaml
foo:
  docker NG.running:
    - image: bar/baz:latest
    - cap_drop:
        - SYS_ADMIN
        - MKNOD
```
### extra_hosts

Additional hosts to add to the container’s `/etc/hosts` file. Can be passed as a comma-separated list or a Python list. The below two examples are equivalent:

```yaml
foo:
  dockerng.running:
    - image: bar/baz:latest
    - extra_hosts: web1:10.9.8.7,web2:10.9.8.8
```

```yaml
foo:
  dockerng.running:
    - image: bar/baz:latest
    - extra_hosts:
      - web1:10.9.8.7
      - web2:10.9.8.8
```

### pid_mode

Set to `host` to use the host container’s PID namespace within the container.

```yaml
foo:
  dockerng.running:
    - image: bar/baz:latest
    - pid_mode: host
```

### labels

Add Metadata to the container. Can be a list of strings/dictionaries or a dictionary of strings (keys and values).

```yaml
foo:
  dockerng.running:
    - image: bar/baz:latest
    - labels:
      - LABEL1
      - LABEL2
```

```yaml
foo:
  dockerng.running:
    - image: bar/baz:latest
    - labels:
      KEY1: VALUE1
      KEY2: VALUE2
```
foo:
  dockerng.running:
    - image: bar/baz:latest
    - labels:
      - KEY1: VALUE1
      - KEY2: VALUE2

start [True] Set to False to suppress starting of the container if it exists, matches the desired configuration, but is not running. This is useful for data-only containers, or for non-daemonized container processes, such as the django migrate and collectstatic commands. In instances such as this, the container only needs to be started the first time.

salt.states.dockerng.stopped(name=None, containers=None, stop_timeout=10, unpause=False, error_on_absent=True)
Ensure that a container (or containers) is stopped

name Name or ID of the container

containers Run this state on more than one container at a time. The following two examples accomplish the same thing:

stopped_containers:
  dockerng.stopped:
    - names:
      - foo
      - bar
      - baz

stopped_containers:
  dockerng.stopped:
    - containers:
      - foo
      - bar
      - baz

However, the second example will be a bit quicker since Salt will stop all specified containers in a single run, rather than executing the state separately on each image (as it would in the first example).

stop_timeout [10] Timeout for graceful shutdown of the container. If this timeout is exceeded, the container will be killed.

unpause [False] Set to True to unpause any paused containers before stopping. If unset, then an error will be raised for any container that was paused.

error_on_absent [True] By default, this state will return an error if any of the specified containers are absent. Set this to False to suppress that error.

salt.states.dockerng.volume_absent(name, driver=None)
Ensure that a volume is absent.

New in version 2015.8.4.

name Name of the volume

Usage Examples:

volume_foo:
  dockerng.volume_absent
salt.states.dockerng.volume_present(name, driver=None, driver_opts=None, force=False)

Ensure that a volume is present.

New in version 2015.8.4.

Changed in version 2015.8.6: This function no longer deletes and re-creates a volume if the existing volume's driver does not match the driver parameter (unless the force parameter is set to True).

name Name of the volume

driver Type of driver for that volume. If None and the volume does not yet exist, the volume will be created using Docker's default driver. If None and the volume does exist, this function does nothing, even if the existing volume's driver is not the Docker default driver. (To ensure that an existing volume's driver matches the Docker default, you must explicitly name Docker's default driver here.)

driver_opts Options for the volume driver

force [False] If the volume already exists but the existing volume's driver does not match the driver specified by the driver parameter, this parameter controls whether the function errors out (if False) or deletes and re-creates the volume (if True).

Usage Examples:

```python
volume_foo:
    dockerng.volume_present

volume_bar:
    dockerng.volume_present
    - name: bar
    - driver: local
    - driver_opts:
        foo: bar

volume_bar:
    dockerng.volume_present
    - name: bar
    - driver: local
    - driver_opts:
        foo: bar
        option: value
```

32.29.45 salt.states.drac

Management of Dell DRAC

The DRAC module is used to create and manage DRAC cards on Dell servers

Ensure the user damian is present

```python
damian:
    drac.present:
    - name: damian
    - password: secret
    - permission: login,test_alerts,clear_logs
```

Ensure the user damian does not exist
**Salt Documentation, Release 2015.8.12**

```yaml
damian:
  drac.absent:
    - name: damian
```

Ensure DRAC network is in a consistent state

```yaml
my_network:
  drac.network:
    - ip: 10.225.108.29
    - netmask: 255.255.255.224
    - gateway: 10.225.108.1
```

`salt.states.drac.absent(name)`
Ensure a user does not exist on the Dell DRAC

- **name**: The users username

`salt.states.drac.network(ip, netmask, gateway)`
Ensure the DRAC network settings are consistent

`salt.states.drac.present(name, password, permission)`
Ensure the user exists on the Dell DRAC

- **name**: The users username

- **password**: The password used to authenticate

- **permission**: The permissions that should be assigned to a user

**32.29.46 salt.states.elasticsearch_index**

State module to manage Elasticsearch indices

New in version 2015.8.0.

`salt.states.elasticsearch_index.absent(name)`
Ensure that the named index is absent

`salt.states.elasticsearch_index.present(name, definition)`
Ensure that the named index is present

**32.29.47 salt.states.elasticsearch_index_template**

State module to manage Elasticsearch index templates

New in version 2015.8.0.

`salt.states.elasticsearch_index_template.absent(name)`
Ensure that the named index template is absent

`salt.states.elasticsearch_index_template.present(name, definition=None)`
Ensure that the named index template is present

**32.29.48 salt.states.environ**

Support for getting and setting the environment variables of the current salt process.
**salt.states.environ.setenv**(*name*, *value*, *false_unsets=False*, *clear_all=False*, *update_minion=False*)

Set the salt process environment variables.

- **name** The environment key to set. Must be a string.
- **value** Either a string or dict. When string, it will be the value set for the environment key of `name` above. When a dict, each key/value pair represents an environment variable to set.
- **false_unsets** If a key's value is False and false_unsets is True, then the key will be removed from the salt processes environment dict entirely. If a key's value is False and false_unsets is not True, then the key's value will be set to an empty string. Default: False
- **clear_all** USE WITH CAUTION! This option can unset environment variables needed for salt to function properly. If clear_all is True, then any environment variables not defined in the environ dict will be deleted. Default: False
- **update_minion** If True, apply these environ changes to the main salt-minion process. If False, the environ changes will only affect the current salt subprocess. Default: False

Example:

```
a_string_env:
  environ.setenv:
    - name: foo
    - value: bar
    - update_minion: True

a_dict_env:
  environ.setenv:
    - name: does_not_matter
    - value:
      foo: bar
      baz: quux
```

### 32.29.49 salt.states.eeselect

**Management of Gentoo configuration using eeselect**

A state module to manage Gentoo configuration via eeselect

```
profile:
  eeselect.set:
    target: hardened/linux/amd64
```

**salt.states.eeselect.set**(*name*, *target*, *module_parameter=None*, *action_parameter=None*)

Verify that the given module is set to the given target

- **name** The name of the module
- **target** The target to be set for this module
- **module_parameter** additional params passed to the defined module
- **action_parameter** additional params passed to the defined action
32.29.50 salt.states.etcd_mod

Manage etcd Keys

New in version 2015.8.0.

depends
  • python-etcd

This state module supports setting and removing keys from etcd.

Configuration

To work with an etcd server you must configure an etcd profile. The etcd config can be set in either the Salt Minion configuration file or in pillar:

```
my_etd_config:
  etcd.host: 127.0.0.1
  etcd.port: 4001
```

It is technically possible to configure etcd without using a profile, but this is not considered to be a best practice, especially when multiple etcd servers or clusters are available.

```
etcd.host: 127.0.0.1
etcd.port: 4001
```

Note: The etcd configuration can also be set in the Salt Master config file, but in order to use any etcd configurations defined in the Salt Master config, the `pillar_opts` must be set to `True`.

Be aware that setting `pillar_opts` to `True` has security implications as this makes all master configuration settings available in all minion's pillars.

Available Functions

• set

This will set a value to a key in etcd. Changes will be returned if the key has been created or the value of the key has been updated. This means you can watch these states for changes.

```
/foo/bar/baz:
  etcd.set:
    - value: foo
    - profile: my_etcd_config
```

• wait_set

Performs the same functionality as `set` but only if a watch requisite is `True`.

```
/some/file.txt:
  file.managed:
    - source: salt://file.txt

/foo/bar/baz:
  etcd.wait_set:
```
- value: foo
- profile: my_etcd_config
- watch:
  - file: /some/file.txt

• `rm`
This will delete a key from etcd. If the key exists then changes will be returned and thus you can watch for changes on the state, if the key does not exist then no changes will occur.

```yaml
/foo/bar/baz:
  etcd.rm:
    - profile: my_etcd_config
```

• `wait_rm`
Performs the same functionality as `rm` but only if a watch requisite is True.

```yaml
/some/file.txt:
  file.managed:
    - source: salt://file.txt

/foo/bar/baz:
  etcd.wait_rm:
    - profile: my_etcd_config
    - watch:
      - file: /some/file.txt
```

salt.states.etcd_mod.mod_watch(name, **kwargs)
Execute a etcd function based on a watch call requisite.

salt.states.etcd_mod.rm(name, recurse=False, profile=None)
Deletes a key from etcd. This function is also aliased as `rm`.

  name  The etcd key name to remove, for example `/foo/bar/baz`.
  recurse  Optional, defaults to `False`. If `True` performs a recursive delete.
  profile  Optional, defaults to `None`. Sets the etcd profile to use which has been defined in the Salt Master config.

salt.states.etcd_mod.set(name, value, profile=None)
Set a key in etcd and can be called as `set`.

  name  The etcd key name, for example: `/foo/bar/baz`.
  value  The value the key should contain.
  profile  Optional, defaults to `None`. Sets the etcd profile to use which has been defined in the Salt Master config.

salt.states.etcd_mod.wait_rm(name, recurse=False, profile=None)
Deletes a key from etcd only if the watch statement calls it. This function is also aliased as `wait_rm`.

  name  The etcd key name to remove, for example `/foo/bar/baz`.
  recurse  Optional, defaults to `False`. If `True` performs a recursive delete, see: https://python-etcd.readthedocs.org/en/latest/#delete-a-key.
  profile  Optional, defaults to `None`. Sets the etcd profile to use which has been defined in the Salt Master config.

32.29. Full list of builtin state modules 1949
salt.states.etcd_mod.wait_set(name, value, profile=None)
   Set a key in etcd only if the watch statement calls it. This function is also aliased as wait_set.
   name  The etcd key name, for example: /foo/bar/baz.
   value  The value the key should contain.
   profile  The etcd profile to use that has been configured on the Salt Master, this is optional and defaults to None.

32.29.51  salt.states.esxi

Manage VMware ESXi Hosts.
New in version 2015.8.4.

Dependencies

- pyVmomi Python Module
- ESXCLI

pyVmomi

PyVmomi can be installed via pip:

```
pip install pyVmomi
```

Note: Version 6.0 of pyVmomi has some problems with SSL error handling on certain versions of Python. If using version 6.0 of pyVmomi, Python 2.6, Python 2.7.9, or newer must be present. This is due to an upstream dependency in pyVmomi 6.0 that is not supported in Python versions 2.7 to 2.7.8. If the version of Python is not in the supported range, you will need to install an earlier version of pyVmomi. See Issue #29537 for more information.

Based on the note above, to install an earlier version of pyVmomi than the version currently listed in PyPi, run the following:

```
pip install pyVmomi==5.5.0.2014.1.1
```

The 5.5.0.2014.1.1 is a known stable version that this original ESXi State Module was developed against.

ESXCLI

Currently, about a third of the functions used in the vSphere Execution Module require the ESXCLI package be installed on the machine running the Proxy Minion process.

The ESXCLI package is also referred to as the VMware vSphere CLI, or vCLI. VMware provides vCLI package installation instructions for vSphere 5.5 and vSphere 6.0.

Once all of the required dependencies are in place and the vCLI package is installed, you can check to see if you can connect to your ESXi host or vCenter server by running the following command:

```
esxcli -s <host-location> -u <username> -p <password> system syslog config get
```
If the connection was successful, ESXCLI was successfully installed on your system. You should see output related to the ESXi host's syslog configuration.

Note: Be aware that some functionality in this state module may depend on the type of license attached to the ESXi host.

For example, certain services are only available to manipulate service state or policies with a VMware vSphere Enterprise or Enterprise Plus license, while others are available with a Standard license. The `ntpd` service is restricted to an Enterprise Plus license, while `sshd` is available via the Standard license.

Please see the vSphere Comparison page for more information.

About

This state module was written to be used in conjunction with Salt's ESXi Proxy Minion. For a tutorial on how to use Salt's ESXi Proxy Minion, please refer to the ESXi Proxy Minion Tutorial for configuration examples, dependency installation instructions, how to run remote execution functions against ESXi hosts via a Salt Proxy Minion, and a larger state example.

```
salt.states.esxi.coredump_configured(name, enabled, dump_ip, host_vnic='vmk0', dump_port=6500)
```

Ensures a host's core dump configuration.

- **name** Name of the state.
- **enabled** Sets whether or not ESXi core dump collection should be enabled. This is a boolean value set to True or False to enable or disable core dumps.

  Note that ESXi requires that the core dump must be enabled before any other parameters may be set. This also affects the changes results in the state return dictionary. If enabled is False, we can’t obtain any previous settings to compare other state variables, resulting in many old references returning None.

  Once enabled is True the changes dictionary comparisons will be more accurate. This is due to the way the system coredemp network configuration command returns data.

- **dump_ip** The IP address of host that will accept the dump.
- **host_vnic** Host VNic port through which to communicate. Defaults to `vmk0`.
- **dump_port** TCP port to use for the dump. Defaults to 6500.

Example:

```
configure-host-coredump:
  esxi.coredump_configured:
    - enabled: True
    - dump_ip: 'my-coredump-ip.example.com'
```

```
salt.states.esxi.ntp_configured(name, service_running, ntp_servers=None, service_policy=None, service_restart=False, update_datetime=False)
```

Ensures a host's NTP server configuration such as setting NTP servers, ensuring the NTP daemon is running or stopped, or restarting the NTP daemon for the ESXi host.

- **name** Name of the state.
- **service_running** Ensures the running state of the ntp daemon for the host. Boolean value where True indicates that ntpd should be running and False indicates that it should be stopped.
- **ntp_servers** A list of servers that should be added to the ESXi host's NTP configuration.
**service_policy**  The policy to set for the NTP service.

Note: When setting the service policy to off or on, you **must** quote the setting. If you don’t, the yaml parser will set the string to a boolean, which will cause trouble checking for stateful changes and will error when trying to set the policy on the ESXi host.

**service_restart** If set to True, the ntp daemon will be restarted, regardless of its previous running state. Default is False.

**update_datetime** If set to True, the date/time on the given host will be updated to UTC. Default setting is False. This option should be used with caution since network delays and execution delays can result in time skews.

Example:

```
configure-host-ntp:
esxi.ntp_configured:
  - service_running: True
  - ntp_servers:
    - 192.174.1.100
    - 192.174.1.200
  - service_policy: 'on'
  - service_restart: True
```

**salt.states.esxi.password_present(name, password)**

Ensures the given password is set on the ESXi host. Passwords cannot be obtained from host, so if a password is set in this state, the vsphere.update_host_password function will always run (except when using test=True functionality) and the state’s changes dictionary will always be populated.

The username for which the password will change is the same username that is used to authenticate against the ESXi host via the Proxy Minion. For example, if the pillar definition for the proxy username is defined as root, then the username that the password will be updated for via this state is root.

**name** Name of the state.

**password** The new password to change on the host.

Example:

```
configure-host-password:
esxi.password_present:
  - password: 'new-bad-password'
```

**salt.states.esxi.ssh_configured(name, service_running, ssh_key=None, ssh_key_file=None, service_policy=None, service_restart=False, certificate_verify=False)**

Manage the SSH configuration for a host including whether or not SSH is running or the presence of a given SSH key. Note: Only one ssh key can be uploaded for root. Uploading a second key will replace any existing key.

**name** Name of the state.

**service_running** Ensures whether or not the SSH service should be running on a host. Represented as a boolean value where True indicates that SSH should be running and False indicates that SSH should stopped.

In order to update SSH keys, the SSH service must be running.
ssh_key Public SSH key to be added to the authorized_keys file on the ESXi host. You can use ssh_key or ssh_key_file, but not both.

ssh_key_file File containing the public SSH key to be added to the authorized_keys file on the ESXi host. You can use ssh_key_file or ssh_key, but not both.

service_policy The policy to set for the NTP service.

Note: When setting the service policy to off or on, you must quote the setting. If you don’t, the yaml parser will set the string to a boolean, which will cause trouble checking for stateful changes and will error when trying to set the policy on the ESXi host.

service_restart If set to True, the SSH service will be restarted, regardless of its previous running state. Default is False.

certificate_verify If set to True, the SSL connection must present a valid certificate. Default is False.

Example:

```yaml
configure-host-ssh:
esxi.ssh_configured:
  - service_running: True
  - ssh_key_file: /etc/salt/ssh_keys/my_key.pub
  - service_policy: 'on'
  - service_restart: True
  - certificate_verify: True
```

salt.states.esxi.syslog_configured(name, syslog_configs, firewall=True, reset_service=True, reset_syslog_config=False, reset_configs=None)

Ensures the specified syslog configuration parameters. By default, this state will reset the syslog service after any new or changed parameters are set successfully.

name Name of the state.

syslog_configs Name of parameter to set (corresponds to the command line switch for esxcli without the double dashes (--) )

Valid syslog_config values are logdir, loghost, logdir-unique, default-rotate, default-size, and default-timeout.

Each syslog_config option also needs a configuration value to set. For example, loghost requires URLs or IP addresses to use for logging. Multiple log servers can be specified by listing them, comma-separated, but without spaces before or after commas.

(Reference: https://blogs.vmware.com/vsphere/2012/04/configuring-multiple-syslog-servers-for-esxi-5. html)

firewall Enable the firewall rule set for syslog. Defaults to True.

reset_service After a successful parameter set, reset the service. Defaults to True.

reset_syslog_config Resets the syslog service to its default settings. Defaults to False. If set to True, default settings defined by the list of syslog configs in reset_configs will be reset before running any other syslog settings.

reset_configs A comma-delimited list of parameters to reset. Only runs if reset_syslog_config is set to True. If reset_syslog_config is set to True, but no syslog configs are listed in reset_configs, then reset_configs will be set to all by default.

See syslog_configs parameter above for a list of valid options.
Example:

```bash
configure-host-syslog:
esxi.syslog_configured:
    - syslog_configs:
default-timeout: 120
    - firewall: True
    - reset_service: True
    - reset_syslog_config: True
    - reset_configs: loghost,default-timeout
```

`salt.states.esxi.vmotion_configured(name, enabled, device='vmk0')`
Configures a host's VMotion properties such as enabling VMotion and setting the device VirtualNic that VMotion will use.

**name** Name of the state.

**enabled** Ensures whether or not VMotion should be enabled on a host as a boolean value where True indicates that VMotion should be enabled and False indicates that VMotion should be disabled.

**device** The device that uniquely identifies the VirtualNic that will be used for VMotion for the host. Defaults to vmk0.

Example:

```bash
configure-vmotion:
esxi.vmotion_configured:
    - enabled: True
    - device: sample-device
```

`salt.states.esxi.vsan_configured(name, enabled, add_disks_to_vsan=False)`
Configures a host's VSAN properties such as enabling or disabling VSAN, or adding VSAN-eligible disks to the VSAN system for the host.

**name** Name of the state.

**enabled** Ensures whether or not VSAN should be enabled on a host as a boolean value where True indicates that VSAN should be enabled and False indicates that VSAN should be disabled.

**add_disks_to_vsan** If set to True, any VSAN-eligible disks for the given host will be added to the host's VSAN system. Default is False.

Example:

```bash
configure-host-vsan:
esxi.vsan_configured:
    - enabled: True
    - add_disks_to_vsan: True
```

### 32.29.52 salt.states.event

Send events through Salt's event system during state runs

*salt.states.event.send(name, data=None, preload=None, with_env=False, with_grains=False, with_pillar=False, **kwargs)*

Send an event to the Salt Master

New in version 2014.7.0.
Accepts the same arguments as the `event.send` execution module of the same name.

Example:

```bash
# ...snip bunch of states above
mycompany/mystaterun/status/update:
  event.send:
    - data:
      status: "Half-way through the state run!"
# ...snip bunch of states below
```

### `salt.states.event.wait(name, sfun=None)`

Fire an event on the Salt master event bus if called from a watch statement

New in version 2014.7.0.

Example:

```bash
# Stand up a new web server.
apache:
  pkg:
    - installed
    - name: httpd
  service:
    - running
    - enable: True
    - name: httpd

# Notify the load balancer to update the pool once Apache is running.
refresh_pool:
  event:
    - wait
    - name: mycompany/loadbalancer/pool/update
    - data:
      new_web_server_ip: {{ grains['ipv4'] | first() }}
    - watch:
      - pkg: apache
```

#### 32.29.53 `salt.states.file`

**Operations on regular files, special files, directories, and symlinks**

Salt States can aggressively manipulate files on a system. There are a number of ways in which files can be managed. Regular files can be enforced with the `file.managed` state. This state downloads files from the salt master and places them on the target system. Managed files can be rendered as a jinja, mako, or wempy template, adding a dynamic component to file management. An example of `file.managed` which makes use of the jinja templating system would look like this:

```bash
/etc/http/conf/http.conf:
  file.managed:
    - source: salt://apache/http.conf
    - user: root
    - group: root
    - mode: 644
    - template: jinja
```
It is also possible to use the \texttt{py renderer} as a templating option. The template would be a Python script which would need to contain a function called \texttt{run()}, which returns a string. All arguments to the state will be made available to the Python script as globals. The returned string will be the contents of the managed file. For example:

```python
def run():
    lines = ['foo', 'bar', 'baz']
    lines.extend([source, name, user, context])  # Arguments as globals
    return '

'.join(lines)
```

\textbf{Note:} The \texttt{defaults} and \texttt{context} arguments require extra indentation (four spaces instead of the normal two) in order to create a nested dictionary. More information.

If using a template, any user-defined template variables in the file defined in \texttt{source} must be passed in using the \texttt{defaults} and/or \texttt{context} arguments. The general best practice is to place default values in \texttt{defaults}, with conditional overrides going into \texttt{context}, as seen above.

The template will receive a variable \texttt{custom\_var}, which would be accessed in the template using \texttt{{\{ custom\_var \}}}. If the operating system is Ubuntu, the value of the variable \texttt{custom\_var} would be \texttt{override}, otherwise it is the default \texttt{default value}.

The \texttt{source} parameter can be specified as a list. If this is done, then the first file to be matched will be the one that is used. This allows you to have a default file on which to fall back if the desired file does not exist on the salt fileserver. Here's an example:

```
/etc/foo.conf:
  file.managed:
    - source:
      - salt://foo.conf.{{ grains['fqdn'] }}
      - salt://foo.conf.fallback
      - user: foo
      - group: users
      - mode: 644
      - backup: minion
```

\textbf{Note:} Salt supports backing up managed files via the backup option. For more details on this functionality please review the \texttt{backup\_mode documentation}.

The \texttt{source} parameter can also specify a file in another Salt environment. In this example \texttt{foo.conf} in the \texttt{dev} environment will be used instead.

```
/etc/foo.conf:
  file.managed:
    - source:
      - salt://foo.conf?saltenv=dev
      - user: foo
```
- group: users
- mode: '0644'

**Warning:** When using a mode that includes a leading zero you must wrap the value in single quotes. If the value is not wrapped in quotes it will be read by YAML as an integer and evaluated as an octal.

Special files can be managed via the `mknod` function. This function will create and enforce the permissions on a special file. The function supports the creation of character devices, block devices, and fifo pipes. The function will create the directory structure up to the special file if it is needed on the minion. The function will not overwrite or operate on (change major/minor numbers) existing special files with the exception of user, group, and permissions. In most cases the creation of some special files require root permissions on the minion. This would require that the minion to be run as the root user. Here is an example of a character device:

```
/var/named/chroot/dev/random:
  file.mknod:
  - ntype: c
  - major: 1
  - minor: 8
  - user: named
  - group: named
  - mode: 660
```

Here is an example of a block device:

```
/var/named/chroot/dev/loop0:
  file.mknod:
  - ntype: b
  - major: 7
  - minor: 0
  - user: named
  - group: named
  - mode: 660
```

Here is an example of a fifo pipe:

```
/var/named/chroot/var/log/logfifo:
  file.mknod:
  - ntype: p
  - user: named
  - group: named
  - mode: 660
```

Directories can be managed via the `directory` function. This function can create and enforce the permissions on a directory. A directory statement will look like this:

```
/srv/stuff/substuf:
  file.directory:
  - user: fred
  - group: users
  - mode: 755
  - makedirs: True
```

If you need to enforce user and/or group ownership or permissions recursively on the directory's contents, you can do so by adding a `recurse` directive:
As a default, mode will resolve to **dir_mode** and **file_mode**, to specify both directory and file permissions, use this form:

```
/srv/stuff/substuf:
  file.directory:
   - user: fred
   - group: users
   - file_mode: 744
   - dir_mode: 755
   - makedirs: True
   - recurse:
     - user
     - group
     - mode
```

Symlinks can be easily created; the symlink function is very simple and only takes a few arguments:

```
/etc/grub.conf:
  file.symlink:
   - target: /boot/grub/grub.conf
```

Recursive directory management can also be set via the **recurse** function. Recursive directory management allows for a directory on the salt master to be recursively copied down to the minion. This is a great tool for deploying large code and configuration systems. A state using **recurse** would look something like this:

```
/opt/code/flask:
  file.recurse:
   - source: salt://code/flask
   - include_empty: True
```

A more complex **recurse** example:

```
{% set site_user = 'testuser' %}
{% set site_name = 'test_site' %}
{% set project_name = 'test_proj' %}
{% set sites_dir = 'test_dir' %}

django-project:
  file.recurse:
   - name: {{ sites_dir }}/{{ site_name }}/{{ project_name }}
   - user: {{ site_user }}
   - dir_mode: 2775
   - file_mode: '0644'
   - template: jinja
   - source: salt://project/templates_dir
   - include_empty: True
```
salt.states.file.absent(name)
Make sure that the named file or directory is absent. If it exists, it will be deleted. This will work to reverse any of the functions in the file state module. If a directory is supplied, it will be recursively deleted.

name The path which should be deleted

salt.states.file.accumulated(name, filename, text, **kwargs)
Prepare accumulator which can be used in template in file.managed state. Accumulator dictionary becomes available in template. It can also be used in file.blockreplace.

name Accumulator name
filename Filename which would receive this accumulator (see file.managed state documentation about name)
text String or list for adding in accumulator
require_in / watch_in One of them required for sure we fill up accumulator before we manage the file. Probably the same as filename

Example:
Given the following:

```
animals_doing_things:
  file.accumulated:
    - filename: /tmp/animal_file.txt
    - text: 'jumps over the lazy dog.'
    - require_in:
      - file: animal_file

animal_file:
  file.managed:
    - name: /tmp/animal_file.txt
    - source: salt://animal_file.txt
    - template: jinja
```

One might write a template for `animal_file.txt` like the following:

```
The quick brown fox{% for animal in accumulator['animals_doing_things'] %}{% if animal %}over the lazy dog.\n{% endif %}{% endfor %}
```

Collectively, the above states and template file will produce:

```
The quick brown fox jumps over the lazy dog.
```

Multiple accumulators can be `chained` together.

Note: The `accumulator` data structure is a Python dictionary. Do not expect any loop over the keys in a deterministic order!

salt.states.file.append(name, text=None, makedirs=False, source=None, source_hash=None, template='jinja', sources=None, source_hashes=None, defaults=None, context=None, ignore_whitespace=True)
Ensure that some text appears at the end of a file.

The text will not be appended if it already exists in the file. A single string of text or a list of strings may be appended.

name The location of the file to append to.
text  The text to be appended, which can be a single string or a list of strings.

makedirs If the file is located in a path without a parent directory, then the state will fail. If makedirs is set
to True, then the parent directories will be created to facilitate the creation of the named file. Defaults to
False.

source A single source file to append. This source file can be hosted on either the salt master server,
or on an HTTP or FTP server. Both HTTPS and HTTP are supported as well as downloading di-
rectly from Amazon S3 compatible URLs with both pre-configured and automatic IAM credentials
(see s3.get state documentation). File retrieval from Openstack Swift object storage is supported via
swift://container/object_path URLs (see swift.get documentation).

For files hosted on the salt file server, if the file is located on the master in the directory named spam,
and is called eggs, the source string is salt://spam/eggs.

If the file is hosted on an HTTP or FTP server, the source_hash argument is also required.

source_hash

This can be one of the following:

1. a source hash string

2. the URI of a file that contains source hash strings

The function accepts the first encountered long unbroken alphanumerical string of correct length as a valid
hash, in order from most secure to least secure:

<table>
<thead>
<tr>
<th>Type</th>
<th>Length</th>
</tr>
</thead>
<tbody>
<tr>
<td>sha512</td>
<td>128</td>
</tr>
<tr>
<td>sha384</td>
<td>96</td>
</tr>
<tr>
<td>sha256</td>
<td>64</td>
</tr>
<tr>
<td>sha224</td>
<td>56</td>
</tr>
<tr>
<td>sha1</td>
<td>40</td>
</tr>
<tr>
<td>md5</td>
<td>32</td>
</tr>
</tbody>
</table>

The file can contain several checksums for several files. Each line must contain both the file name and
the hash. If no file name is matched, the first hash encountered will be used, otherwise the most secure
hash with the correct source file name will be used.

Debian file type *.dsc is supported.

Examples:

/etc/rc.conf ef6e82e4006dee563d98ada2a2a80a27
    sha254c8525ae419eb649f0233be91c151178b30f0dff8ebbdcc8de71b1d5c8b06a /etc/
    → resolv.conf
    ead48423703509d37c4a90e6a0d53e143b6fc268

Known issues: If the remote server URL has the hash file as an apparent sub-directory of the source file,
the module will discover that it has already cached a directory where a file should be cached. For
example:

tomdroid-src-0.7.3.tar.gz:
    file.managed:
    - name: /tmp/tomdroid-src-0.7.3.tar.gz
    - source: https://launchpad.net/tomdroid/beta/0.7.3/+download/tomdroid-
    → src-0.7.3.tar.gz
    - source_hash: https://launchpad.net/tomdroid/beta/0.7.3/+download/
    → tomdroid-src-0.7.3.tar.gz/+md5
**template** [jinja] The named templating engine will be used to render the appended-to file. Defaults to jinja.

**sources** A list of source files to append. If the files are hosted on an HTTP or FTP server, the source_hashes argument is also required.

**source_hashes** A list of source_hashes corresponding to the sources list specified in the sources argument.

**defaults** Default context passed to the template.

**context** Overrides default context variables passed to the template.

**ignore_whitespace** New in version 2015.8.4.

Spaces and Tabs in text are ignored by default, when searching for the appending content, one space or multiple tabs are the same for salt. Set this option to False if you want to change this behavior.

Multi-line example:

```bash
/etc/motd:
  file.append:
    - text: |
      Thou hadst better eat salt with the Philosophers of Greece, than sugar with the Courtiers of Italy.
      - Benjamin Franklin
```

Multiple lines of text:

```bash
/etc/motd:
  file.append:
    - text:
      - Trust no one unless you have eaten much salt with him.
      - "Salt is born of the purest of parents: the sun and the sea."
```

Gather text from multiple template files:

```bash
/etc/motd:
  file:
    - append
    - template: jinja
    - sources:
      - salt://motd/devops-messages.tmpl
      - salt://motd/hr-messages.tmpl
      - salt://motd/general-messages.tmpl
```

New in version 0.9.5.

**salt.states.file.blockreplace**

```python
(name, marker_start='## start managed zone --', marker_end='## end managed zone --', source=None, source_hash=None, template='jinja', sources=None, source_hashes=None, defaults=None, context=None, content='`, append_if_not_found=False, prepend_if_not_found=False, backup='.bak', show_changes=True)
```

Maintain an edit in a file in a zone delimited by two line markers

New in version 2014.1.0.

A block of content delimited by comments can help you manage several lines entries without worrying about old entries removal. This can help you maintaining an un-managed file containing manual edits. Note: this function will store two copies of the file in-memory (the original version and the edited version) in order to detect changes and only edit the targeted file if necessary.

**name** Filesystem path to the file to be edited
**marker_start** The line content identifying a line as the start of the content block. Note that the whole line containing this marker will be considered, so whitespace or extra content before or after the marker is included in final output.

**marker_end** The line content identifying a line as the end of the content block. Note that the whole line containing this marker will be considered, so whitespace or extra content before or after the marker is included in final output. Note: you can use file.accumulated and target this state. All accumulated data dictionaries content will be added as new lines in the content.

**content** The content to be used between the two lines identified by **marker_start** and **marker_end**.

**source** The source file to download to the minion, this source file can be hosted on either the salt master server, or on an HTTP or FTP server. Both HTTPS and HTTP are supported as well as downloading directly from Amazon S3 compatible URLs with both pre-configured and automatic IAM credentials. (see s3.get state documentation) File retrieval from Openstack Swift object storage is supported via swift://container/object_path URLs, see swift.get documentation. For files hosted on the salt file server, if the file is located on the master in the directory named spam, and is called eggs, the source string is salt://spam/eggs. If source is left blank or None (use ~ in YAML), the file will be created as an empty file and the content will not be managed. This is also the case when a file already exists and the source is undefined; the contents of the file will not be changed or managed. If the file is hosted on a HTTP or FTP server then the source_hash argument is also required.

A list of sources can also be passed in to provide a default source and a set of fallbacks. The first source in the list that is found to exist will be used and subsequent entries in the list will be ignored.

```yaml
file_override_example:
  file.managed:
    - source:
      - salt://file_that_does_not_exist
      - salt://file_that_exists
```

**source_hash**

This can be one of the following:

1. a source hash string
2. the URI of a file that contains source hash strings

The function accepts the first encountered long unbroken alphanumeric string of correct length as a valid hash, in order from most secure to least secure:

<table>
<thead>
<tr>
<th>Type</th>
<th>Length</th>
</tr>
</thead>
<tbody>
<tr>
<td>sha512</td>
<td>128</td>
</tr>
<tr>
<td>sha384</td>
<td>96</td>
</tr>
<tr>
<td>sha256</td>
<td>64</td>
</tr>
<tr>
<td>sha224</td>
<td>56</td>
</tr>
<tr>
<td>sha1</td>
<td>40</td>
</tr>
<tr>
<td>md5</td>
<td>32</td>
</tr>
</tbody>
</table>

**Using a Source Hash File** The file can contain several checksums for several files. Each line must contain both the file name and the hash. If no file name is matched, the first hash encountered will be used, otherwise the most secure hash with the correct source file name will be used.

When using a source hash file the source_hash argument needs to be a url, the standard download urls are supported, ftp, http, salt etc:

Example:
tomdroid-src-0.7.3.tar.gz:
  file.managed:
    - name: /tmp/tomdroid-src-0.7.3.tar.gz
    - source: https://launchpad.net/tomdroid/beta/0.7.3/+download/tomdroid-src-0.7.3.tar.gz
    - source_hash: https://launchpad.net/tomdroid/beta/0.7.3/+download/tomdroid-src-0.7.3.hash

The following is an example of the supported source_hash format:

```
/etc/rc.conf ef6e82e4006dee563d98ada2a2a80a27
  sha254c8525aee419eb649f0233be91c151178b30f0dff8ebbdc8de71b1d5c8bcco6a
/etc/resolv.conf
  ead48423703509d37c4a90e6a0d53e143b6fc268
```

Debian file type *.dsc files are also supported.

## Inserting the Source Hash in the sls Data

**Examples:**

```
tomdroid-src-0.7.3.tar.gz:
  file.managed:
    - name: /tmp/tomdroid-src-0.7.3.tar.gz
    - source: https://launchpad.net/tomdroid/beta/0.7.3/+download/tomdroid-src-0.7.3.tar.gz
    - source_hash: md5=79eef25f9b0b2c642c62b7f737d4f53f
```

**template**  If this setting is applied then the named templating engine will be used to render the downloaded file, currently jinja, mako, and wempy are supported

**context**  Overrides default context variables passed to the template.

**defaults**  Default context passed to the template.

**append_if_not_found**  If markers are not found and set to True then the markers and content will be appended to the file. Default is False.

**prepend_if_not_found**  If markers are not found and set to True then the markers and content will be prepended to the file. Default is False.

**backup**  The file extension to use for a backup of the file if any edit is made. Set this to False to skip making a backup.

**dry_run**  Don't make any edits to the file.

**show_changes**  Output a unified diff of the old file and the new file. If False return a boolean if any changes were made.

Example of usage with an accumulator and with a variable:

```
{% set myvar = 42 %}
hosts-config-block-{{ myvar }}:
  file.blockreplace:
    - name: /etc/hosts
    - marker_start: "# START managed zone {{ myvar }} -DO-NOT-EDIT-
    - marker_end: "# END managed zone {{ myvar }} --"
    - content: 'First line of content'
    - append_if_not_found: True
    - backup: '.bak'
    - show_changes: True
```
hosts-config-block-{{ myvar }}-accumulated1:
  file.accumulated:
    - filename: /etc/hosts
    - name: my-accumulator-{{ myvar }}
    - text: "text 2"
    - require_in:
      - file: hosts-config-block-{{ myvar }}

hosts-config-block-{{ myvar }}-accumulated2:
  file.accumulated:
    - filename: /etc/hosts
    - name: my-accumulator-{{ myvar }}
    - text: |
      text 3
text 4
    - require_in:
      - file: hosts-config-block-{{ myvar }}

will generate and maintain a block of content in /etc/hosts:

```
# START managed zone 42 -DO-NOT-EDIT-
First line of content
text 2
text 3
text 4
# END managed zone 42 --
```

salt.states.file.comment(name, regex, char='#', backup='.bak')

Comment out specified lines in a file.

- **name** The full path to the file to be edited
- **regex** A regular expression used to find the lines that are to be commented; this pattern will be wrapped in parenthesis and will move any preceding/trailing ^ or $ characters outside the parenthesis (e.g., the pattern ^foo$ will be rewritten as ^(foo)$) Note that you _need_ the leading ^, otherwise each time you run highstate, another comment char will be inserted.
- **char** [#] The character to be inserted at the beginning of a line in order to comment it out
- **backup** [.bak] The file will be backed up before edit with this file extension

**Warning:** This backup will be overwritten each time sed / comment / uncomment is called. Meaning the backup will only be useful after the first invocation.

Usage:

```
/etc/fstab:
  file.comment:
    - regex: ^bind 127.0.0.1
```

New in version 0.9.5.

salt.states.file.copy(name, source, force=False, makedirs=False, preserve=False, user=None, group=None, mode=None, subdir=False, **kwargs)

If the source file exists on the system, copy it to the named file. The named file will not be overwritten if it already exists unless the force option is set to True.

- **name** The location of the file to copy to
source  The location of the file to copy to the location specified with name

force  If the target location is present then the file will not be moved, specify `force: True` to overwrite the
target file

makedirs  If the target subdirectories don’t exist create them

preserve  New in version 2015.5.0.

Set preserve: True to preserve user/group ownership and mode after copying. Default is False.
If preserve is set to True, then user/group/mode attributes will be ignored.

user  New in version 2015.5.0.

The user to own the copied file, this defaults to the user salt is running as on the minion. If preserve
is set to True, then this will be ignored

group  New in version 2015.5.0.

The group to own the copied file, this defaults to the group salt is running as on the minion. If preserve
is set to True or on Windows this will be ignored

mode  New in version 2015.5.0.

The permissions to set on the copied file, aka 644, `0775', `4664'. If preserve is set to True, then this
will be ignored. Not supported on Windows

subdir  New in version 2015.5.0.

If the name is a directory then place the file inside the named directory

Note:  The copy function accepts paths that are local to the Salt minion. This function does not sup-
port salt://, http://, or the other additional file paths that are supported by states.file.managed and
states.file.recurse.

salt.states.file.directory(name, user=None, group=None, recurse=None, dir_mode=None,
    file_mode=None, makedirs=False, clean=False, **kwargs)

Ensure that a named directory is present and has the right perms

name  The location to create or manage a directory

user  The user to own the directory; this defaults to the user salt is running as on the minion

group  The group ownership set for the directory; this defaults to the group salt is running as on the minion.
    On Windows, this is ignored

recurse  Enforce user/group ownership and mode of directory recursively. Accepts a list of strings represent-
ing what you would like to recurse. If mode is defined, will recurse on both file_mode and dir_mode
if they are defined. If ignore_files or ignore_dirs is included, files or directories will be left un-
changed respectively. Example:

    /var/log/httpd:
    file.directory:
    - user: root
    - group: root
    - dir_mode: 755
    - file_mode: 644
    - recurse:
      - user
Leave files or directories unchanged:

```
/var/log/httpd:
  file.directory:
    - user: root
    - group: root
    - dir_mode: 755
    - file_mode: 644
    - recurse:
      - user
      - group
      - mode
      - ignore_dirs
```

New in version 2015.5.0.

**dir_mode / mode**  The permissions mode to set any directories created. Not supported on Windows.

**file_mode**  The permissions mode to set any files created if `mode' is run in `recurse'. This defaults to dir_mode. Not supported on Windows.

**makedirs**  If the directory is located in a path without a parent directory, then the state will fail. If makedirs is set to True, then the parent directories will be created to facilitate the creation of the named file.

**clean**  Make sure that only files that are set up by salt and required by this function are kept. If this option is set then everything in this directory will be deleted unless it is required.

**require**  Require other resources such as packages or files.

**exclude_pat**  When `clean' is set to True, exclude this pattern from removal list and preserve in the destination.

**follow_symlinks**  [False] If the desired path is a symlink (or recurse is defined and a symlink is encountered while recursing), follow it and check the permissions of the directory/file to which the symlink points.

New in version 2014.1.4.

**force**  If the name of the directory exists and is not a directory and force is set to False, the state will fail. If force is set to True, the file in the way of the directory will be deleted to make room for the directory, unless backupname is set, then it will be renamed.

New in version 2014.7.0.

**backupname**  If the name of the directory exists and is not a directory, it will be renamed to the backupname. If the backupname already exists and force is False, the state will fail. Otherwise, the backupname will be removed first.

New in version 2014.7.0.

**allow_symlink**  [True] If allow_symlink is True and the specified path is a symlink, it will be allowed to remain if it points to a directory. If allow_symlink is False then the state will fail, unless force is also set to True, in which case it will be removed or renamed, depending on the value of the backupname argument.

New in version 2014.7.0.

**salt.states.file.exists(name)**

Verify that the named file or directory is present or exists. Ensures pre-requisites outside of Salt’s purview (e.g., keytabs, private keys, etc.) have been previously satisfied before deployment.

**name**  Absolute path which must exist
salt.states.file.line (name, content, match=None, mode=None, location=None, before=None, after=None, show_changes=True, backup=False, quiet=False, indent=True)

Line-based editing of a file.

New in version 2015.8.0.

Parameters

- **name** -- Filesystem path to the file to be edited.
- **content** -- Content of the line.
- **match** -- Match the target line for an action by a fragment of a string or regular expression.
- **mode** --
  - Ensure If line does not exist, it will be added.
  - Replace If line already exist, it will be replaced.
  - Delete Delete the line, once found.
  - Insert Insert a line.
- **location** --
  - start Place the content at the beginning of the file.
  - end Place the content at the end of the file.
- **before** -- Regular expression or an exact case-sensitive fragment of the string.
- **after** -- Regular expression or an exact case-sensitive fragment of the string.
- **show_changes** -- Output a unified diff of the old file and the new file. If False return a boolean if any changes were made. Default is True

Note: Using this option will store two copies of the file in-memory (the original version and the edited version) in order to generate the diff.

- **backup** -- Create a backup of the original file with the extension: ```Year-Month-Day-Hour-Minutes-Seconds```.
- **quiet** -- Do not raise any exceptions. E.g. ignore the fact that the file that is tried to be edited does not exist and nothing really happened.
- **indent** -- Keep indentation with the previous line.

salt.states.file.managed (name, source=None, source_hash=None, user=None, group=None, mode=None, template=None, makedirs=False, dir_mode=None, context=None, replace=True, defaults=None, env=None, backup=None, show_diff=True, create=True, contents=None, contents_pillar=None, contents_grains=None, contents_newline=True, contents_delimiter=':', allow_empty=True, follow_symlinks=True, check_cmd=None, **kwargs)

Manage a given file, this function allows for a file to be downloaded from the salt master and potentially run through a templating system.

name The location of the file to manage

source The source file to download to the minion, this source file can be hosted on either the salt master server (salt://), the salt minion local file system (/), or on an HTTP or FTP server (http(s)://, ftp://).
Both HTTPS and HTTP are supported as well as downloading directly from Amazon S3 compatible URLs with both pre-configured and automatic IAM credentials. (see s3.get state documentation) File retrieval from Openstack Swift object storage is supported via swift://container/object_path URLs, see swift.get documentation. For files hosted on the salt file server, if the file is located on the master in the directory named spam, and is called eggs, the source string is salt://spam/eggs. If source is left blank or None (use ~ in YAML), the file will be created as an empty file and the content will not be managed. This is also the case when a file already exists and the source is undefined; the contents of the file will not be changed or managed.

If the file is hosted on a HTTP or FTP server then the source_hash argument is also required

A list of sources can also be passed in to provide a default source and a set of fallbacks. The first source in the list that is found to exist will be used and subsequent entries in the list will be ignored. Source list functionality only supports local files and remote files hosted on the salt master server or retrievable via HTTP, HTTPS, or FTP.

```
file_override_example:
  file.managed:
    - source:
      - salt://file_that_does_not_exist
      - salt://file_that_exists
```

source_hash

This can be one of the following:

1. a source hash string
2. the URI of a file that contains source hash strings

The function accepts the first encountered long unbroken alphanumeric string of correct length as a valid hash, in order from most secure to least secure:

<table>
<thead>
<tr>
<th>Type</th>
<th>Length</th>
</tr>
</thead>
<tbody>
<tr>
<td>sha512</td>
<td>128</td>
</tr>
<tr>
<td>sha384</td>
<td>96</td>
</tr>
<tr>
<td>sha256</td>
<td>64</td>
</tr>
<tr>
<td>sha224</td>
<td>56</td>
</tr>
<tr>
<td>sha1</td>
<td>40</td>
</tr>
<tr>
<td>md5</td>
<td>32</td>
</tr>
</tbody>
</table>

Using a Source Hash File The file can contain several checksums for several files. Each line must contain both the file name and the hash. If no file name is matched, the first hash encountered will be used, otherwise the most secure hash with the correct source file name will be used.

When using a source hash file the source_hash argument needs to be a url, the standard download urls are supported, ftp, http, salt etc:

Example:

```
tomdroid-src-0.7.3.tar.gz:
  file.managed:
    - name: /tmp/tomdroid-src-0.7.3.tar.gz
    - source: https://launchpad.net/tomdroid/beta/0.7.3/+download/tomdroid-
      src-0.7.3.tar.gz
    - source_hash: https://launchpad.net/tomdroid/beta/0.7.3/+download/
      tomdroid-src-0.7.3.hash
```
The following is an example of the supported source_hash format:

```
/etc/rc.conf ef6e82e4006dee563d98ada2a2a80a27
sha254c8525aee419eb649f6233be91c15117b30f0dff8ebbdcc8de71b1d5c8bcc06a /
/etc/resolv.conf
ead4823763509d37c4a90e6a0d53e143b6fc268
```

Debian file type *.dsc files are also supported.

**Inserting the Source Hash in the sls Data**

**Examples:**

- **tomdroid-src-0.7.3.tar.gz:**
  ```
  file.managed:
  - name: /tmp/tomdroid-src-0.7.3.tar.gz
  - source: https://launchpad.net/tomdroid/beta/0.7.3/+download/tomdroid-
  - source_hash: md5=79eef25f9b0b2c642c62b7f737d4f53f
  ```

**Known issues:** If the remote server URL has the hash file as an apparent sub-directory of the source file, the module will discover that it has already cached a directory where a file should be cached. For example:

- **tomdroid-src-0.7.3.tar.gz:**
  ```
  file.managed:
  - name: /tmp/tomdroid-src-0.7.3.tar.gz
  - source: https://launchpad.net/tomdroid/beta/0.7.3/+download/tomdroid-
  - source_hash: https://launchpad.net/tomdroid/beta/0.7.3/+download/
tomdroid-src-0.7.3.tar.gz/+md5
  ```

**User** The user to own the file, this defaults to the user salt is running as on the minion.

**Group** The group ownership set for the file, this defaults to the group salt is running as on the minion. On Windows, this is ignored.

**Mode** The permissions to set on this file, aka 644, 0775, 4664. Not supported on Windows.

**Template** If this setting is applied then the named templating engine will be used to render the downloaded file, currently jinja, mako, and wempy are supported.

**Makedirs** [False] If set to True, then the parent directories will be created to facilitate the creation of the named file. If False, and the parent directory of the destination file doesn’t exist, the state will fail.

**Dir_mode** If directories are to be created, passing this option specifies the permissions for those directories. If this is not set, directories will be assigned permissions from the mode argument.

**Replace** [True] If set to False and the file already exists, the file will not be modified even if changes would otherwise be made. Permissions and ownership will still be enforced, however.

**Context** Overrides default context variables passed to the template.

**Defaults** Default context passed to the template.

**Backup** Overrides the default backup mode for this specific file.

**Show_diff** [True] If set to False, the diff will not be shown in the return data if changes are made.

**Create** [True] If set to False, then the file will only be managed if the file already exists on the system.

**Contents** Specify the contents of the file. Cannot be used in combination with source. Ignores hashes and does not use a templating engine.
This value can be either a single string, a multiline YAML string or a list of strings. If a list of strings, then the strings will be joined together with newlines in the resulting file. For example, the below two example states would result in identical file contents:

```yaml
/path/to/file1:
  file.managed:
    - contents:
      - This is line 1
      - This is line 2

/path/to/file2:
  file.managed:
    - contents:
      | 
      - This is line 1
      - This is line 2
```

**contents_pillar**  New in version 0.17.0.

Operates like `contents`, but draws from a value stored in pillar, using the pillar path syntax used in `pillar.get`. This is useful when the pillar value contains newlines, as referencing a pillar variable using a Jinja/mako template can result in YAML formatting issues due to the newlines causing indentation mismatches.

For example, the following could be used to deploy an SSH private key:

```yaml
/home/deployer/.ssh/id_rsa:
  file.managed:
    - user: deployer
    - group: deployer
    - mode: 600
    - contents_pillar: userdata:deployer:id_rsa
```

This would populate `/home/deployer/.ssh/id_rsa` with the contents of `pillar['userdata']['deployer']['id_rsa']`. An example of this pillar setup would be like so:

```yaml
userdata:
  deployer:
    id_rsa: |
      -----BEGIN RSA PRIVATE KEY-----
      MIIEowIBAAKCAQEAoQiwO3JhBquPAalQF9qP1lLZNXvjYMIswrMe2HcWUVBgh+vVUt5Cwx/dH6+vVNmCoqmNnP+8gTPKGl1vgAObJAnMT623dMxjVkwEagZPRJIxDyB/HaRe9euNiY3LvIzBTWRSeMfT+rvWvIKVBPvwlGGrfgz7om8pqxu+UyFbAGL1n+GpxzZAMaFpZw4sSbILRuissXZj/sHpQb8p9M5Ie04Z3jrkCP1cxl
      -----END RSA PRIVATE KEY-----
```

**Note:** The private key above is shortened to keep the example brief, but shows how to do multiline string in YAML. The key is followed by a pipe character, and the multiline string is indented two more spaces.

To avoid the hassle of creating an indented multiline YAML string, the `file_tree external pillar` can be used instead. However, this will not work for binary files in Salt releases before 2015.8.4.

**contents_grains**  New in version 2014.7.0.

Operates like `contents`, but draws from a value stored in grains, using the grains path syntax used in `grains.get`. This functionality works similarly to `contents_pillar`, but with grains.
For example, the following could be used to deploy a "message of the day" file:

```yaml
write_motd:
  file.managed:
    - name: /etc/motd
    - contents_grains: motd
```

This would populate /etc/motd file with the contents of the motd grain. The motd grain is not a default grain, and would need to be set prior to running the state:

```bash
salt '*' grains.set motd 'Welcome! This system is managed by Salt.'
```

**contents_newline** [True] New in version 2014.7.0.

Changed in version 2015.8.4: This option is now ignored if the contents being deployed contain binary data.

If True, files managed using contents, contents_pillar, or contents_grains will have a newline added to the end of the file if one is not present. Setting this option to False will omit this final newline.

**contents_delimiter** New in version 2015.8.4.

Can be used to specify an alternate delimiter for contents_pillar or contents_grains. This delimiter will be passed through to pillar.get or grains.get when retrieving the contents.

If set to False, then the state will fail if the contents specified by contents_pillar or contents_grains are empty.

**follow_symlinks** [True] New in version 2014.7.0.

If the desired path is a symlink follow it and make changes to the file to which the symlink points.

**check_cmd** New in version 2014.7.0.

The specified command will be run with the managed file as an argument. If the command exits with a nonzero exit code, the state will fail and no changes will be made to the file.

For example, the following could be used to verify sudoers before making changes:

```bash
/etc/sudoers:
  file.managed:
    - user: root
    - group: root
    - mode: 0440
    - source: salt://sudoers/files/sudoers.jinja
    - template: jinja
    - check_cmd: /usr/sbin/visudo -c -f
```

salt.states.file**.missing**(name)

Verify that the named file or directory is missing, this returns True only if the named file is missing but does not remove the file if it is present.

**name** Absolute path which must NOT exist

salt.states.file**.mknod**(name, ntype, major=0, minor=0, user=’None’, group=’None’, mode=’0600’)

Create a special file similar to the ‘nix mknod command. The supported device types are p (fifo pipe), c (character device), and b (block device). Provide the major and minor numbers when specifying a character device or block device. A fifo pipe does not require this information. The command will create the necessary dirs if needed. If a file of the same name not of the same type/major/minor exists, it will not be overwritten.
or unlinked (deleted). This is logically in place as a safety measure because you can really shoot yourself in
the foot here and it is the behavior of `nix mknod. It is also important to note that not just anyone can create
special devices. Usually this is only done as root. If the state is executed as none other than root on a minion,
you may receive a permission error.

name name of the file
ntype node type `p' (fifo pipe), `c' (character device), or `b' (block device)
major major number of the device does not apply to a fifo pipe
minor minor number of the device does not apply to a fifo pipe
user owning user of the device/pipe
group owning group of the device/pipe
mode permissions on the device/pipe

Usage:

/dev/chr:
file.mknod:
   - ntype: c
   - major: 180
   - minor: 31
   - user: root
   - group: root
   - mode: 660

/dev/blk:
file.mknod:
   - ntype: b
   - major: 8
   - minor: 999
   - user: root
   - group: root
   - mode: 660

/dev/fifo:
file.mknod:
   - ntype: p
   - user: root
   - group: root
   - mode: 660

New in version 0.17.0.
salt.states.file.mod_run_check_cmd(cmd, filename, **check_cmd_opts)
 Execute the check_cmd logic.
 Return a result dict if check_cmd succeeds (check_cmd == 0) otherwise return True
salt.states.file.patch(name, source=None, hash=None, options='', dry_run_first=True, env=None, **kwargs)
 Apply a patch to a file.

Note: A suitable patch executable must be available on the minion when using this state function.

name The file to which the patch will be applied.
source  The source patch to download to the minion, this source file must be hosted on the salt master server. If the file is located in the directory named spam, and is called eggs, the source string is salt://spam/eggs. A source is required.

hash  Hash of the patched file. If the hash of the target file matches this value then the patch is assumed to have been applied. The hash string is the hash algorithm followed by the hash of the file:

```
md5=e138491e9d5b97023cea823fe17bac22
```

options  Extra options to pass to patch.

dry_run_first  [True] Run patch with --dry-run first to check if it will apply cleanly.

env  Specify the environment from which to retrieve the patch file indicated by the source parameter. If not provided, this defaults to the environment from which the state is being executed.

Usage:

```
# Equivalent to `patch --forward /opt/file.txt file.patch`

[/opt/file.txt:

  file.patch:
  - source: salt://file.patch
  - hash: md5=e138491e9d5b97023cea823fe17bac22

salt.states.file.prepend(name=text=None, makedirs=False, source=None, source_hash=None, template='jinja', sources=None, source_hashes=None, defaults=None, context=None)

Ensure that some text appears at the beginning of a file

The text will not be prepended again if it already exists in the file. You may specify a single line of text or a list of lines to append.

Multi-line example:

```
/etc/motd:

  file.prepend:
  - text: |
    Thou hadst better eat salt with the Philosophers of Greece,
    than sugar with the Courtiers of Italy.
    - Benjamin Franklin
```

Multiple lines of text:

```
/etc/motd:

  file.prepend:
  - text:
    - Trust no one unless you have eaten much salt with him.
    - "Salt is born of the purest of parents: the sun and the sea."
```

Gather text from multiple template files:

```
/etc/motd:

  file:
  - prepend
  - template: jinja
  - sources:
    - salt://motd/devops-messages.tmpl
    - salt://motd/hr-messages.tmpl
    - salt://motd/general-messages.tmpl
```

New in version 2014.7.0.
salt.states.file.recurse(name, source, clean=False, require=None, user=None, group=None, dir_mode=None, file_mode=None, sym_mode=None, template=None, context=None, defaults=None, env=None, include_empty=False, backup='`, include_pat=None, exclude_pat=None, maxdepth=None, keep_symlinks=False, force_symlinks=False, **kwargs)

Recurse through a subdirectory on the master and copy said subdirectory over to the specified path.

**name**  The directory to set the recursion in

**source**  The source directory, this directory is located on the salt master file server and is specified with the salt:// protocol. If the directory is located on the master in the directory named spam, and is called eggs, the source string is salt://spam/eggs

**clean**  Make sure that only files that are set up by salt and required by this function are kept. If this option is set then everything in this directory will be deleted unless it is required.

**require**  Require other resources such as packages or files

**user**  The user to own the directory. This defaults to the user salt is running as on the minion

**group**  The group ownership set for the directory. This defaults to the group salt is running as on the minion. On Windows, this is ignored

**dir_mode**  The permissions mode to set on any directories created. Not supported on Windows

**file_mode**  The permissions mode to set on any files created. Not supported on Windows

**sym_mode**  The permissions mode to set on any symlink created. Not supported on Windows

**template**  If this setting is applied then the named templating engine will be used to render the downloaded file. Supported templates are: jinja, mako and wempy.

---

**Note:** The template option is required when recursively applying templates.

**context**  Overrides default context variables passed to the template.

**defaults**  Default context passed to the template.

**include_empty**  Set this to True if empty directories should also be created (default is False)

**include_pat**  When copying, include only this pattern from the source. Default is glob match; if prefixed with 'E@', then regexp match. Example:

- **include_pat**: hello*  :: glob matches 'hello01', 'hello02'
  ... but not 'otherhello'
- **include_pat**: E@hello  :: regexp matches 'otherhello',
  'hello01' ...

**exclude_pat**  Exclude this pattern from the source when copying. If both include_pat and exclude_pat are supplied, then it will apply conditions cumulatively. i.e. first select based on include_pat, and then within that result apply exclude_pat.

Also, when `clean=True`, exclude this pattern from the removal list and preserve in the destination. Example:

- **exclude_pat**: APPDATA*  :: glob matches APPDATA.01,
  APPDATA.02,.. for exclusion
- **exclude_pat**: E@(APPDATA)|(TEMPDATA)  :: regexp matches APPDATA
  or TEMPDATA for exclusion
**maxdepth** When copying, only copy paths which are of depth `maxdepth` from the source path. Example:

<table>
<thead>
<tr>
<th><code>maxdepth</code></th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Only include files located in the source directory</td>
</tr>
<tr>
<td>1</td>
<td>Only include files located in the source or immediate subdirectories</td>
</tr>
</tbody>
</table>

**keep_symlinks** Keep symlinks when copying from the source. This option will cause the copy operation to terminate at the symlink. If desire behavior similar to rsync, then set this to True.

**force_symlinks** Force symlink creation. This option will force the symlink creation. If a file or directory is obstructing symlink creation it will be recursively removed so that symlink creation can proceed. This option is usually not needed except in special circumstances.

```
salt.states.file.rename(name, source, force=False, makedirs=False)
```

If the source file exists on the system, rename it to the named file. The named file will not be overwritten if it already exists unless the force option is set to True.

- **name** The location of the file to rename to
- **source** The location of the file to move to the location specified with `name`
- **force** If the target location is present then the file will not be moved, specify `force: True` to overwrite the target file
- **makedirs** If the target subdirectories don’t exist create them

```
salt.states.file.replace(name, pattern, repl, count=0, flags=8, bufsize=1, append_if_not_found=False, prepend_if_not_found=False, not_found_content=None, backup='.bak', show_changes=True)
```

Maintain an edit in a file.

- **name** Filesystem path to the file to be edited.
- **pattern** A regular expression, to be matched using Python’s `search()`.
- **repl** The replacement text
- **count** Maximum number of pattern occurrences to be replaced. Defaults to 0. If count is a positive integer n, no more than n occurrences will be replaced, otherwise all occurrences will be replaced.
- **flags** A list of flags defined in the `re` module documentation. Each list item should be a string that will correlate to the human-friendly flag name. E.g., `['IGNORECASE', 'MULTILINE']`. Optionally, `flags` may be an int, with a value corresponding to the XOR (|) of all the desired flags. Defaults to 8 (which equates to `['MULTILINE']`).

**Note:** `file.replace` reads the entire file as a string to support multiline regex patterns. Therefore, when using anchors such as `^` or `$` in the pattern, those anchors may be relative to the line OR relative to the file. The default for `file.replace` is to treat anchors as relative to the line, which is implemented by setting the default value of `flags` to `['MULTILINE']`. When overriding the default value for `flags`, if `MULTILINE` is not present then anchors will be relative to the file. If the desired behavior is for anchors to be relative to the line, then simply add `MULTILINE` to the list of flags.

- **bufsize** How much of the file to buffer into memory at once. The default value 1 processes one line at a time. The special value `file` may be specified which will read the entire file into memory before processing.
- **append_if_not_found** [False] If set to True, and pattern is not found, then the content will be appended to the file.
prepend_if_not_found  [False] If set to True and pattern is not found, then the content will be prepended to the file.

New in version 2014.7.0.

not_found_content  Content to use for append/prepend if not found. If None (default), uses repl. Useful when repl uses references to group in pattern.

New in version 2014.7.0.

backup  The file extension to use for a backup of the file before editing. Set to False to skip making a backup.

show_changes  [True] Output a unified diff of the old file and the new file. If False return a boolean if any changes were made. Returns a boolean or a string.

For complex regex patterns, it can be useful to avoid the need for complex quoting and escape sequences by making use of YAML's multiline string syntax.

```
complex_search_and_replace:
  file.replace:
    # <...snip...>
    - pattern: |
      CentOS \(2.6.32[^\n]+\n\s+root[^\n]+\n\)+

Note: When using YAML multiline string syntax in pattern:, make sure to also use that syntax in the repl: part, or you might loose line feeds.
```

salt.states.file.serialize(name, dataset=None, dataset_pillar=None, user=None, group=None, mode=None, env=None, backup='`, makedirs=False, show_diff=True, create=True, merge_if_exists=False, **kwargs)

Serializes dataset and store it into managed file. Useful for sharing simple configuration files.

name  The location of the file to create

dataset  The dataset that will be serialized

dataset_pillar  Operates like dataset, but draws from a value stored in pillar, using the pillar path syntax used in pillar.get. This is useful when the pillar value contains newlines, as referencing a pillar variable using a jinja/mako template can result in YAML formatting issues due to the newlines causing indentation mismatches.

New in version 2015.8.0.

formatter  Write the data as this format. Supported output formats:

- JSON
- YAML
- Python (via pprint.pformat)

user  The user to own the directory, this defaults to the user salt is running as on the minion

group  The group ownership set for the directory, this defaults to the group salt is running as on the minion

mode  The permissions to set on this file, aka 644, 0775, 4664

backup  Overrides the default backup mode for this specific file.

makedirs  Create parent directories for destination file.

New in version 2014.1.3.
show_diff  If set to False, the diff will not be shown.

create  Default is True, if create is set to False then the file will only be managed if the file already exists on
the system.

merge_if_exists  Default is False, if merge_if_exists is True then the existing file will be parsed and the dataset
passed in will be merged with the existing content.

New in version 2014.7.0.

For example, this state:

```
/etc/dummy/package.json:
  file.serialize:
    - dataset:
      name: naive
      description: A package using naive versioning
      author: A confused individual <iam@confused.com>
      dependencies:
        express: >= 1.2.0
        optimist: >= 0.1.0
      engine: node 0.4.1
    - formatter: json
```

will manage the file /etc/dummy/package.json:

```
{
  "author": "A confused individual <iam@confused.com>",
  "dependencies": {
    "express": ">= 1.2.0",
    "optimist": ">= 0.1.0"
  },
  "description": "A package using naive versioning",
  "engine": "node 0.4.1",
  "name": "naive"
}
```

salt.states.file.symlink(name, target, force=False, backupname=None, makedirs=False, user=None, group=None, mode=None, **kwargs)

Create a symbolic link (symlink, soft link)

If the file already exists and is a symlink pointing to any location other than the specified target, the symlink
will be replaced. If the symlink is a regular file or directory then the state will return False. If the regular file or
directory is desired to be replaced with a symlink pass force: True, if it is to be renamed, pass a backupname.

name  The location of the symlink to create

target  The location that the symlink points to

force  If the name of the symlink exists and is not a symlink and force is set to False, the state will fail. If force
is set to True, the file or directory in the way of the symlink file will be deleted to make room for the
symlink, unless backupname is set, when it will be renamed

backupname  If the name of the symlink exists and is not a symlink, it will be renamed to the backupname. If
the backupname already exists and force is False, the state will fail. Otherwise, the backupname will be
removed first.

makedirs  If the location of the symlink does not already have a parent directory then the state will fail, setting
makedirs to True will allow Salt to create the parent directory

user  The user to own the file, this defaults to the user salt is running as on the minion
**group**  The group ownership set for the file, this defaults to the group salt is running as on the minion. On Windows, this is ignored

**mode**  The permissions to set on this file, aka 644, 0775, 4664. Not supported on Windows

---

**salt.states.file.touch** *(name, atime=None, mtime=None, makedirs=False)*

Replicate the `nix `touch`` command to create a new empty file or update the atime and mtime of an existing file.

Note that if you just want to create a file and don't care about atime or mtime, you should use `file.managed` instead, as it is more feature-complete. (Just leave out the `source/template/contents` arguments, and it will just create the file and/or check its permissions, without messing with contents)

**name**  name of the file

**atime**  atime of the file

**mtime**  mtime of the file

**makedirs**  whether we should create the parent directory/directories in order to touch the file

Usage:

```
/var/log/httpd/logrotate.empty:
 file.touch
```

New in version 0.9.5.

**salt.states.file.uncomment** *(name, regex, char='#', backup='.bak)*

Uncomment specified commented lines in a file

**name**  The full path to the file to be edited

**regex**  A regular expression used to find the lines that are to be uncommented. This regex should not include the comment character. A leading `^` character will be stripped for convenience (for easily switching between `comment()` and `uncomment()`). The regex will be searched for from the beginning of the line, ignoring leading spaces (we prepend `^[ ]*')`

**char**  [#] The character to remove in order to uncomment a line

**backup**  [.bak] The file will be backed up before edit with this file extension;

---

**Warning:** This backup will be overwritten each time `sed / comment / uncomment` is called. Meaning the backup will only be useful after the first invocation.

Usage:

```
/etc/adduser.conf:
 file.uncomment:
  - regex: EXTRA_GROUPS
```

New in version 0.9.5.

---

**32.29.54 salt.states.firewalld**

Management of firewalld

New in version 2015.8.0.
The following example applies changes to the public zone, blocks echo-reply and echo-request packets, does not set the zone to be the default, enables masquerading, and allows ports 22/tcp and 25/tcp.

```yaml
public:
    firewalld.present:
        - name: public
        - block_icmp:
            - echo-reply
            - echo-request
        - default: False
        - masquerade: True
        - ports:
            - 22/tcp
            - 25/tcp
```

The following example applies changes to the public zone, enables masquerading and configures port forwarding TCP traffic from port 22 to 2222, and forwards TCP traffic from port 80 to 443 at 192.168.0.1.

```yaml
my_zone:
    firewalld.present:
        - name: public
        - masquerade: True
        - port_fwd:
            - 22:2222:tcp
            - 80:443:tcp:192.168.0.1
```

```
salt.states.firewalld.present(name, block_icmp=None, default=None, masquerade=False, ports=None, port_fwd=None, services=None)
```

Ensure a zone has specific attributes.

### 32.29.55 salt.states.gem

**Installation of Ruby modules packaged as gems**

A state module to manage rubygems. Gems can be set up to be installed or removed. This module will use RVM or rbenv if they are installed. In that case, you can specify what ruby version and gemset to target.

```yaml
addressable:
    gem.installed:
        - user: rvm
        - ruby: jruby@jgemset
```

```
salt.states.gem.installed(name, ruby=None, gem_bin=None, user=None, version=None, rdoc=False, ri=False, pre_releases=False, proxy=None)
```

Make sure that a gem is installed.

- **name** The name of the gem to install
- **ruby**: `None` Only for RVM or rbenv installations: the ruby version and gemset to target.
- **gem_bin**: `None` Custom `gem` command to run instead of the default. Use this to install gems to a non-default ruby install. If you are using rvm or rbenv use the ruby argument instead.
- **user**: `None` The user under which to run the `gem` command
  - New in version 0.17.0.
- **version** `[None]` Specify the version to install for the gem. Doesn't play nice with multiple gems at once
rdoc [False] Generate RDoc documentation for the gem(s).
ri [False] Generate RI documentation for the gem(s).
pre_releases [False] Install pre-release version of gem(s) if available.
proxy [None] Use the specified HTTP proxy server for all outgoing traffic. Format: http://hostname[:port]
salt.states.gem.removed(name, ruby=None, user=None, gem_bin=None)
Make sure that a gem is not installed.
   name The name of the gem to uninstall
   gem_bin [None] Full path to gem binary to use.
   ruby [None] If RVM or rbenv are installed, the ruby version and gemset to use. Ignored if gem_bin is specified.
   user: None The user under which to run the gem command
   New in version 0.17.0.
salt.states.gem.sources_add(name, ruby=None, user=None)
Make sure that a gem source is added.
   name The URL of the gem source to be added
   ruby: None For RVM or rbenv installations: the ruby version and gemset to target.
   user: None The user under which to run the gem command
   New in version 0.17.0.
salt.states.gem.sources_remove(name, ruby=None, user=None)
Make sure that a gem source is removed.
   name The URL of the gem source to be removed
   ruby: None For RVM or rbenv installations: the ruby version and gemset to target.
   user: None The user under which to run the gem command
   New in version 0.17.0.

32.29.56 salt.states.git

States to manage git repositories and git configuration

Important: Before using git over ssh, make sure your remote host fingerprint exists in your ~/.ssh/known_hosts file.

Changed in version 2015.8.8: This state module now requires git 1.6.5 (released 10 October 2009) or newer.
salt.states.git.config_set(name, value=None, multivar=None, repo=None, user=None, **kwargs)
New in version 2014.7.0.
   Changed in version 2015.8.0: Renamed from git.config to git.config_set. For earlier versions, use git.config.
   Ensure that a config value is set to the desired value(s)
   name Name of the git config value to set
   value Set a single value for the config item
**multivar** Set multiple values for the config item

---

**Note:** The order matters here, if the same parameters are set but in a different order, they will be removed and replaced in the order specified.

---

New in version 2015.8.0.

**repo** Location of the git repository for which the config value should be set. Required unless **global** is set to True.

**user** Optional name of a user as whom **git config** will be run

**global** [False] If True, this will set a global git config option

Changed in version 2015.8.0: Option renamed from **is_global** to **global**. For earlier versions, use **is_global**.

Local Config Example:

```yaml
# Single value
mylocalrepo:
git.config_set:
  - name: user.email
  - value: foo@bar.net
  - repo: /path/to/repo

# Multiple values
mylocalrepo:
git.config_set:
  - name: mysection.myattribute
  - multivar:
    - foo
    - bar
    - baz
  - repo: /path/to/repo
```

Global Config Example (User `foo`):

```yaml
mylocalrepo:
git.config_set:
  - name: user.name
  - value: Foo Bar
  - user: foo
  - global: True
```

salt.states.git.**config_unset**(name, value_regex=None, repo=None, user=None, **kwargs)

New in version 2015.8.0.

Ensure that the named config key is not present

**name** The name of the configuration key to unset. This value can be a regex, but the regex must match the entire key name. For example, `foo\.\+` would not match all keys in the `foo` section, it would be necessary to use `foo\.+` to do so.

**value_regex** Regex indicating the values to unset for the matching key(s)

---

**Note:** This option behaves differently depending on whether or not **all** is set to True. If it is, then all values matching the regex will be deleted (this is the only way to delete multiple values from a multivar).
If all is set to False, then this state will fail if the regex matches more than one value in a multivar.

all [False] If True, unset all matches

repo Location of the git repository for which the config value should be set. Required unless global is set to True.

user Optional name of a user as whom git config will be run

global [False] If True, this will set a global git config option

Examples:

```
# Value matching 'baz'
mylocalrepo:
    git.config_unset:
        - name: foo.bar
        - value_regex: 'baz'
        - repo: /path/to/repo

# Ensure entire multivar is unset
mylocalrepo:
    git.config_unset:
        - name: foo.bar
        - all: True

# Ensure all variables in 'foo' section are unset, including multivars
mylocalrepo:
    git.config_unset:
        - name: 'foo\..+'
        - all: True

# Ensure that global config value is unset
mylocalrepo:
    git.config_unset:
        - name: foo.bar
        - global: True
```

salt.states.git.latest(name, rev='HEAD', target=None, branch=None, user=None, update_head=True, force_checkout=False, force_clone=False, force_fetch=False, force_reset=False, submodules=False, bare=False, mirror=False, remote='origin', fetch_tags=True, depth=None, identity=None, https_user=None, https_pass=None, onlyif=False, unless=False, **kwargs)

Make sure the repository is cloned to the given directory and is up-to-date.

name Address of the remote repository as passed to `git clone`

rev [HEAD] The remote branch, tag, or revision ID to checkout after clone / before update. If specified, then Salt will also ensure that the tracking branch is set to `<remote>/<rev>`, unless rev refers to a tag or SHA1, in which case Salt will ensure that the tracking branch is unset.

If rev is not specified, it will be assumed to be HEAD, and Salt will not manage the tracking branch at all.

Changed in version 2015.8.0: If not specified, rev now defaults to the remote repository's HEAD.

target Name of the target directory where repository is about to be cloned

branch Name of the branch into which to checkout the specified rev. If not specified, then Salt will not care what branch is being used locally and will just use whatever branch is currently there.
Note: If not specified, this means that the local branch name will not be changed if the repository is reset to another branch/tag/SHA1.

New in version 2015.8.0.

user User under which to run git commands. By default, commands are run by the user under which the minion is running.

New in version 0.17.0.

update_head [True] If set to False, then the remote repository will be fetched (if necessary) to ensure that the commit to which rev points exists in the local checkout, but no changes will be made to the local HEAD.

New in version 2015.8.3.

force [False] Deprecated since version 2015.8.0: Use force_clone instead. For earlier Salt versions, force must be used.

force_checkout [False] When checking out the local branch, the state will fail if there are unwritten changes. Set this argument to True to discard unwritten changes when checking out.

force_clone [False] If the target directory exists and is not a git repository, then this state will fail. Set this argument to True to remove the contents of the target directory and clone the repo into it.

force_fetch [False] If a fetch needs to be performed, non-fast-forward fetches will cause this state to fail. Set this argument to True to force the fetch even if it is a non-fast-forward update.

New in version 2015.8.0.

force_reset [False] If the update is not a fast-forward, this state will fail. Set this argument to True to force a hard-reset to the remote revision in these cases.

submodules [False] Update submodules on clone or branch change

bare [False] Set to True if the repository is to be a bare clone of the remote repository.

mirror Set to True if the repository is to be a mirror of the remote repository. This implies that bare set to True, and thus is incompatible with rev.

remote [origin] Git remote to use. If this state needs to clone the repo, it will clone it using this value as the initial remote name. If the repository already exists, and a remote by this name is not present, one will be added.

remote_name Deprecated since version 2015.8.0: Use remote instead. For earlier Salt versions, remote_name must be used.

fetch_tags [True] If True, then when a fetch is performed all tags will be fetched, even those which are not reachable by any branch on the remote.

depth Defines depth in history when git a clone is needed in order to ensure latest. E.g. depth: 1 is useful when deploying from a repository with a long history. Use rev to specify branch. This is not compatible with tags or revision IDs.

identity Path to a private key to use for ssh URLs. This can be either a single string, or a list of strings. For example:

```yaml
# Single key
git@github.com:user/repo.git:
git.latest:
  - user: deployer
  - identity: /home/deployer/.ssh/id_rsa
```
# Two keys

git@github.com:user/repo.git:
git.latest:
  - user: deployer
  - identity:
    - /home/deployer/.ssh/id_rsa
    - /home/deployer/.ssh/id_rsa_alternate

If multiple keys are specified, they will be tried one-by-one in order for each git command which needs to authenticate.

**Warning:** Unless Salt is invoked from the minion using `salt-call`, the key(s) must be passphrase-less. For greater security with passphraseless private keys, see the `sshd(8)` manpage for information on securing the keypair from the remote side in the `authorized_keys` file.

Changed in version 2015.8.7: Salt will no longer attempt to use passphrase-protected keys unless invoked from the minion using `salt-call`, to prevent blocking waiting for user input.

**https_user** HTTP Basic Auth username for HTTPS (only) clones

New in version 2015.5.0.

**https_pass** HTTP Basic Auth password for HTTPS (only) clones

New in version 2015.5.0.

**onlyif** A command to run as a check, run the named command only if the command passed to the `onlyif` option returns true

**unless** A command to run as a check, only run the named command if the command passed to the `unless` option returns false

**Note:** Clashing ID declarations can be avoided when including different branches from the same git repository in the same sls file by using the `name` declaration. The example below checks out the `gh-pages` and `gh-pages-prod` branches from the same repository into separate directories. The example also sets up the `ssh_known_hosts` ssh key required to perform the git checkout.

```yaml
# gitlab.example.com:
git.latest:
  - name: git@gitlab.example.com:user/website.git
  - rev: gh-pages
  - target: /usr/share/nginx/staging
  - identity: /root/.ssh/website_id_rsa
  - require:
    - pkg: git
    - ssh_known_hosts: gitlab.example.com

# git-website-staging:
git.latest:
  - name: git@gitlab.example.com:user/website.git
  - rev: gh-pages
  - target: /usr/share/nginx/staging
  - identity: /root/.ssh/website_id_rsa
  - require:
    - pkg: git
    - ssh_known_hosts: gitlab.example.com
```

```yaml
# git-website-prod:
```
```
git.latest:
  - name: git@gitlab.example.com:user/website.git
  - rev: gh-pages-prod
  - target: /usr/share/nginx/prod
  - identity: /root/.ssh/website_id_rsa
  - require:
    - pkg: git
    - ssh_known_hosts: gitlab.example.com

salt.states.git.mod_run_check(cmd_kwargs, onlyif, unless)
   Execute the onlyif and unless logic. Return a result dict if:
   • onlyif failed (onlyif != 0)
   • unless succeeded (unless == 0)
   Otherwise, returns True

salt.states.git.present(name, force=False, bare=True, template=None, separate_git_dir=None, shared=None, user=None)
   Ensure that a repository exists in the given directory

   Warning: If the minion has Git 2.5 or later installed, name points to a worktree, and force is set to True, then the worktree will be deleted. This has been corrected in Salt 2015.8.0.

   name  Path to the directory
          Changed in version 2015.8.0: This path must now be absolute

   force  [False] If True, and if name points to an existing directory which does not contain a git repository, then the contents of that directory will be recursively removed and a new repository will be initialized in its place.

   bare  [True] If True, and a repository must be initialized, then the repository will be a bare repository.

   Note: This differs from the default behavior of git.init, make sure to set this value to False if a bare repo is not desired.

   template  If a new repository is initialized, this argument will specify an alternate `template directory`
          New in version 2015.8.0.

   separate-git_dir  If a new repository is initialized, this argument will specify an alternate $GIT_DIR
          New in version 2015.8.0.

   shared  Set sharing permissions on git repo. See git-init(1) for more details.
          New in version 2015.5.0.

   user  User under which to run git commands. By default, commands are run by the user under which the minion is running.
          New in version 0.17.0.
```
32.29.57 salt.states.glance

Managing Images in OpenStack Glance

```
salt.states.glance.image_present(name, visibility='public', protected=None, checksum=None, location=None, wait_for=None, timeout=30)
```

Checks if given image is present with properties set as specified.

An image should go through the stages `queued', `saving' before becoming `active'. The attribute `checksum' can only be checked once the image is active. If you don't specify `wait_for' but `checksum' the function will wait for the image to become active before comparing checksums. If you don't specify checksum either the function will return when the image reached `saving'. The default timeout for both is 30 seconds.

**Supported properties:**

- visibility (`public' or `private')
- protected (bool)
- checksum (string, md5sum)
- location (URL, to copy from)

32.29.58 salt.states.glusterfs

Manage glusterfs pool.

```
salt.states.glusterfs.add_volume_bricks(name, bricks)
```

Add brick(s) to an existing volume

- **name** Volume name
- **bricks** List of bricks to add to the volume

```yaml
myvolume:
  glusterfs.add_volume_bricks:
    - bricks:
      - host1:/srv/gluster/drive1
      - host2:/srv/gluster/drive2

Replicated Volume:
  glusterfs.add_volume_bricks:
    - name: volume2
      - bricks:
        - host1:/srv/gluster/drive2
        - host2:/srv/gluster/drive3
```

```
salt.states.glusterfs.created(name, bricks, stripe=False, replica=False, device_vg=False, transport='tcp', start=False, force=False)
```

Check if volume already exists

- **name** name of the volume

```yaml
myvolume:
  glusterfs.created:
    - bricks:
      - host1:/srv/gluster/drive1
      - host2:/srv/gluster/drive2

Replicated Volume:
  glusterfs.created:
    - bricks:
      - host1:/srv/gluster/drive2
      - host2:/srv/gluster/drive3
```
glusterfs.created:
  - name: volume2
  - bricks:
    - host1:/srv/gluster/drive2
    - host2:/srv/gluster/drive3
  - replica: 2
  - start: True

salt.states.glusterfs.peered(name)
Check if node is peered.

  name  The remote host with which to peer.

peer-cluster:
glusterfs.peered:
  - name: two
peer-clusters:
glusterfs.peered:
  - names:
    - one
    - two
    - three
    - four

salt.states.glusterfs.started(name)
Check if volume has been started

  name  name of the volume

mycluster:
glusterfs.started: []

32.29.59 salt.states.gnomedesktop

Configuration of the GNOME desktop

Control the GNOME settings

localdesktop_wm_prefs:
gnomedesktop.wm_preferences:
  - user: username
  - audible_bell: false
  - action_double_click_titlebar: 'toggle-maximize'
  - visual_bell: true
  - num_workspaces: 6
localdesktop_lockdown:
gnomedesktop.desktop_lockdown:
  - user: username
  - disable_user_switching: true
localdesktop_interface:
gnomedesktop.desktop_interface:
  - user: username
  - clock_show_date: true

32.29.60 salt.states.grafana

Manage Grafana Dashboards

This module uses elasticsearch, which can be installed via package, or pip.

You can specify elasticsearch hosts directly to the module, or you can use an elasticsearch profile via pillars:

```yaml
mygrafanaprofile:
  hosts:
    - es1.example.com:9200
    - es2.example.com:9200
  index: grafana-dash
```

# Basic usage (uses default pillar profile key 'grafana')
Ensure myservice dashboard is managed:
```yaml
grafana.dashboard_present:
  - name: myservice
    - dashboard_from_pillar: default
    - rows_from_pillar:
      - systemhealth
      - requests
```

# Passing hosts in
Ensure myservice dashboard is managed:
```yaml
grafana.dashboard_present:
  - name: myservice
    - dashboard_from_pillar: default
    - rows:
      - collapse: false
        editable: true
        height: 150px
        title: System Health
        panels:
          - aliasColors: {}
            id: 200000
            annotate:
              enable: false
            bars: false
datasource: null
            editable: true
```
error: false
fill: 7
grid:
  leftMax: 100
  leftMin: null
  rightMax: null
  rightMin: null
  threshold1: 60
  threshold1Color: rgb(216, 27, 27)
  threshold2: null
  threshold2Color: rgba(234, 112, 112, 0.22)
leftYAxisLabel: ''
legend:

      rows_from_pillars:
        - systemhealth
        - requests
      profile: mygrafanaprofile
The behavior of this module is to create dashboards if they do not exist, to add rows if they do not exist in existing dashboards, and to update rows if they exist in dashboards. The module will not manage rows that are not defined, allowing users to manage their own custom rows.

salt.states.grafana.dashboard_absent(name, hosts=None, profile='grafana')

Ensure the named grafana dashboard is deleted.

    name        Name of the grafana dashboard.
    profile     A pillar key or dict that contains a list of hosts and an elasticsearch index to use.

salt.states.grafana.dashboard_present(name, dashboard=None, dashboard_from_pillar=None, rows=None, rows_from_pillar=None, profile='grafana')

Ensure the grafana dashboard exists and is managed.

    name        Name of the grafana dashboard.
    dashboard   A dict that defines a dashboard that should be managed.
    dashboard_from_pillar A pillar key that contains a grafana dashboard dict. Mutually exclusive with dashboard.
    rows        A list of grafana rows.
    rows_from_pillar A list of pillar keys that contain lists of grafana dashboard rows. Rows defined in the pillars will be appended to the rows defined in the state.
    profile     A pillar key or dict that contains a list of hosts and an elasticsearch index to use.

32.29.61 salt.states.grains

Manage grains on the minion

This state allows for grains to be set. Grains set or altered this way are stored in the `grains' file on the minions, by default at: /etc/salt/grains

Note: This does not override any grains set in the minion file.

salt.states.grains.absent(name, destructive=False, delimiter=':', force=False)

New in version 2014.7.0.

Delete a grain from the grains config file

    name        The grain name
    destructive If destructive is True, delete the entire grain. If destructive is False, set the grain's value to None.
                Defaults to False.
    force       If force is True, the existing grain will be overwritten regardless of its existing or provided value type.
                Defaults to False
                New in version v2015.8.2.
    delimiter   A delimiter different from the default can be provided.
                New in version v2015.8.2.

Changed in version v2015.8.2.

This state now support nested grains and complex values. It is also more conservative: if a grain has a value that is a list or a dict, it will not be removed unless the force parameter is True.
**salt.states.grains.append** *(name, value, convert=False, delimiter=':'*)

New in version 2014.7.0.

Append a value to a list in the grains config file. The grain that is being appended to (name) must exist before the new value can be added.

- **name** The grain name.
- **value** The value to append.
- **convert** If convert is True, convert non-list contents into a list. If convert is False and the grain contains non-list contents, an error is given. Defaults to False.
- **delimiter** A delimiter different from the default can be provided.

New in version v2015.8.2.

```python
grain_name:
    grains.append:
        - value: to_be_appended
```

**salt.states.grains.list_absent** *(name, value, delimiter=':')*

Delete a value from a grain formed as a list.

New in version 2014.1.0.

- **name** The grain name.
- **value** The value to delete from the grain list.
- **delimiter** A delimiter different from the default can be provided.

New in version v2015.8.2.

The grain should be list type

```python
grain_name:
    grains.list_absent:
        - value: db
```

For multiple grains, the syntax looks like:

```python
roles:
    grains.list_absent:
        - value:
            - web
            - dev
```

**salt.states.grains.list_present** *(name, value, delimiter=':')*

New in version 2014.1.0.

Ensure the value is present in the list-type grain. Note: If the grain that is provided in name is not present on the system, this new grain will be created with the corresponding provided value.

- **name** The grain name.
- **value** The value is present in the list type grain.
- **delimiter** A delimiter different from the default can be provided.

New in version v2015.8.2.
The grain should be list type

```
roles:
  grains.list_present:
    - value: web
```

For multiple grains, the syntax looks like:

```
roles:
  grains.list_present:
    - value:
      - web
      - dev
```

salt.states.grains.present

Ensure that a grain is set

Changed in version v2015.8.2.

**name**  The grain name

**value**  The value to set on the grain

**force**  If force is True, the existing grain will be overwritten regardless of its existing or provided value type. Defaults to False

New in version v2015.8.2.

**delimiter**  A delimiter different from the default can be provided.

New in version v2015.8.2.

It is now capable to set a grain to a complex value (ie. lists and dicts) and supports nested grains as well.

If the grain does not yet exist, a new grain is set to the given value. For a nested grain, the necessary keys are created if they don’t exist. If a given key is an existing value, it will be converted, but an existing value different from the given key will fail the state.

If the grain with the given name exists, its value is updated to the new value unless its existing or provided value is complex (list or dict). Use `force: True` to overwrite.

```
cheese:
  grains.present:
    - value: edam

nested_grain_with_complex_value:
  grains.present:
    - name: icinga:Apache SSL
    - value:
      - command: check_https
        - params: -H localhost -p 443 -S

with,a,custom,delimiter:
  grains.present:
    - value: yay
    - delimiter: ,
```
32.29.62  salt.states.group

Management of user groups

The group module is used to create and manage unix group settings, groups can be either present or absent:

```yaml
cheese:
  group.present:
    - gid: 7648
    - system: True
    - addusers:
      - user1
      - users2
    - delusers:
      - foo

cheese:
  group.present:
    - gid: 7648
    - system: True
    - members:
      - foo
      - bar
      - user1
      - user2
```

```python
salt.states.group.absent(name)

Ensure that the named group is absent

name  The name of the group to remove
```

```python
salt.states.group.present(name, gid=None, system=False, addusers=None, delusers=None, members=None)

Ensure that a group is present

name  The name of the group to manage

gid  The group id to assign to the named group; if left empty, then the next available group id will be assigned

system  Whether or not the named group is a system group. This is essentially the `-r' option of `groupadd'.

addusers  List of additional users to be added as a group members.

delusers  Ensure these user are removed from the group membership.

members  Replace existing group members with a list of new members.

Note: Options `members' and `addusers/delusers' are mutually exclusive and  can not be used together.
```

32.29.63  salt.states.hg

Interaction with Mercurial repositories

Before using hg over ssh, make sure the remote host fingerprint already exists in `~/.ssh/known_hosts', and the remote host has this host's public key.

```python
https://bitbucket.org/example_user/example_repo:
  hg.latest:
    - rev: tip
    - target: /tmp/example_repo
```
salt.states.hg.latest(name, rev=None, target=None, clean=False, user=None, identity=None, force=False, opts=False)

Make sure the repository is cloned to the given directory and is up to date

name Address of the remote repository as passed to `hg clone`
rev The remote branch, tag, or revision hash to clone/pull
target Target destination directory path on minion to clone into
clean Force a clean update with -C (Default: False)
user Name of the user performing repository management operations
    New in version 0.17.0.
identity Private SSH key on the minion server for authentication (ssh://)
    New in version 2015.5.0.
force Force hg to clone into pre-existing directories (deletes contents)
opts Include additional arguments and options to the hg command line

32.29.64 salt.states.hipchat

Send a message to Hipchat

This state is useful for sending messages to Hipchat during state runs.

New in version 2015.5.0.

```yaml
salt.states.hipchat.send_message:
    hipchat.send_message:
        - room_id: 123456
        - from_name: SuperAdmin
        - message: 'This state was executed successfully.'
        - api_key: peWcBiMOS9HrZG15peWcBiMOS9HrZG15
        - api_version: v1
```

The api key can be specified in the master or minion configuration like below:

```yaml
hipchat:
    api_key: peWcBiMOS9HrZG15peWcBiMOS9HrZG15
    api_version: v1
```

```yaml
salt.states.hipchat.send_message(name, room_id, from_name, message, api_key=None, api_version=None, message_color='yellow', notify=False)
```

Send a message to a Hipchat room.

```yaml
salt.states.hipchat.send_message:
    hipchat.send_message:
        - room_id: 123456
        - from_name: SuperAdmin
        - message: 'This state was executed successfully.'
        - api_key: peWcBiMOS9HrZG15peWcBiMOS9HrZG15
        - api_version: v1
        - color: green
        - notify: True
```
The following parameters are required:

name The unique name for this event.
room_id The room to send the message to. Can either be the ID or the name.
from_name The name of that is to be shown in the `from` field. If not specified, defaults to.
message The message that is to be sent to the Hipchat room.

The following parameters are optional:

api_key The api key for Hipchat to use for authentication, if not specified in the configuration options of master or minion.
api_version The api version for Hipchat to use, if not specified in the configuration options of master or minion.
color The color the Hipchat message should be displayed in. One of the following, default: yellow `yellow`, `red`, `green`, `purple`, `gray`, or `random`.
notify Should a notification in the room be raised.

32.29.65 salt.states.host

Management of addresses and names in hosts file

The `/etc/hosts` file can be managed to contain definitions for specific hosts:

```yaml
salt-master:
  host.present:
    - ip: 192.168.0.42
```

Or using the `names` directive, you can put several names for the same IP. (Do not try one name with space-separated values).

```yaml
server1:
  host.present:
    - ip: 192.168.0.42
    - names:
       - server1
       - florida
```

**Note:** Changing the names in `host.present` does not cause an update to remove the old entry.

```yaml
server1:
  host.present:
    - ip:
        - 192.168.0.42
        - 192.168.0.43
        - 192.168.0.44
    - names:
       - server1
```

salt.states.host.absent(name, ip)
Ensure that the named host is absent

name The host to remove
ip  The ip addr(s) of the host to remove

```python
salt.states.host.present(name, ip)
```
Ensures that the named host is present with the given ip

- name  The host to assign an ip to
- ip  The ip addr(s) to apply to the host

### 32.29.66 salt.states.htpasswd

Support for htpasswd module. Requires the apache2-utils package for Debian-based distros.

New in version 2014.7.0.

```python
username:
    webutil.user_exists:
        - password: secr3t
        - htpasswd_file: /etc/nginx/htpasswd
        - options: d
        - force: true
```

```python
salt.states.htpasswd.user_exists(name, password=None, htpasswd_file=None, options=``
force=False, runas=None)
```
Make sure the user is inside the specified htpasswd file

- name  User name
- password  User password
- htpasswd_file  Path to the htpasswd file
- options  See salt.modules.htpasswd.useradd
- force  Touch the file even if user already created
- runas  The system user to run htpasswd command with

### 32.29.67 salt.states.http

HTTP monitoring states

Perform an HTTP query and statefully return the result

New in version 2015.5.0.

```python
salt.states.http.query(name, match=None, match_type='string', status=None, **kwargs)
```
Perform an HTTP query and statefully return the result

- name  The name of the query.
- match  Specifies a pattern to look for in the return text. By default, this will perform a string comparison of looking for the value of match in the return text.
- match_type  Specifies the type of pattern matching to use. Default is string, but can also be set to pcre to use regular expression matching if a more complex pattern matching is required.
**Note:** Despite the name of `match_type` for this argument, this setting actually uses Python's `re.search()` function rather than Python's `re.match()` function.

**status** The status code for a URL for which to be checked. Can be used instead of or in addition to the `match` setting.

If both `match` and `status` options are set, both settings will be checked. However, note that if only one option is `True` and the other is `False`, then `False` will be returned. If this case is reached, the comments in the return data will contain troubleshooting information.

For more information about the `http.query` state, refer to the [HTTP Tutorial](#).

```yaml
query_example:
  http.query:
    - name: 'http://example.com/'
    - status: '200'
```

### 32.29.68 `salt.states.ifttt`

**Trigger an event in IFTTT**

This state is useful for triggering events in IFTTT.

New in version 2015.8.0.

```python
# ifttt-event
ifttt.trigger_event:
  - event: TestEvent
    - value1: 'This state was executed successfully.'
    - value2: 'Another value we can send.'
    - value3: 'A third value we can send.'
```

The api key can be specified in the master or minion configuration like below: .. code-block:: yaml

```yaml
ifttt: secret_key: bzMRb-KKIAaNOwKEEw792J7Eb-B3z7muhdlhYblJn4V6
```

**salt.states.ifttt.trigger_event**(*name*, *event*, *value1=None*, *value2=None*, *value3=None*)

Trigger an event in IFTTT

```python
# ifttt-event
ifttt.trigger_event:
  - event: TestEvent
    - value1: 'A value that we want to send.'
    - value2: 'A second value that we want to send.'
    - value3: 'A third value that we want to send.'
```

The following parameters are required:

**name** The unique name for this event.

**event** The name of the event to trigger in IFTTT.

The following parameters are optional:

**value1** One of the values that we can send to IFTTT.

**value2** One of the values that we can send to IFTTT.

**value3** One of the values that we can send to IFTTT.
32.29.69 salt.states.incron

Management of incron, the inotify cron

The incron state module allows for user incrontabs to be cleanly managed.

Incron declarations require a number of parameters. The parameters needed to be declared: `path`, `mask`, and `cmd`. The `user` whose incrontab is to be edited also needs to be defined.

When making changes to an existing incron job, the `path` declaration is the unique factor, so if an existing cron that looks like this:

```
Watch for modifications in /home/user:
  incron.present:
    - user: root
    - path: /home/user
    - mask: IN_MODIFY
    - cmd: 'echo "$$ $@"'
```

Is changed to this:

```
Watch for modifications and access in /home/user:
  incron.present:
    - user: root
    - path: /home/user
    - mask: IN_MODIFY
    - cmd: 'echo "$$ $@"'
```

Then the existing cron will be updated, but if the cron command is changed, then a new cron job will be added to the user's crontab.

New in version 0.17.0.

**salt.states.incron.absent** (`name`, `path`, `mask`, `cmd`, `user='root'`)

Verifies that the specified incron job is absent for the specified user; only the name is matched when removing a incron job.

- `name` Unique comment describing the entry
- `path` The path that should be watched
- `user` The name of the user who's crontab needs to be modified, defaults to the root user
- `mask` The mask of events that should be monitored for
- `cmd` The cmd that should be executed

**salt.states.incron.present** (`name`, `path`, `mask`, `cmd`, `user='root'`)

Verifies that the specified incron job is present for the specified user. For more advanced information about what exactly can be set in the cron timing parameters, check your incron system's documentation. Most Unix-like systems' incron documentation can be found via the incrontab man page: `man 5 incrontab`.

- `name` Unique comment describing the entry
- `path` The path that should be watched
- `user` The name of the user who's crontab needs to be modified, defaults to the root user
- `mask` The mask of events that should be monitored for
cmd  The cmd that should be executed

32.29.70  salt.states.influxdb_database

Management of InfluxDB databases

(compatible with InfluxDB version 0.5+)

New in version 2014.7.0.

salt.states.influxdb_database.absent(name, user=None, password=None, host=None, port=None)

Ensure that the named database is absent

name  The name of the database to remove
user  The user to connect as (must be able to remove the database)
password  The password of the user
host  The host to connect to
port  The port to connect to

salt.states.influxdb_database.present(name, user=None, password=None, host=None, port=None)

Ensure that the named database is present

name  The name of the database to create
user  The user to connect as (must be able to remove the database)
password  The password of the user
host  The host to connect to
port  The port to connect to

32.29.71  salt.states.influxdb_user

Management of InfluxDB users

(compatible with InfluxDB version 0.5+)

New in version 2014.7.0.

salt.states.influxdb_user.absent(name, database=None, user=None, password=None, host=None, port=None)

Ensure that the named cluster admin or database user is absent.

name  The name of the user to remove
database  The database to remove the user from
user  The user to connect as (must be able to remove the user)
password  The password of the user
host  The host to connect to
port  The port to connect to
salt.states.influxdb_user.present(name, passwd, database=None, user=None, password=None, host=None, port=None)

Ensure that the cluster admin or database user is present.

- **name** The name of the user to manage
- **passwd** The password of the user
- **database** The database to create the user in
- **user** The user to connect as (must be able to create the user)
- **password** The password of the user
- **host** The host to connect to
- **port** The port to connect to

### 32.29.72 salt.states.ini_manage

**Manage ini files**

- **maintainer** <akilesh1597@gmail.com>
- **maturity** new
- **depends** re
- **platform** all

use section as DEFAULT.IMPLICIT if your ini file does not have any section for example /etc/sysctl.conf

salt.states.ini_manage.options_absent(name, sections=None)

```ini
/home/saltminion/api-paste.ini:
ini.options_present:
- sections:
  test:
  - testkey
  - secondoption
  test1:
  - testkey1
```

options present in file and not specified in sections dict will be untouched
changes dict will contain the list of changes made

salt.states.ini_manage.options_present(name, sections=None)

```ini
/home/saltminion/api-paste.ini:
in.options_present:
- sections:
  test:
  testkey: 'testval'
  secondoption: 'secondvalue'
  test1:
  testkey1: 'testval121'
```
options present in file and not specified in sections dict will be untouched
changes dict will contain the list of changes made

salt.states.ini_manage.sections_absent(name, sections=None)

```
/home/saltminion/api-paste.ini:
ini.sections_absent:
    - sections:
        - test
        - test1
```

options present in file and not specified in sections will be deleted changes dict will contain the sections that changed

salt.states.ini_manage.sections_present(name, sections=None)

```
/home/saltminion/api-paste.ini:
ini.sections_present:
    - sections:
        test:
            testkey: testval
            secondoption: secondvalue
        test1:
            testkey1: 'testval121'
```

options present in file and not specified in sections will be deleted changes dict will contain the sections that changed

### 32.29.73 salt.states.ipmi

Manage IPMI devices over LAN

The following configuration defaults can be defined in the minion, master config or pillar:

```
ipmi.config:
    api_host: 127.0.0.1
    api_user: admin
    api_pass: apassword
    api_port: 623
    api_kg: None
```

Every call can override the config defaults:

```
ensure myipmi system is set to network boot:
ipmi.boot_device:
    - name: network
    - api_host: myipmi.hostname.com
    - api_user: root
    - api_pass: apassword
    - api_kg: None

ensure myipmi system is powered on:
ipmi.power:
    - name: boot
    - api_host: myipmi.hostname.com
```
salt.states.ipmi.boot_device(name='default', **kwargs)
Request power state change

name = default

- network -- Request network boot
- hd -- Boot from hard drive
- safe -- Boot from hard drive, requesting `safe mode'
- optical -- Boot from CD/DVD/BD drive
- setup -- Boot into setup utility
- default -- remove any IPMI directed boot device request

kwargs

- api_host=localhost
- api_user=admin
- api_pass=
- api_port=623
- api_kg=None

salt.states.ipmi.power(name='power_on', wait=300, **kwargs)
Request power state change

name

Ensure power state one of:

- power_on -- system turn on
- power_off -- system turn off (without waiting for OS)
- shutdown -- request OS proper shutdown
- reset -- reset (without waiting for OS)
- boot -- If system is off, then `on', else `reset'

wait wait X seconds for the job to complete before forcing. (defaults to 300 seconds)

kwargs

- api_host=localhost
- api_user=admin
- api_pass=
- api_port=623
- api_kg=None

salt.states.ipmi.user_absent(name, channel=14, **kwargs)
Remove user Delete all user (uid) records having the matching name.

name string name of user to delete

channel channel to remove user access from defaults to 14 for auto.
Salt Documentation, Release 2015.8.12

kwargs

- api_host=localhost
- api_user=admin
- api_pass=
- api_port=623
- api_kg=None

salt.states.ipmi.user_present(name, uid, password, channel=14, callback=False, link_auth=True, ipmi_msg=True, privilege_level='administrator', **kwargs)

Ensure IPMI user and user privileges.

name  name of user (limit 16 bytes)

uid  user id number (1 to 7)

password  user password (limit 16 bytes)

channel  ipmi channel defaults to 14 for auto

callback  User Restricted to Callback

False = User Privilege Limit is determined by the User Privilege Limit parameter privilege_level, for both callback and non-callback connections.

True = User Privilege Limit is determined by the privilege_level parameter for callback connections, but is restricted to Callback level for non-callback connections. Thus, a user can only initiate a Callback when they `call in' to the BMC, but once the callback connection has been made, the user could potentially establish a session as an Operator.

link_auth  User Link authentication True/False user name and password information will be used for link authentication, e.g. PPP CHAP) for the given channel. Link authentication itself is a global setting for the channel and is enabled/disabled via the serial/modem configuration parameters.

ipmi_msg  User IPMI Messaging True/False user name and password information will be used for IPMI Messaging. In this case, 'IPMI Messaging' refers to the ability to execute generic IPMI commands that are not associated with a particular payload type. For example, if IPMI Messaging is disabled for a user, but that user is enabled for activating the SOL payload type, then IPMI commands associated with SOL and session management, such as Get SOL Configuration Parameters and Close Session are available, but generic IPMI commands such as Get SEL Time are unavailable.) ipmi_msg

privilege_level

- callback
- user
- operator
- administrator
- proprietary
- no_access

kwargs

- api_host=localhost
- api_user=admin
- api_pass=
- api_port=623

32.29. Full list of builtin state modules
32.29.74 salt.states.ipset

Management of ipsets

This is an ipset-specific module designed to manage IPSets for use in IPTables Firewalls.

```python
setname:
ipset.set_present:
- set_type: bitmap:ip
- range: 192.168.0.0/16
- comment: True

setname:
ipset.set_absent:
- set_type: bitmap:ip
- range: 192.168.0.0/16
- comment: True

setname_entries:
ipset.present:
- set_name: setname
- entry: 192.168.0.3
- comment: Hello
- require:
  - ipset: baz

setname_entries:
ipset.present:
- set_name: setname
- entry:
  - 192.168.0.3
  - 192.168.1.3
- comment: Hello
- require:
  - ipset: baz

setname_entries:
ipset.absent:
- set_name: setname
- entry:
  - 192.168.0.3
  - 192.168.1.3
- comment: Hello
- require:
  - ipset: baz

setname:
ipset.flush:
```

salt.states.ipset.absent(name, entry=None, entries=None, family='ipv4', **kwargs)

New in version 2014.7.0.

Remove a entry or entries from a chain

**name** A user-defined name to call this entry by in another part of a state or formula. This should not be an actual entry.
family  Network family, ipv4 or ipv6.

```
salt.states.ipset.flush(name, family='ipv4', **kwargs)
```
New in version 2014.7.0.
Flush current ipset set

```
salt.states.ipset.present(name, entry=None, family='ipv4', **kwargs)
```
New in version 2014.7.0.
Append a entry to a set

```
salt.states.ipset.set_absent(name, family='ipv4', **kwargs)
```
New in version 2014.7.0.
Verify the set is absent.

```
salt.states.ipset.set_present(name, set_type, family='ipv4', **kwargs)
```
New in version 2014.7.0.
Verify the chain is exist.

32.29.75 salt.states.iptables

Management of iptables

This is an iptables-specific module designed to manage Linux firewalls. It is expected that this state module, and other system-specific firewall states, may at some point be deprecated in favor of a more generic `firewall` state.

```
httpd:
    iptables.append:
        - table: filter
        - chain: INPUT
        - jump: ACCEPT
        - match: state
        - connstate: NEW
        - dport: 80
        - proto: tcp
        - sport: 1025:65535
        - save: True

httpd:
    iptables.append:
        - table: filter
        - chain: INPUT
```

- dport: 80
- proto: tcp
- sport: 1025:65535
- save: True

httpd:
iptables.delete:
- table: filter
- family: ipv6
- chain: INPUT
- jump: ACCEPT
- match: state
- connstate: NEW
- dport: 80
- proto: tcp
- sport: 1025:65535
- save: True

default to accept:
iptables.set_policy:
- chain: INPUT
- policy: ACCEPT

Note: Various functions of the iptables module use the --check option. If the version of iptables on the target system does not include this option, an alternate version of this check will be performed using the output of iptables-save. This may have unintended consequences on legacy releases of iptables.

salt.states.iptables.append(name, table='filter', family='ipv4', **kwargs)
New in version 0.17.0.
Add a rule to the end of the specified chain.

name A user-defined name to call this rule by in another part of a state or formula. This should not be an actual rule.
table The table that owns the chain which should be modified
family Network family, ipv4 or ipv6.
All other arguments are passed in with the same name as the long option that would normally be used for
iptables, with one exception: --state is specified as connstate instead of state (not to be confused with
cstate).

Jump options that doesn’t take arguments should be passed in with an empty string.

salt.states.iptables.chain_absent(name, table='filter', family='ipv4')
New in version 2014.1.0.
Verify the chain is absent.

  table  The table to remove the chain from

  family  Networking family, either ipv4 or ipv6

salt.states.iptables.chain_present(name, table='filter', family='ipv4')
New in version 2014.1.0.
Verify the chain is exist.

  name  A user-defined chain name.

  table  The table to own the chain.

  family  Networking family, either ipv4 or ipv6

salt.states.iptables.delete(name, table='filter', family='ipv4', **kwargs)
New in version 2014.1.0.
Delete a rule to a chain

  name  A user-defined name to call this rule by in another part of a state or formula. This should not be an
        actual rule.

  table  The table that owns the chain that should be modified

  family  Networking family, either ipv4 or ipv6

All other arguments are passed in with the same name as the long option that would normally be used for
iptables, with one exception: --state is specified as connstate instead of state (not to be confused with
cstate).

Jump options that doesn't take arguments should be passed in with an empty string.

salt.states.iptables.flush(name, table='filter', family='ipv4', **kwargs)
New in version 2014.1.0.
Flush current iptables state

  table  The table that owns the chain that should be modified

  family  Networking family, either ipv4 or ipv6

salt.states.iptables.insert(name, table='filter', family='ipv4', **kwargs)
New in version 2014.1.0.
Insert a rule into a chain

  name  A user-defined name to call this rule by in another part of a state or formula. This should not be an
        actual rule.

  table  The table that owns the chain that should be modified

  family  Networking family, either ipv4 or ipv6

  position  The numerical representation of where the rule should be inserted into the chain. Note that -1 is
            not a supported position value.

32.29. Full list of builtin state modules
All other arguments are passed in with the same name as the long option that would normally be used for `iptables`, with one exception: `--state` is specified as `connstate` instead of `state` (not to be confused with `ctstate`).

Jump options that don’t take arguments should be passed in with an empty string.

`salt.states.iptables.mod_aggregate( low, chunks, running )`

The `mod_aggregate` function which looks up all rules in the available low chunks and merges them into a single rules ref in the present low data

`salt.states.iptables.set_policy( name, table='filter', family='ipv4', **kwargs )`

New in version 2014.1.0.

Sets the default policy for iptables firewall tables

- `table` The table that owns the chain that should be modified
- `family` Networking family, either ipv4 or ipv6
- `policy` The requested table policy

### 32.29.76 salt.states.jboss7

Manage JBoss 7 Application Server via CLI interface

New in version 2015.5.0.

This state uses `jboss-cli.sh` script from JBoss installation and parses its output to determine execution result.

In order to run each state, `jboss_config` dictionary with the following properties must be passed:

```yaml
jboss:
  cli_path: '/opt/jboss/jboss-7.0/bin/jboss-cli.sh'
  controller: 10.11.12.13:9999
  cli_user: 'jbossadm'
  cli_password: 'jbossadm'
```

If controller doesn’t require password, then passing `cli_user` and `cli_password` parameters is not obligatory.

Example of application deployment:

```yaml
application_deployed:
  jboss7.deployed:
    - artifact:
      artifact_url: http://artifactory.intranet.example.com/artifactory
      repository: 'ext-release-local'
      artifact_id: 'webcomponent'
      group_id: 'com.company.application'
      packaging: 'war'
      version: '0.1'
      target_dir: '/tmp'
    - jboss_config:
      cli_path: '/opt/jboss/jboss-7.0/bin/jboss-cli.sh'
      controller: 10.11.12.13:9999
      cli_user: 'jbossadm'
      cli_password: 'jbossadm'
```

Since same dictionary with configuration will be used in all the states, it is much more convenient to move `jboss` configuration and other properties to pillar. For example, configuration of `jboss` server, artifactory address and application version could be moved to pillars:
**application_deployed:**

```yaml
jboss7.deployed:
- artifact:
  - artifactfactory_url: {{ pillar['artifactfactory']['url'] }}
  repository: {{ pillar['artifactfactory']['repository'] }}
  artifact_id: 'webcomponent'
  group_id: 'com.company.application'
  packaging: 'war'
  version: {{ pillar['webcomponent-artifact']['version'] }}
  latest_snapshot: {{ pillar['webcomponent-artifact']['latest_snapshot'] }}
  repository: {{ pillar['webcomponent-artifact']['repository'] }}
- jboss_config: {{ pillar['jboss'] }}
```

**Configuration in pillars:**

```yaml
artifactfactory:
  url: 'http://artifactfactory.intranet.example.com/artifactory'
  repository: 'libs-snapshots-local'

webcomponent-artifact:
  repository: 'libs-snapshots-local'
  latest_snapshot: True
  version: -1  #If latest_snapshot then version is ignored
```

For the sake of brevity, examples for each state assume that `jboss_config` is moved to pillars.

**salt.states.jboss7.bindings_exist**(name, jboss_config, bindings)

Ensures that given JNDI binding are present on the server. If a binding doesn’t exist on the server it will be created. If it already exists its value will be changed.

- **jboss_config**: Dict with connection properties (see state description)
- **bindings**: Dict with bindings to set.

Example:

```yaml
jndi_entries_created:
jboss7.bindings_exist:
- bindings:
  - 'java:global/sampleapp/environment': 'DEV'
  - 'java:global/sampleapp/configurationFile': '/var/opt/sampleapp/config.properties'
  - jboss_config: {{ pillar['jboss'] }}
```

**salt.states.jboss7.datasource_exists**(name, jboss_config, datasource_properties, recreate=False)

Ensures that a datasource with given properties exist on the jboss instance. If datasource doesn’t exist, it is created, otherwise only the properties that are different will be updated.

- **name**  Data source property name
- **jboss_config**: Dict with connection properties (see state description)
- **datasource_properties**: Dict with datasource properties
- **recreate** [False] If set to True and datasource exists it will be removed and created again. However, if there are deployments that depend on the datasource, it will not be possible to remove it.

Example:
sampleDS:

jboss7.datasource_exists:
- recreate: False
- datasource_properties:
  driver-name: mysql
  connection-url: 'jdbc:mysql://localhost:3306/sampleDatabase'
  jndi-name: 'java:jboss/datasources/sampleDS'
  user-name: sampleuser
  password: secret
  min-pool-size: 3
  use-java-context: True
- jboss_config: {{ pillar['jboss'] }}

salt.states.jboss7.deployed(name, jboss_config, artifact=None, salt_source=None)
Ensures that the given application is deployed on server.

jboss_config: Dict with connection properties (see state description)

artifact:
If set, the artifact will be fetched from artifactory. This is a Dict object with the following properties:

- artifactory_url: Full url to artifactory instance, for example: http://artifactory.intranet.example.com/artifactory
- repository: One of the repositories, for example: libs-snapshots, ext-release-local, etc..
- artifact_id: Artifact ID of the artifact
- group_id: Group ID of the artifact
- packaging: war/jar/ear, etc...
- version: Artifact version. If latest_snapshot is set to True, the value of this attribute will be ignored, and newest snapshot will be taken instead.
- latest_snapshot: If set to True and repository is a snapshot repository it will automatically select the newest snapshot.
- snapshot_version: Exact version of the snapshot (with timestamp). A snapshot version may have several builds and a way to differentiate is to provide a build timestamp.
- target_dir: Temporary directory on minion where artifacts will be downloaded

salt_source:
If set, the artifact to be deployed will be fetched from salt master. This is a Dict object with the following properties:

- source: File on salt master (eg. salt://application-web-0.39.war)
- target_file: Temporary file on minion to save file to (eg. `/tmp/application-web-0.39.war`)
- undeploy: Regular expression to match against existing deployments. If any deployment matches the regular expression then it will be undeployed.

The deployment consists of the following steps:

- Fetch artifact (salt filesystem, artifact or filesystem on minion)
- Check if same artifact is not deployed yet (perhaps with different version)
- Undeploy the artifact if it is already deployed
• Deploy the new artifact

Examples:

Deployment of a file from Salt file system:

```python
application_deployed:
    jboss7.deployed:
        - salt_source:
            source: salt://application-web-0.39.war
            target_file: '/tmp/application-web-0.39.war'
            undeploy: 'application-web-.*'
        - jboss_config: {{ pillar['jboss'] }}
```

Here, application-web-0.39.war file is downloaded from Salt file system to /tmp/application-web-0.39.war file on minion. Existing deployments are checked if any of them matches `application-web-.*` regular expression, and if so then it is undeployed before deploying the application. This is useful to automate deployment of new application versions.

JBoss state is capable of deploying artifacts directly from Artifactory repository. Here are some examples of deployments:

1. Deployment of released version of artifact from Artifactory.

```python
application_deployed:
    jboss7.deployed:
        - artifact:
            artifact_url: http://artifactory.intranet.example.com/artifactory
            repository: 'ext-release-local'
            artifact_id: 'webcomponent'
            group_id: 'com.company.application'
            packaging: 'war'
            version: '0.1'
            target_dir: '/tmp'
        - jboss_config: {{ pillar['jboss'] }}
```

This performs the following operations:

• Download artifact from artifactory. In the example above the artifact will be fetched from: http://artifactory.intranet.example.com/artifactory/ext-release-local/com/company/application/webcomponent/0.1/webcomponent-0.1.war As a rule, for released versions the artifacts are downloaded from: artifactory_url/repository/group_id_with_slashed_instead_of_dots/artifact_id/version/artifact_id-package. This follows artifactory convention for artifact resolution. By default the artifact will be downloaded to /tmp directory on minion.

• Connect to JBoss via controller (defined in jboss_config dict) and check if the artifact is not deployed already. In case of artifactory it will check if any deployment's name starts with artifact_id value. If deployment already exists it will be undeployed

• Deploy the downloaded artifact to JBoss via cli interface.

2. Deployment of last updated version of given SNAPSHOT version of artifact from Artifactory.

```python
application_deployed:
    jboss7.deployed:
        - artifact:
            artifact_url: http://artifactory.intranet.example.com/artifactory
            repository: 'ext-snapshot-local'
```

32.29. Full list of builtin state modules

2015
Deploying snapshot version involves an additional step of resolving the exact version of the artifact (including the timestamp), which is not necessary when deploying a release. In the example above first a request will be made to retrieve the update timestamp from: http://artifactory.intranet.example.com/artifactory/ext-snapshot-local/com/company/application/webcomponent/0.1-SNAPSHOT/maven-metadata.xml Then the artifact will be fetched from http://artifactory.intranet.example.com/artifactory/ext-snapshot-local/com/company/application/webcomponent/0.1-SNAPSHOT/webcomponent-RESOLVED_SNAPSHOT_VERSION.war

Note: In order to perform a snapshot deployment you have to:

- Set repository to a snapshot repository.
- Choose a version that ends with ``SNAPSHOT'' string. Snapshot repositories have a different layout and provide some extra information that is needed for deployment of the last or a specific snapshot.

3. Deployment of SNAPSHOT version (with exact timestamp) of artifact from Artifactory.

If you need to deploy an exact version of the snapshot you may provide snapshot_version parameter.

```
application_deployed:
  jboss7.deployed:
    - artifact:
        artifactory_url: http://artifactory.intranet.example.com/artifactory
        repository: 'ext-snapshot-local'
        artifact_id: 'webcomponent'
        group_id: 'com.company.application'
        packaging: 'war'
        version: '0.1-SNAPSHOT'
        snapshot_version: '0.1-20141023.131756-19'
        jboss_config: {{ pillar['jboss'] }}
```

In this example the artifact will be retrieved from: http://artifactory.intranet.example.com/artifactory/ext-snapshot-local/com/company/application/webcomponent/0.1-SNAPSHOT/webcomponent-0.1-20141023.131756-19.war

4. Deployment of latest snapshot of artifact from Artifactory.

```
application_deployed:
  jboss7.deployed:
    - artifact:
        artifactory_url: http://artifactory.intranet.example.com/artifactory
        repository: 'ext-snapshot-local'
        artifact_id: 'webcomponent'
        group_id: 'com.company.application'
        packaging: 'war'
        latest_snapshot: True
        jboss_config: {{ pillar['jboss'] }}
```

Instead of providing an exact version of a snapshot it is sometimes more convenient to get the newest version. If artifact.latest_snapshot is set to True, then the newest snapshot will be downloaded from Artifactory. In
this case it is not necessary to specify version. This is particulary useful when integrating with CI tools that will deploy the current snapshot to the Artifactory.

**salt.states.jboss7.reloaded**

```
salt.states.jboss7.reloaded(name, jboss_config, timeout=60, interval=5)
```

Reloads configuration of jboss server.

- **jboss_config**: Dict with connection properties (see state description)
- **timeout**: Time to wait until jboss is back in running state. Default timeout is 60s.
- **interval**: Interval between state checks. Default interval is 5s. Decreasing the interval may slightly decrease waiting time but be aware that every status check is a call to jboss-cli which is a java process. If interval is smaller than process cleanup time it may easily lead to excessive resource consumption.

This step performs the following operations:

- Ensures that server is in running or reload-required state (by reading server-state attribute)
- Reloading configuration
- Waiting for server to reload and be in running state

Example:

```
configuration_reloaded:
    jboss7.reloaded:
        - jboss_config: {{ pillar['jboss'] }}
```

### 32.29.77 salt.states.keyboard

**Management of keyboard layouts**

The keyboard layout can be managed for the system:

```
us:
    keyboard.system
```

Or it can be managed for XOrg:

```
us:
    keyboard.xorg
```

```
salt.states.keyboard.system(name)
    Set the keyboard layout for the system
    name: The keyboard layout to use
```

```
salt.states.keyboard.xorg(name)
    Set the keyboard layout for XOrg
    layout: The keyboard layout to use
```

### 32.29.78 salt.states.keystone

**Management of Keystone users**

```
depends
    - keystoneclient Python module
```
configuration See salt.modules.keystone for setup instructions.

Keystone tenants:
keystone.tenant_present:
  - names:
    - admin
    - demo
    - service

Keystone roles:
keystone.role_present:
  - names:
    - admin
    - Member

admin:
keystone.user_present:
  - password: R00T_4CC3SS
  - email: admin@domain.com
  - roles:
    - admin: # tenants
    - admin # roles
    - service:
    - admin
    - Member
  - require:
    - keystone: Keystone tenants
    - keystone: Keystone roles

nova:
keystone.user_present:
  - password: 'Sup3rn0v4'
  - email: nova@domain.com
  - tenant: service
  - roles:
    - service:
    - admin
    - require:
      - keystone: Keystone tenants
      - keystone: Keystone roles

demo:
keystone.user_present:
  - password: 'd3m0n$trati0n'
  - email: demo@domain.com
  - tenant: demo
  - roles:
    - demo:
    - Member
    - require:
      - keystone: Keystone tenants
      - keystone: Keystone roles

nova service:
keystone.service_present:
  - name: nova
  - service_type: compute
  - description: OpenStack Compute Service
salt.states.keystone.endpoint_absent(name, profile=None, **connection_args)
Ensure that the endpoint for a service doesn't exist in Keystone catalog

name The name of the service whose endpoints should not exist

salt.states.keystone.endpoint_present(name, publicurl=None, internalurl=None, adminurl=None, region='RegionOne', profile=None, **connection_args)
Ensure the specified endpoints exists for service

name The Service name
public url The public url of service endpoint
internal url The internal url of service endpoint
admin url The admin url of the service endpoint
region The region of the endpoint

salt.states.keystone.role_absent(name, profile=None, **connection_args)
Ensure that the keystone role is absent.

name The name of the role that should not exist

salt.states.keystone.role_present(name, profile=None, **connection_args)
Ensures that the keystone role exists

name The name of the role that should be present

salt.states.keystone.service_absent(name, profile=None, **connection_args)
Ensure that the service doesn't exist in Keystone catalog

name The name of the service that should not exist

salt.states.keystone.service_present(name, service_type, description=None, profile=None, **connection_args)
Ensure service present in Keystone catalog

name The name of the service
service_type The type of Openstack Service
description (optional) Description of the service

salt.states.keystone.tenant_absent(name, profile=None, **connection_args)
Ensure that the keystone tenant is absent.

name The name of the tenant that should not exist

salt.states.keystone.tenant_present(name, description=None, enabled=True, profile=None, **connection_args)
Ensures that the keystone tenant exists

name The name of the tenant to manage
description The description to use for this tenant
enabled Availability state for this tenant

salt.states.keystone.user_absent(name, profile=None, **connection_args)
Ensure that the keystone user is absent.

name The name of the user that should not exist
salt.states.keystone.user_present(name, password, email, tenant=None, enabled=True, roles=None, profile=None, **connection_args)

Ensure that the keystone user is present with the specified properties.

- **name**: The name of the user to manage
- **password**: The password to use for this user
- **email**: The email address for this user
- **tenant**: The tenant for this user
- **enabled**: Availability state for this user
- **roles**: The roles the user should have under given tenants. Passed as a dictionary mapping tenant names to a list of roles in this tenant, i.e.:

```
roles:
    admin:    # tenant
        - admin  # role
    service:
        - admin
        - Member
```

### 32.29.79 salt.states.kmod

**Loading and unloading of kernel modules**

The Kernel modules on a system can be managed cleanly with the kmod state module:

```
kvm_amd:
    kmod.present
pcspkr:
    kmod.absent
```

salt.states.kmod.absent(name, persist=False, comment=True)

Verify that the named kernel module is not loaded

- **name**: The name of the kernel module to verify is not loaded
- **persist**: Delete module from /etc/modules
- **comment**: Don't remove module from /etc/modules, only comment it

salt.states.kmod.present(name, persist=False)

Ensure that the specified kernel module is loaded

- **name**: The name of the kernel module to verify is loaded
- **persist**: Also add module to /etc/modules

### 32.29.80 salt.states.layman

**Management of Gentoo Overlays using layman**

A state module to manage Gentoo package overlays via layman

```
sunrise:
    layman.present
```
salt.states.layman.absent(name)
Verify that the overlay is absent
  name The name of the overlay to delete
salt.states.layman.present(name)
Verify that the overlay is present
  name The name of the overlay to add

32.29.81 salt.states.libvirt

Manage libvirt certificates
This state uses the external pillar in the master to call for the generation and signing of certificates for systems running libvirt:

```yaml
libvirt_keys:
  libvirt.keys

salt.states.libvirt.keys(name, basepath='/etc/pki')
Manage libvirt keys.
  name The name variable used to track the execution
    basepath Defaults to /etc/pki, this is the root location used for libvirt keys on the hypervisor

32.29.82 salt.states.linux_acl

Linux File Access Control Lists
Ensure a Linux ACL is present

```yaml
root:
  acl.present:
    - name: /root
    - acl_type: user
    - acl_name: damian
    - perms: rwx

Ensure a Linux ACL does not exist

```yaml
root:
  acl.absent:
    - name: /root
    - acl_type: user
    - acl_name: damian
    - perms: rwx

salt.states.linux_acl.absent(name, acl_type, acl_name='', perms='', recurse=False)
Ensure a Linux ACL does not exist
salt.states.linux_acl.present(name, acl_type, acl_name='', perms='', recurse=False)
Ensure a Linux ACL is present

32.29. Full list of builtin state modules 2021
32.29.83 salt.states.locale

Management of languages/locales

Manage the available locales and the system default:

```yaml
us_locale:
    locale.present:
        - name: en_US.UTF-8

default_locale:
    locale.system:
        - name: en_US.UTF-8
        - require:
            - locale: us_locale
```

**salt.states.locale.

- present**(name)**
  Generate a locale if it is not present

  New in version 2014.7.0.

  **name** The name of the locale to be present. Some distributions require the charmap to be specified as part of the locale at this point.

- system**(name)**
  Set the locale for the system

  **name** The name of the locale to use

32.29.84 salt.states.lvm

Management of Linux logical volumes

A state module to manage LVMs

```yaml
/dev/sda:
    lvm.pv_present

my_vg:
    lvm.vg_present:
        - devices: /dev/sda

lvroot:
    lvm.lv_present:
        - vgname: my_vg
        - size: 10G
        - stripes: 5
        - stripe-size: 8K
```

**salt.states.lvm.

- lv_absent**(name, vgname=\-None)**
  Remove a given existing logical volume from a named existing volume group

  **name** The logical volume to remove

  **vgname** The volume group name

- lv_present**(name, vgname=None, size=None, extents=None, snapshot=None, pv=``, **kwargs)**
  Create a new logical volume
name  The name of the logical volume
vgname  The volume group name for this logical volume
size  The initial size of the logical volume
extents  The number of logical extents to allocate
snapshot  The name of the snapshot
pv  The physical volume to use
kwargs  Any supported options to lvcreate. See `linux_lvm` for more details.

salt.states.lvm.pv_absent(name)
Ensure that a Physical Device is not being used by lvm

name  The device name to initialize.

salt.states.lvm.pv_present(name, **kwargs)
Set a physical device to be used as an LVM physical volume

name  The device name to initialize.
kwargs  Any supported options to pvcreate. See `linux_lvm` for more details.

salt.states.lvm.vg_absent(name)
Remove an LVM volume group

name  The volume group to remove

salt.states.lvm.vg_present(name, devices=None, **kwargs)
Create an LVM volume group

name  The volume group name to create
devices  A list of devices that will be added to the volume group
kwargs  Any supported options to vgcreate. See `linux_lvm` for more details.

32.29.85  salt.states.lvs_server

Management of LVS (Linux Virtual Server) Real Server

salt.states.lvs_server.absent(name, protocol=None, service_address=None, server_address=None)
Ensure the LVS Real Server in specified service is absent.

name  The name of the LVS server.
protocol  The service protocol (only support tcp, udp and fwmark service).
service_address  The LVS service address.
server_address  The LVS real server address.

salt.states.lvs_server.present(name, protocol=None, service_address=None, server_address=None, packet_forward_method='dr', weight=1)
Ensure that the named service is present.

name  The LVS server name
protocol  The service protocol
service_address  The LVS service address
server_address  The real server address.

packet_forward_method  The LVS packet forwarding method (dr for direct routing, tunnel for tunneling, nat for network access translation).

weight  The capacity of a server relative to the others in the pool.

### 32.29.86 salt.states.lvs_service

Management of LVS (Linux Virtual Server) Service

salt.states.lvs_service.absent(name, protocol=None, service_address=None)
Ensure the LVS service is absent.

- name  The name of the LVS service
- protocol  The service protocol
- service_address  The LVS service address

salt.states.lvs_service.present(name, protocol=None, service_address=None, scheduler='wlc')
Ensure that the named service is present.

- name  The LVS service name
- protocol  The service protocol
- service_address  The LVS service address
- scheduler  Algorithm for allocating TCP connections and UDP datagrams to real servers.

### 32.29.87 salt.states.lxc

Manage Linux Containers

salt.states.lxc.absent(name, stop=False, path=None)
Ensure a container is not present, destroying it if present

- name  Name of the container to destroy
- stop  stop before destroying default: false
  New in version 2015.5.2.
path path to the container parent default: /var/lib/lxc (system default)

New in version 2015.8.0.

```yaml
web01:
  lxc.absent
```

salt.states.lxc.cloned(name, orig, snapshot=True, size=None, vgname=None, path=None, profile=None)

Deprecated since version 2015.5.0: Use lxc.present

salt.states.lxc.created(name, **kwargs)

Deprecated since version 2015.5.0: Use lxc.present

salt.states.lxc.edited_conf(name, lxc_conf=None, lxc_conf_unset=None)

**Warning:** This state is unsuitable for setting parameters that appear more than once in an LXC config file, or parameters which must appear in a certain order (such as when configuring more than one network interface). It is slated to be replaced, and as of version 2015.5.0 it is deprecated.

Edit LXC configuration options

**path** path to the container parent default: /var/lib/lxc (system default)

New in version 2015.8.0.

```yaml
setconf:
  lxc.edited_conf:
    - name: ubuntu
      lxc_conf:
        - network.ipv4.ip: 10.0.3.6
      lxc_conf_unset:
        - lxc.utsname
```

salt.states.lxc.frozen(name, start=True, path=None)

New in version 2015.5.0.

Ensure that a container is frozen

**Note:** This state does not enforce the existence of the named container, it just freezes the container if it is running. To ensure that the named container exists, use lxc.present.

name The name of the container

path path to the container parent default: /var/lib/lxc (system default)

New in version 2015.8.0.

start [True] Start container first, if necessary. If False, then this state will fail if the container is not running.

```yaml
web01:
  lxc.frozen

web02:
  lxc.frozen:
    - start: False
```
salt.states.lxc.present(name, running=None, clone_from=None, snapshot=False, profile=None, network_profile=None, template=None, options=None, image=None, config=None, fstype=None, size=None, backing=None, vname=None, lvname=None, path=None)

Changed in version 2015.8.0: The `lxc.created` state has been renamed to `lxc.present`, and the `lxc.cloned` state has been merged into this state.

Create the named container if it does not exist

**name**  The name of the container to be created

**path**  path to the container parent default: /var/lib/lxc (system default)

New in version 2015.8.0.

**running**  [False]

- If True, ensure that the container is running
- If False, ensure that the container is stopped
- If None, do nothing with regards to the running state of the container

New in version 2015.8.0.

**clone_from**  Create named container as a clone of the specified container

**snapshot**  [False] Use Copy On Write snapshots (LVM). Only supported with `clone_from`.

**profile**  Profile to use in container creation (see the `LXC Tutorial` for more information). Values in a profile will be overridden by the parameters listed below.

**network_profile**  Network Profile to use in container creation (see the `LXC Tutorial` for more information). Values in a profile will be overridden by the parameters listed below.

New in version 2015.5.2.

**template**  The template to use. E.g., `ubuntu` or `fedora`. Conflicts with the `image` argument.

**options**  New in version 2015.5.0.

Template-specific options to pass to the lxc-create command. These correspond to the long options (ones beginning with two dashes) that the template script accepts. For example:

```
web01:
lxc.present:
  - template: download
  - options:
    dist: centos
    release: 6
    arch: amd64
```
Remember to double-indent the options, due to *how PyYAML works.*

**image**  A tar archive to use as the rootfs for the container. Conflicts with the `template` argument.

**backing**  The type of storage to use. Set to `lvm` to use an LVM group. Defaults to filesystem within `/var/lib/lxc`.

**fstype**  Filesystem type to use on LVM logical volume

**size**  Size of the volume to create. Only applicable if `backing` is set to `lvm`.

**vgname**  `[lxc] Name of the LVM volume group in which to create the volume for this container. Only applicable if `backing` is set to `lvm`.

**lvname**  Name of the LVM logical volume in which to create the volume for this container. Only applicable if `backing` is set to `lvm`.

**salt.states.lxc.running** *(name, restart=False, path=None)*

Changed in version 2015.5.0: The `lxc.started` state has been renamed to `lxc.running`

Ensure that a container is running

**Note:** This state does not enforce the existence of the named container, it just starts the container if it is not running. To ensure that the named container exists, use `lxc.present`.

**name**  The name of the container

**path**  path to the container parent default: `/var/lib/lxc` (system default)

- New in version 2015.8.0.

**restart**  [False] Restart container if it is already running

```
web01:
  lxc.running

web02:
  lxc.running:
    - restart: True
```

**salt.states.lxc.set_pass** *(name, **kwargs)*

Deprecated since version 2015.5.0.

This state function has been disabled, as it did not conform to design guidelines. Specifically, due to the fact that `lxc.set_password` uses `chpasswd(8)` to set the password, there was no method to make this action idempotent (in other words, the password would be changed every time). This makes this state redundant, since the following state will do the same thing:

```
setpass:
  module.run:
    - name: set_pass
    - m_name: root
    - password: secret
```

**salt.states.lxc.started** *(name, path=None, restart=False)*

Deprecated since version 2015.5.0: Use `lxc.running`
salt.states.lxc.stopped(name, kill=False, path=None)
Ensure that a container is stopped

Note: This state does not enforce the existence of the named container, it just stops the container if it running or frozen. To ensure that the named container exists, use lxc.present, or use the lxc.absent state to ensure that the container does not exist.

name The name of the container
path path to the container parent default: /var/lib/lxc (system default)
   New in version 2015.8.0.
kill [False] Do not wait for the container to stop, kill all tasks in the container. Older LXC versions will stop containers like this irrespective of this argument.
   New in version 2015.5.0.

web01:
 lxc.stopped

32.29.88 salt.states.makeconf

Management of Gentoo make.conf

A state module to manage Gentoo's make.conf file

makeopts:
  makeconf.present:
    - value: '-j3'

salt.states.makeconf.absent(name)
Verify that the variable is not in the make.conf.

name The variable name. This will automatically be converted to upper case since variables in make.conf are in upper case

class: salt.states.makeconf.absent(name='myvar')

salt.states.makeconf.present(name, value=None, contains=None, excludes=None)
Verify that the variable is in the make.conf and has the provided settings. If value is set, contains and excludes will be ignored.

name The variable name. This will automatically be converted to upper case since variables in make.conf are in upper case
value Enforce that the value of the variable is set to the provided value
contains Enforce that the value of the variable contains the provided value
excludes Enforce that the value of the variable does not contain the provided value.

32.29.89 salt.states.mdadm

Managing software RAID with mdadm

A state module for creating or destroying software RAID devices.
salt.states.mdadm.absent\(name\)
Verify that the raid is absent

\texttt{name} The name of raid device to be destroyed

Example:

```
salt.states.mdadm.absent(name)
```

salt.states.mdadm.present\(name, level, devices, **kwargs\)
Verify that the raid is present

Changed in version 2014.7.0.

\texttt{name} The name of raid device to be created

\texttt{level} The RAID level to use when creating the raid.

\texttt{devices} A list of devices used to build the array.

\texttt{kwargs} Optional arguments to be passed to mdadm.

Example:

```
salt.states.mdadm.present(name, level, devices, **kwargs)
```

### 32.29.90 salt.states.memcached

**States for Management of Memcached Keys**

New in version 2014.1.0.

salt.states.memcached.absent\(name, value=\text{None}, host=’127.0.0.1’, port=11211, time=0\)
Ensure that a memcached key is not present.

\texttt{name} The key

\texttt{value} [\text{None}] If specified, only ensure that the key is absent if it matches the specified value.

\texttt{host} The memcached server IP address

\texttt{port} The memcached server port
foo:
  memcached.absent

bar:
  memcached.absent:
    - host: 10.0.0.1

salt.states.memcached.managed(name, value=None, host='127.0.0.1', port=11211, time=0, min_compress_len=0)

Manage a memcached key.

name  The key to manage
value  The value to set for that key
host  The memcached server IP address
port  The memcached server port

foo:
  memcached.managed:
    - value: bar

32.29.91 salt.states.modjk

State to control Apache modjk

salt.states.modjk.worker_activated(name, workers=None, profile='default')

Activate all the workers in the modjk load balancer

Example:

loadbalancer:
  modjk.worker_activated:
    - workers:
      - app1
      - app2

salt.states.modjk.worker_disabled(name, workers=None, profile='default')

Disable all the workers in the modjk load balancer

Example:

loadbalancer:
  modjk.worker_disabled:
    - workers:
      - app1
      - app2

salt.states.modjk.worker_recover(name, workers=None, profile='default')

Recover all the workers in the modjk load balancer

Example:

loadbalancer:
  modjk.worker_recover:
    - workers:
      - app1
      - app2
salt.states.modjk_worker.stopped(name, workers=None, profile='default')
Stop all the workers in the modjk load balancer

Example:
```
loadbalancer:
  modjk.worker_stopped:
    - workers:
      - app1
      - app2
```

32.29.92 salt.states.modjk_worker

Manage modjk workers

Send commands to a modjk load balancer via the peer system.
This module can be used with the prereq requisite to remove/add the worker from the load balancer before deploying/restarting service.

Mandatory Settings:
  - The minion needs to have permission to publish the modjk.* functions (see here for information on configuring peer publishing permissions)
  - The modjk load balancer must be configured as stated in the modjk execution module documentation

salt.states.modjk_worker.activate(name, lbn, target, profile='default', expr_form='glob')
Activate the named worker from the lbn load balancers at the targeted minions

Example:
```
disable-before-deploy:
  modjk_worker.activate:
    - name: {{ grains['id'] }}
    - lbn: application
    - target: 'roles:balancer'
    - expr_form: grain
```

salt.states.modjk_worker.disable(name, lbn, target, profile='default', expr_form='glob')
Disable the named worker from the lbn load balancers at the targeted minions. The worker will get traffic only for current sessions and won't get new ones.

Example:
```
disable-before-deploy:
  modjk_worker.disable:
    - name: {{ grains['id'] }}
    - lbn: application
    - target: 'roles:balancer'
    - expr_form: grain
```

salt.states.modjk_worker.stop(name, lbn, target, profile='default', expr_form='glob')
Stop the named worker from the lbn load balancers at the targeted minions The worker won't get any traffic from the lbn

Example:
disable-before-deploy:
  modjk_worker.stop:
    - name: {{ grains['id'] }}
    - lbn: application
    - target: 'roles:balancer'
    - expr_form: grain

32.29.93 salt.states.module

Execution of Salt modules from within states

These states allow individual execution module calls to be made via states. To call a single module function use a module.run state:

```yaml
mine.send:
  module.run:
    - name: network.interfaces
```

Note that this example is probably unnecessary to use in practice, since the mine_functions and mine_interval config parameters can be used to schedule updates for the mine (see here for more info).

It is sometimes desirable to trigger a function call after a state is executed, for this the module.wait state can be used:

```yaml
mine.send:
  module.wait:
    - name: network.interfaces
    - watch:
      - file: /etc/network/interfaces
```

All arguments that the module state does not consume are passed through to the execution module function being executed:

```yaml
fetch_out_of_band:
  module.run:
    - name: git.fetch
    - cwd: /path/to/my/repo
    - user: myuser
    - opts: '--all'
```

Due to how the state system works, if a module function accepts an argument called, name, then m_name must be used to specify that argument, to avoid a collision with the name argument.

Here is a list of keywords hidden by the state system, which must be prefixed with m_:

- fun
- name
- names
- state
- saltenv

For example:
disable_nfs:
  module.run:
    - name: service.disable
    - m_name: nfs

Note that some modules read all or some of the arguments from a list of keyword arguments. For example:

mine.send:
  module.run:
    - func: network.ip_addrs
    - kwargs:
        interface: eth0

cloud.create:
  module.run:
    - func: cloud.create
    - provider: test-provider
    - m_names:
        - test-vlad
    - kwargs: {
        ssh_username: 'ubuntu',
        image: 'ami-8d6d9daa',
        securitygroup: 'default',
        size: 'c3.large',
        location: 'ap-northeast-1',
        delvol_on_destroy: 'True'
    }

salt.states.module.mod_watch(name, **kwargs)
This function is an alias of run.

  Run a single module function

    name  The module function to execute

    returner Specify the returner to send the return of the module execution to

    **kwargs Pass any arguments needed to execute the function

salt.states.module.run(name, **kwargs)
Run a single module function

    name  The module function to execute

    returner Specify the returner to send the return of the module execution to

    **kwargs Pass any arguments needed to execute the function

salt.states.module.wait(name, **kwargs)
Run a single module function only if the watch statement calls it

    name  The module function to execute

    **kwargs Pass any arguments needed to execute the function

Note: Like the cmd.run state, this state will return True but not actually execute, unless one of the following two things happens:

1. The state has a watch requisite, and the state which it is watching changes.
2. Another state has a `watch_in requisite` which references this state, and the state with the `watch_in` changes.

32.29.94 `salt.states.mongodb_database`  

Management of MongoDB databases

Only deletion is supported, creation doesn't make sense and can be done using `mongodb_user.present`

```
salt.states.mongodb_database.absent(name, user=None, password=None, host=None, port=None)
```

Ensure that the named database is absent

- `name` The name of the database to remove
- `user` The user to connect as (must be able to create the user)
- `password` The password of the user
- `host` The host to connect to
- `port` The port to connect to

32.29.95 `salt.states.mongodb_user`  

Management of MongoDB users

**Note:** This module requires PyMongo to be installed.

```
salt.states.mongodb_user.absent(name, user=None, password=None, host=None, port=None, database='admin')
```

Ensure that the named user is absent

- `name` The name of the user to remove
- `user` MongoDB user with sufficient privilege to create the user
- `password` Password for the admin user specified by the `user` parameter
- `host` The hostname/IP address of the MongoDB server
- `port` The port on which MongoDB is listening
- `database` The database from which to remove the user specified by the `name` parameter

```
salt.states.mongodb_user.present(name, passwd, database='admin', user=None, password=None, host='localhost', port=27017)
```

Ensure that the user is present with the specified properties

- `name` The name of the user to manage
- `passwd` The password of the user to manage
- `user` MongoDB user with sufficient privilege to create the user
- `password` Password for the admin user specified with the `user` parameter
- `host` The hostname/IP address of the MongoDB server
- `port` The port on which MongoDB is listening
database  The database in which to create the user

Note: If the database doesn’t exist, it will be created.

Example:

```yaml
mongouser-myapp:
  mongodb_user.present:
    - name: myapp
    - passwd: password-of-myapp
    # Connect as admin:sekrit
    - user: admin
    - password: sekrit
```

32.29.96  salt.states.monit

Monit state

Manage monit states

```yaml
monit_enable_service_monitoring:
  monit.monitor:
    - name: service

monit_disable_service_monitoring:
  monit.unmonitor:
    - name: service
```

Note: Use of these states require that the `monit` execution module is available.

```python
salt.states.monit.monitor(name)
Get the summary from module monit and try to see if service is being monitored. If not then monitor the service.

salt.states.monit.unmonitor(name)
Get the summary from module monit and try to see if service is being monitored. If it is then stop monitoring the service.
```

32.29.97  salt.states.mount

Mounting of filesystems

Mount any type of mountable filesystem with the mounted function:

```yaml
/mnt/sdb:
  mount.mounted:
    - device: /dev/sdb1
    - fstype: ext4
```
- mkmnt: True
- opts: 
  - defaults

/srv/bigdata:
  mount.mounted:
    - device: UUID=066e0200-2867-4ebe-b9e6-f30026ca2314
    - fstype: xfs
    - opts: nobootwait,noatime,nodiratime,nobarrier,logbufs=8
    - dump: 0
    - pass_num: 2
    - persist: True
    - mkmnt: True

salt.states.mount.mod_watch(name, user=None, **kwargs)
  The mounted watcher, called to invoke the watch command.

  name  The name of the mount point

salt.states.mount.mounted(name, device, fstype, mkmnt=False, opts='defaults', dump=0, pass_num=0, config='/etc/fstab', persist=True, mount=True, user=None, match_on='auto', hidden_opts=None)

  Verify that a device is mounted

  name  The path to the location where the device is to be mounted

  device The device name, typically the device node, such as /dev/sdb1 or UUID=066e0200-2867-4ebe-b9e6-f30026ca2314 or LABEL=DATA

  fstype The filesystem type, this will be xfs, ext2/3/4 in the case of classic filesystems, and fuse in the case of fuse mounts

  mkmnt If the mount point is not present then the state will fail, set mkmnt: True to create the mount point if it is otherwise not present

  opts A list object of options or a comma delimited list

  dump The dump value to be passed into the fstab, Default is 0

  pass_num The pass value to be passed into the fstab, Default is 0

  config Set an alternative location for the fstab, Default is /etc/fstab

  persist Set if the mount should be saved in the fstab, Default is True

  mount Set if the mount should be mounted immediately, Default is True

  user The user to own the mount; this defaults to the user salt is running as on the minion

  match_on A name or list of fstab properties on which this state should be applied. Default is auto, a special value indicating to guess based on fstype. In general, auto matches on name for recognized special devices and device otherwise.

  hidden_opts A list of mount options that will be ignored when considering a remount as part of the state application

  New in version 2015.8.2.

salt.states.mount.swap(name, persist=True, config='/etc/fstab')

  Activates a swap device

  /root/swapfile:
    mount.swap
salt.states.mount.unmounted(name, device=None, config='/etc/fstab', persist=False, user=None)

New in version 0.17.0.

Verify that a device is not mounted

name The path to the location where the device is to be unmounted from

device The device to be unmounted. This is optional because the device could be mounted in multiple places.

New in version 2015.5.0.

cfg Set an alternative location for the fstab, Default is /etc/fstab

persist Set if the mount should be purged from the fstab, Default is False

user The user to own the mount; this defaults to the user salt is running as on the minion

32.29.98 salt.states.mysql_database

Management of MySQL databases (schemas)

depends

MySQLdb Python module

configuration See salt.modules.mysql for setup instructions.

The mysql_database module is used to create and manage MySQL databases. Databases can be set as either absent or present.

```
frank:
    mysql_database.present
```

salt.states.mysql_database.absent(name, **connection_args)

Ensure that the named database is absent

name The name of the database to remove

salt.states.mysql_database.present(name, **connection_args)

Ensure that the named database is present with the specified properties

name The name of the database to manage

32.29.99 salt.states.mysql_grants

Management of MySQL grants (user permissions)

depends

MySQLdb Python module

configuration See salt.modules.mysql for setup instructions.

The mysql_grants module is used to grant and revoke MySQL permissions.
The name you pass in purely symbolic and does not have anything to do with the grant itself.
The `database` parameter needs to specify a `priv_level` in the same specification as defined in the MySQL documentation:

- `*`
- `db_name.*`
- `db_name.tbl_name`
- etc...

This state is not able to set password for the permission from the specified host. See `salt.states.mysql_user` for further instructions.

```yaml
frank_exampledb:
  mysql_grants.present:
    - grant: select,insert,update
    - database: exampledb.*
    - user: frank
    - host: localhost

frank_otherdb:
  mysql_grants.present:
    - grant: all privileges
    - database: otherdb.*
    - user: frank

restricted_singletable:
  mysql_grants.present:
    - grant: select
    - database: somedb.sometable
    - user: joe
```

```
salt.states.mysql_grants.absent(name, grant=None, database=None, user=None, host='localhost', grant_option=False, escape=True, **connection_args)
```

Ensure that the grant is absent

- **name**: The name (key) of the grant to add
- **grant**: The grant `priv_type` (i.e. `select,insert,update` OR all privileges)
- **database**: The database `priv_level` (i.e. `db.tbl` OR `db.*`)
- **user**: The user to apply the grant to
- **host**: The network/host that the grant should apply to

```
salt.states.mysql_grants.present(name, grant=None, database=None, user=None, host='localhost', grant_option=False, escape=True, revoke_first=False, ssl_option=False, **connection_args)
```

Ensure that the grant is present with the specified properties

- **name**: The name (key) of the grant to add
- **grant**: The grant `priv_type` (i.e. `select,insert,update` OR all privileges)
- **database**: The database `priv_level` (i.e. `db.tbl` OR `db.*`)
- **user**: The user to apply the grant to
- **host**: The network/host that the grant should apply to
- **grant_option**: Adds the WITH GRANT OPTION to the defined grant. Default is `False`
escape  Defines if the database value gets escaped or not. Default is True

revoke_first  By default, MySQL will not do anything if you issue a command to grant privileges that are more restrictive than what’s already in place. This effectively means that you cannot downgrade permissions without first revoking permissions applied to a db.table/user pair first.

To have Salt forcibly revoke perms before applying a new grant, enable the `revoke_first` options.

WARNING: This will remove permissions for a database before attempting to apply new permissions. There is no guarantee that new permissions will be applied correctly which can leave your database security in an unknown and potentially dangerous state. Use with caution!

Default is False

ssl_option  Adds the specified ssl options for the connecting user as requirements for this grant. Value is a list of single-element dicts corresponding to the list of ssl options to use.

Possible key/value pairings for the dicts in the value:

- SSL: True
- X509: True
- SUBJECT: <subject>
- ISSUER: <issuer>
- CIPHER: <cipher>

The non-boolean ssl options take a string as their values, which should be an appropriate value as specified by the MySQL documentation for these options.

Default is False (no ssl options will be used)

32.29.100  salt.states.mysql_query

Execution of MySQL queries

New in version 2014.7.0.

depends

- MySQLdb Python module

configuration  See salt.modules.mysql for setup instructions.

The mysql_query module is used to execute queries on MySQL databases. Its output may be stored in a file or in a grain.

query_id:

```
mysql_query.run
  - database: my_database
  - query:  "SELECT * FROM table;"
  - output:  "/tmp/query_id.txt"
```

```
salt.states.mysql_query.run(name, database, query, output=None, grain=None, key=None, overwrite=True, **connection_args)

Execute an arbitrary query on the specified database

name  Used only as an ID

database  The name of the database to execute the query on

query  The query to execute

output  grain: output in a grain other: the file to store results None: output to the result comment (default)
```

32.29.  Full list of builtin state modules 2039
grain: grain to store the output (need output=grain)

key: the specified grain will be treated as a dictionary, the result of this state will be stored under the specified key.

overwrite: The file or grain will be overwritten if it already exists (default)

32.29.101  salt.states.mysql_user

Management of MySQL users

depends

- MySQLdb Python module

configuration See salt.modules.mysql for setup instructions.

```
frank:
  mysql_user.present:
    - host: localhost
    - password: "bob@cat"
```

New in version 0.16.2: Authentication overrides have been added.

The MySQL authentication information specified in the minion config file can be overridden in states using the following arguments: connection_host, connection_port, connection_user, connection_pass, connection_db, connection_unix_socket, connection_default_file and connection_charset.

```
frank:
  mysql_user.present:
    - host: localhost
    - password: "bob@cat"
    - connection_user: someuser
    - connection_pass: somepass
    - connection_charset: utf8
    - saltenv: 
      - LC_ALL: "en_US.utf8"
```

This state is not able to grant permissions for the user. See salt.states.mysql_grants for further instructions.

salt.states.mysql_user.absent(name, host='localhost', **connection_args)

Ensure that the named user is absent

name  The name of the user to remove

salt.states.mysql_user.present(name, host='localhost', password=None, password_hash=None, allow_passwordless=False, unix_socket=False, **connection_args)

Ensure that the named user is present with the specified properties. A passwordless user can be configured by omitting password and password_hash, and setting allow_passwordless to True.

name  The name of the user to manage

host  Host for which this user/password combo applies

password  The password to use for this user. Will take precedence over the password_hash option if both are specified.
**password_hash**  The password in hashed form. Be sure to quote the password because YAML doesn't like the *.* A password hash can be obtained from the mysql command-line client like so:

```
mysql> SELECT PASSWORD('mypass');
+---------------------------+
| PASSWORD('mypass')         |
| '+6C8989366EAF75BB670AD8EA7A7FC1176A95CEF4' |
+---------------------------+
1 row in set (0.00 sec)
```

**allow_passwordless**  If True, then **password** and **password_hash** can be omitted to permit a password-less login.

New in version 0.16.2.

**unix_socket**  If True and allow_passwordless is True, the unix_socket auth plugin will be used.

### 32.29.102  **salt.states.network**

**Configuration of network interfaces**

The network module is used to create and manage network settings, interfaces can be set as either managed or ignored. By default all interfaces are ignored unless specified.

**Note:**  Prior to version 2014.1.0, only RedHat-based systems (RHEL, CentOS, Scientific Linux, etc.) are supported. Support for Debian/Ubuntu is new in 2014.1.0 and should be considered experimental.

Other platforms are not yet supported.

```
system:
  network.system:
    - enabled: True
    - hostname: server1.example.com
    - gateway: 192.168.0.1
    - gatewaydev: eth0
    - nozeroconf: True
    - nisdomain: example.com
    - require_reboot: True

eth0:
  network.managed:
    - enabled: True
    - type: eth
    - proto: none
    - ipaddr: 10.1.0.1
    - netmask: 255.255.255.0
    - dns:
      - 8.8.8.8
      - 8.8.4.4

eth0-range0:
  network.managed:
    - type: eth
    - ipaddr_start: 192.168.1.1
    - ipaddr_end: 192.168.1.10
```
- clonenum_start: 10
  - mtu: 9000

**bond0-range0:**
  *network.managed:*
  - type: eth
  - ipaddr_start: 192.168.1.1
  - ipaddr_end: 192.168.1.10
  - clonenum_start: 10
  - mtu: 9000

**eth1.0-range0:**
  *network.managed:*
  - type: eth
  - ipaddr_start: 192.168.1.1
  - ipaddr_end: 192.168.1.10
  - clonenum_start: 10
  - vlan: True
  - mtu: 9000

**bond0.1-range0:**
  *network.managed:*
  - type: eth
  - ipaddr_start: 192.168.1.1
  - ipaddr_end: 192.168.1.10
  - clonenum_start: 10
  - vlan: True
  - mtu: 9000

.. note::
   add support of ranged interfaces (vlan, bond and eth) for redhat system,
   Important: type must be eth.

**routes:**
  *network.routes:*
  - name: eth0
    - routes:
      - name: secure_network
        ipaddr: 10.2.0.0
        netmask: 255.255.255.0
        gateway: 10.1.0.3

      - 10.1.0.12/32
- ipv6addrs:
  - fc00::1/128
  - fc00::100/128

.. note::
   Apply changes to hostname immediately.
.. versionadded:: 2015.5.0

Note: When managing bridged interfaces on a Debian or Ubuntu based system, the ports argument is required. Red Hat systems will ignore the argument.

```python
salt.states.network.managed(name, type, enabled=True, **kwargs)

Ensure that the named interface is configured properly.

name The name of the interface to manage

<table>
<thead>
<tr>
<th>name</th>
<th>The name of the interface to manage</th>
</tr>
</thead>
</table>

<table>
<thead>
<tr>
<th>type</th>
<th>Type of interface and configuration.</th>
</tr>
</thead>
</table>

<table>
<thead>
<tr>
<th>enabled</th>
<th>Designates the state of this interface.</th>
</tr>
</thead>
</table>

<table>
<thead>
<tr>
<th>kwargs</th>
<th>The IP parameters for this interface.</th>
</tr>
</thead>
</table>

salt.states.network.routes(name, **kwargs)

Manage network interface static routes.

name Interface name to apply the route to.

<table>
<thead>
<tr>
<th>name</th>
<th>Interface name to apply the route to.</th>
</tr>
</thead>
</table>

<table>
<thead>
<tr>
<th>kwargs</th>
<th>Named routes</th>
</tr>
</thead>
</table>

salt.states.network.system(name, **kwargs)

Ensure that global network settings are configured properly.

name Custom name to represent this configuration change.

<table>
<thead>
<tr>
<th>name</th>
<th>Custom name to represent this configuration change.</th>
</tr>
</thead>
</table>

<table>
<thead>
<tr>
<th>kwargs</th>
<th>The global parameters for the system.</th>
</tr>
</thead>
</table>
```

32.29.103 salt.states.nftables

Management of nftables

This is an nftables-specific module designed to manage Linux firewalls. It is expected that this state module, and other system-specific firewall states, may at some point be deprecated in favor of a more generic firewall state.

```python
httpd:
    nftables.append:
        - table: filter
        - chain: input
        - jump: accept
        - match: state
        - connstate: new
        - dport: 80
        - proto: tcp
        - sport: 1025:65535
        - save: True

httpd:
    nftables.append:
```
- table: filter
  - family: ipv6
  - chain: INPUT
  - jump: ACCEPT
  - match: state
  - connstate: NEW
  - dport: 80
  - proto: tcp
  - sport: 1025:65535
  - save: True

httpd:
  nftables.insert:

  - save: True

salt.states.nftables.append

    New in version 0.17.0.

    Append a rule to a chain

    name    A user-defined name to call this rule by in another part of a state or formula. This should not be an actual rule.

    family   Network family, ipv4 or ipv6.

    All other arguments are passed in with the same name as the long option that would normally be used for nftables, with one exception: --state is specified as connstate instead of state (not to be confused with ctstate).

salt.states.nftables.chain_absent

    New in version 2014.7.0.

    Verify the chain is absent.

    family   Networking family, either ipv4 or ipv6

salt.states.nftables.chain_present

    New in version 2014.7.0.

    Verify the chain is exist.

    name    A user-defined chain name.

    table    The table to own the chain.

    family   Networking family, either ipv4 or ipv6

salt.states.nftables.delete

    New in version 2014.7.0.

    Delete a rule to a chain

    name    A user-defined name to call this rule by in another part of a state or formula. This should not be an actual rule.

    family   Networking family, either ipv4 or ipv6

    All other arguments are passed in with the same name as the long option that would normally be used for nftables, with one exception: --state is specified as connstate instead of state (not to be confused with ctstate).
salt.states.nftables.flush(name, family='ipv4', **kwargs)

New in version 2014.7.0.

Flush current nftables state

family  Networking family, either ipv4 or ipv6

salt.states.nftables.insert(name, family='ipv4', **kwargs)

New in version 2014.7.0.

Insert a rule into a chain

name  A user-defined name to call this rule by in another part of a state or formula. This should not be an actual rule.

family  Networking family, either ipv4 or ipv6

All other arguments are passed in with the same name as the long option that would normally be used for nftables, with one exception: --state is specified as connstate instead of state (not to be confused with ctstate).

# 32.29.104 salt.states.npm

## Installation of NPM Packages

These states manage the installed packages for node.js using the Node Package Manager (npm). Note that npm must be installed for these states to be available, so npm states should include a requisite to a pkg.installed state for the package which provides npm (simply npm in most cases). Example:

```yaml
npm:
  pkg.installed

yaml:
  npm.installed:
    - require:
      - pkg: npm
```

salt.states.npm.bootstrap(name, user=None, silent=True)

Bootstraps a node.js application.

Will execute `npm install --json' on the specified directory.

user  The user to run NPM with

New in version 0.17.0.

salt.states.npm.installed(name, pkgs=None, dir=None, user=None, force_reinstall=False, registry=None, env=None)

Verify that the given package is installed and is at the correct version (if specified).

```yaml
coffee-script:
  npm.installed:
    - user: someuser

coffee-script@1.0.1:
  npm.installed: []
```

name  The package to install

Changed in version 2014.7.2: This parameter is no longer lowercased by salt so that case-sensitive NPM package names will work.
pkgs A list of packages to install with a single npm invocation; specifying this argument will ignore the name argument
    New in version 2014.7.0.
dir The target directory in which to install the package, or None for global installation
user The user to run NPM with
    New in version 0.17.0.
registry The NPM registry from which to install the package
    New in version 2014.7.0.
env A list of environment variables to be set prior to execution. The format is the same as the cmd.run.state function.
    New in version 2014.7.0.
force_reinstall Install the package even if it is already installed

salt.states.npm.removed(name, dir=None, user=None)
    Verify that the given package is not installed.
    dir The target directory in which to install the package, or None for global installation
    user The user to run NPM with
    New in version 0.17.0.

32.29.105 salt.states.ntp

Management of NTP servers

New in version 2014.1.0.

This state is used to manage NTP servers. Currently only Windows is supported.

```
win_ntp:
    ntp.managed:
        - servers:
            - pool.ntp.org
            - us.pool.ntp.org
```

salt.states.ntp.managed(name, servers=None)
    Manage NTP servers
    servers A list of NTP servers

32.29.106 salt.states.openstack_config

Manage OpenStack configuration file settings.

maintainer Jeffrey C. Ollie <jeff@ocjtech.us>
maturity new
depends
platform linux
**salt.states.openstack_config.absent**(name, filename, section, parameter=None)

Ensure a value is not set in an OpenStack configuration file.

- **filename** The full path to the configuration file
- **section** The section in which the parameter will be set
- **parameter (optional)** The parameter to change. If the parameter is not supplied, the name will be used as the parameter.

**salt.states.openstack_config.present**(name, filename, section, value, parameter=None)

Ensure a value is set in an OpenStack configuration file.

- **filename** The full path to the configuration file
- **section** The section in which the parameter will be set
- **parameter (optional)** The parameter to change. If the parameter is not supplied, the name will be used as the parameter.
- **value** The value to set

### 32.29.107 salt.states.pagerduty

**Create an Event in PagerDuty**

New in version 2014.1.0.

This state is useful for creating events on the PagerDuty service during state runs.

```yaml
cserver-warning-message:
pagerduty.create_event:
  - name: 'This is a server warning message'
  - details: 'This is a much more detailed message'
  - service_key: 9abcd123456789efabcde362783cdbaf
  - profile: my-pagerduty-account
```

**salt.states.pagerduty.create_event**(name, details, service_key, profile)

Create an event on the PagerDuty service

```yaml
cserver-warning-message:
pagerduty.create_event:
  - name: 'This is a server warning message'
  - details: 'This is a much more detailed message'
  - service_key: 9abcd123456789efabcde362783cdbaf
  - profile: my-pagerduty-account
```

The following parameters are required:

- **name** This is a short description of the event.
- **details** This can be a more detailed description of the event.
- **service_key** This key can be found by using pagerduty.list_services.
- **profile** This refers to the configuration profile to use to connect to the PagerDuty service.
32.29.108 salt.states.pagerduty_escalation_policy

Manage PagerDuty escalation policies.

Schedules and users can be referenced by pagerduty ID, or by name, or by email address.

For example:

```yaml
ensure test escalation policy:
  pagerduty_escalation_policy.present:
    - name: bruce test escalation policy
    - escalation_rules:
      - targets:
        - type: schedule
          id: 'bruce test schedule level1'
        - type: user
          id: 'Bruce Sherrod'
          escalation_delay_in_minutes: 15
      - targets:
        - type: schedule
          id: 'bruce test schedule level2'
          escalation_delay_in_minutes: 15
        - targets:
          - type: user
            id: 'Bruce TestUser1'
            id: 'Bruce TestUser2'
          - type: user
            id: 'Bruce TestUser3'
          - type: user
            id: 'bruce+test4@lyft.com'
            escalation_delay_in_minutes: 15
```

salt.states.pagerduty_escalation_policy.absent(profile='pagerduty', subdomain=None, api_key=None, **kwargs)

Ensure that a PagerDuty escalation policy does not exist. Accepts all the arguments that pagerduty_escalation_policy.present accepts; but ignores all arguments except the name.

Name can be the escalation policy id or the escalation policy name.

salt.states.pagerduty_escalation_policy.present(profile='pagerduty', subdomain=None, api_key=None, **kwargs)

Ensure that a pagerduty escalation policy exists. Will create or update as needed.

This method accepts as args everything defined in https://developer.pagerduty.com/documentation/rest/escalation_policies/create. In addition, user and schedule id’s will be translated from name (or email address) into PagerDuty unique ids. For example:

```yaml
pagerduty_escalation_policy.present:
  - name: bruce test escalation policy
  - escalation_rules:
    - targets:
      - type: schedule id: 'bruce test schedule level1'
      - type: user id: 'Bruce Sherrod'
```
In this example, 'Bruce Sherrod' will be looked up and replaced with the PagerDuty id (usually a 7 digit all-caps string, e.g. PX6GQL7)

32.29.109 salt.states.pagerduty_schedule

Manage PagerDuty schedules.
Example:

```yaml
ensure test schedule:
  pagerduty_schedule.present:
    - name: `bruce test schedule level1`
    - schedule:
        name: `bruce test schedule level1` time_zone: `Pacific Time (US & Canada)`
        schedule_layers:
          - name: `Schedule Layer 1` start: `2015-01-01T00:00:00` users:
            * user: `id': `Bruce TestUser1` member_order: 1
            * user: `id': `Bruce TestUser2` member_order: 2
            * user: `id': `bruce+test3@lyft.com` member_order: 3
            * user: `id': `bruce+test4@lyft.com` member_order: 4
        rotation_virtual_start: `2015-01-01T00:00:00` priority: 1 rotation_turn_length_seconds: 604800
```

salt.states.pagerduty_schedule.absent(profile='pagerduty', subdomain=None, api_key=None, **kwargs)

Ensure that a pagerduty schedule does not exist. Name can be pagerduty schedule id or pagerduty schedule name.

salt.states.pagerduty_schedule.present(profile='pagerduty', subdomain=None, api_key=None, **kwargs)

Ensure that a pagerduty schedule exists. This method accepts as args everything defined in https://developer.pagerduty.com/documentation/rest/schedules/create. This means that most arguments are in a dict called `schedule`.

User id's can be pagerduty id, or name, or email address.

32.29.110 salt.states.pagerduty_service

Manage PagerDuty services

Escalation policies can be referenced by pagerduty ID or by name.

For example:
ensure test service

```python
pagerduty_service.present:

  • name: `my service'
  • escalation_policy_id: `my escalation policy'
  • type: nagios

salt.states.pagerduty_service.absent(profile='pagerduty', subdomain=None, api_key=None, **kwargs)
```

Ensure a pagerduty service does not exist. Name can be the service name or pagerduty service id.

```python
salt.states.pagerduty_service.present(profile='pagerduty', subdomain=None, api_key=None, **kwargs)
```

Ensure pagerduty service exists. This method accepts as arguments everything defined in https://developer.pagerduty.com/documentation/rest/services/create

Note that many arguments are mutually exclusive, depending on the `"type"` argument.

Examples:

```bash
# create a PagerDuty email service at test-email@DOMAIN.pagerduty.com ensure generic email service exists:

```python
pagerduty_service.present:

  • name: my email service
  • service: description: `"email service controlled by salt"' escalation_policy_id: `"my escalation policy"' type: `"generic_email"' service_key: `"test-email"

```bash
# create a pagerduty service using cloudwatch integration ensure my cloudwatch service exists:

```python
pagerduty_service.present:

  • name: my cloudwatch service
  • service: escalation_policy_id: `"my escalation policy"' type: aws_cloudwatch description: `"my cloudwatch service controlled by salt"

TODO: aws_cloudwatch type should be integrated with boto_sns
```

32.29.111 salt.states.pagerduty_user

Manage PagerDuty users.

Example:

```bash
ensure bruce test user 1:

```python
pagerduty.user_present:

  • name: 'Bruce TestUser1'
  • email: bruce+test1@lyft.com
  • requester_id: P1GV5NT
```
salt.states.pagerduty_user.absent(profile='pagerduty', subdomain=None, api_key=None, **kwargs)

Ensure pagerduty user does not exist. Name can be pagerduty id, email address, or user name.

salt.states.pagerduty_user.present(profile='pagerduty', subdomain=None, api_key=None, **kwargs)

32.29.112 salt.states.pecl

Installation of PHP Extensions Using pecl

These states manage the installed pecl extensions. Note that php-pear must be installed for these states to be available, so pecl states should include a requisite to a pkg.installed state for the package which provides pecl (php-pear in most cases). Example:

```
php-pear:
  pkg.installed

mongo:
  pecl.installed:
    - require:
    - pkg: php-pear

salt.states.pecl.installed(name, version=None, defaults=False, force=False, preferred_state='stable')

New in version 0.17.0.

Make sure that a pecl extension is installed.
name The pecl extension name to install
version The pecl extension version to install. This option may be ignored to install the latest stable version.
defaults Use default answers for extensions such as pecl_http which ask questions before installation. Without this option, the pecl.installed state will hang indefinitely when trying to install these extensions.
force Whether to force the installed version or not
preferred_state The pecl extension state to install
```

salt.states.pecl.removed(name)

Make sure that a pecl extension is not installed.
name The pecl extension name to uninstall

32.29.113 salt.states.pip_state

Installation of Python Packages Using pip

These states manage system installed python packages. Note that pip must be installed for these states to be available, so pip states should include a requisite to a pkg.installed state for the package which provides pip (python-pip in most cases). Example:

```
python-pip:
  pkg.installed

virtualenvwrapper:
  pip.installed:
```
- require:
  - pkg: python-pip

salt.states.pip_state.installed(name, pkgs=None, pip_bin=None, requirements=None, env=None, bin_env=None, use_wheel=False, no_use_wheel=False, log=None, proxy=None, timeout=None, repo=None, editable=None, find_links=None, index_url=None, extra_index_url=None, no_index=False, mirrors=None, build=None, target=None, download=None, download_cache=None, source=None, upgrade=False, force_reinstall=False, ignore_installed=False, exists_action=None, no_deps=False, no_install=False, no_download=False, install_options=None, global_options=None, user=None, no_chown=False, cwd=None, activate=False, pre_releases=False, cert=None, allow_all_external=False, allow_external=None, allow_unverified=None, process_dependency_links=False, env_vars=None, use_vt=False, trusted_host=None)

Make sure the package is installed

name The name of the python package to install. You can also specify version numbers here using the standard operators ==, >, <=. If requirements is given, this parameter will be ignored.

Example:

django:
  pip.installed:
    - name: django >= 1.6, <= 1.7
    - require:
      - pkg: python-pip

This will install the latest Django version greater than 1.6 but less than 1.7.

requirements Path to a pip requirements file. If the path begins with salt:// the file will be transferred from the master file server.

user The user under which to run pip

use_wheel [False] Prefer wheel archives (requires pip>=1.4)

no_use_wheel [False] Force to not use wheel archives (requires pip>=1.4)

log Log file where a complete (maximum verbosity) record will be kept

proxy Specify a proxy in the form user:passwd@proxy.server:port. Note that the user:password@ is optional and required only if you are behind an authenticated proxy. If you provide user@proxy.server:port then you will be prompted for a password.

timeout Set the socket timeout (default 15 seconds)

editable install something editable (i.e. git+https://github.com/worldcompany/djangoembed.git#egg=djangoembed)

find_links URL to look for packages at

index_url Base URL of Python Package Index

extra_index_url Extra URLs of package indexes to use in addition to index_url

no_index Ignore package index

mirrors Specific mirror URL(s) to query (automatically adds --use-mirrors)

build Unpack packages into build dir

target Install packages into target dir

download Download packages into download instead of installing them

download_cache Cache downloaded packages in download_cache dir

source Check out editable packages into source dir

upgrade Upgrade all packages to the newest available version

force_reinstall When upgrading, reinstall all packages even if they are already up-to-date.

ignore_installed Ignore the installed packages (reinstalling instead)
**exists_action** Default action when a path already exists: (s)witch, (i)gnore, (w)ipe, (b)ackup

**no_deps** Ignore package dependencies

**no_install** Download and unpack all packages, but don't actually install them

**no_chown** When user is given, do not attempt to copy and chown a requirements file

**cwd** Current working directory to run pip from

**activate** Activates the virtual environment, if given via bin_env, before running install.

Deprecated since version 2014.7.2: If bin_env is given, pip will already be sourced from that virtualenv, making activate effectively a noop.

**pre_releases** Include pre-releases in the available versions

**cert** Provide a path to an alternate CA bundle

**allow_all_external** Allow the installation of all externally hosted files

**allow_external** Allow the installation of externally hosted files (comma separated list)

**allow_unverified** Allow the installation of insecure and unverifiable files (comma separated list)

**process_dependency_links** Enable the processing of dependency links

**bin_env** [None] Absolute path to a virtual environment directory or absolute path to a pip executable. The example below assumes a virtual environment has been created at /foo/.virtualenvs/bar.

**env_vars** Add or modify environment variables. Useful for tweaking build steps, such as specifying INCLUDE or LIBRARY paths in Makefiles, build scripts or compiler calls. This must be in the form of a dictionary or a mapping.

Example:

```yaml
django:
pip.installed:
  - name: django_app
  - env_vars:
    CUSTOM_PATH: /opt/django_app
    VERBOSE: True
```

**use_vt** Use VT terminal emulation (see output while installing)

**trusted_host** Mark this host as trusted, even though it does not have valid or any HTTPS.

Example:

```yaml
django:
pip.installed:
  - name: django >= 1.6, <= 1.7
  - bin_env: /foo/.virtualenvs/bar
  - require:
    - pkg: python-pip
```

Or

Example:

```yaml
django:
pip.installed:
  - name: django >= 1.6, <= 1.7
  - bin_env: /foo/.virtualenvs/bar/bin/pip
  - require:
    - pkg: python-pip
```

**Attention**

The following arguments are deprecated, do not use.

**pip_bin** [None] Deprecated, use bin_env
env  [None] Deprecated, use bin_env

Changed in version 0.17.0: use_wheel option added.

install_options
Extra arguments to be supplied to the setup.py install command. If you are using an option with a directory path, be sure to use absolute path.

Example:

```python
django:
pip.installed:
  - name: django
  - install_options:
    - --prefix=/blah
  - require:
    - pkg: python-pip
```

global_options  Extra global options to be supplied to the setup.py call before the install command.

New in version 2014.1.3.

**Attention**

As of Salt 0.17.0 the pip state needs an importable pip module. This usually means having the system's pip package installed or running Salt from an active virtualenv.

The reason for this requirement is because pip already does a pretty good job parsing its own requirements. It makes no sense for Salt to do pip requirements parsing and validation before passing them to the pip library. It's functionality duplication and it's more error prone.

**Attention**

Please set reload_modules: True to have the salt minion import this module after installation.

Example:

```python
pyopenssl:
pip.installed:
  - name: pyOpenSSL
  - reload_modules: True
  - exists_action: i
```

salt.states.pip_state.removed(name, requirements=None, bin_env=None, log=None, proxy=None, timeout=None, user=None, cwd=None, use_vt=False)

Make sure that a package is not installed.

- **name**  The name of the package to uninstall
- **user**  The user under which to run pip
- **bin_env**  [None] the pip executable or virtualenv to use
- **use_vt**  Use VT terminal emulation (see output while installing)

New in version 2015.5.0.

salt.states.pip_state.uptodate(name, bin_env=None, user=None, cwd=None, use_vt=False)

Verify that the system is completely up to date.

- **name**  The name has no functional value and is only used as a tracking reference
- **user**  The user under which to run pip

32.29.  Full list of builtin state modules
bin_env  the pip executable or virtualenv to use
use_vt  Use VT terminal emulation (see output while installing)

32.29.114  salt.states.pkg

Installation of packages using OS package managers such as yum or apt-get

Note:  On minions running systemd>=205, as of version 2015.8.12, 2016.3.3, and Carbon, systemd-run(1) is now used to isolate commands which modify installed packages from the salt-minion daemon's control group. This is done to keep systemd from killing the package manager commands spawned by Salt, when Salt updates itself (see KillMode in the systemd.kill(5) manpage for more information). If desired, usage of systemd-run(1) can be suppressed by setting a config option called systemd.use_scope, with a value of False (no quotes).

Salt can manage software packages via the pkg state module, packages can be set up to be installed, latest, removed and purged. Package management declarations are typically rather simple:

```
vim:
  pkg.installed
```

A more involved example involves pulling from a custom repository.

```
base:
  pkgrepo.managed:
    - humanname: Logstash PPA
    - name: ppa:wolfnet/logstash
    - dist: precise
    - file: /etc/apt/sources.list.d/logstash.list
    - keyid: 28B04E4A
    - keyserver: keyserver.ubuntu.com

logstash:
  pkg.installed
  - fromrepo: ppa:wolfnet/logstash
```

Multiple packages can also be installed with the use of the pkgs state module

```
dotdeb.repo:
  pkgrepo.managed:
    - humanname: Dotdeb
    - name: deb http://packages.dotdeb.org wheezy-php55 all
    - dist: wheezy-php55
    - file: /etc/apt/sources.list.d/dotdeb.list
    - keyid: 89DF5277
    - keyserver: keys.gnupg.net
    - refresh_db: true

php.packages:
  pkg.installed:
    - fromrepo: wheezy-php55
    - pkgs:
      - php5-fpm
      - php5-cli
      - php5-curl
```
Warning: Package names are currently case-sensitive. If the minion is using a package manager which is not case-sensitive (such as pkgng), then this state will fail if the proper case is not used. This will be addressed in a future release of Salt.

salt.states.pkg.group_installed

New in version 2015.8.0.

Ensure that an entire package group is installed. This state is currently only supported for the yum package manager.

skip Packages that would normally be installed by the package group (``default'' packages), which should not be installed.

Load Balancer:

``pkg.group_installed``:
- skip:
  - piranha

include Packages which are included in a group, which would not normally be installed by a yum groupinstall (``optional'' packages). Note that this will not enforce group membership; if you include packages which are not members of the specified groups, they will still be installed.

Load Balancer:

``pkg.group_installed``:
- include:
  - haproxy

Changed in version Boron: This option can no longer be passed as a comma-separated list, it must now be passed as a list (as shown in the above example).

Note: Because this is essentially a wrapper around pkg.install, any argument which can be passed to pkg.install may also be included here, and it will be passed on to the call to pkg.install.

salt.states.pkg.installed

Ensure that the package is installed, and that it is the correct version (if specified).

Parameters

- name (str) -- The name of the package to be installed. This parameter is ignored if either `pkgs` or `sources` is used. Additionally, please note that this option can only be used to install packages from a software repository. To install a package file manually, use the `sources` option detailed below.

- version (str) -- Install a specific version of a package. This option is ignored if `sources` is used. Currently, this option is supported for the following pkg providers: `apt`, `ebuild`, `pacman`, `win_pkg`, `yumpkg`, and `zypper`. The version number includes the release designation where applicable, to allow Salt to target a specific release of a given version. When in doubt, using the pkg.latest_version function for an uninstalled package will tell you the version available.

```
# salt myminion pkg.latest_version vim-enhanced
myminion:
  2:7.4.160-1.el7
```

Important: As of version 2015.8.7, for distros which use yum/dnf, packages which
have a version with a nonzero epoch (that is, versions which start with a number
followed by a colon like in the pkg.latest_version output above) must have
the epoch included when specifying the version number. For example:

```
vim-enhanced:
pkg.installed:
  - version: 2:7.4.160-1.el7
```

In version 2015.8.9, an ignore_epoch argument has been added to pkg.installed,
pkg.removed, and pkg.purged states, which causes the epoch to be disregarded
when the state checks to see if the desired version was installed.

Also, while this function is not yet implemented for all pkg frontends,
pkg.list_repo_pkgs will show all versions available in the various repos-
itories for a given package, irrespective of whether or not it is installed.

```
# salt myminion pkg.list_repo_pkgs httpd
myminion:
  ---------------
  base:
    |___
    httpd:
      2.2.15-29.el6.centos
  updates:
    |___
    httpd:
      2.2.15-30.el6.centos
```

The version strings returned by either of these functions can be used as version spec-
ifiers in pkg states.

You can install a specific version when using the pkgs argument by including the
version after the package:

```
common_packages:
pkg.installed:
  - pkgs:
    - unzip
    - dos2unix
    - salt-minion: 2015.8.5-1.el6
```

If the version given is the string latest, the latest available package version will be
installed à la pkg.latest.

- **refresh** *(bool)* -- This parameter controls whether or not the package repo database
  is updated prior to installing the requested package(s).

  If True, the package database will be refreshed (apt-get update or equivalent,
  depending on platform) before installing.

  If False, the package database will not be refreshed before installing.

  If unset, then Salt treats package database refreshes differently depending on whether
  or not a pkg state has been executed already during the current Salt run. Once a
  refresh has been performed in a pkg state, for the remainder of that Salt run no other
  refreshes will be performed for pkg states which do not explicitly set refresh to
  True. This prevents needless additional refreshes from slowing down the Salt run.
• **fromrepo**(str) -- Specify a repository from which to install

**Note:** Distros which use APT (Debian, Ubuntu, etc.) do not have a concept of repositories, in the same way as YUM-based distros do. When a source is added, it is assigned to a given release. Consider the following source configuration:

```bash
deb http://ppa.launchpad.net/saltstack/salt/ubuntu precise main
```

The packages provided by this source would be made available via the precise release, therefore fromrepo would need to be set to precise for Salt to install the package from this source.

Having multiple sources in the same release may result in the default install candidate being newer than what is desired. If this is the case, the desired version must be specified using the version parameter.

If the pkgs parameter is being used to install multiple packages in the same state, then instead of using version, use the method of version specification described in the Multiple Package Installation Options section below.

Running the shell command `apt-cache policy pkgname` on a minion can help elucidate the APT configuration and aid in properly configuring states:

```
root@saltmaster:~# salt ubuntu01 cmd.run 'apt-cache policy ffmpeg'
ubuntu01:
   ffmpeg:
      Installed: (none)
      Candidate: 7:0.10.11-1~precise1
      Version table:
        7:0.10.11-1~precise1 0
          500 http://ppa.launchpad.net/jon-severinsson/ffmpeg/
        --ubuntu/ precise/main amd64 Packages
          4:0.8.10-0ubuntu0.12.04.1 0
          500 http://us.archive.ubuntu.com/ubuntu/ precise-
        --updates/main amd64 Packages
          500 http://security.ubuntu.com/ubuntu/ precise-
        --security/main amd64 Packages
          4:0.8.1-0ubuntu1 0
          500 http://us.archive.ubuntu.com/ubuntu/ precise/
        --main amd64 Packages
```

The release is located directly after the source's URL. The actual release name is the part before the slash, so to install version `4:0.8.10-0ubuntu0.12.04.1` either `precise-updates` or `precise-security` could be used for the fromrepo value.

• **skip_verify**(bool) -- Skip the GPG verification check for the package to be installed

• **skip_suggestions**(bool) -- Force strict package naming. Disables lookup of package alternatives.

  New in version 2014.1.1.

• **allow_updates**(bool) -- Allow the package to be updated outside Salt's control (e.g. auto updates on Windows). This means a package on the Minion can have a newer version than the latest available in the repository without enforcing a re-installation of the package.
New in version 2014.7.0.

Example:

```python
httpd:
    pkg.installed:
        - fromrepo: mycustomrepo
        - skip_verify: True
        - skip_suggestions: True
        - version: 2.0.6-ubuntu3
        - refresh: True
        - allow_updates: True
        - hold: False
```

- **pkg_verify** *(bool)* -- New in version 2014.7.0.

For requested packages that are already installed and would not be targeted for upgrade or downgrade, use pkg.verify to determine if any of the files installed by the package have been altered. If files have been altered, the reinstall option of pkg.install is used to force a reinstall. Types to ignore can be passed to pkg.verify (see example below). Currently, this option is supported for the following pkg providers: yumpkg.

Examples:

```python
httpd:
    pkg.installed:
        - version: 2.2.15-30.el6.centos
        - pkg_verify: True

mypkgs:
    pkg.installed:
        - pkgs:
            - foo
            - bar: 1.2.3-4
            - baz
        - pkg_verify:
            - ignore_types: [config, doc]
```

- **normalize** *(bool)* -- Normalize the package name by removing the architecture, if the architecture of the package is different from the architecture of the operating system. The ability to disable this behavior is useful for poorly-created packages which include the architecture as an actual part of the name, such as kernel modules which match a specific kernel version.

New in version 2014.7.0.

Example:

```python
gpfs.gplbin-2.6.32-279.31.1.el6.x86_64:
    pkg.installed:
        - normalize: False
```

- **ignore_epoch** *(bool)* -- When a package version contains an non-zero epoch (e.g. 1:3.14.159-2.el7, and a specific version of a package is desired, set this option to True to ignore the epoch when comparing versions. This allows for the following SLS to be used:

```bash
# Actual vim-enhanced version: 2:7.4.160-1.el7
vim-enhanced:
```
pkg.installed:
  - version: 7.4.160-1.el7
  - ignore_epoch: True

Without this option set to True in the above example, the package would be installed, but the state would report as failed because the actual installed version would be 2:7.4.160-1.el7. Alternatively, this option can be left as False and the full version string (with epoch) can be specified in the SLS file:

vim-enhanced:
  pkg.installed:
    - version: 2:7.4.160-1.el7

New in version 2015.8.9.

MULTIPLE PACKAGE INSTALLATION OPTIONS: (not supported in pkgng)
Parameters

- **pkgs**(list)-- A list of packages to install from a software repository. All packages listed under pkgs will be installed via a single command.

Example:

mypkgs:
  pkg.installed:
    - pkgs:
      - foo
      - bar
      - baz
      - hold: True

NOTE: For **apt, ebuild, pacman, yumpkg**, and **zypper**, version numbers can be specified in the pkgs argument. For example:

mypkgs:
  pkg.installed:
    - pkgs:
      - foo
      - bar: 1.2.3-4
      - baz

Additionally, **ebuild, pacman** and **zypper** support the <, <=, =>, and > operators for more control over what versions will be installed. For

Example:

mypkgs:
  pkg.installed:
    - pkgs:
      - foo
      - bar: '>=1.2.3-4'
      - baz
NOTE: When using comparison operators, the expression must be enclosed in quotes
to avoid a YAML render error.

With ebuild is also possible to specify a use flag list and/or if the given packages
should be in package.accept_keywords file and/or the overlay from which you want
the package to be installed.

For example:

```yaml
mypkgs:
  pkg.installed:
    - pkgs:
        - foo: '~=1.2:slot::overlay[use,-otheruse]'  
        - bar: '>=1.2:slot::overlay[use,-otheruse]' 
        - baz
```

- **sources (list)** -- A list of packages to install, along with the source URI or local
  path from which to install each package. In the example below, foo, bar, baz, etc. re-
  fer to the name of the package, as it would appear in the output of the pkg.version
  or pkg.list_pkgs salt CLI commands.

  ```yaml
  mypkgs:
    pkg.installed:
      - sources:
          - foo: salt://rpms/foo.rpm
          - bar: http://somesite.org/bar.rpm
          - baz: ftp://someothersite.org/baz.rpm
          - qux: /minion/path/to/qux.rpm
  ```

**PLATFORM-SPECIFIC ARGUMENTS**

These are specific to each OS. If it does not apply to the execution module for your OS, it is ignored.

**Parameters**

- **hold (bool)** -- Force the package to be held at the current installed version. Currently
  works with YUM & APT based systems.

  New in version 2014.7.0.

- **names (list)** -- A list of packages to install from a software repository. Each package
  will be installed individually by the package manager.

  ```yaml
  mypkgs:
    pkg.installed:
      - names:
          - foo: salt://rpms/foo.rpm
          - bar: http://somesite.org/bar.rpm
          - baz: ftp://someothersite.org/baz.rpm
          - qux: /minion/path/to/qux.rpm
  ```

  **Warning**: Unlike pkgs, the names parameter cannot specify a version. In addi-
  tion, it makes a separate call to the package management frontend to install each
  package, whereas pkgs makes just a single call. It is therefore recommended to
  use pkgs instead of names to install multiple packages, both for the additional
  features and the performance improvement that it brings.

- **install_recommends (bool)** -- Whether to install the packages marked as re-
  commended. Default is True. Currently only works with APT-based systems.

  New in version 2015.5.0.

  ```yaml
  httpd:
    pkg.installed:
      - install_recommends: False
  ```

- **only_upgrade (bool)** -- Only upgrade the packages, if they are already installed.
  Default is False. Currently only works with APT-based systems.
New in version 2015.5.0.

```
httpd:
  pkg.installed:
    - only_upgrade: True
```

**Note:** If this parameter is set to True and the package is not already installed, the state will fail.

**Returns**  A dictionary containing the state of the software installation

**Rtype**  dict

**Note:** The `pkg.installed` state supports the usage of `reload_modules`. This functionality allows you to force Salt to reload all modules. In many cases, Salt is clever enough to transparently reload the modules. For example, if you install a package, Salt reloads modules because some other module or state might require the package which was installed. However, there are some edge cases where this may not be the case, which is what `reload_modules` is meant to resolve.

You should only use `reload_modules` if your `pkg.installed` does some sort of installation where if you do not reload the modules future items in your state which rely on the software being installed will fail. Please see the `Reloading Modules` documentation for more information.

```
salt.states.pkg.latest(name, refresh=None, fromrepo=None, skip_verify=False, pkgs=None, watch_flags=True, **kwargs)
```

Ensure that the named package is installed and the latest available package. If the package can be updated, this state function will update the package. Generally it is better for the `installed` function to be used, as `latest` will update the package whenever a new package is available.

- **name**  The name of the package to maintain at the latest available version. This parameter is ignored if `pkgs` is used.
- **fromrepo**  Specify a repository from which to install
- **skip_verify**  Skip the GPG verification check for the package to be installed
- **refresh**  This parameter controls whether or not the package repo database is updated prior to checking for the latest available version of the requested packages.
  - If True, the package database will be refreshed (apt-get update or equivalent, depending on platform) before checking for the latest available version of the requested packages.
  - If False, the package database will not be refreshed before checking.

If unset, then Salt treats package database refreshes differently depending on whether or not a `pkg` state has been executed already during the current Salt run. Once a refresh has been performed in a `pkg` state, for the remainder of that Salt run no other refreshes will be performed for `pkg` states which do not explicitly set `refresh` to True. This prevents needless additional refreshes from slowing down the Salt run.

**Multiple Package Installation Options:**

(Not yet supported for: FreeBSD, OpenBSD, MacOS, and Solaris pkgutil)

- **pkgs**  A list of packages to maintain at the latest available version.

```
mpkgs:
  pkg.latest:
    - pkgs:
      - foo
      - bar
      - baz
```
install_recommends Whether to install the packages marked as recommended. Default is True. Currently only works with APT-based systems.

New in version 2015.5.0.

```
httpd:
pkg.latest:
  - install_recommends: False
```

only_upgrade Only upgrade the packages, if they are already installed. Default is False. Currently only works with APT-based systems.

New in version 2015.5.0.

```
httpd:
pkg.latest:
  - only_upgrade: True
```

**Note:** If this parameter is set to True and the package is not already installed, the state will fail.

salt.states.pkg.mod_aggregate (low, chunks, running)
The mod_aggregate function which looks up all packages in the available low chunks and merges them into a single pkgs ref in the present low data

salt.states.pkg.purged (name, version=None, pkgs=None, normalize=True, ignore_epoch=False, **kwargs)
Verify that a package is not installed, calling pkg.purge if necessary to purge the package. All configuration files are also removed.

name The name of the package to be purged.
version The version of the package that should be removed. Don’t do anything if the package is installed with an unmatching version.

**Important:** As of version 2015.8.7, for distros which use yum/dnf, packages which have a version with a nonzero epoch (that is, versions which start with a number followed by a colon like in the example above) must have the epoch included when specifying the version number. For example:

```
vim-enhanced:
pkg.installed:
  - version: 2:7.4.160-1.el7
```

In version 2015.8.9, an ignore_epoch argument has been added to pkg.installed, pkg.removed, and pkg.purged states, which causes the epoch to be disregarded when the state checks to see if the desired version was installed. If ignore_epoch was not set to True, and instead of 2:7.4.160-1.el7 a version of 7.4.160-1.el7 were used, this state would report success since the actual installed version includes the epoch, and the specified version would not match.

normalize [True] Normalize the package name by removing the architecture, if the architecture of the package is different from the architecture of the operating system. The ability to disable this behavior is useful for poorly-created packages which include the architecture as an actual part of the name, such as kernel modules which match a specific kernel version.

New in version 2015.8.0.

ignore_epoch [False] When a package version contains a non-zero epoch (e.g. 1:3.14.159-2.el7, and a specific version of a package is desired, set this option to True to ignore the epoch when comparing versions. This allows for the following SLS to be used:
Without this option set to True in the above example, the state would falsely report success since the actual installed version is 2:7.4.160-1.el7. Alternatively, this option can be left as False and the full version string (with epoch) can be specified in the SLS file:

```
vim-enhanced:
  pkg.purged:
    - version: 2:7.4.160-1.el7
    - ignore_epoch: True
```

New in version 2015.8.9.

Multiple Package Options:

**pkgs** A list of packages to purge. Must be passed as a python list. The name parameter will be ignored if this option is passed. It accepts version numbers as well.

New in version 0.16.0.

salt.states.pkg.removed(name, version=None, pkgs=None, normalize=True, ignore_epoch=False, **kwargs)

Verify that a package is not installed, calling pkg.remove if necessary to remove the package.

name The name of the package to be removed.

version The version of the package that should be removed. Don’t do anything if the package is installed with an unmatching version.

**Important:** As of version 2015.8.7, for distros which use yum/dnf, packages which have a version with a nonzero epoch (that is, versions which start with a number followed by a colon like in the example above) must have the epoch included when specifying the version number. For example:

```
vim-enhanced:
  pkg.installed:
    - version: 2:7.4.160-1.el7
```

In version 2015.8.9, an ignore_epoch argument has been added to pkg.installed, pkg.removed, and pkg.purged states, which causes the epoch to be disregarded when the state checks to see if the desired version was installed. If ignore_epoch was not set to True, and instead of 2:7.4.160-1.el7 a version of 7.4.160-1.el7 were used, this state would report success since the actual installed version includes the epoch, and the specified version would not match.

**normalize** [True] Normalize the package name by removing the architecture, if the architecture of the package is different from the architecture of the operating system. The ability to disable this behavior is useful for poorly-created packages which include the architecture as an actual part of the name, such as kernel modules which match a specific kernel version.

New in version 2015.8.0.

**ignore_epoch** [False] When a package version contains a non-zero epoch (e.g. 1:3.14.159-2.el7, and a specific version of a package is desired, set this option to True to ignore the epoch when comparing versions. This allows for the following SLS to be used:

```
# Actual vim-enhanced version: 2:7.4.160-1.el7
vim-enhanced:
  pkg.removed:
    - version: 7.4.160-1.el7
    - ignore_epoch: True
```
Without this option set to True in the above example, the state would falsely report success since the actual installed version is 2:7.4.160-1.el7. Alternatively, this option can be left as False and the full version string (with epoch) can be specified in the SLS file:

```
vim-enhanced:
  pkg.removed:
    - version: 2:7.4.160-1.el7
```

New in version 2015.8.9.

Multiple Package Options:

```
pkgs
```
A list of packages to remove. Must be passed as a python list. The name parameter will be ignored if this option is passed. It accepts version numbers as well.

New in version 0.16.0.

```
salt.states.pkg.uptodate(name, refresh=False, **kwargs)
```
Verify that the system is completely up to date.

- name: The name has no functional value and is only used as a tracking reference
- refresh: refresh the package database before checking for new upgrades
- kwargs: Any keyword arguments to pass through to pkg.upgrade.

New in version 2015.5.0.

### 32.29.115 salt.states.pkgbuild

The pkgbuild state is the front of Salt package building backend. It automatically

New in version 2015.8.0.

```
salt_2015.5.2:
  pkgbuild.built:
    - runas: thatch
    - results:
      - salt-2015.5.2-2.el7.centos.noarch.rpm
      - salt-api-2015.5.2-2.el7.centos.noarch.rpm
      - salt-cloud-2015.5.2-2.el7.centos.noarch.rpm
      - salt-master-2015.5.2-2.el7.centos.noarch.rpm
      - salt-minion-2015.5.2-2.el7.centos.noarch.rpm
      - salt-ssh-2015.5.2-2.el7.centos.noarch.rpm
      - salt-syndic-2015.5.2-2.el7.centos.noarch.rpm
    - dest_dir: /tmp/pkg
    - spec: salt://pkg/salt/spec/salt.spec
    - template: jinja
    - deps:
      - salt://pkg/salt/sources/required_dependency.rpm
    - tgt: epel-7-x86_64
    - sources:
      - salt://pkg/salt/sources/logrotate.salt
      - salt://pkg/salt/sources/README.fedora
      - salt://pkg/salt/sources/salt-2015.5.2.tar.gz
      - salt://pkg/salt/sources/salt-2015.5.2-tests.patch
      - salt://pkg/salt/sources/salt-api
      - salt://pkg/salt/sources/salt-api.service
      - salt://pkg/salt/sources/salt-master
      - salt://pkg/salt/sources/salt-master.service
      - salt://pkg/salt/sources/salt-minion
      - salt://pkg/salt/sources/salt-minion.service
```
salt.states.pkgbuild.built

- `name` The name to track the build, the name value is otherwise unused
- `runas` The user to run the build process as
- `dest_dir` The directory on the minion to place the built package(s)
- `spec` The location of the spec file (used for rpms)
- `sources` The list of package sources
- `tgt` The target platform to run the build on
- `template` Run the spec file through a templating engine

Ensure that the named package is built and exists in the named directory

Changed in version 2015.8.2: This argument is now optional, allowing for no templating engine to be used if none is desired.

- `deps` Packages required to ensure that the named package is built can be hosted on either the salt master server or on an HTTP or FTP server. Both HTTPS and HTTP are supported as well as downloading directly from Amazon S3 compatible URLs with both pre-configured and automatic IAM credentials
- `env` A dictionary of environment variables to be set prior to execution. Example:

  ```
  env:
    DEB_BUILD_OPTIONS: 'nocheck'
  ```

Warning: The above illustrates a common PyYAML pitfall, that yes, no, on, off, true, and false are all loaded as boolean True and False values, and must be enclosed in quotes to be used as strings. More info on this (and other) PyYAML idiosyncrasies can be found here.

- `results` The names of the expected rpms that will be built
- `force` If True, packages will be built even if they already exist in the dest_dir. This is useful when building a package for continuous or nightly package builds.

  New in version 2015.8.2.
- `always` If True, packages will be built even if they already exist in the dest_dir. This is useful when building a package for continuous or nightly package builds.

Deprecated since version 2015.8.2: Use force instead.

- `saltenv` The saltenv to use for files downloaded from the salt filesever
- `log_dir` [/var/log/salt/rpmbuild] Root directory for log files created from the build. Logs will be organized by package name, version, OS release, and CPU architecture under this directory.

  New in version 2015.8.2.

salt.states.pkgbuild.repo

- `name` The directory to find packages that will be in the repository
- `keyid` Optional Key ID to use in signing repository
- `env` A dictionary of environment variables to be utilized in creating the repository. Example:
- env:
  OPTIONS: 'ask-passphrase'

**Warning:** The above illustrates a common PyYAML pitfall, that *yes, no, on, off, true, and false* are all loaded as boolean *True* and *False* values, and must be enclosed in quotes to be used as strings. More info on this (and other) PyYAML idiosyncrasies can be found [here](#).

Use of OPTIONS on some platforms, for example: ask-passphrase, will require gpg-agent or similar to cache passphrases.

### 32.29.116 salt.states.pkgng

Manage package remote repo using FreeBSD pkgng

Salt can manage the URL pkgng pulls packages from. ATM the state and module are small so use cases are typically rather simple:

```
pkgng_clients:
  pkgng.update_packaging_site:
  - name: "http://192.168.0.2"
```

**salt.states.pkgng.update_packaging_site**(name)

### 32.29.117 salt.states.pkgrepo

Management of APT/YUM package repos

Package repositories for APT-based and YUM-based distros can be managed with these states. Here is some example SLS:

```
base:
  pkgrepo.managed:
    - humanname: CentOS-$releasever - Base
    - mirrorlist: http://mirrorlist.centos.org/?release=$releasever&arch=$basearch&
    - repo=os
    - comments:
      - 'http://mirror.centos.org/centos/$releasever/os/$basearch/'
    - gpgcheck: 1
    - gpgkey: file:///etc/pki/rpm-gpg/RPM-GPG-KEY-CentOS-6
```

```
base:
  pkgrepo.managed:
    - humanname: Logstash PPA
    - name: deb http://ppa.launchpad.net/wolfnet/logstash/ubuntu precise main
    - dist: precise
    - file: /etc/apt/sources.list.d/logstash.list
    - keyid: 28B04E4A
    - keyserver: keyserver.ubuntu.com
    - require_in:
      - pkg: logstash
```

**pkg.latest:**
- name: logstash
  refresh: True

base:
  pkgrepo.managed:
  - humanname: deb-multimedia
    name: deb http://www.deb-multimedia.org stable main
    file: /etc/apt/sources.list.d/deb-multimedia.list
    key_url: salt://deb-multimedia/files/marillat.pub

base:
  pkgrepo.managed:
  - humanname: Google Chrome
    name: deb http://dl.google.com/linux/chrome/deb/ stable main
    dist: stable
    file: /etc/apt/sources.list.d/chrome-browser.list
    require_in: 
      - pkg: google-chrome-stable
    gpgcheck: 1
    key_url: https://dl-ssl.google.com/linux/linux_signing_key.pub

base:
  pkgrepo.managed:
  - ppa: wolfnet/logstash
  pkg.latest:
  - name: logstash
  - refresh: True

Note: On Ubuntu systems, the python-software-properties package should be installed for better support of PPA repositories. To check if this package is installed, run `dpkg -l python-software-properties`.

Also, some Ubuntu releases have a bug in their python-software-properties package, a missing dependency on pycurl, so python-pycurl will need to be manually installed if it is not present once python-software-properties is installed.

On Ubuntu & Debian systems, the `python-apt` package is required to be installed. To check if this package is installed, run `dpkg -l python-software-properties`. python-apt will need to be manually installed if it is not present.

```
salt.states.pkgrepo.absent(name, **kwargs)
```
This function deletes the specified repo on the system, if it exists. It is essentially a wrapper around `pkg.del_repo`.

**name** The name of the package repo, as it would be referred to when running the regular package manager commands.

**UBUNTU-SPECIFIC OPTIONS**

**ppa** On Ubuntu, you can take advantage of Personal Package Archives on Launchpad simply by specifying the user and archive name.

```
logstash-ppa:
  pkgrepo.absent:
    - ppa: wolfnet/logstash
```

**ppa_auth** For Ubuntu PPAs there can be private PPAs that require authentication to access. For these PPAs the username/password can be specified. This is required for matching if the name format uses the `ppa:` specifier and is private (requires username/password to access, which is encoded in the URI).
```python
logstash-ppa:
pkgrepo.absent:
  - ppa: wolfnet/logstash
  - ppa_auth: username:password
```

**keyid** If passed, then the GPG key corresponding to the passed KeyID will also be removed.

**keyid_ppa** [False] If set to `True`, the GPG key's ID will be looked up from ppa.launchpad.net and removed, and the `keyid` argument will be ignored.

**Note:** This option will be disregarded unless the `ppa` argument is present.

```python
salt.states.pkgrepo.managed(name, ppa=None, **kwargs)
```

This state manages software package repositories. Currently, `yum`, `apt`, and `zypper` repositories are supported.

**YUM OR ZYPPER-BASED SYSTEMS**

**Note:** One of `baseurl` or `mirrorlist` below is required. Additionally, note that this state is not presently capable of managing more than one repo in a single repo file, so each instance of this state will manage a single repo file containing the configuration for a single repo.

**name** This value will be used in two ways: Firstly, it will be the repo ID, as seen in the entry in square brackets (e.g. `[foo]`) for a given repo. Secondly, it will be the name of the file as stored in `/etc/yum.repos.d` (e.g. `/etc/yum.repos.d/foo.conf`).

**humanname** This is used as the `name` value in the repo file in `/etc/yum.repos.d/` (or `/etc/zypp/repos.d` for Suse distros).

**baseurl** The URL to a yum repository

**mirrorlist** A URL which points to a file containing a collection of baseurls

**comments** Sometimes you want to supply additional information, but not as enabled configuration. Anything supplied for this list will be saved in the repo configuration with a comment marker (#) in front.

Additional configuration values seen in yum repo files, such as `gpgkey` or `gpgcheck`, will be used directly as key-value pairs. For example:

```python
foo:
pkgrepo.managed:
  - humanname: Personal repo for foo
  - baseurl: https://mydomain.tld/repo/foo/$releasever/$basearch
  - gpgkey: file:///etc/pki/rpm-gpg/foo-signing-key
  - gpgcheck: 1
```

**APT-BASED SYSTEMS**

**ppa** On Ubuntu, you can take advantage of Personal Package Archives on Launchpad simply by specifying the user and archive name. The keyid will be queried from launchpad and everything else is set automatically. You can override any of the below settings by simply setting them as you would normally. For example:

```python
logstash-ppa:
pkgrepo.managed:
  - ppa: wolfnet/logstash
```

**ppa_auth** For Ubuntu PPAs there can be private PPAs that require authentication to access. For these PPAs the username/password can be passed as an HTTP Basic style username/password combination.
logstash-ppa:
pkgrepo.managed:
  - ppa: wolfnet/logstash
  - ppa_auth: username:password

name  On apt-based systems this must be the complete entry as it would be seen in the sources.list file. This can have a limited subset of components (i.e. `main`) which can be added/modified with the comps option.

precise-repo:
pkgrepo.managed:
  - name: deb http://us.archive.ubuntu.com/ubuntu precise main

Note: The above example is intended as a more readable way of configuring the SLS, it is equivalent to the following:

'deb http://us.archive.ubuntu.com/ubuntu precise main':
pkgrepo.managed

disabled  Toggles whether or not the repo is used for resolving dependencies and/or installing packages.
comps  On apt-based systems, comps dictate the types of packages to be installed from the repository (e.g. main, nonfree, ...). For purposes of this, comps should be a comma-separated list.
file  The filename for the .list that the repository is configured in. It is important to include the full-path AND make sure it is in a directory that APT will look in when handling packages
dist  This dictates the release of the distro the packages should be built for. (e.g. unstable). This option is rarely needed.
keyid  The KeyID of the GPG key to install. This option also requires the keyserver option to be set.
keyserver  This is the name of the keys server to retrieve gpg keys from. The keyid option must also be set for this option to work.
key_url  URL to retrieve a GPG key from. Allows the usage of http://, https:// as well as salt://.

Note: Use either keyid/keyserver or key_url, but not both.

consolidate  If set to true, this will consolidate all sources definitions to the sources.list file, cleanup the now unused files, consolidate components (e.g. main) for the same URI, type, and architecture to a single line, and finally remove comments from the sources.list file. The consolidate will run every time the state is processed. The option only needs to be set on one repo managed by salt to take effect.
clean_file  If set to true, empty file before config repo, dangerous if use multiple sources in one file.

New in version 2015.8.0.
refresh_db  If set to false this will skip refreshing the apt package database on debian based systems.
require_in  Set this to a list of pkg.installed or pkg.latest to trigger the running of apt-get update prior to attempting to install these packages. Setting a require in the pkg will not work for this.

32.29.118  salt.states.portage_config

Management of Portage package configuration on Gentoo

A state module to manage Portage configuration on Gentoo

salt:
  portage_config.flags:
- use:
  - openssl

salt.states.portage_config.flags(name, use=None, accept_keywords=None, env=None, license=None, properties=None, unmask=False, mask=False)

Enforce the given flags on the given package or DEPEND atom.

**Warning:** In most cases, the affected package(s) need to be rebuilt in order to apply the changes.

- **name**: The name of the package or its DEPEND atom
- **use**: A list of USE flags
- **accept_keywords**: A list of keywords to accept. ~ARCH means current host arch, and will be translated into a line without keywords
- **env**: A list of environment files
- **license**: A list of accepted licenses
- **properties**: A list of additional properties
- **unmask**: A boolean to unmask the package
- **mask**: A boolean to mask the package

### 32.29.119 salt.states.ports

Manage software from FreeBSD ports

New in version 2014.1.0.

**Note:** It may be helpful to use a higher timeout when running a `ports.installed` state, since compiling the port may exceed Salt's timeout.

```
salt -t 1200 '*' state.highstate
```

salt.states.ports.installed(name, options=None)

Verify that the desired port is installed, and that it was compiled with the desired options.

- **options**: Make sure that the desired non-default options are set

**Warning:** Any build options not passed here assume the default values for the port, and are not just differences from the existing cached options from a previous `make config`.

Example usage:

```
security/nmap:
  ports.installed:
    - options:
      - IPV6: off
```
32.29.120  salt.states.postgres_database

Management of PostgreSQL databases

The postgres_database module is used to create and manage Postgres databases. Databases can be set as either absent or present.

```python
frank:
  postgres_database.present
```

```python
salt.states.postgres_database.absent(name, user=None, maintenance_db=None, 
  db_password=None, db_host=None, db_port=None, db_user=None)
```

Ensure that the named database is absent

- **name**: The name of the database to remove
- **db_user**: database username if different from config or default
- **db_password**: user password if any password for a specified user
- **db_host**: Database host if different from config or default
- **db_port**: Database port if different from config or default
- **user**: System user all operations should be performed on behalf of

New in version 0.17.0.

```python
salt.states.postgres_database.present(name, tablespace=None, encoding=None, 
  lc_collate=None, lc_ctype=None, owner=None, 
  owner_recurse=False, template=None, user=None, 
  maintenance_db=None, db_password=None, 
  db_host=None, db_port=None, db_user=None)
```

Ensure that the named database is present with the specified properties. For more information about all of these options see man createdb(1)

- **name**: The name of the database to manage
- **tablespace**: Default tablespace for the database
- **encoding**: The character encoding scheme to be used in this database
- **lc_collate**: The LC_COLLATE setting to be used in this database
- **lc_ctype**: The LC_CTYPE setting to be used in this database
- **owner**: The username of the database owner
- **owner_recurse**: Recurse owner change to all relations in the database
- **template**: The template database from which to build this database
- **user**: System user all operations should be performed on behalf of
- **db_user**: database username if different from config or default
- **db_password**: user password if any password for a specified user
- **db_host**: Database host if different from config or default
- **db_port**: Database port if different from config or default

New in version 0.17.0.

32.29.121  salt.states.postgres_extension

Management of PostgreSQL extensions

A module used to install and manage PostgreSQL extensions.

```python
adminpack:
  postgres_extension.present
```
New in version 2014.7.0.

salt.states.postgres_extension.absent(name, if_exists=None, restrict=None, cascade=None, user=None, maintenance_db=None, db_user=None, db_password=None, db_host=None, db_port=None)

Ensure that the named extension is absent.

- **name**: Extension name of the extension to remove
- **if_exists**: Add if exist slug
- **restrict**: Add restrict slug
- **cascade**: Drop on cascade
- **user**: System user all operations should be performed on behalf of
- **maintenance_db**: Database to act on
- **db_user**: Database username if different from config or default
- **db_password**: User password if any password for a specified user
- **db_host**: Database host if different from config or default
- **db_port**: Database port if different from config or default

salt.states.postgres_extension.present(name, if_not_exists=None, schema=None, ext_version=None, from_version=None, user=None, maintenance_db=None, db_user=None, db_password=None, db_host=None, db_port=None)

Ensure that the named extension is present.

**Note:** Before you can use the state to load an extension into a database, the extension's supporting files must be already installed.

For more information about all of these options see CREATE EXTENSION SQL command reference in the PostgreSQL documentation.

- **name**: The name of the extension to be installed
- **if_not_exists**: Add an IF NOT EXISTS parameter to the DDL statement
- **schema**: Schema to install the extension into
- **ext_version**: Version to install
- **from_version**: Old extension version if already installed
- **user**: System user all operations should be performed on behalf of
- **maintenance_db**: Database to act on
- **db_user**: Database username if different from config or default
- **db_password**: User password if any password for a specified user
- **db_host**: Database host if different from config or default
- **db_port**: Database port if different from config or default

### 32.29.122 salt.states.postgres_group

**Management of PostgreSQL groups (roles)**

The postgres_group module is used to create and manage Postgres groups.

```
frank:
    postgres_group.present
```

salt.states.postgres_group.absent(name, user=None, maintenance_db=None, db_user=None, db_password=None, db_host=None, db_port=None)

Ensure that the named group is absent.

- **name**: The groupname of the group to remove
user  System user all operations should be performed on behalf of
New in version 0.17.0.
db_user  database username if different from config or default
db_password  user password if any password for a specified user
db_host  Database host if different from config or default
db_port  Database port if different from config or default

salt.states.postgres_group.present(name, createdb=None, createroles=None, createuser=None, encrypted=None, superuser=None, login=None, replication=None, password=None, refresh_password=None, groups=None, user=None, maintenance_db=None, db_password=None, db_host=None, db_port=None, db_user=None)

Ensure that the named group is present with the specified privileges Please note that the user/group notion in postgresql is just abstract, we have roles, where users can be seen as roles with the LOGIN privilege and groups the others.

name  The name of the group to manage
createdb  Is the group allowed to create databases?
createroles  Is the group allowed to create other roles/users
createuser  Alias to create roles, and history problem, in pgsql normally createuser == superuser
encrypted  Should the password be encrypted in the system catalog?
login  Should the group have login perm
inherit  Should the group inherit permissions
superuser  Should the new group be a `superuser`
replication  Should the new group be allowed to initiate streaming replication
password  The Group’s password It can be either a plain string or a md5 postgresql hashed password:

```
'md5{MD5OF{{password}{role}}}'
```

If encrypted is None or True, the password will be automatically encrypted to the previous format if it is not already done.

refresh_password  Password refresh flag

Boolean attribute to specify whether to password comparison check should be performed.
If refresh_password is True, the password will be automatically updated without extra password change check.

This behaviour makes it possible to execute in environments without superuser access available, e.g. Amazon RDS for PostgreSQL.
groups  A string of comma separated groups the group should be in
user  System user all operations should be performed on behalf of
New in version 0.17.0.

db_user  database username if different from config or default
db_password  user password if any password for a specified user
db_host  Database host if different from config or default
db_port  Database port if different from config or default

32.29.123  salt.states.postgres_schema

Management of PostgreSQL schemas

The postgres_schemas module is used to create and manage Postgres schemas.
```python
public:
    postgres_schema.present 'dbname' 'name'

salt.states.postgres_schema.absent(dbname, name, db_user=None, db_password=None, 
    db_host=None, db_port=None)

    Ensure that the named schema is absent.
    dbname  The database's name will work on
    name    The name of the schema to remove
    db_user database username if different from config or default
    db_password user password if any password for a specified user
    db_host  Database host if different from config or default
    db_port  Database port if different from config or default

salt.states.postgres_schema.present(dbname, name, owner=None, db_user=None, 
    db_password=None, db_host=None, db_port=None)

    Ensure that the named schema is present in the database.
    dbname  The database's name will work on
    name    The name of the schema to manage
    owner   The database user that will be the owner of the schema
    db_user database username if different from config or default
    db_password user password if any password for a specified user
    db_host  Database host if different from config or default
    db_port  Database port if different from config or default
```

32.29.124 salt.states.postgres_tablespace

Management of PostgreSQL tablespace

A module used to create and manage PostgreSQL tablespaces.

```yaml
ssd-tablespace:
    postgres_tablespace.present:
        - name: indexes
        - directory: /mnt/ssd-data
```

New in version 2015.8.0.

```python
salt.states.postgres_tablespace.absent(name, user=None, maintenance_db=None, 
    db_user=None, db_password=None, db_host=None, db_port=None)

    Ensure that the named tablespace is absent.
    name     The name of the tablespace to remove
    user     System user all operations should be performed on behalf of
    maintenance_db Database to act on
    db_user  Database username if different from config or default
    db_password User password if any password for a specified user
    db_host  Database host if different from config or default
    db_port  Database port if different from config or default

salt.states.postgres_tablespace.present(name, directory, options=None, owner=None, 
    user=None, maintenance_db=None, db_password=None, db_host=None, db_port=None, 
    db_user=None)

    Ensure that the named tablespace is present with the specified properties. For more information about all of
    these options see man ``create_tablespace``(7).
```
name  The name of the tablespace to create/manage.
directory The directory where the tablespace will be located, must already exist
options A dictionary of options to specify for the tablespace. Currently, the only tablespace options supported
are seq_page_cost and random_page_cost. Default values are shown in the example below:

<table>
<thead>
<tr>
<th>my_space:</th>
</tr>
</thead>
<tbody>
<tr>
<td>postgres_tablespace.present:</td>
</tr>
<tr>
<td>- directory: /srv/my_tablespace</td>
</tr>
<tr>
<td>- options:</td>
</tr>
<tr>
<td>seq_page_cost: 1.0</td>
</tr>
<tr>
<td>random_page_cost: 4.0</td>
</tr>
</tbody>
</table>

owner  The database user that will be the owner of the tablespace. Defaults to the user executing the command
(i.e. the user option)
user System user all operations should be performed on behalf of
maintenance_db Database to act on
db_user Database username if different from config or default
db_password User password if any password for a specified user
db_host Database host if different from config or default
db_port Database port if different from config or default

32.29.125 salt.states.postgres_user

Management of PostgreSQL users (roles)

The postgres_users module is used to create and manage Postgres users.

frank:
  postgres_user.present

salt.states.postgres_user.absent(name, user=None, maintenance_db=None, db_password=None, db_host=None, db_port=None, db_user=None)

Ensure that the named user is absent
name The username of the user to remove
user System user all operations should be performed on behalf of
New in version 0.17.0.
  db_user database username if different from config or default
  db_password user password if any password for a specified user
  db_host Database host if different from config or default
db_port Database port if different from config or default

salt.states.postgres_user.present(name, createdb=None, creatoroles=None, createuser=None, encrypted=None, superuser=None, replication=None, inherit=None, login=None, password=None, refresh_password=None, groups=None, user=None, maintenance_db=None, db_password=None, db_host=None, db_port=None, db_user=None)

Ensure that the named user is present with the specified privileges Please note that the user/group notion in
postgresql is just abstract, we have roles, where users can be seen as roles with the LOGIN privilege and
groups the others.
name The name of the system user to manage.
createdb Is the user allowed to create databases?
creatoroles Is the user allowed to create other users?
createuser Alias to create roles
crypted Should the password be encrypted in the system catalog?
**login** Should the group have login perm
**inherit** Should the group inherit permissions
**superuser** Should the new user be a "superuser"
**replication** Should the new user be allowed to initiate streaming replication
**password** The system user’s password. It can be either a plain string or a md5 postgresql hashed password:

```python
'md5{MD5OF{{password}{role}}}'
```

If encrypted is None or True, the password will be automatically encrypted to the previous format if it is not already done.

**refresh_password** Password refresh flag

Boolean attribute to specify whether to password comparison check should be performed.

If refresh_password is True, the password will be automatically updated without extra password change check.

This behaviour makes it possible to execute in environments without superuser access available, e.g. Amazon RDS for PostgreSQL

**groups** A string of comma separated groups the user should be in

**user** System user all operations should be performed on behalf of

New in version 0.17.0.

**db_user** Postres database username, if different from config or default.

**db_password** Postgres user’s password, if any password, for a specified db_user.

**db_host** Postgres database host, if different from config or default.

**db_port** Postgres database port, if different from config or default.

### 32.29.126 salt.states.powerpath

**Powerpath configuration support**

Allows configuration of EMC Powerpath. Currently only addition/deletion of licenses is supported.

```yaml
key:
    powerpath.license_present: []

salt.states.powerpath.license_absent(name)
    Ensures that the specified PowerPath license key is absent on the host.
    name  The license key to ensure is absent

salt.states.powerpath.license_present(name)
    Ensures that the specified PowerPath license key is present on the host.
    name  The license key to ensure is present
```

### 32.29.127 salt.states.process

**Process Management**

Ensure a process matching a given pattern is absent.

```yaml
httpd-absent:
    process.absent:
        - name: apache2
```
salt.states.process.absent(name, user=None, signal=None)
Ensures that the named command is not running.
  name  The pattern to match.
  user  The user process belongs
  signal  Signal to send to the process(es).

32.29.128 salt.states.pushover

Send a message to PushOver

This state is useful for sending messages to PushOver during state runs.
New in version Lithium.

```
pushover-message:
pusher.post_message:
  - user: xxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx
  - token: xxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx
  - title: Salt Returner
  - device: phone
  - priority: -1
  - expire: 3600
  - retry: 5
  - message: 'This state was executed successfully.'
```

The api key can be specified in the master or minion configuration like below:
```
pushover:
token: peWcBiMOS9HrZG15peWcBiMOS9HrZG15
```

salt.states.pushover.post_message(name, user=None, device=None, message=None, title=None, priority=None, expire=None, retry=None, sound=None, api_version=1, token=None)

Send a message to a PushOver channel.

```
pushover-message:
pusher.post_message:
  - user: xxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx
  - token: xxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx
  - title: Salt Returner
  - device: phone
  - priority: -1
  - expire: 3600
  - retry: 5
```

The following parameters are required:
  name  The unique name for this event.
  user  The user or group of users to send the message to. Must be ID of user, not name or email address.
  message  The message that is to be sent to the PushOver channel.

The following parameters are optional:
  title  The title to use for the message.
  device  The device for the user to send the message to.
  priority  The priority for the message.
  expire  The message should expire after specified amount of seconds.
  retry  The message should be resent this many times.
  token  The token for PushOver to use for authentication, if not specified in the configuration options of master or minion.
32.29.129 salt.states.pyenv

Managing python installations with pyenv

This module is used to install and manage python installations with pyenv. Different versions of python can be installed, and uninstalled. pyenv will be installed automatically the first time it is needed and can be updated later. This module will not automatically install packages which pyenv will need to compile the versions of python.

If pyenv is run as the root user then it will be installed to /usr/local/pyenv, otherwise it will be installed to the users ~/.pyenv directory. To make pyenv available in the shell you may need to add the pyenv/shims and pyenv/bin directories to the users PATH. If you are installing as root and want other users to be able to access pyenv then you will need to add pyenv_ROOT to their environment.

This is how a state configuration could look like:

```yaml
pyenv-deps:
  pkg.installed:
    - pkgs:
      - make
      - build-essential
      - libssl-dev
      - zlib1g-dev
      - libbz2-dev
      - libreadline-dev
      - libsqlite3-dev
      - wget
      - curl
      - llvm
python-2.6:
  pyenv.absent:
    - require:
      - pkg: pyenv-deps

python-2.7.6:
  pyenv.installed:
    - default: True
    - require:
      - pkg: pyenv-deps
```

salt.states.pyenv.absent(name, user=None)

Verify that the specified python is not installed with pyenv. pyenv is installed if necessary.

- **name**: The version of python to uninstall
- **user**: None The user to run pyenv as.

New in version 0.17.0.

New in version 0.16.0.

salt.states.pyenv.install_pyenv(name, user=None)

Install pyenv if not installed. Allows you to require pyenv be installed prior to installing the plugins. Useful if you want to install pyenv plugins via the git or file modules and need them installed before installing any rubies.

Use the pyenv.root configuration option to set the path for pyenv if you want a system wide install that is not in a user home dir.

- **user**: None The user to run pyenv as.

salt.states.pyenv.installed(name, default=False, user=None)

Verify that the specified python is installed with pyenv. pyenv is installed if necessary.

- **name**: The version of python to install
default  [False]  Whether to make this python the default.
user:  None  The user to run pyenv as.

New in version 0.17.0.
New in version 0.16.0.

### 32.29.130 salt.states.pyrax_queues

**Manage Rackspace Queues**

New in version 2015.5.0.

Create and destroy Rackspace queues. Be aware that this interacts with Rackspace's services, and so may incur charges.

This module uses `pyrax`, which can be installed via package, or `pip`. This module is greatly inspired by `boto_*` modules from SaltStack code source.

```yaml
myqueue:
  ppyrax_queues.present:
    - provider: my-pyrax

myqueue:
  ppyrax_queues.absent:
    - provider: my-pyrax
```

**salt.states.pyrax_queues.absent** (*name*, *provider*)

Ensure the named Rackspace queue is deleted.
- **name**  Name of the Rackspace queue.
- **provider**  Salt Cloud provider

**salt.states.pyrax_queues.present** (*name*, *provider*)

Ensure the RackSpace queue exists.
- **name**  Name of the Rackspace queue.
- **provider**  Salt Cloud Provider

### 32.29.131 salt.states.quota

**Management of POSIX Quotas**

The quota can be managed for the system:

```yaml
/: 
  quota.mode:
    mode: off
    quotatype: user
```

**salt.states.quota.mode** (*name*, *mode*, *quotatype*)

Set the quota for the system.
- **name**  The filesystem to set the quota mode on
- **mode**  Whether the quota system is on or off
- **quotatype**  Must be user or group

---

32.29.  Full list of builtin state modules  2083
32.29.132 salt.states.rabbitmq_cluster

Manage RabbitMQ Clusters

Example:

```
rabbit@rabbit.example.com:
  rabbitmq_cluster.join:
    - user: rabbit
    - host: rabbit.example.com
```

salt.states.rabbitmq_cluster.join(name, host, user='rabbit', ram_node=None, runas='root')

This function is an alias of joined.

- name: Irrelevant, not used (recommended: user@host)
- user: The user of node to join to (default: rabbit)
- host: The host of node to join to
- ram_node: Join node as a RAM node
- runas: The user to run the rabbitmq command as

32.29.133 salt.states.rabbitmq_plugin

Manage RabbitMQ Plugins

New in version 2014.1.0.

Example:

```
some_plugin:
  rabbitmq_plugin.enabled: []
```

salt.states.rabbitmq_plugin.disabled(name, runas=None)

- name: The name of the plugin
- runas: The user to run the rabbitmq-plugin command as

salt.states.rabbitmq_plugin.enabled(name, runas=None)

- name: The name of the plugin
- runas: The user to run the rabbitmq-plugin command as
32.29.134 salt.states.rabbitmq_policy

Manage RabbitMQ Policies

maintainer Benn Eichhorn <benn@getlocalmeasure.com>
maturity new
platform all

Example:

```yaml
rabbit_policy:
rabbitmq_policy.present:
  - name: HA
  - pattern: '.*'
  - definition: '{"ha-mode": "all"}'
```

salt.states.rabbitmq_policy.absent(name, vhost='', runas=None)

Ensure the named policy is absent

Reference: http://www.rabbitmq.com/ha.html
name The name of the policy to remove
runas Name of the user to run the command as

salt.states.rabbitmq_policy.present(name, pattern, definition, priority=0, vhost='', runas=None)

Ensure the RabbitMQ policy exists.

Reference: http://www.rabbitmq.com/ha.html
name Policy name
pattern A regex of queues to apply the policy to
definition A json dict describing the policy
priority Priority (defaults to 0)
vhost Virtual host to apply to (defaults to '/')
runas Name of the user to run the command as

32.29.135 salt.states.rabbitmq_user

Manage RabbitMQ Users

Example:

```yaml
rabbit_user:
rabbitmq_user.present:
  - password: password
  - force: True
  - tags:
    - monitoring
    - user
  - perms:
    - '/':
      - '.*'
      - '.*'
    - '.*'
  - runas: rabbitmq
```
salt.states.rabbitmq_user.absent(name, runas=None)
    Ensure the named user is absent
    name  The name of the user to remove
    runas User to run the command

salt.states.rabbitmq_user.present(name, password=None, force=False, tags=None, perms=(), runas=None)
    Ensure the RabbitMQ user exists.
    name  User name
    password  User's password, if one needs to be set
    force  If user exists, forcibly change the password
    tags  Optional list of tags for the user
    perms  A list of dicts with vhost keys and 3-tuple values
    runas  Name of the user to run the command

32.29.136  salt.states.rabbitmq_vhost

Manage RabbitMQ Virtual Hosts

Example:

virtual_host:
    rabbitmq_vhost.present:
    - user: rabbit_user
    - conf: .*
    - write: .*
    - read: .*

salt.states.rabbitmq_vhost.absent(name)
    Ensure the RabbitMQ Virtual Host is absent
    name  Name of the Virtual Host to remove
    runas User to run the command

         Deprecated since version 2015.8.0.

salt.states.rabbitmq_vhost.present(name)
    Ensure the RabbitMQ VHost exists.
    name  VHost name
    user  Initial user permission to set on the VHost, if present

         Deprecated since version 2015.8.0.
    owner  Initial owner permission to set on the VHost, if present

         Deprecated since version 2015.8.0.
    conf  Initial conf string to apply to the VHost and user. Defaults to .*

         Deprecated since version 2015.8.0.
    write  Initial write permissions to apply to the VHost and user. Defaults to .*

         Deprecated since version 2015.8.0.
    read  Initial read permissions to apply to the VHost and user. Defaults to .*

         Deprecated since version 2015.8.0.
    runas  Name of the user to run the command

         Deprecated since version 2015.8.0.
32.29.137 salt.states.rbenv

Managing Ruby installations with rbenv

This module is used to install and manage Ruby installations with rbenv and the ruby-build plugin. Different versions of Ruby can be installed, and uninstalled. Rbenv will be installed automatically the first time it is needed and can be updated later. This module will not automatically install packages which rbenv will need to compile the versions of Ruby. If your version of Ruby fails to install, refer to the ruby-build documentation to verify you are not missing any dependencies: https://github.com/sstephenson/ruby-build/wiki

If rbenv is run as the root user then it will be installed to /usr/local/rbenv, otherwise it will be installed to the user’s .rbenv directory. To make rbenv available in the shell you may need to add the rbenv/shims and rbenv/bin directories to the user’s PATH. If you are installing as root and want other users to be able to access rbenv then you will need to add RBENV_ROOT to their environment.

The following state configuration demonstrates how to install Ruby 1.9.x and 2.x using rbenv on Ubuntu/Debian:

```
rbenv-deps:
  pkg.installed:
    - names:
      - bash
      - git
      - openssl
      - libssl-dev
      - make
      - curl
      - autoconf
      - bison
      - build-essential
      - libffi-dev
      - libyaml-dev
      - libreadline6-dev
      - zlib1g-dev
      - libncurses5-dev

ruby-1.9.3-p429:
  rbenv.absent:
    - require:
      - pkg: rbenv-deps

ruby-2.0.0-p598:
  rbenv.installed:
    - default: True
    - require:
      - pkg: rbenv-deps
```

salt.states.rbenv.absent(name, user=None)

Verify that the specified Ruby is not installed with rbenv. Rbenv is installed if necessary.

- **name**: The version of Ruby to uninstall

- **user**: None The user to run rbenv as.

New in version 0.17.0.
New in version 0.16.0.

salt.states.rbenv.install_rbenv(name, user=None)

Install rbenv if not installed. Allows you to require rbenv be installed prior to installing the plugins. Useful if you want to install rbenv plugins via the git or file modules and need them installed before installing any Rubies.

32.29. Full list of builtin state modules 2087
Use the rbenv.root configuration option to set the path for rbenv if you want a system wide install that is not in a user home dir.

user: None  The user to run rbenv as.

salt.states.rbenv.**installed**(name, default=False, user=None)
Verify that the specified ruby is installed with rbenv. Rbenv is installed if necessary.

- **name** The version of ruby to install
- **default** [False] Whether to make this ruby the default.
- **user**: None  The user to run rbenv as.

New in version 0.17.0.
New in version 0.16.0.

32.29.138  salt.states.rdp

Manage RDP Service on Windows servers

salt.states.rdp.**disabled**(name)
Disable the RDP service

salt.states.rdp.**enabled**(name)
Enable the RDP service and make sure access to the RDP port is allowed in the firewall configuration

32.29.139  salt.states.redismod

Management of Redis server

New in version 2014.7.0.

- **depends**
  - redis Python module

- **configuration** See salt.modules.redis for setup instructions.

```
key_in_redis:
  redis.string:
    - value: string data
```

The redis server information specified in the minion config file can be overridden in states using the following arguments: host, port, db, password.

```
key_in_redis:
  redis.string:
    - value: string data
    - host: localhost
    - port: 6379
    - db: 0
    - password: somuchkittycat
```

salt.states.redismod.**absent**(name, keys=None, **connection_args)
Ensure key absent from redis

- **name**: Key to ensure absent from redis
- **keys**: list of keys to ensure absent, name will be ignored if this is used

salt.states.redismod.**string**(name, value, expire=None, expireat=None, **connection_args)
Ensure that the key exists in redis with the value specified
name  Redis key to manage  
value  Data to persist in key  
expire  Sets time to live for key in seconds  
expireat  Sets expiration time for key via UNIX timestamp, overrides expire

32.29.140 salt.states.reg

Manage the Windows registry

Many python developers think of registry keys as if they were python keys in a dictionary which is not the case. The windows registry is broken down into the following components:

Hives

This is the top level of the registry. They all begin with HKEY. - HKEY_CLASSES_ROOT (HKCR) - HKEY_CURRENT_USER(HKCU) - HKEY_LOCAL_MACHINE (HKLM) - HKEY_USER (HKU) - HKEY_CURRENT_CONFIG

Keys

Hives contain keys. These are basically the folders beneath the hives. They can contain any number of subkeys.

Values or Entries

Values or Entries are the name/data pairs beneath the keys and subkeys. All keys have a default name/data pair. It is usually ``(Default)"="(value not set)''. The actual value for the name and the date is Null. The registry editor will display ``(Default)' and ``(value not set)''.

Example

The following example is taken from the windows startup portion of the registry: ```
[HKEY_LOCAL_MACHINE\SOFTWARE\Microsoft\Windows\CurrentVersion\Run]   "RTHDVCPL"="C:\Program Files\Realtek\Audio\HDA\RtkNGUI64.exe"   -s
"NvBackend"="C:\Program Files (x86)\NVIDIA Corporation\UpdateCore\NvBackend.exe"
"BTMTrayAgent"="rundll32.exe "C:\Program Files (x86)\Intel\Bluetooth\btmshelllex.dll",TrayApp" ``` In this example these are the values for each:

Hive: HKEY_LOCAL_MACHINE

Key and subkeys: SOFTWAREMicrosoftWindowsCurrentVersionRun

Value:

- There are 3 value names: RTHDVCP, NvBackend, and BTMTrayAgent
- Each value name has a corresponding value

salt.states.reg.absent(name, vname=None, use_32bit_registry=False)  
Ensure a registry value is removed. To remove a key use key_absent.

Parameters name (str) -- A string value representing the full path of the key to
include the HIVE, Key, and all Subkeys. For example:

HKEY_LOCAL_MACHINE\SOFTWARE\Salt

Valid hive values include:
- HKEY_CURRENT_USER or HKCU
- HKEY_LOCAL_MACHINE or HKLM
- HKEY_USERS or HKU

Parameters vname (str) -- The name of the value you'd like to create beneath the Key. If this parameter is not passed it will assume you want to set the (Default) value

Parameters use_32bit_registry (bool) -- Use the 32bit portion of the registry. Applies only to 64bit windows. 32bit Windows will ignore this parameter. Default if False.

Returns Returns a dictionary showing the results of the registry operation.

Return type dict

CLI Example:

```
HKEY_CURRENT_USER\SOFTWARE\Salt\version':
  reg.absent
```

In the above example the path is interpreted as follows:
- HKEY_CURRENT_USER is the hive
- SOFTWARE\Salt is the key
- version is the value name

So the value version will be deleted from the SOFTWARE\Salt key in the HKEY_CURRENT_USER hive.

salt.states.reg.key_absent (name, force=False, use_32bit_registry=False)
New in version 2015.5.4.

Ensure a registry key is removed. This will remove a key and all value entries it contains. It will fail if the key contains subkeys.

Parameters name (str) -- A string representing the full path to the key to be removed to include the hive and the keypath. The hive can be any of the following:
- HKEY_LOCAL_MACHINE or HKLM
- HKEY_CURRENT_USER or HKCU
- HKEY_USER or HKU

Parameters force (bool) -- A boolean value indicating that all subkeys should be deleted with the key. If force=False and subkeys exists beneath the key you want to delete, key_absent will fail. Use with caution. The default is False.

Returns Returns a dictionary showing the results of the registry operation.

Return type dict

The following example will delete the SOFTWARE\Salt key and all subkeys under the HKEY_CURRENT_USER hive.

Example:

```
'HKEY_CURRENT_USER\SOFTWARE\Salt':
  reg.key_absent:
    - force: True
```

In the above example the path is interpreted as follows:
- HKEY_CURRENT_USER is the hive
- SOFTWARE\Salt is the key
salt.states.reg.present(name, value=None, vname=None, vdata=None, vtype='REG_SZ', reflection=True, use_32bitRegistry=False)

Ensure a registry key or value is present.

**Parameters**

- **name (str)** -- A string value representing the full path of the key to include the HIVE, Key, and all Subkeys. For example:

  HKEY_LOCAL_MACHINE\SOFTWARE\Salt

  Valid hive values include: - HKEY_CURRENT_USER or HKCU - HKEY_LOCAL_MACHINE or HKLM - HKEY_USERS or HKU

- **value (str)** -- Deprecated. Use vname and vdata instead. Included here for backwards compatibility.

- **vname (str)** -- The name of the value you'd like to create beneath the Key. If this parameter is not passed it will assume you want to set the (Default) value

- **vdata (str)** -- The value you'd like to set for the Key. If a value name (vname) is passed, this will be the data for that value name. If not, this will be the (Default) value for the key.

  The type for the (Default) value is always REG_SZ and cannot be changed. This parameter is optional. If not passed, the Key will be created with no associated item/value pairs.

- **vtype (str)** -- The value type for the data you wish to store in the registry. Valid values are:

  - REG_BINARY
  - REG_DWORD
  - REG_EXPAND_SZ
  - REG_MULTI_SZ
  - REG_SZ (Default)

- **reflection (bool)** -- On 64 bit machines a duplicate value will be created in the Wow6432Node for 32bit programs. This only applies to the SOFTWARE key. This option is ignored on 32bit operating systems. This value defaults to True. Set it to False to disable reflection.

  Deprecated since version 2015.8.2: Use use_32bitRegistry instead. The parameter seems to have no effect since Windows 7 / Windows 2008R2 removed support for reflection. The parameter will be removed in Boron.

- **use_32bitRegistry (bool)** -- Use the 32bit portion of the registry. Applies only to 64bit windows. 32bit Windows will ignore this parameter. Default if False.

**Returns** Returns a dictionary showing the results of the registry operation.

**Return type** dict

The following example will set the (Default) value for the SOFTWARE\Salt key in the HKEY_CURRENT_USER hive to 0.15.3. The value will not be reflected in Wow6432Node:

Example:

```
HKEY_CURRENT_USER\SOFTWARE\Salt:
  reg.present:
    - vdata: 0.15.3
    - reflection: False
```

The following example will set the value for the version entry under the SOFTWARE\Salt key in the HKEY_CURRENT_USER hive to 0.15.3. The value will be reflected in Wow6432Node:

Example:

```
HKEY_CURRENT_USER\SOFTWARE\Salt:
  reg.present:
    - vname: version
    - vdata: 0.15.3
```
In the above example the path is interpreted as follows: - `HKEY_CURRENT_USER` is the hive - `SOFTWARE\Salt` is the key - `vname` is the value name ('version') that will be created under the key - `vdata` is the data that will be assigned to 'version'

32.29.141 salt.states.rvm

Managing Ruby installations and gemsets with Ruby Version Manager (RVM)

This module is used to install and manage ruby installations and gemsets with RVM, the Ruby Version Manager. Different versions of ruby can be installed and gemsets created. RVM itself will be installed automatically if it's not present. This module will not automatically install packages that RVM depends on or ones that are needed to build ruby. If you want to run RVM as an unprivileged user (recommended) you will have to create this user yourself.

This is how a state configuration could look like:

```bash
rvm:
  group.present: []
  user.present:
    - gid: rvm
    - home: /home/rvm
    - require:
      - group: rvm

rvm-deps:
  pkg.installed:
    - pkgs:
      - bash
      - coreutils
      - gzip
      - bzip2
      - gawk
      - sed
      - curl
      - git-core
      - subversion

mri-deps:
  pkg.installed:
    - pkgs:
      - build-essential
      - openssl
      - libreadline6
      - libreadline6-dev
      - curl
      - git-core
      - zlib1g
      - zlib1g-dev
      - libssl-dev
      - libyaml-dev
      - libsqlite3-0
      - libsqlite3-dev
      - sqlite3
      - libxml2-dev
      - libxslt1-dev
      - autoconf
      - libc6-dev
      - libncurses5-dev
```
- automake
- libtool
- bison
- subversion
- ruby

jruby-deps:
pkg.installed:
  - pkgs:
    - curl
    - g++
    - openjdk-6-jre-headless

ruby-1.9.2:
rvm.installed:
  - default: True
  - user: rvm
  - require:
    - pkg: rvm-deps
    - pkg: mri-deps
    - user: rvm

jruby:
rvm.installed:
  - user: rvm
  - require:
    - pkg: rvm-deps
    - pkg: jruby-deps
    - user: rvm

jgemset:
rvm.gemset_present:
  - ruby: jruby
  - user: rvm
  - require:
    - rvm: jruby

mygemset:
rvm.gemset_present:
  - ruby: ruby-1.9.2
  - user: rvm
  - require:
    - rvm: ruby-1.9.2

salt.states.rvm.gemset_present(name, ruby='default', user=None)
  Verify that the gemset is present.
  name  The name of the gemset.
  ruby: default  The ruby version this gemset belongs to.
  user: None  The user to run rvm as.

  New in version 0.17.0.

salt.states.rvm.installed(name, default=False, user=None)
  Verify that the specified ruby is installed with RVM. RVM is installed when necessary.
  name  The version of ruby to install
  default  [False] Whether to make this ruby the default.
  user: None  The user to run rvm as.
New in version 0.17.0.

32.29.142 salt.states.saltmod

Control the Salt command interface

This state is intended for use from the Salt Master. It provides access to sending commands down to minions as well as access to executing master-side modules. These state functions wrap Salt’s Python API.

See also:

More Orchestrate documentation

- Full Orchestrate Tutorial
- The Orchestrate runner

salt.states.saltmod.function(name, tgt, ssh=False, tgt_type=None, expr_form=None, ret='`, expect_minions=False, fail_minions=None, fail_function=None, arg=None, kwarg=None, timeout=None)

Execute a single module function on a remote minion via salt or salt-ssh

name The name of the function to run, aka cmd.run or pkg.install
tgt The target specification, aka `*` for all minions
tgt_type | expr_form The target type, defaults to glob
arg The list of arguments to pass into the function
kwarg The list of keyword arguments to pass into the function
ret Optionally set a single or a list of returners to use
expect_minions An optional boolean for failing if some minions do not respond
fail_minions An optional list of targeted minions where failure is an option
fail_function An optional string that points to a salt module that returns True or False based on the returned data dict for individual minions
ssh Set to True to use the ssh client instead of the standard salt client

salt.states.saltmod.runner(name, **kwargs)

Execute a runner module on the master

New in version 2014.7.0.

name The name of the function to run
kwargs Any keyword arguments to pass to the runner function

run-manage-up:
salt.runner:
- name: manage.up

salt.states.saltmod.state(name, tgt, ssh=False, tgt_type=None, expr_form=None, ret='`, highstate=None, sls=None, top=None, env=None, test=False, pillar=None, expect_minions=False, fail_minions=None, allow_fail=0, concurrent=False, timeout=None, queue=False)

Invoke a state run on a given target

name An arbitrary name used to track the state execution
tgt The target specification for the state run.
tgt_type | expr_form The target type to resolve, defaults to glob
ret Optionally set a single or a list of returners to use
highstate Defaults to None, if set to True the target systems will ignore any sls references specified in the sls option and call state.highstate on the targeted minions
top Should be the name of a top file. If set state.top is called with this top file instead of state.sls.
sls  A group of sls files to execute. This can be defined as a single string containing a single sls file, or a list of
sls files

test  Pass test=true through to the state function
pillar  Pass the pillar kwarg through to the state function
saltenv  The default salt environment to pull sls files from
ssh  Set to True to use the ssh client instead of the standard salt client
roster  In the event of using salt-ssh, a roster system can be set
expect_minions  An optional boolean for failing if some minions do not respond
fail_minions  An optional list of targeted minions where failure is an option
allow_fail  Pass in the number of minions to allow for failure before setting the result of the execution to False
concurrent  Allow multiple state runs to occur at once.

WARNING: This flag is potentially dangerous. It is designed for use when multiple state runs can safely
be run at the same Do not use this flag for performance optimization.

queue  Pass queue=true through to the state function

Examples:

Run a list of sls files via state.sls on target minions:

```yaml
webservers:
  salt.state:
    - tgt: 'web*'  
    - sls: apache
      - django
      - core
    - saltenv: prod
```

Run a full state.highstate on target minions.

```yaml
databases:
  salt.state:
    - tgt: role:database
    - tgt_type: grain
    - highstate: True
```

salt.states.saltmod.wait_for_event(name, id_list, event_id='id', timeout=300)

Watch Salt's event bus and block until a condition is met

New in version 2014.7.0.

name  An event tag to watch for; supports Reactor-style globbing.
id_list  A list of event identifiers to watch for -- usually the minion ID. Each time an event tag is matched
the event data is inspected for event_id, if found it is removed from id_list. When id_list is empty this function returns success.

event_id [id]  The name of a key in the event data. Default is id for the minion ID, another common value is
name for use with orchestrating salt-cloud events.

timeout  [300]  The maximum time in seconds to wait before failing.

The following example blocks until all the listed minions complete a restart and reconnect to the Salt master:

```yaml
reboot_all_minions:
  salt.function:
    - name: system.reboot
      - tgt: '*'

wait_for_reboots:
  salt.wait_for_event:
    - name: salt/minion/*/start
    - id_list:
```
salt.states.saltmod.wheel(name, **kwargs)
Execute a wheel module on the master

New in version 2014.7.0.
name The name of the function to run
kwargs Any keyword arguments to pass to the wheel function

accept_minion_key:
salt.wheel:
- name: key.accept
- match: frank

32.29.143 salt.states.schedule

Management of the Salt scheduler

job3:
  schedule.present:
    - function: test.ping
    - seconds: 3600
    - splay: 10

This will schedule the command: test.ping every 3600 seconds (every hour) splaying the time between 0 and 10 seconds

job2:
  schedule.present:
    - function: test.ping
    - seconds: 15
    - splay:
      - start: 10
      - end: 20

This will schedule the command: test.ping every 3600 seconds (every hour) splaying the time between 10 and 20 seconds

job1:
  schedule.present:
    - function: state.sls
    - job_args:
      - httpd
    - job_kwargs:
      - test: True
    - when:
      - Monday 5:00pm
      - Tuesday 3:00pm
      - Wednesday 5:00pm
This will schedule the command: state.sls httpd test=True at 5pm on Monday, 
Wednesday and Friday, and 3pm on Tuesday and Thursday. Requires that 
python-dateutil is installed on the minion.

```
job1:
  schedule.present:
    - function: state.sls
    - job_args: 
      - httpd
    - job_kwargs: 
      test: True
    - cron: '*/5 * * * *
```

Scheduled jobs can also be specified using the format used by cron. This will 
schedule the command: state.sls httpd test=True to run every 5 minutes. Requires 
that python-croniter is installed on the minion.

```
job1:
  schedule.present:
    - function: state.sls
    - job_args: 
      - httpd
    - job_kwargs: 
      test: True
    - when:
      - Monday 5:00pm
      - Tuesday 3:00pm
      - Wednesday 5:00pm
      - Thursday 3:00pm
      - Friday 5:00pm
    - returner: xmpp
    - return_config: xmpp_state_run
```

This will schedule the command: state.sls httpd test=True at 5pm on Monday, 
Wednesday and Friday, and 3pm on Tuesday and Thursday. Using the xmpp returner 
to return the results of the scheduled job, with the alternative configuration 
options found in the xmpp_state_run section.

```
salt.states.schedule.absent(name, **kwargs)
    Ensure a job is absent from the schedule

name  The unique name that is given to the scheduled job.
persist  Whether the job should persist between minion restarts, defaults to True.
```

```
salt.states.schedule.disabled(name, **kwargs)
    Ensure a job is disabled in the schedule

name  The unique name that is given to the scheduled job.
persist  Whether the job should persist between minion restarts, defaults to True.
```

```
salt.states.schedule.enabled(name, **kwargs)
    Ensure a job is enabled in the schedule

name  The unique name that is given to the scheduled job.
persist  Whether the job should persist between minion restarts, defaults to True.
```

```
salt.states.schedule.present(name, **kwargs)
    Ensure a job is present in the schedule
```

32.29. Full list of builtin state modules
name The unique name that is given to the scheduled job.
seconds The scheduled job will be executed after the specified number of seconds have passed.
minutes The scheduled job will be executed after the specified number of minutes have passed.
hours The scheduled job will be executed after the specified number of hours have passed.
days The scheduled job will be executed after the specified number of days have passed.
when This will schedule the job at the specified time(s). The when parameter must be a single value or a
dictionary with the date string(s) using the dateutil format. Requires python-dateutil.
cron This will schedule the job at the specified time(s) using the crontab format. Requires python-croniter.
function The function that should be executed by the scheduled job.
job_args The arguments that will be used by the scheduled job.
job_kwargs The keyword arguments that will be used by the scheduled job.
maxrunning Ensure that there are no more than N copies of a particular job running.
jid_include Include the job into the job cache.
splay The amount of time in seconds to splay a scheduled job. Can be specified as a single value in seconds
or as a dictionary range with `start' and `end' values.
range This will schedule the command within the range specified. The range parameter must be a dictionary
with the date strings using the dateutil format. Requires python-dateutil.
once This will schedule a job to run once on the specified date.
one_fmt The default date format is ISO 8601 but can be overridden by also specifying the once_fmt option.
enabled Whether the job should be enabled or disabled. Value should be a boolean.
return_job Whether to return information to the Salt master upon job completion.
metadata Using the metadata parameter special values can be associated with a scheduled job. These values
are not used in the execution of the job, but can be used to search for specific jobs later if combined with
the return_job parameter. The metadata parameter must be specified as a dictionary, otherwise it will be
ignored.
returner The returner to use to return the results of the scheduled job.
return_config The alternative configuration to use for returner configuration options.
persist Whether the job should persist between minion restarts, defaults to True.

32.29.144 salt.states.selinux

Management of SELinux rules

If SELinux is available for the running system, the mode can be managed and booleans can be set.

```
# enforcing:
    selinux.mode

# samba_create_home_dirs:
    selinux.boolean:
        - value: True
        - persist: True
```

Note: Use of these states require that the selinux execution module is available.

salt.states.selinux.boolean(name, value, persist=False)
Set up an SELinux boolean
name The name of the boolean to set
value The value to set on the boolean
persist Defaults to False, set persist to true to make the boolean apply on a reboot

salt.states.selinux.mode(name)
Verifies the mode SELinux is running in, can be set to enforcing or permissive
name  The mode to run SELinux in, permissive or enforcing

32.29.145  salt.states.serverdensity_device

Monitor Server with Server Density

New in version 2014.7.0.

Server Density  Is a hosted monitoring service.

Warning:  This state module is beta. It might be changed later to include more or less automation.

Note:  This state module requires a pillar for authentication with Server Density:

```yaml
classroom:
    api_token: "b97da80a41c4f61bff85975ee51eb1aa"
    account_url: "https://your-account.serverdensity.io"
```

Note:  Although Server Density allows duplicate device names in its database, this module will raise an exception if you try monitoring devices with the same name.

Example:

```yaml
'server_name':
    serverdensity_device.monitored

salt.states.serverdensity_device.monitored(name, group=None, salt_name=True, salt_params=True, **params)

Device is monitored with Server Density.

name  Device name in Server Density.

salt_name  If True (default), takes the name from the id grain. If False, the provided name is used.

group  Group name under with device will appear in Server Density dashboard. Default - None.

salt_params  If True (default), needed config parameters will be sourced from grains and from status.all_status.

params  Add parameters that you want to appear in the Server Density dashboard. Will overwrite the salt_params parameters. For more info, see the API docs.

Usage example:

```yaml
'server_name':
    serverdensity_device.monitored

'server_name':
    serverdensity_device.monitored:
        - group: web-servers

'my_special_server':
    serverdensity_device.monitored:
        - salt_name: False
        - group: web-servers
```
32.29.146 salt.states.service

Starting or restarting of services and daemons

Services are defined as system daemons typically started with system init or rc scripts. The service state uses whichever service module that is loaded on the minion with the virtualname of service. Services can be defined as running or dead.

If you need to know if your init system is supported, see the list of supported service modules for your desired init system (systemd, sysvinit, launchctl, etc.).

Note that Salt’s service execution module, and therefore this service state, uses OS grains to ascertain which service module should be loaded and used to execute service functions. As existing distributions change init systems or new distributions are created, OS detection can sometimes be incomplete. If your service states are running into trouble with init system detection, please see the Overriding Virtual Module Providers section of Salt’s module documentation to work around possible errors.

Note: The current status of a service is determined by the return code of the init/rc script status command. A status return code of 0 it is considered running. Any other return code is considered dead.

httpd:
  service.running: []

The service can also be set to be started at runtime via the enable option:

openvpn:
  service.running:
    - enable: True

By default if a service is triggered to refresh due to a watch statement the service is by default restarted. If the desired behavior is to reload the service, then set the reload value to True:

redis:
  service.running:
    - enable: True
    - reload: True
    - watch:
      - pkg: redis

Note: More details regarding watch can be found in the Requisites documentation.

salt.states.service.dead(name, enable=None, sig=None, **kwargs)

Ensure that the named service is dead by stopping the service if it is running

name The name of the init or rc script used to manage the service
enable Set the service to be enabled at boot time, True sets the service to be enabled, False sets the named service to be disabled. The default is None, which does not enable or disable anything.
sig The string to search for when looking for the service process with ps
salt.states.service.disabled(name, **kwargs)
Ensure that the service is disabled on boot, only use this state if you don’t want to manage the running process, remember that if you want to disable a service to use the enable: False option for the running or dead function.

name The name of the init or rc script used to manage the service

salt.states.service.enabled(name, **kwargs)
Ensure that the service is enabled on boot, only use this state if you don’t want to manage the running process, remember that if you want to enable a running service to use the enable: True option for the running or dead function.

name The name of the init or rc script used to manage the service

salt.states.service.mod_watch(name, sfun=None, sig=None, reload=False, full_restart=False, init_delay=None, force=False, **kwargs)
The service watcher, called to invoke the watch command.

name The name of the init or rc script used to manage the service
sfun The original function which triggered the mod_watch call (service.running, for example).
sig The string to search for when looking for the service process with ps
reload Use reload instead of the default restart (exclusive option with full_restart, defaults to reload if both are used)
full_restart Use service.full_restart instead of restart (exclusive option with reload)
force Use service.force_reload instead of reload (needs reload to be set to True)
init_delay Add a sleep command (in seconds) before the service is restarted/reloaded

salt.states.service.running(name, enable=None, sig=None, init_delay=None, **kwargs)
Ensure that the service is running

name The name of the init or rc script used to manage the service
enable Set the service to be enabled at boot time, True sets the service to be enabled, False sets the named service to be disabled. The default is None, which does not enable or disable anything.
sig The string to search for when looking for the service process with ps
init_delay Some services may not be truly available for a short period after their startup script indicates to the system that they are. Provide an ‘init_delay’ to specify that this state should wait an additional given number of seconds after a service has started before returning. Useful for requisite states wherein a dependent state might assume a service has started but is not yet fully initialized.

Note:
watch can be used with service.running to restart a service when another state changes (example: a file.managed state that creates the service’s config file). More details regarding watch can be found in the Requisites documentation.

32.29.147 salt.states.slack

Send a message to Slack

This state is useful for sending messages to Slack during state runs.

New in version 2015.5.0.

slack-message:
  slack.post_message:
    - channel: '#general'
    - from_name: SuperAdmin
    - message: 'This state was executed successfully.'
    - api_key: peWcBiMOS9HzG15peWcBiMOS9HzG15

The api key can be specified in the master or minion configuration like below:
slack:
  api_key: peWcBiMOS9HrZG15peWcBiMOS9HrZG15

salt.states.slack.post_message(name, channel, from_name, message, api_key=None)
Send a message to a Slack channel.

```python
slack-message:
salt.post_message:
- channel: '#general'
- from_name: SuperAdmin
- message: 'This state was executed successfully.'
- api_key: peWcBiMOS9HrZG15peWcBiMOS9HrZG15
```

The following parameters are required:

- **name**  The unique name for this event.
- **channel**  The channel to send the message to. Can either be the ID or the name.
- **from_name**  The name of that is to be shown in the ``from`` field.
- **message**  The message that is to be sent to the Slack channel.

The following parameters are optional:

- **api_key**  The api key for Slack to use for authentication, if not specified in the configuration options of master or minion.

### 32.29.148 salt.states.smtp

**Sending Messages via SMTP**

New in version 2014.7.0.

This state is useful for firing messages during state runs, using the SMTP protocol.

```python
server-warning-message:
salt.smtp.send_msg:
- name: 'This is a server warning message'
- profile: my-smtp-account
- recipient: admins@example.com
```

salt.states.smtp.send_msg(name, recipient, subject, sender, profile, use_ssl='True')
Send a message via SMTP.

```python
server-warning-message:
salt.smtp.send_msg:
- name: 'This is a server warning message'
- profile: my-smtp-account
- subject: 'Message from Salt'
- recipient: admin@example.com
- sender: admin@example.com
- use_ssl: True
```

- **name**  The message to send via SMTP.

### 32.29.149 salt.states.splunk_search

**Splunk Search State Module**

New in version 2015.5.0.
This state is used to ensure presence of splunk searches.

```python
server-warning-message:
splunk_search.present:
  - name: This is the splunk search name
  - search: index=main sourcetype=
```

```python
salt.states.splunk_search.absent(name, profile='splunk')
Ensure a search is absent

API Error Search:
splunk_search.absent

The following parameters are required:
name This is the name of the search in splunk
```

```python
salt.states.splunk_search.present(name, profile='splunk', **kwargs)
Ensure a search is present

API Error Search:
splunk_search.present:
  search: index=main sourcetype=blah
  template: alert_5min

The following parameters are required:
name This is the name of the search in splunk
```

### 32.29.150 salt.states.ssh_auth

Control of entries in SSH authorized_key files

The information stored in a user's SSH authorized key file can be easily controlled via the ssh_auth state. Defaults can be set by the enc, options, and comment keys. These defaults can be overridden by including them in the name.

Since the YAML specification limits the length of simple keys to 1024 characters, and since SSH keys are often longer than that, you may have to use a YAML `explicit key`, as demonstrated in the second example below.

```yaml
AAAAB3NzaC1kc3MAAACCBAL0sQ9fJ5bYTEyY==:
ssh_auth.present:
  - user: root
  - enc: ssh-dss

? AAAAB3NzaC1kc3MAAACCBAL0sQ9fJ5bYTEyY==...
:
ssh_auth.present:
  - user: root
  - enc: ssh-dss

thatch:
ssh_auth.present:
  - user: root
  - source: salt://ssh_keys/thatch.id_rsa.pub
  - config: '%h/.ssh/authorized_keys'

sshkeys:
ssh_auth.present:
  - user: root
```

32.29. Full list of builtin state modules
salt.states.ssh_auth.absent(name, user, enc='ssh-rsa', comment='`, source=`, options=None, config='`.ssh/authorized_keys`')

Verifies that the specified SSH key is absent

name The SSH key to manage
user The user who owns the SSH authorized keys file to modify
enc Defines what type of key is being used; can be ed25519, ecdsa, ssh-rsa or ssh-dss
comment The comment to be placed with the SSH public key
options The options passed to the key, pass a list object
source The source file for the key(s). Can contain any number of public keys, in standard ``.authorized_keys` format. If this is set, comment, enc and options will be ignored.

New in version 2015.8.0.
config The location of the authorized keys file relative to the user's home directory, defaults to ``.ssh/authorized_keys`. Token expansion %u and %h for username and home path supported.

salt.states.ssh_auth.present(name, user, enc='ssh-rsa', comment='`, source=`, options=None, config='`.ssh/authorized_keys`', **kwargs)

Verifies that the specified SSH key is present for the specified user

name The SSH key to manage
user The user who owns the SSH authorized keys file to modify
enc Defines what type of key is being used; can be ed25519, ecdsa, ssh-rsa or ssh-dss
comment The comment to be placed with the SSH public key
source The source file for the key(s). Can contain any number of public keys, in standard ``.authorized_keys` format. If this is set, comment and enc will be ignored.

Note: The source file must contain keys in the format `<enc> <key> <comment>`. If you have generated a keypair using PuTTYgen, then you will need to do the following to retrieve an OpenSSH-compatible public key.

1. In PuTTYgen, click Load, and select the private key file (not the public key), and click Open.
2. Copy the public key from the box labeled Public key for pasting into OpenSSH authorized_keys file.
3. Paste it into a new file.

options The options passed to the key, pass a list object
config The location of the authorized keys file relative to the user's home directory, defaults to ``.ssh/authorized_keys`. Token expansion %u and %h for username and home path supported.

32.29.151 salt.states.ssh_known_hosts

Control of SSH known_hosts entries

Manage the information stored in the known_hosts files.
github.com:
  ssh_known_hosts:
  - present
  - user: root

example.com:
  ssh_known_hosts:
  - absent
  - user: root

salt.states.ssh_known_hosts.absent(name, user=None, config=None)
Verifies that the specified host is not known by the given user
name The host name
user The user who owns the ssh authorized keys file to modify
config The location of the authorized keys file relative to the user's home directory, defaults to ".ssh/known_hosts". If no user is specified, defaults to `"/etc/ssh/ssh_known_hosts"`. If present, must be an absolute path when a user is not specified.

salt.states.ssh_known_hosts.present(name, user=None, fingerprint=None, key=None, port=None, enc=None, config=None, hash_hostname=True, hash_known_hosts=True)
Verifies that the specified host is known by the specified user
On many systems, specifically those running with openssh 4 or older, the enc option must be set, only openssh 5 and above can detect the key type.
name The name of the remote host (e.g. `"github.com"`)
user The user who owns the ssh authorized keys file to modify
fingerprint The fingerprint of the key which must be present in the known_hosts file (optional if key specified)
key The public key which must be present in the known_hosts file (optional if fingerprint specified)
port optional parameter, port which will be used to when requesting the public key from the remote host, defaults to port 22.
enc Defines what type of key is being used, can be ed25519, edsa ssh-rsa or ssh-dss
config The location of the authorized keys file relative to the user's home directory, defaults to ".ssh/known_hosts". If no user is specified, defaults to `"/etc/ssh/ssh_known_hosts"`. If present, must be an absolute path when a user is not specified.
hash_hostname [True] Hash all hostnames and addresses in the known hosts file.
  Deprecated since version Carbon: Please use hash_known_hosts instead.
hash_known_hosts [True] Hash all hostnames and addresses in the known hosts file.

32.29.152 salt.states.stateconf

Stateconf System
The stateconf system is intended for use only with the stateconf renderer. This State module presents the set function. This function does not execute any functionality, but is used to interact with the stateconf renderer.

salt.states.stateconf.context(name, **kwargs)
No-op state to support state config via the stateconf renderer.

salt.states.stateconf.set(name, **kwargs)
No-op state to support state config via the stateconf renderer.
32.29.153 salt.states.status

Minion status monitoring

Maps to the status execution module.

salt.states.status.loadavg(name, maximum=None, minimum=None)

Return the current load average for the specified minion. Available values for name are 1-min, 5-min and 15-min. minimum and maximum values should be passed in as strings.

salt.states.status.process(name)

Return whether the specified signature is found in the process tree. This differs slightly from the services states, in that it may refer to a process that is not managed via the init system.

32.29.154 salt.states.stormpath_account

Support for Stormpath.

New in version 2015.8.0.

salt.states.stormpath_account.absent(name, directory_id=None)

Ensure that an account associated with the given email address is absent. Will search all directories for the account, unless a directory_id is specified.

name The email address of the account to delete.

directory_id Optional. The ID of the directory that the account is expected to belong to. If not specified, then a list of directories will be retrieved, and each will be scanned for the account. Specifying a directory_id will therefore cut down on the number of requests to Stormpath, and increase performance of this state.

salt.states.stormpath_account.present(name, **kwargs)

Ensure that an account is present and properly configured

name The email address associated with the Stormpath account

directory_id The ID of a directory which the account belongs to. Required.

password Required when creating a new account. If specified, it is advisable to reference the password in another database using an sdb:// URL. Will NOT update the password if an account already exists.

givenName Required when creating a new account.

surname Required when creating a new account.

username Optional. Must be unique across the owning directory. If not specified, the username will default to the email field.

middleName Optional.

status enabled accounts are able to login to their assigned applications, disabled accounts may not login to applications, unverified accounts are disabled and have not verified their email address.

customData. Optional. Must be specified as a dict.

32.29.155 salt.states.supervisord

Interaction with the Supervisor daemon

wsgi_server:
  supervisord.running:
    - require:
      - pkg: supervisor
    - watch:
      - file: /etc/nginx/sites-enabled/wsgi_server.conf
Salt Documentation, Release 2015.8.12

salt.states.supervisord.dead(name, user=None, conf_file=None, bin_env=None, **kwargs)
Ensure the named service is dead (not running).
  name Service name as defined in the supervisor configuration file
  user Name of the user to run the supervisorctl command

New in version 0.17.0.
  conf_file path to supervisorctl config file
  bin_env path to supervisorctl bin or path to virtualenv with supervisor installed

salt.states.supervisord.mod_watch(name, restart=True, update=False, user=None, conf_file=None, bin_env=None, **kwargs)

salt.states.supervisord.running(name, restart=False, update=False, user=None, conf_file=None, bin_env=None, **kwargs)
Ensure the named service is running.
  name Service name as defined in the supervisor configuration file
  restart Whether to force a restart
  update Whether to update the supervisor configuration.
  user Name of the user to run the supervisorctl command

New in version 0.17.0.
  conf_file path to supervisorctl config file
  bin_env path to supervisorctl bin or path to virtualenv with supervisor installed

32.29.156 salt.states.svn

Manage SVN repositories

Manage repository checkouts via the svn vcs system. Note that subversion must be installed for these states to be available, so svn states should include a requisite to a pkg.installed state for the package which provides subversion (subversion in most cases). Example:

```
subversion:
  pkg.installed

http://unladen-swallow.googlecode.com/svn/trunk/:
  svn.latest:
    - target: /tmp/swallow
```

salt.states.svn.dirty(name, target=None, user=None, username=None, password=None, ignore_unversioned=False)
Determine if the working directory has been changed.

salt.states.svn.export(name, target=None, rev=None, user=None, username=None, password=None, force=False, overwrite=False, externals=True, trust=False)
Export a file or directory from an SVN repository
  name Address and path to the file or directory to be exported.
  target Name of the target directory where the checkout will put the working directory
  rev [None] The name revision number to checkout. Enable ``force'' if the directory already exists.
  user [None] Name of the user performing repository management operations
  username [None] The user to access the name repository with. The svn default is the current user
  password Connect to the Subversion server with this password

New in version 0.17.0.
  force [False] Continue if conflicts are encountered
  overwrite [False] Overwrite existing target
  externals [True] Change to False to not checkout or update externals

32.29. Full list of builtin state modules 2107
trust [False] Automatically trust the remote server. SVN's --trust-server-cert

salt.states.svn.latest(name, target=None, rev=None, user=None, username=None, password=None, force=False, externals=True, trust=False)

Checkout or update the working directory to the latest revision from the remote repository.

name Address of the name repository as passed to ``svn checkout``

target Name of the target directory where the checkout will put the working directory

rev [None] The name revision number to checkout. Enable ``force`` if the directory already exists.

user [None] Name of the user performing repository management operations

username [None] The user to access the name repository with. The svn default is the current user

password Connect to the Subversion server with this password

New in version 0.17.0.

force [False] Continue if conflicts are encountered

externals [True] Change to False to not checkout or update externals

trust [False] Automatically trust the remote server. SVN's --trust-server-cert

32.29.157 salt.states.sysctl

Configuration of the Linux kernel using sysctl

Control the kernel sysctl system.

```
vm.swappiness:
   sysctl.present:
     - value: 20
```

salt.states.sysctl.present(name, value, config=None)

Ensure that the named sysctl value is set in memory and persisted to the named configuration file. The default sysctl configuration file is /etc/sysctl.conf

name The name of the sysctl value to edit

value The sysctl value to apply

config The location of the sysctl configuration file. If not specified, the proper location will be detected based on platform.

32.29.158 salt.states.syslog_ng

State module for syslog_ng

maintainer Tibor Benke <btibi@sch.bme.hu>
maturity new
depends cmd, ps, syslog_ng
platform all

Users can generate syslog-ng configuration files from YAML format or use plain ones and reload, start, or stop their syslog-ng by using this module.

Details

The service module is not available on all system, so this module includes syslog_ng.reloaded, syslog_ng.stopped, and syslog_ng.started functions. If the service module is available on the computers, users should use that.
Users can generate syslog-ng configuration with `syslog_ng.config` function. For more information see `syslog-ng state usage`.

Syslog-ng configuration file format

The syntax of a configuration snippet in syslog-ng.conf:

```
object_type object_id {<options>};
```

These constructions are also called statements. There are options inside of them:

```
option(parameter1, parameter2); option2(parameter1, parameter2);
```

salt.states.syslog_ng.config(name, config, write=True)

Builds syslog-ng configuration.

- `name`: the id of the Salt document
- `config`: the parsed YAML code
- `write`: if True, it writes the config into the configuration file, otherwise just returns it

salt.states.syslog_ng.reloaded(name)

Reloads syslog-ng.

salt.states.syslog_ng.started(name=None, user=None, group=None, chroot=None, caps=None, no_caps=False, pidfile=None, enable_core=False, fd_limit=None, verbose=False, debug=False, trace=False, yydebug=False, persist_file=None, control=None, worker_threads=None, **kwargs)

Ensures, that syslog-ng is started via the given parameters.

- Users shouldn't use this function, if the service module is available on their system.

salt.states.syslog_ng.stopped(name=None)

Kills syslog-ng.

32.29.159 salt.states.sysrc

salt.states.sysrc.absent(name, **kwargs)

Ensure a sysrc variable is absent.

- `name`: The variable name to set
- `file` (optional): The rc file to add the variable to.
- `jail` (optional): the name or JID of the jail to set the value in.

salt.states.sysrc.managed(name, value, **kwargs)

Ensure a sysrc variable is set to a specific value.

- `name`: The variable name to set
- `value`: Value to set the variable to
- `file` (optional): The rc file to add the variable to.
- `jail` (optional): the name or JID of the jail to set the value in.
32.29.160  salt.states.test

Test States

Provide test case states that enable easy testing of things to do with state calls, e.g. running, calling, logging, output filtering etc.

```python
always-passes-with-any-kwarg:
    test.nop:
        - name: foo
        - something: else
        - foo: bar

always-passes:
    test.succeed_without_changes:
        - name: foo

always-fails:
    test.fail_without_changes:
        - name: foo

always-changes-and-succeeds:
    test.succeed_with_changes:
        - name: foo

always-changes-and-fails:
    test.fail_with_changes:
        - name: foo

my-custom-combo:
    test.configurable_test_state:
        - name: foo
        - changes: True
        - result: False
        - comment: bar.baz

is-pillar-foo-present-and-bar-is-int:
    test.check_pillar:
        - present:
            - foo
        - integer:
            - bar
```

```
salt.states.test.check_pillar(name, present=None, boolean=None, integer=None, string=None, listing=None, dictionary=None, verbose=False)

Checks the presence and, optionally, the type of given keys in Pillar. Supported kwargs for types are: - boolean (bool) - integer (int) - string (str) - listing (list) - dictionary (dict)

Checking for None type pillars is not implemented yet.
```

```python
is-pillar-foo-present-and-bar-is-int:
    test.check_pillar:
        - present:
            - foo
        - integer:
            - bar
```

```
salt.states.test.configurable_test_state(name, changes=True, result=True, comment='')
```
A configurable test state which determines its output based on the inputs.

New in version 2014.7.0.
name: A unique string.
changes: Do we return anything in the changes field? Accepts True, False, and 'Random'. Default is True
result: Do we return successfully or not? Accepts True, False, and 'Random'. Default is True If test is True and
changes is True, this will be None. If test is True and and changes is False, this will be True.
comment: String to fill the comment field with. Default is ''

salt.states.test.fail_with_changes(name)
Returns failure and changes is not empty.

New in version 2014.7.0.
name: A unique string.

salt.states.test.fail_without_changes(name)
Returns failure.

New in version 2014.7.0.
name: A unique string.

salt.states.test.mod_watch(name, sfun=None, **kwargs)
' Call this function via a watch statement

New in version 2014.7.0.

Any parameters in the state return dictionary can be customized by adding the keywords result, comment, and changes.

```python
this_state_will_return_changes:
    test.succeed_with_changes

this_state_will_NOT_return_changes:
    test.succeed_without_changes

this_state_is_watching_another_state:
    test.succeed_without_changes:
        - comment: 'This is a custom comment'
        - watch:
            - test: this_state_will_return_changes
            - test: this_state_will_NOT_return_changes

this_state_is_also_watching_another_state:
    test.succeed_without_changes:
        - watch:
            - test: this_state_will_NOT_return_changes
```

salt.states.test.nop(name, **kwargs)
A no-op state that does nothing. Useful in conjunction with the use requisite, or in templates which could
otherwise be empty due to jinja rendering

salt.states.test.show_notification(name, text=None, **kwargs)
Simple notification using text argument.

New in version 2015.8.0.
name A unique string.
text Text to return in the comment.

salt.states.test.succeed_with_changes(name)
Returns successful and changes is not empty
name: A unique string.

salt.states.test.succeed_without_changes(name)
Returns successful.

name: A unique string.

32.29.161 salt.states.timezone

Management of timezones

The timezone can be managed for the system:

<table>
<thead>
<tr>
<th>American/Denver: timezone.system</th>
</tr>
</thead>
</table>

The system and the hardware clock are not necessarily set to the same time. By default, the hardware clock is set to local time, meaning it is set to the same time as the system clock. If utc is set to True, then the hardware clock will be set to UTC, and the system clock will be an offset of that.

<table>
<thead>
<tr>
<th>American/Denver: timezone.system:</th>
</tr>
</thead>
<tbody>
<tr>
<td>- utc: True</td>
</tr>
</tbody>
</table>

The Ubuntu community documentation contains an explanation of this setting, as it applies to systems that dual-boot with Windows. This is explained in greater detail here.

salt.states.timezone.system(name, utc=True)
Set the timezone for the system.

name: The name of the timezone to use (e.g.: America/Denver)
utc: Whether or not to set the hardware clock to UTC (default is True)

32.29.162 salt.states.tls

Enforce state for SSL/TLS

salt.states.tls.valid_certificate(name, weeks=0, days=0, hours=0, minutes=0, seconds=0)
Verify that a TLS certificate is valid now and (optionally) will be valid for the time specified through weeks, days, hours, minutes, and seconds.

32.29.163 salt.states.tomcat

This state uses the manager webapp to manage Apache tomcat webapps. This state requires the manager webapp to be enabled.

The following grains/pillar should be set:

<table>
<thead>
<tr>
<th>tomcat-manager:user: admin user name</th>
</tr>
</thead>
<tbody>
<tr>
<td>tomcat-manager:passwd: password</td>
</tr>
</tbody>
</table>

and also configure a user in the conf/tomcat-users.xml file:
<?xml version='1.0' encoding='utf-8'?>
<tomcat-users>
  <role rolename="manager-script"/>
  <user username="tomcat" password="tomcat" roles="manager-script"/>
</tomcat-users>

Notes:

- Not supported multiple version on the same context path
- if you use only this module for deployments you might want to restrict access to the manager so its only accessible via localhost for more info: [http://tomcat.apache.org/tomcat-7.0-doc/manager-howto.html#Configuring_Manager_Application_Access](http://tomcat.apache.org/tomcat-7.0-doc/manager-howto.html#Configuring_Manager_Application_Access)

- Tested on:
  JVM Vendor: Sun Microsystems Inc.
  JVM Version: 1.6.0_43-b01
  OS Architecture: amd64
  OS Name: Linux
  OS Version: 2.6.32-358.el6.x86_64
  Tomcat Version: Apache Tomcat/7.0.37

salt.states.tomcat.mod_watch(name, url='http://localhost:8080/manager', timeout=180)
The tomcat watcher function. When called it will reload the webapp in question

salt.states.tomcat.undeployed(name, url='http://localhost:8080/manager', timeout=180)
Enforce that the WAR will be un-deployed from the server
name the context path to deploy
url [http://localhost:8080/manager] the URL of the server manager webapp
timeout [180] timeout for HTTP request to the tomcat manager
Example:

```yaml
jenkins:
  tomcat.undeployed:
    - name: /ran
    - require:
      - service: application-service
```

salt.states.tomcat.wait(name, url='http://localhost:8080/manager', timeout=180)
Wait for the tomcat manager to load

Notice that if tomcat is not running we won't wait for it start and the state will fail. This state can be required in the tomcat.war_deployed state to make sure tomcat is running and that the manager is running as well and ready for deployment
url [http://localhost:8080/manager] the URL of the server manager webapp
timeout [180] timeout for HTTP request to the tomcat manager
Example:

```yaml
tomcat-service:
  service.running:
    - name: tomcat
    - enable: True
```
wait-for-tomcatmanager:
  tomcat.wait:
  - timeout: 300
  - require:
    - service: tomcat-service

jenkins:
  tomcat.war_deployed:
  - name: /ran
  - war: salt://jenkins-1.2.4.war
  - require:
    - tomcat: wait-for-tomcatmanager

salt.states.tomcat.war_deployed(name, war, force=False, url='http://localhost:8080/manager',
  timeout=180, temp_war_location=None, version=''
)
Enforce that the WAR will be deployed and started in the context path it will make use of WAR versions
for more info: http://tomcat.apache.org/tomcat-7.0-doc/config/context.html#Naming
name the context path to deploy
war absolute path to WAR file (should be accessible by the user running tomcat) or a path supported by the
salt.modules.cp.get_url function
force force deploy even if version strings are the same, False by default.
url [http://localhost:8080/manager] the URL of the server manager webapp
timeout [180] timeout for HTTP request to the tomcat manager
temp_war_location [None] use another location to temporarily copy to war file by default the system's temp
directory is used
version [''] Specify the war version. If this argument is provided, it overrides the version encoded in the war
file name, if one is present.
Example:

jenkins:
  tomcat.war_deployed:
  - name: /ran
  - war: salt://jenkins-1.2.4.war
  - require:
    - tomcat: wait-for-tomcatmanager

32.29.164 salt.states.trafficserver

Control Apache Traffic Server
New in version 2015.8.0.
salt.states.trafficserver.bounce_cluster(name)
Bounce all Traffic Server nodes in the cluster. Bouncing Traffic Server shuts down and immediately restarts
Traffic Server, node-by-node.

bounce_ats_cluster:
  trafficserver.bounce_cluster

salt.states.trafficserver.bounce_local(name, drain=False)
Bounce Traffic Server on the local node. Bouncing Traffic Server shuts down and immediately restarts the
Traffic Server node.
This option modifies the behavior of `traffic_line -b` and `traffic_line -L` such that `traffic_server` is not shut down until the number of active client connections drops to the number given by the `proxy.config.restart.active_client_threshold` configuration variable.

```
bounce_ats_local:
  trafficserver.bounce_local

bounce_ats_local:
  trafficserver.bounce_local
  - drain: True

salt.states.trafficserver.clear_cluster(name)
Claes accumulated statistics on all nodes in the cluster.

clear_ats_cluster:
  trafficserver.clear_cluster

salt.states.trafficserver.clear_node(name)
Claes accumulated statistics on the local node.

clear_ats_node:
  trafficserver.clear_node

salt.states.trafficserver.offline(name, path)
Mark a cache storage device as offline. The storage is identified by a path which must match exactly a path specified in `storage.config`. This removes the storage from the cache and redirects requests that would have used this storage to other storage. This has exactly the same effect as a disk failure for that storage. This does not persist across restarts of the `traffic_server` process.

```
offline_ats_path:
  trafficserver.offline:
    - path: /path/to/cache
```

salt.states.trafficserver.refresh(name)
Initiate a Traffic Server configuration file reread. Use this command to update the running configuration after any configuration file modification.

The timestamp of the last reconfiguration event (in seconds since epoch) is published in the `proxy.node.config.reconfigure_time` metric.

```
refresh_ats:
  trafficserver.refresh
```

salt.states.trafficserver.restart_cluster(name)
Restart the traffic_manager process and the traffic_server process on all the nodes in a cluster.

```
restart_ats_cluster:
  trafficserver.restart_cluster
```

salt.states.trafficserver.restart_local(name, drain=False)
Restart the traffic_manager and traffic_server processes on the local node.

This option modifies the behavior of `traffic_line -b` and `traffic_line -L` such that `traffic_server` is not shut down until the number of active client connections drops to the number given by the `proxy.config.restart.active_client_threshold` configuration variable.

```
restart_ats_local:
  trafficserver.restart_local
```
restart_ats_local_drain:
  trafficserver.restart_local
  - drain: True

salt.states.trafficserver.set_var(name, value)
Set Traffic Server variable values

proxy.config.proxy_name:
  trafficserver.set_var:
    - value: cdn.site.domain.tld

OR

traffic_server_setting:
  trafficserver.set_var:
    - name: proxy.config.proxy_name
    - value: cdn.site.domain.tld

salt.states.trafficserver.shutdown(name)
Shut down Traffic Server on the local node.

shutdown_ats:
  trafficserver.shutdown

salt.states.trafficserver.startup(name)
Start Traffic Server on the local node.

startup_ats:
  trafficserver.startup

salt.states.trafficserver.zero_cluster(name)
Reset performance statistics to zero across the cluster.

zero_ats_cluster:
  trafficserver.zero_cluster

salt.states.trafficserver.zero_node(name)
Reset performance statistics to zero on the local node.

zero_ats_node:
  trafficserver.zero_node

32.29.165 salt.states.tuned

Interface to Red Hat tuned-adm module

maintainer Syed Ali <alicsyed@gmail.com>
maturity new
depends cmd.run
platform Linux

salt.states.tuned.off(name=None)
  Turns ‘tuned’ off. Example tuned.sls file for turning tuned off:
tuned: tuned.off: []
To see a valid list of states call execution module: tuned.list

salt.states.tuned.profile(name)
This state module allows you to modify system tuned parameters
Example tuned.sls file to set profile to virtual-guest

```yaml
tuned:
  • profile
  • name: virtual-guest
name tuned profile name to set the system to
To see a valid list of states call execution module: tuned.list
```

32.29.166  salt.states.uptime

Monitor Web Server with Uptime

Uptime is an open source remote monitoring application using Node.js, MongoDB, and Twitter Bootstrap.

**Warning:** This state module is beta. It might be changed later to include more or less automation.

**Note:** This state module requires a pillar to specify the location of your uptime install

```yaml
uptime:
  application_url: "http://uptime-url.example.org"
```

Example:

```yaml
url:
  uptime.monitored
url/sitemap.xml:
  uptime.monitored:
    polling: 600 # every hour
```

salt.states.uptime.monitored(name, **params)
Makes sure an URL is monitored by uptime. Checks if URL is already monitored, and if not, adds it.

32.29.167  salt.states.user

Management of user accounts

The user module is used to create and manage user settings, users can be set as either absent or present

```yaml
fred:
  user.present:
    - fullname: Fred Jones
    - shell: /bin/zsh
    - home: /home/fred
```

32.29. Full list of builtin state modules
- uid: 4000
- gid: 4000
- groups:
  - wheel
  - storage
  - games

testuser:
  user.absent

salt.states.user.absent(name, purge=False, force=False)
Ensure that the named user is absent
name The name of the user to remove
purge Set purge to True to delete all of the user's files as well as the user, Default is False.
force If the user is logged in, the absent state will fail. Set the force option to True to remove the user even if
they are logged in. Not supported in FreeBSD and Solaris, Default is False.
salt.states.user.present(name, uid=None, gid=None, gid_from_name=False, groups=None, optional_groups=None, remove_groups=True, home=None, createhome=True, password=None, enforce_password=True, empty_password=False, shell=None, unique=True, system=False, fullname=None, roomnumber=None, workphone=None, homephone=None, loginclass=None, date=None, mindays=None, maxdays=None, inactdays=None, warndays=None, expire=None, win_homedrive=None, win_profile=None, win_logonscript=None, win_description=None)
Ensure that the named user is present with the specified properties
name The name of the user to manage
uid The user id to assign, if left empty then the next available user id will be assigned
gid The default group id. Also accepts group name.
gid_from_name If True, the default group id will be set to the id of the group with the same name as the user,
  Default is False.
groups A list of groups to assign the user to, pass a list object. If a group specified here does not exist on the
  minion, the state will fail. If set to the empty list, the user will be removed from all groups except the
group default group. If unset, salt will assume current groups are still wanted (see issue #28706).
optional_groups A list of groups to assign the user to, pass a list object. If a group specified here does not
  exist on the minion, the state will silently ignore it.
NOTE: If the same group is specified in both `groups` and `optional_groups`, then it will be assumed to be
  required and not optional.
remove_groups Remove groups that the user is a member of that weren't specified in the state, Default is
  True.
home The custom login directory of user. Uses default value of underlying system if not set. Notice that this
directory does not have to exists. This also the location of the home directory to create if createhome is
set to True.
createhome [True] If set to False, the home directory will not be created if it doesn't already exist.

| Warning: Not supported on Windows or Mac OS. |
| Additionally, parent directories will not be created. The parent directory for home must already exist. |

password A password hash to set for the user. This field is only supported on Linux, FreeBSD, NetBSD,
OpenBSD, and Solaris. If the empty_password argument is set to True then password is ignored.
For Windows this is the plain text password.
Changed in version 0.16.0: BSD support added.
**enforce_password** Set to False to keep the password from being changed if it has already been set and the password hash differs from what is specified in the ```password``` field. This option will be ignored if ```password``` is not specified, Default is True.

**empty_password** Set to True to enable password-less login for user, Default is False.

**shell** The login shell, defaults to the system default shell

**unique** Require a unique UID, Default is True.

**system** Choose UID in the range of FIRST_SYSTEM_UID and LAST_SYSTEM_UID, Default is False.

**loginclass** The login class, defaults to empty (BSD only)

User comment field (GECOS) support (currently Linux, BSD, and MacOS only):

The below values should be specified as strings to avoid ambiguities when the values are loaded. (Especially the phone and room number fields which are likely to contain numeric data)

**fullname** The user's full name

**roomnumber** The user's room number (not supported in MacOS)

**workphone** The user's work phone number (not supported in MacOS)

**homephone** The user's home phone number (not supported in MacOS)

Changed in version 2014.7.0: Shadow attribute support added.

Shadow attributes support (currently Linux only):

The below values should be specified as integers.

**date** Date of last change of password, represented in days since epoch (January 1, 1970).

**mindays** The minimum number of days between password changes.

**maxdays** The maximum number of days between password changes.

**inactdays** The number of days after a password expires before an account is locked.

**warndays** Number of days prior to maxdays to warn users.

**expire** Date that account expires, represented in days since epoch (January 1, 1970).

The below parameters apply to windows only:

**win_homedrive** (Windows Only) The drive letter to use for the home directory. If not specified the home directory will be a unc path. Otherwise the home directory will be mapped to the specified drive. Must be a letter followed by a colon. Because of the colon, the value must be surrounded by single quotes. ie:

```
- win_homedrive: `U:
```

Changed in version 2015.8.0.

**win_profile** (Windows Only) The custom profile directory of the user. Uses default value of underlying system if not set.

Changed in version 2015.8.0.

**win_logonscript** (Windows Only) The full path to the logon script to run when the user logs in.

Changed in version 2015.8.0.

**win_description** (Windows Only) A brief description of the purpose of the users account.

Changed in version 2015.8.0.

### 32.29.168 salt.states.vbox_guest

VirtualBox Guest Additions installer state

salt.states.vbox_guest.additions_installed(name, reboot=False, upgrade_os=False)

Ensure that the VirtualBox Guest Additions are installed. Uses the CD, connected by VirtualBox.

**name** The name has no functional value and is only used as a tracking reference.

**reboot** [False] Restart OS to complete installation.

**upgrade_os** [False] Upgrade OS (to ensure the latests version of kernel and developer tools installed).

salt.states.vbox_guest.additions_removed(name, force=False)

Ensure that the VirtualBox Guest Additions are removed. Uses the CD, connected by VirtualBox.
To connect VirtualBox Guest Additions via VirtualBox graphical interface press 'Host+D' ('Host' is usually 'Right Ctrl').

- **name**: The name has no functional value and is only used as a tracking reference.
- **force**: Force VirtualBox Guest Additions removing.

```
salt.states.vbox_guest.grant_access_to_shared_folders_to(name, users=None)
```

Grant access to auto-mounted shared folders to the users.

- **name**: Name of the user to grant access to auto-mounted shared folders to.
- **users**: List of names of users to grant access to auto-mounted shared folders to. If specified, **name** will not be taken into account.

### 32.29.169 salt.states.victorops

Create an Event in VictorOps

New in version 2015.8.0.

This state is useful for creating events on the VictorOps service during state runs.

```
webserver-warning-message:
   victorops.create_event:
      - message_type: 'CRITICAL'
      - entity_id: 'webserver/diskspace'
      - state_message: 'Webserver diskspace is low.'
```

```
salt.states.victorops.create_event(name, message_type, routing_key='everyone', **kwargs)
```

Create an event on the VictorOps service

```
webserver-warning-message:
   victorops.create_event:
      - message_type: 'CRITICAL'
      - entity_id: 'webserver/diskspace'
      - state_message: 'Webserver diskspace is low.'
```

```
database-server-warning-message:
   victorops.create_event:
      - message_type: 'WARNING'
      - entity_id: 'db_server/load'
      - state_message: 'Database Server load is high.'
      - entity_is_host: True
      - entity_display_name: 'dbdserver.example.com'
```

The following parameters are required:

- **name**: This is a short description of the event.
- **message_type**: One of the following values: INFO, WARNING, ACKNOWLEDGEMENT, CRITICAL, RECOVERY.

The following parameters are optional:

- **routing_key**: The key for where messages should be routed. By default, sent to `everyone` route.
- **entity_id**: The name of alerting entity. If not provided, a random name will be assigned.
- **timestamp**: Timestamp of the alert in seconds since epoch. Defaults to the time the alert is received at VictorOps.
- **timestamp_fmt**: The date format for the timestamp parameter. Defaults to `%Y-%m-%dT%H:%M:%S'.
state_start_time  The time this entity entered its current state (seconds since epoch). Defaults to the time alert is received.

state_start_time_fmt  The date format for the timestamp parameter. Defaults to `%Y-%m-%dT%H:%M:%S`.

state_message  Any additional status information from the alert item.

entity_is_host  Used within VictorOps to select the appropriate display format for the incident.

entity_display_name  Used within VictorOps to display a human-readable name for the entity.

ack_message  A user entered comment for the acknowledgment.

ack_author  The user that acknowledged the incident.

32.29.170  salt.states.virtualenv

Setup of Python virtualenv sandboxes.

New in version 0.17.0.

salt.states.virtualenv_mod.managed(name,  
venv_bin=None,  
requirements=None,  
system_site_packages=False,  
distribute=False,  
use_wheel=False,  
clear=False,  
python=None,  
extra_search_dir=None,  
never_download=False,  
prompt=None,  
user=None,  
no_chown=False,  
cwd=None,  
index_url=None,  
extra_index_url=None,  
pre_releases=False,  
no_deps=False,  
pip_download=None,  
pip_download_cache=None,  
pip_exists_action=None,  
proxy=None,  
use_vt=False,  
env_vars=None,  
pip_upgrade=False,  
pip_pkgs=None)

Create a virtualenv and optionally manage it with pip

name  Path to the virtualenv.

requirements: None  Path to a pip requirements file. If the path begins with salt:// the file will be transferred from the master file server.

use_wheel: False  Prefer wheel archives (requires pip >= 1.4).

user: None  The user under which to run virtualenv and pip.

no_chown: False  When user is given, do not attempt to copy and chown a requirements file (needed if the requirements file refers to other files via relative paths, as the copy-and-chown procedure does not account for such files)

cwd: None  Path to the working directory where pip install is executed.

no_deps: False  Pass --no-deps to pip install.

pip_exists_action: None  Default action of pip when a path already exists: (s)witch, (i)gnore, (w)ipe, (b)ackup.

proxy: None  Proxy address which is passed to pip install.

env_vars: None  Set environment variables that some builds will depend on. For example, a Python C-module may have a Makefile that needs INCLUDE_PATH set to pick up a header file while compiling.

pip_upgrade: False  Pass --upgrade to pip install.

pip_pkgs: None  As an alternative to requirements, pass a list of pip packages that should be installed. Also accepts any kwargs that the virtualenv module will. However, some kwargs, such as the pip option, require --distribute: True.

//var/www/myvirtualenv.com:
virtualenv.managed:
  - system_site_packages: False
  - requirements: salt://REQUIREMENTS.txt
32.29.171 salt.states.win_dacl

Windows Object Access Control Lists

Ensure an ACL is present

parameters: name - the path of the object objectType - Registry/File/Directory user - user account for the ace permission - permission for the ace (see module win_acl for available permissions for each objectType) acetype - Allow/Deny propagation - how the ACL should apply to child objects (see module win_acl for available propagation types)

```
addAcl:
  win_dacl.present:
    - name: HKEY_LOCAL_MACHINE\SOFTWARE\mykey
    - objectType: Registry
    - user: FakeUser
    - permission: FullControl
    - acetype: ALLOW
    - propagation: KEY&SUBKEYS
```

Ensure an ACL does not exist

parameters: name - the path of the object objectType - Registry/File/Directory user - user account for the ace permission - permission for the ace (see module win_acl for available permissions for each objectType) acetype - Allow/Deny propagation - how the ACL should apply to child objects (see module win_acl for available propagation types)

```
removeAcl:
  win_dacl.absent:
    - name: HKEY_LOCAL_MACHINE\SOFTWARE\mykey
    - objectType: Registry
    - user: FakeUser
    - permission: FullControl
    - acetype: ALLOW
    - propagation: KEY&SUBKEYS
```

Ensure an object is inheriting permissions

parameters: name - the path of the object objectType - Registry/File/Directory clear_existing_acl - True/False - when inheritance is enabled, should the existing ACL be kept or cleared out

```
eInherit:
  win_dacl.enableinheritance:
    - name: HKEY_LOCAL_MACHINE\SOFTWARE\mykey
    - objectType: Registry
    - clear_existing_acl: True
```

Ensure an object is not inheriting permissions
**parameters:** name - the path of the object objectType - Registry/File/Directory copy_inherited_acl - True/False - if inheritance is enabled, should the inherited permissions be copied to the ACL when inheritance is disabled

**salt.states.win_dacl**

- **absent**(name, objectType, user, permission, acetype, propagation)
  Ensure a Linux ACL does not exist
- **disinherit**(name, objectType, copy_inherited_acl=True)
  Ensure an object is not inheriting ACLs from its parent
- **inherit**(name, objectType, clear_existing_acl=False)
  Ensure an object is inheriting ACLs from its parent
- **present**(name, objectType, user, permission, acetype, propagation)
  Ensure an ACE is present

**32.29.172 salt.states.win_dns_client**

Module for configuring DNS Client on Windows systems

- **dns_dhcp**(name, interface='Local Area Connection')
  Configure the DNS server list from DHCP Server
- **dns_exists**(name, servers=None, interface='Local Area Connection', replace=False)
  Configure the DNS server list in the specified interface

Example:

```python
config_dns_servers:
  win_dns_client.dns_exists:
    - replace: True #remove any servers not in the "servers" list, default is False
    - servers:
      - 8.8.8.8
      - 8.8.8.9
```

- **primary_suffix**(name, suffix=None, updates=False)
  New in version 2014.7.0.
  Configure the global primary DNS suffix of a DHCP client.
  suffix [None] The suffix which is advertised for this client when acquiring a DHCP lease When none is set, the explicitly configured DNS suffix will be removed.
  updates [False] Allow syncing the DNS suffix with the AD domain when the client’s AD domain membership changes

Example:

```python
primary_dns_suffix:
  win_dns_client.primary_suffix:
    - suffix: sub.domain.tld
    - updates: True
```
32.29.173 salt.states.win_firewall

State for configuring Windows Firewall

salt.states.win_firewall.add_rule(name, localport, protocol='tcp', action='allow', dir='in')
Add a new firewall rule (Windows only)

salt.states.win_firewall.disabled(name)
Disable all the firewall profiles (Windows only)

32.29.174 salt.states.win_network

Configuration of network interfaces on Windows hosts

New in version 2014.1.0.

This module provides the network state(s) on Windows hosts. DNS servers, IP addresses and default gateways can currently be managed.

Below is an example of the configuration for an interface that uses DHCP for both DNS servers and IP addresses:

```
Local Area Connection #2:
  network.managed:
    - dns_proto: dhcp
    - ip_proto: dhcp
```

Note: Both the dns_proto and ip_proto arguments are required.

Static DNS and IP addresses can be configured like so:

```
Local Area Connection #2:
  network.managed:
    - dns_proto: static
      - dns_servers:
        - 8.8.8.8
        - 8.8.4.4
    - ip_proto: static
      - ip_addrs:
        - 10.2.3.4/24
```

Note: IP addresses are specified using the format <ip-address>/<subnet-length>. Salt provides a convenience function called ip.get_subnet_length to calculate the subnet length from a netmask.

Optionally, if you are setting a static IP address, you can also specify the default gateway using the gateway parameter:

```
Local Area Connection #2:
  network.managed:
    - dns_proto: static
      - dns_servers:
        - 8.8.8.8
```
salt.states.win_network.managed(name, dns_proto=None, dns_servers=None, ip_proto=None, ip_addrs=None, gateway=None, enabled=True, **kwargs)

Ensure that the named interface is configured properly.

- **name** The name of the interface to manage
- **dns_proto** [None] Set to static and use the dns_servers parameter to provide a list of DNS name-servers. Set to dhcp to use DHCP to get the DNS servers.
- **dns_servers** [None] A list of static DNS servers.
- **ip_proto** [None] Set to static and use the ip_addrs and (optionally) gateway parameters to provide a list of static IP addresses and the default gateway. Set to dhcp to use DHCP.
- **ip_addrs** [None] A list of static IP addresses.
- **gateway** [None] A list of static IP addresses.
- **enabled** [True] Set to False to ensure that this interface is disabled.

### 32.29.175 salt.states.win_path

Manage the Windows System PATH

salt.states.win_path.absent(name)

Remove the directory from the SYSTEM path

- **index** where the directory should be placed in the PATH (default: 0)

Example:

```
'C:\sysinternals':
  win_path.absent
```

salt.states.win_path.exists(name, index=None)

Add the directory to the system PATH at index location

- **index** where the directory should be placed in the PATH (default: None) [Note: Providing no index will append directory to PATH and will not enforce its location within the PATH.]

Example:

```
'C:\python27':
  win_path.exists
'C:\sysinternals':
  win_path.exists:
    index: 0
```

### 32.29.176 salt.states.win_powercfg

This module allows you to control the power settings of a windows minion via powercfg.

New in version 2015.8.0.
monitor:
    powercfg.set_timeout:
    - value: 30
    - power: dc

salt.states.win_powercfg.set_timeout(name, value, power='ac')

Set the sleep timeouts of specific items such as disk, monitor.

CLI Example:

    monitor:
        powercfg.set_timeout:
          - value: 30
          - power: dc
    disk:
        powercfg.set_timeout:
          - value: 12
          - power: ac

name  The setting to change, can be one of the following: monitor, disk, standby, hibernate

timeout  The amount of time in minutes before the item will timeout i.e the monitor
timeout

power  Should we set the value for AC or DC (battery)? Valid options ac,dc.

32.29.177 salt.states.win_servermanager

Manage Windows features via the ServerManager powershell module

salt.states.win_servermanager.installed(name, recurse=False, force=False, source=None, restart=False, exclude=None)

Install the windows feature

Args:

name (str): Short name of the feature (the right column in win_servermanager.list_available)

recurse (Optional[bool]): install all sub-features as well force (Optional[bool]): if the feature is installed but one of its

sub-features are not installed set this to True to force the installation of the sub-features

source (Optional[str]): Path to the source files if missing from the target system. None means that the system will use windows update services to find the required files. Default is None

restart (Optional[bool]): Restarts the computer when installation is complete, if required by the role-feature installed. Default is False

exclude (Optional[str]): The name of the feature to exclude when installing the named feature.

Note: Some features require reboot after un/installation. If so, until the server is restarted other features can not be installed!

Example: Run salt minionName win_servermanager.list_available to get a list of available roles and features. Use the name in the right column. Do not use the role or feature names mentioned in the PKGMGR documentation. In this example for IIS-WebServerRole the name to be used is Web-Server.

ISWebserverRole:
  win_servermanager.installed:
    - force: True
salt.states.win_servermanager.removed(name, remove_payload=False, restart=False)

Remove the windows feature

Args:

- name (str): Short name of the feature (the right column in win_servermanager.list_available)
- remove_payload (Optional[bool]): True will case the feature to be removed from the side-by-side store
- restart (Optional[bool]): Restarts the computer when uninstall is complete, if required by the role/feature removed. Default is False

Note: Some features require a reboot after uninstallation. If so the feature will not be completely uninstalled until the server is restarted.

Example: Run salt MinionName win_servermanager.list_installed to get a list of all features installed. Use the top name listed for each feature, not the indented one. Do not use the role or feature names mentioned in the PKGMGR documentation.

32.29.178 salt.states.win_system

Management of Windows system information

New in version 2014.1.0.

This state is used to manage system information such as the computer name and description.

salt.states.win_system.computer_desc(name)
Manage the computer's description field

name The desired computer description

salt.states.win_system.computer_name(name)
Manage the computer's name

name The desired computer name

32.29.179 salt.states.win_update

Management of the windows update agent

New in version 2014.7.0.

Set windows updates to run by category. Default behavior is to install all updates that do not require user interaction to complete.
Optionally set category to a category of your choice to only install certain updates. Default is to set to install all available updates.

The following example will install all Security and Critical Updates, and download but not install standard updates.

```yaml
updates:
  win_update.installed:
    - categories:
    - 'Critical Updates'
    - 'Security Updates'
    - skips:
      - downloaded
  win_update.downloaded:
    - categories:
    - 'Updates'
    - skips:
      - downloaded
```

You can also specify a number of features about the update to have a fine grain approach to specific types of updates. These are the following features/states of updates available for configuring:

- 'UI' - User interaction required, skipped by default
- 'downloaded' - Already downloaded, included by default
- 'present' - Present on computer, skipped by default
- 'installed' - Already installed, skipped by default
- 'reboot' - Reboot required, included by default
- 'hidden' - Skip updates that have been hidden, skipped by default
- 'software' - Software updates, included by default
- 'driver' - driver updates, included by default

The following example installs all driver updates that don't require a reboot:

```yaml
gryffindor:
  win_update.installed:
    - skips: - driver: True - software: False - reboot: False
```

To just update your windows machine, add this your sls:

```python
class salt.states.win_update.PyWinUpdater(categories=None, skipUI=True, skipDownloaded=False, skipInstalled=True, skipReboot=False, skipPresent=False, skipSoftwareUpdates=False, skipDriverUpdates=False, skipHidden=True)
```

AutoSearch()
Download()
GetAvailableCategories()
GetCategories()
GetDownloadResults()
GetInstallationResults()
Install()
Search(searchString)
SetCategories(categories)
SetSkip(skip, state)
**SetSkips** *(skips)*

* `salt.states.win_update.downloaded(name, categories=None, skips=None, retries=10)`: Cache updates for later install.
  - **name**: if categories is left empty, it will be assumed that you are passing the category option through the name. These are separate because you can only have one name, but can have multiple categories.
  - **categories**: the list of categories to be downloaded. These are simply strings in the update's information, so there is no enumeration of the categories available. Some known categories:

<table>
<thead>
<tr>
<th>Updates</th>
<th>Windows 7</th>
<th>Critical Updates</th>
<th>Security Updates</th>
<th>Update Rollups</th>
</tr>
</thead>
<tbody>
<tr>
<td>'Updates'</td>
<td>'Windows 7'</td>
<td>'Critical Updates'</td>
<td>'Security Updates'</td>
<td>'Update Rollups'</td>
</tr>
</tbody>
</table>

  - **skips**: a list of features of the updates to cull by. Available features:

    | 'UI' | 'downloaded' | 'present' | 'installed' | 'reboot' | 'hidden' | 'software' | 'driver' |
    |------|-------------|-----------|-------------|--------|--------|-----------|--------|
    | 'UI' | 'downloaded' | 'present' | 'installed' | 'reboot' | 'hidden' | 'software' | 'driver' |

  - **retries**: Number of retries to make before giving up. This is total, not per step.

* `salt.states.win_update.installed(name, categories=None, skips=None, retries=10)`: Install specified windows updates.
  - **name**: if categories is left empty, it will be assumed that you are passing the category option through the name. These are separate because you can only have one name, but can have multiple categories.
  - **categories**: the list of categories to be downloaded. These are simply strings in the update's information, so there is no enumeration of the categories available. Some known categories:

<table>
<thead>
<tr>
<th>Updates</th>
<th>Windows 7</th>
<th>Critical Updates</th>
<th>Security Updates</th>
<th>Update Rollups</th>
</tr>
</thead>
<tbody>
<tr>
<td>'Updates'</td>
<td>'Windows 7'</td>
<td>'Critical Updates'</td>
<td>'Security Updates'</td>
<td>'Update Rollups'</td>
</tr>
</tbody>
</table>

  - **skips**: a list of features of the updates to cull by. Available features:

    | 'UI' | 'downloaded' | 'present' | 'installed' | 'reboot' | 'hidden' | 'software' | 'driver' |
    |------|-------------|-----------|-------------|--------|--------|-----------|--------|
    | 'UI' | 'downloaded' | 'present' | 'installed' | 'reboot' | 'hidden' | 'software' | 'driver' |

  - **retries**: Number of retries to make before giving up. This is total, not per step.

### 32.29.180 `salt.states.winrepo`

Manage Windows Package Repository

* `salt.states.winrepo.genrepo(name, force=False, allow_empty=False)`: Refresh the winrepo.p file of the repository (salt-run winrepo.genrepo)
If `force` is `True` no checks will be made and the repository will be generated if `allow_empty` is `True` then the state will not return an error if there are 0 packages.

---

**Note:** This state only loads on minions that have the roles: `salt-master` grain set.

Example:

```yaml
winrepo:
  - winrepo.genrepo
```

### 32.29.181 salt.states.x509

Manage X509 Certificates

New in version 2015.8.0.

This module can enable managing a complete PKI infrastructure including creating private keys, CAs, certificates and CRLs. It includes the ability to generate a private key on a server, and have the corresponding public key sent to a remote CA to create a CA signed certificate. This can be done in a secure manner, where private keys are always generated locally and never moved across the network.

Here is a simple example scenario. In this example `ca` is the CA server, and `www` is a web server that needs a certificate signed by `ca`.

For remote signing, peers must be permitted to remotely call the `sign_remote_certificate` function.

```
/etc/salt/master.d/peer.conf
```

```yaml
peer:
  .*:
    - x509.sign_remote_certificate
```

```
/srv/salt/top.sls
```

```yaml
base:
  'x*':
    - cert
  'ca':
    - ca
  'www':
    - www
```

This state creates the CA key, certificate and signing policy. It also publishes the certificate to the mine where it can be easily retrieved by other minions.

```
/srv/salt/ca.sls
```

```yaml
salt-minion:
  service.running:
    - enable: True
    - listen:
      - file: /etc/salt/minion.d/signing_policies.conf

/etc/salt/minion.d/signing_policies.conf:
  file.managed:
    - source: salt://signing_policies.conf
```
The signing policy defines properties that override any property requested or included in a CRL. It also can define a restricted list of minions which are allowed to remotely invoke this signing policy.

```
/etc/pki:
  file.directory: []

/etc/pki/issued_certs:
  file.directory: []

/etc/pki/ca.key:
  x509.private_key_managed:
    - bits: 4096
    - backup: True
    - require:
      - file: /etc/pki

/etc/pki/ca.crt:
  x509.certificate_managed:
    - signing_private_key: /etc/pki/ca.key
    - CN: ca.example.com
    - C: US
    - ST: Utah
    - L: Salt Lake City
    - basicConstraints: "critical CA:true"
    - keyUsage: "critical cRLSign, keyCertSign"
    - subjectKeyIdentifier: hash
    - authorityKeyIdentifier: keyid,issuer:always
    - days_valid: 3650
    - days_remaining: 0
    - backup: True
    - require:
      - x509: /etc/pki/ca.key

mine.send:
  module.run:
    - func: x509.get_pem_entries
    - kwargs:
      - glob_path: /etc/pki/ca.crt
    - onchanges:
      - x509: /etc/pki/ca.crt

```

```
x509_signing_policies:
  www:
    - minions: 'www'
    - signing_private_key: /etc/pki/ca.key
    - signing_cert: /etc/pki/ca.crt
    - C: US
    - ST: Utah
    - L: Salt Lake City
    - basicConstraints: "critical CA:false"
    - keyUsage: "critical cRLSign, keyCertSign"
    - subjectKeyIdentifier: hash
    - authorityKeyIdentifier: keyid,issuer:always
    - days_valid: 90
    - copypath: /etc/pki/issued_certs/
```
This state will instruct all minions to trust certificates signed by our new CA. Using Jinja to strip newlines from the text avoids dealing with newlines in the rendered yaml, and the `sign_remote_certificate` state will handle properly formatting the text before writing the output.

```
/srv/salt/cert.sls

/usr/local/share/ca-certificates:
    file.directory: []

/usr/local/share/ca-certificates/intca.crt:
    x509.pem_managed:
        - text: {{ salt['mine.get']('ca', 'x509.get_pem_entries')['ca']=['/etc/pki/ca.crt']|replace('
', '') }}

This state creates a private key then requests a certificate signed by ca according to the www policy.

/srv/salt/www.sls

/etc/pki/www.key:
    x509.private_key_managed:
        - bits: 4096

/etc/pki/www.crt:
    x509.certificate_managed:
        - ca_server: ca
        - signing_policy: www
        - public_key: /etc/pki/www.key
        - CN: www.example.com
        - days_remaining: 30
        - backup: True

salt.states.x509.certificate_managed(name, days_remaining=90, backup=False, **kwargs)
Manage a Certificate

name: Path to the certificate
days_remaining: The minimum number of days remaining when the certificate should be recreated. Default is 90. A value of 0 disables automatic renewal.
backup: When replacing an existing file, backup the old file on the minion. Default is False.
kwargs: Any arguments supported by x509.create_certificate are supported.
Examples:

/etc/pki/ca.crt:
    x509.certificate_managed:
        - signing_private_key: /etc/pki/ca.key
        - CN: ca.example.com
        - C: US
        - ST: Utah
        - L: Salt Lake City
        - basicConstraints: "critical CA:true"
        - keyUsage: "critical cRLSign, keyCertSign"
        - subjectKeyIdentifier: hash
        - authorityKeyIdentifier: keyid,issuer:always
        - days_valid: 3650
        - days_remaining: 0
        - backup: True

/etc/ssl/www.crt:
    x509.certificate_managed:
        - ca_server: pki
```
- signing_policy: www
- public_key: /etc/ssl/www.key
- CN: www.example.com
- days_valid: 90
- days_remaining: 30
- backup: True

salt.states.x509.crl_managed(name, signing_private_key, signing_cert=None, revoked=None, days_valid=100, days_remaining=30, include_expired=False, backup=False)

Manage a Certificate Revocation List
name: Path to the certificate
signing_private_key: The private key that will be used to sign this crl. This is usually your CA's private key.
signing_cert: The certificate of the authority that will be used to sign this crl. This is usually your CA's certificate.
revoked: A list of certificates to revoke. Must include either a serial number or a the certificate itself. Can optionally include the revocation date and notAfter date from the certificate. See example below for details.
days_valid: The number of days the certificate should be valid for. Default is 100.
days_remaining: The crl should be automatically recreated if there are less than days_remaining days until the crl expires. Set to 0 to disable automatic renewal. Default is 30.
include_expired: Include expired certificates in the CRL. Default is False.
backup: When replacing an existing file, backup the old file on the minion. Default is False.

Example:

/etc/pki/ca.crl:
x509.crl_managed:
  - signing_private_key: /etc/pki/myca.key
  - signing_cert: /etc/pki/myca.crt
  - revoked:
    - compromised_web_key:
      - certificate: /etc/pki/certs/badweb.crt
      - revocation_date: 2015-03-01 00:00:00
      - reason: keyCompromise
    - terminated_vpn_user:
      - serial_number: D6:D2:DC:D8:4D:5C:C0:F4
      - not_after: 2016-01-01 00:00:00
      - revocation_date: 2015-02-25 00:00:00
      - reason: cessationOfOperation

salt.states.x509.csr_managed(name, backup=False, **kwargs)

Manage a Certificate Signing Request
name: Path to the CSR
properties: The properties to be added to the certificate request, including items like subject, extensions and public key. See above for valid properties.

Example:

/etc/pki/mycert.csr:
x509.csr_managed:
  - public_key: /etc/pki/mycert.key
  - CN: www.example.com
  - C: US
  - ST: Utah
  - L: Salt Lake City
  - keyUsage: 'critical dataEncryption'
salt.states.x509.pem_managed(name, text, backup=False)

Manage the contents of a PEM file directly with the content in text, ensuring correct formatting.

- **name**: The path to the file to manage
- **text**: The PEM formatted text to write.
- **backup**: When replacing an existing file, backup the old file on the minion. Default is False.

salt.states.x509.private_key_managed(name, bits=2048, new=False, backup=False)

Manage a private key's existence.

- **name**: Path to the private key
- **bits**: Key length in bits. Default 2048.
- **new**: Always create a new key. Defaults to False. Combining new with prereq can allow key rotation whenever a new certificate is generated.
- **backup**: When replacing an existing file, backup the old file on the minion. Default is False.

Example:
The jinja templating in this example ensures a private key is generated if the file doesn't exist and that a new private key is generated whenever the certificate that uses it is to be renewed.

```
/etc/pki/www.key:
  x509.private_key_managed:
    - bits: 4096
    - new: True
    {% if salt['file.file_exists']('/etc/pki/ca.key') -%}
    - prereq:
      - x509: /etc/pki/www.crt
    {%- endif %}
```

32.29.182 salt.states.xmpp

Sending Messages over XMPP

New in version 2014.1.0.

This state is useful for firing messages during state runs, using the XMPP protocol

```
salt.states.xmpp.send_msg(name, recipient, profile)

Send a message to an XMPP user

```

```
salt.states.xmpp.send_msg_multi(name, profile, recipients=None, rooms=None)

Send a message to an list of recipients or rooms

```

name The message to send to the XMPP user
name: 'This is a server warning message'
- profile: my-xmpp-account
- recipients:
  - admins@xmpp.example.com/salt
- rooms:
  - qa@conference.xmpp.example.com

name  The message to send to the XMPP user

### 32.29.183  salt.states.zcbuildout

Management of zc.buildout

This module is inspired from minitage’s buildout maker ([https://github.com/minitage/minitage/blob/master/src/minitage/core/makers/buildout.py](https://github.com/minitage/minitage/blob/master/src/minitage/core/makers/buildout.py))

New in version Boron.

**Note:** This state module is beta; the API is subject to change and no promise as to performance or functionality is yet present

#### Available Functions

- built

```python
installed1
buildout.installed:
  - name: /path/to/buildout

installed2
buildout.installed:
  - name: /path/to/buildout
  - parts:
    - a
    - b
  - python: /path/to/pythonpath/bin/python
  - unless: /bin/test_something_installed
  - onlyif: /bin/test_else_installed
```

**salt.states.zcbuildout**.installed(name, config='buildout.cfg', quiet=False, parts=None, user=None, env=(), buildout_ver=None, test_release=False, distribute=None, new_st=None, offline=False, newest=False, python='usr/bin/python', debug=False, verbose=False, unless=None, onlyif=None, use_vt=False, loglevel='debug', **kwargs)

Install buildout in a specific directory

It is a thin wrapper to modules.buildout.buildout

- **name**  directory to execute in
- **quiet**  do not output console & logs
- **config**  buildout config to use (default: buildout.cfg)
parts specific buildout parts to run
user user used to run buildout as

New in version 2014.1.4.
env environment variables to set when running
buildout_ver force a specific buildout version (1 | 2)
test_release buildout accept test release
new_st Forcing use of setuptools >= 0.7
distribute use distribute over setuptools if possible
offline does buildout run offline
python python to use
debg run buildout with -D debug flag
onlyif Only execute cmd if statement on the host return 0
unless Do not execute cmd if statement on the host return 0
newest run buildout in newest mode
verbose run buildout in verbose mode (-vvvvv)
use_vt Use the new salt VT to stream output [experimental]
loglevel loglevel for buildout commands

32.29.184 salt.states.zk_concurrency

Control concurrency of steps within state execution using zookeeper

This module allows you to "wrap" a state's execution with concurrency control. This is useful to protect against all hosts executing highstate simultaneously if your services don't all HUP restart. The common way of protecting against this is to run in batch mode, but that doesn't protect from another person running the same batch command (and thereby having 2x the number of nodes deploying at once).

This module will block while acquiring a slot, meaning that however the command gets called it will coordinate with zookeeper to ensure that no more than max_concurrency steps are executing with a single path.

```yaml
acquire_lock:
  zk_concurrency.lock:
    - name: /trafficeserver
    - zk_hosts: 'zookeeper:2181'
    - max_concurrency: 4
    - prereq:
      - service: trafficserver

trafficserver:
  service.running:
    - watch:
      - file: /etc/trafficeserver/records.config

/etc/trafficeserver/records.config:
  file.managed:
    - source: salt://records.config

release_lock:
  zk_concurrency.unlock:
    - name: /trafficeserver
    - require:
      - service: trafficserver
```

This example would allow the file state to change, but would limit the concurrency of the trafficserver service restart to 4.
salt.states.zk_concurrency.lock(name, zk_hosts, identifier=None, max_concurrency=1, timeout=None, ephemeral_lease=False)

Block state execution until you are able to get the lock (or hit the timeout)

salt.states.zk_concurrency.min_party(name, zk_hosts, min_nodes)

Ensure that there are min_nodes in the party at name.

salt.states.zk_concurrency.unlock(name, zk_hosts=None, identifier=None, max_concurrency=1, ephemeral_lease=False)

Remove lease from semaphore.

32.30 Execution Modules

Salt execution modules are the functions called by the `salt` command.

**Note:** Salt execution modules are different from state modules and cannot be called directly within state files. You must use the `module` state module to call execution modules within state runs.

See also:

Full list of builtin modules

Salt ships with many modules that cover a wide variety of tasks.

32.30.1 Modules Are Easy to Write!

Writing Salt execution modules is straightforward.

A Salt execution module is a Python or Cython module placed in a directory called `_modules/` within the `file_roots` as specified by the master config file. By default this is `/srv/salt/_modules` on Linux systems.

Modules placed in `_modules/` will be synced to the minions when any of the following Salt functions are called:

- `state.apply`
- `saltutil.sync_modules`
- `saltutil.sync_all`

Note that a module's default name is its filename (i.e. `foo.py` becomes module `foo`), but that its name can be overridden by using a `__virtual__ function`.

If a Salt module has errors and cannot be imported, the Salt minion will continue to load without issue and the module with errors will simply be omitted.

If adding a Cython module the file must be named `<modulename>.pyx` so that the loader knows that the module needs to be imported as a Cython module. The compilation of the Cython module is automatic and happens when the minion starts, so only the `.pyx` file is required.

32.30.2 Zip Archives as Modules

Python 2.3 and higher allows developers to directly import zip archives containing Python code. By setting `enable_zip_modules` to `True` in the minion config, the Salt loader will be able to import `.zip` files in this fashion. This allows Salt module developers to package dependencies with their modules for ease of deployment, isolation, etc.
For a user, Zip Archive modules behave just like other modules. When executing a function from a module provided as the file `my_module.zip`, a user would call a function within that module as `my_module.<function>`.

### Creating a Zip Archive Module

A Zip Archive module is structured similarly to a simple Python package. The `.zip` file contains a single directory with the same name as the module. The module code traditionally in `<module_name>.py` goes in `<module_name>/__init__.py`. The dependency packages are subdirectories of `<module_name>/`.

Here is an example directory structure for the `lumberjack` module, which has two library dependencies (sleep and work) to be included.

```bash
modules $ ls -R lumberjack
__init__.py  sleep  work
lumberjack/sleep:  __init__.py
lumberjack/work:   __init__.py
```

The contents of `lumberjack/__init__.py` show how to import and use these included libraries.

```python
# Libraries included in lumberjack.zip
from lumberjack import sleep, work

def is_ok(person):
    ''' Checks whether a person is really a lumberjack '''
    return sleep.all_night(person) and work.all_day(person)
```

Then, create the zip:

```bash
modules $ zip -r lumberjack lumberjack
adding: lumberjack/ (stored 0%)
adding: lumberjack/__init__.py (deflated 39%)
adding: lumberjack/sleep/ (stored 0%)
adding: lumberjack/sleep/__init__.py (deflated 7%)
adding: lumberjack/work/ (stored 0%)
adding: lumberjack/work/__init__.py (deflated 7%)
modules $ unzip -l lumberjack.zip
Archive: lumberjack.zip
Length Date Time Name
-------- ---- ---- ----
348 08-21-15 20:08 lumberjack/__init__.py
0 08-21-15 19:53 lumberjack/sleep/
0 08-21-15 19:53 lumberjack/sleep/__init__.py
83 08-21-15 19:53 lumberjack/work/
0 08-21-15 19:53 lumberjack/work/__init__.py
81 08-21-15 19:21 lumberjack/work/__init__.py
512
```

Once placed in `file_roots`, Salt users can distribute and use `lumberjack.zip` like any other module.

```bash
$ sudo salt minion1 saltutil.sync_modules
minion1:
```
$ sudo salt minion1 lumberjack.is_ok 'Michael Palin'
iminion1:
  True

32.30.3 Cross Calling Execution Modules

All of the Salt execution modules are available to each other and modules can call functions available in other
execution modules.

The variable __salt__ is packed into the modules after they are loaded into the Salt minion.

The __salt__ variable is a Python dictionary containing all of the Salt functions. Dictionary keys are strings
representing the names of the modules and the values are the functions themselves.

Salt modules can be cross-called by accessing the value in the __salt__ dict:

```python
def foo(bar):
    return __salt__['cmd.run'](bar)
```

This code will call the run function in the cmd module and pass the argument bar to it.

32.30.4 Preloaded Execution Module Data

When interacting with execution modules often it is nice to be able to read information dynamically about the minion
or to load in configuration parameters for a module.

Salt allows for different types of data to be loaded into the modules by the minion.

Grains Data

The values detected by the Salt Grains on the minion are available in a dict named __grains__ and can be accessed
from within callable objects in the Python modules.

To see the contents of the grains dictionary for a given system in your deployment run the grains.items() function:

```bash
salt 'hostname' grains.items --output=pprint
```

Any value in a grains dictionary can be accessed as any other Python dictionary. For example, the grain rep-
resenting the minion ID is stored in the id key and from an execution module, the value would be stored in
__grains__['id'].

Module Configuration

Since parameters for configuring a module may be desired, Salt allows for configuration information from the minion
configuration file to be passed to execution modules.

Since the minion configuration file is a YAML document, arbitrary configuration data can be passed in the minion
config that is read by the modules. It is therefore strongly recommended that the values passed in the configuration
file match the module name. A value intended for the test execution module should be named test.<value>.

The test execution module contains usage of the module configuration and the default configuration file for the min-
ion contains the information and format used to pass data to the modules. salt.modules.test.conf/minion.
### 32.30.5 Printout Configuration

Since execution module functions can return different data, and the way the data is printed can greatly change the presentation, Salt has a printout configuration.

When writing a module the `__outputter__` dictionary can be declared in the module. The `__outputter__` dictionary contains a mapping of function name to Salt Outputter.

```python
__outputter__ = {
    'run': 'txt'
}
```

This will ensure that the text outputter is used.

### 32.30.6 Virtual Modules

Virtual modules let you override the name of a module in order to use the same name to refer to one of several similar modules. The specific module that is loaded for a virtual name is selected based on the current platform or environment.

For example, packages are managed across platforms using the `pkg` module. `pkg` is a virtual module name that is an alias for the specific package manager module that is loaded on a specific system (for example, `yumpkg` on RHEL/CentOS systems, and `aptpkg` on Ubuntu).

Virtual module names are set using the `__virtual__` function and the `virtual name`.

### 32.30.7 `__virtual__` Function

The `__virtual__` function returns either a string, `True`, `False`, or `False` with an error string. If a string is returned then the module is loaded using the name of the string as the virtual name. If `True` is returned the module is loaded using the current module name. If `False` is returned the module is not loaded. `False` lets the module perform system checks and prevent loading if dependencies are not met.

Since `__virtual__` is called before the module is loaded, `__salt__` will be unavailable as it will not have been packed into the module at this point in time.

**Note:** Modules which return a string from `__virtual__` that is already used by a module that ships with Salt will _override_ the stock module.

#### Returning Error Information from `__virtual__`

Optionally, Salt plugin modules, such as execution, state, returner, beacon, etc. modules may additionally return a string containing the reason that a module could not be loaded. For example, an execution module called `cheese` and a corresponding state module also called `cheese`, both depending on a utility called `enzymes` should have `__virtual__` functions that handle the case when the dependency is unavailable.

```python
# Cheese execution (or returner/beacon/etc.) module

try:
    import enzymes
    HAS_ENZYMES = True
except ImportError:
```

---

2140 Chapter 32. Reference
HAS_ENZYMES = False

def __virtual__():
    '''
    only load cheese if enzymes are available
    '''
    if HAS_ENZYMES:
        return 'cheese'
    else:
        return False, 'The cheese execution module cannot be loaded: enzymes unavailable.'

def __virtual__():
    '''
    only load cheese if enzymes are available
    '''
    # predicate loading of the cheese state on the corresponding execution module
    if 'cheese.slice' in __salt__:
        return 'cheese'
    else:
        return False, 'The cheese state module cannot be loaded: enzymes unavailable.'

Examples

The package manager modules are among the best examples of using the __virtual__ function. A table of all the virtual pkg modules can be found here.

Overriding Virtual Module Providers

Salt often uses OS grains (os, osrelease, os_family, etc.) to determine which module should be loaded as the virtual module for pkg, service, etc. Sometimes this OS detection is incomplete, with new distros popping up, existing distros changing init systems, etc. The virtual modules likely to be affected by this are in the list below (click each item for more information):

- pkg
- service
- user
- shadow
- group

If Salt is using the wrong module for one of these, first of all, please report it on the issue tracker, so that this issue can be resolved for a future release. To make it easier to troubleshoot, please also provide the grains.items output, taking care to redact any sensitive information.

Then, while waiting for the SaltStack development team to fix the issue, Salt can be made to use the correct module using the providers option in the minion config file:
The above example will force the minion to use the `systemd` module to provide service management, and the `aptpkg` module to provide package management.

### 32.30.8 __virtualname__

`__virtualname__` is a variable that is used by the documentation build system to know the virtual name of a module without calling the `__virtual__` function. Modules that return a string from the `__virtual__` function must also set the `__virtualname__` variable.

To avoid setting the virtual name string twice, you can implement `__virtual__` to return the value set for `__virtualname__` using a pattern similar to the following:

```python
# Define the module's virtual name
__virtualname__ = 'pkg'

def __virtual__():
    '''
    Confine this module to Mac OS with Homebrew.
    '''
    if salt.utils.which('brew') and __grains__['os'] == 'MacOS':
        return __virtualname__
    return False
```

### 32.30.9 Documentation

Salt execution modules are documented. The `sys.doc()` function will return the documentation for all available modules:

```
salt '*' sys.doc
```

The `sys.doc` function simply prints out the docstrings found in the modules; when writing Salt execution modules, please follow the formatting conventions for docstrings as they appear in the other modules.

#### Adding Documentation to Salt Modules

It is strongly suggested that all Salt modules have documentation added.

To add documentation add a Python docstring to the function.

```python
def spam(eggs):
    '''
    A function to make some spam with eggs!
    
    CLI Example::
    
    salt '*' test.spam eggs
    '''
    return eggs
```
Now when the sys.doc call is executed the docstring will be cleanly returned to the calling terminal.

Documentation added to execution modules in docstrings will automatically be added to the online web-based documentation.

### Add Execution Module Metadata

When writing a Python docstring for an execution module, add information about the module using the following field lists:

```
:maintainer: Thomas Hatch <thatch@saltstack.com, Seth House <shouse@saltstack.com>
:maturity: new
:depends: python-mysqldb
:platform: all
```

The maintainer field is a comma-delimited list of developers who help maintain this module.

The maturity field indicates the level of quality and testing for this module. Standard labels will be determined.

The depends field is a comma-delimited list of modules that this module depends on.

The platform field is a comma-delimited list of platforms that this module is known to run on.

### 32.30.10 Log Output

You can call the logger from custom modules to write messages to the minion logs. The following code snippet demonstrates writing log messages:

```python
import logging

log = logging.getLogger(__name__)

log.info('Here is Some Information')
log.warning('You Should Not Do That')
log.error('It Is Busted')
```

### 32.30.11 Aliasing Functions

Sometimes one wishes to use a function name that would shadow a python built-in. A common example would be `set()`. To support this, append an underscore to the function definition, `def set_():`, and use the `__func_alias__` feature to provide an alias to the function.

`__func_alias__` is a dictionary where each key is the name of a function in the module, and each value is a string representing the alias for that function. When calling an aliased function from a different execution module, state module, or from the cli, the alias name should be used.

```python
__func_alias__ = {
    'set_': 'set',
    'list_': 'list',
}
```
32.30.12 Private Functions

In Salt, Python callable objects contained within an execution module are made available to the Salt minion for use. The only exception to this rule is a callable object with a name starting with an underscore `_`.

**Objects Loaded Into the Salt Minion**

```python
def foo(bar):
    return bar
class baz:
    def __init__(self, quo):
        pass
```

**Objects NOT Loaded into the Salt Minion**

```python
def _foobar(baz):
    # Preceded with an _
    return baz
cheese = {}  # Not a callable Python object
```

32.30.13 Useful Decorators for Modules

**Depends Decorator**

When writing execution modules there are many times where some of the module will work on all hosts but some functions have an external dependency, such as a service that needs to be installed or a binary that needs to be present on the system.

Instead of trying to wrap much of the code in large try/except blocks, a decorator can be used.

If the dependencies passed to the decorator don’t exist, then the salt minion will remove those functions from the module on that host.

If a `''fallback_function''` is defined, it will replace the function instead of removing it

```python
import logging
from salt.utils.decorators import depends

log = logging.getLogger(__name__)

try:
    import dependency_that_sometimes_exists
except ImportError as e:
    log.trace('Failed to import dependency_that_sometimes_exists: {0}'.format(e))

@depends('dependency_that_sometimes_exists')
def foo():
    '''
    Function with a dependency on the "dependency_that_sometimes_exists" module,
    if the "dependency_that_sometimes_exists" is missing this function will not exist
    '''
    return True
```
def _fallback():
    
    Fallback function for the depends decorator to replace a function with
    
    return '"dependency_that_sometimes_exists" needs to be installed for this function to exist!'

@depends('dependency_that_sometimes_exists', fallback_function=_fallback)
def foo():
    
    Function with a dependency on the "dependency_that_sometimes_exists" module. If the "dependency_that_sometimes_exists" is missing this function will be replaced with "_fallback"
    
    return True

In addition to global dependencies the depends decorator also supports raw booleans.

```
from salt.utils.decorators import depends

HAS_DEP = False
try:
    import dependency_that_sometimes_exists
    HAS_DEP = True
except ImportError:
    pass

@depends(HAS_DEP)
def foo():
    return True
```

## 32.31 Master Tops

Salt includes a number of built-in subsystems to generate top file data, they are listed listed at [Full list of builtin master tops modules](#). The source for the built-in Salt master tops can be found here: https://github.com/saltstack/salt/blob/develop/salt/tops

### 32.32 Full list of builtin master tops modules

<p>| | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>cobbler</td>
<td>Cobbler Tops</td>
</tr>
<tr>
<td>ext_nodes</td>
<td>External Nodes Classifier</td>
</tr>
<tr>
<td>mongo</td>
<td>Read tops data from a mongodb collection</td>
</tr>
<tr>
<td>reclass_adapter</td>
<td>Read tops data from a reclass database</td>
</tr>
</tbody>
</table>
32.32.1 salt.tops.cobbler

Cobbler Tops

Cobbler Tops is a master tops subsystem used to look up mapping information from Cobbler via its API. The same cobbler.* parameters are used for both the Cobbler tops and Cobbler pillar modules.

```yaml
master_tops:
  cobbler: {}
cobbler.url: https://example.com/cobbler_api #default is http://localhost/cobbler_api
cobbler.user: username # default is no username
cobbler.password: password # default is no password
```

Module Documentation

salt.tops.cobbler.top(**kwargs)

Look up top data in Cobbler for a minion.

32.32.2 salt.tops.ext_nodes

External Nodes Classifier

The External Nodes Classifier is a master tops subsystem that retrieves mapping information from major configuration management systems. One of the most common external nodes classifiers system is provided by Cobbler and is called cobbler-ext-nodes.

The cobbler-ext-nodes command can be used with this configuration:

```yaml
master_tops:
  ext_nodes: cobbler-ext-nodes
```

It is noteworthy that the Salt system does not directly ingest the data sent from the cobbler-ext-nodes command, but converts the data into information that is used by a Salt top file.

Any command can replace the call to `cobbler-ext-nodes' above, but currently the data must be formatted in the same way that the standard `cobbler-ext-nodes' does.

See (admittedly degenerate and probably not complete) example:

```yaml
classes:
  - basepackages
  - database
```

The above essentially is the same as a top.sls containing the following:

```yaml
base:
  '*':
    - basepackages
    - database
```

```yaml
base:
  '*':
    - basepackages
    - database
```
salt.tops.ext_nodes.top(**kwargs)
    Run the command configured

32.32.3 salt.tops.mongo

Read tops data from a mongodb collection
This module will load tops data from a mongo collection. It uses the node's id for lookups.

Salt Master Mongo Configuration

The module shares the same base mongo connection variables as salt.returners.mongo_return. These variables go in your master config file.

- **mongo.db** - The mongo database to connect to. Defaults to 'salt'.
- **mongo.host** - The mongo host to connect to. Supports replica sets by specifying all hosts in the set, comma-delimited. Defaults to 'salt'.
- **mongo.port** - The port that the mongo database is running on. Defaults to 27017.
- **mongo.user** - The username for connecting to mongo. Only required if you are using mongo authentication. Defaults to ''.  
- **mongo.password** - The password for connecting to mongo. Only required if you are using mongo authentication. Defaults to ''. 

Configuring the Mongo Tops Subsystem

```yaml
master_tops:
  mongo:
    collection: tops
    id_field: _id
    re_replace: ""
    re_pattern: \.example\.com
    states_field: states
    environment_field: environment
```

Module Documentation

salt.tops.mongo.top(**kwargs)
    Connect to a mongo database and read per-node tops data.

Parameters:

- **collection**: The mongodb collection to read data from. Defaults to 'tops'.
- **id_field**: The field in the collection that represents an individual minion id. Defaults to '_id'.
- **re_pattern**: If your naming convention in the collection is shorter than the minion id, you can use this to trim the name. re_pattern will be used to match the name, and re_replace will be used to replace it. Backrefs are supported as they are in the Python standard library. If None, no mangling of the name will be performed - the collection will be searched with the entire minion id. Defaults to None.
- **re_replace**: Use as the replacement value in node ids matched with re_pattern. Defaults to ''. Feel free to use backreferences here.
• `states_field`: The name of the field providing a list of states.
• `environment_field`: The name of the field providing the environment. Defaults to `environment`.

### 32.32.4 `salt.tops.reclass_adapter`

Read tops data from a reclass database

This `master_tops` plugin provides access to the reclass database, such that state information (top data) are retrieved from reclass.

You can find more information about reclass at [http://reclass.pantsfullofunix.net](http://reclass.pantsfullofunix.net).

To use the plugin, add it to the `master_tops` list in the Salt master config and tell reclass by way of a few options how and where to find the inventory:

```yaml
master_tops:
  reclass:
    storage_type: yaml_fs
    inventory_base_uri: /srv/salt
```

This would cause reclass to read the inventory from YAML files in `/srv/salt/nodes` and `/srv/salt/classes`.

If you are also using reclass as `ext_pillar` plugin, and you want to avoid having to specify the same information for both, use YAML anchors (take note of the differing data types for `ext_pillar` and `master_tops`):

```yaml
reclass: &reclass
  storage_type: yaml_fs
  inventory_base_uri: /srv/salt
  reclass_source_path: ~/code/reclass

ext_pillar:
  - reclass: *reclass
master_tops:
  reclass: *reclass
```

If you want to run reclass from source, rather than installing it, you can either let the master know via the `PYTHON-PATH` environment variable, or by setting the configuration option, like in the example above.

```python
salt.tops.reclass_adapter.top(**kwargs)
```

Query reclass for the top data (states of the minions).

### 32.33 Full list of builtin wheel modules

<table>
<thead>
<tr>
<th>Module</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>config</code></td>
<td>Manage the master configuration file</td>
</tr>
<tr>
<td><code>error</code></td>
<td>Error generator to enable integration testing of salt wheel error handling</td>
</tr>
<tr>
<td><code>file_roots</code></td>
<td>Read in files from the <code>file_root</code> and save files to the <code>file_root</code></td>
</tr>
<tr>
<td><code>key</code></td>
<td>Wheel system wrapper for key system</td>
</tr>
<tr>
<td><code>minions</code></td>
<td>Wheel system wrapper for connected minions</td>
</tr>
<tr>
<td><code>pillar_roots</code></td>
<td>The <code>pillar_roots</code> wheel module is used to manage files under the pillar roots directories on the master server.</td>
</tr>
</tbody>
</table>
32.33.1 salt.wheel.config

Manage the master configuration file

salt.wheel.config.apply(key, value)
Set a single key

Note: This will strip comments from your config file

salt.wheel.config.update_config(file_name, yaml_contents)
Update master config with yaml_contents.

Writes yaml_contents to a file named file_name.conf under the folder specified by default_include. This folder is named master.d by default. Please look at include-configuration for more information.

Example low data:

```python
data = {
    'username': 'salt',
    'password': 'salt',
    'fun': 'config.update_config',
    'file_name': 'gui',
    'yaml_contents': {'id': 1},
    'client': 'wheel',
    'eauth': 'pam',
}
```

salt.wheel.config.values()
Return the raw values of the config file

32.33.2 salt.wheel.error

Error generator to enable integration testing of salt wheel error handling

salt.wheel.error.error(name=None, message='')
If name is None Then return empty dict
Otherwise raise an exception with __name__ from name, message from message

CLI Example:

```bash
salt-wheel error
salt-wheel error.error name="Exception" message="This is an error."
```

32.33.3 salt.wheel.file_roots

Read in files from the file_root and save files to the file root

salt.wheel.file_roots.find(path, saltenv='base', env=None)
Return a dict of the files located with the given path and environment

salt.wheel.file_roots.list_env(saltenv='base', env=None)
Return all of the file paths found in an environment

salt.wheel.file_roots.list_roots()
Return all of the files names in all available environments
salt.wheel.file_roots.read(path, saltenv='base', env=None)
Read the contents of a text file, if the file is binary then

salt.wheel.file_roots.write(data, path, saltenv='base', index=0, env=None)
Write the named file, by default the first file found is written, but the index of the file can be specified to write to a lower priority file root

32.33.4 salt.wheel.key
Wheel system wrapper for key system

salt.wheel.key.accept(match)
Accept keys based on a glob match

salt.wheel.key.accept_dict(match)
Accept keys based on a dict of keys

Example to move a list of keys from the minions_pre (pending) directory to the minions (accepted) directory:

```python
{
    'minions_pre': [
        'jerry',
        'stuart',
        'bob',
    ],
}
```

salt.wheel.key.delete(match)
Delete keys based on a glob match

salt.wheel.key.delete_dict(match)
Delete keys based on a dict of keys

salt.wheel.key.finger(match)
Return the matching key fingerprints

salt.wheel.key.gen(id_=None, keysize=2048)
Generate a key pair. No keys are stored on the master, a keypair is returned as a dict containing pub and priv keys

salt.wheel.key.gen_accept(id_, keysize=2048, force=False)
Generate a key pair then accept the public key. This function returns the key pair in a dict, only the public key is preserved on the master.

salt.wheel.key.key_str(match)
Return the key strings

salt.wheel.key.list(match)
List all the keys under a named status

salt.wheel.key.list_all()
List all the keys

salt.wheel.key.reject(match)
Reject keys based on a glob match

salt.wheel.key.reject_dict(match)
Reject keys based on a dict of keys
32.33.5 salt.wheel.minions

Wheel system wrapper for connected minions
salt.wheel.minions.connected()
    List all connected minions on a salt-master

32.33.6 salt.wheel.pillar_roots

The pillar_roots wheel module is used to manage files under the pillar roots directories on the master server.
salt.wheel.pillar_roots.find(path, saltenv='base', env=None)
    Return a dict of the files located with the given path and environment
salt.wheel.pillar_roots.list_env(saltenv='base', env=None)
    Return all of the file paths found in an environment
salt.wheel.pillar_roots.list_roots()
    Return all of the files names in all available environments
salt.wheel.pillar_roots.read(path, saltenv='base', env=None)
    Read the contents of a text file, if the file is binary then
salt.wheel.pillar_roots.write(data, path, saltenv='base', index=0, env=None)
    Write the named file, by default the first file found is written, but the index of the file can be specified to write
to a lower priority file root

32.34 Full list of builtin beacon modules

<table>
<thead>
<tr>
<th>beacon</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>btmp</td>
<td>Beacon to fire events at failed login of users</td>
</tr>
<tr>
<td>diskusage</td>
<td>Beacon to monitor disk usage.</td>
</tr>
<tr>
<td>inotify</td>
<td>Watch files and translate the changes into salt events</td>
</tr>
<tr>
<td>journald</td>
<td>A simple beacon to watch journald for specific entries</td>
</tr>
<tr>
<td>load</td>
<td>Beacon to emit system load averages</td>
</tr>
<tr>
<td>network_info</td>
<td>Beacon to monitor statistics from ethernet adapters</td>
</tr>
<tr>
<td>ps</td>
<td>Send events covering service status</td>
</tr>
<tr>
<td>service</td>
<td>Send events covering service status</td>
</tr>
<tr>
<td>sh</td>
<td>Watch the shell commands being executed actively.</td>
</tr>
<tr>
<td>twilio_txt_msg</td>
<td>Beacon to emit Twilio text messages</td>
</tr>
<tr>
<td>wtmp</td>
<td>Beacon to fire events at login of users as registered in the wtmp file</td>
</tr>
</tbody>
</table>

32.34.1 salt.beacons.btmp

Beacon to fire events at failed login of users

beacons:
    btmp: {}

salt.beacons.btmp.beacon(config)
    Read the last btmp file and return information on the failed logins
beacons:
    btmp: {}

salt.beacons.btmp.validate(config)
Validate the beacon configuration

32.34.2 salt.beacons.diskusage

Beacon to monitor disk usage.
New in version 2015.5.0.

    depends python-psutil

salt.beacons.diskusage.beacon(config)
Monitor the disk usage of the minion

    Specify thresholds for each disk and only emit a beacon if any of them are exceeded.

    beacons:
        diskusage:
            - /: 63%
            - /mnt/nfs: 50%

salt.beacons.diskusage.validate(config)
Validate the beacon configuration

32.34.3 salt.beacons.inotify

Watch files and translate the changes into salt events

    depends
        • pyinotify Python module >= 0.9.5

    Caution Using generic mask options like open, access, ignored, and closed_nowrite with reactors can
    easily cause the reactor to loop on itself. To mitigate this behavior, consider setting the disable_during_state_run flag to True in the beacon configuration.

    note The inotify beacon only works on OSes that have inotify kernel support. Currently this excludes FreeBSD, Mac OS X, and Windows.

salt.beacons.inotify.beacon(config)
Watch the configured files

Example Config

    beacons:
        inotify:
            /path/to/file/or/dir:
                mask:
                    - open
                    - create
                    - close_write
                recurse: True
                auto_add: True

The mask list can contain the following events (the default mask is create, delete, and modify):
- access File accessed
- attrib File metadata changed
- close_nowrite Unwritable file closed
- close_write Writable file closed
- create File created in watched directory
- delete File deleted from watched directory
- delete_self Watched file or directory deleted
- modify File modified
- moved_from File moved out of watched directory
- moved_to File moved into watched directory
- move_self Watched file moved
- open File opened

The mask can also contain the following options:
- dont_follow Don’t dereference symbolic links
- excl_unlink Omit events for children after they have been unlinked
- oneshot Remove watch after one event
- onlydir Operate only if name is directory

**recurse**: Recursively watch files in the directory
**auto_add**: Automatically start watching files that are created in the watched directory

```python
salt.beacons.inotify.validate(config)
```
Validate the beacon configuration

### 32.34.4 salt.beacons.journald
A simple beacon to watch journald for specific entries

```python
salt.beacons.journald.beacon(config)
```
The journald beacon allows for the systemd journal to be parsed and linked objects to be turned into events.

This beacon’s config will return all sshd journal entries

```yaml
beacons:
  journald:
    sshd:
      SYSLOG_IDENTIFIER: sshd
      PRIORITY: 6
```

```python
salt.beacons.journald.validate(config)
```
Validate the beacon configuration

### 32.34.5 salt.beacons.load
Beacon to emit system load averages

```python
salt.beacons.load.beacon(config)
```
Emit the load averages of this host.

Specify thresholds for each load average and only emit a beacon if any of them are exceeded.

```yaml
beacons:
  load:
    1m:
      - 0.0
      - 2.0
```

32.34. Full list of builtin beacon modules 2153
salt.beacons.load.validate(config)
Validate the beacon configuration

32.34.6 salt.beacons.network_info

Beacon to monitor statistics from ethernet adapters
New in version 2015.5.0.
salt.beacons.network_info.beacon(config)
Emit the network statistics of this host.

Specify thresholds for each network stat and only emit a beacon if any of them are exceeded.

Emit beacon when any values are equal to configured values.

```yaml
beacons:
  network_info:
    eth0:
      - type: equal
      - bytes_sent: 100000
      - bytes_recv: 100000
      - packets_sent: 100000
      - packets_recv: 100000
      - errin: 100
      - errout: 100
      - dropin: 100
      - dropout: 100
```

Emit beacon when any values are greater than to configured values.

```yaml
beacons:
  network_info:
    eth0:
      - type: greater
      - bytes_sent: 100000
      - bytes_recv: 100000
      - packets_sent: 100000
      - packets_recv: 100000
      - errin: 100
      - errout: 100
      - dropin: 100
      - dropout: 100
```

salt.beacons.network_info.validate(config)
Validate the beacon configuration

32.34.7 salt.beacons.ps module

Send events covering service status
salt.beacons.ps.beacon(config)
Scan for processes and fire events

Example Config

```
beacons:
  ps:
    salt-master: running
    mysql: stopped
```

The config above sets up beacons to check that processes are running or stopped.

salt.beacons.ps.validate(config)
Validate the beacon configuration

---

**32.34.8 salt.beacons.service**

Send events covering service status

salt.beacons.service.beacon(config)
Scan for the configured services and fire events

Example Config

```
beacons:
  service:
    salt-master:
    mysql:
```

The config above sets up beacons to check for the salt-master and mysql services.

The config also supports two other parameters for each service:

*onchangeonly*: when *onchangeonly* is True the beacon will fire events only when the service status changes. Otherwise, it will fire an event at each beacon interval. The default is False.

*uncleanshutdown*: If *uncleanshutdown* is present it should point to the location of a pid file for the service. Most services will not clean up this pid file if they are shutdown uncleanly (e.g. via kill -9) or if they are terminated through a crash such as a segmentation fault. If the file is present, then the beacon will add *uncleanshutdown*: True to the event. If not present, the field will be False. The field is only added when the service is NOT running. Omitting the configuration variable altogether will turn this feature off.

Please note that some init systems can remove the pid file if the service registers as crashed. One such example is nginx on CentOS 7, where the service unit removes the pid file when the service shuts down (IE: the pid file is observed as removed when kill -9 is sent to the nginx master process). The `uncleanshutdown` option might not be of much use there, unless the unit file is modified.

Here is an example that will fire an event whenever the state of nginx changes and report an uncleanshutdown. This example is for Arch, which places nginx's pid file in /run.

```
beacons:
  service:
    nginx:
      onchangeonly: True
      uncleanshutdown: /run/nginx.pid
```

salt.beacons.service.validate(config)
Validate the beacon configuration
32.34.9  salt.beacons.sh

Watch the shell commands being executed actively. This beacon requires strace.

```python
salt.beacons.sh.beacon(config)
  Scan the shell execve routines. This beacon will convert all login shells
  beacons:
    sh: {}
```

```python
salt.beacons.sh.validate(config)
  Validate the beacon configuration
```

32.34.10  salt.beacons.twilio_txt_msg

Beacon to emit Twilio text messages

```python
salt.beacons.twilio_txt_msg.beacon(config)
  Emit a dict name `texts` whose value is a list of texts.
  beacons:
    twilio_txt_msg:
      account_sid: "<account sid>"
      auth_token: "<auth token>"
      twilio_number: "+15555555555"
      interval: 10
```

```python
salt.beacons.twilio_txt_msg.validate(config)
  Validate the beacon configuration
```

32.34.11  salt.beacons.wtmp

Beacon to fire events at login of users as registered in the wtmp file

```python
salt.beacons.wtmp.beacon(config)
  Read the last wtmp file and return information on the logins
  beacons:
    wtmp: {}
```

```python
salt.beacons.wtmp.validate(config)
  Validate the beacon configuration
```

32.35  Full list of built-in engine modules

<table>
<thead>
<tr>
<th>Engine</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>logstash</td>
<td>An engine that reads messages from the salt event bus and pushes them onto a logstash endpoint.</td>
</tr>
<tr>
<td>sqs_events</td>
<td>An engine that continuously reads messages from SQS and fires them as events.</td>
</tr>
</tbody>
</table>

Continued on next page
32.35.1 salt.engines.logstash

An engine that reads messages from the salt event bus and pushes them onto a logstash endpoint.

**configuration**

Example configuration

```yaml
engines:
  • logstash: host: log.my_network.com port: 5959
```

```yaml
depends  logstash
```

```yaml
salt.engines.logstash.start(host, port=5959, tag='salt/engine/logstash')
```

Listen to salt events and forward them to logstash

32.35.2 salt.engines.sqs_events

An engine that continuously reads messages from SQS and fires them as events.

Note that long polling is utilized to avoid excessive CPU usage.

New in version 2015.8.0.

```yaml
depends  boto
```

**Configuration**

This engine can be run on the master or on a minion.

Example Config:

```yaml
engines:
  - sqs_events:
      queue: test
      profile: my-sqs-profile  #optional
```

Explicit sqs credentials are accepted but this engine can also utilize IAM roles assigned to the instance through Instance Profiles. Dynamic credentials are then automatically obtained from AWS API and no further configuration is necessary. More information available at:

If IAM roles are not used you need to specify them either in a pillar or in the config file of the master or minion, as appropriate:

```yaml
sqs.keyid: GKTADJGHEIQSXMKKRBJ08H
sqs.key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
```

A region may also be specified in the configuration:

```yaml
sqs.region: us-east-1
```
If a region is not specified, the default is us-east-1.

It’s also possible to specify key, keyid and region via a profile:

```yaml
myprofile:
  keyid: GKTADJGHEIQSXMKKRBJ08H
  key: askdjghsdfjkgHwupUjasdfklfklgjsdfjajkghs
  region: us-east-1
```

```python
salt.engines.sqs_events.start(queue, profile=None, tag='salt/engine/sqs')
  # Listen to events and write them to a log file
```

### 32.35.3 salt.engines.test

A simple test engine, not intended for real use but as an example

```python
salt.engines.test.start()
  # Listen to events and write them to a log file
```

### 32.36 Full list of builtin sdb modules

<table>
<thead>
<tr>
<th>Module</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>couchdb</td>
<td>CouchDB sdb Module</td>
</tr>
<tr>
<td>etcd_db</td>
<td>etcd Database Module</td>
</tr>
<tr>
<td>keyring_db</td>
<td>Keyring Database Module</td>
</tr>
<tr>
<td>memcached</td>
<td>Memcached sdb Module</td>
</tr>
<tr>
<td>sqlite3</td>
<td>SQLite sdb Module</td>
</tr>
</tbody>
</table>

### 32.36.1 salt.sdb.couchdb

CouchDB sdb Module

- **maintainer**: SaltStack
- **maturity**: New
- **depends**: python2-couchdb
- **platform**: all

This allow interaction between Salt and a CouchDB [couchdb.apache.org] database. It uses salt's sdb system to allow for inserts and retrievals using the sdb:// prefix in salt configuration files.

To use the couchbase sdb module, it must first be configured in the salt master or minion config. The following arguments are required:

```yaml
couchdb_sdb:
  driver: couchdb
  host: localhost
  port: 5984
  database: salt_sdb
```

One could then query the CouchDB instance via an sdb:// URI such as the following:

```bash
password: sdb://couchdb_sdb/mykey
```
To use this interface, you must track IDs on your own or have another source to do the map-reduce logic necessary to calculate the ID you wish to fetch.

Additional contributions to build true map-reduce functionality into this module would be welcome.

```
salt.sdb.couchdb.get(key, profile=None)
    Get a value from couchdb by id
salt.sdb.couchdb.set(key, value, profile=None)
    Set a key/value pair in couchdb
```

### 32.36.2 salt.sdb.etcd_db

etcd Database Module

- **maintainer**: SaltStack
- **maturity**: New
- **depends**: python-etcd
- **platform**: all

New in version 2015.5.0.

This module allows access to the etcd database using an sdb:// URI. This package is located at https://pypi.python.org/pypi/python-etcd.

Like all sdb modules, the etcd module requires a configuration profile to be configured in either the minion or master configuration file. This profile requires very little. In the example:

```
myetcd:
    driver: etcd
drivers.host: 127.0.0.1
drivers.port: 4001
```

The **driver** refers to the etcd module, **etcd.host** refers to the host that is hosting the etcd database and **etcd.port** refers to the port on that host.

```
password: sdb://myetcd/mypassword
```

```
salt.sdb.etcd_db.get(key, service=None, profile=None)
    Get a value from the etcd service
salt.sdb.etcd_db.set(key, value, service=None, profile=None)
    Set a key/value pair in the etcd service
```

### 32.36.3 salt.sdb.keyring_db

Keyring Database Module

- **maintainer**: SaltStack
- **maturity**: New
- **depends**: keyring
- **platform**: all

32.36. Full list of built-in sdb modules
This module allows access to the keyring package using an sdb:// URI. This package is located at https://pypi.python.org/pypi/keyring.

Care must be taken when using keyring. Not all keyring backends are supported on all operating systems. Also, many backends require an agent to be running in order to work. For instance, the "Secret Service" backend requires a compatible agent such as gnome-keyring-daemon or kwallet to be running. The keyczar backend does not seem to enjoy the benefits of an agent, and so using it will require either that the password is typed in manually (which is unreasonable for the salt-minion and salt-master daemons, especially in production) or an agent is written for it.

Like all sdb modules, the keyring module requires a configuration profile to be configured in either the minion or master configuration file. This profile requires very little. In the example:

```yaml
mykeyring:
    driver: keyring
    service: system
```

The `driver` refers to the keyring module, `service` refers to the service that will be used inside of keyring (which may be likened unto a database table) and `mykeyring` refers to the name that will appear in the URI:

```plaintext
password: sdb://mykeyring/mypassword
```

The underlying backend configuration must be configured via keyring itself. For examples and documentation, see keyring:

https://pypi.python.org/pypi/keyring

New in version 2014.1.4.

```python
salt.sdb.keyring_db.get(key, service=None, profile=None)
Get a value from a keyring service
```

```python
salt.sdb.keyring_db.set(key, value, service=None, profile=None)
Set a key/value pair in a keyring service
```

### 32.36.4 salt.sdb.memcached

Memcached sdb Module

```
maintainer SaltStack
maturity New
depends python-memcached
platform all
```

This module allows access to memcached using an sdb:// URI. This package is located at https://pypi.python.org/pypi/python-memcached.

Like all sdb modules, the memcached module requires a configuration profile to be configured in either the minion or master configuration file. This profile requires very little. In the example:

```yaml
mymemcache:
    driver: memcached
    host: localhost
    port: 11211
```

The `driver` refers to the memcached module, `host` and `port` the memcached server to connect to (defaults to localhost and 11211, and `mymemcache` refers to the name that will appear in the URI:
password: sdb://mymemcached/mykey

salt.sdb.memcached.get(key, profile=None)
    Get a value from memcached

salt.sdb.memcached.set(key, value, profile=None)
    Set a key/value pair in memcached

32.36.5 salt.sdb.sqlite3

SQLite sdb Module

    maintainer  SaltStack
    maturity    New
    platform    all

This module allows access to sqlite3 using an sdb:// URI

Like all sdb modules, the sqlite3 module requires a configuration profile to be configured in either the minion or master configuration file. This profile requires very little. For example:

```
sqlite:
    driver: sqlite3
    database: /tmp/sdb.sqlite
    table: sdb
    create_table: True
```

The `driver` refers to the sqlite3 module, `database` refers to the sqlite3 database file. `table` is the table within the db that will hold keys and values (defaults to sdb). The database and table will be created if they do not exist.

Advanced Usage:

Instead of a table name, it is possible to provide custom SQL statements to create the table(s) and get and set values.

salt.sdb.sqlite3.get(key, profile=None)
    Get a value from sqlite3

salt.sdb.sqlite3.set(key, value, profile=None)
    Set a key/value pair in sqlite3

32.37 Full list of builtin serializers

<p>| | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>json</td>
<td>salt.serializers.json</td>
</tr>
<tr>
<td>msgpack</td>
<td>salt.serializers.msgpack</td>
</tr>
<tr>
<td>yaml</td>
<td>salt.serializers.yaml</td>
</tr>
<tr>
<td>yamlex</td>
<td>salt.serializers.yamlex</td>
</tr>
</tbody>
</table>
### 32.37.1 `salt.serializers.json`

`salt.serializers.json`

Implements JSON serializer.

It's just a wrapper around json (or simplejson if available).

**Deserialization**

```python
salt.serializers.json.deserialize(stream_or_string, **options)
```

Deserialize any string of stream like object into a Python data structure.

**Parameters**

- `stream_or_string` -- stream or string to deserialize.
- `options` -- options given to lower json/simplejson module.

**Serialization**

```python
salt.serializers.json.serialize(obj, **options)
```

Serialize Python data to JSON.

**Parameters**

- `obj` -- the data structure to serialize
- `options` -- options given to lower json/simplejson module.

### 32.37.2 `salt.serializers.msgpack`

`salt.serializers.msgpack`

Implements MsgPack serializer.

**Deserialization**

```python
salt.serializers.msgpack.deserialize(stream_or_string, **options)
```

Deserialize any string of stream like object into a Python data structure.

**Parameters**

- `stream_or_string` -- stream or string to deserialize.
- `options` -- options given to lower msgpack module.

**Serialization**

```python
salt.serializers.msgpack.serialize(obj, **options)
```

Serialize Python data to MsgPack.

**Parameters**

- `obj` -- the data structure to serialize
- `options` -- options given to lower msgpack module.

### 32.37.3 `salt.serializers.yaml`

`salt.serializers.yaml`

Implements YAML serializer.

Underneath, it is based on pyyaml and use the safe dumper and loader. It also use C bindings if they are available.

**Deserialization**

```python
salt.serializers.yaml.deserialize(stream_or_string, **options)
```

Deserialize any string of stream like object into a Python data structure.

**Parameters**

- `stream_or_string` -- stream or string to deserialize.
• **options** -- options given to lower yaml module.

```python
salt.serializers.yaml.serialize(obj, **options)
```

Serialize Python data to YAML.

**Parameters**

• **obj** -- the data structure to serialize

• **options** -- options given to lower yaml module.

### 32.37.4 `salt.serializers.yamllex`

`salt.serializers.yamllex`

YAML EX is a format that allows for things like sls files to be more intuitive.

It’s an extension of YAML that implements all the salt magic: - it implies omap for any dict like. - it implies that string like data are str, not unicode - ...

For example, the file `states.sls` has this contents:

```yaml
foo:
  bar: 42
  baz: [1, 2, 3]
```

The file can be parsed into Python like this

```python
from salt.serializers import yamllex

with open('state.sls', 'r') as stream:
    obj = yamllex.deserialize(stream)
```

Check that `obj` is an OrderedDict

```python
from salt.utils.odict import OrderedDict

assert isinstance(obj, dict)
assert isinstance(obj, OrderedDict)
```

`yamllex.__repr__ and __str__` objects’ methods render YAML understandable string. It means that they are template friendly.

```python
print '{0}'.format(obj)
```

returns:

```python
{foo: {bar: 42, baz: [1, 2, 3]}}
```

and they are still valid YAML:

```python
from salt.serializers import yaml

yml_obj = yaml.deserialize(str(obj))

assert yml_obj == obj
```

`yamllex` implements also custom tags:

`!aggregate`
this tag allows structures aggregation.

For example:

```
placeholder: !aggregate foo
placeholder: !aggregate bar
placeholder: !aggregate baz
```

is rendered as

```
placeholder: [foo, bar, baz]
```

!reset

this tag flushes the computing value.

```
placeholder: {!aggregate foo: {foo: 42}}
placeholder: {!aggregate foo: {bar: null}}
!reset placeholder: {!aggregate foo: {baz: inga}}
```

is roughly equivalent to

```
placeholder: {!aggregate foo: {baz: inga}}
```

Document is defacto an aggregate mapping.

```
salt.serializers.yamlex.deserialize(stream_or_string, **options)
```

Deserialize any string of stream like object into a Python data structure.

**Parameters**

- `stream_or_string` -- stream or string to deserialize.
- `options` -- options given to lower yaml module.

```
salt.serializers.yamlex.serialize(obj, **options)
```

Serialize Python data to YAML.

**Parameters**

- `obj` -- the data structure to serialize
- `options` -- options given to lower yaml module.

### 32.38 Full list of builtin queues

**sqlite_queue**

New in version 2014.7.0.

**32.38.1 salt.queues.sqlite_queue module**

New in version 2014.7.0.

This is the default local master event queue built on sqlite. By default, an sqlite3 database file is created in the `sqlite_queue_dir` which is found at:

```
/var/cache/salt/master/queues
```

It's possible to store the sqlite3 database files by setting `sqlite_queue_dir` to another location:
sqlite_queue_dir: /home/myuser/salt/master/queues

```python
salt.queues.sqlite_queue.delete(queue, items)
    Delete an item or items from a queue
salt.queues.sqlite_queue.insert(queue, items)
    Add an item or items to a queue
salt.queues.sqlite_queue.list_items(queue)
    List contents of a queue
salt.queues.sqlite_queue.list_length(queue)
    Provide the number of items in a queue
salt.queues.sqlite_queue.list_queues()
    Return a list of Salt Queues on the Salt Master
salt.queues.sqlite_queue.pop(queue, quantity=1)
    Pop one or more or all items from the queue return them.
```
Salt's extreme flexibility leads to many questions concerning the structure of configuration files. This document exists to clarify these points through examples and code.

### 33.1 General rules

1. Modularity and clarity should be emphasized whenever possible.
2. Create clear relations between pillars and states.
3. Use variables when it makes sense but don’t overuse them.
4. Store sensitive data in pillar.
5. Don’t use grains for matching in your pillar top file for any sensitive pillars.

### 33.2 Structuring States and Formulas

When structuring Salt States and Formulas it is important to begin with the directory structure. A proper directory structure clearly defines the functionality of each state to the user via visual inspection of the state’s name.

Reviewing the MySQL Salt Formula it is clear to see the benefits to the end-user when reviewing a sample of the available states:

```plaintext
/srv/salt/mysql/files/
/srv/salt/mysql/client.sls
/srv/salt/mysql/map.jinja
/srv/salt/mysql/python.sls
/srv/salt/mysql/server.sls
```

This directory structure would lead to these states being referenced in a top file in the following way:

```plaintext
base:
  'web*':
    - mysql.client
    - mysql.python
  'db*':
    - mysql.server
```
This clear definition ensures that the user is properly informed of what each state will do.

Another example comes from the vim-formula:

```
/srv/salt/vim/files/
/srv/salt/vim/absent.sls
/srv/salt/vim/init.sls
/srv/salt/vim/map.jinja
/srv/salt/vim/nerdtree.sls
/srv/salt/vim/pyflakes.sls
/srv/salt/vim/salt.sls
```

Once again viewing how this would look in a top file:

```
/srv/salt/top.sls:

base:
  'web*':
    - vim
    - vim.nerdtree
    - vim.pyflakes
    - vim.salt
  'db*':
    - vim.absent
```

The usage of a clear top-level directory as well as properly named states reduces the overall complexity and leads a user to both understand what will be included at a glance and where it is located.

In addition Formulas should be used as often as possible.

**Note:** Formulas repositories on the saltstack-formulas GitHub organization should not be pointed to directly from systems that automatically fetch new updates such as GitFS or similar tooling. Instead formulas repositories should be forked on GitHub or cloned locally, where unintended, automatic changes will not take place.

### 33.3 Structuring Pillar Files

**Pillars** are used to store secure and insecure data pertaining to minions. When designing the structure of the /srv/pillar directory, the pillars contained within should once again be focused on clear and concise data which users can easily review, modify, and understand.

The /srv/pillar/ directory is primarily controlled by top.sls. It should be noted that the pillar top.sls is not used as a location to declare variables and their values. The top.sls is used as a way to include other pillar files and organize the way they are matched based on environments or grains.

An example top.sls may be as simple as the following:

```
/srv/pillar/top.sls:

base:
  '*':
    - packages
```

Any number of matchers can be added to the base environment. For example, here is an expanded version of the Pillar top file stated above:

```
/srv/pillar/top.sls:
```

---

2168 Chapter 33. Salt Best Practices
Or an even more complicated example, using a variety of matchers in numerous environments:

/srv/pillar/top.sls:

```
base:
  '*':
    - apache
dev:
  'os:Debian':
    - match: grain
    - vim
test:
  '* and not G@os: Debian':
    - match: compound
    - emacs
```

It is clear to see through these examples how the top file provides users with power but when used incorrectly it can lead to confusing configurations. This is why it is important to understand that the top file for pillar is not used for variable definitions.

Each SLS file within the `/srv/pillar/` directory should correspond to the states which it matches.

This would mean that the `apache` pillar file should contain data relevant to Apache. Structuring files in this way once again ensures modularity, and creates a consistent understanding throughout our Salt environment. Users can expect that pillar variables found in an Apache state will live inside of an Apache pillar:

```
apache:
  lookup:
    name: httpd
  config:
    tmpl: /etc/httpd/httpd.conf
```

While this pillar file is simple, it shows how a pillar file explicitly relates to the state it is associated with.

### 33.4 Variable Flexibility

Salt allows users to define variables in SLS files. When creating a state variables should provide users with as much flexibility as possible. This means that variables should be clearly defined and easy to manipulate, and that sane defaults should exist in the event a variable is not properly defined. Looking at several examples shows how these different items can lead to extensive flexibility.

Although it is possible to set variables locally, this is generally not preferred:

```
/srv/salt/apache/conf.sls:

{% set name = 'httpd' %}
{% set tmpl = 'salt://apache/files/httpd.conf' %}
```
When generating this information it can be easily transitioned to the pillar where data can be overwritten, modified, and applied to multiple states, or locations within a single state:

```
/srv/pillar/apache.sls:
```

```
apache:
    lookup:
        name: httpd
        config:
            tmpl: salt://apache/files/httpd.conf
```

```
/srv/salt/apache/conf.sls:
```

```
{% from "apache/map.jinja" import apache with context %}
include:
    - apache

apache_conf:
    file.managed:
        - name: {{ salt['pillar.get']('apache:lookup:name') }}
        - source: {{ salt['pillar.get']('apache:lookup:config:tmpl') }}
        - template: jinja
        - user: root
        - watch_in:
            - service: apache
```

This flexibility provides users with a centralized location to modify variables, which is extremely important as an environment grows.

### 33.5 Modularity Within States

Ensuring that states are modular is one of the key concepts to understand within Salt. When creating a state a user must consider how many times the state could be re-used, and what it relies on to operate. Below are several examples which will iteratively explain how a user can go from a state which is not very modular to one that is:

```
/srv/salt/apache/init.sls:
```

```
httpd:
    pkg.installed: []
    service.running:
        - enable: True
```

```
/etc/httpd/httpd.conf:
```
The example above is probably the worst-case scenario when writing a state. There is a clear lack of focus by naming both the pkg/service, and managed file directly as the state ID. This would lead to changing multiple requires within this state, as well as others that may depend upon the state.

Imagine if a require was used for the `httpd` package in another state, and then suddenly it’s a custom package. Now changes need to be made in multiple locations which increases the complexity and leads to a more error prone configuration.

There is also the issue of having the configuration file located in the init, as a user would be unable to simply install the service and use the default conf file.

Our second revision begins to address the referencing by using `-name`, as opposed to direct ID references:

```
/srv/salt/apache/init.sls:

apache:
  pkg.installed:
    - name: httpd
  service.running:
    - name: httpd
    - enable: True

apache_conf:
  file.managed:
    - name: /etc/httpd/httpd.conf
    - source: salt://apache/files/httpd.conf
    - template: jinja
    - watch_in:
      - service: apache
```

The above init file is better than our original, yet it has several issues which lead to a lack of modularity. The first of these problems is the usage of static values for items such as the name of the service, the name of the managed file, and the source of the managed file. When these items are hard coded they become difficult to modify and the opportunity to make mistakes arises. It also leads to multiple edits that need to occur when changing these items (imagine if there were dozens of these occurrences throughout the state!). There is also still the concern of the configuration file data living in the same state as the service and package.

In the next example steps will be taken to begin addressing these issues. Starting with the addition of a map.jinja file (as noted in the `Formula documentation`), and modification of static values:

```
/srv/salt/apache/map.jinja:

{% set apache = salt['grains.filter_by']({
    'Debian': {
        'server': 'apache2',
        'service': 'apache2',
        'conf': '/etc/apache2/apache2.conf',
    },
    'RedHat': {
        'server': 'httpd',
        'service': 'httpd',
        'conf': '/etc/httpd/httpd.conf',
    },
})
```

33.5. Modularity Within States
The changes to this state now allow us to easily identify the location of the variables, as well as ensuring they are flexible and easy to modify. While this takes another step in the right direction, it is not yet complete. Suppose the user did not want to use the provided conf file, or even their own configuration file, but the default apache conf. With the current state setup this is not possible. To attain this level of modularity this state will need to be broken into two states.

/srv/salt/apache/map.jinja:

```jinja
{% set apache = salt['grains.filter_by']({
    'Debian': {
        'server': 'apache2',
        'service': 'apache2',
        'conf': '/etc/apache2/apache.conf',
    },
    'RedHat': {
        'server': 'httpd',
        'service': 'httpd',
        'conf': '/etc/httpd/httpd.conf',
    },
}), merge=salt['pillar.get']('apache:lookup')) %}
```

/srv/pillar/apache.sls:

```yaml
apache:
  lookup:
    config:
      tmpl: salt://apache/files/httpd.conf
```

/srv/salt/apache/init.sls:

```jinja
{% from "apache/map.jinja" import apache with context %}
apache:
  pkg.installed:
    - name: {{ apache.server }}
  service.running:
    - name: {{ apache.service }}
    - enable: True
  apache_conf:
    file.managed:
      - name: {{ apache.conf }}
      - source: {{ salt['pillar.get']('apache:lookup:config:tmpl') }}
      - template: jinja
      - user: root
      - watch_in:
        - service: apache
```

The changes to this state now allow us to easily identify the location of the variables, as well as ensuring they are flexible and easy to modify. While this takes another step in the right direction, it is not yet complete. Suppose the user did not want to use the provided conf file, or even their own configuration file, but the default apache conf. With the current state setup this is not possible. To attain this level of modularity this state will need to be broken into two states.

/srv/pillar/apache.sls:

```yaml
apache:
  lookup:
    config:
      tmpl: salt://apache/files/httpd.conf
```
This new structure now allows users to choose whether they only wish to install the default Apache, or if they wish, overwrite the default package, service, configuration file location, or the configuration file itself. In addition to this the data has been broken between multiple files allowing for users to identify where they need to change the associated data.

### 33.6 Storing Secure Data

Secure data refers to any information that you would not wish to share with anyone accessing a server. This could include data such as passwords, keys, or other information.

As all data within a state is accessible by EVERY server that is connected it is important to store secure data within pillar. This will ensure that only those servers which require this secure data have access to it. In this example a use can go from an insecure configuration to one which is only accessible by the appropriate hosts:

```
/srv/salt/mysql/testerdb.sls:

testdb:
  mysql_database.present:
    - name: testerdb

/srv/salt/mysql/user.sls:

include:
  - mysql.testerdb

testdb_user:
  mysql_user.present:
    - name: frank
    - password: "test3rdb"
```
Many users would review this state and see that the password is there in plain text, which is quite problematic. It results in several issues which may not be immediately visible.

The first of these issues is clear to most users -- the password being visible in this state. This means that any minion will have a copy of this, and therefore the password which is a major security concern as minions may not be locked down as tightly as the master server.

The other issue that can be encountered is access by users on the master. If everyone has access to the states (or their repository), then they are able to review this password. Keeping your password data accessible by only a few users is critical for both security and peace of mind.

There is also the issue of portability. When a state is configured this way it results in multiple changes needing to be made. This was discussed in the sections above but it is a critical idea to drive home. If states are not portable it may result in more work later!

Fixing this issue is relatively simple, the content just needs to be moved to the associated pillar:

```
/srv/pillar/mysql.sls:

mysql:
  lookup:
    name: testerdb
    password: test3rdb
    user: frank
    host: localhost
```

```
/srv/salt/mysql/testerdb.sls:

testdb:
  mysql_database.present:
    - name: {{ salt['pillar.get']('mysql:lookup:name') }}
```

```
/srv/salt/mysql/user.sls:

include:
  - mysql.testerdb

testdb_user:
  mysql_user.present:
    - name: {{ salt['pillar.get']('mysql:lookup:user') }}
    - password: {{ salt['pillar.get']('mysql:lookup:password') }}
    - host: {{ salt['pillar.get']('mysql:lookup:host') }}
    - require:
      - sls: mysql.testerdb
```

Now that the database details have been moved to the associated pillar file, only machines which are targeted via pillar will have access to these details. Access to users who should not be able to review these details can also be prevented while ensuring that they are still able to write states which take advantage of this information.
This topic contains tips you can use to secure and harden your Salt environment. How you best secure and harden your Salt environment depends heavily on how you use Salt, where you use Salt, how your team is structured, where you get data from, and what kinds of access (internal and external) you require.

### 34.1 General hardening tips

- Restrict who can directly log into your Salt master system.
- Use SSH keys secured with a passphrase to gain access to the Salt master system.
- Track and secure SSH keys and any other login credentials you and your team need to gain access to the Salt master system.
- Use a hardened bastion server or a VPN to restrict direct access to the Salt master from the internet.
- Don’t expose the Salt master any more than what is required.
- Harden the system as you would with any high-priority target.
- Keep the system patched and up-to-date.
- Use tight firewall rules.

### 34.2 Salt hardening tips

- Subscribe to salt-users or salt-announce so you know when new Salt releases are available. Keep your systems up-to-date with the latest patches.
- Use Salt’s Client ACL system to avoid having to give out root access in order to run Salt commands.
- Use Salt’s Client ACL system to restrict which users can run what commands.
- Use external Pillar to pull data into Salt from external sources so that non-sysadmins (other teams, junior admins, developers, etc) can provide configuration data without needing access to the Salt master.
- Make heavy use of SLS files that are version-controlled and go through a peer-review/code-review process before they’re deployed and run in production. This is good advice even for “one-off” CLI commands because it helps mitigate typos and mistakes.
- Use salt-api, SSL, and restrict authentication with the external auth system if you need to expose your Salt master to external services.
• Make use of Salt's event system and reactor to allow minions to signal the Salt master without requiring direct access.

• Run the salt-master daemon as non-root.

• Disable which modules are loaded onto minions with the disable_modules setting. (for example, disable the cmd module if it makes sense in your environment.)

• Look through the fully-commented sample master and minion config files. There are many options for securing an installation.

• Run masterless-mode minions on particularly sensitive minions. There is also Salt SSH or the modules.sudo if you need to further restrict a minion.
CHAPTER 35

Troubleshooting

The intent of the troubleshooting section is to introduce solutions to a number of common issues encountered by users and the tools that are available to aid in developing States and Salt code.

35.1 Troubleshooting the Salt Master

If your Salt master is having issues such as minions not returning data, slow execution times, or a variety of other issues, the following links contain details on troubleshooting the most common issues encountered:

35.1.1 Troubleshooting the Salt Master

Running in the Foreground

A great deal of information is available via the debug logging system, if you are having issues with minions connecting or not starting run the master in the foreground:

```
# salt-master -l debug
```

Anyone wanting to run Salt daemons via a process supervisor such as monit, runit, or supervisord, should omit the -d argument to the daemons and run them in the foreground.

What Ports does the Master Need Open?

For the master, TCP ports 4505 and 4506 need to be open. If you've put both your Salt master and minion in debug mode and don't see an acknowledgment that your minion has connected, it could very well be a firewall interfering with the connection. See our firewall configuration page for help opening the firewall on various platforms.

If you’ve opened the correct TCP ports and still aren’t seeing connections, check that no additional access control system such as SELinux or AppArmor is blocking Salt.

Too many open files

The salt-master needs at least 2 sockets per host that connects to it, one for the Publisher and one for response port. Thus, large installations may, upon scaling up the number of minions accessing a given master, encounter:
The solution to this would be to check the number of files allowed to be opened by the user running salt-master (root by default):

```
[root@salt-master ~]# ulimit -n
1024
```

If this value is not equal to at least twice the number of minions, then it will need to be raised. For example, in an environment with 1800 minions, the nofile limit should be set to no less than 3600. This can be done by creating the file `/etc/security/limits.d/99-salt.conf`, with the following contents:

```
root hard nofile 4096
root soft nofile 4096
```

Replace `root` with the user under which the master runs, if different.

If your master does not have an `/etc/security/limits.d` directory, the lines can simply be appended to `/etc/security/limits.conf`.

As with any change to resource limits, it is best to stay logged into your current shell and open another shell to run `ulimit -n` again and verify that the changes were applied correctly. Additionally, if your master is running upstart, it may be necessary to specify the nofile limit in `/etc/default/salt-master` if upstart isn’t respecting your resource limits:

```
limit nofile 4096 4096
```

**Note:** The above is simply an example of how to set these values, and you may wish to increase them even further if your Salt master is doing more than just running Salt.

---

**Salt Master Stops Responding**

There are known bugs with ZeroMQ versions less than 2.1.11 which can cause the Salt master to not respond properly. If you’re running a ZeroMQ version greater than or equal to 2.1.9, you can work around the bug by setting the sysctls `net.core.rmem_max` and `net.core.wmem_max` to 16777216. Next, set the third field in `net.ipv4.tcp_rmem` and `net.ipv4.tcp_wmem` to at least 16777216.

You can do it manually with something like:

```
# echo 16777216 > /proc/sys/net/core/rmem_max
# echo 16777216 > /proc/sys/net/core/wmem_max
# echo "4096 87380 16777216" > /proc/sys/net/ipv4/tcp_rmem
# echo "4096 87380 16777216" > /proc/sys/net/ipv4/tcp_wmem
```

Or with the following Salt state:

```python
# net.core.rmem_max:
#   sysctl:
#     - present
#     - value: 16777216

# net.core.wmem_max:
#   sysctl:
```
Live Python Debug Output

If the master seems to be unresponsive, a SIGUSR1 can be passed to the salt-master threads to display what piece of code is executing. This debug information can be invaluable in tracking down bugs.

To pass a SIGUSR1 to the master, first make sure the minion is running in the foreground. Stop the service if it is running as a daemon, and start it in the foreground like so:

```
# salt-master -l debug
```

Then pass the signal to the master when it seems to be unresponsive:

```
# killall -SIGUSR1 salt-master
```

When filing an issue or sending questions to the mailing list for a problem with an unresponsive daemon, be sure to include this information if possible.

Live Salt-Master Profiling

When faced with performance problems one can turn on master process profiling by sending it SIGUSR2.

```
# killall -SIGUSR2 salt-master
```

This will activate `yappi` profiler inside salt-master code, then after some time one must send SIGUSR2 again to stop profiling and save results to file. If run in foreground salt-master will report filename for the results, which are usually located under `/tmp` on Unix-based OSes and `c:\temp` on windows.

Results can then be analyzed with `kcachegrind` or similar tool.

Commands Time Out or Do Not Return Output

Depending on your OS (this is most common on Ubuntu due to apt-get) you may sometimes encounter times where a `state.apply`, or other long running commands do not return output.

By default the timeout is set to 5 seconds. The timeout value can easily be increased by modifying the `timeout` line within your `/etc/salt/master` configuration file.

Having keys accepted for Salt minions that no longer exist or are not reachable also increases the possibility of timeouts, since the Salt master waits for those systems to return command results.
Passing the `-c` Option to Salt Returns a Permissions Error

Using the `-c` option with the Salt command modifies the configuration directory. When the configuration file is read it will still base data off of the `root_dir` setting. This can result in unintended behavior if you are expecting files such as `/etc/salt/pki` to be pulled from the location specified with `-c`. Modify the `root_dir` setting to address this behavior.

Salt Master Doesn’t Return Anything While Running jobs

When a command being run via Salt takes a very long time to return (package installations, certain scripts, etc.) the master may drop you back to the shell. In most situations the job is still running but Salt has exceeded the set timeout before returning. Querying the job queue will provide the data of the job but is inconvenient. This can be resolved by either manually using the `-t` option to set a longer timeout when running commands (by default it is 5 seconds) or by modifying the master configuration file: `/etc/salt/master` and setting the `timeout` value to change the default timeout for all commands, and then restarting the salt-master service.

Salt Master Auth Flooding

In large installations, care must be taken not to overwhelm the master with authentication requests. Several options can be set on the master which mitigate the chances of an authentication flood from causing an interruption in service.

**Note:**

- `recon_default`: The average number of seconds to wait between reconnection attempts.
- `recon_max`: The maximum number of seconds to wait between reconnection attempts.
- `recon_randomize`: A flag to indicate whether the `recon_default` value should be randomized.
- `acceptance_wait_time`: The number of seconds to wait for a reply to each authentication request.
- `random_reauth_delay`: The range of seconds across which the minions should attempt to randomize authentication attempts.
- `auth_timeout`: The total time to wait for the authentication process to complete, regardless of the number of attempts.

35.1.2 Running state locally

To debug the states, you can use call locally.

```
salt-call -l trace --local state.highstate
```

The top.sls file is used to map what SLS modules get loaded onto what minions via the state system. It is located in the file defined in the `file_roots` variable of the salt master configuration file which is defined by found in `CONFIG_DIR/master`, normally `/etc/salt/master`

The default configuration for the `file_roots` is:

```
file_roots:
  base:
    - /srv/salt
```

So the top file is defaulted to the location `/srv/salt/top.sls`
Salt Master Umask

The salt master uses a cache to track jobs as they are published and returns come back. The recommended umask for a salt-master is 022, which is the default for most users on a system. Incorrect umasks can result in permission-denied errors when the master tries to access files in its cache.

35.2 Troubleshooting the Salt Minion

In the event that your Salt minion is having issues, a variety of solutions and suggestions are available. Please refer to the following links for more information:

35.2.1 Troubleshooting the Salt Minion

Running in the Foreground

A great deal of information is available via the debug logging system, if you are having issues with minions connecting or not starting run the minion in the foreground:

```
# salt-minion -l debug
```

Anyone wanting to run Salt daemons via a process supervisor such as monit, runit, or supervisord, should omit the -d argument to the daemons and run them in the foreground.

What Ports does the Minion Need Open?

No ports need to be opened on the minion, as it makes outbound connections to the master. If you've put both your Salt master and minion in debug mode and don't see an acknowledgment that your minion has connected, it could very well be a firewall interfering with the connection. See our firewall configuration page for help opening the firewall on various platforms.

If you have netcat installed, you can check port connectivity from the minion with the `nc` command:

```
$ nc -v -z salt.master.ip.addr 4505
Connection to salt.master.ip.addr 4505 port [tcp/unknown] succeeded!
$ nc -v -z salt.master.ip.addr 4506
Connection to salt.master.ip.addr 4506 port [tcp/unknown] succeeded!
```

The `Nmap` utility can also be used to check if these ports are open:

```
# nmap -sS -q -p 4505-4506 salt.master.ip.addr
Starting Nmap 6.40 ( http://nmap.org ) at 2013-12-29 19:44 CST
Nmap scan report for salt.master.ip.addr (10.0.0.10)
Host is up (0.0026s latency).
PORT STATE SERVICE
4505/tcp open unknown
4506/tcp open unknown
MAC Address: 00:11:22:AA:BB:CC (Intel)
Nmap done: 1 IP address (1 host up) scanned in 1.64 seconds
```

If you've opened the correct TCP ports and still aren't seeing connections, check that no additional access control system such as SELinux or AppArmor is blocking Salt.
Using salt-call

The `salt-call` command was originally developed for aiding in the development of new Salt modules. Since then, many applications have been developed for running any Salt module locally on a minion. These range from the original intent of `salt-call` (development assistance), to gathering more verbose output from calls like `state.apply`.

When initially creating your state tree, it is generally recommended to invoke highstates by running `state.apply` directly from the minion with `salt-call`, rather than remotely from the master. This displays far more information about the execution than calling it remotely. For even more verbosity, increase the loglevel using the `-l` argument:

```
# salt-call -l debug state.apply
```

The main difference between using `salt` and using `salt-call` is that `salt-call` is run from the minion, and it only runs the selected function on that minion. By contrast, `salt` is run from the master, and requires you to specify the minions on which to run the command using `salt`'s targeting system.

Live Python Debug Output

If the minion seems to be unresponsive, a SIGUSR1 can be passed to the process to display what piece of code is executing. This debug information can be invaluable in tracking down bugs.

To pass a SIGUSR1 to the minion, first make sure the minion is running in the foreground. Stop the service if it is running as a daemon, and start it in the foreground like so:

```
# salt-minion -l debug
```

Then pass the signal to the minion when it seems to be unresponsive:

```
# killall -SIGUSR1 salt-minion
```

When filing an issue or sending questions to the mailing list for a problem with an unresponsive daemon, be sure to include this information if possible.

Multiprocessing in Execution Modules

As is outlined in GitHub issue #6300, Salt cannot use Python's multiprocessing pipes and queues from execution modules. Multiprocessing from the execution modules is perfectly viable, it is just necessary to use Salt's event system to communicate back with the process.

The reason for this difficulty is that Python attempts to pickle all objects in memory when communicating, and it cannot pickle function objects. Since the Salt loader system creates and manages function objects this causes the pickle operation to fail.

Salt Minion Doesn't Return Anything While Running Jobs Locally

When a command being run via Salt takes a very long time to return (package installations, certain scripts, etc.) the minion may drop you back to the shell. In most situations the job is still running but Salt has exceeded the set timeout before returning. Querying the job queue will provide the data of the job but is inconvenient. This can be resolved by either manually using the `-t` option to set a longer timeout when running commands (by default it is 5 seconds) or by modifying the minion configuration file: `/etc/salt/minion` and setting the timeout value to change the default timeout for all commands, and then restarting the salt-minion service.
Note: Modifying the minion timeout value is not required when running commands from a Salt Master. It is only required when running commands locally on the minion.

35.3 Running in the Foreground

A great deal of information is available via the debug logging system, if you are having issues with minions connecting or not starting run the minion and/or master in the foreground:

```
salt-master -l debug
salt-minion -l debug
```

Anyone wanting to run Salt daemons via a process supervisor such as monit, runit, or supervisord, should omit the -d argument to the daemons and run them in the foreground.

35.4 What Ports do the Master and Minion Need Open?

No ports need to be opened up on each minion. For the master, TCP ports 4505 and 4506 need to be open. If you’ve put both your Salt master and minion in debug mode and don’t see an acknowledgment that your minion has connected, it could very well be a firewall.

You can check port connectivity from the minion with the nc command:

```
nc -v -z salt.master.ip 4505
nc -v -z salt.master.ip 4506
```

There is also a firewall configuration document that might help as well.

If you’ve enabled the right TCP ports on your operating system or Linux distribution’s firewall and still aren’t seeing connections, check that no additional access control system such as SELinux or AppArmor is blocking Salt.

35.5 Using salt-call

The salt-call command was originally developed for aiding in the development of new Salt modules. Since then, many applications have been developed for running any Salt module locally on a minion. These range from the original intent of salt-call, development assistance, to gathering more verbose output from calls like state.apply.

When initially creating your state tree, it is generally recommended to invoke state.apply directly from the minion with salt-call, rather than remotely from the master. This displays far more information about the execution than calling it remotely. For even more verbosity, increase the loglevel using the -l argument:

```
salt-call -l debug state.apply
```

The main difference between using salt and using salt-call is that salt-call is run from the minion, and it only runs the selected function on that minion. By contrast, salt is run from the master, and requires you to specify the minions on which to run the command using salt’s targeting system.
35.6 Too many open files

The salt-master needs at least 2 sockets per host that connects to it, one for the Publisher and one for response port. Thus, large installations may, upon scaling up the number of minions accessing a given master, encounter:

```
12:45:29,289 [salt.master ][INFO ] Starting Salt worker process 38
Too many open files
sock != -1 (tcp_listener.cpp:335)
```

The solution to this would be to check the number of files allowed to be opened by the user running salt-master (root by default):

```
[root@salt-master ~]# ulimit -n
1024
```

And modify that value to be at least equal to the number of minions x 2. This setting can be changed in limits.conf as the nofile value(s), and activated upon new a login of the specified user.

So, an environment with 1800 minions, would need 1800 x 2 = 3600 as a minimum.

35.7 Salt Master Stops Responding

There are known bugs with ZeroMQ versions less than 2.1.11 which can cause the Salt master to not respond properly. If you’re running a ZeroMQ version greater than or equal to 2.1.9, you can work around the bug by setting the sysctls `net.core.rmem_max` and `net.core.wmem_max` to 16777216. Next, set the third field in `net.ipv4.tcp_rmem` and `net.ipv4.tcp_wmem` to at least 16777216.

You can do it manually with something like:

```
# echo 16777216 > /proc/sys/net/core/rmem_max
# echo 16777216 > /proc/sys/net/core/wmem_max
# echo "4096 87380 16777216" > /proc/sys/net/ipv4/tcp_rmem
# echo "4096 87380 16777216" > /proc/sys/net/ipv4/tcp_wmem
```

Or with the following Salt state:

```
net.core.rmem_max:
  sysctl:
    - present
    - value: 16777216

net.core.wmem_max:
  sysctl:
    - present
    - value: 16777216

net.ipv4.tcp_rmem:
  sysctl:
    - present
    - value: 4096 87380 16777216

net.ipv4.tcp_wmem:
  sysctl:
    - present
    - value: 4096 87380 16777216
```
35.8 Salt and SELinux

Currently there are no SELinux policies for Salt. For the most part Salt runs without issue when SELinux is running in Enforcing mode. This is because when the minion executes as a daemon the type context is changed to initrc_t. The problem with SELinux arises when using salt-call or running the minion in the foreground, since the type context stays unconfined_t.

This problem is generally manifest in the rpm install scripts when using the pkg module. Until a full SELinux Policy is available for Salt the solution to this issue is to set the execution context of salt-call and salt-minion to rpm_exec_t:

```
# CentOS 5 and RHEL 5:
chcon -t system_u:system_r:rpm_exec_t:s0 /usr/bin/salt-minion
chcon -t system_u:system_r:rpm_exec_t:s0 /usr/bin/salt-call

# CentOS 6 and RHEL 6:
chcon system_u:object_r:rpm_exec_t:s0 /usr/bin/salt-minion
chcon system_u:object_r:rpm_exec_t:s0 /usr/bin/salt-call
```

This works well, because the rpm_exec_t context has very broad control over other types.

35.9 Red Hat Enterprise Linux 5

Salt requires Python 2.6 or 2.7. Red Hat Enterprise Linux 5 and its variants come with Python 2.4 installed by default. When installing on RHEL 5 from the EPEL repository this is handled for you. But, if you run Salt from git, be advised that its dependencies need to be installed from EPEL and that Salt needs to be run with the python26 executable.

35.10 Common YAML Gotchas

An extensive list of YAML idiosyncrasies has been compiled:

35.10.1 YAML Idiosyncrasies

One of Salt’s strengths, the use of existing serialization systems for representing SLS data, can also backfire. YAML is a general purpose system and there are a number of things that would seem to make sense in an sls file that cause YAML issues. It is wise to be aware of these issues. While reports or running into them are generally rare they can still crop up at unexpected times.

Spaces vs Tabs

YAML uses spaces, period. Do not use tabs in your SLS files! If strange errors are coming up in rendering SLS files, make sure to check that no tabs have crept in! In Vim, after enabling search highlighting with: `:set hlsearch`, you can check with the following key sequence in normal mode(you can hit ESC twice to be sure): ` /, Ctrl-v, Tab`, then hit `Enter`. Also, you can convert tabs to 2 spaces by these commands in Vim: `:set tabstop=2 expandtab` and then `:retab`. 
**Indentation**

The suggested syntax for YAML files is to use 2 spaces for indentation, but YAML will follow whatever indentation system that the individual file uses. Indentation of two spaces works very well for SLS files given the fact that the data is uniform and not deeply nested.

**Nested Dictionaries**

When dicts are nested within other data structures (particularly lists), the indentation logic sometimes changes. Examples of where this might happen include context and defaults options from the file.managed state:

```
/etc/http/conf/http.conf:
  file:
    - managed
    - source: salt://apache/http.conf
    - user: root
    - group: root
    - mode: 644
    - template: jinja
    - context:
      custom_var: "override"
    - defaults:
      custom_var: "default value"
      other_var: 123
```

Notice that while the indentation is two spaces per level, for the values under the context and defaults options there is a four-space indent. If only two spaces are used to indent, then those keys will be considered part of the same dictionary that contains the context key, and so the data will not be loaded correctly. If using a double indent is not desirable, then a deeply-nested dict can be declared with curly braces:

```
/etc/http/conf/http.conf:
  file:
    - managed
    - source: salt://apache/http.conf
    - user: root
    - group: root
    - mode: 644
    - template: jinja
    - context: {
      custom_var: "override"
    }
    - defaults: {
      custom_var: "default value",
      other_var: 123
    }
```

Here is a more concrete example of how YAML actually handles these indentations, using the Python interpreter on the command line:

```
>>> import yaml
>>> yaml.safe_load('''mystate:
...   file.managed:
...     - context:
...       some: var'''))
{'mystate': {'file.managed': [{'context': {'some': 'var'}}]}}
```
Note that in the second example, *some* is added as another key in the same dictionary, whereas in the first example, it’s the start of a new dictionary. That’s the distinction. *context* is a common example because it is a keyword arg for many functions, and should contain a dictionary.

**True/False, Yes/No, On/Off**

PyYAML will load these values as boolean *True* or *False*. Un-capitalized versions will also be loaded as booleans (*true*, *false*, *yes*, *no*, *on*, and *off*). This can be especially problematic when constructing Pillar data. Make sure that your Pillars which need to use the string versions of these values are enclosed in quotes.

**The `%' Sign**

The `%` symbol has a special meaning in YAML, it needs to be passed as a string literal:

```yaml
cheese:
  ssh_auth.present:
    - user: tbortels
    - source: salt://ssh_keys/chease.pub
    - config: '%h/.ssh/authorized_keys'
```

**Integers are Parsed as Integers**

NOTE: This has been fixed in salt 0.10.0, as of this release passing an integer that is preceded by a 0 will be correctly parsed

When passing *integers* into an SLS file, they are passed as integers. This means that if a state accepts a string value and an integer is passed, that an integer will be sent. The solution here is to send the integer as a string.

This is best explained when setting the mode for a file:

```
/etc/vimrc:
  file:
    - managed
    - source: salt://edit/vimrc
    - user: root
    - group: root
    - mode: 644
```

Salt manages this well, since the mode is passed as 644, but if the mode is zero padded as 0644, then it is read by YAML as an integer and evaluated as an octal value, 0644 becomes 420. Therefore, if the file mode is preceded by a 0 then it needs to be passed as a string:

```
/etc/vimrc:
  file:
    - managed
    - source: salt://edit/vimrc
    - user: root
    - group: root
    - mode: '0644'
```
YAML does not like `Double Short Decs`

If I can find a way to make YAML accept `Double Short Decs` then I will, since I think that double short decs would be awesome. So what is a `Double Short Dec`? It is when you declare a multiple short decs in one ID. Here is a standard short dec, it works great:

```
vim:
  pkg.installed
```

The short dec means that there are no arguments to pass, so it is not required to add any arguments, and it can save space.

YAML though, gets upset when declaring multiple short decs, for the record...

THIS DOES NOT WORK:

```
vim:
  pkg.installed
  user.present
```

Similarly declaring a short dec in the same ID dec as a standard dec does not work either...

ALSO DOES NOT WORK:

```
fred:
  user.present
  ssh_auth.present:
    - name: AAAAB3NzaC...
    - user: fred
    - enc: ssh-dss
    - require:
      - user: fred
```

The correct way is to define them like this:

```
vim:
  pkg.installed: []
  user.present: []

fred:
  user.present: []
  ssh_auth.present:
    - name: AAAAB3NzaC...
    - user: fred
    - enc: ssh-dss
    - require:
      - user: fred
```

Alternatively, they can be defined the `old way`, or with multiple `full decs`:

```
vim:
  pkg:
    - installed
  user:
    - present

fred:
  user:
    - present
```
ssh_auth:
  - present
  - name: AAAAB3NzaC...
  - user: fred
  - enc: ssh-dss
  - require:
    - user: fred

YAML support only plain ASCII

According to YAML specification, only ASCII characters can be used.
Within double-quotes, special characters may be represented with C-style escape sequences starting with a backslash (\).
Examples:

- micro: "\u00b5"
- copyright: "\u00A9"
- A: "\x41"
- alpha: "\u0251"
- Alef: "\u05d0"

List of usable Unicode characters will help you to identify correct numbers.
Python can also be used to discover the Unicode number for a character:

```python
repr(u"Text with wrong characters i need to figure out")
```

This shell command can find wrong characters in your SLS files:

```
find . -name '*.sls' -exec grep --color='auto' -P -n '^[\x00-\x7F]\{0\}';
```

Alternatively you can toggle the `yaml_utf8` setting in your master configuration file. This is still an experimental setting but it should manage the right encoding conversion in salt after yaml states compilations.

Underscores stripped in Integer Definitions

If a definition only includes numbers and underscores, it is parsed by YAML as an integer and all underscores are stripped. To ensure the object becomes a string, it should be surrounded by quotes. More information here.

Here's an example:

```python
>>> import yaml
>>> yaml.safe_load('2013_05_10')
20130510
>>> yaml.safe_load('"2013_05_10"')
'2013_05_10'
```

Automatic datetime conversion

If there is a value in a YAML file formatted 2014-01-20 14:23:23 or similar, YAML will automatically convert this to a Python datetime object. These objects are not msgpack serializable, and so may break core salt functionality. If values such as these are needed in a salt YAML file (specifically a configuration file), they should be formatted with surrounding strings to force YAML to serialize them as strings.
Additionally, numbers formatted like XXXX-XX-XX will also be converted (or YAML will attempt to convert them, and error out if it doesn't think the date is a real one). Thus, for example, if a minion were to have an ID of 4017-16-20 the minion would not start because YAML would complain that the date was out of range. The workaround is the same, surround the offending string with quotes:

```python
>>> import yaml
>>> yaml.safe_load('4017-16-20')
'4017-16-20'
```

Keys Limited to 1024 Characters

Simple keys are limited to a single line and cannot be longer than 1024 characters. This is a limitation from PyYaml, as seen in a comment in PyYAML's code, and applies to anything parsed by YAML in Salt.

35.11 Live Python Debug Output

If the minion or master seems to be unresponsive, a SIGUSR1 can be passed to the processes to display where in the code they are running. If encountering a situation like this, this debug information can be invaluable. First make sure the master of minion are running in the foreground:

```bash
salt-master -l debug
salt-minion -l debug
```

Then pass the signal to the master or minion when it seems to be unresponsive:

```bash
killall -SIGUSR1 salt-master
killall -SIGUSR1 salt-minion
```
Also under BSD and Mac OS X in addition to SIGUSR1 signal, debug subroutine set up for SIGINFO which has an advantage of being sent by Ctrl+T shortcut.

When filing an issue or sending questions to the mailing list for a problem with an unresponsive daemon this information can be invaluable.

### 35.12 Salt 0.16.x minions cannot communicate with a 0.17.x master

As of release 0.17.1 you can no longer run different versions of Salt on your Master and Minion servers. This is due to a protocol change for security purposes. The Salt team will continue to attempt to ensure versions are as backwards compatible as possible.

### 35.13 Debugging the Master and Minion

A list of common *master* and *minion* troubleshooting steps provide a starting point for resolving issues you may encounter.
36.1 Overview

In its most typical use, Salt is a software application in which clients, called "minions" can be commanded and controlled from a central command server called a "master".

Commands are normally issued to the minions (via the master) by calling a client script simply called, 'salt'.

Salt features a pluggable transport system to issue commands from a master to minions. The default transport is ZeroMQ.

36.2 Salt Client

36.2.1 Overview

The salt client is run on the same machine as the Salt Master and communicates with the salt-master to issue commands and to receive the results and display them to the user.

The primary abstraction for the salt client is called 'LocalClient'.

When LocalClient wants to publish a command to minions, it connects to the master by issuing a request to the master's ReqServer (TCP: 4506)

The LocalClient system listens to responses for its requests by listening to the master event bus publisher (master_event_pub.ipc).

36.3 Salt Master

36.3.1 Overview

The salt-master daemon runs on the designated Salt master and performs functions such as authenticating minions, sending, and receiving requests from connected minions and sending and receiving requests and replies to the 'salt' CLI.
36.3.2 Moving Pieces

When a Salt master starts up, a number of processes are started, all of which are called `salt-master' in a process-list but have various role categories.

Among those categories are:

- Publisher
- EventPublisher
- MWorker

36.3.3 Publisher

The Publisher process is responsible for sending commands over the designated transport to connected minions. The Publisher is bound to the following:

- TCP: port 4505
- IPC: publish_pull.ipc

Each salt minion establishes a connection to the master Publisher.

36.3.4 EventPublisher

The EventPublisher publishes events onto the event bus. It is bound to the following:

- IPC: master_event_pull.ipc
- IPC: master_event_pub.ipc

36.3.5 MWorker

Worker processes manage the back-end operations for the Salt Master.

The number of workers is equivalent to the number of `worker_threads' specified in the master configuration and is always at least one.

Workers are bound to the following:

- IPC: workers.ipc

36.3.6 ReqServer

The Salt request server takes requests and distributes them to available MWorker processes for processing. It also receives replies back from minions.

The ReqServer is bound to the following:

- TCP: 4506
- IPC: workers.ipc

Each salt minion establishes a connection to the master ReqServer.
36.3.7 Job Flow

The Salt master works by always publishing commands to all connected minions and the minions decide if the command is meant for them by checking themselves against the command target.

The typical lifecycle of a salt job from the perspective of the master might be as follows:

1. A command is issued on the CLI. For example, `salt my_minion test.ping'.
2) The `salt' command uses LocalClient to generate a request to the salt master by connecting to the ReqServer on TCP:4506 and issuing the job.
3) The salt-master ReqServer sees the request and passes it to an available MWorker over workers.ipc.
4) A worker picks up the request and handles it. First, it checks to ensure that the requested user has permissions to issue the command. Then, it sends the publish command to all connected minions. For the curious, this happens in ClearFuncs.publish().
5) The worker announces on the master event bus that it is about to publish a job to connected minions. This happens by placing the event on the master event bus (master_event_pull.ipc) where the EventPublisher picks it up and distributes it to all connected event listeners on master_event_pub.ipc.
6) The message to the minions is encrypted and sent to the Publisher via IPC on publish_pull.ipc.
7) Connected minions have a TCP session established with the Publisher on TCP port 4505 where they await commands. When the Publisher receives the job over publish_pull, it sends the jobs across the wire to the minions for processing.
8) After the minions receive the request, they decrypt it and perform any requested work, if they determine that they are targeted to do so.
9) When the minion is ready to respond, it publishes the result of its job back to the master by sending the encrypted result back to the master on TCP 4506 where it is again picked up by the ReqServer and forwarded to an available MWorker for processing. (Again, this happens in AESFuncs._return().)
10) When the MWorker receives the job it decrypts it and fires an event onto the master event bus (master_event_pull.ipc). (Again for the curious, this happens in AESFuncs._return().)
11) The EventPublisher sees this event and re-publishes it on the bus to all connected listeners of the master event bus (on master_event_pub.ipc). This is where the LocalClient has been waiting, listening to the event bus for minion replies. It gathers the job and stores the result.
12) When all targeted minions have replied or the timeout has been exceeded, the salt client displays the results of the job to the user on the CLI.

36.4 Salt Minion

36.4.1 Overview

The salt-minion is a single process that sits on machines to be managed by Salt. It can either operate as a stand-alone daemon which accepts commands locally via `salt-call' or it can connect back to a master and receive commands remotely.

When starting up, salt minions connect _back_ to a master defined in the minion config file. The connect to two ports on the master:

- TCP: 4505 This is the connection to the master Publisher. It is on this port that the minion receives jobs from the master.
- TCP: 4506 This is the connection to the master ReqServer. It is on this port that the minion sends job results back to the master.

### 36.4.2 Event System

Similar to the master, a salt-minion has its own event system that operates over IPC by default. The minion event system operates on a push/pull system with IPC files at `minion_event_<unique_id>_<pull>` and `minion_event_<unique_id>_<pub>`.  

The astute reader might ask why have an event bus at all with a single-process daemon. The answer is that the salt-minion may fork other processes as required to do the work without blocking the main salt-minion process and this necessitates a mechanism by which those processes can communicate with each other. Secondarily, this provides a bus by which any user with sufficient permissions can read or write to the bus as a common interface with the salt minion.

### 36.4.3 Job Flow

When a salt minion starts up, it attempts to connect to the Publisher and the ReqServer on the salt master. It then attempts to authenticate and once the minion has successfully authenticated, it simply listens for jobs.

Jobs normally come either from the `salt-call` script run by a local user on the salt minion or they can come directly from a master.

### 36.4.4 Master Job Flow

1) A master publishes a job that is received by a minion as outlined by the master’s job flow above.

2) The minion is polling its receive socket that’s connected to the master Publisher (TCP 4505 on master). When it detects an incoming message, it picks it up from the socket and decrypts it.
