We're not just talking about NaCl.

1.1 The 30 second summary

Salt is:

- a configuration management system, capable of maintaining remote nodes in defined states (for example, ensuring that specific packages are installed and specific services are running)
- a distributed remote execution system used to execute commands and query data on remote nodes, either individually or by arbitrary selection criteria

It was developed in order to bring the best solutions found in the world of remote execution together and make them better, faster, and more malleable. Salt accomplishes this through its ability to handle large loads of information, and not just dozens but hundreds and even thousands of individual servers quickly through a simple and manageable interface.

1.2 Simplicity

Providing versatility between massive scale deployments and smaller systems may seem daunting, but Salt is very simple to set up and maintain, regardless of the size of the project. The architecture of Salt is designed to work with any number of servers, from a handful of local network systems to international deployments across different data centers. The topology is a simple server/client model with the needed functionality built into a single set of daemons. While the default configuration will work with little to no modification, Salt can be fine tuned to meet specific needs.

1.3 Parallel execution

The core functions of Salt:

- enable commands to remote systems to be called in parallel rather than serially
- use a secure and encrypted protocol
- use the smallest and fastest network payloads possible
- provide a simple programming interface

Salt also introduces more granular controls to the realm of remote execution, allowing systems to be targeted not just by hostname, but also by system properties.
1.4 Building on proven technology

Salt takes advantage of a number of technologies and techniques. The networking layer is built with the excellent ZeroMQ networking library, so the Salt daemon includes a viable and transparent AMQ broker. Salt uses public keys for authentication with the master daemon, then uses faster AES encryption for payload communication; authentication and encryption are integral to Salt. Salt takes advantage of communication via msgpack, enabling fast and light network traffic.

1.5 Python client interface

In order to allow for simple expansion, Salt execution routines can be written as plain Python modules. The data collected from Salt executions can be sent back to the master server, or to any arbitrary program. Salt can be called from a simple Python API, or from the command line, so that Salt can be used to execute one-off commands as well as operate as an integral part of a larger application.

1.6 Fast, flexible, scalable

The result is a system that can execute commands at high speed on target server groups ranging from one to very many servers. Salt is very fast, easy to set up, amazingly malleable and provides a single remote execution architecture that can manage the diverse requirements of any number of servers. The Salt infrastructure brings together the best of the remote execution world, amplifies its capabilities and expands its range, resulting in a system that is as versatile as it is practical, suitable for any network.

1.7 Open

Salt is developed under the Apache 2.0 license, and can be used for open and proprietary projects. Please submit your expansions back to the Salt project so that we can all benefit together as Salt grows. Please feel free to sprinkle Salt around your systems and let the deliciousness come forth.

1.8 Salt Community

Join the Salt!

There are many ways to participate in and communicate with the Salt community.

Salt has an active IRC channel and a mailing list.

1.9 Mailing List

Join the salt-users mailing list. It is the best place to ask questions about Salt and see what's going on with Salt development! The Salt mailing list is hosted by Google Groups. It is open to new members.

https://groups.google.com/forum/#!forum/salt-users

There is also a low-traffic list used to announce new releases called salt-announce

https://groups.google.com/forum/#!forum/salt-announce
1.10 IRC

The #salt IRC channel is hosted on the popular Freenode network. You can use the Freenode webchat client right from your browser.

Logs of the IRC channel activity are being collected courtesy of Moritz Lenz.

If you wish to discuss the development of Salt itself join us in #salt-devel.

1.11 Follow on GitHub

The Salt code is developed via GitHub. Follow Salt for constant updates on what is happening in Salt development:

https://github.com/saltstack/salt

1.12 Blogs

SaltStack Inc. keeps a blog with recent news and advancements:

http://www.saltstack.com/blog/

Thomas Hatch also shares news and thoughts on Salt and related projects in his personal blog The Red45:

http://red45.wordpress.com/

1.13 Example Salt States

The official salt-states repository is: https://github.com/saltstack/salt-states

1.16 Hack the Source

If you want to get involved with the development of source code or the documentation efforts, please review the hacking section!
See also:
*Installing Salt for development* and contributing to the project.

## 2.1 Quick Install

On most distributions, you can set up a Salt Minion with the Salt Bootstrap.

## 2.2 Platform-specific Installation Instructions

These guides go into detail how to install Salt on a given platform.

### 2.2.1 Arch Linux

**Installation**

Salt (stable) is currently available via the Arch Linux Official repositories. There are currently -git packages available in the Arch User repositories (AUR) as well.

**Stable Release**

Install Salt stable releases from the Arch Linux Official repositories as follows:

```
pacman -S salt-zmq
```

To install Salt stable releases using the RAET protocol, use the following:

```
pacman -S salt-raet
```

**Note:** transports

Unlike other linux distributions, please be aware that Arch Linux’s package manager pacman defaults to RAET as the Salt transport. If you want to use ZeroMQ instead, make sure to enter the associated number for the salt-zmq repository when prompted.
Tracking develop

To install the bleeding edge version of Salt (may include bugs!), use the -git package. Installing the -git package as follows:

```
wget https://aur.archlinux.org/packages/sa/salt-git/salt-git.tar.gz
tar xf salt-git.tar.gz
cd salt-git/
makpkg -is
```

Note: yaourt

If a tool such as Yaourt is used, the dependencies will be gathered and built automatically.

The command to install salt using the yaourt tool is:

```
yaourt salt-git
```

Post-installation tasks

systemd

Activate the Salt Master and/or Minion via systemctl as follows:

```
systemctl enable salt-master.service
systemctl enable salt-minion.service
```

Start the Master

Once you've completed all of these steps you're ready to start your Salt Master. You should be able to start your Salt Master now using the command seen here:

```
systemctl start salt-master
```

Now go to the Configuring Salt page.

2.2.2 Debian GNU/Linux / Raspbian

Debian GNU/Linux distribution and some derivatives such as Raspbian already have included Salt packages to their repositories. However, current stable release codenamed ``Jessie'' contains old outdated Salt release. It is recommended to use SaltStack repository for Debian as described below.

Installation from official Debian and Raspbian repositories is described here.

Installation from the Official SaltStack Repository

Packages for Debian 8 (Jessie) and Debian 7 (Wheezy) are available in the Official SaltStack repository.

Instructions are at http://repo.saltstack.com/#debian.
Installation from the Debian / Raspbian Official Repository

Stretch (Testing) and Sid (Unstable) distributions are already contain mostly up-to-date Salt packages built by Debian Salt Team. You can install Salt components directly from Debian.

On Jessie ( Stable) there is an option to install Salt minion from Stretch with python-tornado dependency from jessie-backports repositories.

To install fresh release of Salt minion on Jessie:

1. Add jessie-backports and stretch repositories:
   - **Debian:**
     ```
     echo 'deb http://httpredir.debian.org/debian jessie-backports main' >> /etc/apt/sources.list
     echo 'deb http://httpredir.debian.org/debian stretch main' >> /etc/apt/sources.list
     ```
   - **Raspbian:**
     ```
     echo 'deb http://archive.raspbian.org/raspbian/ stretch main' >> /etc/apt/sources.list
     ```

2. Make Jessie a default release:
   ```
   echo 'APT::Default-Release "jessie";' > /etc/apt/apt.conf.d/10apt
   ```

3. Install Salt dependencies:
   - **Debian:**
     ```
     apt-get update
     apt-get install python-zmq python-tornado/jessie-backports salt-common/stretch
     ```
   - **Raspbian:**
     ```
     apt-get update
     apt-get install python-zmq python-tornado/stretch salt-common/stretch
     ```

4. Install Salt minion package from Stretch:
   ```
   apt-get install salt-minion/stretch
   ```

Install Packages

Install the Salt master, minion or other packages from the repository with the `apt-get` command. These examples each install one of Salt components, but more than one package name may be given at a time:

- `apt-get install salt-api`
- `apt-get install salt-cloud`
- `apt-get install salt-master`
- `apt-get install salt-minion`
- `apt-get install salt-ssh`
- `apt-get install salt-syndic`
Post-installation tasks

Now, go to the Configuring Salt page.

2.2.3 Fedora

Beginning with version 0.9.4, Salt has been available in the primary Fedora repositories and EPEL. It is installable using yum or dnf, depending on your version of Fedora.

Note: Released versions of Salt starting with 2015.5.2 through 2016.3.2 do not have Fedora packages available through EPEL. To install a version of Salt within this release array, please use SaltStack’s Bootstrap Script and use the git method of installing Salt using the version’s associated release tag. Release 2016.3.3 and onward will have packaged versions available via EPEL.

WARNING: Fedora 19 comes with systemd 204. Systemd has known bugs fixed in later revisions that prevent the salt-master from starting reliably or opening the network connections that it needs to. It’s not likely that a salt-master will start or run reliably on any distribution that uses systemd version 204 or earlier. Running salt-minions should be OK.

Installation

Salt can be installed using yum and is available in the standard Fedora repositories.

Stable Release

Salt is packaged separately for the minion and the master. It is necessary only to install the appropriate package for the role the machine will play. Typically, there will be one master and multiple minions.

```
yum install salt-master
yum install salt-minion
```

Installing from updates-testing

When a new Salt release is packaged, it is first admitted into the updates-testing repository, before being moved to the stable repo.

To install from updates-testing, use the enablerepo argument for yum:

```
yum --enablerepo=updates-testing install salt-master
yum --enablerepo=updates-testing install salt-minion
```

Installation Using pip

Since Salt is on PyPI, it can be installed using pip, though most users prefer to install using a package manager. Installing from pip has a few additional requirements:

- Install the group `Development Tools`, dnf groupinstall 'Development Tools'
- Install the `zeromq-devel` package if it fails on linking against that afterwards as well.
A pip install does not make the init scripts or the /etc/salt directory, and you will need to provide your own systemd service unit.

Installation from pip:

```
pip install salt
```

**Warning:** If installing from pip (or from source using `setup.py install`), be advised that the `yum-utils` package is needed for Salt to manage packages. Also, if the Python dependencies are not already installed, then you will need additional libraries/tools installed to build some of them. More information on this can be found [here](#).

---

### Post-installation tasks

**Master**

To have the Master start automatically at boot time:

```
systemctl enable salt-master.service
```

To start the Master:

```
systemctl start salt-master.service
```

**Minion**

To have the Minion start automatically at boot time:

```
systemctl enable salt-minion.service
```

To start the Minion:

```
systemctl start salt-minion.service
```

Now go to the [Configuring Salt](#) page.

---

### 2.2.4 FreeBSD

**Installation**

Salt is available in binary package form from both the FreeBSD pkgng repository or directly from SaltStack. The instructions below outline installation via both methods:

**FreeBSD repo**

The FreeBSD pkgng repository is preconfigured on systems 10.x and above. No configuration is needed to pull from these repositories.

```
pkg install py27-salt
```

These packages are usually available within a few days of upstream release.
Salt Documentation, Release 2015.8.12

SaltStack repo

SaltStack also hosts internal binary builds of the Salt package, available from https://repo.saltstack.com/freebsd/. To make use of this repository, add the following file to your system:

```
/usr/local/etc/pkg/repos/saltstack.conf:

saltstack: {
    url: "https://repo.saltstack.com/freebsd/${ABI}/",
    enabled: yes
}
```

You should now be able to install Salt from this new repository:

```
pkg install py27-salt
```

These packages are usually available earlier than upstream FreeBSD. Also available are release candidates and development releases. Use these pre-release packages with caution.

Post-installation tasks

Master

Copy the sample configuration file:

```
cp /usr/local/etc/salt/master.sample /usr/local/etc/salt/master
```

rc.conf

Activate the Salt Master in /etc/rc.conf:

```
sysrc salt_master_enable="YES"
```

Start the Master

Start the Salt Master as follows:

```
service salt_master start
```

Minion

Copy the sample configuration file:

```
cp /usr/local/etc/salt/minion.sample /usr/local/etc/salt/minion
```

rc.conf

Activate the Salt Minion in /etc/rc.conf:

```
sysrc salt_minion_enable="YES"
```

Start the Minion

Start the Salt Minion as follows:

```
service salt_minion start
```

Now go to the Configuring Salt page.

10 Chapter 2. Installation
2.2.5 Gentoo

Salt can be easily installed on Gentoo via Portage:

```
emerge app-admin/salt
```

**Post-installation tasks**

Now go to the *Configuring Salt* page.

2.2.6 OpenBSD

Salt was added to the OpenBSD ports tree on Aug 10th 2013. It has been tested on OpenBSD 5.5 onwards.

Salt is dependent on the following additional ports. These will be installed as dependencies of the `sysutils/salt` port:

```
devel/py-futures
devel/py-progressbar
net/py-msgpack
net/py-zmq
security/py-crypto
security/py-M2Crypto
textproc/py-MarkupSafe
textproc/py-yaml
www/py-jinja2
www/py-requests
www/py-tornado
```

**Installation**

To install Salt from the OpenBSD pkg repo, use the command:

```
pkg_add salt
```

**Post-installation tasks**

**Master**

To have the Master start automatically at boot time:

```
rcctl enable salt_master
```

To start the Master:

```
rcctl start salt_master
```

**Minion**

To have the Minion start automatically at boot time:

```
rcctl enable salt_minion
```
To start the Minion:

```
rcctl start salt_minion
```

Now go to the Configuring Salt page.

## 2.2.7 OS X

### Dependency Installation

It should be noted that Homebrew explicitly discourages the use of sudo:

Homebrew is designed to work without using sudo. You can decide to use it but we strongly recommend not to do so. If you have used sudo and run into a bug then it is likely to be the cause. Please don't file a bug report unless you can reproduce it after reinstalling Homebrew from scratch without using sudo.

So when using Homebrew, if you want support from the Homebrew community, install this way:

```
brew install saltstack
```

When using MacPorts, install this way:

```
sudo port install salt
```

When only using the OS X system's pip, install this way:

```
sudo pip install salt
```

### Salt-Master Customizations

To run salt-master on OS X, the root user maxfiles limit must be increased:

Note: On OS X 10.10 (Yosemite) and higher, maxfiles should not be adjusted. The default limits are sufficient in all but the most extreme scenarios. Overriding these values with the setting below will cause system instability!

```
sudo launchctl limit maxfiles 4096 8192
```

And sudo add this configuration option to the /etc/salt/master file:

```
max_open_files: 8192
```

Now the salt-master should run without errors:

```
sudo salt-master --log-level=all
```

### Post-installation tasks

Now go to the Configuring Salt page.
2.2.8 RHEL / CentOS / Scientific Linux / Amazon Linux / Oracle Linux

Salt should work properly with all mainstream derivatives of Red Hat Enterprise Linux, including CentOS, Scientific Linux, Oracle Linux, and Amazon Linux. Report any bugs or issues on the issue tracker.

Installation from the Official SaltStack Repository

Packages for Redhat, CentOS, and Amazon Linux are available in the SaltStack Repository.

- Red Hat / CentOS
- Amazon Linux

Note: As of 2015.8.0, EPEL repository is no longer required for installing on RHEL systems. SaltStack repository provides all needed dependencies.

Warning: If installing on Red Hat Enterprise Linux 7 with disabled (not subscribed on) 'RHEL Server Releases' or 'RHEL Server Optional Channel' repositories, append CentOS 7 GPG key URL to SaltStack yum repository configuration to install required base packages:

[saltstack-repo]
name=SaltStack repo for Red Hat Enterprise Linux $releasever
baseurl=https://repo.saltstack.com/yum/redhat/$releasever/$basearch/latest
enabled=1
gpgcheck=1
gpgkey=https://repo.saltstack.com/yum/redhat/$releasever/$basearch/latest/SALTSTACK-GPG-KEY.pub

Note: systemctl and python-systemd are required by Salt, but are not installed by the Red Hat 7 @base installation or by the Salt installation. These dependencies might need to be installed before Salt.

Installation from the Community-Maintained Repository

Beginning with version 0.9.4, Salt has been available in EPEL. For RHEL/CentOS 5, Fedora COPR is a single community repository that provides Salt packages due to the removal from EPEL5.

Note: Packages in these repositories are built by community, and it can take a little while until the latest stable SaltStack release become available.

RHEL/CentOS 6 and 7, Scientific Linux, etc.
Warning: Salt 2015.8 is currently not available in EPEL due to unsatisfied dependencies: `python-crypto` 2.6.1 or higher, and `python-tornado` version 4.2.1 or higher. These packages are not currently available in EPEL for Red Hat Enterprise Linux 6 and 7.

Enabling EPEL

If the EPEL repository is not installed on your system, you can download the RPM for RHEL/CentOS 6 or for RHEL/CentOS 7 and install it using the following command:

```
rpm -Uvh epel-release-X-Y.rpm
```

Replace `epel-release-X-Y.rpm` with the appropriate filename.

Installing Stable Release

Salt is packaged separately for the minion and the master. It is necessary to install only the appropriate package for the role the machine will play. Typically, there will be one master and multiple minions.

- `yum install salt-master`
- `yum install salt-minion`
- `yum install salt-ssh`
- `yum install salt-syndic`
- `yum install salt-cloud`

Installing from `epel-testing`

When a new Salt release is packaged, it is first admitted into the `epel-testing` repository, before being moved to the stable EPEL repository.

To install from `epel-testing`, use the `enablerepo` argument for `yum`:

```
yum --enablerepo=epel-testing install salt-minion
```

Installation Using pip

Since Salt is on PyPI, it can be installed using pip, though most users prefer to install using RPM packages (which can be installed from EPEL).

Installing from pip has a few additional requirements:

- Install the group `Development Tools`, `yum groupinstall 'Development Tools'`
- Install the `zeromq-devel` package if it fails on linking against that afterwards as well.

A pip install does not make the init scripts or the `/etc/salt` directory, and you will need to provide your own systemd service unit.

Installation from pip:

```
pip install salt
```
Warning: If installing from pip (or from source using setup.py install), be advised that the `yum-utils` package is needed for Salt to manage packages. Also, if the Python dependencies are not already installed, then you will need additional libraries/tools installed to build some of them. More information on this can be found here.

ZeroMQ 4

We recommend using ZeroMQ 4 where available. SaltStack provides ZeroMQ 4.0.5 and pyzmq 14.5.0 in the SaltStack Repository as well as a separate `zeromq4 COPR` repository.

If this repository is added before Salt is installed, then installing either `salt-master` or `salt-minion` will automatically pull in ZeroMQ 4.0.5, and additional steps to upgrade ZeroMQ and pyzmq are unnecessary.

Warning: RHEL/CentOS 5 Users Using COPR repos on RHEL/CentOS 5 requires that the `python-hashlib` package be installed. Not having it present will result in checksum errors because YUM will not be able to process the SHA256 checksums used by COPR.

Note: For RHEL/CentOS 5 installations, if using the SaltStack repo or Fedora COPR to install Salt (as described above), then it is not necessary to enable the `zeromq4 COPR`, because those repositories already include ZeroMQ 4.

Package Management

Salt's interface to `yum` makes heavy use of the `repoquery` utility, from the `yum-utils` package. This package will be installed as a dependency if salt is installed via EPEL. However, if salt has been installed using pip, or a host is being managed using salt-ssh, then as of version 2014.7.0 `yum-utils` will be installed automatically to satisfy this dependency.

Post-installation tasks

Master

To have the Master start automatically at boot time:

RHEL/CentOS 5 and 6

```
chkconfig salt-master on
```

RHEL/CentOS 7

```
systemctl enable salt-master.service
```

To start the Master:

RHEL/CentOS 5 and 6

```
service salt-master start
```

RHEL/CentOS 7

2.2. Platform-specific Installation Instructions
systemctl start salt-master.service

Minion

To have the Minion start automatically at boot time:

RHEL/CentOS 5 and 6

chkconfig salt-minion on

RHEL/CentOS 7

systemctl enable salt-minion.service

To start the Minion:

RHEL/CentOS 5 and 6

service salt-minion start

RHEL/CentOS 7

systemctl start salt-minion.service

Now go to the Configuring Salt page.

2.2.9 Solaris

Salt was added to the OpenCSW package repository in September of 2012 by Romeo Theriault <romeot@hawaii.edu> at version 0.10.2 of Salt. It has mainly been tested on Solaris 10 (sparc), though it is built for and has been tested minimally on Solaris 10 (x86), Solaris 9 (sparc/x86) and 11 (sparc/x86). (Please let me know if you're using it on these platforms!) Most of the testing has also just focused on the minion, though it has verified that the master starts up successfully on Solaris 10.

Comments and patches for better support on these platforms is very welcome.

As of version 0.10.4, Solaris is well supported under salt, with all of the following working well:

1. remote execution
2. grain detection
3. service control with SMF
4. `pkg` states with `pkgadd` and `pkgutil` modules
5. cron modules/states
6. user and group modules/states
7. shadow password management modules/states

Salt is dependent on the following additional packages. These will automatically be installed as dependencies of the py_salt package:

- py_yaml
- py_pyzmq
- py_jinja2
Installation

To install Salt from the OpenCSW package repository you first need to install `pkgutil` assuming you don't already have it installed:

On Solaris 10:
```
pkgadd -d http://get.opencsw.org/now
```

On Solaris 9:
```
wget http://mirror.opencsw.org/opencsw/pkgutil.pkg
pkgadd -d pkgutil.pkg all
```

Once `pkgutil` is installed you'll need to edit it's config file `/etc/opt/csw/pkgutil.conf` to point it at the unstable catalog:
```
- #mirror=http://mirror.opencsw.org/opencsw/testing
+ mirror=http://mirror.opencsw.org/opencsw/unstable
```

OK, time to install salt.
```
# Update the catalog
root> /opt/csw/bin/pkgutil -U
# Install salt
root> /opt/csw/bin/pkgutil -i -y py_salt
```

Minion Configuration

Now that salt is installed you can find it's configuration files in `/etc/opt/csw/salt/`.

You'll want to edit the minion config file to set the name of your salt master server:
```
- #master: salt
+ master: your-salt-server
```

If you would like to use `pkgutil` as the default package provider for your Solaris minions, you can do so using the `providers` option in the minion config file.

You can now start the salt minion like so:

On Solaris 10:
```
svcadm enable salt-minion
```

On Solaris 9:
```
/etc/init.d/salt-minion start
```

You should now be able to log onto the salt master and check to see if the salt-minion key is awaiting acceptance:
salt-key -l un

Accept the key:
salt-key -a <your-salt-minion>

Run a simple test against the minion:
salt '<your-salt-minion>' test.ping

Troubleshooting
Logs are in /var/log/salt

2.2.10 Ubuntu

Installation from the Official SaltStack Repository

Packages for Ubuntu 14 (Trusty) and Ubuntu 12 (Precise) are available in the SaltStack repository. Instructions are at http://repo.saltstack.com/#ubuntu.

Installation from the Community-Maintained Repository

Packages for Ubuntu are also published in the saltstack PPA. If you have the add-apt-repository utility, you can add the repository and import the key in one step:

```
sudo add-apt-repository ppa:saltstack/salt
```

In addition to the main repository, there are secondary repositories for each individual major release. These repositories receive security and point releases but will not upgrade to any subsequent major release. There are currently several available repos: salt16, salt17, salt2014-1, salt2014-7, salt2015-5. For example to follow 2015.5.x releases:

```
sudo add-apt-repository ppa:saltstack/salt2015-5
```

add-apt-repository: command not found?
The add-apt-repository command is not always present on Ubuntu systems. This can be fixed by installing python-software-properties:

```
sudo apt-get install python-software-properties
```

The following may be required as well:

```
sudo apt-get install software-properties-common
```

Note that since Ubuntu 12.10 (Raring Ringtail), add-apt-repository is found in the software-properties-common package, and is part of the base install. Thus, add-apt-repository should be able to be used out-of-the-box to add the PPA.

Alternately, manually add the repository and import the PPA key with these commands:
echo deb http://ppa.launchpad.net/saltstack/salt/ubuntu `lsb_release -sc` main | sudo tee /etc/apt/sources.list.d/saltstack.list
wget -q -O- "http://keyserver.ubuntu.com:11371/pks/lookup?op=get&search=0x4759FA960E27C0A6" | sudo apt-key add -

After adding the repository, update the package management database:

```
sudo apt-get update
```

**Install Packages**

Install the Salt master, minion or other packages from the repository with the `apt-get` command. These examples each install one of Salt components, but more than one package name may be given at a time:

- `apt-get install salt-api`
- `apt-get install salt-cloud`
- `apt-get install salt-master`
- `apt-get install salt-minion`
- `apt-get install salt-ssh`
- `apt-get install salt-syndic`

**Post-installation tasks**

Now go to the [Configuring Salt](#) page.

### 2.2.11 Windows

Salt has full support for running the Salt Minion on Windows.

There are no plans for the foreseeable future to develop a Salt Master on Windows. For now you must run your Salt Master on a supported operating system to control your Salt Minions on Windows.

Many of the standard Salt modules have been ported to work on Windows and many of the Salt States currently work on Windows, as well.

**Windows Installer**

Salt Minion Windows installers can be found here. The output of `md5sum <salt-minion exe>` should match the contents of the corresponding md5 file.

**Latest stable build from the selected branch:**

- Earlier builds from supported branches
- Archived builds from unsupported branches

**Note:** The installation executable installs dependencies that the Salt minion requires.
The 64bit installer has been tested on Windows 7 64bit and Windows Server 2008R2 64bit. The 32bit installer has been tested on Windows 2003 Server 32bit. Please file a bug report on our GitHub repo if issues for other platforms are found.

The installer asks for 2 bits of information; the master hostname and the minion name. The installer will update the minion config with these options and then start the minion.

The `salt-minion` service will appear in the Windows Service Manager and can be started and stopped there or with the command line program `sc` like any other Windows service.

If the minion won’t start, try installing the Microsoft Visual C++ 2008 x64 SP1 redistributable. Allow all Windows updates to run salt-minion smoothly.

**Silent Installer Options**

The installer can be run silently by providing the `/S` option at the command line. The installer also accepts the following options for configuring the Salt Minion silently:

- `/master=` A string value to set the IP address or host name of the master. Default value is `salt`
- `/minion-name=` A string value to set the minion name. Default is `hostname`
- `/start-service=` Either a 1 or 0. `1` will start the service, `0` will not. Default is to start the service after installation.

Here's an example of using the silent installer:

```
Salt-Minion-2015.5.6-Setup-amd64.exe /S /master=yoursaltmaster /minion-name=yourminionname /start-service=0
```

**Running the Salt Minion on Windows as an Unprivileged User**

**Notes:**
- These instructions were tested with Windows Server 2008 R2
- They are generalizable to any version of Windows that supports a salt-minion

**A. Create the Unprivileged User that the Salt Minion will Run As**

1. Click Start > Control Panel > User Accounts.
2. Click Add or remove user accounts.
3. Click Create new account.
4. Enter salt-user (or a name of your preference) in the New account name field.
5. Select the Standard user radio button.
6. Click the Create Account button.
7. Click on the newly created user account.
8. Click the Create a password link.
9. In the New password and Confirm new password fields, provide a password (e.g. `"SuperSecretMinionPassword4Me!"`).
10. In the Type a password hint field, provide appropriate text (e.g. `"My Salt Password"`).
11. Click the Create password button.
12. Close the Change an Account window.

B. Add the New User to the Access Control List for the Salt Folder

1. In a File Explorer window, browse to the path where Salt is installed (the default path is C:\Salt).
2. Right-click on the Salt folder and select Properties.
3. Click on the Security tab.
4. Click the Edit button.
5. Click the Add button.
6. Type the name of your designated Salt user and click the OK button.
7. Check the box to Allow the Modify permission.
8. Click the OK button.
9. Click the OK button to close the Salt Properties window.

C. Update the Windows Service User for the salt-minion Service

1. Click Start > Administrative Tools > Services.
2. In the Services list, right-click on salt-minion and select Properties.
3. Click the Log On tab.
4. Click the This account radio button.
5. Provide the account credentials created in section A.
6. Click the OK button.
7. Click the OK button to the prompt confirming that the user has been granted the Log On As A Service right.
8. Click the OK button to the prompt confirming that The new logon name will not take effect until you stop and restart the service.
9. Right-Click on salt-minion and select Stop.
10. Right-Click on salt-minion and select Start.

Setting up a Windows build environment

This document will explain how to set up a development environment for salt on Windows. The development environment allows you to work with the source code to customize or fix bugs. It will also allow you to build your own installation.

The Easy Way

Prerequisite Software

To do this the easy way you only need to install Git for Windows.
Create the Build Environment

1. Clone the Salt-Windows-Dev repo from github.
   Open a command line and type:
   ```
   git clone https://github.com/saltstack/salt-windows-dev
   ```

2. Build the Python Environment
   Go into the salt-windows-dev directory. Right-click the file named dev_env.ps1 and select Run with Powershell
   If you get an error, you may need to change the execution policy.
   Open a powershell window and type the following:
   ```
   Set-ExecutionPolicy RemoteSigned
   ```
   This will download and install Python with all the dependencies needed to develop and build salt.

3. Build the Salt Environment
   Right-click on the file named dev_env_salt.ps1 and select Run with Powershell
   This will clone salt into C:\Salt-Dev\salt and set it to the 2015.5 branch. You could optionally run the command from a powershell window with a -Version switch to pull a different version. For example:
   ```
   dev_env_salt.ps1 -Version '2014.7'
   ```
   To view a list of available branches and tags, open a command prompt in your C:Salt-Dev\salt directory and type:
   ```
   git branch -a
   git tag -n
   ```

The Hard Way

Prerequisite Software

Install the following software:
   1. Git for Windows
   2. Nullsoft Installer

Download the Prerequisite zip file for your CPU architecture from the SaltStack download site:
   - Salt32.zip
   - Salt64.zip

These files contain all software required to build and develop salt. Unzip the contents of the file to C:\Salt-Dev\temp.

Create the Build Environment

1. Build the Python Environment
• Install Python:

Browse to the `C:\Salt-Dev\temp` directory and find the Python installation file for your CPU Architecture under the corresponding subfolder. Double-click the file to install python.

Make sure the following are in your PATH environment variable:

```
C:\Python27
C:\Python27\Scripts
```

• Install Pip

Open a command prompt and navigate to `C:\Salt-Dev\temp` Run the following command:

```
python get-pip.py
```

• Easy Install compiled binaries.

M2Crypto, PyCrypto, and PyWin32 need to be installed using Easy Install. Open a command prompt and navigate to `C:\Salt-Dev\temp\<cpuarch>`. Run the following commands:

```
easy_install -Z <M2Crypto file name>
easy_install -Z <PyCrypto file name>
easy_install -Z <PyWin32 file name>
```

Note: You can type the first part of the file name and then press the tab key to auto-complete the name of the file.

• Pip Install Additional Prerequisites

All remaining prerequisites need to be pip installed. These prerequisites are as follow:

- MarkupSafe
- Jinja
- MsgPack
- PSUtil
- PyYAML
- PyZMQ
- WMI
- Requests
- Certifi

Open a command prompt and navigate to `C:\Salt-Dev\temp`. Run the following commands:

```
pip install <cpuarch>\<MarkupSafe file name>
pip install <Jinja file name>
pip install <cpuarch>\<MsgPack file name>
pip install <cpuarch>\<psutil file name>
pip install <cpuarch>\<PyYAML file name>
pip install <cpuarch>\<pyzmq file name>
pip install <WMI file name>
pip install <requests file name>
pip install <certifi file name>
```
2. Build the Salt Environment

- Clone Salt

Open a command prompt and navigate to C:\Salt-Dev. Run the following command to clone salt:

```bash
git clone https://github.com/saltstack/salt
```

- Checkout Branch

Checkout the branch or tag of salt you want to work on or build. Open a command prompt and navigate to C:\Salt-Dev\salt. Get a list of available tags and branches by running the following commands:

```bash
git fetch --all
To view a list of available branches:
git branch -a
To view a list of available tags:
git tag -n
```

Checkout the branch or tag by typing the following command:

```bash
git checkout <branch/tag name>
```

- Clean the Environment

When switching between branches residual files can be left behind that will interfere with the functionality of salt. Therefore, after you check out the branch you want to work on, type the following commands to clean the salt environment:

Developing with Salt

There are two ways to develop with salt. You can run salt's setup.py each time you make a change to source code or you can use the setup tools develop mode.

Configure the Minion

Both methods require that the minion configuration be in the C:\salt directory. Copy the conf and var directories from C:\Salt-Dev\salt\pkg\windows\buildenv to C:\salt. Now go into the C:\salt\conf directory and edit the file name minion (no extension). You need to configure the master and id parameters in this file. Edit the following lines:

```ini
master: <ip or name of your master>
id: <name of your minion>
```

Setup.py Method

Go into the C:\Salt-Dev\salt directory from a cmd prompt and type:

```bash
python setup.py install --force
```

This will install python into your python installation at C:\Python27. Everytime you make an edit to your source code, you'll have to stop the minion, run the setup, and start the minion.
To start the salt-minion go into C:\Python27\Scripts from a cmd prompt and type:

```bash
salt-minion
```

For debug mode type:

```bash
salt-minion -l debug
```

To stop the minion press Ctrl+C.

Setup Tools Develop Mode (Preferred Method)

To use the Setup Tools Develop Mode go into C:\Salt-Dev\salt from a cmd prompt and type:

```bash
pip install -e .
```

This will install pointers to your source code that resides at C:\Salt-Dev\salt. When you edit your source code you only have to restart the minion.

Build the windows installer

This is the method of building the installer as of version 2014.7.4.

Clean the Environment

Make sure you don’t have any leftover salt files from previous versions of salt in your Python directory.

1. Remove all files that start with salt in the C:\Python27\Scripts directory
2. Remove all files and directories that start with salt in the C:\Python27\Lib\site-packages directory

Install Salt

Install salt using salt’s setup.py. From the C:\Salt-Dev\salt directory type the following command:

```bash
python setup.py install --force
```

Build the Installer

From cmd prompt go into the C:\Salt-Dev\salt\pkg\windows directory. Type the following command for the branch or tag of salt you’re building:

```bash
BuildSalt.bat <branch or tag>
```

This will copy python with salt installed to the buildenv\bin directory, make it portable, and then create the windows installer. The .exe for the windows installer will be placed in the installer directory.
Testing the Salt minion

1. Create the directory C:salt (if it doesn't exist already)
2. Copy the example conf and var directories from pkg/windows/buildenv/ into C:salt
3. Edit C:salt\conf\minion

```
master: ipaddress or hostname of your salt-master
```

4. Start the salt-minion

```
cd C:\Python27\Scripts
python salt-minion
```

5. On the salt-master accept the new minion's key

```
sudo salt-key -A
```

This accepts all unaccepted keys. If you're concerned about security just accept the key for this specific minion.

6. Test that your minion is responding

On the salt-master run:

```
sudo salt '*' test.ping
```

You should get the following response: {"your minion hostname": True}

Single command bootstrap script

On a 64 bit Windows host the following script makes an unattended install of salt, including all dependencies:

```
# (All in one line.)

```

You can execute the above command remotely from a Linux host using winexe:

```
winexe -U "administrator" //fqdn "PowerShell (New-Object .......);"
```

For more info check http://csa-net.dk/salt

Packages management under Windows 2003

On windows Server 2003, you need to install optional component "wmi windows installer provider" to have full list of installed packages. If you don't have this, salt-minion can't report some installed software.
2.2.12 SUSE

Installation from the SaltStack Repository

Packages for SUSE 12 SP1, SUSE 12, SUSE 11, openSUSE 13 and openSUSE Leap 42.1 are available in the SaltStack Repository.

Instructions are at http://repo.saltstack.com/#suse.

Installation from the SUSE Repository

With openSUSE 13.2, Salt 2014.1.11 is available in the primary repositories. The devel:language:python repo will have more up to date versions of salt, all package development will be done there.

Installation

Salt can be installed using zypper and is available in the standard openSUSE repositories.

Stable Release

Salt is packaged separately for the minion and the master. It is necessary only to install the appropriate package for the role the machine will play. Typically, there will be one master and multiple minions.

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>zypper install salt-master</td>
<td>Install Salt on the master</td>
</tr>
<tr>
<td>zypper install salt-minion</td>
<td>Install Salt on the minions</td>
</tr>
</tbody>
</table>

Post-installation tasks openSUSE

Master

To have the Master start automatically at boot time:

```
systemctl enable salt-master.service
```

To start the Master:

```
systemctl start salt-master.service
```

Minion

To have the Minion start automatically at boot time:

```
systemctl enable salt-minion.service
```

To start the Minion:

```
systemctl start salt-minion.service
```
Post-installation tasks SLES

Master
To have the Master start automatically at boot time:

chkconfig salt-master on

To start the Master:

rcsalt-master start

Minion
To have the Minion start automatically at boot time:

chkconfig salt-minion on

To start the Minion:

rcsalt-minion start

Unstable Release

openSUSE

For openSUSE Factory run the following as root:

zypper addrepo http://download.opensuse.org/repositories/devel:languages:python/
                      openSUSE_Factory/devel:languages:python.repo
zypper refresh
zypper install salt salt-minion salt-master

For openSUSE 13.2 run the following as root:

zypper addrepo http://download.opensuse.org/repositories/devel:languages:python/
                      openSUSE_13.2/devel:languages:python.repo
zypper refresh
zypper install salt salt-minion salt-master

For openSUSE 13.1 run the following as root:

zypper addrepo http://download.opensuse.org/repositories/devel:languages:python/
                      openSUSE_13.1/devel:languages:python.repo
zypper refresh
zypper install salt salt-minion salt-master

For bleeding edge python Factory run the following as root:

zypper addrepo http://download.opensuse.org/repositories/devel:languages:python/
                      bleeding_edge_python_Factory/devel:languages:python.repo
zypper refresh
zypper install salt salt-minion salt-master
Suse Linux Enterprise

For SLE 12 run the following as root:

```bash
zypper refresh
zypper install salt salt-minion salt-master
```

For SLE 11 SP3 run the following as root:

```bash
zypper refresh
zypper install salt salt-minion salt-master
```

For SLE 11 SP2 run the following as root:

```bash
zypper refresh
zypper install salt salt-minion salt-master
```

Now go to the Configuring Salt page.

### 2.3 Dependencies

Salt should run on any Unix-like platform so long as the dependencies are met.

- **Python 2.6 >= 2.6 <3.0**
- **msgpack-python** - High-performance message interchange format
- **YAML** - Python YAML bindings
- **Jinja2** - parsing Salt States (configurable in the master settings)
- **MarkupSafe** - Implements a XML/HTML/XHTML Markup safe string for Python
- **apache-libcloud** - Python lib for interacting with many of the popular cloud service providers using a unified API
- **Requests** - HTTP library

Depending on the chosen Salt transport, **ZeroMQ** or **RAET**, dependencies vary:

- **ZeroMQ**:
  - **ZeroMQ >= 3.2.0**
  - **pyzmq >= 2.2.0** - ZeroMQ Python bindings
  - **PyCrypto** - The Python cryptography toolkit

- **RAET**:
  - **libnacl** - Python bindings to **libsodium**
  - **ioflo** - The flo programming interface raet and salt-raet is built on
  - **RAET** - The worlds most awesome UDP protocol
Salt defaults to the ZeroMQ transport, and the choice can be made at install time, for example:

```
python setup.py --salt-transport=raet install
```

This way, only the required dependencies are pulled by the setup script if need be.

If installing using pip, the `--salt-transport` install option can be provided like:

```
pip install --install-option="--salt-transport=raet" salt
```

**Note:** Salt does not bundle dependencies that are typically distributed as part of the base OS. If you have unmet dependencies and are using a custom or minimal installation, you might need to install some additional packages from your OS vendor.

### 2.4 Optional Dependencies

- mako - an optional parser for Salt States (configurable in the master settings)
- gcc - dynamic Cython module compiling

### 2.5 Upgrading Salt

When upgrading Salt, the master(s) should always be upgraded first. Backward compatibility for minions running newer versions of salt than their masters is not guaranteed.

Whenever possible, backward compatibility between new masters and old minions will be preserved. Generally, the only exception to this policy is in case of a security vulnerability.

### 2.6 Building Packages using Salt Pack

Salt-pack is an open-source package builder for most commonly used Linux platforms, for example: Redhat/CentOS and Debian/Ubuntu families, utilizing SaltStack states and execution modules to build Salt and a specified set of dependencies, from which a platform specific repository can be built.

[https://github.com/saltstack/salt-pack](https://github.com/saltstack/salt-pack)
3.1 Introduction

3.1.1 Salt Masterless Quickstart

Running a masterless salt-minion lets you use Salt's configuration management for a single machine without calling out to a Salt master on another machine.

Since the Salt minion contains such extensive functionality it can be useful to run it standalone. A standalone minion can be used to do a number of things:

- Stand up a master server via States (Salting a Salt Master)
- Use salt-call commands on a system without connectivity to a master
- Masterless States, run states entirely from files local to the minion

It is also useful for testing out state trees before deploying to a production setup.

Bootstrap Salt Minion

The salt-bootstrap script makes bootstrapping a server with Salt simple for any OS with a Bourne shell:

```
curl -L https://bootstrap.saltstack.com -o bootstrap_salt.sh
sudo sh bootstrap_salt.sh
```

See the salt-bootstrap documentation for other one liners. When using Vagrant to test out salt, the Vagrant salt provisioner will provision the VM for you.

Telling Salt to Run Masterless

To instruct the minion to not look for a master, the file_client configuration option needs to be set in the minion configuration file. By default the file_client is set to remote so that the minion gathers file server and pillar data from the salt master. When setting the file_client option to local the minion is configured to not gather this data from the master.

```
file_client: local
```

Now the salt minion will not look for a master and will assume that the local system has all of the file and pillar resources.
Note: When running Salt in masterless mode, do not run the salt-minion daemon. Otherwise, it will attempt to connect to a master and fail. The salt-call command stands on its own and does not need the salt-minion daemon.

Create State Tree

Following the successful installation of a salt-minion, the next step is to create a state tree, which is where the SLS files that comprise the possible states of the minion are stored.

The following example walks through the steps necessary to create a state tree that ensures that the server has the Apache webserver installed.

Note: For a complete explanation on Salt States, see the tutorial.

1. Create the top.sls file:

```
/srv/salt/top.sls:

base:
  '*':
    - webserver
```

2. Create the webserver state tree:

```
/srv/salt/webserver.sls:

apache:
  # ID declaration
pkg:
  # state declaration
- installed
  # function declaration
```

Note: The apache package has different names on different platforms, for instance on Debian/Ubuntu it is apache2, on Fedora/RHEL it is httpd and on Arch it is apache

The only thing left is to provision our minion using salt-call.

Salt-call

The salt-call command is used to run remote execution functions locally on a minion instead of executing them from the master. Normally the salt-call command checks into the master to retrieve file server and pillar data, but when running standalone salt-call needs to be instructed to not check the master for this data:

```
salt-call --local state.apply
```

The --local flag tells the salt-minion to look for the state tree in the local file system and not to contact a Salt Master for instructions.

To provide verbose output, use -l debug:

```
salt-call --local state.apply -l debug
```

The minion first examines the top.sls file and determines that it is a part of the group matched by * glob and that the webserver SLS should be applied.
It then examines the \texttt{webserver.sls} file and finds the \texttt{apache} state, which installs the Apache package.

The minion should now have Apache installed, and the next step is to begin learning how to write \textit{more complex states}.

### 3.2 Basics

#### 3.2.1 Standalone Minion

Since the Salt minion contains such extensive functionality it can be useful to run it standalone. A standalone minion can be used to do a number of things:

- Use salt-call commands on a system without connectivity to a master
- Masterless States, run states entirely from files local to the minion

\textbf{Note:} When running Salt in masterless mode, do not run the salt-minion daemon. Otherwise, it will attempt to connect to a master and fail. The salt-call command stands on its own and does not need the salt-minion daemon.

#### Minion Configuration

Throughout this document there are several references to setting different options to configure a masterless Minion. Salt Minions are easy to configure via a configuration file that is located, by default, in \texttt{/etc/salt/minion}. Note, however, that on FreeBSD systems, the minion configuration file is located in \texttt{/usr/local/etc/salt/minion}.

You can learn more about minion configuration options in the \textit{Configuring the Salt Minion} docs.

#### Telling Salt Call to Run Masterless

The salt-call command is used to run module functions locally on a minion instead of executing them from the master. Normally the salt-call command checks into the master to retrieve file server and pillar data, but when running standalone salt-call needs to be instructed to not check the master for this data. To instruct the minion to not look for a master when running salt-call the \texttt{file_client} configuration option needs to be set. By default the \texttt{file_client} is set to \texttt{remote} so that the minion knows that file server and pillar data are to be gathered from the master. When setting the \texttt{file_client} option to \texttt{local} the minion is configured to not gather this data from the master.

```
file_client: local
```

Now the salt-call command will not look for a master and will assume that the local system has all of the file and pillar resources.

#### Running States Masterless

The state system can be easily run without a Salt master, with all needed files local to the minion. To do this the minion configuration file needs to be set up to know how to return file\_roots information like the master. The \texttt{file\_roots} setting defaults to \texttt{/srv/salt} for the base environment just like on the master:
Now set up the Salt State Tree, top file, and SLS modules in the same way that they would be set up on a master. Now, with the `file_client` option set to `local` and an available state tree then calls to functions in the state module will use the information in the `file_roots` on the minion instead of checking in with the master.

Remember that when creating a state tree on a minion there are no syntax or path changes needed, SLS modules written to be used from a master do not need to be modified in any way to work with a minion.

This makes it easy to “script” deployments with Salt states without having to set up a master, and allows for these SLS modules to be easily moved into a Salt master as the deployment grows.

The declared state can now be executed with:

```
salt-call state.apply
```

Or the salt-call command can be executed with the `--local` flag, this makes it unnecessary to change the configuration file:

```
salt-call state.apply --local
```

**External Pillars**

External pillars are supported when running in masterless mode.

### 3.2.2 Opening the Firewall up for Salt

The Salt master communicates with the minions using an AES-encrypted ZeroMQ connection. These communications are done over TCP ports 4505 and 4506, which need to be accessible on the master only. This document outlines suggested firewall rules for allowing these incoming connections to the master.

**Note:** No firewall configuration needs to be done on Salt minions. These changes refer to the master only.

**Fedora 18 and beyond / RHEL 7 / CentOS 7**

Starting with Fedora 18 **FirewallD** is the tool that is used to dynamically manage the firewall rules on a host. It has support for IPv4/6 settings and the separation of runtime and permanent configurations. To interact with FirewallD use the command line client `firewall-cmd`.

**firewall-cmd example:**

```
firewall-cmd --permanent --zone=<zone> --add-port=4505-4506/tcp
```

Please choose the desired zone according to your setup. Don’t forget to reload after you made your changes.

```
firewall-cmd --reload
```
RHEL 6 / CentOS 6

The lokkit command packaged with some Linux distributions makes opening iptables firewall ports very simple via the command line. Just be careful to not lock out access to the server by neglecting to open the ssh port.

lokkit example:

```
```

The system-config-firewall-tui command provides a text-based interface to modifying the firewall.

system-config-firewall-tui:

```
```

openSUSE

Salt installs firewall rules in `/etc/sysconfig/SuSEfirewall2.d/services/salt`. Enable with:

```
SuSEfirewall2 open
SuSEfirewall2 start
```

If you have an older package of Salt where the above configuration file is not included, the SuSEfirewall2 command makes opening iptables firewall ports very simple via the command line.

SuSEfirewall example:

```
SuSEfirewall2 open EXT TCP 4505
SuSEfirewall2 open EXT TCP 4506
```

The firewall module in YaST2 provides a text-based interface to modifying the firewall.

YaST2:

```
yast2 firewall
```

iptables

Different Linux distributions store their `iptables` (also known as `netfilter`) rules in different places, which makes it difficult to standardize firewall documentation. Included are some of the more common locations, but your mileage may vary.

Fedora / RHEL / CentOS:

```
/etc/sysconfig/iptables
```

Arch Linux:

```
/etc/iptables/iptables.rules
```

Debian

Follow these instructions: [https://wiki.debian.org/iptables](https://wiki.debian.org/iptables)

Once you’ve found your firewall rules, you’ll need to add the two lines below to allow traffic on `tcp/4505` and `tcp/4506`:

```
3.2. Basics 35
```
Ubuntu

Salt installs firewall rules in `/etc/ufw/applications.d/salt.ufw`. Enable with:

```
ufw allow salt
```

**pf.conf**

The BSD-family of operating systems uses packet filter (pf). The following example describes the additions to `pf.conf` needed to access the Salt master.

```
pass in on $int_if proto tcp from any to $int_if port 4505
pass in on $int_if proto tcp from any to $int_if port 4506
```

Once these additions have been made to the `pf.conf` the rules will need to be reloaded. This can be done using the `pfctl` command.

```
pfctl -vf /etc/pf.conf
```

### 3.2.3 Whitelist communication to Master

There are situations where you want to selectively allow Minion traffic from specific hosts or networks into your Salt Master. The first scenario which comes to mind is to prevent unwanted traffic to your Master out of security concerns, but another scenario is to handle Minion upgrades when there are backwards incompatible changes between the installed Salt versions in your environment.

Here is an example `Linux iptables` ruleset to be set on the Master:

```
# Allow Minions from these networks
-I INPUT -s 10.1.2.0/24 -p tcp -m multiport --dports 4505,4506 -j ACCEPT
-I INPUT -s 10.1.3.0/24 -p tcp -m multiport --dports 4505,4506 -j ACCEPT

# Allow Salt to communicate with Master on the loopback interface
-A INPUT -i lo -p tcp -m multiport --dports 4505,4506 -j ACCEPT

# Reject everything else
-A INPUT -p tcp -m multiport --dports 4505,4506 -j REJECT
```

**Note:** The important thing to note here is that the `salt` command needs to communicate with the listening network socket of `salt-master` on the `loopback` interface. Without this you will see no outgoing Salt traffic from the master, even for a simple `salt '*' test.ping`, because the `salt` client never reached the `salt-master` to tell it to carry out the execution.

### 3.2.4 Using cron with Salt

The Salt Minion can initiate its own `highstate` using the `salt-call` command.

```
$ salt-call state.apply
```

This will cause the minion to check in with the master and ensure it is in the correct `''state``.!
3.2.5 Use cron to initiate a highstate

If you would like the Salt Minion to regularly check in with the master you can use cron to run the `salt-call` command:

```
0 0 * * * salt-call state.apply
```

The above cron entry will run a highstate every day at midnight.

**Note:** When executing Salt using cron, keep in mind that the default PATH for cron may not include the path for any scripts or commands used by Salt, and it may be necessary to set the PATH accordingly in the crontab:

```
PATH=/bin:/sbin:/usr/bin:/usr/sbin:/usr/local/bin:/usr/local/sbin:/opt/bin
0 0 * * * salt-call state.apply
```

3.2.6 Remote execution tutorial

**Before continuing** make sure you have a working Salt installation by following the `installation` and the `configuration` instructions.

**Stuck?**

There are many ways to *get help from the Salt community* including our [mailing list](mailto:mailing.list) and our IRC channel [#salt](http://example.org).

**Order your minions around**

Now that you have a *master* and at least one *minion* communicating with each other you can perform commands on the minion via the `salt` command. Salt calls are comprised of three main components:

```
salt 'target' <function> [arguments]
```

See also:

`salt` manpage

**target**

The target component allows you to filter which minions should run the following function. The default filter is a glob on the minion id. For example:

```
salt '*' test.ping
salt '*.example.org' test.ping
```

Targets can be based on minion system information using the Grains system:

```
salt -G 'os:Ubuntu' test.ping
```

See also:

`Grains system`
Targets can be filtered by regular expression:

```
salt -E 'virtmach[0-9]' test.ping
```

Targets can be explicitly specified in a list:

```
salt -L 'foo,bar,baz,quo' test.ping
```

Or Multiple target types can be combined in one command:

```
salt -C 'G@os:Ubuntu and webser* or E@database.*' test.ping
```

### function

A function is some functionality provided by a module. Salt ships with a large collection of available functions. List all available functions on your minions:

```
salt '*' sys.doc
```

Here are some examples:

Show all currently available minions:

```
salt '*' test.ping
```

Run an arbitrary shell command:

```
salt '*' cmd.run 'uname -a'
```

See also:

*the full list of modules*

### arguments

Space-delimited arguments to the function:

```
salt '*' cmd.exec_code python 'import sys; print sys.version'
```

Optional, keyword arguments are also supported:

```
salt '*' pip.install salt timeout=5 upgrade=True
```

They are always in the form of `key=argument`.

### 3.2.7 Pillar Walkthrough

Note: This walkthrough assumes that the reader has already completed the initial Salt *walkthrough*.

Pillars are tree-like structures of data defined on the Salt Master and passed through to minions. They allow confidential, targeted data to be securely sent only to the relevant minion.
Note: Grains and Pillar are sometimes confused, just remember that Grains are data about a minion which is stored or generated from the minion. This is why information like the OS and CPU type are found in Grains. Pillar is information about a minion or many minions stored or generated on the Salt Master.

Pillar data is useful for:

**Highly Sensitive Data:** Information transferred via pillar is guaranteed to only be presented to the minions that are targeted, making Pillar suitable for managing security information, such as cryptographic keys and passwords.

**Minion Configuration:** Minion modules such as the execution modules, states, and returners can often be configured via data stored in pillar.

**Variables:** Variables which need to be assigned to specific minions or groups of minions can be defined in pillar and then accessed inside sls formulas and template files.

**Arbitrary Data:** Pillar can contain any basic data structure in dictionary format, so a key/value store can be defined making it easy to iterate over a group of values in sls formulas.

Pillar is therefore one of the most important systems when using Salt. This walkthrough is designed to get a simple Pillar up and running in a few minutes and then to dive into the capabilities of Pillar and where the data is available.

**Setting Up Pillar**

The pillar is already running in Salt by default. To see the minion's pillar data:

```
salt '*' pillar.items
```

Note: Prior to version 0.16.2, this function is named `pillar.data`. This function name is still supported for backwards compatibility.

By default the contents of the master configuration file are loaded into pillar for all minions. This enables the master configuration file to be used for global configuration of minions.

Similar to the state tree, the pillar is comprised of sls files and has a top file. The default location for the pillar is in `/srv/pillar`.

Note: The pillar location can be configured via the `pillar_roots` option inside the master configuration file. It must not be in a subdirectory of the state tree or file_roots. If the pillar is under file_roots, any pillar targeting can be bypassed by minions.

To start setting up the pillar, the `/srv/pillar` directory needs to be present:

```
mkdir /srv/pillar
```

Now create a simple top file, following the same format as the top file used for states:

```
/srv/pillar/top.sls:

base:
  '*':
    - data
```

This top file associates the data.sls file to all minions. Now the `/srv/pillar/data.sls` file needs to be populated:
/srv/pillar/data.sls:

info: some data

To ensure that the minions have the new pillar data, issue a command to them asking that they fetch their pillars from the master:

```
salt '*' saltutil.refresh_pillar
```

Now that the minions have the new pillar, it can be retrieved:

```
salt '*' pillar.items
```

The key `info` should now appear in the returned pillar data.

**More Complex Data**

Unlike states, pillar files do not need to define formulas. This example sets up user data with a UID:

/srv/pillar/users/init.sls:

```
users:
  thatch: 1000
  shouse: 1001
  utahdave: 1002
  redbeard: 1003
```

**Note:** The same directory lookups that exist in states exist in pillar, so the file `users/init.sls` can be referenced with `users` in the `top file`.

The top file will need to be updated to include this sls file:

/srv/pillar/top.sls:

```
base:
  '*':
    - data
    - users
```

Now the data will be available to the minions. To use the pillar data in a state, you can use Jinja:

/srv/salt/users/init.sls

```
{% for user, uid in pillar.get('users', {}).items() %}
{{ user }}:
  - uid: {{ uid }}
{% endfor %}
```

This approach allows for users to be safely defined in a pillar and then the user data is applied in an sls file.

**Parameterizing States With Pillar**

Pillar data can be accessed in state files to customise behavior for each minion. All pillar (and grain) data applicable to each minion is substituted into the state files through templating before being run. Typical uses include setting
directories appropriate for the minion and skipping states that don't apply.

A simple example is to set up a mapping of package names in pillar for separate Linux distributions:

/srv/pillar/pkg/init.sls:

```python
pkgs:
  {% if grains['os_family'] == 'RedHat' %}
    apache: httpd
    vim: vim-enhanced
  {% elif grains['os_family'] == 'Debian' %}
    apache: apache2
    vim: vim
  {% elif grains['os'] == 'Arch' %}
    apache: apache
    vim: vim
  {% endif %}
```

The new `pkg` sls needs to be added to the top file:

/srv/pillar/top.sls:

```yaml
base:
  '*':
    - data
    - users
    - pkg
```

Now the minions will auto map values based on respective operating systems inside of the pillar, so sls files can be safely parameterized:

/srv/salt/apache/init.sls:

```yaml
apache:
  pkg.installed:
    - name: {{ pillar['pkgs']->{'apache'} }}
```

Or, if no pillar is available a default can be set as well:

```yaml
apache:
  pkg.installed:
    - name: {{ salt['pillar.get']('pkgs:apache', 'httpd') }}
```

In the above example, if the pillar value `pillar['pkgs']['apache']` is not set in the minion's pillar, then the default of `httpd` will be used.

---

**Note:** Under the hood, pillar is just a Python dict, so Python dict methods such as `get` and `items` can be used.

---

**Pillar Makes Simple States Grow Easily**

One of the design goals of pillar is to make simple sls formulas easily grow into more flexible formulas without refactoring or complicating the states.

---

3.2. Basics
A simple formula:
/srv/salt/edit/vim.sls:

vim:
  pkg.installed: []

/etc/vimrc:
  file.managed:
    - source: salt://edit/vimrc
    - mode: 644
    - user: root
    - group: root
    - require:
      - pkg: vim

Can be easily transformed into a powerful, parameterized formula:
/srv/salt/edit/vim.sls:

vim:
  pkg.installed:
    - name: {{ pillar['pkgs']['vim'] }}

/etc/vimrc:
  file.managed:
    - source: {{ pillar['vimrc'] }}
    - mode: 644
    - user: root
    - group: root
    - require:
      - pkg: vim

Where the vimrc source location can now be changed via pillar:
/srv/pillar/edit/vim.sls:

{% if grains['id'].startswith('dev') %}
  vimrc: salt://edit/dev_vimrc
{% elif grains['id'].startswith('qa') %}
  vimrc: salt://edit/qa_vimrc
{% else %}
  vimrc: salt://edit/vimrc
{% endif %}

Ensuring that the right vimrc is sent out to the correct minions.

Setting Pillar Data on the Command Line

Pillar data can be set on the command line when running state.apply <salt.modules.state.apply_() like so:

salt '* state.apply pillar="foo" "bar"
 salt '* state.apply my_sls_file pillar="hello": "world"
Note: If a key is passed on the command line that already exists on the minion, the key that is passed in will overwrite the entire value of that key, rather than merging only the specified value set via the command line.

The example below will swap the value for vim with telnet in the previously specified list, notice the nested pillar dict:

```
salt '*' state.apply edit.vim pillar='{"pkgs": {"vim": "telnet"}}'
```

Note: This will attempt to install telnet on your minions, feel free to uninstall the package or replace telnet value with anything else.

More On Pillar

Pillar data is generated on the Salt master and securely distributed to minions. Salt is not restricted to the pillar sls files when defining the pillar but can retrieve data from external sources. This can be useful when information about an infrastructure is stored in a separate location.

Reference information on pillar and the external pillar interface can be found in the Salt documentation:

**Pillar**

Minion Config in Pillar

Minion configuration options can be set on pillars. Any option that you want to modify, should be in the first level of the pillars, in the same way you set the options in the config file. For example, to configure the MySQL root password to be used by MySQL Salt execution module:

```
mysql.pass: hardtoguesspassword
```

This is very convenient when you need some dynamic configuration change that you want to be applied on the fly. For example, there is a chicken and the egg problem if you do this:

```
mysql-admin-passwd:
  mysql_user.present:
    - name: root
    - password: somepasswd

mydb:
  mysql_db.present
```

The second state will fail, because you changed the root password and the minion didn’t notice it. Setting mysql.pass in the pillar, will help to sort out the issue. But always change the root admin password in the first place.

This is very helpful for any module that needs credentials to apply state changes: mysql, keystone, etc.

### 3.3 States

#### 3.3.1 How Do I Use Salt States?

Simplicity, Simplicity, Simplicity
Many of the most powerful and useful engineering solutions are founded on simple principles. Salt States strive to do just that: K.I.S.S. (Keep It Stupidly Simple)

The core of the Salt State system is the SLS, or Salt State file. The SLS is a representation of the state in which a system should be in, and is set up to contain this data in a simple format. This is often called configuration management.

**Note:** This is just the beginning of using states, make sure to read up on pillar *Pillar* next.

---

### It is All Just Data

Before delving into the particulars, it will help to understand that the SLS file is just a data structure under the hood. While understanding that the SLS is just a data structure isn't critical for understanding and making use of Salt States, it should help bolster knowledge of where the real power is.

SLS files are therefore, in reality, just dictionaries, lists, strings, and numbers. By using this approach Salt can be much more flexible. As one writes more state files, it becomes clearer exactly what is being written. The result is a system that is easy to understand, yet grows with the needs of the admin or developer.

---

### The Top File

The example SLS files in the below sections can be assigned to hosts using a file called `top.sls`. This file is described in-depth [here](#).

---

### Default Data - YAML

By default Salt represents the SLS data in what is one of the simplest serialization formats available - YAML.

A typical SLS file will often look like this in YAML:

```yaml
apache:
  pkg.installed: []
  service.running:
    - require:
      - pkg: apache
```

This SLS data will ensure that the package named apache is installed, and that the apache service is running. The components can be explained in a simple way.

The first line is the ID for a set of data, and it is called the ID Declaration. This ID sets the name of the thing that needs to be manipulated.

The second and third lines contain the state module function to be run, in the format `<state_module>.<function>`. The `pkg.installed` state module function ensures that a software package is installed via the system's native package manager. The `service.running` state module function ensures that a given system daemon is running.

---

---
Finally, on line five, is the word require. This is called a Requisite Statement, and it makes sure that the Apache service is only started after a successful installation of the apache package.

### Adding Configs and Users

When setting up a service like an Apache web server, many more components may need to be added. The Apache configuration file will most likely be managed, and a user and group may need to be set up.

```yaml
apache:
  pkg.installed: []
  service.running:
    - watch:
      - pkg: apache
      - file: /etc/httpd/conf/httpd.conf
      - user: apache
  user.present:
    - uid: 87
    - gid: 87
    - home: /var/www/html
    - shell: /bin/nologin
    - require:
      - group: apache
  group.present:
    - gid: 87
    - require:
      - pkg: apache

/etc/httpd/conf/httpd.conf:
  file.managed:
    - source: salt://apache/httpd.conf
    - user: root
    - group: root
    - mode: 644
```

This SLS data greatly extends the first example, and includes a config file, a user, a group and new requisite statement: watch.

Adding more states is easy, since the new user and group states are under the Apache ID, the user and group will be the Apache user and group. The require statements will make sure that the user will only be made after the group, and that the group will be made only after the Apache package is installed.

Next, the require statement under service was changed to watch, and is now watching 3 states instead of just one. The watch statement does the same thing as require, making sure that the other states run before running the state with a watch, but it adds an extra component. The watch statement will run the state's watcher function for any changes to the watched states. So if the package was updated, the config file changed, or the user uid modified, then the service state's watcher will be run. The service state's watcher just restarts the service, so in this case, a change in the config file will also trigger a restart of the respective service.

### Moving Beyond a Single SLS

When setting up Salt States in a scalable manner, more than one SLS will need to be used. The above examples were in a single SLS file, but two or more SLS files can be combined to build out a State Tree. The above example also references a file with a strange source - salt://apache/httpd.conf. That file will need to be available as well.
The SLS files are laid out in a directory structure on the Salt master; an SLS is just a file and files to download are just files.

The Apache example would be laid out in the root of the Salt file server like this:

```
apache/init.sls
apache/httpd.conf
```

So the httpd.conf is just a file in the apache directory, and is referenced directly.

---

Do not use dots in SLS file names or their directories

The initial implementation of `top.sls` and `Include declaration` followed the python import model where a slash is represented as a period. This means that a SLS file with a period in the name (besides the suffix period) cannot be referenced. For example, `webserver_1.0.sls` is not referenceable because `webserver_1.0` would refer to the directory/file `webserver_1/0.sls`.

The same applies for any subdirectories, this is especially `tricky` when git repos are created. Another command that typically can't render it's output is `state.show_sls` of a file in a path that contains a dot.

But when using more than one single SLS file, more components can be added to the toolkit. Consider this SSH example:

```
ssh/init.sls:

  openssh-client:
    pkg.installed

  /etc/ssh/ssh_config:
    file.managed:
      - user: root
      - group: root
      - mode: 644
      - source: salt://ssh/ssh_config
      - require:
        - pkg: openssh-client

ssh/server.sls:

  include:
    - ssh

  openssh-server:
    pkg.installed

  ssdh:
    service.running:
      - require:
        - pkg: openssh-client
        - pkg: openssh-server
        - file: /etc/ssh/banner
        - file: /etc/ssh/sshd_config

  /etc/ssh/sshd_config:
    file.managed:
      - user: root
      - group: root
      - mode: 644
```
- source: salt://ssh/sshd_config
  - require:
    - pkg: openssh-server

/etc/ssh/banner:
  file:
    - managed
    - user: root
    - group: root
    - mode: 644
    - source: salt://ssh/banner
    - require:
      - pkg: openssh-server

Note: Notice that we use two similar ways of denoting that a file is managed by Salt. In the /etc/ssh/sshd_config state section above, we use the file.managed state declaration whereas with the /etc/ssh/banner state section, we use the file state declaration and add a managed attribute to that state declaration. Both ways produce an identical result; the first way -- using file.managed -- is merely a shortcut.

Now our State Tree looks like this:

apache/init.sls
apache/httpd.conf
ssh/init.sls
ssh/server.sls
ssh/banner
ssh/sshd_config
ssh/sshd_config

This example now introduces the include statement. The include statement includes another SLS file so that components found in it can be required, watched or as will soon be demonstrated - extended.

The include statement allows for states to be cross linked. When an SLS has an include statement it is literally extended to include the contents of the included SLS files.

Note that some of the SLS files are called init.sls, while others are not. More info on what this means can be found in the States Tutorial.

Extending Included SLS Data

Sometimes SLS data needs to be extended. Perhaps the apache service needs to watch additional resources, or under certain circumstances a different file needs to be placed.

In these examples, the first will add a custom banner to ssh and the second will add more watchers to apache to include mod_python.

ssh/custom-server.sls:

include:
  - ssh.server

extend:
  /etc/ssh/banner:
    file:
      - source: salt://ssh/custom-banner
python/mod_python.sls:

```yaml
include:
   - apache
extend:
   apache:
      service:
         - watch:
         - pkg: mod_python
mod_python:
   pkg.installed
```

The `custom-server.sls` file uses the `extend` statement to overwrite where the banner is being downloaded from, and therefore changing what file is being used to configure the banner.

In the new mod_python SLS the mod_python package is added, but more importantly the apache service was extended to also watch the mod_python package.

**Using extend with require or watch**

The `extend` statement works differently for `require` or `watch`. It appends to, rather than replacing the requisite component.

---

**Understanding the Render System**

Since SLS data is simply that (data), it does not need to be represented with YAML. Salt defaults to YAML because it is very straightforward and easy to learn and use. But the SLS files can be rendered from almost any imaginable medium, so long as a renderer module is provided.

The default rendering system is the `yaml_jinja` renderer. The `yaml_jinja` renderer will first pass the template through the Jinja2 templating system, and then through the YAML parser. The benefit here is that full programming constructs are available when creating SLS files.

Other renderers available are `yaml_mako` and `yaml_wempy` which each use the Mako or Wempy templating system respectively rather than the jinja templating system, and more notably, the pure Python or `pydsl` & `pyobjects` renderers. The `py` renderer allows for SLS files to be written in pure Python, allowing for the utmost level of flexibility and power when preparing SLS data; while the `pydsl` renderer provides a flexible, domain-specific language for authoring SLS data in Python; and the `pyobjects` renderer gives you a "Pythonic" interface to building state data.

**Note:** The templating engines described above aren't just available in SLS files. They can also be used in `file.managed` states, making file management much more dynamic and flexible. Some examples for using templates in managed files can be found in the documentation for the `file states`, as well as the `MooseFS example` below.

---

**Getting to Know the Default - yaml_jinja**

The default renderer - `yaml_jinja`, allows for use of the jinja templating system. A guide to the Jinja templating system can be found here: [http://jinja.pocoo.org/docs](http://jinja.pocoo.org/docs)

When working with renderers a few very useful bits of data are passed in. In the case of templating engine based renderers, three critical components are available, `salt`, `grains`, and `pillar`. The `salt` object allows for any
Salt function to be called from within the template, and **grains** allows for the Grains to be accessed from within
the template. A few examples:

```
apache/init.sls:

apache:
    pkg.installed:
      {% if grains['os'] == 'RedHat' %}
        - name: httpd
      {% endif %}
    service.running:
      {% if grains['os'] == 'RedHat' %}
        - name: httpd
      {% endif %}
      - watch:
        - pkg: apache
        - file: /etc/httpd/conf/httpd.conf
        - user: apache
    user.present:
      - uid: 87
      - gid: 87
      - home: /var/www/html
      - shell: /bin/nologin
      - require:
        - group: apache
    group.present:
      - gid: 87
      - require:
        - pkg: apache

/etc/httpd/conf/httpd.conf:
    file.managed:
      - source: salt://apache/httpd.conf
      - user: root
      - group: root
      - mode: 644
```

This example is simple. If the **os** grain states that the operating system is Red Hat, then the name of the Apache
package and service needs to be httpd. A more aggressive way to use Jinja can be found here, in a module to set up
a MooseFS distributed filesystem chunkserver:

```
moosefs/chunk.sls:

include:
  - moosefs

{% for mnt in salt['cmd.run']('ls /dev/data/moose*').split() %}
/mnt/moose{{ mnt[-1] }}:
  mount.mounted:
    - device: {{ mnt }}
    - fstype: xfs
    - mkmnt: True
  file.directory:
    - user: mfs
    - group: mfs
    - require:
      - user: mfs
      - group: mfs
{% endfor %}
```
This example shows much more of the available power of Jinja. Multiple for loops are used to dynamically detect available hard drives and set them up to be mounted, and the salt object is used multiple times to call shell commands to gather data.

Introducing the Python, PyDSL, and the Pyobjects Renderers

Sometimes the chosen default renderer might not have enough logical power to accomplish the needed task. When this happens, the Python renderer can be used. Normally a YAML renderer should be used for the majority of SLS files, but an SLS file set to use another renderer can be easily added to the tree.

This example shows a very basic Python SLS file:

```python
#!/py

def run():
    # Install the django package
    return {'include': ['python'],
            'django': {'pkg': ['installed']}}
```
This is a very simple example; the first line has an SLS shebang that tells Salt to not use the default renderer, but to use the py renderer. Then the run function is defined, the return value from the run function must be a Salt friendly data structure, or better known as a Salt HighState data structure.

Alternatively, using the pydsl renderer, the above example can be written more succinctly as:

```python
#include('python', delayed=True)
state('django').pkg.installed()
```

The pyobjects renderer provides an `Pythonic` object based approach for building the state data. The above example could be written as:

```python
#include('python')
Pkg.installed("django")
```

These Python examples would look like this if they were written in YAML:

```yaml
include:
  - python
django:
    pkg.installed
```

This example clearly illustrates that; one, using the YAML renderer by default is a wise decision and two, unbridled power can be obtained where needed by using a pure Python SLS.

### Running and Debugging Salt States

Once the rules in an SLS are ready, they should be tested to ensure they work properly. To invoke these rules, simply execute `salt '*' state.apply` on the command line. If you get back only hostnames with a `:` after, but no return, chances are there is a problem with one or more of the sls files. On the minion, use the `salt-call` command to examine the output for errors:

```
salt-call state.apply -l debug
```

This should help troubleshoot the issue. The minion can also be started in the foreground in debug mode by running `salt-minion -l debug`.

### Next Reading

With an understanding of states, the next recommendation is to become familiar with Salt’s pillar interface:

*Pillar Walkthrough*

### 3.3.2 States tutorial, part 1 - Basic Usage

The purpose of this tutorial is to demonstrate how quickly you can configure a system to be managed by Salt States. For detailed information about the state system please refer to the full *states reference.*

This tutorial will walk you through using Salt to configure a minion to run the Apache HTTP server and to ensure the server is running.
Before continuing make sure you have a working Salt installation by following the installation and the configuration instructions.

Stuck?
There are many ways to get help from the Salt community including our mailing list and our IRC channel #salt.

Setting up the Salt State Tree

States are stored in text files on the master and transferred to the minions on demand via the master's File Server. The collection of state files make up the State Tree.

To start using a central state system in Salt, the Salt File Server must first be set up. Edit the master config file (file_roots) and uncomment the following lines:

```yaml
code
file_roots:
  base:
    - /srv/salt
```

Note: If you are deploying on FreeBSD via ports, the file_roots path defaults to /usr/local/etc/salt/states.

Restart the Salt master in order to pick up this change:

```
pkill salt-master
salt-master -d
```

Preparing the Top File

On the master, in the directory uncommented in the previous step, (/srv/salt by default), create a new file called top.sls and add the following:

```yaml
code
base:
  '*':
    - webserver
```

The top file is separated into environments (discussed later). The default environment is base. Under the base environment a collection of minion matches is defined; for now simply specify all hosts (*).

Targeting minions

The expressions can use any of the targeting mechanisms used by Salt — minions can be matched by glob, PCRE regular expression, or by grains. For example:

```yaml
code
base:
  'G@os:Fedora':
    - match: grain
    - webserver
```

Create an sls file

In the same directory as the top file, create a file named webserver.sls, containing the following:

```
apache:               # ID declaration
  pkg:               # state declaration
    - installed    # function declaration
```

The first line, called the ID declaration, is an arbitrary identifier. In this case it defines the name of the package to be installed.

Note: The package name for the Apache httpd web server may differ depending on OS or distro — for example, on Fedora it is httpd but on Debian/Ubuntu it is apache2.

The second line, called the State declaration, defines which of the Salt States we are using. In this example, we are using the pkg state to ensure that a given package is installed.

The third line, called the Function declaration, defines which function in the pkg state module to call.

Renderers

States sls files can be written in many formats. Salt requires only a simple data structure and is not concerned with how that data structure is built. Templating languages and DSLs are a dime-a-dozen and everyone has a favorite.

Building the expected data structure is the job of Salt renderers and they are dead-simple to write.

In this tutorial we will be using YAML in Jinja2 templates, which is the default format. The default can be changed by editing renderer in the master configuration file.

Install the package

Next, let’s run the state we created. Open a terminal on the master and run:

```
salt '*' state.apply
```

Our master is instructing all targeted minions to run state.apply. When this function is executed without any SLS targets, a minion will download the top file and attempt to match the expressions within it. When the minion does match an expression the modules listed for it will be downloaded, compiled, and executed.

Note: This action is referred to as a "highstate", and can be run using the state.highstate function. However, to make the usage easier to understand ("highstate" is not necessarily an intuitive name), a state.apply function was added in version 2015.5.0, which when invoked without any SLS names will trigger a highstate. state.highstate still exists and can be used, but the documentation (as can be seen above) has been updated to reference state.apply, so keep the following in mind as you read the documentation:

- state.apply invoked without any SLS names will run state.highstate
- state.apply invoked with SLS names will run state.sls

Once completed, the minion will report back with a summary of all actions taken and all changes made.
Warning: If you have created custom grain modules, they will not be available in the top file until after the first highstate. To make custom grains available on a minion's first highstate, it is recommended to use this example to ensure that the custom grains are synced when the minion starts.

SLS File Namespace

Note that in the example above, the SLS file `webserver.sls` was referred to simply as `webserver`. The namespace for SLS files when referenced in `top.sls` or an include declaration follows a few simple rules:

1. The `.sls` is discarded (i.e. `webserver.sls` becomes `webserver`).
2. Subdirectories can be used for better organization.
   - Each subdirectory is represented with a dot (following the Python import model) in Salt states and on the command line. `webserver/dev.sls` on the filesystem is referred to as `webserver.dev` in Salt
   - Because slashes are represented as dots, SLS files can not contain dots in the name (other than the dot for the SLS suffix). The SLS file `webserver_1.0.sls` can not be matched, and `webserver_1.0` would match the directory/file `webserver_1/0.sls`
3. A file called `init.sls` in a subdirectory is referred to by the path of the directory. So, `webserver/init.sls` is referred to as `webserver`.
4. If both `webserver.sls` and `webserver/init.sls` happen to exist, `webserver/init.sls` will be ignored and `webserver.sls` will be the file referred to as `webserver`.

Troubleshooting Salt

If the expected output isn't seen, the following tips can help to narrow down the problem.

Turn up logging  Salt can be quite chatty when you change the logging setting to debug:

```bash
salt-minion -l debug
```

Run the minion in the foreground  By not starting the minion in daemon mode (`-d`) one can view any output from the minion as it works:

```bash
salt-minion
```

Increase the default timeout value when running `salt`. For example, to change the default timeout to 60 seconds:

```bash
salt -t 60
```

For best results, combine all three:

```bash
salt-minion -l debug  # On the minion
salt '*' state.apply -t 60  # On the master
```

Next steps

This tutorial focused on getting a simple Salt States configuration working. Part 2 will build on this example to cover more advanced SLS syntax and will explore more of the states that ship with Salt.
3.3.3 States tutorial, part 2 - More Complex States, Requisites

Note: This tutorial builds on topics covered in part 1. It is recommended that you begin there.

In the last part of the Salt States tutorial we covered the basics of installing a package. We will now modify our `webserver.sls` file to have requirements, and use even more Salt States.

Call multiple States

You can specify multiple State declaration under an ID declaration. For example, a quick modification to our `webserver.sls` to also start Apache if it is not running:

```
apache:
  pkg.installed: []
  service.running:
    - require:
      - pkg: apache
```

Try stopping Apache before running `state.apply` once again and observe the output.

Note: For those running RedhatOS derivatives (Centos, AWS), you will want to specify the service name to be httpd. More on state service here, service state. With the example above, just add `- name: httpd` above the require line and with the same spacing.

Require other states

We now have a working installation of Apache so let’s add an HTML file to customize our website. It isn’t exactly useful to have a website without a webserver so we don’t want Salt to install our HTML file until Apache is installed and running. Include the following at the bottom of your `webserver/init.sls` file:

```
apache:
  pkg.installed: []
  service.running:
    - require:
      - pkg: apache

/var/www/index.html:
  file:
    - managed
    - source: salt://webserver/index.html
    - require:
      - pkg: apache
```

Line 7 is the ID declaration. In this example it is the location we want to install our custom HTML file. (Note: the default location that Apache serves may differ from the above on your OS or distro. `/srv/www` could also be a likely place to look.)

Line 8 the State declaration. This example uses the Salt file state.

Line 9 is the Function declaration. The managed function will download a file from the master and install it in the location specified.
Line 10 is a Function arg declaration which, in this example, passes the source argument to the managed function.

Line 11 is a Requisite declaration.

Line 12 is a Requisite reference which refers to a state and an ID. In this example, it is referring to the ID declaration from our example in part 1. This declaration tells Salt not to install the HTML file until Apache is installed.

Next, create the index.html file and save it in the webserver directory:

```
<!DOCTYPE html>
<html>
  <head><title>Salt rocks</title></head>
  <body>
    <h1>This file brought to you by Salt</h1>
  </body>
</html>
```

Last, call state.apply again and the minion will fetch and execute the highstate as well as our HTML file from the master using Salt's File Server:

```
salt '*' state.apply
```

Verify that Apache is now serving your custom HTML.

(require vs. watch)

There are two Requisite declaration, "require", and "watch". Not every state supports "watch". The service state does support "watch" and will restart a service based on the watch condition.

For example, if you use Salt to install an Apache virtual host configuration file and want to restart Apache whenever that file is changed you could modify our Apache example from earlier as follows:

```
/etc/httpd/extra/httpd-vhosts.conf:
  file.managed:
    - source: salt://webserver/httpd-vhosts.conf

apache:
  pkg.installed: []
  service.running:
    - watch:
      - file: /etc/httpd/extra/httpd-vhosts.conf
    - require:
      - pkg: apache
```

If the pkg and service names differ on your OS or distro of choice you can specify each one separately using a Name declaration which explained in Part 3.

Next steps

In part 3 we will discuss how to use includes, extends, and templating to make a more complete State Tree configuration.

3.3.4 States tutorial, part 3 - Templating, Includes, Extends
This tutorial builds on topics covered in part 1 and part 2. It is recommended that you begin there.

This part of the tutorial will cover more advanced templating and configuration techniques for SLS files.

### Templating SLS modules

SLS modules may require programming logic or inline execution. This is accomplished with module templating. The default module templating system used is Jinja2 and may be configured by changing the `renderer` value in the master config.

All states are passed through a templating system when they are initially read. To make use of the templating system, simply add some templating markup. An example of an SLS module with templating markup may look like this:

```yaml
{% for usr in ['moe','larry','curly'] %}
  {{ usr }}: user.present
{% endfor %}
```

This templated SLS file once generated will look like this:

```yaml
moe: user.present
larry: user.present
curly: user.present
```

Here's a more complex example:

```yaml
# Comments in yaml start with a hash symbol.
# Since jinja rendering occurs before yaml parsing, if you want to include jinja
# in the comments you may need to escape them using 'jinja' comments to prevent
# jinja from trying to render something which is not well-defined jinja.
# e.g.
{% for usr in 'moe','larry','curly' %}
  group:
    present
  user:
    present
    gid_from_name: True
    require:
      group: {{ usr }}
{% endfor %}
```

### Using Grains in SLS modules

Often times a state will need to behave differently on different systems. Salt grains objects are made available in the template context. The grains can be used from within SLS modules:

```yaml
apache:
  pkg.installed:
```

3.3. States
Using Environment Variables in SLS modules

You can use `salt['environ.get']('VARNAME')` to use an environment variable in a Salt state.

```
MYENVVAR="world" salt-call state.template test.sls
```

Create a file with contents from an environment variable:
```
file.managed:
  - name: /tmp/hello
  - contents: {{ salt['environ.get']('MYENVVAR') }}
```

Error checking:
```
{% set myenvvar = salt['environ.get']('MYENVVAR') %}
{% if myenvvar %}
Create a file with contents from an environment variable:
  file.managed:
    - name: /tmp/hello
    - contents: {{ salt['environ.get']('MYENVVAR') }}
{% else %}
Fail - no environment passed in:
  test:
    A. fail_without_changes
{% endif %}
```

Calling Salt modules from templates

All of the Salt modules loaded by the minion are available within the templating system. This allows data to be gathered in real time on the target system. It also allows for shell commands to be run easily from within the sls modules.

The Salt module functions are also made available in the template context as `salt`:

The following example illustrates calling the `group_to_gid` function in the `file` execution module with a single positional argument called `some_group_that_exists`.

```
moe:
  user.present:
    - gid: {{ salt['file.group_to_gid']('some_group_that_exists') }}
```

One way to think about this might be that the `gid` key is being assigned a value equivalent to the following python pseudo-code:

```
import salt.modules.file
file.group_to_gid('some_group_that_exists')
```
Note that for the above example to work, `some_group_that_exists` must exist before the state file is processed by the templating engine.

Below is an example that uses the `network.hw_addr` function to retrieve the MAC address for eth0:

```python
salt['network.hw_addr']['eth0']
```

To examine the possible arguments to each execution module function, one can examine the module reference documentation:

Advanced SLS module syntax

Lastly, we will cover some incredibly useful techniques for more complex State trees.

Include declaration

A previous example showed how to spread a Salt tree across several files. Similarly, `requisites` span multiple files by using an Include declaration. For example:

```python
python/python-libs.sls:

    python-dateutil:
        pkg.installed

python/django.sls:

    include:
        - python.python-libs
django:
    pkg.installed:
        - require:
          - pkg: python-dateutil
```

Extend declaration

You can modify previous declarations by using an Extend declaration. For example the following modifies the Apache tree to also restart Apache when the vhosts file is changed:

```python
apache/apache.sls:

    apache:
        pkg.installed

apache/mywebsite.sls:

    include:
        - apache.apache
    extend:
        apache:
            service:
                - running
                - watch:
                    - file: /etc/httpd/extra/httpd-vhosts.conf
```
Using extend with require or watch
The `extend` statement works differently for `require` or `watch`. It appends to, rather than replacing the requisite component.

Name declaration
You can override the ID declaration by using a Name declaration. For example, the previous example is a bit more maintainable if rewritten as follows:

```yaml
apache/mywebsite.sls:

include:
  - apache.apache

extend:
  apache:
    service:
      - running
      - watch:
        - file: mywebsite

mywebsite:
  file.managed:
    - name: /etc/httpd/extra/httpd-vhosts.conf
    - source: salt://apache/httpd-vhosts.conf
```

Names declaration
Even more powerful is using a Names declaration to override the ID declaration for multiple states at once. This often can remove the need for looping in a template. For example, the first example in this tutorial can be rewritten without the loop:

```yaml
stooges:
  user.present:
    - names:
      - moe
      - larry
      - curly
```

Next steps
In part 4 we will discuss how to use salt's `file_roots` to set up a workflow in which states can be ``promoted'' from dev, to QA, to production.
3.3.5 States tutorial, part 4

Note: This tutorial builds on topics covered in part 1, part 2 and part 3. It is recommended that you begin there.

This part of the tutorial will show how to use salt’s file_roots to set up a workflow in which states can be ‘promoted’ from dev, to QA, to production.

Salt fileservers path inheritance

Salt’s fileserver allows for more than one root directory per environment, like in the below example, which uses both a local directory and a secondary location shared to the salt master via NFS:

```
# In the master config file (/etc/salt/master)
file_roots:
  base:
    - /srv/salt
    - /mnt/salt-nfs/base
```

Salt’s fileserver collapses the list of root directories into a single virtual environment containing all files from each root. If the same file exists at the same relative path in more than one root, then the top-most match ‘wins’. For example, if /srv/salt/foo.txt and /mnt/salt-nfs/base/foo.txt both exist, then salt://foo.txt will point to /srv/salt/foo.txt.

Note: When using multiple fileserver backends, the order in which they are listed in the fileserver_backend parameter also matters. If both roots and git backends contain a file with the same relative path, and roots appears before git in the fileserver_backend list, then the file in roots will ‘win’, and the file in gitfs will be ignored.

A more thorough explanation of how Salt’s modular fileserver works can be found here. We recommend reading this.

Environment configuration

Configure a multiple-environment setup like so:

```
file_roots:
  base:
    - /srv/salt/prod
  qa:
    - /srv/salt/qa
    - /srv/salt/prod
  dev:
    - /srv/salt/dev
    - /srv/salt/qa
    - /srv/salt/prod
```

Given the path inheritance described above, files within /srv/salt/prod would be available in all environments. Files within /srv/salt/qa would be available in both qa, and dev. Finally, the files within /srv/salt/dev would only be available within the dev environment.

Based on the order in which the roots are defined, new files/states can be placed within /srv/salt/dev, and pushed out to the dev hosts for testing.
Those files/states can then be moved to the same relative path within `/srv/salt/qa`, and they are now available only in the `dev` and `qa` environments, allowing them to be pushed to QA hosts and tested.

Finally, if moved to the same relative path within `/srv/salt/prod`, the files are now available in all three environments.

**Requesting files from specific fileserver environments**

See [here](#) for documentation on how to request files from specific environments.

**Practical Example**

As an example, consider a simple website, installed to `/var/www/foobarcom`. Below is a top.sls that can be used to deploy the website:

```
/srv/salt/prod/top.sls:

base:
  'web*prod*':
    - webserver.foobarcom
qa:
  'web*qa*':
    - webserver.foobarcom
dev:
  'web*dev*':
    - webserver.foobarcom
```

Using pillar, roles can be assigned to the hosts:

```
/srv/pillar/top.sls:

base:
  'web*prod*':
    - webserver.prod
  'web*qa*':
    - webserver.qa
  'web*dev*':
    - webserver.dev
```

```
/srv/pillar/webserver/prod.sls:

webserver_role: prod
```

```
/srv/pillar/webserver/qa.sls:

webserver_role: qa
```

```
/srv/pillar/webserver/dev.sls:

webserver_role: dev
```

And finally, the SLS to deploy the website:

```
/srv/salt/prod/webserver/foobarcom.sls:
```

Given the above SLS, the source for the website should initially be placed in /srv/salt/dev/webserver/src/foobarcom.

First, let's deploy to dev. Given the configuration in the top file, this can be done using `state.apply`:

```bash
class --pillar 'webserver_role:dev' state.apply
```

However, in the event that it is not desirable to apply all states configured in the top file (which could be likely in more complex setups), it is possible to apply just the states for the foobarcom website, by invoking `state.apply` with the desired SLS target as an argument:

```bash
class --pillar 'webserver_role:dev' state.apply webserver.foobarcom
```

Once the site has been tested in dev, then the files can be moved from /srv/salt/dev/webserver/src/foobarcom to /srv/salt/qa/webserver/src/foobarcom, and deployed using the following:

```bash
class --pillar 'webserver_role:qa' state.apply webserver.foobarcom
```

Finally, once the site has been tested in qa, then the files can be moved from /srv/salt/qa/webserver/src/foobarcom to /srv/salt/prod/webserver/src/foobarcom, and deployed using the following:

```bash
class --pillar 'webserver_role:prod' state.apply webserver.foobarcom
```

Thanks to Salt's fileserver inheritance, even though the files have been moved to within /srv/salt/prod, they are still available from the same `salt://` URI in both the qa and dev environments.

### Continue Learning

The best way to continue learning about Salt States is to read through the [reference documentation](https://docs.saltstack.com/en/latest/) and to look through examples of existing state trees. Many pre-configured state trees can be found on GitHub in the `saltstack-formulas` collection of repositories.

If you have any questions, suggestions, or just want to chat with other people who are using Salt, we have a very [active community](https://saltstack.com/community/) and we'd love to hear from you.

In addition, by continuing to [part 5](#), you can learn about the powerful orchestration of which Salt is capable.

### 3.3.6 States Tutorial, Part 5 - Orchestration with Salt

**Note:** This tutorial builds on some of the topics covered in the earlier `States Walkthrough` pages. It is recommended to start with [Part 1](#) if you are not familiar with how to use states.
Orchestration is accomplished in salt primarily through the Orchestrate Runner. Added in version 0.17.0, this Salt Runner can use the full suite of requisites available in states, and can also execute states/functions using salt-ssh.

**The Orchestrate Runner**

New in version 0.17.0.

---

**Note:** Orchestrate Deprecates OverState

The Orchestrate Runner (originally called the state.sls runner) offers all the functionality of the OverState, but with some advantages:

- All requisites available in states can be used.
- The states/functions will also work on salt-ssh minions.

The Orchestrate Runner was added with the intent to eventually deprecate the OverState system, however the Over-State will still be maintained until Salt 2015.8.0.

---

The orchestrate runner generalizes the Salt state system to a Salt master context. Whereas `state.apply` is concurrently and independently executed on each Salt minion, the `state.orchestrate` runner is executed on the master, giving it a master-level view and control over requisites, such as state ordering and conditionals. This allows for inter minion requisites, like ordering the application of states on different minions that must not happen simultaneously, or for halting the state run on all minions if a minion fails one of its states.

If you want to setup a load balancer in front of a cluster of web servers, for example, you can ensure the load balancer is setup before the web servers or stop the state run altogether if one of the minions does not set up correctly.

`state.apply` allows you to statefully manage each minion and the `state.orchestrate` runner allows you to statefully manage your entire infrastructure.

**Executing the Orchestrate Runner**

The Orchestrate Runner command format is the same as for the `state.sls` function, except that since it is a runner, it is executed with `salt-run` rather than `salt`. Assuming you have a state.sls file called `/srv/salt/orch/webserver.sls` the following command run on the master will apply the states defined in that file.

```
salt-run state.orchestrate orch.webserver
```

**Note:** `state.orch` is a synonym for `state.orchestrate`

Changed in version 2014.1.1: The runner function was renamed to `state.orchestrate` to avoid confusion with the `state.sls` remote execution function. In versions 0.17.0 through 2014.1.0, `state.sls` must be used.

**Examples**

**Function**

To execute a function, use `salt.function:`
# /srv/salt/orch/cleanfoo.sls

```python
cmd.run:
    salt.function:
        - tgt: '*'
        - arg: rm -rf /tmp/foo
```

```
salt-run state.orchestrate orch.cleanfoo
```

**State**

To execute a state, use `salt.state`.

```python
# /srv/salt/orch/webserver.sls
install_nginx:
    salt.state:
        - tgt: 'web*'
        - sls: nginx
```

```
salt-run state.orchestrate orch.webserver
```

**Highstate**

To run a `highstate`, set `highstate: True` in your state config:

```python
# /srv/salt/orch/web_setup.sls
webserver_setup:
    salt.state:
        - tgt: 'web*'
        - highstate: True
```

```
salt-run state.orchestrate orch.web_setup
```

**More Complex Orchestration**

Many states/functions can be configured in a single file, which when combined with the full suite of `requisites`, can be used to easily configure complex orchestration tasks. Additionally, the states/functions will be executed in the order in which they are defined, unless prevented from doing so by any `requisites`, as is the default in SLS files since 0.17.0.

```python
cmd.run:
    salt.function:
        - tgt: 10.0.0.0/24
        - tgt_type: ipcidr
        - arg: bootstrap

storage_setup:
    salt.state:
        - tgt: 'role:storage'
```

---

**3.3. States**
Given the above setup, the orchestration will be carried out as follows:

1. The shell command `bootstrap` will be executed on all minions in the 10.0.0.0/24 subnet.
2. A Highstate will be run on all minions whose ID starts with `web`, since the `storage_setup` state requires it.
3. Finally, the `ceph` SLS target will be executed on all minions which have a grain called `role` with a value of `storage`.

Note: Remember, salt-run is always executed on the master.

### 3.3.7 Syslog-ng usage

**Overview**

Syslog_ng state module is for generating syslog-ng configurations. You can do the following things:

- generate syslog-ng configuration from YAML,
- use non-YAML configuration,
- start, stop or reload syslog-ng.

There is also an execution module, which can check the syntax of the configuration, get the version and other information about syslog-ng.

**Configuration**

Users can create syslog-ng configuration statements with the `syslog_ng.config` function. It requires a `name` and a `config` parameter. The `name` parameter determines the name of the generated statement and the `config` parameter holds a parsed YAML structure.

A statement can be declared in the following forms (both are equivalent):

```
source.s_localhost:
  syslog_ng.config:
    - config:
      - tcp:
        - ip: "127.0.0.1"
        - port: 1233

s_localhost:
  syslog_ng.config:
    - config:
```
source:
- tcp:
  - ip: "127.0.0.1"
  - port: 1233

The first one is called short form, because it needs less typing. Users can use lists and dictionaries to specify their configuration. The format is quite self-describing and there are more examples [at the end](#examples) of this document.

**Quotation**

The quotation can be tricky sometimes but here are some rules to follow:

- when a string meant to be "string" in the generated configuration, it should be like ""string"" in the YAML document
- similarly, users should write "'string'" to get 'string' in the generated configuration

**Full example**

The following configuration is an example, how a complete syslog-ng configuration looks like:

```yaml
# Set the location of the configuration file
set_location:
  module.run:
    - name: syslog_ng.set_config_file
      - m_name: "/home/tibi/install/syslog-ng/etc/syslog-ng.conf"

# The syslog-ng and syslog-ng-ctl binaries are here. You needn't use
# this method if these binaries can be found in a directory in your PATH.
set_bin_path:
  module.run:
    - name: syslog_ng.set_binary_path
      - m_name: "/home/tibi/install/syslog-ng/sbin"

# Writes the first lines into the config file, also erases its previous
# content
write_version:
  module.run:
    - name: syslog_ng.write_version
      - m_name: "3.6"

# There is a shorter form to set the above variables
set_variables:
  module.run:
    - name: syslog_ng.set_parameters
      - version: "3.6"
      - binary_path: "/home/tibi/install/syslog-ng/sbin"
      - config_file: "/home/tibi/install/syslog-ng/etc/syslog-ng.conf"

# Some global options
options.global_options:
  syslog_ng.config:
    - config:
      - time_reap: 30
```

3.3. States
- mark_freq: 10
- keep_hostname: "yes"

source.s_localhost:
syslog_ng.config:
  - config:
    - tcp:
      - ip: "127.0.0.1"
      - port: 1233

destination.d_log_server:
syslog_ng.config:
  - config:
    - tcp:
      - "127.0.0.1"
      - port: 1234

log.l_log_to_central_server:
syslog_ng.config:
  - config:
    - source: s_localhost
    - destination: d_log_server

some_comment:
module.run:
  - name: syslog_ng.write_config
  - config: |
    # Multi line
    # comment

# Another mode to use comments or existing configuration snippets
config.other_comment_form:
syslog_ng.config:
  - config: |
    # Multi line
    # comment

The `syslog_ng.reloaded` function can generate syslog-ng configuration from YAML. If the statement (source, destination, parser, etc.) has a name, this function uses the id as the name, otherwise (log statement) it's purpose is like a mandatory comment.

After execution this example the syslog_ng state will generate this file:

```yaml
#Generated by Salt on 2014-08-18 00:11:11
@version: 3.6

options {
    time_reap(
        30
    );
    mark_freq(
        10
    );
    keep_hostname(
        yes
    );
};
```
Users can include arbitrary texts in the generated configuration with using the `config` statement (see the example above).

**Syslog_ng module functions**

You can use `syslog_ng.set_binary_path` to set the directory which contains the syslog-ng and syslog-ng-ctl binaries. If this directory is in your PATH, you don’t need to use this function. There is also a `syslog_ng.set_config_file` function to set the location of the configuration file.
Examples

Simple source

```yaml
source s_tail {
  file(
    "/var/log/apache/access.log",
    follow_freq(1),
    flags(no-parse, validate-utf8)
  );
};
```

```
# Salt will call the source function of syslog_ng module
syslog_ng.config:
  - config:
    source:
      - file:
        - file: "/var/log/apache/access.log"
        - follow_freq : 1
        - flags:
          - no-parse
          - validate-utf8
```

OR

```
source.s_tail:
  syslog_ng.config:
    - config:
      source:
        - file:
          - file: "/var/log/apache/access.log"
          - follow_freq : 1
          - flags:
            - no-parse
            - validate-utf8
```

OR

```
source.s_tail:
  syslog_ng.config:
    - config:
      - file:
        - file: "/var/log/apache/access.log"
        - follow_freq : 1
        - flags:
          - no-parse
          - validate-utf8
```

Complex source

```yaml
source s_gsoc2014 {
  tcp(
    ip("0.0.0.0"),
    port(1234),
```
flags(no-parse)
);
}

s_gsoc2014:
syslog_ng.config:
  - config:
    source:
      - tcp:
        - ip: 0.0.0.0
        - port: 1234
        - flags: no-parse

Filter

filter f_json {
  match("@json:");
}

f_json:
syslog_ng.config:
  - config:
    filter:
      - match: '""@json:"!

Template

template t_demo_filetemplate {
  template("$ISODATE $HOST $MSG ");
  template_escape(no);
}

t_demo_filetemplate:
syslog_ng.config:
  - config:
    template:
      - template:
        - template: '""$ISODATE $HOST $MSG\n"'
        - template_escape:
          - "no"

3.3. States
Rewrite

```plaintext
rewrite r_set_message_to_MESSAGE {
    set(
        "${.json.message}",
        value("$MESSAGE")
    );
};
```

```
\begin{verbatim}

r_set_message_to_MESSAGE:
    syslog_ng.config:
        - config:
            rewrite:
                - set:
                    - '${.json.message}'
                    - value : '${$MESSAGE}'

\end{verbatim}
```

Global options

```plaintext
options {
    time_reap(30);
    mark_freq(10);
    keep_hostname(yes);
};
```

```
\begin{verbatim}

global_options:
    syslog_ng.config:
        - config:
            options:
                - time_reap: 30
                - mark_freq: 10
                - keep_hostname: "yes"

\end{verbatim}
```

Log

```plaintext
log {
    source(s_gsoc2014);
    junction {
        channel {
            filter(f_json);
            parser(p_json);
            rewrite(r_set_json_tag);
            rewrite(r_set_message_to_MESSAGE);
            destination {
                file(
                    "/tmp/json-input.log",
                    template(t_gsoc2014)
                );
            }
            flags(final);
        }
        channel {
            filter(f_not_json);
        }
    }
};
```

3.4 Advanced Topics

3.4.1 SaltStack Walk-through

Note: Welcome to SaltStack! I am excited that you are interested in Salt and starting down the path to better infrastructure management. I developed (and am continuing to develop) Salt with the goal of making the best software available to manage computers of almost any kind. I hope you enjoy working with Salt and that the software can solve your real world needs!

- Thomas S Hatch
Getting Started

What is Salt?

Salt is a different approach to infrastructure management, founded on the idea that high-speed communication with large numbers of systems can open up new capabilities. This approach makes Salt a powerful multitasking system that can solve many specific problems in an infrastructure.

The backbone of Salt is the remote execution engine, which creates a high-speed, secure and bi-directional communication net for groups of systems. On top of this communication system, Salt provides an extremely fast, flexible, and easy-to-use configuration management system called Salt States.

Installing Salt

SaltStack has been made to be very easy to install and get started. The installation documents contain instructions for all supported platforms.

Starting Salt

Salt functions on a master/minion topology. A master server acts as a central control bus for the clients, which are called minions. The minions connect back to the master.

Setting Up the Salt Master

Turning on the Salt Master is easy -- just turn it on! The default configuration is suitable for the vast majority of installations. The Salt Master can be controlled by the local Linux/Unix service manager:

On Systemd based platforms (OpenSuse, Fedora):

```bash
systemctl start salt-master
```

On Upstart based systems (Ubuntu, older Fedora/RHEL):

```bash
service salt-master start
```

On SysV Init systems (Debian, Gentoo etc.):

```
/etc/init.d/salt-master start
```

Alternatively, the Master can be started directly on the command-line:

```
salt-master -d
```

The Salt Master can also be started in the foreground in debug mode, thus greatly increasing the command output:

```
salt-master -l debug
```
The Salt Master needs to bind to two TCP network ports on the system. These ports are 4505 and 4506. For more in depth information on firewalling these ports, the firewall tutorial is available here.

Setting up a Salt Minion

**Note:** The Salt Minion can operate with or without a Salt Master. This walk-through assumes that the minion will be connected to the master, for information on how to run a master-less minion please see the master-less quick-start guide:

*Masterless Minion Quickstart*

The Salt Minion only needs to be aware of one piece of information to run, the network location of the master.

By default the minion will look for the DNS name `salt` for the master, making the easiest approach to set internal DNS to resolve the name `salt` back to the Salt Master IP.

Otherwise, the minion configuration file will need to be edited so that the configuration option `master` points to the DNS name or the IP of the Salt Master:

**Note:** The default location of the configuration files is `/etc/salt`. Most platforms adhere to this convention, but platforms such as FreeBSD and Microsoft Windows place this file in different locations.

```
/etc/salt/minion:
master: saltmaster.example.com
```

Now that the master can be found, start the minion in the same way as the master; with the platform init system or via the command line directly:

As a daemon:

`salt-minion -d`

In the foreground in debug mode:

`salt-minion -l debug`

When the minion is started, it will generate an `id` value, unless it has been generated on a previous run and cached in the configuration directory, which is `/etc/salt` by default. This is the name by which the minion will attempt to authenticate to the master. The following steps are attempted, in order to try to find a value that is not `localhost`:

1. The Python function `socket.getfqdn()` is run
2. `/etc/hostname` is checked (non-Windows only)
3. `/etc/hosts` ( `%WINDIR%\system32\drivers\etc\hosts` on Windows hosts) is checked for host-names that map to anything within `127.0.0.0/8`.

If none of the above are able to produce an id which is not `localhost`, then a sorted list of IP addresses on the minion (excluding any within `127.0.0.0/8`) is inspected. The first publicly-routable IP address is used, if there is one. Otherwise, the first privately-routable IP address is used.

If all else fails, then `localhost` is used as a fallback.

**Note:** Overriding the `id`
The minion id can be manually specified using the `id` parameter in the minion config file. If this configuration value is specified, it will override all other sources for the `id`.

Now that the minion is started, it will generate cryptographic keys and attempt to connect to the master. The next step is to venture back to the master server and accept the new minion’s public key.

**Using salt-key**

Salt authenticates minions using public-key encryption and authentication. For a minion to start accepting commands from the master, the minion keys need to be accepted by the master.

The `salt-key` command is used to manage all of the keys on the master. To list the keys that are on the master:

```
salt-key -L
```

The keys that have been rejected, accepted, and pending acceptance are listed. The easiest way to accept the minion key is to accept all pending keys:

```
salt-key -A
```

**Note:** Keys should be verified! Print the master key fingerprint by running `salt-key -F master` on the Salt master. Copy the `master.pub` fingerprint from the Local Keys section, and then set this value as the `master_finger` in the minion configuration file. Restart the Salt minion.

On the master, run `salt-key -f minion-id` to print the fingerprint of the minion’s public key that was received by the master. On the minion, run `salt-call key.finger --local` to print the fingerprint of the minion key.

On the master:

```
# salt-key -f foo.domain.com
Unaccepted Keys:
```

On the minion:

```
# salt-call key.finger --local
local:
```

If they match, approve the key with `salt-key -a foo.domain.com`.

**Sending the First Commands**

Now that the minion is connected to the master and authenticated, the master can start to command the minion.

Salt commands allow for a vast set of functions to be executed and for specific minions and groups of minions to be targeted for execution.

The `salt` command is comprised of command options, target specification, the function to execute, and arguments to the function.

A simple command to start with looks like this:
salt '*' test.ping

The * is the target, which specifies all minions.

test.ping tells the minion to run the test.ping function.

In the case of test.ping, test refers to a execution module. ping refers to the ping function contained in the aforementioned test module.

Note: Execution modules are the workhorses of Salt. They do the work on the system to perform various tasks, such as manipulating files and restarting services.

The result of running this command will be the master instructing all of the minions to execute test.ping in parallel and return the result.

This is not an actual ICMP ping, but rather a simple function which returns True. Using test.ping is a good way of confirming that a minion is connected.

Note: Each minion registers itself with a unique minion ID. This ID defaults to the minion’s hostname, but can be explicitly defined in the minion config as well by using the id parameter.

Of course, there are hundreds of other modules that can be called just as test.ping can. For example, the following would return disk usage on all targeted minions:
salt '*' disk.usage

Getting to Know the Functions

Salt comes with a vast library of functions available for execution, and Salt functions are self-documenting. To see what functions are available on the minions execute the sys.doc function:

salt '*' sys.doc

This will display a very large list of available functions and documentation on them.

Note: Module documentation is also available on the web.

These functions cover everything from shelling out to package management to manipulating database servers. They comprise a powerful system management API which is the backbone to Salt configuration management and many other aspects of Salt.

Note: Salt comes with many plugin systems. The functions that are available via the salt command are called Execution Modules.

Helpful Functions to Know

The cmd module contains functions to shell out on minions, such as cmd.run and cmd.run_all.
salt '*' cmd.run 'ls -l /etc'

The pkg functions automatically map local system package managers to the same salt functions. This means that pkg.install will install packages via yum on Red Hat based systems, apt on Debian systems, etc.:

salt '*' pkg.install vim

Note: Some custom Linux spins and derivatives of other distributions are not properly detected by Salt. If the above command returns an error message saying that pkg.install is not available, then you may need to override the pkg provider. This process is explained here.

The network.interfaces function will list all interfaces on a minion, along with their IP addresses, netmasks, MAC addresses, etc:

salt '*' network.interfaces

Changing the Output Format

The default output format used for most Salt commands is called the nested outputter, but there are several other outputters that can be used to change the way the output is displayed. For instance, the pprint outputter can be used to display the return data using Python's pprint module:

```
root@saltmaster:~# salt myminion grains.item pythonpath --out=pprint
{'myminion': {'pythonpath': ['/usr/lib64/python2.7/',
'/usr/lib/python2.7/plat-linux2/',
'/usr/lib64/python2.7/lib-tk',
'/usr/lib/python2.7/lib-tk',
'/usr/lib/python2.7/site-packages',
'/usr/lib/python2.7/site-packages/gst-0.10',
'/usr/lib/python2.7/site-packages/gtk-2.0']}}
```

The full list of Salt outputters, as well as example output, can be found here.

salt-call

The examples so far have described running commands from the Master using the salt command, but when troubleshooting it can be more beneficial to login to the minion directly and use salt-call.

Doing so allows you to see the minion log messages specific to the command you are running (which are not part of the return data you see when running the command from the Master using salt), making it unnecessary to tail the minion log. More information on salt-call and how to use it can be found here.

Grains

Salt uses a system called Grains to build up static data about minions. This data includes information about the operating system that is running, CPU architecture and much more. The grains system is used throughout Salt to deliver platform data to many components and to users.

Grains can also be statically set, this makes it easy to assign values to minions for grouping and managing.

A common practice is to assign grains to minions to specify what the role or roles a minion might be. These static grains can be set in the minion configuration file or via the grains.setval function.
Targeting

Salt allows for minions to be targeted based on a wide range of criteria. The default targeting system uses globular expressions to match minions, hence if there are minions named `larry1`, `larry2`, `curly1`, and `curly2`, a glob of `larry*` will match `larry1` and `larry2`, and a glob of `*1` will match `larry1` and `curly1`.

Many other targeting systems can be used other than globs, these systems include:

- **Regular Expressions** Target using PCRE-compliant regular expressions
- **Grains** Target based on grains data: [Targeting with Grains](#)
- **Pillar** Target based on pillar data: [Targeting with Pillar](#)
- **IP** Target based on IP address/subnet/range
- **Compound** Create logic to target based on multiple targets: [Targeting with Compound](#)
- **Nodegroup** Target with nodegroups: [Targeting with Nodegroup](#)

The concepts of targets are used on the command line with Salt, but also function in many other areas as well, including the state system and the systems used for ACLs and user permissions.

Passing in Arguments

Many of the functions available accept arguments which can be passed in on the command line:

```bash
salt '*' pkg.install vim
```

This example passes the argument `vim` to the `pkg.install` function. Since many functions can accept more complex input than just a string, the arguments are parsed through YAML, allowing for more complex data to be sent on the command line:

```bash
salt '*' test.echo 'foo: bar'
```

In this case Salt translates the string `foo: bar` into the dictionary `"{`foo": `bar"}`

**Note:** Any line that contains a newline will not be parsed by YAML.

Salt States

Now that the basics are covered the time has come to evaluate **States**. Salt **States**, or the **State System** is the component of Salt made for configuration management.

The state system is already available with a basic Salt setup, no additional configuration is required. States can be set up immediately.

**Note:** Before diving into the state system, a brief overview of how states are constructed will make many of the concepts clearer. Salt states are based on data modeling and build on a low level data structure that is used to execute each state function. Then more logical layers are built on top of each other.

The high layers of the state system which this tutorial will cover consists of everything that needs to be known to use states, the two high layers covered here are the `sls` layer and the highest layer `highstate`.

Understanding the layers of data management in the State System will help with understanding states, but they never need to be used. Just as understanding how a compiler functions assists when learning a programming language,
understanding what is going on under the hood of a configuration management system will also prove to be a valuable asset.

The First SLS Formula

The state system is built on SLS formulas. These formulas are built out in files on Salt's file server. To make a very basic SLS formula open up a file under `/srv/salt` named `vim.sls`. The following state ensures that vim is installed on a system to which that state has been applied.

```
/srv/salt/vim.sls:

vim:
  pkg.installed
```

Now install vim on the minions by calling the SLS directly:

```
salt '*' state.apply vim
```

This command will invoke the state system and run the `vim` SLS.

Now, to beef up the `vim` SLS formula, a `vimrc` can be added:

```
/srv/salt/vim.sls:

vim:
  pkg.installed: []

/etc/vimrc:
  file.managed:
    - source: salt://vimrc
    - mode: 644
    - user: root
    - group: root
```

Now the desired `vimrc` needs to be copied into the Salt file server to `/srv/salt/vimrc`. In Salt, everything is a file, so no path redirection needs to be accounted for. The `vimrc` file is placed right next to the `vim.sls` file. The same command as above can be executed to all the `vim` SLS formulas and now include managing the file.

**Note:** Salt does not need to be restarted/reloaded or have the master manipulated in any way when changing SLS formulas. They are instantly available.

Adding Some Depth

Obviously maintaining SLS formulas right in a single directory at the root of the file server will not scale out to reasonably sized deployments. This is why more depth is required. Start by making an `nginx` formula a better way, make an `nginx` subdirectory and add an `init.sls` file:

```
/srv/salt/nginx/init.sls:

nginx:
  pkg.installed: []
  service.running:
    - require:
      - pkg: nginx
```
A few concepts are introduced in this SLS formula.

First is the service statement which ensures that the nginx service is running.

Of course, the nginx service can't be started unless the package is installed -- hence the require statement which sets up a dependency between the two.

The require statement makes sure that the required component is executed before and that it results in success.

**Note:** The require option belongs to a family of options called requisites. Requisites are a powerful component of Salt States, for more information on how requisites work and what is available see: Requisites

Also evaluation ordering is available in Salt as well: Ordering States

This new sls formula has a special name -- init.sls. When an SLS formula is named init.sls it inherits the name of the directory path that contains it. This formula can be referenced via the following command:

```
salt '*' state.apply nginx
```

**Note:**  state.apply is just another remote execution function, just like test.ping or disk.usage. It simply takes the name of an SLS file as an argument.

Now that subdirectories can be used, the vim.sls formula can be cleaned up. To make things more flexible, move the vim.sls and vimrc into a new subdirectory called edit and change the vim.sls file to reflect the change:

```
/srv/salt/edit/vim.sls:

vim:
  pkg.installed

/etc/vimrc:
  file.managed:
    - source: salt://edit/vimrc
    - mode: 644
    - user: root
    - group: root
```

Only the source path to the vimrc file has changed. Now the formula is referenced as edit.vim because it resides in the edit subdirectory. Now the edit subdirectory can contain formulas for emacs, nano, joe or any other editor that may need to be deployed.

**Next Reading**

Two walk-throughs are specifically recommended at this point. First, a deeper run through States, followed by an explanation of Pillar.

1. Starting States
2. Pillar Walkthrough

An understanding of Pillar is extremely helpful in using States.
Getting Deeper Into States

Two more in-depth States tutorials exist, which delve much more deeply into States functionality.

1. *How Do I Use Salt States?*, covers much more to get off the ground with States.
2. The *States Tutorial* also provides a fantastic introduction.

These tutorials include much more in-depth information including templating SLS formulas etc.

So Much More!

This concludes the initial Salt walk-through, but there are many more things still to learn! These documents will cover important core aspects of Salt:

- *Pillar*
- *Job Management*

A few more tutorials are also available:

- *Remote Execution Tutorial*
- *Standalone Minion*

This still is only scratching the surface, many components such as the reactor and event systems, extending Salt, modular components and more are not covered here. For an overview of all Salt features and documentation, look at the *Table of Contents*.

3.4.2 running salt as normal user tutorial

**Before continuing** make sure you have a working Salt installation by following the *installation* and the *configuration* instructions.

**Stuck?**

There are many ways to *get help from the Salt community* including our *mailing list* and our IRC channel *#salt*.

**Running Salt functions as non root user**

If you don't want to run salt cloud as root or even install it you can configure it to have a virtual root in your working directory.

The salt system uses the *salt.syspath* module to find the variables

If you run the salt-build, it will generated in:

```
./build/lib.linux-x86_64-2.7/salt/_syspaths.py
```

To generate it, run the command:

```
python setup.py build
```

Copy the generated module into your salt directory

```
cp ./build/lib.linux-x86_64-2.7/salt/_syspaths.py salt/_syspaths.py
```
Edit it to include needed variables and your new paths

```python
# you need to edit this
ROOT_DIR = *your current dir* + '/salt/root'

# you need to edit this
INSTALL_DIR = *location of source code*

CONFIG_DIR = ROOT_DIR + '/etc/salt'
CACHE_DIR = ROOT_DIR + '/var/cache/salt'
SOCK_DIR = ROOT_DIR + '/var/run/salt'
SRV_ROOT_DIR = ROOT_DIR + '/srv'
BASE_FILE_ROOTS_DIR = ROOT_DIR + '/srv/salt'
BASE_PILLAR_ROOTS_DIR = ROOT_DIR + '/srv/pillar'
BASE_MASTER_ROOTS_DIR = ROOT_DIR + '/srv/salt-master'
LOGS_DIR = ROOT_DIR + '/var/log/salt'
PIDFILE_DIR = ROOT_DIR + '/var/run'
CLOUD_DIR = INSTALL_DIR + '/cloud'
BOOTSTRAP = CLOUD_DIR + '/deploy/bootstrap-salt.sh'
```

Create the directory structure

```bash
mkdir -p root/etc/salt root/var/cache/salt root/var/run root/salt root/srv
```

Populate the configuration files:

```bash
cp -r conf/* root/etc/salt/
```

Edit your `root/etc/salt/master` configuration that is used by salt-cloud:

```bash
user: *your user name*
```

Run like this:

```bash
PYTHONPATH=`pwd` scripts/salt-cloud
```

### 3.4.3 MinionFS Backend Walkthrough

#### Propagating Files

New in version 2014.1.0.

Sometimes, one might need to propagate files that are generated on a minion. Salt already has a feature to send files from a minion to the master.

#### Enabling File Propagation

To enable propagation, the `file_recv` option needs to be set to True.

```yaml
file_recv: True
```

These changes require a restart of the master, then new requests for the `salt://minion-id/` protocol will send files that are pushed by `cp.push` from `minion-id` to the master.
This command will store the file, including its full path, under `cachedir /master/minions/minion-id/files`. With the default `cachedir` the example file above would be stored as `/var/cache/salt/master/minions/minion-id/files/path/to/the/file`.

**Note:** This walkthrough assumes basic knowledge of Salt and `cp.push`. To get up to speed, check out the walkthrough.

### MinionFS Backend

Since it is not a good idea to expose the whole `cachedir`, MinionFS should be used to send these files to other minions.

### Simple Configuration

To use the minionfs backend only two configuration changes are required on the master. The `fileserver_backend` option needs to contain a value of `minion` and `file_recv` needs to be set to `true`:

```yaml
fileserver_backend:
  - roots
  - minion
file_recv: True
```

These changes require a restart of the master, then new requests for the `salt://minion-id/` protocol will send files that are pushed by `cp.push` from `minion-id` to the master.

**Note:** All of the files that are pushed to the master are going to be available to all of the minions. If this is not what you want, please remove `minion` from `fileserver_backend` in the master config file.

**Note:** Having directories with the same name as your minions in the root that can be accessed like `salt://minion-id/` might cause confusion.

### Commandline Example

Let’s assume that we are going to generate SSH keys on a minion called `minion-source` and put the public part in `~/.ssh/authorized_keys` of root user of a minion called `minion-destination`.

First, let’s make sure that `/root/.ssh` exists and has the right permissions:

```bash
[root@salt-master file]# salt '*' file.mkdir dir_path=/root/.ssh user=root group=root mode=700
```

```
minion-source:
  None
minion-destination:
  None
```
We create an RSA key pair without a passphrase *:

```bash
[root@salt-master file]# salt 'minion-source' cmd.run 'ssh-keygen -N "" -f /root/.ssh/id_rsa'
minion-source:
  Generating public/private rsa key pair.
  Your identification has been saved in /root/.ssh/id_rsa.
  Your public key has been saved in /root/.ssh/id_rsa.pub.
  The key fingerprint is:
  The key's randomart image is:
  +----[ RSA 2048]------+
  |    |
  |    |
  |  o |
  | o o S o |
  |+ + . B o |
  |o+ E B = |
  |+ . .+ o |
  |o ...ooo |
  +-----------------+
```

and we send the public part to the master to be available to all minions:

```bash
[root@salt-master file]# salt 'minion-source' cp.push /root/.ssh/id_rsa.pub
minion-source:
  True
```

now it can be seen by everyone:

```bash
[root@salt-master file]# salt 'minion-destination' cp.list_master_dirs
minion-destination:
- .
- etc
- minion-source/root
- minion-source/root/.ssh
```

Let's copy that as the only authorized key to `minion-destination`:

```bash
[root@salt-master file]# salt 'minion-destination' cp.get_file salt://minion-source/root/.ssh/id_rsa.pub /root/.ssh/authorized_keys
minion-destination:
  /root/.ssh/authorized_keys
```

Or we can use a more elegant and salty way to add an SSH key:

```bash
[root@salt-master file]# salt 'minion-destination' ssh.set_auth_key_from_file user=root source=salt://minion-source/root/.ssh/id_rsa.pub
minion-destination:
  new
```

### 3.4.4 Automatic Updates / Frozen Deployments

New in version 0.10.3.d.

* Yes, that was the actual key on my server, but the server is already destroyed.
Salt has support for the `Esky` application freezing and update tool. This tool allows one to build a complete zipfile out of the salt scripts and all their dependencies - including shared objects / DLLs.

**Getting Started**

To build frozen applications, suitable build environment will be needed for each platform. You should probably set up a virtualenv in order to limit the scope of Q/A.

This process does work on Windows. Directions are available at [https://github.com/saltstack/salt-windows-install](https://github.com/saltstack/salt-windows-install) for details on installing Salt in Windows. Only the 32-bit Python and dependencies have been tested, but they have been tested on 64-bit Windows.

Install `bbfreeze`, and then `esky` from PyPI in order to enable the `bdist_esky` command in `setup.py`. Salt itself must also be installed, in addition to its dependencies.

**Building and Freezing**

Once you have your tools installed and the environment configured, use `setup.py` to prepare the distribution files.

```
python setup.py sdist
python setup.py bdist
```

Once the distribution files are in place, Esky can be used traverse the module tree and pack all the scripts up into a redistributable.

```
python setup.py bdist_esky
```

There will be an appropriately versioned `salt-VERSION.zip` in `dist/` if everything went smoothly.

**Windows**

`C:\Python27\lib\site-packages\zmq` will need to be added to the PATH variable. This helps `bbfreeze` find the `zmq` DLL so it can pack it up.

**Using the Frozen Build**

Unpack the zip file in the desired install location. Scripts like `salt-minion` and `salt-call` will be in the root of the zip file. The associated libraries and bootstrapping will be in the directories at the same level. (Check the `Esky` documentation for more information).

To support updating your minions in the wild, put the builds on a web server that the minions can reach. `salt.modules.saltutil.update()` will trigger an update and (optionally) a restart of the minion service under the new version.

**Troubleshooting**

**A Windows minion isn't responding**

The process dispatch on Windows is slower than it is on nix. It may be necessary to add `-t 15` to salt commands to give minions plenty of time to return.
Windows and the Visual Studio Redist

The Visual C++ 2008 32-bit redistributable will need to be installed on all Windows minions. Esky has an option to pack the library into the zipfile, but OpenSSL does not seem to acknowledge the new location. If a no OPENSSL_Applink error appears on the console when trying to start a frozen minion, the redistributable is not installed.

Mixed Linux environments and Yum

The Yum Python module doesn't appear to be available on any of the standard Python package mirrors. If RHEL/CentOS systems need to be supported, the frozen build should created on that platform to support all the Linux nodes. Remember to build the virtualenv with --system-site-packages so that the yum module is included.

Automatic (Python) module discovery

Automatic (Python) module discovery does not work with the late-loaded scheme that Salt uses for (Salt) modules. Any misbehaving modules will need to be explicitly added to the freezer_includes in Salt's setup.py. Always check the zipped application to make sure that the necessary modules were included.

3.4.5 Multi Master Tutorial

As of Salt 0.16.0, the ability to connect minions to multiple masters has been made available. The multi-master system allows for redundancy of Salt masters and facilitates multiple points of communication out to minions. When using a multi-master setup, all masters are running hot, and any active master can be used to send commands out to the minions.

Note: If you need failover capabilities with multiple masters, there is also a MultiMaster-PKI setup available, that uses a different topology MultiMaster-PKI with Failover Tutorial

In 0.16.0, the masters do not share any information, keys need to be accepted on both masters, and shared files need to be shared manually or use tools like the git filesystem backend to ensure that the file_roots are kept consistent.

Summary of Steps

1. Create a redundant master server
2. Copy primary master key to redundant master
3. Start redundant master
4. Configure minions to connect to redundant master
5. Restart minions
6. Accept keys on redundant master
Prepping a Redundant Master

The first task is to prepare the redundant master. If the redundant master is already running, stop it. There is only one requirement when preparing a redundant master, which is that masters share the same private key. When the first master was created, the master's identifying key pair was generated and placed in the master's pki_dir. The default location of the master's key pair is /etc/salt/pki/master/. Take the private key, master.pem, and copy it to the same location on the redundant master. Do the same for the master's public key, master.pub. Assuming that no minions have yet been connected to the new redundant master, it is safe to delete any existing key in this location and replace it.

Note: There is no logical limit to the number of redundant masters that can be used.

Once the new key is in place, the redundant master can be safely started.

Configure Minions

Since minions need to be master-aware, the new master needs to be added to the minion configurations. Simply update the minion configurations to list all connected masters:

```yaml
master:
  - saltmaster1.example.com
  - saltmaster2.example.com
```

Now the minion can be safely restarted.

Note: If the ipc_mode for the minion is set to TCP (default in Windows), then each minion in the multi-minion setup (one per master) needs its own tcp_pub_port and tcp_pull_port.

If these settings are left as the default 4510/4511, each minion object will receive a port 2 higher than the previous. Thus the first minion will get 4510/4511, the second will get 4512/4513, and so on. If these port decisions are unacceptable, you must configure tcp_pub_port and tcp_pull_port with lists of ports for each master. The length of these lists should match the number of masters, and there should not be overlap in the lists.

Now the minions will check into the original master and also check into the new redundant master. Both masters are first-class and have rights to the minions.

Note: Minions can automatically detect failed masters and attempt to reconnect to reconnect to them quickly. To enable this functionality, set master_alive_interval in the minion config and specify a number of seconds to poll the masters for connection status.

If this option is not set, minions will still reconnect to failed masters but the first command sent after a master comes back up may be lost while the minion authenticates.

Sharing Files Between Masters

Salt does not automatically share files between multiple masters. A number of files should be shared or sharing of these files should be strongly considered.
Minion Keys

Minion keys can be accepted the normal way using `salt-key` on both masters. Keys accepted, deleted, or rejected on one master will NOT be automatically managed on redundant masters; this needs to be taken care of by running `salt-key` on both masters or sharing the `/etc/salt/pki/master/{minions,minions_pre,minions_rejected}` directories between masters.

**Note:** While sharing the `/etc/salt/pki/master` directory will work, it is strongly discouraged, since allowing access to the `master.pem` key outside of Salt creates a SERIOUS security risk.

File_Roots

The `file_roots` contents should be kept consistent between masters. Otherwise state runs will not always be consistent on minions since instructions managed by one master will not agree with other masters.

The recommended way to sync these is to use a fileserver backend like gitfs or to keep these files on shared storage.

**Important:** If using gitfs/git_pillar with the cachedir shared between masters using GlusterFS, nfs, or another network filesystem, and the masters are running Salt 2015.5.9 or later, it is strongly recommended not to turn off `gitfs_global_lock/git_pillar_global_lock` as doing so will cause lock files to be removed if they were created by a different master.

Pillar_Roots

Pillar roots should be given the same considerations as `file_roots`.

Master Configurations

While reasons may exist to maintain separate master configurations, it is wise to remember that each master maintains independent control over minions. Therefore, access controls should be in sync between masters unless a valid reason otherwise exists to keep them inconsistent.

These access control options include but are not limited to:

- `external_auth`
- `client_acl`
- `peer`
- `peer_run`

3.4.6 Multi-Master-PKI Tutorial With Failover

This tutorial will explain, how to run a salt-environment where a single minion can have multiple masters and fail-over between them if its current master fails.

The individual steps are:

- setup the master(s) to sign its auth-replies
• setup minion(s) to verify master-public-keys
• enable multiple masters on minion(s)
• enable master-check on minion(s)

Please note, that it is advised to have good knowledge of the salt- authentication and communication-process to understand this tutorial. All of the settings described here, go on top of the default authentication/communication process.

Motivation

The default behaviour of a salt-minion is to connect to a master and accept the masters public key. With each publication, the master sends his public-key for the minion to check and if this public-key ever changes, the minion complains and exits. Practically this means, that there can only be a single master at any given time.

Would it not be much nicer, if the minion could have any number of masters (1:n) and jump to the next master if its current master died because of a network or hardware failure?

Note: There is also a MultiMaster-Tutorial with a different approach and topology than this one, that might also suite your needs or might even be better suited Multi-Master Tutorial

It is also desirable, to add some sort of authenticity-check to the very first public key a minion receives from a master. Currently a minions takes the first masters public key for granted.

The Goal

Setup the master to sign the public key it sends to the minions and enable the minions to verify this signature for authenticity.

Prepping the master to sign its public key

For signing to work, both master and minion must have the signing and/or verification settings enabled. If the master signs the public key but the minion does not verify it, the minion will complain and exit. The same happens, when the master does not sign but the minion tries to verify.

The easiest way to have the master sign its public key is to set

```
master_sign_pubkey: True
```

After restarting the salt-master service, the master will automatically generate a new key-pair

```
master_sign.pem
master_sign.pub
```

A custom name can be set for the signing key-pair by setting

```
master_sign_key_name: <name_without_suffix>
```

The master will then generate that key-pair upon restart and use it for creating the public keys signature attached to the auth-reply.

The computation is done for every auth-request of a minion. If many minions auth very often, it is advised to use conf_master:master_pubkey_signature and conf_master:master_use_pubkey_signature settings described below.
If multiple masters are in use and should sign their auth-replies, the signing key-pair master_sign.* has to be copied to each master. Otherwise a minion will fail to verify the masters public when connecting to a different master than it did initially. That is because the public keys signature was created with a different signing key-pair.

**Prepping the minion to verify received public keys**

The minion must have the public key (and only that one!) available to be able to verify a signature it receives. That public key (defaults to master_sign.pub) must be copied from the master to the minions pki-directory.

```
/etc/salt/pki/minion/master_sign.pub
```

DO NOT COPY THE master_sign.pem FILE. IT MUST STAY ON THE MASTER AND ONLY THERE!

When that is done, enable the signature checking in the minions configuration

```
verify_master_pubkey_sign: True
```

and restart the minion. For the first try, the minion should be run in manual debug mode.

```
$ salt-minion -l debug
```

Upon connecting to the master, the following lines should appear on the output:

```
[DEBUG] Attempting to authenticate with the Salt Master at 172.16.0.10
[DEBUG] Loaded minion key: /etc/salt/pki/minion/minion.pem
[DEBUG] salt.crypt.verify_signature: Loading public key
[DEBUG] salt.crypt.verify_signature: Verifying signature
[DEBUG] Successfully verified signature of master public key with verification public key master_sign.pub
[INFO] Received signed and verified master pubkey from master 172.16.0.10
[DEBUG] Decrypting the current master AES key
```

If the signature verification fails, something went wrong and it will look like this

```
[DEBUG] Attempting to authenticate with the Salt Master at 172.16.0.10
[DEBUG] Loaded minion key: /etc/salt/pki/minion/minion.pem
[DEBUG] salt.crypt.verify_signature: Loading public key
[DEBUG] salt.crypt.verify_signature: Verifying signature
[DEBUG] Failed to verify signature of public key
[CRITICAL] The Salt Master server's public key did not authenticate!
```

In a case like this, it should be checked, that the verification pubkey (master_sign.pub) on the minion is the same as the one on the master.

Once the verification is successful, the minion can be started in daemon mode again.

For the paranoid among us, its also possible to verify the publication whenever it is received from the master. That is, for every single auth-attempt which can be quite frequent. For example just the start of the minion will force the signature to be checked 6 times for various things like auth, mine, highstate, etc.

If that is desired, enable the setting

```
always_verify_signature: True
```
Multiple Masters For A Minion

Configuring multiple masters on a minion is done by specifying two settings:

- a list of masters addresses
- what type of master is defined

```
master:
- 172.16.0.10  
- 172.16.0.11  
- 172.16.0.12
```

```
master_type: failover
```

This tells the minion that all the master above are available for it to connect to. When started with this configuration, it will try the master in the order they are defined. To randomize that order, set

```
master_shuffle: True
```

The master-list will then be shuffled before the first connection attempt.

The first master that accepts the minion, is used by the minion. If the master does not yet know the minion, that counts as accepted and the minion stays on that master.

For the minion to be able to detect if its still connected to its current master enable the check for it

```
master_alive_interval: <seconds>
```

If the loss of the connection is detected, the minion will temporarily remove the failed master from the list and try one of the other masters defined (again shuffled if that is enabled).

Testing the setup

At least two running masters are needed to test the failover setup.

Both masters should be running and the minion should be running on the command line in debug mode

```
$ salt-minion -l debug
```

The minion will connect to the first master from its master list

```
[DEBUG] Attempting to authenticate with the Salt Master at 172.16.0.10
[DEBUG] Loaded minion key: /etc/salt/pki/minion/minion.pem
[DEBUG] salt.crypt.verify_signature: Loading public key
[DEBUG] salt.crypt.verify_signature: Verifying signature
[DEBUG] Successfully verified signature of master public key with verification\[ PUBLIC KEY master_sign.pub\]
[INFO] Received signed and verified master pubkey from master 172.16.0.10
[DEBUG] Decrypting the current master AES key
```

A test.ping on the master the minion is currently connected to should be run to test connectivity.

If successful, that master should be turned off. A firewall-rule denying the minions packets will also do the trick.

Depending on the configured `conf_minion:master_alive_interval`, the minion will notice the loss of the connection and log it to its logfile.
INFO ] Connection to master 172.16.0.10 lost
INFO ] Trying to tune in to next master from master-list

The minion will then remove the current master from the list and try connecting to the next master

INFO ] Removing possibly failed master 172.16.0.10 from list of masters
WARNING ] Master ip address changed from 172.16.0.10 to 172.16.0.11
DEBUG ] Attempting to authenticate with the Salt Master at 172.16.0.11

If everything is configured correctly, the new masters public key will be verified successfully

DEBUG ] Loaded minion key: /etc/salt/pki/minion/minion.pem
DEBUG ] salt.crypt.verify_signature: Loading public key
DEBUG ] salt.crypt.verify_signature: Verifying signature
DEBUG ] Successfully verified signature of master public key with verification
-public key master_sign.pub

the authentication with the new master is successful

INFO ] Received signed and verified master pubkey from master 172.16.0.11
DEBUG ] Decrypting the current master AES key
DEBUG ] Loaded minion key: /etc/salt/pki/minion/minion.pem
INFO ] Authentication with master successful!

and the minion can be pinged again from its new master.

Performance Tuning

With the setup described above, the master computes a signature for every auth-request of a minion. With many minions and many auth-requests, that can chew up quite a bit of CPU-Power.

To avoid that, the master can use a pre-created signature of its public-key. The signature is saved as a base64 encoded string which the master reads once when starting and attaches only that string to auth-replies.

Enabling this also gives paranoid users the possibility, to have the signing key-pair on a different system than the actual salt-master and create the public keys signature there. Probably on a system with more restrictive firewall rules, without internet access, less users, etc.

That signature can be created with

```
$ salt-key --gen-signature
```

This will create a default signature file in the master pki-directory

```
/etc/salt/pki/master/master_pubkey_signature
```

It is a simple text-file with the binary-signature converted to base64.

If no signing-pair is present yet, this will auto-create the signing pair and the signature file in one call

```
$ salt-key --gen-signature --auto-create
```

Telling the master to use the pre-created signature is done with

```
master_use_pubkey_signature: True
```

3.4. Advanced Topics
That requires the file `master_pubkey_signature` to be present in the masters pki-directory with the correct signature.

If the signature file is named differently, its name can be set with

```
master_pubkey_signature: <filename>
```

With many masters and many public-keys (default and signing), it is advised to use the salt-masters hostname for the signature-files name. Signatures can be easily confused because they do not provide any information about the key the signature was created from.

Verifying that everything works is done the same way as above.

**How the signing and verification works**

The default key-pair of the salt-master is

```
/etc/salt/pki/master/master.pem
/etc/salt/pki/master/master.pub
```

To be able to create a signature of a message (in this case a public-key), another key-pair has to be added to the setup. Its default name is:

```
master_sign.pem
master_sign.pub
```

The combination of the master.* and master_sign.* key-pairs give the possibility of generating signatures. The signature of a given message is unique and can be verified, if the public-key of the signing-key-pair is available to the recipient (the minion).

The signature of the masters public-key in master.pub is computed with

```
M2Crypto.EVP.sign_update()
```

This results in a binary signature which is converted to base64 and attached to the auth-reply send to the minion.

With the signing-pairs public-key available to the minion, the attached signature can be verified with

```
M2Crypto.EVP.verify_update().
```

When running multiple masters, either the signing key-pair has to be present on all of them, or the master_pubkey_signature has to be pre-computed for each master individually (because they all have different public-keys).

**DO NOT PUT THE SAME master.pub ON ALL MASTERS FOR EASE OF USE.**

### 3.4.7 Preseed Minion with Accepted Key

In some situations, it is not convenient to wait for a minion to start before accepting its key on the master. For instance, you may want the minion to bootstrap itself as soon as it comes online. You may also want to to let your developers provision new development machines on the fly.

**See also:**

Many ways to preseed minion keys
Salt has other ways to generate and pre-accept minion keys in addition to the manual steps outlined below. salt-cloud performs these same steps automatically when new cloud VMs are created (unless instructed not to). salt-api exposes an HTTP call to Salt's REST API to generate and download the new minion keys as a tarball.

There is a general four step process to do this:

1. Generate the keys on the master:

   ```
   root@saltmaster# salt-key --gen-keys=[key_name]
   ```

   Pick a name for the key, such as the minion's id.

2. Add the public key to the accepted minion folder:

   ```
   root@saltmaster# cp key_name.pub /etc/salt/pki/master/minions/[minion_id]
   ```

   It is necessary that the public key file has the same name as your minion id. This is how Salt matches minions with their keys. Also note that the pki folder could be in a different location, depending on your OS or if specified in the master config file.

3. Distribute the minion keys.

   There is no single method to get the keypair to your minion. The difficulty is finding a distribution method which is secure. For Amazon EC2 only, an AWS best practice is to use IAM Roles to pass credentials. (See blog post, [http://blogs.aws.amazon.com/security/post/Tx6I0S2MLVZWEA/Using-IAM-roles-to-distribute-non-AWS-credentials-to-your-EC2-instances](http://blogs.aws.amazon.com/security/post/Tx6I0S2MLVZWEA/Using-IAM-roles-to-distribute-non-AWS-credentials-to-your-EC2-instances))

   **Security Warning**

   Since the minion key is already accepted on the master, distributing the private key poses a potential security risk. A malicious party will have access to your entire state tree and other sensitive data if they gain access to a preseeded minion key.

4. Preseed the Minion with the keys

   You will want to place the minion keys before starting the salt-minion daemon:

   ```
   /etc/salt/pki/minion/minion.pem
   /etc/salt/pki/minion/minion.pub
   ```

   Once in place, you should be able to start salt-minion and run `salt-call state.apply` or any other salt commands that require master authentication.

### 3.4.8 Salt Bootstrap

The Salt Bootstrap script allows for a user to install the Salt Minion or Master on a variety of system distributions and versions. This shell script known as `bootstrap-salt.sh` runs through a series of checks to determine the operating system type and version. It then installs the Salt binaries using the appropriate methods. The Salt Bootstrap script installs the minimum number of packages required to run Salt. This means that in the event you run the bootstrap to install via package, Git will not be installed. Installing the minimum number of packages helps ensure the script stays as lightweight as possible, assuming the user will install any other required packages after the Salt binaries are present on the system. The script source is available on GitHub: [https://github.com/saltstack/salt-bootstrap](https://github.com/saltstack/salt-bootstrap)
Supported Operating Systems

Note: In the event you do not see your distribution or version available please review the develop branch on GitHub as it main contain updates that are not present in the stable release: https://github.com/saltstack/salt-bootstrap/tree/develop

Debian and derivatives

- Debian GNU/Linux 7/8
- Linux Mint Debian Edition 1 (based on Debian 8)
- Kali Linux 1.0 (based on Debian 7)

Red Hat family

- Amazon Linux 2012.09/2013.03/2013.09/2014.03/2014.09
- CentOS 5/6/7
- Fedora 17/18/20/21/22
- Oracle Linux 5/6/7
- Red Hat Enterprise Linux 5/6/7
- Scientific Linux 5/6/7

SUSE family

- openSUSE 12/13
- openSUSE Leap 42
- openSUSE Tumbleweed 2015
- SUSE Linux Enterprise Server 11 SP1/11 SP2/11 SP3/12

Ubuntu and derivatives

- Elementary OS 0.2 (based on Ubuntu 12.04)
- Linaro 12.04
- Linux Mint 13/14/16/17
- Trisquel GNU/Linux 6 (based on Ubuntu 12.04)
- Ubuntu 10.x/11.x/12.x/13.x/14.x/15.04

Other Linux distro

- Arch Linux
- Gentoo
UNIX systems

BSD:
- OpenBSD (pip installation)
- FreeBSD 9/10/11

SunOS:
- SmartOS

Example Usage

If you’re looking for the one-liner to install Salt, please scroll to the bottom and use the instructions for Installing via an Insecure One-Liner

Note: In every two-step example, you would be well-served to examine the downloaded file and examine it to ensure that it does what you expect.

The Salt Bootstrap script has a wide variety of options that can be passed as well as several ways of obtaining the bootstrap script itself.

Note: These examples below show how to bootstrap Salt directly from GitHub or other Git repository. Run the script without any parameters to get latest stable Salt packages for your system from SaltStack corporate repository. See first example in the Install using wget section.

Install using curl

Using curl to install latest development version from GitHub:

```
curl -o bootstrap_salt.sh -L https://bootstrap.saltstack.com
sudo sh bootstrap_salt.sh git develop
```

If you want to install a specific release version (based on the Git tags):

```
curl -o bootstrap_salt.sh -L https://bootstrap.saltstack.com
sudo sh bootstrap_salt.sh git v2015.8.8
```

To install a specific branch from a Git fork:

```
curl -o bootstrap_salt.sh -L https://bootstrap.saltstack.com
sudo sh bootstrap_salt.sh -g https://github.com/myuser/salt.git git mybranch
```

If all you want is to install a salt-master using latest Git:

```
curl -o bootstrap_salt.sh -L https://bootstrap.saltstack.com
sudo sh bootstrap_salt.sh -M -N git develop
```

If your host has Internet access only via HTTP proxy:
PROXY='http://user:password@myproxy.example.com:3128'
curl -o bootstrap_salt.sh -L -x "$PROXY" https://bootstrap.saltstack.com
sudo sh bootstrap_salt.sh -G -H "$PROXY" git

Install using wget

Using wget to install your distribution’s stable packages:

wget -O bootstrap_salt.sh https://bootstrap.saltstack.com
sudo sh bootstrap_salt.sh

Downloading the script from develop branch:

wget -O bootstrap_salt.sh https://bootstrap.saltstack.com/develop
sudo sh bootstrap_salt.sh

Installing a specific version from git using wget:

wget -O bootstrap_salt.sh https://bootstrap.saltstack.com
sudo sh bootstrap_salt.sh -P git v2015.8.8

Note: On the above example we added -P which will allow PIP packages to be installed if required but it’s not a necessary flag for Git based bootstraps.

Install using Python

If you already have Python installed, python 2.6, then it’s as easy as:

python -m urllib "https://bootstrap.saltstack.com" > bootstrap_salt.sh
sudo sh bootstrap_salt.sh git develop

All Python versions should support the following in-line code:

python -c "import urllib; print urllib.urlopen("https://bootstrap.saltstack.com").read()" > bootstrap_salt.sh
sudo sh bootstrap_salt.sh git develop

Install using fetch

On a FreeBSD base system you usually don’t have either of the above binaries available. You do have fetch available though:

fetch -o bootstrap_salt.sh https://bootstrap.saltstack.com
sudo sh bootstrap_salt.sh

If you have any SSL issues install ca_root_nssp:

pkg install ca_root_nssp

And either copy the certificates to the place where fetch can find them:
 cp /usr/local/share/certs/ca-root-nss.crt /etc/ssl/cert.pem

Or link them to the right place:

 ln -s /usr/local/share/certs/ca-root-nss.crt /etc/ssl/cert.pem

**Installing via an Insecure One-Liner**

The following examples illustrate how to install Salt via a one-liner.

**Note:** Warning! These methods do not involve a verification step and assume that the delivered file is trustworthy.

Any of the example above which use two-lines can be made to run in a single-line configuration with minor modifications.

For example, using `curl` to install your distribution's stable packages:

```bash
curl -L https://bootstrap.saltstack.com | sudo sh
```

Using `wget` to install your distribution's stable packages:

```bash
wget -O - https://bootstrap.saltstack.com | sudo sh
```

Installing the latest develop branch of Salt:

```bash
curl -L https://bootstrap.saltstack.com | sudo sh -s -- git develop
```

**Command Line Options**

Here's a summary of the command line options:

```bash
$ sh bootstrap-salt.sh -h

Usage : bootstrap-salt.sh [options] <install-type> <install-type-args>

Installation types:
- stable (default)
- stable [version] (ubuntu specific)
- daily (ubuntu specific)
- testing (redhat specific)
- git

Examples:
- bootstrap-salt.sh
- bootstrap-salt.sh stable
- bootstrap-salt.sh stable 2014.7
- bootstrap-salt.sh daily
- bootstrap-salt.sh testing
- bootstrap-salt.sh git
- bootstrap-salt.sh git develop
- bootstrap-salt.sh git v0.17.0
- bootstrap-salt.sh git 8c3fadf15ec183e5ce8c63739850d543617e4357

Options:
```
-h Display this message
-v Display script version
-n No colours.
-D Show debug output.
-c Temporary configuration directory
-g Salt repository URL. (default: git://github.com/saltstack/salt.git)
-G Instead of cloning from git://github.com/saltstack/salt.git, clone from https://github.com/saltstack/salt.git (Usually necessary on systems which have the regular
git protocol port blocked, where https usually is not)
-k Temporary directory holding the minion keys which will pre-seed the master.
-s Sleep time used when waiting for daemons to start, restart and when checking for the services running. Default: 3
-M Also install salt-master
-S Also install salt-syndic
-N Do not install salt-minion
-X Do not start daemons after installation
-C Only run the configuration function. This option automatically bypasses any installation.
-P Allow pip based installations. On some distributions the required salt packages or its dependencies are not available as a package for that distribution. Using this flag allows the script to use pip as a last resort method. NOTE: This only works for functions which actually implement pip based installations.
-F Allow copied files to overwrite existing(config, init.d, etc)
-U If set, fully upgrade the system prior to bootstrapping salt
-K If set, keep the temporary files in the temporary directories specified with -c and -k.
-I If set, allow insecure connections while downloading any files. For example, pass '--no-check-certificate' to 'wget' or '--insecure' to 'curl'
-A Pass the salt-master DNS name or IP. This will be stored under ${BS_SALT_ETC_DIR}/minion.d/99-master-address.conf
-i Pass the salt-minion id. This will be stored under ${BS_SALT_ETC_DIR}/minion_id
-L Install the Apache Libcloud package if possible(required for salt-cloud)
-p Extra-package to install while installing salt dependencies. One package per -p flag. You're responsible for providing the proper package name.
-d Disable check_service functions. Setting this flag disables the 'install_<distro>_check_services' checks. You can also do this by touching /tmp/disable_salt_checks on the target host. Defaults ${BS_FALSE}
-H Use the specified http proxy for the installation
-Z Enable external software source for newer ZeroMQ(Only available for RHEL/CentOS/Fedora/Ubuntu based distributions)
-b Assume that dependencies are already installed and software sources are set up. If git is selected, git tree is still checked out as dependency step.

3.4.9 Git Fileserver Backend Walkthrough

Note: This walkthrough assumes basic knowledge of Salt. To get up to speed, check out the Salt Walkthrough.

The gitfs backend allows Salt to serve files from git repositories. It can be enabled by adding git to the file-server_backend list, and configuring one or more repositories in gitfs_remotes.

Branches and tags become Salt fileserver environments.
Installing Dependencies

Beginning with version 2014.7.0, both pygit2 and Dulwich are supported as alternatives to GitPython. The desired provider can be configured using the `gitfs_provider` parameter in the master config file.

If `gitfs_provider` is not configured, then Salt will prefer pygit2 if a suitable version is available, followed by GitPython and Dulwich.

Note: It is recommended to always run the most recent version of any the below dependencies. Certain features of gitfs may not be available without the most recent version of the chosen library.

pygit2

The minimum supported version of pygit2 is 0.20.3. Availability for this version of pygit2 is still limited, though the SaltStack team is working to get compatible versions available for as many platforms as possible.

For the Fedora/EPEL versions which have a new enough version packaged, the following command would be used to install pygit2:

```
# yum install python-pygit2
```

Provided a valid version is packaged for Debian/Ubuntu (which is not currently the case), the package name would be the same, and the following command would be used to install it:

```
# apt-get install python-pygit2
```

If pygit2 is not packaged for the platform on which the Master is running, the pygit2 website has installation instructions here. Keep in mind however that following these instructions will install libgit2 and pygit2 without system packages. Additionally, keep in mind that SSH authentication in pygit2 requires libssh2 (not libssh) development libraries to be present before libgit2 is built. On some Debian-based distros `pkg-config` is also required to link libgit2 with libssh2.

Additionally, version 0.21.0 of pygit2 introduced a dependency on python-cffi, which in turn depends on newer releases of libffi. Upgrading libffi is not advisable as several other applications depend on it, so on older LTS linux releases pygit2 0.20.3 and libgit2 0.20.0 is the recommended combination. While these are not packaged in the official repositories for Debian and Ubuntu, SaltStack is actively working on adding packages for these to our repositories. The progress of this effort can be tracked here.

Warning: pygit2 is actively developed and frequently makes non-backwards-compatible API changes, even in minor releases. It is not uncommon for pygit2 upgrades to result in errors in Salt. Please take care when upgrading pygit2, and pay close attention to the changelog, keeping an eye out for API changes. Errors can be reported on the SaltStack issue tracker.
GitPython

GitPython 0.3.0 or newer is required to use GitPython for gitfs. For RHEL-based Linux distros, a compatible version is available in EPEL, and can be easily installed on the master using yum:

```
# yum install GitPython
```

Ubuntu 14.04 LTS and Debian Wheezy (7.x) also have a compatible version packaged:

```
# apt-get install python-git
```

If your master is running an older version (such as Ubuntu 12.04 LTS or Debian Squeeze), then you will need to install GitPython using either pip or easy_install (it is recommended to use pip). Version 0.3.2.RC1 is now marked as the stable release in PyPI, so it should be a simple matter of running `pip install GitPython` (or `easy_install GitPython`) as root.

**Warning:** Keep in mind that if GitPython has been previously installed on the master using pip (even if it was subsequently uninstalled), then it may still exist in the build cache (typically /tmp/pip-build-root/GitPython) if the cache is not cleared after installation. The package in the build cache will override any requirement specifiers, so if you try upgrading to version 0.3.2.RC1 by running `pip install 'GitPython==0.3.2.RC1'` then it will ignore this and simply install the version from the cache directory. Therefore, it may be necessary to delete the GitPython directory from the build cache in order to ensure that the specified version is installed.

**Warning:** GitPython 2.0.9 and newer is not compatible with Python 2.6. If installing GitPython using pip on a machine running Python 2.6, make sure that a version earlier than 2.0.9 is installed. This can be done on the CLI by running `pip install 'GitPython<2.0.9'`, or in a `pip.installed` state using the following SLS:

```
GitPython:
  pip.installed:
    - name: 'GitPython < 2.0.9'
```

Dulwich

Dulwich 0.9.4 or newer is required to use Dulwich as backend for gitfs.

Dulwich is available in EPEL, and can be easily installed on the master using yum:

```
# yum install python-dulwich
```

For APT-based distros such as Ubuntu and Debian:

```
# apt-get install python-dulwich
```

**Important:** If switching to Dulwich from GitPython/pygit2, or switching from GitPython/pygit2 to Dulwich, it is necessary to clear the gitfs cache to avoid unpredictable behavior. This is probably a good idea whenever switching to a new `gitfs_provider`, but it is less important when switching between GitPython and pygit2.

Beginning in version 2015.5.0, the gitfs cache can be easily cleared using the `fileservers.clear_cache` runner.
salt-run fileserver.clear_cache backend=git

If the Master is running an earlier version, then the cache can be cleared by removing the gitfs and file_lists/gitfs directories (both paths relative to the master cache directory, usually /var/cache/salt/master).

rm -rf /var/cache/salt/master{,/file_lists}/gitfs

Simple Configuration

To use the gitfs backend, only two configuration changes are required on the master:

1. Include git in the fileserver_backend list in the master config file:

   ```
   fileserv backend:
   - git
   ```

2. Specify one or more git://, https://, file://, or ssh:// URLs in gitfs_remotes to configure which repositories to cache and search for requested files:

   ```
   gitfs_remotes:
   - https://github.com/saltstack-formulas/salt-formula.git
   ```

   SSH remotes can also be configured using scp-like syntax:

   ```
   gitfs_remotes:
   - git@github.com:user/repo.git
   - ssh://user@domain.tld/path/to/repo.git
   ```

   Information on how to authenticate to SSH remotes can be found here.

   **Note:** Dulwich does not recognize ssh:// URLs, git+ssh:// must be used instead. Salt version 2015.5.0 and later will automatically add the git+ to the beginning of these URLs before fetching, but earlier Salt versions will fail to fetch unless the URL is specified using git+ssh://.

3. Restart the master to load the new configuration.

**Note:** In a master/minion setup, files from a gitfs remote are cached once by the master, so minions do not need direct access to the git repository.

Multiple Remotes

The gitfs_remotes option accepts an ordered list of git remotes to cache and search, in listed order, for requested files.

A simple scenario illustrates this cascading lookup behavior:

If the gitfs_remotes option specifies three remotes:
And each repository contains some files:

<table>
<thead>
<tr>
<th>Repository</th>
<th>Files</th>
</tr>
</thead>
<tbody>
<tr>
<td>first.git</td>
<td>top.sls, edit/vim.sls, edit/vimrc, nginx/init.sls</td>
</tr>
<tr>
<td>second.git</td>
<td>edit/dev_vimrc, haproxy/init.sls</td>
</tr>
<tr>
<td>third</td>
<td>haproxy/haproxy.conf, edit/dev_vimrc</td>
</tr>
</tbody>
</table>

Salt will attempt to lookup the requested file from each gitfs remote repository in the order in which they are defined in the configuration. The `git://github.com/example/first.git` remote will be searched first. If the requested file is found, then it is served and no further searching is executed. For example:

- A request for the file `salt://haproxy/init.sls` will be served from the `https://github.com/example/second.git` git repo.
- A request for the file `salt://haproxy/haproxy.conf` will be served from the file:///root/third repo.

**Note:** This example is purposefully contrived to illustrate the behavior of the gitfs backend. This example should not be read as a recommended way to lay out files and git repos.

The `file://` prefix denotes a git repository in a local directory. However, it will still use the given `file://` URL as a remote, rather than copying the git repo to the salt cache. This means that any refs you want accessible must exist as local refs in the specified repo.

**Warning:** Salt versions prior to 2014.1.0 are not tolerant of changing the order of remotes or modifying the URI of existing remotes. In those versions, when modifying remotes it is a good idea to remove the gitfs cache directory (`/var/cache/salt/master/gitfs`) before restarting the salt-master service.

**Per-remote Configuration Parameters**

New in version 2014.7.0.

The following master config parameters are global (that is, they apply to all configured gitfs remotes):

- `gitfs_base`
- `gitfs_root`
- `gitfs_mountpoint` (new in 2014.7.0)
- `gitfs_user` *(pygit2 only, new in 2014.7.0)*
- `gitfs_password` *(pygit2 only, new in 2014.7.0)*
• `gitfs_insecure_auth` *(pygit2 only, new in 2014.7.0)*
• `gitfs_pubkey` *(pygit2 only, new in 2014.7.0)*
• `gitfs_privkey` *(pygit2 only, new in 2014.7.0)*
• `gitfs_passphrase` *(pygit2 only, new in 2014.7.0)*

These parameters can now be overridden on a per-remote basis. This allows for a tremendous amount of customization. Here’s some example usage:

```
# gitfs_provider: pygit2
# gitfs_base: develop

# gitfs_remotes:
- https://foo.com/foo.git
- https://foo.com/bar.git:
  - root: salt
  - mountpoint: salt://bar
  - base: salt-base
- https://foo.com/bar.git:
  - name: second_bar_repo
  - root: other/salt
  - mountpoint: salt://other/bar
  - base: salt-base
- http://foo.com/baz.git:
  - root: salt/states
  - user: joe
  - password: mysupersecretpassword
  - insecure_auth: True
```

**Important:** There are two important distinctions which should be noted for per-remote configuration:

1. The URL of a remote which has per-remote configuration must be suffixed with a colon.
2. Per-remote configuration parameters are named like the global versions, with the `gitfs_` removed from the beginning. The exception being the `name` parameter which is only available to per-remote configurations.

In the example configuration above, the following is true:

1. The first and fourth `gitfs` remotes will use the `develop` branch/tag as the `base` environment, while the second and third will use the `salt-base` branch/tag as the `base` environment.
2. The first remote will serve all files in the repository. The second remote will only serve files from the `salt` directory (and its subdirectories). The third remote will only server files from the `other/salt` directory (and its subdirectorys), while the fourth remote will only serve files from the `salt/states` directory (and its subdirectories).
3. The first and fourth remotes will have files located under the root of the Salt fileserver namespace (`salt://`). The files from the second remote will be located under `salt://bar`, while the files from the third remote will be located under `salt://other/bar`.
4. The second and third remotes reference the same repository and unique names need to be declared for duplicate `gitfs` remotes.
5. The fourth remote overrides the default behavior of **not authenticating to insecure (non-HTTPS) remotes**.
Serving from a Subdirectory

The `gitfs_root` parameter allows files to be served from a subdirectory within the repository. This allows for only part of a repository to be exposed to the Salt fileserver.

Assume the below layout:

```
.gitignore
README.txt
foo/
foo/bar/
foo/bar/one.txt
foo/bar/two.txt
foo/bar/three.txt
foo/baz/
foo/baz/top.sls
foo/baz/edit/vim.sls
foo/baz/edit/vimrc
foo/baz/nginx/init.sls
```

The below configuration would serve only the files under `foo/baz`, ignoring the other files in the repository:

```
gitfs_remotes:
  - git://mydomain.com/stuff.git
gitfs_root: foo/baz
```

The root can also be configured on a per-remote basis.

Mountpoints

New in version 2014.7.0.

The `gitfs_mountpoint` parameter will prepend the specified path to the files served from gitfs. This allows an existing repository to be used, rather than needing to reorganize a repository or design it around the layout of the Salt fileserver.

Before the addition of this feature, if a file being served up via gitfs was deeply nested within the root directory (for example, `salt://webapps/foo/files/foo.conf`), it would be necessary to ensure that the file was properly located in the remote repository, and that all of the the parent directories were present (for example, the directories `webapps/foo/files/` would need to exist at the root of the repository).

The below example would allow for a file `foo.conf` at the root of the repository to be served up from the Salt fileserver path `salt://webapps/foo/files/foo.conf`.

```
gitfs_remotes:
  - https://mydomain.com/stuff.git
gitfs_mountpoint: salt://webapps/foo/files
```

Mountpoints can also be configured on a per-remote basis.

Using gitfs Alongside Other Backends

Sometimes it may make sense to use multiple backends; for instance, if `sls` files are stored in git but larger files are stored directly on the master.
The cascading lookup logic used for multiple remotes is also used with multiple backends. If the `fileserver_backend` option contains multiple backends:

```
fileserver_backend:
  - roots
  - git
```

Then the `roots` backend (the default backend of files in `/srv/salt`) will be searched first for the requested file; then, if it is not found on the master, each configured git remote will be searched.

**Branches, Environments, and Top Files**

When using the `gitfs` backend, branches, and tags will be mapped to environments using the branch/tag name as an identifier.

There is one exception to this rule: the `master` branch is implicitly mapped to the `base` environment.

So, for a typical `base`, `qa`, `dev` setup, the following branches could be used:

```
master
qa
dev
```

top.sls files from different branches will be merged into one at runtime. Since this can lead to overly complex configurations, the recommended setup is to have a separate repository, containing only the top.sls file with just one single `master` branch.

To map a branch other than `master` as the `base` environment, use the `gitfs_base` parameter.

```
gitfs_base: salt-base
```

The base can also be configured on a *per-remote basis*.

**Environment Whitelist/Blacklist**

New in version 2014.7.0.

The `gitfs_env_whitelist` and `gitfs_env_blacklist` parameters allow for greater control over which branches/tags are exposed as fileserv environments. Exact matches, globs, and regular expressions are supported, and are evaluated in that order. If using a regular expression, `^` and `$` must be omitted, and the expression must match the entire branch/tag.

```
gitfs_env_whitelist:
  - base
  - v1.*
  - 'mybranch\d+'
```

**Note:** `v1.*`, in this example, will match as both a glob and a regular expression (though it will have been matched as a glob, since globs are evaluated before regular expressions).

The behavior of the blacklist/whitelist will differ depending on which combination of the two options is used:

- If only `gitfs_env_whitelist` is used, then only branches/tags which match the whitelist will be available as environments
- If only `gitfs_env_blacklist` is used, then the branches/tags which match the blacklist will **not** be available as environments
- If both are used, then the branches/tags which match the whitelist, but do **not** match the blacklist, will be available as environments.

**Authentication**

**pygit2**

New in version 2014.7.0.

Both HTTPS and SSH authentication are supported as of version 0.20.3, which is the earliest version of **pygit2** supported by Salt for gitfs.

**Note:** The examples below make use of per-remote configuration parameters, a feature new to Salt 2014.7.0. More information on these can be found [here](#).

**HTTPS**

For HTTPS repositories which require authentication, the username and password can be provided like so:

```bash
# gitfs_remotes:
  - https://domain.tld/myrepo.git:
    - user: git
    - password: mypassword
```

If the repository is served over HTTP instead of HTTPS, then Salt will by default refuse to authenticate to it. This behavior can be overridden by adding an `insecure_auth` parameter:

```bash
# gitfs_remotes:
  - http://domain.tld/insecure_repo.git:
    - user: git
    - password: mypassword
    - insecure_auth: True
```

**SSH**

SSH repositories can be configured using the `ssh://` protocol designation, or using scp-like syntax. So, the following two configurations are equivalent:

- `ssh://git@github.com/user/repo.git`
- `git@github.com:user/repo.git`

Both `gitfs_pubkey` and `gitfs_privkey` (or their **per-remote counterparts**) must be configured in order to authenticate to SSH-based repos. If the private key is protected with a passphrase, it can be configured using `gitfs_passphrase` (or simply `passphrase` if being configured **per-remote**). For example:

```bash
# gitfs_remotes:
  - git@github.com:user/repo.git:
    - pubkey: /root/.ssh/id_rsa.pub
```
- privkey: /root/.ssh/id_rsa
- passphrase: myawesomepassphrase

Finally, the SSH host key must be added to the known_hosts file.

**GitPython**

With GitPython, only passphrase-less SSH public key authentication is supported. The auth parameters (pubkey, privkey, etc.) shown in the pygit2 authentication examples above do not work with GitPython.

```
gitfs_remotes:
  - ssh://git@github.com/example/salt-states.git
```

Since GitPython wraps the git CLI, the private key must be located in `~/.ssh/id_rsa` for the user under which the Master is running, and should have permissions of `0600`. Also, in the absence of a user in the repo URL, GitPython will (just as SSH does) attempt to login as the current user (in other words, the user under which the Master is running, usually root).

If a key needs to be used, then `~/.ssh/config` can be configured to use the desired key. Information on how to do this can be found by viewing the manpage for ssh_config. Here's an example entry which can be added to the `~/.ssh/config` to use an alternate key for gitfs:

```
Host github.com
  IdentityFile /root/.ssh/id_rsa_gitfs
```

The Host parameter should be a hostname (or hostname glob) that matches the domain name of the git repository.

It is also necessary to add the SSH host key to the known_hosts file. The exception to this would be if strict host key checking is disabled, which can be done by adding StrictHostKeyChecking no to the entry in `~/.ssh/config`

```
Host github.com
  IdentityFile /root/.ssh/id_rsa_gitfs
  StrictHostKeyChecking no
```

However, this is generally regarded as insecure, and is not recommended.

**Adding the SSH Host Key to the known_hosts File**

To use SSH authentication, it is necessary to have the remote repository’s SSH host key in the `~/.ssh/known_hosts` file. If the master is also a minion, this can be done using the ssh.set_known_host function:

```
# salt mymaster ssh.set_known_host user=root hostname=github.com
mymaster:
  ----------
  new:
  ----------
  enc:
    ssh-rsa
  fingerprint:
  hostname:
    |1|OiefWwq0D4kw038hoIGa0loR5AA=|BIXVtmcTbPER+68HvXmceodDcfI=
  key:
```

3.4. Advanced Topics
If not, then the easiest way to add the key is to su to the user (usually root) under which the salt-master runs and attempt to login to the server via SSH:

```
$ su -
Password:
# ssh github.com
```

The authenticity of host 'github.com (192.30.252.128)' can't be established.
Are you sure you want to continue connecting (yes/no)? yes
Warning: Permanently added 'github.com,192.30.252.128' (RSA) to the list of known hosts.
Permission denied (publickey).

It doesn't matter if the login was successful, as answering yes will write the fingerprint to the known_hosts file.

### Verifying the Fingerprint

To verify that the correct fingerprint was added, it is a good idea to look it up. One way to do this is to use nmap:

```
$ nmap -p 22 github.com --script ssh-hostkey
```

Starting Nmap 5.51 ( http://nmap.org ) at 2014-08-18 17:47 CDT
Nmap scan report for github.com (192.30.252.129)
Host is up (0.17s latency).
Not shown: 996 filtered ports
PORT STATE SERVICE
22/tcp open ssh
80/tcp open http
443/tcp open https
9418/tcp open git
Nmap done: 1 IP address (1 host up) scanned in 28.78 seconds

Another way is to check one's own known_hosts file, using this one-liner:

```
$ ssh-keygen -l -f /dev/stdin <<<`ssh-keyscan github.com` 2>/dev/null | awk '{print $2}'
```

**Warning:** AWS tracks usage of nmap and may flag it as abuse. On AWS hosts, the ssh-keygen method is recommended for host key verification.

**Note:** As of OpenSSH 6.8 the SSH fingerprint is now shown as a base64-encoded SHA256 checksum of the host key. So, instead of the fingerprint looking like 16:27:ac:a5:76:28:2d:36:63:1b:56:4d:eb:df:a6:48, it
Refreshing gitfs Upon Push

By default, Salt updates the remote fileserver backends every 60 seconds. However, if it is desirable to refresh quicker than that, the Reactor System can be used to signal the master to update the fileserver on each push, provided that the git server is also a Salt minion. There are three steps to this process:

1. On the master, create a file `/srv/reactor/update_fileserver.sls`, with the following contents:

   ```
   update_fileserver:
   runner.fileserver.update
   ```

2. Add the following reactor configuration to the master config file:

   ```
   reactor:
   - 'salt/fileserver/gitfs/update':
     - /srv/reactor/update_fileserver.sls
   ```

3. On the git server, add a post-receive hook with the following contents:

   ```
   #!/usr/bin/env sh
   salt-call event.fire_master update salt/fileserver/gitfs/update
   ```

   The `update` argument right after `event.fire_master` in this example can really be anything, as it represents the data being passed in the event, and the passed data is ignored by this reactor.

   Similarly, the tag name `salt/fileserver/gitfs/update` can be replaced by anything, so long as the usage is consistent.

Using Git as an External Pillar Source

The git external pillar (a.k.a. git_pillar) has been rewritten for the 2015.8.0 release. This rewrite brings with it pygit2 support (allowing for access to authenticated repositories), as well as more granular support for per-remote configuration.

To make use of the new features, changes to the git ext_pillar configuration must be made. The new configuration schema is detailed [here](#).

For Salt releases before 2015.8.0, click [here](#) for documentation.

Why aren’t my custom modules/states/etc. syncing to my Minions?

In versions 0.16.3 and older, when using the git fileserver backend, certain versions of GitPython may generate errors when fetching, which Salt fails to catch. While not fatal to the fetch process, these interrupt the fileserver update that takes place before custom types are synced, and thus interrupt the sync itself. Try disabling the git fileserver backend in the master config, restarting the master, and attempting the sync again.

This issue is worked around in Salt 0.16.4 and newer.
3.4.10 The MacOS X (Maverick) Developer Step By Step Guide To Salt Installation

This document provides a step-by-step guide to installing a Salt cluster consisting of one master, and one minion running on a local VM hosted on Mac OS X.

Note: This guide is aimed at developers who wish to run Salt in a virtual machine. The official (Linux) walkthrough can be found here.

The 5 Cent Salt Intro

Since you're here you've probably already heard about Salt, so you already know Salt lets you configure and run commands on hordes of servers easily. Here's a brief overview of a Salt cluster:

- Salt works by having a "master" server sending commands to one or multiple "minion" servers \(^1\). The master server is the "command center". It is going to be the place where you store your configuration files, aka: "which server is the db, which is the web server, and what libraries and software they should have installed". The minions receive orders from the master. Minions are the servers actually performing work for your business.

- Salt has two types of configuration files:
  1. the "salt communication channels" or "meta" or "config" configuration files (not official names): one for the master (usually is /etc/salt/master, on the master server), and one for minions (default is /etc/salt/minion or /etc/salt/minion.conf, on the minion servers). Those files are used to determine things like the Salt Master IP, port, Salt folder locations, etc.. If these are configured incorrectly, your minions will probably be unable to receive orders from the master, or the master will not know which software a given minion should install.

  2. the "business" or "service" configuration files (once again, not an official name): these are configuration files, ending with "sls" extension, that describe which software should run on which server, along with particular configuration properties for the software that is being installed. These files should be created in the /srv/salt folder by default, but their location can be changed using ... /etc/salt/master configuration file!

Note: This tutorial contains a third important configuration file, not to be confused with the previous two: the virtual machine provisioning configuration file. This in itself is not specifically tied to Salt, but it also contains some Salt configuration. More on that in step 3. Also note that all configuration files are YAML files. So indentation matters.

Before Digging In, The Architecture Of The Salt Cluster

Salt Master

The "Salt master" server is going to be the Mac OS machine, directly. Commands will be run from a terminal app, so Salt will need to be installed on the Mac. This is going to be more convenient for toying around with configuration files.

\(^1\) Salt also works with "masterless" configuration where a minion is autonomous (in which case salt can be seen as a local configuration tool), or in "multiple master" configuration. See the documentation for more on that.
Salt Minion

We'll only have one ``Salt minion`` server. It is going to be running on a Virtual Machine running on the Mac, using VirtualBox. It will run an Ubuntu distribution.

### 3.4.11 Step 1 - Configuring The Salt Master On Your Mac

**official documentation**

Because Salt has a lot of dependencies that are not built in Mac OS X, we will use Homebrew to install Salt. Homebrew is a package manager for Mac, it's great, use it (for this tutorial at least!). Some people spend a lot of time installing libs by hand to better understand dependencies, and then realize how useful a package manager is once they're configuring a brand new machine and have to do it all over again. It also lets you *uninstall* things easily.

Note: Brew is a Ruby program (Ruby is installed by default with your Mac). Brew downloads, compiles, and links software. The linking phase is when compiled software is deployed on your machine. It may conflict with manually installed software, especially in the /usr/local directory. It's ok, remove the manually installed version then refresh the link by typing `brew link 'packageName'`. Brew has a `brew doctor` command that can help you troubleshoot. It's a great command, use it often. Brew requires xcode command line tools. When you run brew the first time it asks you to install them if they're not already on your system. Brew installs software in `/usr/local/bin` (system bins are in `/usr/bin`). In order to use those bins you need your `$PATH` to search there first. Brew tells you if your `$PATH` needs to be fixed.

Tip: Use the keyboard shortcut `cmd + shift + period` in the ``open`` Mac OS X dialog box to display hidden files and folders, such as `.profile`.

**Install Homebrew**

Install Homebrew here [http://brew.sh/](http://brew.sh/) Or just type

```
ruby -e "$(curl -fsSL https://raw.github.com/Homebrew/homebrew/go/install)"
```

Now type the following commands in your terminal (you may want to type `brew doctor` after each to make sure everything's fine):

```
brew install python
brew install swig
brew install zmq
```

Note: zmq is ZeroMQ. It's a fantastic library used for server to server network communication and is at the core of Salt efficiency.

**Install Salt**

You should now have everything ready to launch this command:

```
pip install salt
```
Now type python in a terminal then, import salt. There should be no errors. Now exit the Python terminal using exit().

Create The Master Configuration

If the default /etc/salt/master configuration file was not created, copy-paste it from here: http://docs.saltstack.com/ref/configuration/examples.html#configuration-examples-master

Note: /etc/salt/master is a file, not a folder.

Salt Master configuration changes. The Salt master needs a few customization to be able to run on Mac OS X:

```
sudo launchctl limit maxfiles 4096 8192
```

In the /etc/salt/master file, change max_open_files to 8192 (or just add the line: max_open_files: 8192 (no quote) if it doesn't already exists).

You should now be able to launch the Salt master:

```
sudo salt-master --log-level=all
```

There should be no errors when running the above command.

Note: This command is supposed to be a daemon, but for toying around, we'll keep it running on a terminal to monitor the activity.

Now that the master is set, let's configure a minion on a VM.

3.4.12 Step 2 - Configuring The Minion VM

The Salt minion is going to run on a Virtual Machine. There are a lot of software options that let you run virtual machines on a mac, But for this tutorial we're going to use VirtualBox. In addition to virtualBox, we will use Vagrant, which allows you to create the base VM configuration.

Vagrant lets you build ready to use VM images, starting from an OS image and customizing it using "provisioners". In our case, we'll use it to:

- Download the base Ubuntu image
- Install salt on that Ubuntu image (Salt is going to be the "provisioner" for the VM).
- Launch the VM
- SSH into the VM to debug
- Stop the VM once you're done.
Install VirtualBox

Go get it here: https://www.virtualBox.org/wiki/Downloads (click on VirtualBox for OS X hosts => x86/amd64)

Install Vagrant

Go get it here: http://downloads.vagrantup.com/ and choose the latest version (1.3.5 at time of writing), then the .dmg file. Double-click to install it. Make sure the vagrant command is found when run in the terminal. Type vagrant. It should display a list of commands.

Create The Minion VM Folder

Create a folder in which you will store your minion's VM. In this tutorial, it's going to be a minion folder in the $home directory.

```bash
cd $home
mkdir minion
```

Initialize Vagrant

From the minion folder, type

```bash
vagrant init
```

This command creates a default Vagrantfile configuration file. This configuration file will be used to pass configuration parameters to the Salt provisioner in Step 3.

Import Precise64 Ubuntu Box

```bash
vagrant box add precise64 http://files.vagrantup.com/precise64.box
```

Note: This box is added at the global Vagrant level. You only need to do it once as each VM will use this same file.

Modify the Vagrantfile

Modify ./minion/Vagrantfile to use the precise64 box. Change the config.vm.box line to:

```bash
config.vm.box = "precise64"
```

Uncomment the line creating a host-only IP. This is the ip of your minion (you can change it to something else if that IP is already in use):

```bash
config.vm.network :private_network, ip: "192.168.33.10"
```

At this point you should have a VM that can run, although there won't be much in it. Let's check that.
Checking The VM

From the $home/minion folder type:

```
vagrant up
```

A log showing the VM booting should be present. Once it's done you'll be back to the terminal:

```
ping 192.168.33.10
```

The VM should respond to your ping request.

Now log into the VM in ssh using Vagrant again:

```
vagrant ssh
```

You should see the shell prompt change to something similar to `vagrant@precise64:~$` meaning you're inside the VM. From there, enter the following:

```
ping 10.0.2.2
```

**Note:** That ip is the ip of your VM host (the Mac OS X OS). The number is a VirtualBox default and is displayed in the log after the Vagrant ssh command. We'll use that IP to tell the minion where the Salt master is. Once you're done, end the ssh session by typing `exit`.

It's now time to connect the VM to the salt master

### 3.4.13 Step 3 - Connecting Master and Minion

#### Creating The Minion Configuration File

Create the `/etc/salt/minion` file. In that file, put the following lines, giving the ID for this minion, and the IP of the master:

```
master: 10.0.2.2
id: 'minion1'
file_client: remote
```

Minions authenticate with the master using keys. Keys are generated automatically if you don't provide one and can accept them later on. However, this requires accepting the minion key every time the minion is destroyed or created (which could be quite often). A better way is to create those keys in advance, feed them to the minion, and authorize them once.

#### Preseed minion keys

From the minion folder on your Mac run:

```
sudo salt-key --gen-keys=minion1
```

This should create two files: minion1.pem, and minion1.pub. Since those files have been created using sudo, but will be used by vagrant, you need to change ownership:
sudo chown youruser:yourgroup minion1.pem
sudo chown youruser:yourgroup minion1.pub

Then copy the .pub file into the list of accepted minions:
sudo cp minion1.pub /etc/salt/pki/master/minions/minion1

Modify Vagrantfile to Use Salt Provisioner

Let's now modify the Vagrantfile used to provision the Salt VM. Add the following section in the Vagrantfile (note: it should be at the same indentation level as the other properties):

```ruby
# salt-vagrant config
cfg = config.vm.provision :salt do |salt|
  salt.run_highstate = true
  salt.minion_config = '/etc/salt/minion'
  salt.minion_key = './minion1.pem'
  salt.minion_pub = './minion1.pub'
end
```

Now destroy the vm and recreate it from the /minion folder:
vagrant destroy
vagrant up

If everything is fine you should see the following message:

"Bootstrapping Salt... (this may take a while)
Salt successfully configured and installed!"

Checking Master-Minion Communication

To make sure the master and minion are talking to each other, enter the following:
sudo salt '*' test.ping

You should see your minion answering the ping. It's now time to do some configuration.

3.4.14 Step 4 - Configure Services to Install On the Minion

In this step we'll use the Salt master to instruct our minion to install Nginx.

Checking the system's original state

First, make sure that an HTTP server is not installed on our minion. When opening a browser directed at http://192.168.33.10/ You should get an error saying the site cannot be reached.
Initialize the top.sls file

System configuration is done in /srv/salt/top.sls (and subfiles/folders), and then applied by running the state.apply function to have the Salt master order its minions to update their instructions and run the associated commands.

First Create an empty file on your Salt master (Mac OS X machine):

```
touch /srv/salt/top.sls
```

When the file is empty, or if no configuration is found for our minion an error is reported:

```
sudo salt 'minion1' state.apply
```

This should return an error stating: No Top file or external nodes data matches found.

Create The Nginx Configuration

Now is finally the time to enter the real meat of our server’s configuration. For this tutorial our minion will be treated as a web server that needs to have Nginx installed.

Insert the following lines into /srv/salt/top.sls (which should currently be empty).

```
base:
  'minion1':
    - bin.nginx
```

Now create /srv/salt/bin/nginx.sls containing the following:

```
nginx:
  pkg.installed:
    - name: nginx
  service.running:
    - enable: True
    - reload: True
```

Check Minion State

Finally, run the state.apply function again:

```
sudo salt 'minion1' state.apply
```

You should see a log showing that the Nginx package has been installed and the service configured. To prove it, open your browser and navigate to http://192.168.33.10/, you should see the standard Nginx welcome page.

Congratulations!

Where To Go From Here

A full description of configuration management within Salt (sls files among other things) is available here: http://docs.saltstack.com/en/latest/index.html#configuration-management
3.4.15 Salt’s Test Suite: An Introduction

Note: This tutorial makes a couple of assumptions. The first assumption is that you have a basic knowledge of Salt. To get up to speed, check out the Salt Walkthrough.

The second assumption is that your Salt development environment is already configured and that you have a basic understanding of contributing to the Salt codebase. If you're unfamiliar with either of these topics, please refer to the Installing Salt for Development and the Contributing pages, respectively.

Salt comes with a powerful integration and unit test suite. The test suite allows for the fully automated run of integration and/or unit tests from a single interface.

Salt's test suite is located under the tests directory in the root of Salt's code base and is divided into two main types of tests: unit tests and integration tests. The unit and integration sub-test-suites are located in the tests directory, which is where the majority of Salt's test cases are housed.

Getting Set Up For Tests

There are a couple of requirements, in addition to Salt's requirements, that need to be installed in order to run Salt's test suite. You can install these additional requirements using the files located in the salt/requirements directory, depending on your relevant version of Python:

```
pip install -r requirements/dev_python26.txt
pip install -r requirements/dev_python27.txt
```

Test Directory Structure

As noted in the introduction to this tutorial, Salt’s test suite is located in the tests directory in the root of Salt’s code base. From there, the tests are divided into two groups integration and unit. Within each of these directories, the directory structure roughly mirrors the directory structure of Salt's own codebase. For example, the files inside tests/integration/modules contains tests for the files located within salt/modules.

Note: tests/integration and tests/unit are the only directories discussed in this tutorial. With the exception of the tests/runtests.py file, which is used below in the Running the Test Suite section, the other directories and files located in tests are outside the scope of this tutorial.

Integration vs. Unit

Given that Salt’s test suite contains two powerful, though very different, testing approaches, when should you write integration tests and when should you write unit tests?

Integration tests use Salt masters, minions, and a syndic to test salt functionality directly and focus on testing the interaction of these components. Salt's integration test runner includes functionality to run Salt execution modules, runners, states, shell commands, salt-ssh commands, salt-api commands, and more. This provides a tremendous ability to use Salt to test itself and makes writing such tests a breeze. Integration tests are the preferred method of testing Salt functionality when possible.

Unit tests do not spin up any Salt daemons, but instead find their value in testing singular implementations of individual functions. Instead of testing against specific interactions, unit tests should be used to test a function's logic. Unit tests should be used to test a function's exit point(s) such as any return or raises statements.
Unit tests are also useful in cases where writing an integration test might not be possible. While the integration test suite is extremely powerful, unfortunately at this time, it does not cover all functional areas of Salt's ecosystem. For example, at the time of this writing, there is not a way to write integration tests for Proxy Minions. Since the test runner will need to be adjusted to account for Proxy Minion processes, unit tests can still provide some testing support in the interim by testing the logic contained inside Proxy Minion functions.

**Running the Test Suite**

Once all of the *requirements* are installed, the `runtests.py` file in the `salt/tests` directory is used to instantiate Salt's test suite:

```
python tests/runtests.py [OPTIONS]
```

The command above, if executed without any options, will run the entire suite of integration and unit tests. Some tests require certain flags to run, such as destructive tests. If these flags are not included, then the test suite will only perform the tests that don't require special attention.

At the end of the test run, you will see a summary output of the tests that passed, failed, or were skipped.

The test runner also includes a `--help` option that lists all of the various command line options:

```
python tests/runtests.py --help
```

You can also call the test runner as an executable:

```
./tests/runtests.py --help
```

**Running Integration Tests**

Salt's set of integration tests use Salt to test itself. The integration portion of the test suite includes some built-in Salt daemons that will spin up in preparation of the test run. This list of Salt daemon processes includes:

- 2 Salt Masters
- 2 Salt Minions
- 1 Salt Syndic

These various daemons are used to execute Salt commands and functionality within the test suite, allowing you to write tests to assert against expected or unexpected behaviors.

A simple example of a test utilizing a typical master/minion execution module command is the test for the `test.ping` function in the `tests/integration/modules/test.py` file:

```python
def test_ping(self):
    '''
    test.ping
    '''
    self.assertTrue(self.run_function('test.ping'))
```

The test above is a very simple example where the `test.ping` function is executed by Salt's test suite runner and is asserting that the minion returned with a `True` response.
Test Selection Options

If you look in the output of the `--help` command of the test runner, you will see a section called Tests Selection Options. The options under this section contain various subsections of the integration test suite such as `--modules`, `--ssh`, or `--states`. By selecting any one of these options, the test daemons will spin up and the integration tests in the named subsection will run.

```bash
./tests/runtests.py --modules
```

Note: The testing subsections listed in the Tests Selection Options of the `--help` output only apply to the integration tests. They do not run unit tests.

Running Unit Tests

While `./tests/runtests.py` executes the entire test suite (barring any tests requiring special flags), the `--unit` flag can be used to run only Salt's unit tests. Salt's unit tests include the tests located in the `tests/unit` directory.

The unit tests do not spin up any Salt testing daemons as the integration tests do and execute very quickly compared to the integration tests.

```bash
./tests/runtests.py --unit
```

Running Specific Tests

There are times when a specific test file, test class, or even a single, individual test need to be executed, such as when writing new tests. In these situations, the `--name` option should be used.

For running a single test file, such as the pillar module test file in the integration test directory, you must provide the file path using . instead of / as separators and no file extension:

```bash
./tests/runtests.py --name=integration.modules.pillar
./tests/runtests.py -n integration.modules.pillar
```

Some test files contain only one test class while other test files contain multiple test classes. To run a specific test class within the file, append the name of the test class to the end of the file path:

```bash
./tests/runtests.py --name=integration.modules.pillar.PillarModuleTest
./tests/runtests.py -n integration.modules.pillar.PillarModuleTest
```

To run a single test within a file, append both the name of the test class the individual test belongs to, as well as the name of the test itself:

```bash
./tests/runtests.py --name=integration.modules.pillar.PillarModuleTest.test_data
./tests/runtests.py -n integration.modules.pillar.PillarModuleTest.test_data
```

The `--name` and `-n` options can be used for unit tests as well as integration tests. The following command is an example of how to execute a single test found in the `tests/unit/modules/cp_test.py` file:

```bash
./tests/runtests.py -n unit.modules.cp_test.CpTestCase.test_get_template_success
```
Writing Tests for Salt

Once you’re comfortable running tests, you can now start writing them! Be sure to review the Integration vs. Unit section of this tutorial to determine what type of test makes the most sense for the code you’re testing.

Note: There are many decorators, naming conventions, and code specifications required for Salt test files. We will not be covering all of the these specifics in this tutorial. Please refer to the testing documentation links listed below in the Additional Testing Documentation section to learn more about these requirements.

In the following sections, the test examples assume the ``new'' test is added to a test file that is already present and regularly running in the test suite and is written with the correct requirements.

Writing Integration Tests

Since integration tests validate against a running environment, as explained in the Running Integration Tests section of this tutorial, integration tests are very easy to write and are generally the preferred method of writing Salt tests.

The following integration test is an example taken from the test.py file in the tests/integration/modules directory. This test uses the run_function method to test the functionality of a traditional execution module command.

The run_function method uses the integration test daemons to execute a module.function command as you would with Salt. The minion runs the function and returns. The test also uses Python’s Assert Functions to test that the minion’s return is expected.

```python
def test_ping(self):
    '''
    test.ping
    '''
    self.assertTrue(self.run_function('test.ping'))
```

Args can be passed in to the run_function method as well:

```python
def test_echo(self):
    '''
    test.echo
    '''
    self.assertEqual(self.run_function('test.echo', ['text']), 'text')
```

The next example is taken from the tests/integration/modules/aliases.py file and demonstrates how to pass kwargs to the run_function call. Also note that this test uses another salt function to ensure the correct data is present (via the aliases.set_target call) before attempting to assert what the aliases.get_target call should return.

```python
def test_set_target(self):
    '''
    aliases.set_target and aliases.get_target
    '''
    set_ret = self.run_function(
        'aliases.set_target',
        alias='fred',
        target='bob')
    self.assertTrue(set_ret)
    tgt_ret = self.run_function(
        'aliases.get_target',
        target='bob')
    self.assertEqual(tgt_ret, 'fred')
```

122 Chapter 3. Tutorials
Using multiple Salt commands in this manner provides two useful benefits. The first is that it provides some additional coverage for the `aliases.set_target` function. The second benefit is the call to `aliases.get_target` is not dependent on the presence of any aliases set outside of this test. Tests should not be dependent on the previous execution, success, or failure of other tests. They should be isolated from other tests as much as possible.

While it might be tempting to build out a test file where tests depend on one another before running, this should be avoided. SaltStack recommends that each test should test a single functionality and not rely on other tests. Therefore, when possible, individual tests should also be broken up into singular pieces. These are not hard-and-fast rules, but serve more as recommendations to keep the test suite simple. This helps with debugging code and related tests when failures occur and problems are exposed. There may be instances where large tests use many asserts to set up a use case that protects against potential regressions.

Note: The examples above all use the `run_function` option to test execution module functions in a traditional master/minion environment. To see examples of how to test other common Salt components such as runners, salt-api, and more, please refer to the Integration Test Class Examples documentation.

### Destructive vs Non-destructive Tests

Since Salt is used to change the settings and behavior of systems, often, the best approach to run tests is to make actual changes to an underlying system. This is where the concept of destructive integration tests comes into play. Tests can be written to alter the system they are running on. This capability is what fills in the gap needed to properly test aspects of system management like package installation.

To write a destructive test, import and use the `destructiveTest` decorator for the test method:

```python
import integration
from salttesting.helpers import destructiveTest
class PkgTest(integration.ModuleCase):
    @destructiveTest
    def test_pkg_install(self):
        ret = self.run_function('pkg.install', name='finch')
        self.assertSaltTrueReturn(ret)
        ret = self.run_function('pkg.purge', name='finch')
        self.assertSaltTrueReturn(ret)
```

### Writing Unit Tests

As explained in the Integration vs. Unit section above, unit tests should be written to test the logic of a function. This includes focusing on testing return and raises statements. Substantial effort should be made to mock external resources that are used in the code being tested.

External resources that should be mocked include, but are not limited to, APIs, function calls, external data either globally available or passed in through function arguments, file data, etc. This practice helps to isolate unit tests to test Salt logic. One handy way to think about writing unit tests is to "block all of the exits". More information about how to properly mock external resources can be found in Salt’s Unit Test documentation.

Salt’s unit tests utilize Python’s mock class as well as `MagicMock`. The `@patch` decorator is also heavily used when "blocking all the exits".

---

**3.4. Advanced Topics**

123
A simple example of a unit test currently in use in Salt is the `test_get_file_not_found` test in the `tests/unit/modules/cp_test.py` file. This test uses the `@patch` decorator and `MagicMock` to mock the return of the call to Salt's `cp.hash_file` execution module function. This ensures that we're testing the `cp.get_file` function directly, instead of inadvertently testing the call to `cp.hash_file`, which is used in `cp.get_file`.

```python
@patch('salt.modules.cp.hash_file', MagicMock(return_value=False))
def test_get_file_not_found(self):
    '''
    Test if get_file can't find the file.
    '''
    path = 'salt://saltines'
    dest = '/srv/salt/cheese'
    ret = ''
    self.assertEqual(cp.get_file(path, dest), ret)
```

Note that Salt’s `cp` module is imported at the top of the file, along with all of the other necessary testing imports. The `get_file` function is then called directly in the testing function, instead of using the `run_function` method as the integration test examples do above.

The call to `cp.get_file` returns an empty string when a `hash_file` isn't found. Therefore, the example above is a good illustration of a unit test ``blocking the exits'' via the `@patch` decorator, as well as testing logic via asserting against the return statement in the `if` clause.

There are more examples of writing unit tests of varying complexities available in the following docs:

- Simple Unit Test Example
- Complete Unit Test Example
- Complex Unit Test Example

**Note:** Considerable care should be made to ensure that you're testing something useful in your test functions. It is very easy to fall into a situation where you have mocked so much of the original function that the test results in only asserting against the data you have provided. This results in a poor and fragile unit test.

### Automated Test Runs

SaltStack maintains a Jenkins server which can be viewed at [https://jenkins.saltstack.com](https://jenkins.saltstack.com). The tests executed from this Jenkins server create fresh virtual machines for each test run, then execute the destructive tests on the new, clean virtual machine. This allows for the execution of tests across supported platforms.

### Additional Testing Documentation

In addition to this tutorial, there are some other helpful resources and documentation that go into more depth on Salt's test runner, writing tests for Salt code, and general Python testing documentation. Please see the follow references for more information:

- Salt's Test Suite Documentation
- Integration Tests
- Unit Tests
- `MagicMock`
- `Python Unittest`
• Python's Assert Functions

3.4.16 HTTP Modules

This tutorial demonstrates using the various HTTP modules available in Salt. These modules wrap the Python tornado, urllib2, and requests libraries, extending them in a manner that is more consistent with Salt workflows.

The salt.utils.http Library

This library forms the core of the HTTP modules. Since it is designed to be used from the minion as an execution module, in addition to the master as a runner, it was abstracted into this multi-use library. This library can also be imported by 3rd-party programs wishing to take advantage of its extended functionality.

Core functionality of the execution, state, and runner modules is derived from this library, so common usages between them are described here. Documentation specific to each module is described below.

This library can be imported with:

```python
import salt.utils.http
```

Configuring Libraries

This library can make use of either tornado, which is required by Salt, urllib2, which ships with Python, or requests, which can be installed separately. By default, tornado will be used. In order to switch to urllib2, set the following variable:

```python
backend: urllib2
```

In order to switch to requests, set the following variable:

```python
backend: requests
```

This can be set in the master or minion configuration file, or passed as an option directly to any `http.query()` functions.

salt.utils.http.query()

This function forms a basic query, but with some add-ons not present in the tornado, urllib2, and requests libraries. Not all functionality currently available in these libraries has been added, but can be in future iterations.

A basic query can be performed by calling this function with no more than a single URL:

```python
salt.utils.http.query('http://example.com')
```

By default the query will be performed with a GET method. The method can be overridden with the method argument:

```python
salt.utils.http.query('http://example.com/delete/url', 'DELETE')
```

When using the POST method (and others, such as PUT), extra data is usually sent as well. This data can be sent directly, in whatever format is required by the remote server (XML, JSON, plain text, etc).
Bear in mind that this data must be sent pre-formatted; this function will not format it for you. However, a templated file stored on the local system may be passed through, along with variables to populate it with. To pass through only the file (untemplated):

```python
salt.utils.http.query(
    'http://example.com/delete/url',
    method='POST',
    data=json.loads(mydict)
)
```

To pass through a file that contains Jinja + YAML templating (the default):

```python
salt.utils.http.query(
    'http://example.com/post/url',
    method='POST',
    data_file='/srv/salt/somefile.jinja',
    data_render=True,
    template_data={'key1': 'value1', 'key2': 'value2'}
)
```

To pass through a file that contains Mako templating:

```python
salt.utils.http.query(
    'http://example.com/post/url',
    method='POST',
    data_file='/srv/salt/somefile.mako',
    data_render=True,
    data_renderer='mako',
    template_data={'key1': 'value1', 'key2': 'value2'}
)
```

Because this function uses Salt's own rendering system, any Salt renderer can be used. Because Salt's renderer requires `__opts__` to be set, an `opts` dictionary should be passed in. If it is not, then the default `__opts__` values for the node type (master or minion) will be used. Because this library is intended primarily for use by minions, the default node type is `minion`. However, this can be changed to `master` if necessary.

```python
salt.utils.http.query(
    'http://example.com/post/url',
    method='POST',
    data_file='/srv/salt/somefile.jinja',
    data_render=True,
    template_data={'key1': 'value1', 'key2': 'value2'},
    opts=__opts__
)
```

```python
salt.utils.http.query(
    'http://example.com/post/url',
    method='POST',
    data_file='/srv/salt/somefile.jinja',
    data_render=True,
    template_data={'key1': 'value1', 'key2': 'value2'},
)
```
Headers may also be passed through, either as a header_list, a header_dict, or as a header_file. As with the data_file, the header_file may also be templated. Take note that because HTTP headers are normally syntactically-correct YAML, they will automatically be imported as an a Python dict.

```python
def query(
    url='http://example.com/delete/url',
    method='POST',
    header_file='/srv/salt/headers.jinja',
    header_render=True,
    header_renderer='jinja',
    template_data={'key1': 'value1', 'key2': 'value2'}
):
    return
```

Because much of the data that would be templated between headers and data may be the same, the template_data is the same for both. Correcting possible variable name collisions is up to the user.

The query() function supports basic HTTP authentication. A username and password may be passed in as username and password, respectively.

```python
def query(
    url='http://example.com',
    username='larry',
    password='5700g3543v4r',
):
    return
```

Cookies are also supported, using Python's built-in cookielib. However, they are turned off by default. To turn cookies on, set cookies to True.

```python
def query(
    url='http://example.com',
    cookies=True
):
    return
```

By default cookies are stored in Salt's cache directory, normally /var/cache/salt, as a file called cookies.txt. However, this location may be changed with the cookie_jar argument:

```python
def query(
    url='http://example.com',
    cookies=True,
    cookie_jar='/path/to/cookie_jar.txt'
):
    return
```

By default, the format of the cookie jar is LWP (aka, lib-www-perl). This default was chosen because it is a human-readable text file. If desired, the format of the cookie jar can be set to Mozilla:

```python
def query(
    url='http://example.com',
    cookies=True,
    cookie_jar='/path/to/cookie_jar.txt',
    cookie_format='mozilla'
):
    return
```

Because Salt commands are normally one-off commands that are piped together, this library cannot normally behave as a normal browser, with session cookies that persist across multiple HTTP requests. However, the session
can be persisted in a separate cookie jar. The default filename for this file, inside Salt’s cache directory, is cookies.session.p. This can also be changed.

```python
salt.utils.http.query(
    'http://example.com',
    persist_session=True,
    session_cookie_jar='/path/to/jar.p'
)
```

The format of this file is msgpack, which is consistent with much of the rest of Salt’s internal structure. Historically, the extension for this file is .p. There are no current plans to make this configurable.

**Return Data**

**Note:** Return data encoding

If `decode` is set to `True`, `query()` will attempt to decode the return data. `decode_type` defaults to `auto`. Set it to a specific encoding, `xml`, for example, to override autodetection.

Because Salt’s `http` library was designed to be used with REST interfaces, `query()` will attempt to decode the data received from the remote server when `decode` is set to `True`. First it will check the `Content-type` header to try and find references to XML. If it does not find any, it will look for references to JSON. If it does not find any, it will fall back to plain text, which will not be decoded.

JSON data is translated into a dict using Python’s built-in `json` library. XML is translated using `salt.utils.xml_util`, which will use Python’s built-in XML libraries to attempt to convert the XML into a dict. In order to force either JSON or XML decoding, the `decode_type` may be set:

```python
salt.utils.http.query(
    'http://example.com',
    decode_type='xml'
)
```

Once translated, the return dict from `query()` will include a dict called `dict`.

If the data is not to be translated using one of these methods, decoding may be turned off.

```python
salt.utils.http.query(
    'http://example.com',
    decode=False
)
```

If decoding is turned on, and references to JSON or XML cannot be found, then this module will default to plain text, and return the undecoded data as `text` (even if `text` is set to `False`; see below).

The `query()` function can return the HTTP status code, headers, and/or text as required. However, each must individually be turned on.

```python
salt.utils.http.query(
    'http://example.com',
    status=True,
    headers=True,
    text=True
)
```

The return from these will be found in the return dict as `status`, `headers` and `text`, respectively.
Writing Return Data to Files

It is possible to write either the return data or headers to files, as soon as the response is received from the server, but specifying file locations via the `text_out` or `headers_out` arguments. `text` and `headers` do not need to be returned to the user in order to do this.

```python
salt.utils.http.query(
    'http://example.com',
    text=False,
    headers=False,
    text_out='/path/to/url_download.txt',
    headers_out='/path/to/headers_download.txt',
)
```

SSL Verification

By default, this function will verify SSL certificates. However, for testing or debugging purposes, SSL verification can be turned off.

```python
salt.utils.http.query(
    'https://example.com',
    verify_ssl=False,
)
```

CA Bundles

The `requests` library has its own method of detecting which CA (certificate authority) bundle file to use. Usually this is implemented by the packager for the specific operating system distribution that you are using. However, `urllib2` requires a little more work under the hood. By default, Salt will try to auto-detect the location of this file. However, if it is not in an expected location, or a different path needs to be specified, it may be done so using the `ca_bundle` variable.

```python
salt.utils.http.query(
    'https://example.com',
    ca_bundle='/path/to/ca_bundle.pem',
)
```

Updating CA Bundles

The `update_ca_bundle()` function can be used to update the bundle file at a specified location. If the target location is not specified, then it will attempt to auto-detect the location of the bundle file. If the URL to download the bundle from does not exist, a bundle will be downloaded from the cURL website.

**CAUTION:** The target and the source should always be specified! Failure to specify the target may result in the file being written to the wrong location on the local system. Failure to specify the source may cause the upstream URL to receive excess unnecessary traffic, and may cause a file to be download which is hazardous or does not meet the needs of the user.

```python
call.utils.http.update_ca_bundle(
    target='/path/to/ca-bundle.crt',
    source='https://example.com/path/to/ca-bundle.crt',
)
The `opts` parameter should also always be specified. If it is, then the `target` and the `source` may be specified in the relevant configuration file (master or minion) as `ca_bundle` and `ca_bundle_url`, respectively.

```python
ca_bundle: /path/to/ca-bundle.crt
ca_bundle_url: https://example.com/path/to/ca-bundle.crt
```

If Salt is unable to auto-detect the location of the CA bundle, it will raise an error.

The `update_ca_bundle()` function can also be passed a string or a list of strings which represent files on the local system, which should be appended (in the specified order) to the end of the CA bundle file. This is useful in environments where private certs need to be made available, and are not otherwise reasonable to add to the bundle file.

```python
salt.utils.http.update_ca_bundle(
    opts=__opts__,
    merge_files=[
        '/etc/ssl/private_cert_1.pem',
        '/etc/ssl/private_cert_2.pem',
        '/etc/ssl/private_cert_3.pem',
    ]
)
```

### Test Mode

This function may be run in test mode. This mode will perform all work up until the actual HTTP request. By default, instead of performing the request, an empty dict will be returned. Using this function with TRACE logging turned on will reveal the contents of the headers and POST data to be sent.

Rather than returning an empty dict, an alternate `test_url` may be passed in. If this is detected, then test mode will replace the `url` with the `test_url`, set `test` to `True` in the return data, and perform the rest of the requested operations as usual. This allows a custom, non-destructive URL to be used for testing when necessary.

### Execution Module

The `http` execution module is a very thin wrapper around the `salt.utils.http` library. The `opts` can be passed through as well, but if they are not specified, the minion defaults will be used as necessary.

Because passing complete data structures from the command line can be tricky at best and dangerous (in terms of execution injection attacks) at worse, the `data_file`, and `header_file` are likely to see more use here.

All methods for the library are available in the execution module, as kwargs.

```python
salt myminion http.query http://example.com/restapi method=POST \  username='larry' password='5700g3543v4r' headers=True text=True \  status=True decode_type=xml data_render=True \  header_file=/tmp/headers.txt data_file=/tmp/data.txt \  header_render=True cookies=True persist_session=True
```
Runner Module

Like the execution module, the http runner module is a very thin wrapper around the salt.utils.http library. The only significant difference is that because runners execute on the master instead of a minion, a target is not required, and default opts will be derived from the master config, rather than the minion config.

All methods for the library are available in the runner module, as kwargs.

```
salt-run http.query http://example.com/restapi method=POST \
   username='larry' password='5700g3543v4r' headers=True text=True \
   status=True decode_type=xml data_render=True \
   header_file=/tmp/headers.txt data_file=/tmp/data.txt \
   header_render=True cookies=True persist_session=True
```

State Module

The state module is a wrapper around the runner module, which applies stateful logic to a query. All kwargs as listed above are specified as usual in state files, but two more kwargs are available to apply stateful logic. A required parameter is `match`, which specifies a pattern to look for in the return text. By default, this will perform a string comparison of looking for the value of `match` in the return text. In Python terms this looks like:

```
if match in html_text:
    return True
```

If more complex pattern matching is required, a regular expression can be used by specifying a `match_type`. By default this is set to `string`, but it can be manually set to `pcre` instead. Please note that despite the name, this will use Python's `re.search()` rather than `re.match()`.

Therefore, the following states are valid:

```
http://example.com/restapi:
    http.query:
        - match: 'SUCCESS'
        - username: 'larry'
        - password: '5700g3543v4r'
        - data_render: True
        - header_file: /tmp/headers.txt
        - data_file: /tmp/data.txt
        - header_render: True
        - cookies: True
        - persist_session: True

http://example.com/restapi:
    http.query:
        - match_type: pcre
        - match: '(?!succe[ss|ed])'
        - username: 'larry'
        - password: '5700g3543v4r'
        - data_render: True
        - header_file: /tmp/headers.txt
        - data_file: /tmp/data.txt
        - header_render: True
        - cookies: True
        - persist_session: True
```

In addition to, or instead of a match pattern, the status code for a URL can be checked. This is done using the `status` argument:
If both are specified, both will be checked, but if only one is True and the other is False, then False will be returned. In this case, the comments in the return data will contain information for troubleshooting.

Because this is a monitoring state, it will return extra data to code that expects it. This data will always include text and status. Optionally, headers and dict may also be requested by setting the headers and decode arguments to True, respectively.

### 3.4.17 LXC Management with Salt

**Note:** This walkthrough assumes basic knowledge of Salt. To get up to speed, check out the Salt Walkthrough.

#### Dependencies

Manipulation of LXC containers in Salt requires the minion to have an LXC version of at least 1.0 (an alpha or beta release of LXC 1.0 is acceptable). The following distributions are known to have new enough versions of LXC packaged:

- RHEL/CentOS 6 and later (via EPEL)
- Fedora (All non-EOL releases)
- Debian 8.0 (Jessie)
- Ubuntu 14.04 LTS and later (LXC templates are packaged separately as lxc-templates, it is recommended to also install this package)
- openSUSE 13.2 and later

#### Profiles

Profiles allow for a sort of shorthand for commonly-used configurations to be defined in the minion config file, grains, pillar, or the master config file. The profile is retrieved by Salt using the config.get function, which looks in those locations, in that order. This allows for profiles to be defined centrally in the master config file, with several options for overriding them (if necessary) on groups of minions or individual minions.

There are two types of profiles:

- One for defining the parameters used in container creation/clone.
- One for defining the container's network interface(s) settings.

#### Container Profiles

LXC container profiles are defined defined underneath the lxc.container_profile config option:
Profiles are retrieved using the `config.get` function, with the `recurse` merge strategy. This means that a profile can be defined at a lower level (for example, the master config file) and then parts of it can be overridden at a higher level (for example, in pillar data). Consider the following container profile data:

In the Master config file:

```yaml
lxc.container_profile:
  centos:
    template: centos
    backing: lvm
    vgname: vgl
    lvname: lxclv
    size: 10G
```

In the Pillar data

```yaml
lxc.container_profile:
  centos:
    size: 20G
```

Any minion with the above Pillar data would have the `size` parameter in the `centos` profile overridden to 20G, while those minions without the above Pillar data would have the 10G `size` value. This is another way of achieving the same result as the `centos_big` profile above, without having to define another whole profile that differs in just one value.

Note: In the 2014.7.x release cycle and earlier, container profiles are defined under `lxc.profile`. This parameter will still work in version 2015.5.0, but is deprecated and will be removed in a future release. Please note however that the profile merging feature described above will only work with profiles defined under `lxc.container_profile`, and only in versions 2015.5.0 and later.

Additionally, in version 2015.5.0 container profiles have been expanded to support passing template-specific CLI options to `lxc.create`. Below is a table describing the parameters which can be configured in container profiles:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>2015.5.0 and Newer</th>
<th>2014.7.x and Earlier</th>
</tr>
</thead>
<tbody>
<tr>
<td>template*</td>
<td>Yes</td>
<td>Yes</td>
</tr>
<tr>
<td>options*</td>

1. Parameter is only supported for container creation, and will be ignored if the profile is used when cloning a container.
2. Parameter is only supported for container cloning, and will be ignored if the profile is used when not cloning a container.

Network Profiles

LXC network profiles are defined defined underneath the `lxc.network_profile` config option. By default, the module uses a DHCP based configuration and try to guess a bridge to get connectivity.

| Warning: on pre 2015.5.2, you need to specify explicitly the network bridge |

```yaml
lxc.network_profile:
  centos:
    eth0:
      link: br0
      type: veth
      flags: up
  ubuntu:
    eth0:
      link: lxcbr0
      type: veth
      flags: up
```

As with container profiles, network profiles are retrieved using the `config.get` function, with the `recurse` merge strategy. Consider the following network profile data:

In the Master config file:

```yaml
lxc.network_profile:
  centos:
    eth0:
      link: br0
      type: veth
      flags: up
```

In the Pillar data

```yaml
lxc.network_profile:
  centos:
    eth0:
      link: lxcbr0
```

Any minion with the above Pillar data would use the `lxcbr0` interface as the bridge interface for any container configured using the `centos` network profile, while those minions without the above Pillar data would use the `br0` interface for the same.

| Note: In the 2014.7.x release cycle and earlier, network profiles are defined under `lxc.nic`. This parameter will still work in version 2015.5.0, but is deprecated and will be removed in a future release. Please note however that the profile merging feature described above will only work with profiles defined under `lxc.network_profile`, and only in versions 2015.5.0 and later. |

The following are parameters which can be configured in network profiles. These will directly correspond to a parameter in an LXC configuration file (see `man 5 lxc.container.conf`).
- **type** - Corresponds to `lxc.network.type`
- **link** - Corresponds to `lxc.network.link`
- **flags** - Corresponds to `lxc.network.flags`

Interface-specific options (MAC address, IPv4/IPv6, etc.) must be passed on a container-by-container basis, for instance using the `nic_opts` argument to `lxc.create`:

```bash
salt myminion lxc.create container1 profile=centos network_profile=centos nic_opts='{eth0: {ipv4: 10.0.0.20/24, gateway: 10.0.0.1}}'
```

**Warning:** The `ipv4`, `ipv6`, `gateway`, and `link` (bridge) settings in network profiles/nic_opts will only work if the container doesn't redefine the network configuration (for example in `/etc/sysconfig/network-scripts/ifcfg-<interface_name>` on RHEL/CentOS, or `/etc/network/interfaces` on Debian/Ubuntu/etc.). Use these with caution. The container images installed using the download template, for instance, typically are configured for eth0 to use DHCP, which will conflict with static IP addresses set at the container level.

**Note:** For LXC < 1.0.7 and DHCP support, set `ipv4.gateway: 'auto'` in your network profile, ie.:

```bash
lxc.network_profile.nic:
  debian:
    eth0:
      link: lxcbr0
      ipv4.gateway: 'auto'
```

### Old lxc support (<1.0.7)

With saltstack 2015.5.2 and above, normally these settings are autoselected, but before, you'll need to teach your network profile to set `lxc.network.ipv4.gateway` to `auto` when using a classic ipv4 configuration.

Thus you'll need

```bash
lxc.network_profile.foo:
  eth0:
    link: lxcbr0
    ipv4.gateway: auto
```

### Tricky network setups Examples

This example covers how to make a container with both an internal ip and a public routable ip, wired on two veth pairs.

The another interface which receives directly a public routable ip can't be on the first interface that we reserve for private inter LXC networking.

```bash
lxc.network_profile.foo:
  eth0: {gateway: null, bridge: lxcbr0}
  eth1:
    # replace that by your main interface
    'link': 'br0'
```
Creating a Container on the CLI

From a Template

LXC is commonly distributed with several template scripts in /usr/share/lxc/templates. Some distros may package these separately in an lxc-templates package, so make sure to check if this is the case.

There are LXC template scripts for several different operating systems, but some of them are designed to use tools specific to a given distribution. For instance, the ubuntu template uses deb_bootstrap, the centos template uses yum, etc., making these templates impractical when a container from a different OS is desired.

The lxc.create function is used to create containers using a template script. To create a CentOS container named container1 on a CentOS minion named mycentosminion, using the centos LXC template, one can simply run the following command:

```plaintext
salt mycentosminion lxc.create container1 template=centos
```

For these instances, there is a download template which retrieves minimal container images for several different operating systems. To use this template, it is necessary to provide an options parameter when creating the container, with three values:

1. dist - the Linux distribution (i.e. ubuntu or centos)
2. release - the release name/version (i.e. Trusty or 6)
3. arch - CPU architecture (i.e. amd64 or i386)

The lxc.images function (new in version 2015.5.0) can be used to list the available images. Alternatively, the releases can be viewed on http://images.linuxcontainers.org/images/. The images are organized in such a way that the dist, release, and arch can be determined using the following URL format: http://images.linuxcontainers.org/images/dist/release/arch. For example, http://images.linuxcontainers.org/images/centos/6/amd64 would correspond to a dist of centos, a release of 6, and an arch of amd64.

Therefore, to use the download template to create a new 64-bit CentOS 6 container, the following command can be used:

```plaintext
salt myminion lxc.create container1 template=download options=’{dist: centos, release:6, arch: amd64}’
```

Note: These command-line options can be placed into a container profile, like so:

```yaml
lxc.container_profile.cent6:
  template: download
  options:
    dist: centos
    release: 6
    arch: amd64
```

The options parameter is not supported in profiles for the 2014.7.x release cycle and earlier, so it would still need to be provided on the command-line.
Cloning an Existing Container

To clone a container, use the `lxc.clone` function:

```
salt myminion lxc.clone container2 orig=container1
```

Using a Container Image

While cloning is a good way to create new containers from a common base container, the source container that is being cloned needs to already exist on the minion. This makes deploying a common container across minions difficult. For this reason, Salt's `lxc.create` is capable of installing a container from a tar archive of another container's rootfs. To create an image of a container named `cent6`, run the following command as root:

```
tar czf cent6.tar.gz -C /var/lib/lxc/cent6 rootfs
```

**Note:** Before doing this, it is recommended that the container is stopped.

The resulting tarball can then be placed alongside the files in the salt fileserver and referenced using a `salt://` URL. To create a container using an image, use the `image` parameter with `lxc.create`:

```
salt myminion lxc.create new-cent6 image=salt://path/to/cent6.tar.gz
```

**Note:** Making images of containers with LVM backing

For containers with LVM backing, the rootfs is not mounted, so it is necessary to mount it first before creating the tar archive. When a container is created using LVM backing, an empty `rootfs` dir is handily created within `/var/lib/lxc/container_name`, so this can be used as the mountpoint. The location of the logical volume for the container will be `/dev/vgname/lvname`, where `vgname` is the name of the volume group, and `lvname` is the name of the logical volume. Therefore, assuming a volume group of `vg1`, a logical volume of `lxc-cent6`, and a container name of `cent6`, the following commands can be used to create a tar archive of the rootfs:

```
mount /dev/vg1/lxc-cent6 /var/lib/lxc/cent6/rootfs
tar czf cent6.tar.gz -C /var/lib/lxc/cent6 rootfs
umount /var/lib/lxc/cent6/rootfs
```

**Warning:** One caveat of using this method of container creation is that `/etc/hosts` is left unmodified. This could cause confusion for some distros if salt-minion is later installed on the container, as the functions that determine the hostname take `/etc/hosts` into account.

Additionally, when creating an rootfs image, be sure to remove `/etc/salt/minion_id` and make sure that `id` is not defined in `/etc/salt/minion`, as this will cause similar issues.

Initializing a New Container as a Salt Minion

The above examples illustrate a few ways to create containers on the CLI, but often it is desirable to also have the new container run as a Minion. To do this, the `lxc.init` function can be used. This function will do the following:

1. Create a new container
2. Optionally set password and/or DNS

3. Bootstrap the minion (using either salt-bootstrap or a custom command)

By default, the new container will be pointed at the same Salt Master as the host machine on which the container was created. It will then request to authenticate with the Master like any other bootstrapped Minion, at which point it can be accepted.

```bash
salt myminion lxc.init test1 profile=centos
salt-key -a test1
```

For even greater convenience, the `LXC runner` contains a runner function of the same name (`lxc.init`), which creates a keypair, seeds the new minion with it, and pre-accepts the key, allowing for the new Minion to be created and authorized in a single step:

```bash
salt-run lxc.init test1 host=myminion profile=centos
```

### Running Commands Within a Container

For containers which are not running their own Minion, commands can be run within the container in a manner similar to using (`cmd.run <salt.modules.cmdmod.run`). The means of doing this have been changed significantly in version 2015.5.0 (though the deprecated behavior will still be supported for a few releases). Both the old and new usage are documented below.

#### 2015.5.0 and Newer

New functions have been added to mimic the behavior of the functions in the `cmd` module. Below is a table with the `cmd` functions and their `lxc` module equivalents:

<table>
<thead>
<tr>
<th>Description</th>
<th><code>cmd</code> module</th>
<th><code>lxc</code> module</th>
</tr>
</thead>
<tbody>
<tr>
<td>Run a command and get all output</td>
<td><code>cmd.run</code></td>
<td><code>lxc.run</code></td>
</tr>
<tr>
<td>Run a command and get just stdout</td>
<td><code>cmd.run_stdout</code></td>
<td><code>lxc.run_stdout</code></td>
</tr>
<tr>
<td>Run a command and get just stderr</td>
<td><code>cmd.run_stderr</code></td>
<td><code>lxc.run_stderr</code></td>
</tr>
<tr>
<td>Run a command and get just the retcode</td>
<td><code>cmd.retcode</code></td>
<td><code>lxc.retcode</code></td>
</tr>
<tr>
<td>Run a command and get all information</td>
<td><code>cmd.run_all</code></td>
<td><code>lxc.run_all</code></td>
</tr>
</tbody>
</table>

#### 2014.7.x and Earlier

Earlier Salt releases use a single function (`lxc.run_cmd`) to run commands within containers. Whether stdout, stderr, etc. are returned depends on how the function is invoked.

To run a command and return the stdout:

```bash
salt myminion lxc.run_cmd web1 'tail /var/log/messages'
```

To run a command and return the stderr:

```bash
salt myminion lxc.run_cmd web1 'tail /var/log/messages' stdout=False stderr=True
```

To run a command and return the retcode:

```bash
salt myminion lxc.run_cmd web1 'tail /var/log/messages' stdout=False stderr=False
```

To run a command and return all information:
Container Management Using `salt-cloud`

Salt cloud uses under the hood the salt runner and module to manage containers, Please look at this chapter

Container Management Using States

Several states are being renamed or otherwise modified in version 2015.5.0. The information in this tutorial refers to the new states. For 2014.7.x and earlier, please refer to the documentation for the LXC states.

Ensuring a Container Is Present

To ensure the existence of a named container, use the `lxc.present` state. Here are some examples:

```yaml
# Using a template
web1:
  lxc.present:
    - template: download
    - options:
      - dist: centos
      - release: 6
      - arch: amd64

# Cloning
web2:
  lxc.present:
    - clone_from: web-base

# Using a rootfs image
web3:
  lxc.present:
    - image: salt://path/to/cent6.tar.gz

# Using profiles
web4:
  lxc.present:
    - profile: centos_web
    - network_profile: centos
```

**Warning:** The `lxc.present` state will not modify an existing container (in other words, it will not re-create the container). If an `lxc.present` state is run on an existing container, there will be no change and the state will return a `True` result.

The `lxc.present` state also includes an optional `running` parameter which can be used to ensure that a container is running/stopped. Note that there are standalone `lxc.running` and `lxc.stopped` states which can be used for this purpose.
Ensuring a Container Does Not Exist

To ensure that a named container is not present, use the `lxc.absent` state. For example:

```yaml
web1:
  lxc.absent
```

Ensuring a Container is Running/Stopped/Frozen

Containers can be in one of three states:

- **running** - Container is running and active
- **frozen** - Container is running, but all process are blocked and the container is essentially non-active until the container is "unfrozen"
- **stopped** - Container is not running

Salt has three states (`lxc.running`, `lxc.frozen`, and `lxc.stopped`) which can be used to ensure a container is in one of these states:

```yaml
web1:
  lxc.running
# Restart the container if it was already running
web2:
  lxc.running:
    - restart: True
web3:
  lxc.stopped
# Explicitly kill all tasks in container instead of gracefully stopping
web4:
  lxc.stopped:
    - kill: True
web5:
  lxc.frozen
# If container is stopped, do not start it (in which case the state will fail)
web6:
  lxc.frozen:
    - start: False
```

3.4.18 Using Salt with Stormpath

**Stormpath** is a user management and authentication service. This tutorial covers using SaltStack to manage and take advantage of Stormpath's features.

External Authentication

Stormpath can be used for Salt’s external authentication system. In order to do this, the master should be configured with an `apiid`, `apikey`, and the ID of the application that is associated with the users to be authenticated:
Users that are to be authenticated should be set up under the `stormpath` dict under `external_auth`:

```
external_auth:
  stormpath:
    larry:
      - .*
      - '@runner'
      - '@wheel'
```

Keep in mind that while Stormpath defaults the username associated with the account to the email address, it is better to use a username without an `@` sign in it.

### Configuring Stormpath Modules

Stormpath accounts can be managed via either an execution or state module. In order to use either, a minion must be configured with an API ID and key.

```
stormpath:
  apiid: 367DFSF4FRJ8767FSF4G34FGH
  apikey: FEFREF43t3FEFRe/f323fwer4FWF3445gferWRWEer1
  application: 786786FREFrefreg435fr1
```

Some functions in the `stormpath` modules can make use of other options. The following options are also available.

#### directory

The ID of the directory that is to be used with this minion. Many functions require an ID to be specified to do their work. However, if the ID of a `directory` is specified, then Salt can often look up the resource in question.

#### application

The ID of the application that is to be used with this minion. Many functions require an ID to be specified to do their work. However, if the ID of an `application` is specified, then Salt can often look up the resource in question.

### Managing Stormpath Accounts

With the `stormpath` configuration in place, Salt can be used to configure accounts (which may be thought of as users) on the Stormpath service. The following functions are available.
**stormpath.create_account**

Create an account on the Stormpath service. This requires a `directory_id` as the first argument; it will not be retrieved from the minion configuration. An email address, password, first name (`givenName`) and last name (`surname`) are also required. For the full list of other parameters that may be specified, see:

`http://docs.stormpath.com/rest/product-guide/#account-resource`

When executed with no errors, this function will return the information about the account, from Stormpath.

```shell
salt myminion stormpath.create_account <directory_id> shemp@example.com letmein Shemp\_Howard
```

**stormpath.list_accounts**

Show all accounts on the Stormpath service. This will return all accounts, regardless of directory, application, or group.

```shell
salt myminion stormpath.list_accounts
```

**stormpath.show_account**

Show the details for a specific Stormpath account. An `account_id` is normally required. However, if an email is provided instead, along with either a `directory_id`, `application_id`, or `group_id`, then Salt will search the specified resource to try and locate the `account_id`.

```shell
salt myminion stormpath.show_account <account_id>
salt myminion stormpath.show_account email=<email> directory_id=<directory_id>
```

**stormpath.update_account**

Update one or more items for this account. Specifying an empty value will clear it for that account. This function may be used in one of two ways. In order to update only one key/value pair, specify them in order:

```shell
salt myminion stormpath.update_account <account_id> givenName shemp
salt myminion stormpath.update_account <account_id> middleName ''
```

In order to specify multiple items, they need to be passed in as a dict. From the command line, it is best to do this as a JSON string:

```shell
salt myminion stormpath.update_account <account_id> items='{"givenName": "Shemp"}"
salt myminion stormpath.update_account <account_id> items='{"middlename": ""}"
```

When executed with no errors, this function will return the information about the account, from Stormpath.

**stormpath.delete_account**

Delete an account from Stormpath.
`salt myminion stormpath.delete_account <account_id>`

`stormpath.list_directories`

Show all directories associated with this tenant.

`salt myminion stormpath.list_directories`

**Using Stormpath States**

Stormpath resources may be managed using the state system. The following states are available.

**stormpath_account.present**

Ensure that an account exists on the Stormpath service. All options that are available with the `stormpath.create_account` function are available here. If an account needs to be created, then this function will require the same fields that `stormpath.create_account` requires, including the password. However, if a password changes for an existing account, it will NOT be updated by this state.

```
curly@example.com:
  stormpath_account.present:
    # directory_id: efreg435fr1786786FREFr
    # password: badpass
    - firstName: Curly
    - surname: Howard
    - nickname: curly
```

It is advisable to always set a nickname that is not also an email address, so that it can be used by Salt's external authentication module.

**stormpath_account.absent**

Ensure that an account does not exist on Stormpath. As with `stormpath_account.present`, the name supplied to this state is the email address associated with this account. Salt will use this, with or without the directory ID that is configured for the minion. However, lookups will be much faster with a directory ID specified.

## 3.5 Salt Virt

### 3.5.1 Salt as a Cloud Controller

In Salt 0.14.0, an advanced cloud control system were introduced, allow private cloud vms to be managed directly with Salt. This system is generally referred to as **Salt Virt**.

The Salt Virt system already exists and is installed within Salt itself; this means that beside setting up Salt, no additional salt code needs to be deployed.

The main goal of Salt Virt is to facilitate a very fast and simple cloud. The cloud that can scale and fully featured. Salt Virt comes with the ability to set up and manage complex virtual machine networking, powerful image, and disk management, as well as virtual machine migration with and without shared storage.
This means that Salt Virt can be used to create a cloud from a blade center and a SAN, but can also create a cloud out of a swarm of Linux Desktops without a single shared storage system. Salt Virt can make clouds from truly commodity hardware, but can also stand up the power of specialized hardware as well.

**Setting up Hypervisors**

The first step to set up the hypervisors involves getting the correct software installed and setting up the hypervisor network interfaces.

**Installing Hypervisor Software**

Salt Virt is made to be hypervisor agnostic but currently the only fully implemented hypervisor is KVM via libvirt. The required software for a hypervisor is libvirt and kvm. For advanced features install libguestfs or qemu-nbd.

*Note:* Libguestfs and qemu-nbd allow for virtual machine images to be mounted before startup and get pre-seeded with configurations and a salt minion

This sls will set up the needed software for a hypervisor, and run the routines to set up the libvirt pki keys.

*Note:* Package names and setup used is Red Hat specific, different package names will be required for different platforms

```
libvirt:
  pkg.installed: []
  file.managed:
    - name: /etc/sysconfig/libvirtd
      contents: "LIBVIRT_ARGS="--listen"
    - require:
        - pkg: libvirt
  libvirt.keys:
    - require:
        - pkg: libvirt
  service.running:
    - name: libvirtd
      require:
        - pkg: libvirt
        - network: br0
        - libvirt: libvirt
      watch:
        - file: libvirt

libvirt-python:
  pkg.installed: []

libguestfs:
  pkg.installed:
    - pkgs:
        - libguestfs
        - libguestfs-tools
```
Hypervisor Network Setup

The hypervisors will need to be running a network bridge to serve up network devices for virtual machines, this formula will set up a standard bridge on a hypervisor connecting the bridge to eth0:

```
eth0:
  network.managed:
    - enabled: True
    - type: eth
    - bridge: br0

br0:
  network.managed:
    - enabled: True
    - type: bridge
    - proto: dhcp
    - require:
      - network: eth0
```

Virtual Machine Network Setup

Salt Virt comes with a system to model the network interfaces used by the deployed virtual machines; by default a single interface is created for the deployed virtual machine and is bridged to br0. To get going with the default networking setup, ensure that the bridge interface named br0 exists on the hypervisor and is bridged to an active network device.

**Note:** To use more advanced networking in Salt Virt, read the *Salt Virt Networking* document:

*Salt Virt Networking*

Libvirt State

One of the challenges of deploying a libvirt based cloud is the distribution of libvirt certificates. These certificates allow for virtual machine migration. Salt comes with a system used to auto deploy these certificates. Salt manages the signing authority key and generates keys for libvirt clients on the master, signs them with the certificate authority and uses pillar to distribute them. This is managed via the `libvirt` state. Simply execute this formula on the minion to ensure that the certificate is in place and up to date:

**Note:** The above formula includes the calls needed to set up libvirt keys.

```
libvirt_keys:
  libvirt.keys
```

Getting Virtual Machine Images Ready

Salt Virt, requires that virtual machine images be provided as these are not generated on the fly. Generating these virtual machine images differs greatly based on the underlying platform.

Virtual machine images can be manually created using KVM and running through the installer, but this process is not recommended since it is very manual and prone to errors.
Virtual Machine generation applications are available for many platforms:

**vm-builder**: [https://wiki.debian.org/VMBuilder](https://wiki.debian.org/VMBuilder)

See also:

- [vmbuilder-formula](https://wiki.debian.org/VMBuilder)

Once virtual machine images are available, the easiest way to make them available to Salt Virt is to place them in the Salt file server. Just copy an image into `/srv/salt` and it can now be used by Salt Virt.

For purposes of this demo, the file name `centos.img` will be used.

### Existing Virtual Machine Images

Many existing Linux distributions distribute virtual machine images which can be used with Salt Virt. Please be advised that NONE OF THESE IMAGES ARE SUPPORTED BY SALTSTACK.

#### CentOS

These images have been prepared for OpenNebula but should work without issue with Salt Virt, only the raw qcow image file is needed: [http://wiki.centos.org/Cloud/OpenNebula](http://wiki.centos.org/Cloud/OpenNebula)

#### Fedora Linux

Images for Fedora Linux can be found here: [http://fedoraproject.org/en/get-fedora#clouds](http://fedoraproject.org/en/get-fedora#clouds)

#### Ubuntu Linux

Images for Ubuntu Linux can be found here: [http://cloud-images.ubuntu.com/](http://cloud-images.ubuntu.com/)

### Using Salt Virt

With hypervisors set up and virtual machine images ready, Salt can start issuing cloud commands.

Start by running a Salt Virt hypervisor info command:

```
salt-run virt.hyper_info
```

This will query what the running hypervisor stats are and display information for all configured hypervisors. This command will also validate that the hypervisors are properly configured.

Now that hypervisors are available a virtual machine can be provisioned. The `virt.init` routine will create a new virtual machine:

```
salt-run virt.init centosl 2 512 salt://centos.img
```

This command assumes that the CentOS virtual machine image is sitting in the root of the Salt fileserver. Salt Virt will now select a hypervisor to deploy the new virtual machine on and copy the virtual machine image down to the hypervisor.

Once the VM image has been copied down the new virtual machine will be seeded. Seeding the VMs involves setting pre-authenticated Salt keys on the new VM and if needed, will install the Salt Minion on the new VM before it is started.
Salt Documentation, Release 2015.8.12

Note: The biggest bottleneck in starting VMs is when the Salt Minion needs to be installed. Making sure that the source VM images already have Salt installed will GREATLY speed up virtual machine deployment.

Now that the new VM has been prepared, it can be seen via the `virt.query` command:

```
salt-run virt.query
```

This command will return data about all of the hypervisors and respective virtual machines.

Now that the new VM is booted it should have contacted the Salt Master, a `test.ping` will reveal if the new VM is running.

Migrating Virtual Machines

Salt Virt comes with full support for virtual machine migration, and using the libvirt state in the above formula makes migration possible.

A few things need to be available to support migration. Many operating systems turn on firewalls when originally set up, the firewall needs to be opened up to allow for libvirt and kvm to cross communicate and execution migration routines. On Red Hat based hypervisors in particular port 16514 needs to be opened on hypervisors:

```
iptables -A INPUT -m state --state NEW -m tcp -p tcp --dport 16514 -j ACCEPT
```

Note: More in-depth information regarding distribution specific firewall settings can read in:

*Opening the Firewall up for Salt*

Salt also needs an additional flag to be turned on as well. The `virt.tunnel` option needs to be turned on. This flag tells Salt to run migrations securely via the libvirt TLS tunnel and to use port 16514. Without `virt.tunnel` libvirt tries to bind to random ports when running migrations. To turn on `virt.tunnel` simple apply it to the master config file:

```
virt.tunnel: True
```

Once the master config has been updated, restart the master and send out a call to the minions to refresh the pillar to pick up on the change:

```
salt \* saltutil.refresh_modules
```

Now, migration routines can be run! To migrate a VM, simply run the Salt Virt migrate routine:

```
salt-run virt.migrate centos <new hypervisor>
```

VNC Consoles

Salt Virt also sets up VNC consoles by default, allowing for remote visual consoles to be oped up. The information from a `virt.query` routine will display the vnc console port for the specific vms:

```
centos
  CPU: 2
  Memory: 524288
  State: running
```

3.5. Salt Virt
The line *Graphics: vnc - hyper6:5900* holds the key. First the port named, in this case 5900, will need to be available in the hypervisor’s firewall. Once the port is open, then the console can be easily opened via vncviewer:

```
vncviewer hyper6:5900
```

By default there is no VNC security set up on these ports, which suggests that keeping them firewalled and mandating that SSH tunnels be used to access these VNC interfaces. Keep in mind that activity on a VNC interface that is accessed can be viewed by any other user that accesses that same VNC interface, and any other user logging in can also operate with the logged in user on the virtual machine.

**Conclusion**

Now with Salt Virt running, new hypervisors can be seamlessly added just by running the above states on new bare metal machines, and these machines will be instantly available to Salt Virt.

### 3.6 LXC

### 3.7 ESXi Proxy Minion

#### 3.7.1 ESXi Proxy Minion

New in version 2015.8.4.

**Note:** This tutorial assumes basic knowledge of Salt. To get up to speed, check out the [Salt Walkthrough](#).

This tutorial also assumes a basic understanding of Salt Proxy Minions. If you’re unfamiliar with Salt’s Proxy Minion system, please read the [Salt Proxy Minion](#) documentation and the [Salt Proxy Minion End-to-End Example](#) tutorial.

The third assumption that this tutorial makes is that you also have a basic understanding of ESXi hosts. You can learn more about ESXi hosts on [VMware’s various resources](#).

Salt’s ESXi Proxy Minion allows a VMware ESXi host to be treated as an individual Salt Minion, without installing a Salt Minion on the ESXi host.

Since an ESXi host may not necessarily run on an OS capable of hosting a Python stack, the ESXi host can’t run a regular Salt Minion directly. Therefore, Salt’s Proxy Minion functionality enables you to designate another machine to host a proxy process that ‘`proxies’” communication from the Salt Master to the ESXi host. The master does not know or care that the ESXi target is not a ‘`real’” Salt Minion.

More in-depth conceptual reading on Proxy Minions can be found in the [Proxy Minion](#) section of Salt’s documentation.

Salt’s ESXi Proxy Minion was added in the 2015.8.4 release of Salt.
Note: Be aware that some functionality for the ESXi Proxy Minion may depend on the type of license attached the ESXi host(s).

For example, certain services are only available to manipulate service state or policies with a VMware vSphere Enterprise or Enterprise Plus license, while others are available with a Standard license. The `ntpd` service is restricted to an Enterprise Plus license, while `ssh` is available via the Standard license.

Please see the vSphere Comparison page for more information.

**Dependencies**

Manipulation of the ESXi host via a Proxy Minion requires the machine running the Proxy Minion process to have the ESXCLI package (and all of it’s dependencies) and the pyVmomi Python Library to be installed.

**ESXi Password**

The ESXi Proxy Minion uses VMware's API to perform tasks on the host as if it was a regular Salt Minion. In order to access the API that is already running on the ESXi host, the ESXi host must have a username and password that is used to log into the host. The username is usually `root`. Before Salt can access the ESXi host via VMware's API, a default password *must* be set on the host.

**pyVmomi**

The pyVmomi Python library must be installed on the machine that is running the proxy process. pyVmomi can be installed via pip:

```
pip install pyVmomi
```

Note: Version 6.0 of pyVmomi has some problems with SSL error handling on certain versions of Python. If using version 6.0 of pyVmomi, the machine that you are running the proxy minion process from must have either Python 2.6, Python 2.7.9, or newer. This is due to an upstream dependency in pyVmomi 6.0 that is not supported in Python version 2.7 to 2.7.8. If the version of Python running the proxy process is not in the supported range, you will need to install an earlier version of pyVmomi. See Issue #29537 for more information.

Based on the note above, to install an earlier version of pyVmomi than the version currently listed in PyPi, run the following:

```
pip install pyVmomi==5.5.0.2014.1.1
```

The 5.5.0.2014.1.1 is a known stable version that the original ESXi Proxy Minion was developed against.

**ESXCLI**

Currently, about a third of the functions used for the ESXi Proxy Minion require the ESXCLI package be installed on the machine running the Proxy Minion process.

The ESXCLI package is also referred to as the VMware vSphere CLI, or vCLI. VMware provides vCLI package installation instructions for vSphere 5.5 and vSphere 6.0.
Once all of the required dependencies are in place and the vCLI package is installed, you can check to see if you can connect to your ESXi host by running the following command:

```
esxcli -s <host-location> -u <username> -p <password> system syslog config get
```

If the connection was successful, ESXCLI was successfully installed on your system. You should see output related to the ESXi host’s syslog configuration.

**Configuration**

There are several places where various configuration values need to be set in order for the ESXi Proxy Minion to run and connect properly.

**Proxy Config File**

On the machine that will be running the Proxy Minion process(es), a proxy config file must be in place. This file should be located in the `/etc/salt/` directory and should be named `proxy`. If the file is not there by default, create it.

This file should contain the location of your Salt Master that the Salt Proxy will connect to.

**Note:** If you’re running your ESXi Proxy Minion on version of Salt that is 2015.8.4 or newer, you also need to set `add_proxymodule_to_opts: False` in your proxy config file. The need to specify this configuration will be removed with Salt Boron, the next major feature release. See the [New in 2015.8.2](#) section of the Proxy Minion documentation for more information.

**Example Proxy Config File:**

```
# /etc/salt/proxy
master: <salt-master-location>
add_proxymodule_to_opts: False
```

**Pillar Profiles**

Proxy minions get their configuration from Salt’s Pillar. Every proxy must have a stanza in Pillar and a reference in the Pillar top-file that matches the Proxy ID. At a minimum for communication with the ESXi host, the pillar should look like this:

```
proxy:
    proxytype: esxi
    host: <ip or dns name of esxi host>
    username: <ESXi username>
    passwords:
        - first_password
        - second_password
        - third_password
```

Some other optional settings are `protocol` and `port`. These can be added to the pillar configuration.
proxytype

The **proxytype** key and value pair is critical, as it tells Salt which interface to load from the **proxy** directory in Salt's install hierarchy, or from /srv/salt/_proxy on the Salt Master (if you have created your own proxy module, for example). To use this ESXi Proxy Module, set this to **esxi**.

host

The location, or ip/dns, of the ESXi host. Required.

username

The username used to login to the ESXi host, such as **root**. Required.

passwords

A list of passwords to be used to try and login to the ESXi host. At least one password in this list is required.

The proxy integration will try the passwords listed in order. It is configured this way so you can have a regular password and the password you may be updating for an ESXi host either via the `vsphere.update_host_password` execution module function or via the `esxi.password_present` state function. This way, after the password is changed, you should not need to restart the proxy minion—it should just pick up the the new password provided in the list. You can then change pillar at will to move that password to the front and retire the unused ones.

Use-case/reasoning for using a list of passwords: You are setting up an ESXi host for the first time, and the host comes with a default password. You know that you’ll be changing this password during your initial setup from the default to a new password. If you only have one password option, and if you have a state changing the password, any remote execution commands or states that run after the password change will not be able to run on the host until the password is updated in Pillar and the Proxy Minion process is restarted.

This allows you to use any number of potential fallback passwords.

Note: When a password is changed on the host to one in the list of possible passwords, the further down on the list the password is, the longer individual commands will take to return. This is due to the nature of pyVmomi’s login system. We have to wait for the first attempt to fail before trying the next password on the list.

This scenario is especially true, and even slower, when the proxy minion first starts. If the correct password is not the first password on the list, it may take up to a minute for `test.ping` to respond with a **True** result. Once the initial authorization is complete, the responses for commands will be a little faster.

To avoid these longer waiting periods, SaltStack recommends moving the correct password to the top of the list and restarting the proxy minion at your earliest convenience.

protocol

If the ESXi host is not using the default protocol, set this value to an alternate protocol. Default is **https**. For example:
port

If the ESXi host is not using the default port, set this value to an alternate port. Default is 443.

Example Configuration Files

An example of all of the basic configurations that need to be in place before starting the Proxy Minion processes includes the Proxy Config File, Pillar Top File, and any individual Proxy Minion Pillar files.

In this example, we'll assuming there are two ESXi hosts to connect to. Therefore, we'll be creating two Proxy Minion config files, one config for each ESXi host.

Proxy Config File:

```
# /etc/salt/proxy
master: <salt-master-location>
add_proxymodule_to_opts: False
```

Pillar Top File:

```
# /srv/pillar/top.sls

base:
  'esxi-1':
    - esxi-1
  'esxi-2':
    - esxi-2
```

Pillar Config File for the first ESXi host, esxi-1:

```
# /srv/pillar/esxi-1.sls

proxy:
  proxytype: esxi
  host: esxi-1.example.com
  username: 'root'
  passwords:
    - bad-password-1
    - backup-bad-password-1
```

Pillar Config File for the second ESXi host, esxi-2:

```
# /srv/pillar/esxi-2.sls

proxy:
  proxytype: esxi
  host: esxi-2.example.com
  username: 'root'
  passwords:
    - bad-password-2
    - backup-bad-password-2
```

Starting the Proxy Minion

Once all of the correct configuration files are in place, it is time to start the proxy processes!
1. First, make sure your Salt Master is running.

2. Start the first Salt Proxy, in debug mode, by giving the Proxy Minion process and ID that matches the config file name created in the Configuration section.

```
salt-proxy --proxyid='esxi-1' -l debug
```

1. Accept the `esxi-1` Proxy Minion's key on the Salt Master:

```
# salt-key -L
Accepted Keys:
Denied Keys:
Unaccepted Keys:
    esxi-1
Rejected Keys:
#
# salt-key -a esxi-1
The following keys are going to be accepted:
Unaccepted Keys:
    esxi-1
Proceed? [n/Y] y
Key for minion esxi-1 accepted.
```

1. Repeat for the second Salt Proxy, this time we'll run the proxy process as a daemon, as an example.

```
salt-proxy --proxyid='esxi-2' -d
```

1. Accept the `esxi-2` Proxy Minion's key on the Salt Master:

```
# salt-key -L
Accepted Keys:
esxi-1
Denied Keys:
Unaccepted Keys:
esxi-2
Rejected Keys:
#
# salt-key -a esxi-1
The following keys are going to be accepted:
Unaccepted Keys:
esxi-2
Proceed? [n/Y] y
Key for minion esxi-1 accepted.
```

1. Check and see if your Proxy Minions are responding:

```
# salt 'esxi-*' test.ping
esxi-1:
    True
esxi-3:
    True
```

**Executing Commands**

Now that you've configured your Proxy Minions and have them responding successfully to a `test.ping`, we can start executing commands against the ESXi hosts via Salt.
It’s important to understand how this particular proxy works, and there are a couple of important pieces to be aware of in order to start running remote execution and state commands against the ESXi host via a Proxy Minion: the vSphere Execution Module, the ESXi Execution Module, and the ESXi State Module.

vSphere Execution Module

The Salt.modules.vsphere is a standard Salt execution module that does the bulk of the work for the ESXi Proxy Minion. If you pull up the docs for it you’ll see that almost every function in the module takes credentials (username and password) and a target host argument. When credentials and a host aren’t passed, Salt runs commands through pyVmomi or ESXCLI against the local machine. If you wanted, you could run functions from this module on any machine where an appropriate version of pyVmomi and ESXCLI are installed, and that machine would reach out over the network and communicate with the ESXi host.

You’ll notice that most of the functions in the vSphere module require a host, username, and password. These parameters are contained in the Pillar files and passed through to the function via the proxy process that is already running. You don’t need to provide these parameters when you execute the commands. See the Running Remote Execution Commands section below for an example.

ESXi Execution Module

In order for the Pillar information set up in the Configuration section above to be passed to the function call in the vSphere Execution Module, the salt.modules.esxi execution module acts as a “shim” between the vSphere execution module functions and the proxy process.

The “shim” takes the authentication credentials specified in the Pillar files and passes them through to the host, username, password, and optional protocol and port options required by the vSphere Execution Module functions.

If the function takes more positional, or keyword, arguments you can append them to the call. It’s this shim that speaks to the ESXi host through the proxy, arranging for the credentials and hostname to be pulled from the Pillar section for the ESXi Proxy Minion.

Because of the presence of the shim, to lookup documentation for what functions you can use to interface with the ESXi host, you’ll want to look in salt.modules.vsphere instead of salt.modules.esxi.

Running Remote Execution Commands

To run commands from the Salt Master to execute, via the ESXi Proxy Minion, against the ESXi host, you use the esxi.cmd <vsphere-function-name> syntax to call functions located in the vSphere Execution Module. Both args and kwargs needed for various vsphere execution module functions must be passed through in a kwarg-type manner. For example:

```
salt 'esxi-*' esxi.cmd system_info
salt 'esxi-*' esxi.cmd get_service_running service_name='ssh'
```

ESXi State Module

The ESXi State Module functions similarly to other state modules. The “shim” provided by the ESXi Execution Module passes the necessary host, username, and password credentials through, so those options don’t need to be provided in the state. Other than that, state files are written and executed just like any other Salt state. See the salt.modules.esxi state for ESXi state functions.
The follow state file is an example of how to configure various pieces of an ESXi host including enabling SSH, uploading and SSH key, configuring a coredump network config, syslog, ntp, enabling VMotion, resetting a host password, and more.

```
# /srv/salt/configure-esxi.sls

configure-host-ssh:
  esxi.ssh_configured:
    - service_running: True
    - ssh_key_file: /etc/salt/ssh_keys/my_key.pub
    - service_policy: 'automatic'
    - service_restart: True
    - certificate_verify: True

configure-host-coredump:
  esxi.coredump_configured:
    - enabled: True
    - dump_ip: 'my-coredump-ip.example.com'

configure-host-syslog:
  esxi.syslog_configured:
    - syslog_configs:
      default-timeout: 120
    - firewall: True
    - reset_service: True
    - reset_syslog_config: True
    - reset_configs: loghost,default-timeout

configure-host-ntp:
  esxi.ntp_configured:
    - service_running: True
    - ntp_servers:
      - 192.174.1.100
      - 192.174.1.200
    - service_policy: 'automatic'
    - service_restart: True

configure-vmotion:
  esxi.vmotion_configured:
    - enabled: True

configure-host-vsan:
  esxi.vsan_configured:
    - enabled: True
    - add_disks_to_vsan: True

configure-host-password:
  esxi.password_present:
    - password: 'new-bad-password'
```

States are called via the ESXi Proxy Minion just as they would on a regular minion. For example:

```
salt 'esxi-*' state.sls configure-esxi test=true
salt 'esxi-*' state.sls configure-esxi
```
3.8 Using Salt at scale

3.8.1 Using Salt at scale

The focus of this tutorial will be building a Salt infrastructure for handling large numbers of minions. This will include tuning, topology, and best practices.

For how to install the Salt Master please go here: Installing saltstack

Note: This tutorial is intended for large installations, although these same settings won’t hurt, it may not be worth the complexity to smaller installations.

When used with minions, the term ‘many’ refers to at least a thousand and ‘a few’ always means 500.

For simplicity reasons, this tutorial will default to the standard ports used by Salt.

The Master

The most common problems on the Salt Master are:

1. too many minions authing at once
2. too many minions re-authing at once
3. too many minions re-connecting at once
4. too many minions returning at once
5. too few resources (CPU/HDD)

The first three are all ‘thundering herd’ problems. To mitigate these issues we must configure the minions to back-off appropriately when the Master is under heavy load.

The fourth is caused by masters with little hardware resources in combination with a possible bug in ZeroMQ. At least that’s what it looks like till today (Issue 118651, Issue 5948, Mail thread)

To fully understand each problem, it is important to understand, how Salt works.

Very briefly, the Salt Master offers two services to the minions.

- a job publisher on port 4505
- an open port 4506 to receive the minions returns

All minions are always connected to the publisher on port 4505 and only connect to the open return port 4506 if necessary. On an idle Master, there will only be connections on port 4505.
Too many minions authing

When the Minion service is first started up, it will connect to its Master’s publisher on port 4505. If too many minions are started at once, this can cause a `‘thundering herd’`. This can be avoided by not starting too many minions at once.

The connection itself usually isn’t the culprit, the more likely cause of master-side issues is the authentication that the Minion must do with the Master. If the Master is too heavily loaded to handle the auth request it will time it out. The Minion will then wait \texttt{acceptance_wait_time} to retry. If \texttt{acceptance_wait_time_max} is set then the Minion will increase its wait time by the \texttt{acceptance_wait_time} each subsequent retry until reaching \texttt{acceptance_wait_time_max}.

Too many minions re-authing

This is most likely to happen in the testing phase of a Salt deployment, when all Minion keys have already been accepted, but the framework is being tested and parameters are frequently changed in the Salt Master’s configuration file(s).

The Salt Master generates a new AES key to encrypt its publications at certain events such as a Master restart or the removal of a Minion key. If you are encountering this problem of too many minions re-authing against the Master, you will need to recalibrate your setup to reduce the rate of events like a Master restart or Minion key removal (\texttt{salt-key -d}).

When the Master generates a new AES key, the minions aren’t notified of this but will discover it on the next pub job they receive. When the Minion receives such a job it will then re-auth with the Master. Since Salt does minion-side filtering this means that all the minions will re-auth on the next command published on the master—causing another `‘thundering herd’`. This can be avoided by setting the

\begin{verbatim}
random_reauth_delay: 60
\end{verbatim}

in the minions configuration file to a higher value and stagger the amount of re-auth attempts. Increasing this value will of course increase the time it takes until all minions are reachable via Salt commands.

Too many minions re-connecting

By default the zmq socket will re-connect every 100ms which for some larger installations may be too quick. This will control how quickly the TCP session is re-established, but has no bearing on the auth load.

To tune the minions sockets reconnect attempts, there are a few values in the sample configuration file (default values)

\begin{verbatim}
recon_default: 1000
recon_max: 5000
recon_randomize: True
\end{verbatim}

- \texttt{recon_default}: the default value the socket should use, i.e. 1000. This value is in milliseconds. (1000ms = 1 second)
- \texttt{recon_max}: the max value that the socket should use as a delay before trying to reconnect This value is in milliseconds. (5000ms = 5 seconds)
- \texttt{recon_randomize}: enables randomization between \texttt{recon_default} and \texttt{recon_max}

To tune this values to an existing environment, a few decision have to be made.

1. How long can one wait, before the minions should be online and reachable via Salt?
2. How many reconnects can the Master handle without a syn flood?
These questions can not be answered generally. Their answers depend on the hardware and the administrators requirements.

Here is an example scenario with the goal, to have all minions reconnect within a 60 second time-frame on a Salt Master service restart.

```
recon_default: 1000
recon_max: 59000
recon_randomize: True
```

Each Minion will have a randomized reconnect value between `recon_default' and `recon_default + recon_max', which in this example means between 1000ms and 60000ms (or between 1 and 60 seconds). The generated random-value will be doubled after each attempt to reconnect (ZeroMQ default behavior).

Lets say the generated random value is 11 seconds (or 11000ms).

```
reconnect 1: wait 11 seconds
reconnect 2: wait 22 seconds
reconnect 3: wait 33 seconds
reconnect 4: wait 44 seconds
reconnect 5: wait 55 seconds
reconnect 6: wait time is bigger than 60 seconds (recon_default + recon_max)
reconnect 7: wait 11 seconds
reconnect 8: wait 22 seconds
reconnect 9: wait 33 seconds
reconnect x: etc.
```

With a thousand minions this will mean

\[
1000/60 = \sim 16
\]

round about 16 connection attempts a second. These values should be altered to values that match your environment. Keep in mind though, that it may grow over time and that more minions might raise the problem again.

**Too many minions returning at once**

This can also happen during the testing phase, if all minions are addressed at once with

```
$ salt * disk.usage
```

it may cause thousands of minions trying to return their data to the Salt Master open port 4506. Also causing a flood of syn-flood if the Master can't handle that many returns at once.

This can be easily avoided with Salt's batch mode:

```
$ salt * disk.usage -b 50
```

This will only address 50 minions at once while looping through all addressed minions.

**Too few resources**

The masters resources always have to match the environment. There is no way to give good advise without knowing the environment the Master is supposed to run in. But here are some general tuning tips for different situations:
The Master is CPU bound

Salt uses RSA-Key-Pairs on the masters and minions end. Both generate 4096 bit key-pairs on first start. While the key-size for the Master is currently not configurable, the minions keysize can be configured with different key-sizes. For example with a 2048 bit key:

```
keysize: 2048
```

With thousands of decryptions, the amount of time that can be saved on the masters end should not be neglected. See here for reference: Pull Request 9235 how much influence the key-size can have.

 Downsizing the Salt Master’s key is not that important, because the minions do not encrypt as many messages as the Master does.

 In installations with large or with complex pillar files, it is possible for the master to exhibit poor performance as a result of having to render many pillar files at once. This exhibit itself in a number of ways, both as high load on the master and on minions which block on waiting for their pillar to be delivered to them.

 To reduce pillar rendering times, it is possible to cache pillars on the master. To do this, see the set of master configuration options which are prefixed with `pillar_cache`.

**Note:** Caching pillars on the master may introduce security considerations. Be certain to read caveats outlined in the master configuration file to understand how pillar caching may affect a master’s ability to protect sensitive data!

The Master is disk IO bound

By default, the Master saves every Minion’s return for every job in its job-cache. The cache can then be used later, to lookup results for previous jobs. The default directory for this is:

```
cachedir: /var/cache/salt
```

and then in the `/proc` directory.

Each job return for every Minion is saved in a single file. Over time this directory can grow quite large, depending on the number of published jobs. The amount of files and directories will scale with the number of jobs published and the retention time defined by

```
keep_jobs: 24
```

250 jobs/day * 2000 minions returns = 500,000 files a day

If no job history is needed, the job cache can be disabled:

```
job_cache: False
```

If the job cache is necessary there are (currently) 2 options:

- `ext_job_cache`: this will have the minions store their return data directly into a returner (not sent through the Master)
- `master_job_cache` (New in 2014.7.0): this will make the Master store the job data using a returner (instead of the local job cache on disk).
Targeting Minions

Targeting minions is specifying which minions should run a command or execute a state by matching against hostnames, or system information, or defined groups, or even combinations thereof.

For example the command `salt web1 apache.signal restart` to restart the Apache httpd server specifies the machine `web1` as the target and the command will only be run on that one minion.

Similarly when using States, the following `top file` specifies that only the `web1` minion should execute the contents of `webserver.sls`:

```
base:
  'web1':
    - webserver
```

There are many ways to target individual minions or groups of minions in Salt:

### 4.1 Matching the minion id

Each minion needs a unique identifier. By default when a minion starts for the first time it chooses its FQDN (fully qualified domain name) as that identifier. The minion id can be overridden via the minion's `id` configuration setting.

**Tip:** minion id and minion keys

The `minion id` is used to generate the minion's public/private keys and if it ever changes the master must then accept the new key as though the minion was a new host.

**4.1.1 Globbing**

The default matching that Salt utilizes is `shell-style globbing` around the `minion id`. This also works for states in the `top file`.

**Note:** You must wrap `salt` calls that use globbing in single-quotes to prevent the shell from expanding the globs before Salt is invoked.

Match all minions:
salt '*' test.ping

Match all minions in the example.net domain or any of the example domains:

salt '*.example.net' test.ping
salt '*.example.*' test.ping

Match all the webN minions in the example.net domain (web1.example.net, web2.example.net ... webN.example.net):

salt 'web?.example.net' test.ping

Match the web1 through web5 minions:

salt 'web[1-5]' test.ping

Match the web1 and web3 minions:

salt 'web[1,3]' test.ping

Match the web-x, web-y, and web-z minions:

salt 'web-[x-z]' test.ping

Note: For additional targeting methods please review the compound matchers documentation.

### 4.1.2 Regular Expressions

Minions can be matched using Perl-compatible regular expressions (which is globbing on steroids and a ton of caffeine).

Match both web1-prod and web1-devel minions:

salt -E 'web1-(prod|devel)' test.ping

When using regular expressions in a State's top file, you must specify the matcher as the first option. The following example executes the contents of webserver.sls on the above-mentioned minions.

base:
  'web1-(prod|devel)':
    - match: pcre
    - webserver

### 4.1.3 Lists

At the most basic level, you can specify a flat list of minion IDs:

salt -L 'web1,web2,web3' test.ping
4.2 Grains

Salt comes with an interface to derive information about the underlying system. This is called the grains interface, because it presents salt with grains of information. Grains are collected for the operating system, domain name, IP address, kernel, OS type, memory, and many other system properties.

The grains interface is made available to Salt modules and components so that the right salt minion commands are automatically available on the right systems.

Grain data is relatively static, though if system information changes (for example, if network settings are changed), or if a new value is assigned to a custom grain, grain data is refreshed.

**Note:** Grains resolve to lowercase letters. For example, `FOO`, and `foo` target the same grain.

**Important:** See *Is Targeting using Grain Data Secure?* for important security information.

Match all CentOS minions:

```
salt -G 'os:CentOS' test.ping
```

Match all minions with 64-bit CPUs, and return number of CPU cores for each matching minion:

```
salt -G 'cpuarch:x86_64' grains.item num_cpus
```

Additionally, globs can be used in grain matches, and grains that are nested in a dictionary can be matched by adding a colon for each level that is traversed. For example, the following will match hosts that have a grain called `ec2_tags`, which itself is a dict with a key named `environment`, which has a value that contains the word `production`:

```
salt -G 'ec2_tags:environment:*production*' 
```

4.2.1 Listing Grains

Available grains can be listed by using the `grains.ls` module:

```
salt '*' grains.ls
```

Grains data can be listed by using the `grains.items` module:

```
salt '*' grains.items
```

4.2.2 Grains in the Minion Config

Grains can also be statically assigned within the minion configuration file. Just add the option `grains` and pass options to it:

```
grains:
    roles:
    - webserver
    - memcache
    deployment: datacenter4
```
Then status data specific to your servers can be retrieved via Salt, or used inside of the State system for matching. It also makes targeting, in the case of the example above, simply based on specific data about your deployment.

### 4.2.3 Grains in /etc/salt/grains

If you do not want to place your custom static grains in the minion config file, you can also put them in /etc/salt/grains on the minion. They are configured in the same way as in the above example, only without a top-level grains: key:

```yaml
roles:
  - webserver
  - memcache
deployment: datacenter4
cabinet: 13
cab_u: 14-15
```

### 4.2.4 Matching Grains in the Top File

With correctly configured grains on the Minion, the top file used in Pillar or during Highstate can be made very efficient. For example, consider the following configuration:

```yaml
'node_type:webserver':
  - match: grain
    - webserver

'node_type:postgres':
  - match: grain
    - postgres

'node_type:redis':
  - match: grain
    - redis

'node_type:lb':
  - match: grain
    - lb
```

For this example to work, you would need to have defined the grain node_type for the minions you wish to match. This simple example is nice, but too much of the code is similar. To go one step further, Jinja templating can be used to simplify the top file.

```template
{% set the_node_type = salt['grains.get']('node_type', '') %}

{% if the_node_type %}
'node_type:{{ the_node_type }}':
  - match: grain
    - {{ the_node_type }}
{% endif %}
```

Using Jinja templating, only one match entry needs to be defined.
Note: The example above uses the `grains.get` function to account for minions which do not have the `node_type` grain set.

### 4.2.5 Writing Grains

The grains interface is derived by executing all of the `public` functions found in the modules located in the grains package or the custom grains directory. The functions in the modules of the grains must return a Python `dict`, where the keys in the `dict` are the names of the grains and the values are the values.

Custom grains should be placed in a `_grains` directory located under the `file_roots` specified by the master config file. The default path would be `/srv/salt/_grains`. Custom grains will be distributed to the minions when `state.apply` is run, or by executing the `saltutil.sync_grains` or `saltutil.sync_all` functions.

Grains are easy to write, and only need to return a dictionary. A common approach would be code something similar to the following:

```python
#!/usr/bin/env python

def yourfunction():
    # initialize a grains dictionary
    grains = {}
    # Some code for logic that sets grains like
    grains['yourcustomgrain'] = True
    grains['anothergrain'] = 'somevalue'
    return grains
```

Before adding a grain to Salt, consider what the grain is and remember that grains need to be static data. If the data is something that is likely to change, consider using Pillar instead.

**Warning:** Custom grains will not be available in the top file until after the first highstate. To make custom grains available on a minion's first highstate, it is recommended to use this example to ensure that the custom grains are synced when the minion starts.

### Loading Custom Grains

If you have multiple functions specifying grains that are called from a `main` function, be sure to prepend grain function names with an underscore. This prevents Salt from including the loaded grains from the grain functions in the final grain data structure. For example, consider this custom grain file:

```python
#!/usr/bin/env python

def _my_custom_grain():
    my_grain = {'foo': 'bar', 'hello': 'world'}
    return my_grain

def main():
    # initialize a grains dictionary
    grains = {}
    grains['my_grains'] = _my_custom_grain()
    return grains
```

The output of this example renders like so:
# salt-call --local grains.items
local:
    --------
    <Snipped for brevity>
    my_grains:
    --------
    foo:
    bar
    hello:
    world

However, if you don't prepend the my_custom_grain function with an underscore, the function will be rendered twice by Salt in the items output: once for the my_custom_grain call itself, and again when it is called in the main function:

# salt-call --local grains.items
local:
    --------
    <Snipped for brevity>
    foo:
    bar
    <Snipped for brevity>
    hello:
    world
    <Snipped for brevity>
    my_grains:
    --------
    foo:
    bar
    hello:
    world

## 4.2.6 Precedence

Core grains can be overridden by custom grains. As there are several ways of defining custom grains, there is an order of precedence which should be kept in mind when defining them. The order of evaluation is as follows:

1. Core grains.
2. Custom grains in /etc/salt/grains.
3. Custom grains in /etc/salt/minion.
4. Custom grain modules in _grains directory, synced to minions.

Each successive evaluation overrides the previous ones, so any grains defined by custom grains modules synced to minions that have the same name as a core grain will override that core grain. Similarly, grains from /etc/salt/minion override both core grains and custom grain modules, and grains in _grains will override any grains of the same name.

## 4.2.7 Examples of Grains

The core module in the grains package is where the main grains are loaded by the Salt minion and provides the principal example of how to write grains:

https://github.com/saltstack/salt/blob/develop/salt/grains/core.py
4.2.8 Syncing Grains

Syncing grains can be done in a number of ways, they are automatically synced when `state.apply` is called, or (as noted above) the grains can be manually synced and reloaded by calling the `saltutil.sync_grains` or `saltutil.sync_all` functions.

4.3 Targeting with Pillar

Pillar data can be used when targeting minions. This allows for ultimate control and flexibility when targeting minions.

**Note:** To start using Pillar targeting it is required to make a Pillar data cache on Salt Master for each Minion via following commands: `salt '*' saltutil.refresh_pillar` or `salt '*' saltutil.sync_all`. Also Pillar data cache will be populated during the `highstate` run. Once Pillar data changes, you must refresh the cache by running above commands for this targeting method to work correctly.

Example:

```
salt -I 'somekey:specialvalue' test.ping
```

Like with Grains, it is possible to use globbing as well as match nested values in Pillar, by adding colons for each level that is being traversed. The below example would match minions with a pillar named `foo`, which is a dict containing a key `bar`, with a value beginning with `baz`:

```
salt -I 'foo:bar:baz*' test.ping
```

4.4 Subnet/IP Address Matching

Minions can easily be matched based on IP address, or by subnet (using CIDR notation).

```
salt -S 192.168.40.20 test.ping
salt -S 10.0.0.0/24 test.ping
```

Ipcidr matching can also be used in compound matches

```
salt -C 'S@10.0.0.0/24 and G@os:Debian' test.ping
```

It is also possible to use in both pillar and state-matching

```
'172.16.0.0/12':
  - match: ipcidr
  - internal
```

**Note:** Only IPv4 matching is supported at this time.
4.5 Compound matchers

Compound matchers allow very granular minion targeting using any of Salt’s matchers. The default matcher is a glob match, just as with CLI and top file matching. To match using anything other than a glob, prefix the match string with the appropriate letter from the table below, followed by an @ sign.

<table>
<thead>
<tr>
<th>Letter</th>
<th>Match Type</th>
<th>Example</th>
<th>Alt Delimiter?</th>
</tr>
</thead>
<tbody>
<tr>
<td>G</td>
<td>Grains glob</td>
<td>G@os:Ubuntu</td>
<td>Yes</td>
</tr>
<tr>
<td>E</td>
<td>PCRE Minion ID</td>
<td>E@web\d+.(dev</td>
<td>qa</td>
</tr>
<tr>
<td>P</td>
<td>Grains PCRE</td>
<td>P@os:(RedHat</td>
<td>Fedora</td>
</tr>
<tr>
<td>L</td>
<td>List of minions</td>
<td><a href="mailto:L@minion1.example.com">L@minion1.example.com</a>,minion3.domain.com or bl*.domain.com</td>
<td>No</td>
</tr>
<tr>
<td>I</td>
<td>Pillar glob</td>
<td>I@pdata:foobar</td>
<td>Yes</td>
</tr>
<tr>
<td>J</td>
<td>Pillar PCRE</td>
<td>J@pdata:^(foo</td>
<td>bar)$</td>
</tr>
<tr>
<td>S</td>
<td>Subnet/IP address</td>
<td>S@192.168.1.0/24 or S@192.168.1.100</td>
<td>No</td>
</tr>
<tr>
<td>R</td>
<td>Range cluster</td>
<td>R@%foo.bar</td>
<td>No</td>
</tr>
</tbody>
</table>

Matchers can be joined using boolean and, or, and not operators.

For example, the following string matches all Debian minions with a hostname that begins with webserv, as well as any minions that have a hostname which matches the regular expression web-dc1-srv.*:

```
salt -C 'webserv* and G@os:Debian or E@web-dc1-srv.*' test.ping
```

That same example expressed in a top file looks like the following:

```
base:
   'webserv* and G@os:Debian or E@web-dc1-srv.*':
     - match: compound
     - webserver
```

New in version 2015.8.0.

Excluding a minion based on its ID is also possible:

```
salt -C 'not web-dc1-srv' test.ping
```

Versions prior to 2015.8.0 a leading not was not supported in compound matches. Instead, something like the following was required:

```
salt -C '\* and not G@kernel:Dartarin' test.ping
```

Excluding a minion based on its ID was also possible:

```
salt -C '\* and not web-dc1-srv' test.ping
```

4.5.1 Precedence Matching

Matchers can be grouped together with parentheses to explicitly declare precedence amongst groups.

```
salt -C '( ms-1 or G@id:ms-3 ) and G@id:ms-3' test.ping
```
Note: Be certain to note that spaces are required between the parentheses and targets. Failing to obey this rule may result in incorrect targeting!

### 4.5.2 Alternate Delimiters

New in version 2015.8.0.

Matchers that target based on a key value pair use a colon (:) as a delimiter. Matchers with a Yes in the Alt Delimiters column in the previous table support specifying an alternate delimiter character.

This is done by specifying an alternate delimiter character between the leading matcher character and the @ pattern separator character. This avoids incorrect interpretation of the pattern in the case that : is part of the grain or pillar data structure traversal.

```bash
salt -C 'J|@foo|bar|^foo:bar$ or J|gitrepolhttps://github.com:example/project.git' Ø
--test.ping
```

### 4.6 Node groups

Nodegroups are declared using a compound target specification. The compound target documentation can be found [here](#).

The `nodegroups` master config file parameter is used to define nodegroups. Here's an example nodegroup configuration within `/etc/salt/master`:

```
nodegroups:
  group1: 'L@foo.domain.com,bar.domain.com,baz.domain.com or bl*.domain.com'
  group2: 'G@os:Debian and foo.domain.com'
  group3: 'G@os:Debian and N@group1'
  group4:
    - 'G@foo:bar'
    - 'or'
    - 'G@foo:baz'
```

Note: The L within group1 is matching a list of minions, while the G in group2 is matching specific grains. See the compound matchers documentation for more details.

New in version 2015.8.0.

Note: Nodegroups can reference other nodegroups as seen in group3. Ensure that you do not have circular references. Circular references will be detected and cause partial expansion with a logged error message.

New in version 2015.8.0.

Compound nodegroups can be either string values or lists of string values. When the nodegroup is A string value will be tokenized by splitting on whitespace. This may be a problem if whitespace is necessary as part of a pattern. When a nodegroup is a list of strings then tokenization will happen for each list element as a whole.

To match a nodegroup on the CLI, use the `-N` command-line option:

### 4.6. Node groups
salt -N group1 test.ping

Note: The N@ classifier cannot be used in compound matches within the CLI or top file, it is only recognized in the nodegroups master config file parameter.

To match a nodegroup in your top file, make sure to put `-match: nodegroup` on the line directly following the nodegroup name.

```
base:
  group1:
    - match: nodegroup
    - webserver
```

Note: When adding or modifying nodegroups to a master configuration file, the master must be restarted for those changes to be fully recognized.

A limited amount of functionality, such as targeting with -N from the command-line may be available without a restart.

### 4.6.1 Using Nodegroups in SLS files

To use Nodegroups in Jinja logic for SLS files, the `pillar_opts` option in `/etc/salt/master` must be set to `'True'`. This will pass the master’s configuration as Pillar data to each minion.

Note: If the master’s configuration contains any sensitive data, this will be passed to each minion. Do not enable this option if you have any configuration data that you do not want to get on your minions.

Also, if you make changes to your nodegroups, you might need to run `salt '*' saltutil.refresh_pillar` after restarting the master.

Once pillar_opts is enabled, you can find the nodegroups under the `master` pillar. To make sure that only the correct minions are targeted, you should use each matcher for the nodegroup definition. For example, to check if a minion is in the `webserver` nodegroup:

```
nodegroups:
  webserver: 'G@os:Debian and L@minion1,minion2'
```

```
{% if grains.id in salt['pillar.get']('master:nodegroups:webserver', []) and grains.os in salt['pillar.get']('master:nodegroups:webserver', []) %}
  ...
{% endif %}
```

Note: If you do not include all of the matchers used to define a nodegroup, Salt might incorrectly target minions that meet some of the nodegroup requirements, but not all of them.
4.7 Batch Size

The `-b` (or `--batch-size`) option allows commands to be executed on only a specified number of minions at a time. Both percentages and finite numbers are supported.

```
salt '*' -b 10 test.ping
salt -G 'os:RedHat' --batch-size 25% apache.signal restart
```

This will only run `test.ping` on 10 of the targeted minions at a time and then restart apache on 25% of the minions matching `os:RedHat` at a time and work through them all until the task is complete. This makes jobs like rolling web server restarts behind a load balancer or doing maintenance on BSD firewalls using carp much easier with salt.

The batch system maintains a window of running minions, so, if there are a total of 150 minions targeted and the batch size is 10, then the command is sent to 10 minions, when one minion returns then the command is sent to one additional minion, so that the job is constantly running on 10 minions.

4.8 SECO Range

SECO range is a cluster-based metadata store developed and maintained by Yahoo!

The Range project is hosted here:
https://github.com/ytoolshed/range

Learn more about range here:
https://github.com/ytoolshed/range/wiki/

4.8.1 Prerequisites

To utilize range support in Salt, a range server is required. Setting up a range server is outside the scope of this document. Apache modules are included in the range distribution.

With a working range server, cluster files must be defined. These files are written in YAML and define hosts contained inside a cluster. Full documentation on writing YAML range files is here:
https://github.com/ytoolshed/range/wiki/%22yamlfile%22-module-file-spec

Additionally, the Python seco range libraries must be installed on the salt master. One can verify that they have been installed correctly via the following command:

```
python -c 'import seco.range'
```

If no errors are returned, range is installed successfully on the salt master.

4.8.2 Preparing Salt

Range support must be enabled on the salt master by setting the hostname and port of the range server inside the master configuration file:

```
range_server: my.range.server.com:80
```

Following this, the master must be restarted for the change to have an effect.
4.8.3 Targeting with Range

Once a cluster has been defined, it can be targeted with a salt command by using the --range flags.

For example, given the following range YAML file being served from a range server:

```yaml
$ cat /etc/range/test.yaml
CLUSTER: host1..100.test.com
APPS:
  - frontend
  - backend
  - mysql
```

One might target host1 through host100 in the test.com domain with Salt as follows:

```bash
salt --range %test:CLUSTER test.ping
```

The following salt command would target three hosts: frontend, backend, and mysql:

```bash
salt --range %test:APPS test.ping
```
Storing Static Data in the Pillar

Pillar is an interface for Salt designed to offer global values that can be distributed to all minions. Pillar data is managed in a similar way as the Salt State Tree.

Pillar was added to Salt in version 0.9.8

Note: Storing sensitive data

Unlike state tree, pillar data is only available for the targeted minion specified by the matcher type. This makes it useful for storing sensitive data specific to a particular minion.

5.1 Declaring the Master Pillar

The Salt Master server maintains a pillar_roots setup that matches the structure of the file_roots used in the Salt file server. Like the Salt file server the pillar_roots option in the master config is based on environments mapping to directories. The pillar data is then mapped to minions based on matchers in a top file which is laid out in the same way as the state top file. Salt pillars can use the same matcher types as the standard top file.

The configuration for the pillar_roots in the master config file is identical in behavior and function as file_roots:

```
pillar_roots:
  base:
    - /srv/pillar
```

This example configuration declares that the base environment will be located in the /srv/pillar directory. It must not be in a subdirectory of the state tree.

The top file used matches the name of the top file used for States, and has the same structure:

```
/srv/pillar/top.sls
```

```
base:
  '*':
    - packages
```

In the above top file, it is declared that in the base environment, the glob matching all minions will have the pillar data found in the packages pillar available to it. Assuming the pillar_roots value of /srv/pillar taken from above, the packages pillar would be located at /srv/pillar/packages.sls.
Any number of matchers can be added to the base environment. For example, here is an expanded version of the Pillar top file stated above:

/srv/pillar/top.sls:

```
base:
    'x*':
        - packages
    'web*':
        - vim
```

In this expanded top file, minions that match `web*` will have access to the `/srv/pillar/packages.sls` file, as well as the `/srv/pillar/vim.sls` file.

Another example shows how to use other standard top matching types to deliver specific salt pillar data to minions with different properties.

Here is an example using the `grains` matcher to target pillars to minions by their `os` grain:

/dev:
    'os:Debian':
        - match: grain
        - servers

/srv/pillar/packages.sls

```
{% if grains['os'] == 'RedHat' %}
apache: httpd
git: git
{% elif grains['os'] == 'Debian' %}
apache: apache2
git: git-core
{% endif %}
company: Foo Industries
```

**Important:** See *Is Targeting using Grain Data Secure?* for important security information.

The above pillar sets two key/value pairs. If a minion is running RedHat, then the `apache` key is set to `httpd` and the `git` key is set to the value of `git`. If the minion is running Debian, those values are changed to `apache2` and `git-core` respectively. All minions that have this pillar targeting to them via a top file will have the key of `company` with a value of `Foo Industries`.

Consequently this data can be used from within modules, renderers, State SLS files, and more via the shared pillar `dict`:

```
apache:
    pkg.installed:
        - name: {{ pillar['apache'] }}

git:
    pkg.installed:
        - name: {{ pillar['git'] }}
```

Finally, the above states can utilize the values provided to them via Pillar. All pillar values targeted to a minion are available via the `pillar` dictionary. As seen in the above example, Jinja substitution can then be utilized to access the keys and values in the Pillar dictionary.
Note that you cannot just list key/value-information in `top.sls`. Instead, target a minion to a pillar file and then list the keys and values in the pillar. Here is an example top file that illustrates this point:

```
base:
  '*' :
    - common_pillar
```

And the actual pillar file at `/srv/pillar/common_pillar.sls`:

```
foo: bar
boo: baz
```

### 5.2 Pillar namespace flattened

The separate pillar files all share the same namespace. Given a `top.sls` of:

```
base:
  '*' :
    - packages
    - services
```

A `packages.sls` file of:

```
bind: bind9
```

And a `services.sls` file of:

```
bind: named
```

Then a request for the `bind` pillar will only return `named`; the `bind9` value is not available. It is better to structure your pillar files with more hierarchy. For example your `packages.sls` file could look like:

```
packages:
  bind: bind9
```

### 5.3 Pillar Namespace Merges

With some care, the pillar namespace can merge content from multiple pillar files under a single key, so long as conflicts are avoided as described above.

For example, if the above example were modified as follows, the values are merged below a single key:

```
base:
  '*' :
    - packages
    - services
```

And a `packages.sls` file like:

```
bind:
  package-name: bind9
  version: 9.9.5
```
And a *services.sls* file like:

```yaml
bind:
  port: 53
  listen-on: any
```

The resulting pillar will be as follows:

```
$ salt-call pillar.get bind
local:
  listen-on:
    any
  package-name:
    bind9
  port:
    53
  version:
    9.9.5
```

**Note:** Pillar files are applied in the order they are listed in the top file. Therefore conflicting keys will be overwritten in a 'last one wins' manner! For example, in the above scenario conflicting key values in *services* will overwrite those in *packages* because it's at the bottom of the list.

### 5.4 Including Other Pillars

New in version 0.16.0.

Pillar SLS files may include other pillar files, similar to State files. Two syntaxes are available for this purpose. The simple form simply includes the additional pillar as if it were part of the same file:

```yaml
include:
  - users
```

The full include form allows two additional options -- passing default values to the templating engine for the included pillar file as well as an optional key under which to nest the results of the included pillar:

```yaml
include:
  - users:
      defaults:
        sudo: ['bob', 'paul']
      key: users
```

With this form, the included file (users.sls) will be nested within the `users` key of the compiled pillar. Additionally, the `sudo` value will be available as a template variable to users.sls.

### 5.5 Viewing Minion Pillar

Once the pillar is set up the data can be viewed on the minion via the *pillar* module, the pillar module comes with functions, *pillar.items* and *pillar.raw*. *pillar.items* will return a freshly reloaded pillar and *pillar.raw* will return the current pillar without a refresh:
5.6 Pillar `get" Function

New in version 0.14.0.

The `pillar.get" function works much in the same way as the `get" method in a python dict, but with an enhancement: nested dict components can be extracted using a : delimiter.

If a structure like this is in pillar:

```
foo:
    bar:
        baz: qux
```

Extracting it from the raw pillar in an sls formula or file template is done this way:

```
{{ pillar['foo']['bar']['baz'] }}
```

Now, with the new `pillar.get" function the data can be safely gathered and a default can be set, allowing the template to fall back if the value is not available:

```
{{ salt['pillar.get']('foo:bar:baz', 'qux') }}
```

This makes handling nested structures much easier.

**Note:** `pillar.get"` vs `salt['pillar.get']()`

It should be noted that within templating, the `pillar` variable is just a dictionary. This means that calling `pillar.get()" inside of a template will just use the default dictionary .get()" function which does not include the extra : delimiter functionality. It must be called using the above syntax (`salt['pillar.get']('foo:bar:baz','qux')") to get the salt function, instead of the default dictionary behavior.

5.7 Refreshing Pillar Data

When pillar data is changed on the master the minions need to refresh the data locally. This is done with the `saltutil.refresh_pillar" function.

```
salt '*' saltutil.refresh_pillar
```

This function triggers the minion to asynchronously refresh the pillar and will always return `None".
Salt Documentation, Release 2015.8.12

5.8 Set Pillar Data at the Command Line
Pillar data can be set at the command line like the following example:
salt '*' state.apply pillar='{"cheese": "spam"}'

is will add a Pillar key of cheese with its value set to spam.
Note: Be aware that when sending sensitive data via pillar on the command-line that the publication containing
that data will be received by all minions and will not be restricted to the targeted minions. is may represent a
security concern in some cases.

5.9 Master Config In Pillar
For convenience the data stored in the master conﬁguration ﬁle can be made available in all minion's pillars. is
makes global conﬁguration of services and systems very easy but may not be desired if sensitive data is stored in the
master conﬁguration. is option is disabled by default.
To enable the master conﬁg from being added to the pillar set pillar_opts to True:
pillar_opts: True

5.10 Minion Config in Pillar
Minion conﬁguration options can be set on pillars. Any option that you want to modify, should be in the ﬁrst level
of the pillars, in the same way you set the options in the conﬁg ﬁle. For example, to conﬁgure the MySQL root
password to be used by MySQL Salt execution module, set the following pillar variable:
mysql.pass: hardtoguesspassword

5.11 Master Provided Pillar Error
By default if there is an error rendering a pillar, the detailed error is hidden and replaced with:
Rendering SLS 'my.sls' failed. Please see master log for details.

e error is protected because it's possible to contain templating data which would give that minion information it
shouldn't know, like a password!
To have the master provide the detailed error that could potentially carry protected data set pillar_safe_render_error to False:
pillar_safe_render_error: False

178

Chapter 5. Storing Static Data in the Pillar


Salt version 0.11.0 introduced the reactor system. The premise behind the reactor system is that with Salt’s events and the ability to execute commands, a logic engine could be put in place to allow events to trigger actions, or more accurately, reactions.

This system binds sls files to event tags on the master. These sls files then define reactions. This means that the reactor system has two parts. First, the reactor option needs to be set in the master configuration file. The reactor option allows for event tags to be associated with sls reaction files. Second, these reaction files use highdata (like the state system) to define reactions to be executed.

### 6.1 Event System

A basic understanding of the event system is required to understand reactors. The event system is a local ZeroMQ PUB interface which fires salt events. This event bus is an open system used for sending information notifying Salt and other systems about operations.

The event system fires events with a very specific criteria. Every event has a tag. Event tags allow for fast top level filtering of events. In addition to the tag, each event has a data structure. This data structure is a dict, which contains information about the event.

### 6.2 Mapping Events to Reactor SLS Files

Reactor SLS files and event tags are associated in the master config file. By default this is /etc/salt/master, or /etc/salt/master.d/reactor.conf.

New in version 2014.7.0: Added Reactor support for salt:// file paths.

In the master config section `reactor:` is a list of event tags to be matched and each event tag has a list of reactor SLS files to be run.

```plaintext
reactor: # Master config section "reactor"
- 'salt/minion/*/start': # Match tag "salt/minion/*/start"
  - /srv/reactor/start.sls # Things to do when a minion starts
  - /srv/reactor/monitor.sls # Other things to do
- 'salt/cloud/*/destroyed': # Glob can be used to matching tags
  - /srv/reactor/destroy/*.sls # Glob can be used to match file names
```
- 'myco/custom/event/tag':  # React to custom event tags
- salt://reactor/mycustom.sls  # Reactor files can come from the salt fileserver

Note: In the above example, salt://reactor/mycustom.sls refers to the base environment. To pull this file from a different environment, use the querystring syntax (e.g. salt://reactor/mycustom.sls?saltenv=reactor).

Reactor sls files are similar to state and pillar sls files. They are by default yaml + Jinja templates and are passed familiar context variables.

They differ because of the addition of the tag and data variables.

- The tag variable is just the tag in the fired event.
- The data variable is the event's data dict.

Here is a simple reactor sls:

```jinja
{% if data['id'] == 'mysql1' %}
highstate_run:
  local.state.apply:
    - tgt: mysql1
{% endif %}
```

This simple reactor file uses Jinja to further refine the reaction to be made. If the id in the event data is mysql1 (in other words, if the name of the minion is mysql1) then the following reaction is defined. The same data structure and compiler used for the state system is used for the reactor system. The only difference is that the data is matched up to the salt command API and the runner system. In this example, a command is published to the mysql1 minion with a function of state.apply. Similarly, a runner can be called:

```jinja
{% if data['data']['orchestrate'] == 'refresh' %}
orchestrate_run:
  runner.state.orchestrate
{% endif %}
```

This example will execute the state.orchestrate runner and initiate an orchestrate execution.

### 6.3 Fire an event

To fire an event from a minion call event.send

```
salt-call event.send 'foo' '{orchestrate: refresh}'
```

After this is called, any reactor sls files matching event tag foo will execute with {{ data['data']['orchestrate'] }} equal to 'refresh'.

See `salt.modules.event` for more information.

### 6.4 Knowing what event is being fired

The best way to see exactly what events are fired and what data is available in each event is to use the `state.event runner`.
See also:

*Common Salt Events*

Example usage:

```
salt-run state.event pretty=True
```

Example output:

```
salt/job/20150213001905721678/new {  
  "_stamp": "2015-02-13T00:19:05.724583",  
  "arg": [],  
  "fun": "test.ping",  
  "jid": "20150213001905721678",  
  "minions": [  
    "jerry"  
  ],  
  "tgt": "*",  
  "tgt_type": "glob",  
  "user": "root"
}
salt/job/20150213001910749506/ret/jerry {  
  "_stamp": "2015-02-13T00:19:11.136730",  
  "cmd": "_return",  
  "fun": "saltutil.find_job",  
  "fun_args": [  
    "20150213001905721678"
  ],  
  "id": "jerry",  
  "jid": "20150213001910749506",  
  "retcode": 0,  
  "return": {},  
  "success": true
}
```

### 6.5 Debugging the Reactor

The best window into the Reactor is to run the master in the foreground with debug logging enabled. The output will include when the master sees the event, what the master does in response to that event, and it will also include the rendered SLS file (or any errors generated while rendering the SLS file).

1. Stop the master.

2. Start the master manually:

   ```
salt-master -l debug
   ```

3. Look for log entries in the form:

   ```
   [DEBUG ] Gathering reactors for tag foo/bar
   [DEBUG ] Compiling reactions for tag foo/bar
   [DEBUG ] Rendered data from file: /path/to/the/reactor_file.sls:
   <... Rendered output appears here. ...>
   ```

   The rendered output is the result of the Jinja parsing and is a good way to view the result of referencing Jinja variables. If the result is empty then Jinja produced an empty result and the Reactor will ignore it.
6.6 Understanding the Structure of Reactor Formulas

I.e., when to use `arg` and `kwtarg` and when to specify the function arguments directly.

While the reactor system uses the same basic data structure as the state system, the functions that will be called using that data structure are different functions than are called via Salt's state system. The Reactor can call Runner modules using the `runner` prefix, Wheel modules using the `wheel` prefix, and can also cause minions to run Execution modules using the `local` prefix.

Changed in version 2014.7.0: The `cmd` prefix was renamed to `local` for consistency with other parts of Salt. A backward-compatible alias was added for `cmd`.

The Reactor runs on the master and calls functions that exist on the master. In the case of Runner and Wheel functions the Reactor can just call those functions directly since they exist on the master and are run on the master.

In the case of functions that exist on minions and are run on minions, the Reactor still needs to call a function on the master in order to send the necessary data to the minion so the minion can execute that function.

The Reactor calls functions exposed in Salt's Python API documentation, and thus the structure of Reactor files very transparently reflects the function signatures of those functions.

### 6.6.1 Calling Execution modules on Minions

The Reactor sends commands down to minions in the exact same way Salt's CLI interface does. It calls a function locally on the master that sends the name of the function as well as a list of any arguments and a dictionary of any keyword arguments that the minion should use to execute that function.

Specifically, the Reactor calls the async version of this function. You can see that function has `arg` and `kwtarg` parameters which are both values that are sent down to the minion.

Executing remote commands maps to the `LocalClient` interface which is used by the `salt` command. This interface more specifically maps to the `cmd_async` method inside of the `LocalClient` class. This means that the arguments passed are being passed to the `cmd_async` method, not the remote method. A field starts with `local` to use the `LocalClient` subsystem. The result is, to execute a remote command, a reactor formula would look like this:

```yaml
clean_tmp:
  local.cmd.run:
    - tgt: '*'
    - arg:
      - rm -rf /tmp/*
```

The `arg` option takes a list of arguments as they would be presented on the command line, so the above declaration is the same as running this salt command:

```bash
salt '*' cmd.run 'rm -rf /tmp/*'
```

Use the `expr_form` argument to specify a matcher:

```yaml
clean_tmp:
  local.cmd.run:
    - tgt: 'os:Ubuntu'
    - expr_form: grain
      - arg:
        - rm -rf /tmp/*
```

```yaml
clean_tmp:
  local.cmd.run:
```

---

182 Chapter 6. Reactor System
Any other parameters in the `LocalClient().cmd()` method can be specified as well.

6.6.2 Calling Runner modules and Wheel modules

Calling Runner modules and Wheel modules from the Reactor uses a more direct syntax since the function is being executed locally instead of sending a command to a remote system to be executed there. There are no `arg` or `kwarg` parameters (unless the Runner function or Wheel function accepts a parameter with either of those names.)

For example:

```python
clear_the_grains_cache_for_all_minions:
    runner.cache.clear_grains
```

If the runner takes arguments then they can be specified as well:

```python
spin_up_more_web_machines:
    runner.cloud.profile:
        - prof: centos_6
        - instances:
            - web11  # These VM names would be generated via Jinja in a
            - web12  # real-world example.
```

6.6.3 Passing event data to Minions or Orchestrate as Pillar

An interesting trick to pass data from the Reactor script to `state.apply` is to pass it as inline Pillar data since both functions take a keyword argument named `pillar`.

The following example uses Salt’s Reactor to listen for the event that is fired when the key for a new minion is accepted on the master using `salt-key`.

```
/etc/salt/master.d/reactor.conf:
reactor:
    - 'salt/key':
        - /srv/salt/haproxy/react_new_minion.sls
```

The Reactor then fires a `state.apply` command targeted to the HAProxy servers and passes the ID of the new minion from the event to the state file via inline Pillar.

```
/srv/salt/haproxy/react_new_minion.sls:
{% if data['act'] == 'accept' and data['id'].startswith('web') %}
    add_new_minion_to_pool:
        local.state.apply:
            - tgt: 'haproxy*'  
            - arg:
                - haproxy.refresh_pool  
            - kwarg:
                pillar:
                    new_minion: {{ data['id'] }}
{% endif %}
```
The above command is equivalent to the following command at the CLI:

```sh
salt 'haproxy*' state.apply haproxy.refresh_pool 'pillar={new_minion: minionid}'
```

This works with Orchestrate files as well:

```py
call_some_orchestrate_file:
    runner.state.orchestrate:
        - mods: some_orchestrate_file
        - pillar:
            stuff: things
```

Which is equivalent to the following command at the CLI:

```sh
salt-run state.orchestrate some_orchestrate_file pillar='(stuff: things)'
```

Finally, that data is available in the state file using the normal Pillar lookup syntax. The following example is grabbing web server names and IP addresses from Salt Mine. If this state is invoked from the Reactor then the custom Pillar value from above will be available and the new minion will be added to the pool but with the disabled flag so that HAProxy won’t yet direct traffic to it.

/srv/salt/haproxy/refresh_pool.sls:

```sh
{% set new_minion = salt['pillar.get']('new_minion') %}

listen web *:80
    balance source
    {% for server,ip in salt['mine.get']('web*', 'network.interfaces', ['eth0']).items() %}
        {% if server == new_minion %}
            server {{ server }} {{ ip }}:80 disabled
        {% else %}
            server {{ server }} {{ ip }}:80 check
        {% endif %}
    {% endfor %}
```

## 6.7 A Complete Example

In this example, we're going to assume that we have a group of servers that will come online at random and need to have keys automatically accepted. We'll also add that we don't want all servers being automatically accepted. For this example, we'll assume that all hosts that have an id that starts with `ink` will be automatically accepted and have state.apply executed. On top of this, we're going to add that a host coming up that was replaced (meaning a new key) will also be accepted.

Our master configuration will be rather simple. All minions that attempt to authenticate will match the tag of salt/auth. When it comes to the minion key being accepted, we get a more refined tag that includes the minion id, which we can use for matching.

/etc/salt/master.d/reactor.conf:

```sh
reactor:
    - 'salt/auth':
        - /srv/reactor/auth-pending.sls
    - 'salt/minion/ink*/start':
        - /srv/reactor/auth-complete.sls
```
In this sls file, we say that if the key was rejected we will delete the key on the master and then also tell the master to ssh in to the minion and tell it to restart the minion, since a minion process will die if the key is rejected.

We also say that if the key is pending and the id starts with ink we will accept the key. A minion that is waiting on a pending key will retry authentication every ten seconds by default.

```
/srv/reactor/auth-pending.sls:

{% if not data['result'] and data['id'].startswith('ink') %}
    minion_remove:
        wheel.key.delete:
            match: {{ data['id'] }}
    minion_rejoin:
        local.cmd.run:
            tgt: salt-master.domain.tld
            arg: ssh -o UserKnownHostsFile=/dev/null -o StrictHostKeyChecking=no "{{ data['id'] }}" 'sleep 10 && /etc/init.d/salt-minion restart'
{% endif %}

{% if 'act' in data and data['act'] == 'pend' and data['id'].startswith('ink') %}
    minion_add:
        wheel.key.accept:
            match: {{ data['id'] }}
{% endif %}
```

No if statements are needed here because we already limited this action to just Ink servers in the master configuration.

```
/srv/reactor/auth-complete.sls:

{% when 'act' in data and data['act'] == 'pend' and data['id'].startswith('ink') %}
    highstate_run:
        local.state.apply:
            tgt: {{ data['id'] }}
            ret: smtp
```

The above will also return the highstate result data using the smtp_return returner (use virtualname like when using from the command line with --return). The returner needs to be configured on the minion for this to work. See salt.returners.smtp_return documentation for that.

### 6.8 Syncing Custom Types on Minion Start

Salt will sync all custom types (by running a saltutil.sync_all) on every highstate. However, there is a chicken-and-egg issue where, on the initial highstate, a minion will not yet have these custom types synced when the top file is first compiled. This can be worked around with a simple reactor which watches for minion_start events, which each minion fires when it first starts up and connects to the master.

On the master, create /srv/reactor/sync_grains.sls with the following contents:

```
sync_grains:
    local.saltutil.sync_grains:
        tgt: {{ data['id'] }}
```

And in the master config file, add the following reactor configuration:
reactor:
  - 'minion_start':
    - /srv/reactor/sync_grains.sls

This will cause the master to instruct each minion to sync its custom grains when it starts, making these grains available when the initial `highstate` is executed.

Other types can be synced by replacing `local.saltutil.sync_grains` with `local.saltutil.sync_modules`, `local.saltutil.sync_all`, or whatever else suits the intended use case.
The Salt Mine

The Salt Mine is used to collect arbitrary data from Minions and store it on the Master. This data is then made available to all Minions via the `salt.modules.mine` module.

Mine data is gathered on the Minion and sent back to the Master where only the most recent data is maintained (if long term data is required use returners or the external job cache).

7.1 Mine vs Grains

Mine data is designed to be much more up-to-date than grain data. Grains are refreshed on a very limited basis and are largely static data. Mines are designed to replace slow peer publishing calls when Minions need data from other Minions. Rather than having a Minion reach out to all the other Minions for a piece of data, the Salt Mine, running on the Master, can collect it from all the Minions every mine-interval, resulting in almost fresh data at any given time, with much less overhead.

7.2 Mine Functions

To enable the Salt Mine the `mine_functions` option needs to be applied to a Minion. This option can be applied via the Minion's configuration file, or the Minion's Pillar. The `mine_functions` option dictates what functions are being executed and allows for arguments to be passed in. If no arguments are passed, an empty list must be added:

```
mine_functions:
    test.ping: []
    network.ip_addrs:
        interface: eth0
        cidr: '10.0.0.0/8'
```

7.2.1 Mine Functions Aliases

Function aliases can be used to provide friendly names, usage intentions or to allow multiple calls of the same function with different arguments. There is a different syntax for passing positional and key-value arguments. Mixing positional and key-value arguments is not supported.

New in version 2014.7.0.
7.3 Mine Interval

The Salt Mine functions are executed when the Minion starts and at a given interval by the scheduler. The default interval is every 60 minutes and can be adjusted for the Minion via the `mine_interval` option:

```
mine_interval: 60
```

7.4 Mine in Salt-SSH

As of the 2015.5.0 release of salt, salt-ssh supports `mine.get`.

Because the Minions cannot provide their own `mine_functions` configuration, we retrieve the args for specified mine functions in one of three places, searched in the following order:

1. Roster data
2. Pillar
3. Master config

The `mine_functions` are formatted exactly the same as in normal salt, just stored in a different location. Here is an example of a flat roster containing `mine_functions`:

```
test:
  host: 104.237.131.248
  user: root
  mine_functions:
    cmd.run: ['echo "hello!"']
    network.ip_addrs:
      interface: eth0
```

Note: Because of the differences in the architecture of salt-ssh, `mine.get` calls are somewhat inefficient. Salt must make a new salt-ssh call to each of the Minions in question to retrieve the requested data, much like a publish call. However, unlike publish, it must run the requested function as a wrapper function, so we can retrieve the function args from the pillar of the Minion in question. This results in a non-trivial delay in retrieving the requested data.

7.5 Minions Targeting with Mine

The `mine.get` function supports various methods of Minions targeting to fetch Mine data from particular hosts, such as glob or regular expression matching on Minion id (name), grains, pillars and compound matches. See the
Note: Pillar data needs to be cached on Master for pillar targeting to work with Mine. Read the note in relevant section.

7.6 Example

One way to use data from Salt Mine is in a State. The values can be retrieved via Jinja and used in the SLS file. The following example is a partial HAProxy configuration file and pulls IP addresses from all Minions with the `web` grain to add them to the pool of load balanced servers.

/srv/pillar/top.sls:

```yaml
base:
  'G@roles:web':
    - web
```

/srv/pillar/web.sls:

```yaml
mine_functions:
  network.ip_addrs: [eth0]
```

/etc/salt/minion.d/mine.conf:

```yaml
mine_interval: 5
```

/srv/salt/haproxy.sls:

```yaml
haproxy_config:
  file.managed:
    - name: /etc/haproxy/config
    - source: salt://haproxy_config
    - template: jinja
```

/srv/salt/haproxy_config:

```plaintext
{% for server, addrs in salt['mine.get']('roles:web', 'network.ip_addrs', expr_form= →'grain') | dictsort() %}
server {{ server }} {{ addrs[0] }}:80 check
{% endfor %}
```

...file contents snipped...>
Salt's External Authentication System (eAuth) allows for Salt to pass through command authorization to any external authentication system, such as PAM or LDAP.

Note: eAuth using the PAM external auth system requires salt-master to be run as root as this system needs root access to check authentication.

## 8.1 Access Control System

Note: When to Use `client_acl` and `external_auth`

`client_acl` is useful for allowing local system users to run Salt commands without giving them root access. If you can log into the Salt master directly, then `client_acl` will allow you to use Salt without root privileges. If the local system is configured to authenticate against a remote system, like LDAP or Active Directory, then `client_acl` will interact with the remote system transparently.

`external_auth` is useful for `salt-api` or for making your own scripts that use Salt's Python API. It can be used at the CLI (with the `-a` flag) but it is more cumbersome as there are more steps involved. The only time it is useful at the CLI is when the local system is not configured to authenticate against an external service but you still want Salt to authenticate against an external service.

The external authentication system allows for specific users to be granted access to execute specific functions on specific minions. Access is configured in the master configuration file and uses the `access control system`:

```yaml
external_auth:
  pam:
    thatch:
      - 'web*':
        - test.*
        - network.*
    steve:
      - .*
```

The above configuration allows the user `thatch` to execute functions in the test and network modules on the minions that match the `web*` target. User `steve` is given unrestricted access to minion commands.

Salt respects the current PAM configuration in place, and uses the `login` service to authenticate.
Note: The PAM module does not allow authenticating as root.

To allow access to wheel modules or runner modules the following @ syntax must be used:

```yaml
external_auth:
  pam:
    thatch:
      - '@wheel' # to allow access to all wheel modules
      - '@runner' # to allow access to all runner modules
      - '@jobs' # to allow access to the jobs runner and/or wheel module
```

Note: The runner/wheel markup is different, since there are no minions to scope the acl to.

Note: Globs will not match wheel or runners! They must be explicitly allowed with @wheel or @runner.

The external authentication system can then be used from the command-line by any user on the same system as the master with the -a option:

```
$ salt -a pam web/* test.ping
```

The system will ask the user for the credentials required by the authentication system and then publish the command.

To apply permissions to a group of users in an external authentication system, append a % to the ID:

```
external_auth:
  pam:
    admins%:
      - '*':
      - 'pkg.*'
```

Warning: All users that have external authentication privileges are allowed to run `saltutil.findjob`. Be aware that this could inadvertently expose some data such as minion IDs.

### 8.2 Tokens

With external authentication alone, the authentication credentials will be required with every call to Salt. This can be alleviated with Salt tokens.

Tokens are short term authorizations and can be easily created by just adding a -T option when authenticating:

```
$ salt -T -a pam web/* test.ping
```

Now a token will be created that has a expiration of 12 hours (by default). This token is stored in a file named `salt_token` in the active user's home directory.

Once the token is created, it is sent with all subsequent communications. User authentication does not need to be entered again until the token expires.

Token expiration time can be set in the Salt master config file.
8.2.1 LDAP and Active Directory

Note: LDAP usage requires that you have installed python-ldap.

Salt supports both user and group authentication for LDAP (and Active Directory accessed via its LDAP interface)

8.3 OpenLDAP and similar systems

LDAP configuration happens in the Salt master configuration file.

Server configuration values and their defaults:

```
# Server to auth against
auth.ldap.server: localhost

# Port to connect via
auth.ldap.port: 389

# Use TLS when connecting
auth.ldap.tls: False

# LDAP scope level, almost always 2
auth.ldap.scope: 2

# Server specified in URI format
auth.ldap.uri: ' '  # Overrides .ldap.server, .ldap.port, .ldap.tls above

# Verify server's TLS certificate
auth.ldap.no_verify: False

# Bind to LDAP anonymously to determine group membership
# Active Directory does not allow anonymous binds without special configuration
auth.ldap.anonymous: False

# FOR TESTING ONLY, this is a VERY insecure setting.
# If this is True, the LDAP bind password will be ignored and
# access will be determined by group membership alone with
# the group memberships being retrieved via anonymous bind
auth.ldap.auth_by_group_membership_only: False

# Require authenticating user to be part of this Organizational Unit
# This can be blank if your LDAP schema does not use this kind of OU
auth.ldap.groupbyou: 'Groups'

# Object Class for groups. An LDAP search will be done to find all groups of this
# class to which the authenticating user belongs.
auth.ldap.groupclass: 'posixGroup'

# Unique ID attribute name for the user
auth.ldap.accountattributename: 'memberUid'

# These are only for Active Directory
auth.ldap.activedirectory: False
auth.ldap.persontype: 'person'
```
There are two phases to LDAP authentication. First, Salt authenticates to search for a user's Distinguished Name and group membership. The user it authenticates as in this phase is often a special LDAP system user with read-only access to the LDAP directory. After Salt searches the directory to determine the actual user's DN and groups, it re-authenticates as the user running the Salt commands.

If you are already aware of the structure of your DNs and permissions in your LDAP store are set such that users can look up their own group memberships, then the first and second users can be the same. To tell Salt this is the case, omit the `auth.ldap.bindpw` parameter. You can template the binddn like this:

```yaml
auth.ldap.binddn: uid={{ username }},cn=users,cn=accounts,dc=saltstack,dc=com
```

Salt will use the password entered on the salt command line in place of the bindpw.

To use two separate users, specify the LDAP lookup user in the binddn directive, and include a bindpw like so:

```yaml
auth.ldap.binddn: uid=ldaplookup,cn=sysaccounts,cn=etc,dc=saltstack,dc=com
auth.ldap.bindpw: mypassword
```

As mentioned before, Salt uses a filter to find the DN associated with a user. Salt substitutes the `{{ username }}` value for the username when querying LDAP:

```yaml
auth.ldap.filter: uid={{ username }}
```

For OpenLDAP, to determine group membership, one can specify an OU that contains group data. This is prepended to the basedn to create a search path. Then the results are filtered against `auth.ldap.groupclass`, default `posixGroup`, and the account's 'name' attribute, `memberUid` by default:

```yaml
auth.ldap.groupou: Groups
```

### 8.4 Active Directory

Active Directory handles group membership differently, and does not utilize the `groupou` configuration variable. AD needs the following options in the master config:

```yaml
auth.ldap.activedirectory: True
auth.ldap.filter: sAMAccountName={{username}}
auth.ldap.accountattributename: sAMAccountName
auth.ldap.groupclass: group
auth.ldap.persontype: person
```

To determine group membership in AD, the username and password that is entered when LDAP is requested as the eAuth mechanism on the command line is used to bind to AD's LDAP interface. If this fails, then it doesn't matter what groups the user belongs to, he or she is denied access. Next, the distinguishedName of the user is looked up with the following LDAP search:

```ldap
(&(<value of auth.ldap.accountattributename>={{username}})
    (objectClass=<value of auth.ldap.persontype>))
)
```

This should return a distinguishedName that we can use to filter for group membership. Then the following LDAP query is executed:

```ldap
(&(member=<distinguishedName from search above>)
    (objectClass=<value of auth.ldap.groupclass>))
)
external_auth:
  ldap:
    test_ldap_user:
      - '*':
        - test.ping

To configure an LDAP group, append a % to the ID:

external_auth:
  ldap:
    test_ldap_group%:
      - '*':
        - test.echo
Access Control System

New in version 0.10.4.

Salt maintains a standard system used to open granular control to non administrative users to execute Salt commands. The access control system has been applied to all systems used to configure access to non administrative control interfaces in Salt. These interfaces include, the peer system, the external auth system and the client acl system.

The access control system mandated a standard configuration syntax used in all of the three aforementioned systems. While this adds functionality to the configuration in 0.10.4, it does not negate the old configuration.

Now specific functions can be opened up to specific minions from specific users in the case of external auth and client ACLs, and for specific minions in the case of the peer system.

The access controls are manifested using matchers in these configurations:

```
client_acl:
    fred:
        - web\*:
        - pkg.list_pkgs
        - test.*
        - apache.*
```

In the above example, fred is able to send commands only to minions which match the specified glob target. This can be expanded to include other functions for other minions based on standard targets (all matchers are supported except the compound one).

```
external_auth:
    pam:
        dave:
            - test.ping
            - mongo\*:
                - network.*
            - log\*:
                - network.*
                - pkg.*
                - 'G@os:RedHat':
                    - kmod.*
        steve:
            - .*
```

The above allows for all minions to be hit by test.ping by dave, and adds a few functions that dave can execute on other minions. It also allows steve unrestricted access to salt commands.
Note: Functions are matched using regular expressions.
Job Management

New in version 0.9.7.
Since Salt executes jobs running on many systems, Salt needs to be able to manage jobs running on many systems.

10.1 The Minion proc System

Salt Minions maintain a proc directory in the Salt cachedir. The proc directory maintains files named after the executed job ID. These files contain the information about the current running jobs on the minion and allow for jobs to be looked up. This is located in the proc directory under the cachedir, with a default configuration it is under /var/cache/salt/proc.

10.2 Functions in the saltutil Module

Salt 0.9.7 introduced a few new functions to the saltutil module for managing jobs. These functions are:

1. running Returns the data of all running jobs that are found in the proc directory.
2. find_job Returns specific data about a certain job based on job id.
3. signal_job Allows for a given jid to be sent a signal.
4. term_job Sends a termination signal (SIGTERM, 15) to the process controlling the specified job.
5. kill_job Sends a kill signal (SIGKILL, 9) to the process controlling the specified job.

These functions make up the core of the back end used to manage jobs at the minion level.

10.3 The jobs Runner

A convenience runner front end and reporting system has been added as well. The jobs runner contains functions to make viewing data easier and cleaner.

The jobs runner contains a number of functions...
10.3.1 active

The active function runs saltutil.running on all minions and formats the return data about all running jobs in a much more usable and compact format. The active function will also compare jobs that have returned and jobs that are still running, making it easier to see what systems have completed a job and what systems are still being waited on.

```
# salt-run jobs.active
```

10.3.2 lookup_jid

When jobs are executed the return data is sent back to the master and cached. By default it is cached for 24 hours, but this can be configured via the keep_jobs option in the master configuration. Using the lookup_jid runner will display the same return data that the initial job invocation with the salt command would display.

```
# salt-run jobs.lookup_jid <job id number>
```

10.3.3 list_jobs

Before finding a historic job, it may be required to find the job id. list_jobs will parse the cached execution data and display all of the job data for jobs that have already, or partially returned.

```
# salt-run jobs.list_jobs
```

10.4 Scheduling Jobs

In Salt versions greater than 0.12.0, the scheduling system allows incremental executions on minions or the master. The schedule system exposes the execution of any execution function on minions or any runner on the master.

Scheduling can be enabled by multiple methods:

- `schedule` option in either the master or minion config files. These require the master or minion application to be restarted in order for the schedule to be implemented.
- Minion pillar data. Schedule is implemented by refreshing the minion's pillar data, for example by using `saltutil.refresh_pillar`.
- The `schedule state` or `schedule module`

**Note:** The scheduler executes different functions on the master and minions. When running on the master the functions reference runner functions, when running on the minion the functions specify execution functions.

A scheduled run has no output on the minion unless the config is set to info level or higher. Refer to `minion logging settings`.

Specify `maxrunning` to ensure that there are no more than N copies of a particular routine running. Use this for jobs that may be long-running and could step on each other or otherwise double execute. The default for `maxrunning` is 1.

States are executed on the minion, as all states are. You can pass positional arguments and provide a yaml dict of named arguments.
The below example will schedule the command `state.apply httpd test=True` every 3600 seconds (every hour):

```yaml
schedule:
  job1:
    function: state.apply
    seconds: 3600
    args:
      - httpd
    kwargs:
      test: True
```

This next example will schedule the command `state.apply httpd test=True` every 3600 seconds (every hour) splaying the time between 0 and 15 seconds:

```yaml
schedule:
  job1:
    function: state.apply
    seconds: 3600
    args:
      - httpd
    kwargs:
      test: True
    splay: 15
```

Finally, the next example will schedule the command `state.apply httpd test=True` every 3600 seconds (every hour) splaying the time between 10 and 15 seconds:

```yaml
schedule:
  job1:
    function: state.apply
    seconds: 3600
    args:
      - httpd
    kwargs:
      test: True
    splay:
      start: 10
      end: 15
```

New in version 2014.7.0.

Frequency of jobs can also be specified using date strings supported by the python dateutil library. This requires python-dateutil to be installed on the minion.

For example, this will schedule the command `state.apply httpd test=True` at 5:00pm localtime on the minion.

```yaml
schedule:
  job1:
    function: state.apply
    args:
      - httpd
    kwargs:
      test: True
    when: 5:00pm
```

To schedule the command `state.apply httpd test=True` at 5pm on Monday, Wednesday, and Friday, and 3pm on Tuesday and Thursday, use the following:
Time ranges are also supported. For example, the below configuration will schedule the command `state.apply httpd test=True` every 3600 seconds (every hour) between the hours of 8am and 5pm. The range parameter must be a dictionary with the date strings using the `dateutil` format.

```
schedule:
  job1:
    function: state.apply
    seconds: 3600
    args:
      - httpd
    kwargs:
      test: True
    range:
      start: 8:00am
      end: 5:00pm
```

Note: Using time ranges requires `python-dateutil` to be installed on the minion.

New in version 2014.7.0.

The scheduler also supports ensuring that there are no more than N copies of a particular routine running. Use this for jobs that may be long-running and could step on each other or pile up in case of infrastructure outage.

The default for `maxrunning` is 1.

```
schedule:
  long_running_job:
    function: big_file_transfer
    jid_include: True
```

### 10.4.1 run_on_start

New in version 2015.5.0.

By default, any job scheduled based on the startup time of the minion will run the scheduled job when the minion starts up. Sometimes this is not the desired situation. Using the `run_on_start` parameter set to `False` will cause the scheduler to skip this first run and wait until the next scheduled run.

```
schedule:
  job1:
    function: state.sls
```
10.5 States

```
seconds: 3600
run_on_start: False
args:
    - httpd
kwargs:
    test: True
```

10.6 Highstates

To set up a highstate to run on a minion every 60 minutes set this in the minion config or pillar:

```
schedule:
    highstate:
        function: state.apply
        minutes: 60
```

Time intervals can be specified as seconds, minutes, hours, or days.

10.7 Runners

Runner executions can also be specified on the master within the master configuration file:

```
schedule:
    run_my_orch:
        function: state.orchestrate
        hours: 6
        splay: 600
        args:
            - orchestration.my_orch
```

The above configuration is analogous to running `salt-run state.orch orchestration.my_orch` every 6 hours.
10.8 Scheduler With Returner

The scheduler is also useful for tasks like gathering monitoring data about a minion, this schedule option will gather status data and send it to a MySQL returner database:

```yaml
schedule:
  uptime:
    function: status.uptime
    seconds: 60
    returner: mysql
  meminfo:
    function: status.meminfo
    minutes: 5
    returner: mysql
```

Since specifying the returner repeatedly can be tiresome, the `schedule_returner` option is available to specify one or a list of global returners to be used by the minions when scheduling.

In Salt versions greater than 0.12.0, the scheduling system allows incremental executions on minions or the master. The schedule system exposes the execution of any execution function on minions or any runner on the master.

Scheduling can be enabled by multiple methods:

- schedule option in either the master or minion config files. These require the master or minion application to be restarted in order for the schedule to be implemented.
- Minion pillar data. Schedule is implemented by refreshing the minion's pillar data, for example by using `saltutil.refresh_pillar`.
- The schedule state or schedule module

**Note:** The scheduler executes different functions on the master and minions. When running on the master the functions reference runner functions, when running on the minion the functions specify execution functions.

A scheduled run has no output on the minion unless the config is set to info level or higher. Refer to *minion logging settings*.

Specify `maxrunning` to ensure that there are no more than N copies of a particular routine running. Use this for jobs that may be long-running and could step on each other or otherwise double execute. The default for `maxrunning` is 1.

States are executed on the minion, as all states are. You can pass positional arguments and provide a yaml dict of named arguments.

The below example will schedule the command `state.apply httpd test=True` every 3600 seconds (every hour):

```yaml
schedule:
  job1:
    function: state.apply
    seconds: 3600
    args:
      - httpd
    kwargs:
      test: True
```

This next example will schedule the command `state.apply httpd test=True` every 3600 seconds (every hour) splaying the time between 0 and 15 seconds:
Finally, the next example will schedule the command `state.apply httpd test=True` every 3600 seconds (every hour) splaying the time between 10 and 15 seconds:

```
schedule:
  job1:
    function: state.apply
    seconds: 3600
    args:
      - httpd
    kwargs:
      test: True
    splay:
      start: 10
      end: 15
```

New in version 2014.7.0.

Frequency of jobs can also be specified using date strings supported by the python dateutil library. This requires python-dateutil to be installed on the minion.

For example, this will schedule the command `state.apply httpd test=True` at 5:00pm localtime on the minion.

```
schedule:
  job1:
    function: state.apply
    args:
      - httpd
    kwargs:
      test: True
    when: 5:00pm
```

To schedule the command `state.apply httpd test=True` at 5pm on Monday, Wednesday, and Friday, and 3pm on Tuesday and Thursday, use the following:

```
schedule:
  job1:
    function: state.apply
    args:
      - httpd
    kwargs:
      test: True
    when:
      - Monday 5:00pm
      - Tuesday 3:00pm
      - Wednesday 5:00pm
      - Thursday 3:00pm
      - Friday 5:00pm
```
Time ranges are also supported. For example, the below configuration will schedule the command `state.apply httpd test=True` every 3600 seconds (every hour) between the hours of 8am and 5pm. The range parameter must be a dictionary with the date strings using the `dateutil` format.

```yaml
schedule:
  job1:
    function: state.apply
    seconds: 3600
    args:
      - httpd
    kwargs:
      test: True
    range:
      start: 8:00am
      end: 5:00pm
```

**Note:** Using time ranges requires `python-dateutil` to be installed on the minion.

New in version 2014.7.0.

The scheduler also supports ensuring that there are no more than N copies of a particular routine running. Use this for jobs that may be long-running and could step on each other or pile up in case of infrastructure outage.

The default for `maxrunning` is 1.

```yaml
schedule:
  long_running_job:
    function: big_file_transfer
    jid_include: True
```

### 10.8.1 run_on_start

New in version 2015.5.0.

By default, any job scheduled based on the startup time of the minion will run the scheduled job when the minion starts up. Sometimes this is not the desired situation. Using the `run_on_start` parameter set to `False` will cause the scheduler to skip this first run and wait until the next scheduled run.

```yaml
schedule:
  job1:
    function: state.sls
    seconds: 3600
    run_on_start: False
    args:
      - httpd
    kwargs:
      test: True
```

**States**

```yaml
schedule:
  log-loadavg:
    function: cmd.run
    seconds: 3660
```
Highstates

To set up a highstate to run on a minion every 60 minutes set this in the minion config or pillar:

```yaml
schedule:
  highstate:
    function: state.apply
    minutes: 60
```

Time intervals can be specified as seconds, minutes, hours, or days.

Runners

Runner executions can also be specified on the master within the master configuration file:

```yaml
schedule:
  run_my_orch:
    function: state.orchestrate
    hours: 6
    splay: 600
    args:
      - orchestration.my_orch
```

The above configuration is analogous to running `salt-run state.orch orchestration.my_orch` every 6 hours.

Scheduler With Returner

The scheduler is also useful for tasks like gathering monitoring data about a minion, this schedule option will gather status data and send it to a MySQL returner database:

```yaml
schedule:
  uptime:
    function: status.uptime
    seconds: 60
    returner: mysql
  meminfo:
    function: status.meminfo
    minutes: 5
    returner: mysql
```

Since specifying the returner repeatedly can be tiresome, the schedule_returner option is available to specify one or a list of global returners to be used by the minions when scheduling.
Managing the Job Cache

The Salt Master maintains a job cache of all job executions which can be queried via the jobs runner. This job cache is called the Default Job Cache.

11.1 Default Job Cache

A number of options are available when configuring the job cache. The default caching system uses local storage on the Salt Master and can be found in the job cache directory (on Linux systems this is typically /var/cache/salt/master/jobs). The default caching system is suitable for most deployments as it does not typically require any further configuration or management.

The default job cache is a temporary cache and jobs will be stored for 24 hours. If the default cache needs to store jobs for a different period the time can be easily adjusted by changing the `keep_jobs` parameter in the Salt Master configuration file. The value passed in is measured via hours:

```
keep_jobs: 24
```

11.1.1 Reducing the Size of the Default Job Cache

The Default Job Cache can sometimes be a burden on larger deployments (over 5000 minions). Disabling the job cache will make previously executed jobs unavailable to the jobs system and is not generally recommended. Normally it is wise to make sure the master has access to a faster IO system or a tmpfs is mounted to the jobs dir.

However, you can disable the `job_cache` by setting it to `False` in the Salt Master configuration file. Setting this value to `False` means that the Salt Master will no longer cache minion returns, but a JID directory and `jid` file for each job will still be created. This JID directory is necessary for checking for and preventing JID collisions.

The default location for the job cache is in the `/var/cache/salt/master/jobs/` directory.

Setting the `job_cache` to `False` in addition to setting the `keep_jobs` option to a smaller value, such as 1, in the Salt Master configuration file will reduce the size of the Default Job Cache, and thus the burden on the Salt Master.

**Note:** Changing the `keep_jobs` option sets the number of hours to keep old job information and defaults to 24 hours. Do not set this value to 0 when trying to make the cache cleaner run more frequently, as this means the cache cleaner will never run.
11.2 Additional Job Cache Options

Many deployments may wish to use an external database to maintain a long term register of executed jobs. Salt comes with two main mechanisms to do this, the master job cache and the external job cache.

See *Storing Job Results in an External System*. 
After a job executes, job results are returned to the Salt Master by each Salt Minion. These results are stored in the Default Job Cache.

In addition to the Default Job Cache, Salt provides two additional mechanisms to send job results to other systems (databases, local syslog, and others):

- External Job Cache
- Master Job Cache

The major difference between these two mechanisms is from where results are returned (from the Salt Master or Salt Minion).

### 12.1 External Job Cache - Minion-Side Returner

When an External Job Cache is configured, data is returned to the Default Job Cache on the Salt Master like usual, and then results are also sent to an External Job Cache using a Salt returner module running on the Salt Minion.

- Advantages: Data is stored without placing additional load on the Salt Master.
- Disadvantages: Each Salt Minion connects to the external job cache, which can result in a large number of connections. Also requires additional configuration to get returner module settings on all Salt Minions.
12.2 Master Job Cache - Master-Side Returner

New in version 2014.7.0.

Instead of configuring an External Job Cache on each Salt Minion, you can configure the Master Job Cache to send job results from the Salt Master instead. In this configuration, Salt Minions send data to the Default Job Cache as usual, and then the Salt Master sends the data to the external system using a Salt returner module running on the Salt Master.

- Advantages: A single connection is required to the external system. This is preferred for databases and similar systems.
- Disadvantages: Places additional load on your Salt Master.

12.3 Configure an External or Master Job Cache

12.3.1 Step 1: Understand Salt Returners

Before you configure a job cache, it is essential to understand Salt returner modules (``returners``). Returners are pluggable Salt Modules that take the data returned by jobs, and then perform any necessary steps to send the data to an external system. For example, a returner might establish a connection, authenticate, and then format and transfer data.

The Salt Returner system provides the core functionality used by the External and Master Job Cache systems, and the same returners are used by both systems.

Salt currently provides many different returners that let you connect to a wide variety of systems. A complete list is available at all Salt returners. Each returner is configured differently, so make sure you read and follow the instructions linked from that page.

For example, the MySQL returner requires:

- A database created using provided schema (structure is available at MySQL returner)
- A user created with privileges to the database
- Optional SSL configuration

A simpler returner, such as Slack or HipChat, requires:
- An API key/version
- The target channel/room
- The username that should be used to send the message

12.3.2 Step 2: Configure the Returner

After you understand the configuration and have the external system ready, add the returner configuration settings to the Salt Minion configuration file for the External Job Cache, or to the Salt Master configuration file for the Master Job Cache.

For example, MySQL requires:

```python
def mysql_host: 'salt'
def mysql_user: 'salt'
def mysql_pass: 'salt'
def mysql_db: 'salt'
def mysql_port: 3306
```

Slack requires:

```python
def slack_channel: 'channel'
def slack_api_key: 'key'
def slack_from_name: 'name'
```

After you have configured the returner and added settings to the configuration file, you can enable the External or Master Job Cache.

12.3.3 Step 3: Enable the External or Master Job Cache

Configuration is a single line that specifies an already-configured returner to use to send all job data to an external system.

External Job Cache

To enable a returner as the External Job Cache (Minion-side), add the following line to the Salt Master configuration file:

```python
def ext_job_cache: <returner>
```

For example:

```python
def ext_job_cache: mysql
```

Note: When configuring an External Job Cache (Minion-side), the returner settings are added to the Minion configuration file, but the External Job Cache setting is configured in the Master configuration file.

Master Job Cache

To enable a returner as a Master Job Cache (Master-side), add the following line to the Salt Master configuration file:
master_job_cache: <returner>

For example:

master_job_cache: mysql

Verify that the returner configuration settings are in the Master configuration file, and be sure to restart the salt-master service after you make configuration changes. (service salt-master restart).
The SDB interface is designed to store and retrieve data that, unlike pillars and grains, is not necessarily minion-specific. The initial design goal was to allow passwords to be stored in a secure database, such as one managed by the keyring package, rather than as plain-text files. However, as a generic database interface, it could conceptually be used for a number of other purposes.

SDB was added to Salt in version 2014.7.0.

13.1 SDB Configuration

In order to use the SDB interface, a configuration profile must be set up in either the master or minion configuration file. The configuration stanza includes the name/ID that the profile will be referred to as, a driver setting, and any other arguments that are necessary for the SDB module that will be used. For instance, a profile called mykeyring, which uses the system service in the keyring module would look like:

```
mykeyring:
  driver: keyring
  service: system
```

It is recommended to keep the name of the profile simple, as it is used in the SDB URI as well.

13.2 SDB URIs

SDB is designed to make small database queries (hence the name, SDB) using a compact URL. This allows users to reference a database value quickly inside a number of Salt configuration areas, without a lot of overhead. The basic format of an SDB URI is:

```
sdb://<profile>/<args>
```

The profile refers to the configuration profile defined in either the master or the minion configuration file. The args are specific to the module referred to in the profile, but will typically only need to refer to the key of a key/value pair inside the database. This is because the profile itself should define as many other parameters as possible.

For example, a profile might be set up to reference credentials for a specific OpenStack account. The profile might look like:

```
kevinopenstack:
  driver: keyring
  service: salt.cloud.openstack.kevin
```
And the URI used to reference the password might look like:

```
sdb://kevinopenstack/password
```

### 13.3 Getting and Setting SDB Values

Once an SDB driver is configured, you can use the `sdb` execution module to set and get values from it. There are two functions that will appear in any SDB module: `set` and `get`.

Getting a value requires only the SDB URI to be specified. To retrieve a value from the `kevinopenstack` profile above, you would use:

```
salt-call sdb.get sdb://kevinopenstack/password
```

Some drivers use slightly more complex URIs. For instance, the `vault` driver requires the full path to where the key is stored, followed by a question mark, followed by the key to be retrieved. If you were using a profile called `myvault`, you would use a URI that looks like:

```
salt-call sdb.get 'sdb://myvault/secret/salt?saltstack'
```

Setting a value uses the same URI as would be used to retrieve it, followed by the value as another argument. For the above `myvault` URI, you would set a new value using a command like:

```
salt-call sdb.set 'sdb://myvault/secret/salt?saltstack' 'super awesome'
```

The `sdb.get` and `sdb.set` functions are also available in the runner system:

```
salt-run sdb.get 'sdb://myvault/secret/salt?saltstack'
salt-run sdb.set 'sdb://myvault/secret/salt?saltstack' 'super awesome'
```

### 13.4 Using SDB URIs in Files

SDB URIs can be used in both configuration files, and files that are processed by the renderer system (jinja, mako, etc.). In a configuration file (such as `/etc/salt/master`, `/etc/salt/minion`, `/etc/salt/cloud`, etc.), make an entry as usual, and set the value to the SDB URI. For instance:

```
mykey: sdb://myetcd/mykey
```

To retrieve this value using a module, the module in question must use the `config.get` function to retrieve configuration values. This would look something like:

```
mykey = __salt__['config.get']('mykey')
```

Templating renderers use a similar construct. To get the `mykey` value from above in Jinja, you would use:

```
{{ salt['config.get']('mykey') }}
```

When retrieving data from configuration files using `config.get`, the SDB URI need only appear in the configuration file itself.

If you would like to retrieve a key directly from SDB, you would call the `sdb.get` function directly, using the SDB URI. For instance, in Jinja:
When writing Salt modules, it is not recommended to call `sdb.get` directly, as it requires the user to provide values in SDB, using a specific URI. Use `config.get` instead.

### 13.5 Writing SDB Modules

There is currently one function that MUST exist in any SDB module (`get()`) and one that SHOULD exist (`set_()`). If using a `set_()` function, a `__func_alias__` dictionary MUST be declared in the module as well:

```python
__func_alias__ = {
    'set_': 'set',
}
```

This is because `set` is a Python built-in, and therefore functions should not be created which are called `set()`. The `__func_alias__` functionality is provided via Salt's loader interfaces, and allows legally-named functions to be referred to using names that would otherwise be unwise to use.

The `get()` function is required, as it will be called via functions in other areas of the code which make use of the sdb:// URI. For example, the `config.get` function in the `config` execution module uses this function.

The `set_()` function may be provided, but is not required, as some sources may be read-only, or may be otherwise unwise to access via a URI (for instance, because of SQL injection attacks).

A simple example of an SDB module is `salt/sdb/keyring_db.py`, as it provides basic examples of most, if not all, of the types of functionality that are available not only for SDB modules, but for Salt modules in general.
The Salt Event System is used to fire off events enabling third party applications or external processes to react to behavior within Salt.

The event system is comprised of a two primary components:

- The event sockets which publishes events.
- The event library which can listen to events and send events into the salt system.

## 14.1 Event types

### 14.1.1 Salt Master Events

These events are fired on the Salt Master event bus. This list is not comprehensive.

#### Authentication events

**salt/auth**

Fired when a minion performs an authentication check with the master.

Variables

- **id** -- The minion ID.
- **act** -- The current status of the minion key: accept, pend, reject.
- **pub** -- The minion public key.

Note: Minions fire auth events on fairly regular basis for a number of reasons. Writing reactors to respond to events through the auth cycle can lead to infinite reactor event loops (minion tries to auth, reactor responds by doing something that generates another auth event, minion sends auth event, etc.). Consider reacting to `salt/key` or `salt/minion/<MID>/start` or firing a custom event tag instead.

#### Start events

**salt/minion/<MID>/start**

Fired every time a minion connects to the Salt master.

Variables

- **id** -- The minion ID.
Key events

salt/key
Fired when accepting and rejecting minions keys on the Salt master.

Variables

- **id** -- The minion ID.
- **act** -- The new status of the minion key: *accept*, *pend*, *reject*.

Warning: If a master is in `auto_accept` mode, salt/key events will not be fired when the keys are accepted. In addition, pre-seeding keys (like happens through Salt-Cloud) will not cause firing of these events.

Job events

salt/job/<JID>/new
Fired as a new job is sent out to minions.

Variables

- **jid** -- The job ID.
- **tgt** -- The target of the job: *, a minion ID, `G@os_family:RedHat`, etc.
- **tgt_type** -- The type of targeting used: `glob`, `grain`, `compound`, etc.
- **fun** -- The function to run on minions: `test.ping`, `network.interfaces`, etc.
- **arg** -- A list of arguments to pass to the function that will be called.
- **minions** -- A list of minion IDs that Salt expects will return data for this job.
- **user** -- The name of the user that ran the command as defined in Salt's Client ACL or external auth.

salt/job/<JID>/ret/<MID>
Fired each time a minion returns data for a job.

Variables

- **id** -- The minion ID.
- **jid** -- The job ID.
- **retcode** -- The return code for the job.
- **fun** -- The function the minion ran. E.g., `test.ping`.
- **return** -- The data returned from the execution module.

salt/job/<JID>/prog/<MID>/<RUN NUM>
Fired each time each function in a state run completes execution. Must be enabled using the `state_events` option.

Variables

- **data** -- The data returned from the state module function.
- **id** -- The minion ID.
- **jid** -- The job ID.
Presence events

**salt/presence/present**
Events fired on a regular interval about currently connected, newly connected, or recently disconnected minions. Requires the *presence_events* setting to be enabled.

Variables
- **present** -- A list of minions that are currently connected to the Salt master.

**salt/presence/change**
Fired when the Presence system detects new minions connect or disconnect.

Variables
- **new** -- A list of minions that have connected since the last presence event.
- **lost** -- A list of minions that have disconnected since the last presence event.

Cloud Events

Unlike other Master events, *salt-cloud* events are not fired on behalf of a Salt Minion. Instead, *salt-cloud* events are fired on behalf of a VM. This is because the minion-to-be may not yet exist to fire events to or also may have been destroyed.

This behavior is reflected by the *name* variable in the event data for *salt-cloud* events as compared to the *id* variable for Salt Minion-triggered events.

**salt/cloud/<VM NAME>/creating**
Fired when salt-cloud starts the VM creation process.

Variables
- **name** -- the name of the VM being created.
- **event** -- description of the event.
- **provider** -- the cloud provider of the VM being created.
- **profile** -- the cloud profile for the VM being created.

**salt/cloud/<VM NAME>/deploying**
Fired when the VM is available and salt-cloud begins deploying Salt to the new VM.

Variables
- **name** -- the name of the VM being created.
- **event** -- description of the event.
- **kwargs** -- options available as the deploy script is invoked: `conf_file`, `deploy_command`, `display_ssh_output`, `host`, `keep_tmp`, `key_filename`, `make_minion`, `minion_conf`, `name`, `parallel`, `preseed_minion_keys`, `script`, `script_args`, `script_env`, `sock_dir`, `start_action`, `sudo`, `tmp_dir`, `tty`, `username`

**salt/cloud/<VM NAME>/requesting**
Fired when salt-cloud sends the request to create a new VM.

Variables
- **event** -- description of the event.
- **location** -- the location of the VM being requested.
• `kwargs` -- options available as the VM is being requested: `Action`, `ImageId`, `InstanceType`, `KeyName`, `MaxCount`, `MinCount`, `SecurityGroup`.

`salt/cloud/<VM NAME>/querying`  
Fired when salt-cloud queries data for a new instance.

Variables  
• `event` -- description of the event.  
• `instance_id` -- the ID of the new VM.

`salt/cloud/<VM NAME>/tagging`  
Fired when salt-cloud tags a new instance.

Variables  
• `event` -- description of the event.  
• `tags` -- tags being set on the new instance.

`salt/cloud/<VM NAME>/waiting_for_ssh`  
Fired while the salt-cloud deploy process is waiting for ssh to become available on the new instance.

Variables  
• `event` -- description of the event.  
• `ip_address` -- IP address of the new instance.

`salt/cloud/<VM NAME>/deploy_script`  
Fired once the deploy script is finished.

Variables  
• `event` -- description of the event.

`salt/cloud/<VM NAME>/created`  
Fired once the new instance has been fully created.

Variables  
• `name` -- the name of the VM being created.  
• `event` -- description of the event.  
• `instance_id` -- the ID of the new instance.  
• `provider` -- the cloud provider of the VM being created.  
• `profile` -- the cloud profile for the VM being created.

`salt/cloud/<VM NAME>/destroying`  
Fired when salt-cloud requests the destruction of an instance.

Variables  
• `name` -- the name of the VM being created.  
• `event` -- description of the event.  
• `instance_id` -- the ID of the new instance.

`salt/cloud/<VM NAME>/destroyed`  
Fired when an instance has been destroyed.

Variables  
• `name` -- the name of the VM being created.  
• `event` -- description of the event.
• instance_id -- the ID of the new instance.

14.2 Listening for Events

Salt’s Event Bus is used heavily within Salt and it is also written to integrate heavily with existing tooling and scripts. There is a variety of ways to consume it.

14.2.1 From the CLI

The quickest way to watch the event bus is by calling the state.event runner:

```
salt-run state.event pretty=True
```

That runner is designed to interact with the event bus from external tools and shell scripts. See the documentation for more examples.

14.2.2 Remotely via the REST API

Salt’s event bus can be consumed salt.netapi.rest_cherrypy.app.Events as an HTTP stream from external tools or services.

```
curl -SsNk https://salt-api.example.com:8000/events?token=05A3
```

14.2.3 From Python

Python scripts can access the event bus only as the same system user that Salt is running as.

The event system is accessed via the event library and can only be accessed by the same system user that Salt is running as. To listen to events a SaltEvent object needs to be created and then the get_event function needs to be run. The SaltEvent object needs to know the location that the Salt Unix sockets are kept. In the configuration this is the sock_dir option. The sock_dir option defaults to `/var/run/salt/master` on most systems.

The following code will check for a single event:

```python
import salt.config
import salt.utils.event

opts = salt.config.client_config('/etc/salt/master')

event = salt.utils.event.get_event(  
    'master',
    sock_dir=opts['sock_dir'],
    transport=opts['transport'],
    opts=opts)

data = event.get_event()
```

Events will also use a `tag`. Tags allow for events to be filtered by prefix. By default all events will be returned. If only authentication events are desired, then pass the tag `salt/auth`.

The `get_event` method has a default poll time assigned of 5 seconds. To change this time set the `wait` option. The following example will only listen for auth events and will wait for 10 seconds instead of the default 5.
To retrieve the tag as well as the event data, pass `full=True`:

```python
evdata = event.get_event(wait=10, tag='salt/job', full=True)
tag, data = evdata['tag'], evdata['data']
```

Instead of looking for a single event, the `iter_events` method can be used to make a generator which will continually yield salt events.

The `iter_events` method also accepts a tag but not a wait time:

```python
for data in event.iter_events(tag='salt/auth'):
    print(data)
```

And finally event tags can be globbed, such as they can be in the Reactor, using the `fnmatch` library.

```python
import fnmatch
import salt.config
import salt.utils.event

opts = salt.config.client_config('/etc/salt/master')

sevent = salt.utils.event.get_event(
    'master',
    sock_dir=opts['sock_dir'],
    transport=opts['transport'],
    opts=opts)

while True:
    ret = sevent.get_event(full=True)
    if ret is None:
        continue

    if fnmatch.fnmatch(ret['tag'], 'salt/job/*/ret/*'):
        do_something_with_job_return(ret['data'])
```

### 14.3 Firing Events

It is possible to fire events on either the minion’s local bus or to fire events intended for the master.

To fire a local event from the minion on the command line call the `event.fire` execution function:

```
salt-call event.fire '{"data": "message to be sent in the event"}' 'tag'
```

To fire an event to be sent up to the master from the minion call the `event.send` execution function. Remember YAML can be used at the CLI in function arguments:

```
salt-call event.send 'myco/mytag/success' '{success: True, message: "It works!"}'
```

If a process is listening on the minion, it may be useful for a user on the master to fire an event to it:
# Job on minion

```python
import salt.utils.event

event = salt.utils.event.MinionEvent(**__opts__)

for evdata in event.iter_events(tag='customtag/'):  
    return evdata  # do your processing here...
```

```bash
salt minionname event.fire '{"data": "message for the minion"}' 'customtag/african/unladen'
```

## 14.4 Firing Events from Python

### 14.4.1 From Salt execution modules

Events can be very useful when writing execution modules, in order to inform various processes on the master when a certain task has taken place. This is easily done using the normal cross-calling syntax:

```bash
# /srv/salt/_modules/my_custom_module.py

import salt.utils.event

def do_something():  
    
    Do something and fire an event to the master when finished

    CLI Example:

    ,,,  
    salt '*' my_custom_module:do_something
    ,,,  
    # do something!
    __salt__['event.send']('myco/my_custom_module/finished', {  
        'finished': True,  
        'message': "The something is finished!",
    })
```

### 14.4.2 From Custom Python Scripts

Firing events from custom Python code is quite simple and mirrors how it is done at the CLI:

```python
import salt.client

caller = salt.client.Caller()

caller.sminion.functions['event.send'](
    'myco/myevent/success',
    {
        'success': True,
        'message': "It works!",
    }
)
```
The beacon system allows the minion to hook into a variety of system processes and continually monitor these processes. When monitored activity occurs in a system process, an event is sent on the Salt event bus that can be used to trigger a reactor.

Salt beacons can currently monitor and send Salt events for many system activities, including:

- file system changes
- system load
- service status
- shell activity, such as user login
- network and disk usage

See beacon modules for a current list.

Note: Salt beacons are an event generation mechanism. Beacons leverage the Salt reactor system to make changes when beacon events occur.

### 15.1 Configuring Beacons

Salt beacons do not require any changes to the system process that is being monitored, everything is configured using Salt.

Beacons are typically enabled by placing a beacons: top level block in the minion configuration file:

```yaml
beacons:
  inotify:
    /etc/httpd/conf.d: {}
    /opt: {}
```

The beacon system, like many others in Salt, can also be configured via the minion pillar, grains, or local config file.

Note: The inotify beacon only works on OSes that have inotify kernel support. Currently this excludes FreeBSD, Mac OS X, and Windows.
15.1.1 Beacon Monitoring Interval

Beacons monitor on a 1-second interval by default. To set a different interval, provide an interval argument to a beacon. The following beacons run on 5- and 10-second intervals:

```yaml
beacons:
  inotify:
    /etc/httpd/conf.d: {}
    /opt: {}
    interval: 5
  load:
    1m:
      - 0.0
      - 2.0
    5m:
      - 0.0
      - 1.5
    15m:
      - 0.1
      - 1.0
    interval: 10
```

15.1.2 Avoiding Event Loops

It is important to carefully consider the possibility of creating a loop between a reactor and a beacon. For example, one might set up a beacon which monitors whether a file is read which in turn fires a reactor to run a state which in turn reads the file and re-fires the beacon.

To avoid these types of scenarios, the disable_during_state_run argument may be set. If a state run is in progress, the beacon will not be run on its regular interval until the minion detects that the state run has completed, at which point the normal beacon interval will resume.

```yaml
beacons:
  inotify:
    /etc/passwd: {}
    disable_during_state_run: True
```

15.2 Beacon Example

This example demonstrates configuring the `inotify` beacon to monitor a file for changes, and then create a backup each time a change is detected.

**Note:** The inotify beacon requires Pyinotify on the minion, install it using `salt myminion pkg.install python-inotify`.

First, on the Salt minion, add the following beacon configuration to `/etc/salt/minion`:

```yaml
beacons:
  inotify:
    home/user/importantfile:
      mask:
        - modify
```
Replace user in the previous example with the name of your user account, and then save the configuration file and restart the minion service.

Next, create a file in your home directory named importantfile and add some simple content. The beacon is now set up to monitor this file for modifications.

15.2.1 View Events on the Master

On your Salt master, start the event runner using the following command:

```
salt-run state.event pretty=true
```

This runner displays events as they are received on the Salt event bus. To test the beacon you set up in the previous section, make and save a modification to the importantfile you created. You'll see an event similar to the following on the event bus:

```
salt/beacon/minion1/inotify/home/user/importantfile {
  "_stamp": "2015-09-09T15:59:37.972753",
  "data": {
    "change": "IN_IGNORED",
    "id": "minion1",
    "path": "/home/user/importantfile"
  },
  "tag": "salt/beacon/minion1/inotify/home/user/importantfile"
}
```

This indicates that the event is being captured and sent correctly. Now you can create a reactor to take action when this event occurs.

15.2.2 Create a Reactor

On your Salt master, create a file named srv/reactor/backup.sls. If the reactor directory doesn’t exist, create it. Add the following to backup.sls:

```
backup file:
  cmd.file.copy:
  - tgt: {{ data['data'][id] }}
  - arg:
    - {{ data['data'][path] }}
    - {{ data['data'][path] }}.bak
```

Next, add the code to trigger the reactor to ect/salt/master:

```
reactor:
  - salt/beacon/*/inotify/*/importantfile:
    - /srv/reactor/backup.sls
```

This reactor creates a backup each time a file named importantfile is modified on a minion that has the inotify beacon configured as previously shown.

**Note:** You can have only one top level reactor section, so if one already exists, add this code to the existing section. See *Understanding the Structure of Reactor Formulas* to learn more about reactor SLS syntax.

15.2. Beacon Example
15.2.3 Start the Salt Master in Debug Mode

To help with troubleshooting, start the Salt master in debug mode:

```bash
service salt-master stop
salt-master -l debug
```

When debug logging is enabled, event and reactor data are displayed so you can discover syntax and other issues.

15.2.4 Trigger the Reactor

On your minion, make and save another change to `importantfile`. On the Salt master, you’ll see debug messages that indicate the event was received and the `file.copy` job was sent. When you list the directory on the minion, you’ll now see `importantfile.bak`.

All beacons are configured using a similar process of enabling the beacon, writing a reactor SLS, and mapping a beacon event to the reactor SLS.

15.3 Writing Beacon Plugins

Beacon plugins use the standard Salt loader system, meaning that many of the constructs from other plugin systems holds true, such as the `__virtual__` function.

The important function in the Beacon Plugin is the `beacon` function. When the beacon is configured to run, this function will be executed repeatedly by the minion. The `beacon` function therefore cannot block and should be as lightweight as possible. The `beacon` also must return a list of dicts, each dict in the list will be translated into an event on the master.

Please see the `inotify` beacon as an example.

15.3.1 The beacon Function

The beacons system will look for a function named `beacon` in the module. If this function is not present then the beacon will not be fired. This function is called on a regular basis and defaults to being called on every iteration of the minion, which can be tens to hundreds of times a second. This means that the `beacon` function cannot block and should not be CPU or IO intensive.

The beacon function will be passed in the configuration for the executed beacon. This makes it easy to establish a flexible configuration for each called beacon. This is also the preferred way to ingest the beacon’s configuration as it allows for the configuration to be dynamically updated while the minion is running by configuring the beacon in the minion’s pillar.

15.3.2 The Beacon Return

The information returned from the beacon is expected to follow a predefined structure. The returned value needs to be a list of dictionaries (standard python dictionaries are preferred, no ordered dicts are needed).

The dictionaries represent individual events to be fired on the minion and master event buses. Each dict is a single event. The dict can contain any arbitrary keys but the `tag` key will be extracted and added to the tag of the fired event.

The return data structure would look something like this:
15.3.3 Calling Execution Modules

Execution modules are still the preferred location for all work and system interaction to happen in Salt. For this reason the __salt__ variable is available inside the beacon.

Please be careful when calling functions in __salt__, while this is the preferred means of executing complicated routines in Salt not all of the execution modules have been written with beacons in mind. Watch out for execution modules that may be CPU intense or IO bound. Please feel free to add new execution modules and functions to back specific beacons.

15.3.4 Distributing Custom Beacons

Custom beacons can be distributed to minions using saltutil, see Dynamic Module Distribution.
Salt Engines

New in version 2015.8.0.

Salt Engines are long-running, external system processes that leverage Salt.

- Engines have access to Salt configuration, execution modules, and runners (__opts__, __salt__, and __runners__).
- Engines are executed in a separate process that is monitored by Salt. If a Salt engine stops, it is restarted automatically.
- Engines can run on the Salt master and on Salt minions.

Salt engines enhance and replace the external processes functionality.

16.1 Configuration

Salt engines are configured under an engines top-level section in your Salt master or Salt minion configuration. Provide a list of engines and parameters under this section.

```yaml
engines:
  - logstash:
      host: log.my_network.com
      port: 5959
```

Salt engines must be in the Salt path, or you can add the engines_dir option in your Salt master configuration with a list of directories under which Salt attempts to find Salt engines.

16.2 Writing an Engine

An example Salt engine, https://github.com/saltstack/salt/blob/develop/salt/engines/test.py, is available in the Salt source. To develop an engine, the only requirement is that your module implement the start() function.
Running Custom Master Processes

**Note:** *Salt engines* are a new feature in 2015.8.0 that let you run custom processes on the Salt master and on Salt minions. Salt engines provide more functionality than *ext_processes* by accepting arguments, and by providing access to Salt config, execution modules, and runners.

In addition to the processes that the Salt master automatically spawns, it is possible to configure it to start additional custom processes.

This is useful if a dedicated process is needed that should run throughout the life of the Salt master. For periodic independent tasks, a scheduled runner may be more appropriate.

Processes started in this way will be restarted if they die and will be killed when the Salt master is shut down.

### 17.1 Example Configuration

Processes are declared in the master config file with the *ext_processes* option. Processes will be started in the order they are declared.

```yaml
ext_processes:
   - mymodule.TestProcess
   - mymodule.AnotherProcess
```

### 17.2 Example Process Class

```python
# Import python libs
import time
import logging
from multiprocessing import Process

# Import Salt libs
from salt.utils.event import SaltEvent

log = logging.getLogger(__name__)

class TestProcess(Process):
```

```python
def __init__(self, opts):
    Process.__init__(self)
    self.opts = opts

def run(self):
    self.event = SaltEvent('master', self.opts['sock_dir'])
    i = 0

    while True:
        self.event.fire_event({'iteration': i}, 'ext_processes/test[0]')
        time.sleep(60)
```

236 Chapter 17. Running Custom Master Processes
Salt supports several features for high availability and fault tolerance. Brief documentation for these features is listed alongside their configuration parameters in Configuration file examples.

18.1 Multimaster

Salt minions can connect to multiple masters at one time by configuring the `master` configuration parameter as a YAML list of all the available masters. By default, all masters are "hot", meaning that any master can direct commands to the Salt infrastructure.

In a multimaster configuration, each master must have the same cryptographic keys, and minion keys must be accepted on all masters separately. The contents of file_roots and pillar_roots need to be kept in sync with processes external to Salt as well.

A tutorial on setting up multimaster with "hot" masters is here:

Multimaster Tutorial

18.2 Multimaster with Failover

Changing the `master_type` parameter from `str` to `failover` will cause minions to connect to the first responding master in the list of masters. Every `master_alive_interval` seconds the minions will check to make sure the current master is still responding. If the master does not respond, the minion will attempt to connect to the next master in the list. If the minion runs out of masters, the list will be recycled in case dead masters have been restored. Note that `master_alive_interval` must be present in the minion configuration, or else the recurring job to check master status will not get scheduled.

Failover can be combined with PKI-style encrypted keys, but PKI is NOT REQUIRED to use failover.

Multimaster with PKI and Failover is discussed in this tutorial

`master_type: failover` can be combined with `master_shuffle: True` to spread minion connections across all masters (one master per minion, not each minion connecting to all masters). Adding Salt Syndics into the mix makes it possible to create a load-balanced Salt infrastructure. If a master fails, minions will notice and select another master from the available list.
18.3 Syndic

Salt's Syndic feature is a way to create differing infrastructure topologies. It is not strictly an HA feature, but can be treated as such.

With the syndic, a Salt infrastructure can be partitioned in such a way that certain masters control certain segments of the infrastructure, and "Master of Masters" nodes can control multiple segments underneath them.

Syndics are covered in depth in Salt Syndic.

18.4 Syndic with Multimaster

New in version 2015.5.0.

Syndic with Multimaster lets you connect a syndic to multiple masters to provide an additional layer of redundancy in a syndic configuration.

Syndics are covered in depth in Salt Syndic.
The most basic or typical Salt topology consists of a single Master node controlling a group of Minion nodes. An intermediate node type, called Syndic, when used offers greater structural flexibility and scalability in the construction of Salt topologies than topologies constructed only out of Master and Minion node types.

A Syndic node can be thought of as a special passthrough Minion node. A Syndic node consists of a salt-syndic daemon and a salt-master daemon running on the same system. The salt-master daemon running on the Syndic node controls a group of lower level Minion nodes and the salt-syndic daemon connects higher level Master node, sometimes called a Master of Masters.

The salt-syndic daemon relays publications and events between the Master node and the local salt-master daemon. This gives the Master node control over the Minion nodes attached to the salt-master daemon running on the Syndic node.

### 19.1 Configuring the Syndic

To setup a Salt Syndic you need to tell the Syndic node and its Master node about each other. If your Master node is located at 10.10.0.1, then your configurations would be:

On the Syndic node:

```
# /etc/salt/master
syndic_master: 10.10.0.1  # may be either an IP address or a hostname
```

```
# /etc/salt/minion
# id is shared by the salt-syndic daemon and a possible salt-minion daemon
# on the Syndic node
id: my_syndic
```

On the Master node:

```
# /etc/salt/master
order_masters: True
```

The syndic_master option tells the Syndic node where to find the Master node in the same way that the master option tells a Minion node where to find a Master node.

The id option is used by the salt-syndic daemon to identify with the Master node and if unset will default to the hostname or IP address of the Syndic just as with a Minion.
The order_masters option configures the Master node to send extra information with its publications that is needed by Syndic nodes connected directly to it.

Note: Each Syndic must provide its own file_roots directory. Files will not be automatically transferred from the Master node.

19.2 Configuring the Syndic with Multimaster

New in version 2015.5.0.

Syndic with Multimaster lets you connect a syndic to multiple masters to provide an additional layer of redundancy in a syndic configuration.

Higher level masters should first be configured in a multimaster configuration. See Multimaster Tutorial.

On the syndic, the syndic_master option is populated with a list of the higher level masters.

Since each syndic is connected to each master, jobs sent from any master are forwarded to minions that are connected to each syndic. If the master_id value is set in the master config on the higher level masters, job results are returned to the master that originated the request in a best effort fashion. Events/jobs without a master_id are returned to any available master.

19.3 Running the Syndic

The salt-syndic daemon is a separate process that needs to be started in addition to the salt-master daemon running on the Syndic node. Starting the salt-syndic daemon is the same as starting the other Salt daemons.

The Master node in many ways sees the Syndic as an ordinary Minion node. In particular, the Master will need to accept the Syndic's Minion key as it would for any other Minion.

On the Syndic node:

```
# salt-syndic
or
# service salt-syndic start
```

On the Master node:

```
# salt-key -a my_syndic
```

The Master node will now be able to control the Minion nodes connected to the Syndic. Only the Syndic key will be listed in the Master node's key registry but this also means that key activity between the Syndic's Minions and the Syndic does not encumber the Master node. In this way, the Syndic's key on the Master node can be thought of as a placeholder for the keys of all the Minion and Syndic nodes beneath it, giving the Master node a clear, high level structural view on the Salt cluster.

On the Master node:

```
# salt-key -L
Accepted Keys: my_syndic
Denied Keys: 
Unaccepted Keys: 
Rejected Keys: 
```
# salt '*' test.ping

minion_1:
  True
minion_2:
  True
minion_4:
  True
minion_3:
  True

19.4 Topology

A Master node (a node which is itself not a Syndic to another higher level Master node) must run a salt-master
daemon and optionally a salt-minion daemon.

A Syndic node must run salt-syndic and salt-master daemons and optionally a salt-minion daemon.

A Minion node must run a salt-minion daemon.

When a salt-master daemon issues a command, it will be received by the Syndic and Minion nodes directly
connected to it. A Minion node will process the command in the way it ordinarily would. On a Syndic node, the
salt-syndic daemon will relay the command to the salt-master daemon running on the Syndic node, which
then propagates the command to to the Minions and Syndics connected to it.

When events and job return data are generated by salt-minion daemons, they are aggregated by the salt-
master daemon they are connected to, which salt-master daemon then relays the data back through its salt-
syndic daemon until the data reaches the Master or Syndic node that issued the command.

19.5 Syndic wait

Note: To reduce the amount of time the CLI waits for Minions to respond, install a Minion on the Syndic or tune
the value of the syndic_wait configuration.

While it is possible to run a Syndic without a Minion installed on the same system, it is recommended, for a faster
CLI response time, to do so. Without a Minion installed on the Syndic node, the timeout value of syndic_wait
increases significantly - about three-fold. With a Minion installed on the Syndic, the CLI timeout resides at the value
deefined in syndic_wait.

Note: If you have a very large infrastructure or many layers of Syndics, you may find that the CLI doesn't wait long
enough for the Syndics to return their events. If you think this is the case, you can set the syndic_wait value in
the Master configs on the Master or Syndic nodes from which commands are executed. The default value is 5, and
should work for the majority of deployments.

In order for a Master or Syndic node to return information from Minions that are below their Syndics, the CLI
requires a short wait time in order to allow the Syndics to gather responses from their Minions. This value is defined
in the syndic_wait config option and has a default of five seconds.
19.6 Syndic config options

These are the options that can be used to configure a Syndic node. Note that other than `id`, Syndic config options are placed in the Master config on the Syndic node.

- **id**: Syndic id (shared by the `salt-syndic` daemon with a potential `salt-minion` daemon on the same system)
- **syndic_master**: Master node IP address or hostname
- **syndic_master_port**: Master node ret_port
- **syndic_log_file**: path to the logfile (absolute or not)
- **syndic_pidfile**: path to the pidfile (absolute or not)
- **syndic_wait**: time in seconds to wait on returns from this syndic
Proxy minions are a developing Salt feature that enables controlling devices that, for whatever reason, cannot run a standard salt-minion. Examples include network gear that has an API but runs a proprietary OS, devices with limited CPU or memory, or devices that could run a minion, but for security reasons, will not.

Proxy minions are not an "out of the box" feature. Because there are an infinite number of controllable devices, you will most likely have to write the interface yourself. Fortunately, this is only as difficult as the actual interface to the proxied device. Devices that have an existing Python module (PyUSB for example) would be relatively simple to interface. Code to control a device that has an HTML REST-based interface should be easy. Code to control your typical housecat would be excellent source material for a PhD thesis.

Salt proxy-minions provide the 'plumbing' that allows device enumeration and discovery, control, status, remote execution, and state management.

See the Proxy Minion Walkthrough for an end-to-end demonstration of a working proxy minion.

See the Proxy Minion SSH Walkthrough for an end-to-end demonstration of a working SSH proxy minion.

20.1 New in 2015.8.2

BREAKING CHANGE: Adding the proxymodule variable to __opts__ is deprecated. The proxymodule variable has been moved a new globally-injected variable called __proxy__. A related configuration option called add_proxymodule_to_opts has been added and defaults to True. In the next major release, codenamed Boron, this variable will default to False.

In the meantime, proxies that functioned under 2015.8.0 and .1 should continue to work under 2015.8.2. You should rework your proxy code to use __proxy__ as soon as possible.

The rest_sample example proxy minion has been updated to use __proxy__.

This change was made because proxymodules are a LazyLoader object, but LazyLoaders cannot be serialized. __opts__ gets serialized, and so things like saltutil.sync_all and state.highstate would throw exceptions.

Also in this release, proxymodules can be stored on the master in /srv/salt/_proxy. A new saltutil function called sync_proxies will transfer these to remote proxy minions. Note that you must restart the salt-proxy daemon to pick up these changes.

In addition, a salt.utils helper function called is_proxy() was added to make it easier to tell when the running minion is a proxy minion.
20.2 New in 2015.8

Starting with the 2015.8 release of Salt, proxy processes are no longer forked off from a controlling minion. Instead, they have their own script salt-proxy which takes mostly the same arguments that the standard Salt minion does with the addition of --proxyid. This is the id that the salt-proxy will use to identify itself to the master. Proxy configurations are still best kept in Pillar and their format has not changed.

This change allows for better process control and logging. Proxy processes can now be listed with standard process management utilities (ps from the command line). Also, a full Salt minion is no longer required (though it is still strongly recommended) on machines hosting proxies.

20.3 Getting Started

The following diagram may be helpful in understanding the structure of a Salt installation that includes proxy-minions:
The key thing to remember is the left-most section of the diagram. Salt’s nature is to have a minion connect to a master, then the master may control the minion. However, for proxy minions, the target device cannot run a minion.

After the proxy minion is started and initiates its connection to the `dumb` device, it connects back to the salt-master and for all intents and purposes looks like just another minion to the Salt master.

To create support for a proxied device one needs to create four things:

1. The `proxy_connection_module` (located in salt/proxy).
2. The `grains support code` (located in salt/grains).
3. Salt modules specific to the controlled device.
4. `Salt states` specific to the controlled device.
20.3.1 Configuration parameters

Proxy minions require no configuration parameters in /etc/salt/master.

Salt’s Pillar system is ideally suited for configuring proxy-minions. Proxies can either be designated via a pillar file in pillar_roots, or through an external pillar. External pillars afford the opportunity for interfacing with a configuration management system, database, or other knowledgeable system that may already contain all the details of proxy targets. To use static files in pillar_roots, pattern your files after the following examples, which are based on the diagram above:

/srv/pillar/top.sls

```yaml
base:
  dumbdevice1:
    - dumbdevice1
  dumbdevice2:
    - dumbdevice2
  dumbdevice3:
    - dumbdevice3
  dumbdevice4:
    - dumbdevice4
  dumbdevice5:
    - dumbdevice5
  dumbdevice6:
    - dumbdevice6
  dumbdevice7:
    - dumbdevice7
```

/srv/pillar/dumbdevice1.sls

```yaml
proxy:
  proxytype: networkswitch
  host: 172.23.23.5
  username: root
  passwd: letmein
```

/srv/pillar/dumbdevice2.sls

```yaml
proxy:
  proxytype: networkswitch
  host: 172.23.23.6
  username: root
  passwd: letmein
```

/srv/pillar/dumbdevice3.sls

```yaml
proxy:
  proxytype: networkswitch
  host: 172.23.23.7
  username: root
  passwd: letmein
```

/srv/pillar/dumbdevice4.sls

```yaml
proxy:
  proxytype: i2c_lightshow
  i2c_address: 1
```

/srv/pillar/dumbdevice5.sls
Note the contents of each minioncontroller key may differ widely based on the type of device that the proxy-minion is managing.

In the above example

- dumbdevices 1, 2, and 3 are network switches that have a management interface available at a particular IP address.
- dumbdevices 4 and 5 are very low-level devices controlled over an i2c bus. In this case the devices are physically connected to machine `minioncontroller2', and are addressable on the i2c bus at their respective i2c addresses.
- dumbdevice 6 is a 433 MHz wireless transmitter, also physically connected to minioncontroller2.
- dumbdevice 7 is an SMS gateway connected to machine minioncontroller3 via a serial port.

Because of the way pillar works, each of the salt-proxy processes that fork off the proxy minions will only see the keys specific to the proxies it will be handling.

Also, in general, proxy-minions are lightweight, so the machines that run them could conceivably control a large number of devices. To run more than one proxy from a single machine, simply start an additional proxy process with --proxyid set to the id to which you want the proxy to bind. It is possible for the proxy services to be spread across many machines if necessary, or intentionally run on machines that need to control devices because of some physical interface (e.g. i2c and serial above). Another reason to divide proxy services might be security. In more secure environments only certain machines may have a network path to certain devices.

### 20.3.2 Proxymodules

A proxy module encapsulates all the code necessary to interface with a device. Proxymodules are located inside the salt.proxy module. At a minimum a proxymodule object must implement the following functions:

- `__virtual__()`: This function performs the same duty that it does for other types of Salt modules. Logic goes here to determine if the module can be loaded, checking for the presence of Python modules on which the proxy depends. Returning `False` will prevent the module from loading.

- `init(opts)`: Perform any initialization that the device needs. This is a good place to bring up a persistent connection to a device, or authenticate to create a persistent authorization token.

- `shutdown()`: Code to cleanly shut down or close a connection to a controlled device goes here. This function must exist, but can contain only the keyword `pass` if there is no shutdown logic required.

- `ping()`: While not required, it is highly recommended that this function also be defined in the proxymodule. The code for `ping` should contact the controlled device and make sure it is really available.

Pre 2015.8 the proxymodule also must have an `id()` function. 2015.8 and following don't use this function because the proxy's id is required on the command line.
id(opts): Returns a unique, unchanging id for the controlled device. This is the `name` of the device, and is used by the salt-master for targeting and key authentication.

Here is an example proxymodule used to interface to a very simple REST server. Code for the server is in the salt-contrib GitHub repository.

This proxymodule enables `service` enumeration, starting, stopping, restarting, and status; `package` installation, and a ping.

```python
# -*- coding: utf-8 -*-

'''This is a simple proxy-minion designed to connect to and communicate with
the bottle-based web service contained in
https://github.com/saltstack/salt-contrib/proxyminion_rest_example
'''
from __future__ import absolute_import

# Import python libs
import logging
import salt.utils.http

HAS_REST_EXAMPLE = True

# This must be present or the Salt loader won't load this module
__proxyenabled__ = ['rest_sample']

# Variables are scoped to this module so we can have persistent data
# across calls to fns in here.
GRAINS_CACHE = {}
DETAILS = {}

# Want logging!
log = logging.getLogger(__file__)

# This does nothing, it's here just as an example and to provide a log
# entry when the module is loaded.
def __virtual__():
    '''
    Only return if all the modules are available
    '''
    log.debug('rest_sample proxy __virtual__() called...')
    return True

# Every proxy module needs an 'init', though you can
# just put a 'pass' here if it doesn't need to do anything.
def init(opts):
    log.debug('rest_sample proxy init() called...')

    # Save the REST URL
    DETAILS['url'] = opts['proxy']['url']

    # Make sure the REST URL ends with a '/'
    if not DETAILS['url'].endswith('/'):
        DETAILS['url'] += '/'

def id(opts):
```
Return a unique ID for this proxy minion. This ID MUST NOT CHANGE. If it changes while the proxy is running the salt-master will get really confused and may stop talking to this minion

```python
r = salt.utils.http.query(opts['proxy'][url]+'id', decode_type='json',
--decode=True)
return r['dict']['id'].encode('ascii', 'ignore')
```

def grains():
    
    Get the grains from the proxied device
    
    if not GRAINS_CACHE:
        r = salt.utils.http.query(DETAILS[url]+'info', decode_type='json',
--decode=True)
        GRAINS_CACHE = r['dict']
    return GRAINS_CACHE

def grains_refresh():
    
    Refresh the grains from the proxied device
    
    GRAINS_CACHE = {}
    return grains()

def service_start(name):
    
    Start a "service" on the REST server
    
    r = salt.utils.http.query(DETAILS[url]+'service/start/'+name, decode_type='json',
--decode=True)
    return r['dict']

def service_stop(name):
    
    Stop a "service" on the REST server
    
    r = salt.utils.http.query(DETAILS[url]+'service/stop/'+name, decode_type='json',
--decode=True)
    return r['dict']

def service_restart(name):
    
    Restart a "service" on the REST server
    
    r = salt.utils.http.query(DETAILS[url]+'service/restart/'+name, decode_type='json',
--decode=True)
    return r['dict']

def service_list():
    
```
List "services" on the REST server

```python
r = salt.utils.http.query(DETAILS['url'] + 'service/list', decode_type='json', decode=True)
return r['dict']
```

def service_status(name):
    
    Check if a service is running on the REST server
    
    ```python
    r = salt.utils.http.query(DETAILS['url'] + 'service/status/' + name, decode_type='json', decode=True)
    return r['dict']
    ```

def package_list():
    
    List "packages" installed on the REST server
    
    ```python
    r = salt.utils.http.query(DETAILS['url'] + 'package/list', decode_type='json', decode=True)
    return r['dict']
    ```

def package_install(name, **kwargs):
    
    Install a "package" on the REST server
    
    ```python
    cmd = DETAILS['url'] + 'package/install/' + name
    if 'version' in kwargs:
        cmd += '/{version}
    else:
        cmd += '/1.0'
    r = salt.utils.http.query(cmd, decode_type='json', decode=True)
    ```

def package_remove(name):
    
    Remove a "package" on the REST server
    
    ```python
    r = salt.utils.http.query(DETAILS['url'] + 'package/remove/' + name, decode_type='json', decode=True)
    return r['dict']
    ```

def package_status(name):
    
    Check the installation status of a package on the REST server
    
    ```python
    r = salt.utils.http.query(DETAILS['url'] + 'package/status/' + name, decode_type='json', decode=True)
    return r['dict']
    ```

def ping():
    ```python
    ```
Grains are data about minions. Most proxied devices will have a paltry amount of data as compared to a typical Linux server. By default, a proxy minion will have several grains taken from the host. Salt core code requires values for kernel, os, and os_family—all of these are forced to be proxy for proxy-minions. To add others to your proxy minion for a particular device, create a file in salt/grains named [proxytype].py and place inside it the different functions that need to be run to collect the data you are interested in. Here's an example:

```
Grains are data about minions. Most proxied devices will have a paltry amount of data as compared to a typical Linux server. By default, a proxy minion will have several grains taken from the host. Salt core code requires values for kernel, os, and os_family—all of these are forced to be proxy for proxy-minions. To add others to your proxy minion for a particular device, create a file in salt/grains named [proxytype].py and place inside it the different functions that need to be run to collect the data you are interested in. Here's an example:

20.4 The __proxyenabled__ directive

Salt execution modules, by, and large, cannot "automatically" work with proxied devices. Execution modules like pkg or sqlite3 have no meaning on a network switch or a housecat. For an execution module to be available to a proxy-minion, the __proxyenabled__ variable must be defined in the module as an array containing the names of all the proxytypes that this module can support. The array can contain the special value * to indicate that the module supports all proxies.

If no __proxyenabled__ variable is defined, then by default, the execution module is unavailable to any proxy.

Here is an excerpt from a module that was modified to support proxy-minions:

```
__proxyenabled__ = ['*']

[...]  
def ping():
    if not salt.utils.is_proxy():
        return True
    else:
        ping_cmd = __opts__['proxy'][proxytype] + '.ping'
        if __opts__.get('add_proxymodule_to_opts', False):
            return __opts__['proxymodule'][ping_cmd]()
        else:
            return __proxy__[ping_cmd]()
```

And then in salt.proxy.rest_sample.py we find

```
def ping():
    """
    Is the REST server up?
    """
    r = salt.utils.http.query(DETAILS['url']+'ping', decode_type='json', decode=True)
    try:
```
20.4.1 Salt Proxy Minion End-to-End Example

The following is walkthrough that documents how to run a sample REST service and configure one or more proxy minions to talk to and control it.

1. Ideally, create a Python virtualenv in which to run the REST service. This is not strictly required, but without a virtualenv you will need to install bottle via pip globally on your system.

2. Clone https://github.com/saltstack/salt-contrib and copy the contents of the directory `proxyminion_rest_example` somewhere on a machine that is reachable from the machine on which you want to run the salt-proxy. This machine needs Python 2.7 or later.

3. Install bottle version 0.12.8 via pip or easy_install.

```
pip install bottle==0.12.8
```

4. Run python `rest.py --help` for usage.

5. Start the REST API on an appropriate port and IP.

6. Load the REST service's status page in your browser by going to the IP/port combination (e.g. http://127.0.0.1:8000)

7. You should see a page entitled ``Salt Proxy Minion`` with two sections, one for `services` and one for `packages` and you should see a log entry in the terminal where you started the REST process indicating that the index page was retrieved.

Now, configure your salt-proxy.

1. Edit `/etc/salt/proxy` and add an entry for your master's location

```
master: localhost
```

2. On your salt-master, ensure that pillar is configured properly. Select an ID for your proxy (in this example we will name the proxy with the letter `p` followed by the port the proxy is answering on). In your pillar topfile, place an entry for your proxy:
base:
  'p8000':
    - p8000

This says that Salt’s pillar should load some values for the proxy `p8000` from the file `/srv/pillar/p8000.sls` (if you have not changed your default pillar_roots)

3. In the pillar root for your base environment, create this file:

```
p8000.sls  
---------
proxy:
  proxytype: rest_sample
  url: http://<IP your REST listens on>:port
```

In other words, if your REST service is listening on port 8000 on 127.0.0.1 the `url` key above should say `url: http://127.0.0.1:8000`

4. Make sure your salt-master is running.

5. Start the salt-proxy in debug mode

```
salt-proxy --proxyid=p8000 -l debug
```

6. Accept your proxy’s key on your salt-master

```
salt-key -y -a p8000
The following keys are going to be accepted:
Unaccepted Keys:
p8000
Key for minion p8000 accepted.
```

7. Now you should be able to ping your proxy. When you ping, you should see a log entry in the terminal where the REST service is running.

```
salt p8000 test.ping
```

8. The REST service implements a degenerately simple pkg and service provider as well as a small set of grains. To `install` a package, use a standard `pkg.install`. If you pass `=` and a version number after the package name then the service will parse that and accept that as the package’s version.

9. Try running `salt p8000 grains.items` to see what grains are available. You can target proxies via grains if you like.

10. You can also start and stop the available services (apache, redbull, and postgresql with `service.start`, etc.

11. States can be written to target the proxy. Feel free to experiment with them.

## 20.5 SSH Proxymodules

See above for a general introduction to writing proxy modules. All of the guidelines that apply to REST are the same for SSH. This sections specifically talks about the SSH proxy module and explains the working of the example proxy module `ssh_sample`.

Here is a simple example proxymodule used to interface to a device over SSH. Code for the SSH shell is in the salt-contrib GitHub repository
This proxymodule enables `package` installation.

```python
# -*- coding: utf-8 -*-

'''
This is a simple proxy-minion designed to connect to and communicate with a server that exposes functionality via SSH.
This can be used as an option when the device does not provide an API over HTTP and doesn't have the python stack to run a minion.
'''
from __future__ import absolute_import

# Import python libs
import json
import logging

# Import Salt's libs
from salt.utils.vt_helper import SSHConnection
from salt.utils.vt import TerminalException

# This must be present or the Salt loader won't load this module
__proxyenabled__ = ['ssh_sample']

DETAILS = {}

# Want logging!
log = logging.getLogger(__file__)

# This does nothing, it's here just as an example and to provide a log entry when the module is loaded.
def __virtual__():
    '''
    Only return if all the modules are available
    '''
    log.info('ssh_sample proxy __virtual__() called...
    return True

def init(opts):
    '''
    Required.
    Can be used to initialize the server connection.
    '''
    try:
        DETAILS['server'] = SSHConnection(host=opts['proxy']['host'],
                                           username=opts['proxy']['username'],
                                           password=opts['proxy']['password'])

        # connected to the SSH server
        out, err = DETAILS['server'].sendline('help')
    except TerminalException as e:
        log.error(e)
        return False

def shutdown(opts):
    '''
    Disconnect
    '''
```
def parse(out):
    """
    Extract json from out.
    Parameter
    out: Type string. The data returned by the ssh command.
    """
    jsonret = []
in_json = False
for ln_ in out.split('\n'):
    if '{' in ln_:
        in_json = True
    if in_json:
        jsonret.append(ln_)
    if '}' in ln_:
        in_json = False
    return json.loads('\n'.join(jsonret))

def package_list():
    """
    List "packages" by executing a command via ssh
    This function is called in response to the salt command
    ..code-block::bash
       salt target_minion pkg.list_pkgs
    """
    # Send the command to execute
    out, err = DETAILS['server'].sendline('pkg_list')

    # "scrape" the output and return the right fields as a dict
    return parse(out)

def package_install(name, **kwargs):
    """
    Install a "package" on the REST server
    """
    cmd = 'pkg_install ' + name
    if 'version' in kwargs:
        cmd += '/'+kwargs['version']
    else:
        cmd += '/1.0'

    # Send the command to execute
    out, err = DETAILS['server'].sendline(cmd)

    # "scrape" the output and return the right fields as a dict
    return parse(out)

def package_remove(name):

20.5. SSH Proxymodules
Remove a "package" on the REST server

```

cmd = 'pkg_remove ' + name

# Send the command to execute
out, err = DETAILS['server'].sendline(cmd)

# "scrape" the output and return the right fields as a dict
return parse(out)
```

20.5.1 Connection Setup

The init() method is responsible for connection setup. It uses the host, username and password config variables defined in the pillar data. The prompt kwarg can be passed to SSHConnection if your SSH server's prompt differs from the example's prompt (Cmd). Instantiating the SSHConnection class establishes an SSH connection to the ssh server (using Salt VT).

20.5.2 Command execution

The package_* methods use the SSH connection (established in init()) to send commands out to the SSH server. The sendline() method of SSHConnection class can be used to send commands out to the server. In the above example we send commands like pkg_list or pkg_install. You can send any SSH command via this utility.

20.5.3 Output parsing

Output returned by sendline() is a tuple of strings representing the stdout and the stderr respectively. In the toy example shown we simply scrape the output and convert it to a python dictionary, as shown in the parse method. You can tailor this method to match your parsing logic.

20.5.4 Connection teardown

The shutdown method is responsible for calling the close_connection() method of SSHConnection class. This ends the SSH connection to the server.

For more information please refer to class SSHConnection.

Salt Proxy Minion SSH End-to-End Example

The following is walkthrough that documents how to run a sample SSH service and configure one or more proxy minions to talk to and control it.

1. This walkthrough uses a custom SSH shell to provide an end to end example. Any other shells can be used too.
2. Setup the proxy command shell as shown https://github.com/saltstack/salt-contrib/tree/master/proxyminion_ssh_example

Now, configure your salt-proxy.

1. Edit /etc/salt/proxy and add an entry for your master's location
2. On your salt-master, ensure that pillar is configured properly. Select an ID for your proxy (in this example we will name the proxy with the letter `p' followed by the port the proxy is answering on). In your pillar topfile, place an entry for your proxy:

```
base:
  'p8000':
    - p8000
```

This says that Salt's pillar should load some values for the proxy p8000 from the file /srv/pillar/p8000.sls (if you have not changed your default pillar_roots).

3. In the pillar root for your base environment, create this file:

```
p8000.sls
--------
proxy:
  proxytype: ssh_sample
  host: saltyVM
  username: salt
  password: badpass
```

4. Make sure your salt-master is running.

5. Start the salt-proxy in debug mode

```
salt-proxy --proxyid=p8000 -l debug
```

6. Accept your proxy's key on your salt-master

```
salt-key -y -a p8000
The following keys are going to be accepted:
Unaccepted Keys:
p8000
Key for minion p8000 accepted.
```

7. Now you should be able to run commands on your proxy.

```
salt p8000 pkg.list_pkgs
```

8. The SSH shell implements a degenerately simple pkg. To `install' a package, use a standard pkg.install. If you pass `==' and a version number after the package name then the service will parse that and accept that as the package's version.
The Salt Package Manager, or *SPM*, allows Salt formulas to be packaged, for ease of deployment. The design of SPM was influenced by other existing packaging systems including RPM, Yum, and Pacman.

### 21.1 Building Packages

Before SPM can install packages, they must be built. The source for these packages is often a Git repository, such as those found at the [saltstack-formulas](https://github.com/saltstack/saltstack-formulas) organization on GitHub.

#### 21.1.1 FORMULA

In addition to the formula itself, a FORMULA file must exist which describes the package. An example of this file is:

```plaintext
name: apache
os: RedHat, Debian, Ubuntu, Suse, FreeBSD
os_family: RedHat, Debian, Suse, FreeBSD
version: 201506
release: 2
summary: Formula for installing Apache
description: Formula for installing Apache
```

**Required Fields**

This file must contain at least the following fields:

- **name**

  The name of the package, as it will appear in the package filename, in the repository metadata, and the package database. Even if the source formula has `-formula` in its name, this name should probably not include that. For instance, when packaging the `apache-formula`, the name should be set to `apache`.

- **os**

  The value of the `os` grain that this formula supports. This is used to help users know which operating systems can support this package.
os_family

The value of the os_family grain that this formula supports. This is used to help users know which operating system families can support this package.

version

The version of the package. While it is up to the organization that manages this package, it is suggested that this version is specified in a YYYYMM format. For instance, if this version was released in June 2015, the package version should be 201506. If multiple released are made in a month, the release field should be used.

minimum_version

Minimum recommended version of Salt to use this formula. Not currently enforced.

release

This field refers primarily to a release of a version, but also to multiple versions within a month. In general, if a version has been made public, and immediate updates need to be made to it, this field should also be updated.

summary

A one-line description of the package.

description

A more detailed description of the package which can contain more than one line.

Optional Fields

The following fields may also be present.

top_level_dir

This field is optional, but highly recommended. If it is not specified, the package name will be used.

Formula repositories typically do not store .sls files in the root of the repository; instead they are stored in a subdirectory. For instance, an apache-formula repository would contain a directory called apache, which would contain an init.sls, plus a number of other related files. In this instance, the top_level_dir should be set to apache.

Files outside the top_level_dir, such as README.rst, FORMULA, and LICENSE will not be installed. The exceptions to this rule are files that are already treated specially, such as pillar.example and _modules/.
recommended

A list of optional packages that are recommended to be installed with the package. This list is displayed in an informational message when the package is installed to SPM.

21.1.2 Building a Package

Once a FORMULA file has been created, it is placed into the root of the formula that is to be turned into a package. The `spm build` command is used to turn that formula into a package:

```
spm build /path/to/saltstack-formulas/apache-formula
```

The resulting file will be placed in the build directory. By default this directory is located at `/srv/spm`.

21.2 Building Repositories

Once one or more packages have been built, they can be made available to SPM via a package repository. Place the packages into the directory to be served and issue an `spm create_repo` command:

```
spm create_repo /srv/spm
```

This command is used, even if repository metadata already exists in that directory. SPM will regenerate the repository metadata again, using all of the packages in that directory.

21.3 Configuring Remote Repositories

Before SPM can use a repository, two things need to happen. First, SPM needs to know where the repositories are. Then it needs to pull down the repository metadata.

21.3.1 Repository Configuration Files

Normally repository configuration files are placed in the `/etc/salt/spm.repos.d`. These files contain the name of the repository, and the link to that repository:

```
local_repo:
    url: file:///srv/spm
```

The URL can use http, https, ftp, or file.

```
my_repo:
    url: https://spm.example.com/
```

21.3.2 Updating Local Repository Metadata

Once the repository is configured, its metadata needs to be downloaded. At the moment, this is a manual process, using the `spm update_repo` command:

```
spm update_repo
```
21.4 Installing Packages

Packages may be installed either from a local file, or from an SPM repository. To install from a repository, use the `spm install` command:

```
spm install apache
```

To install from a local file, use the `spm local install` command:

```
spm local install /srv/spm/apache-201506-1.spm
```

Currently, SPM does not check to see if files are already in place before installing them. That means that existing files will be overwritten without warning.

21.5 Pillars

Formula packages include a `pillar.example` file. Rather than being placed in the formula directory, this file is renamed to `<formula name>.sls.orig` and placed in the `pillar_path`, where it can be easily updated to meet the user's needs.

21.6 Loader Modules

When an execution module is placed in `<file_roots>/_modules/` on the master, it will automatically be synced to minions, the next time a sync operation takes place. Other modules are also propagated this way: state modules can be placed in `_states/`, and so on.

When SPM detects a file in a package which resides in one of these directories, that directory will be placed in `<file_roots>` instead of in the formula directory with the rest of the files.

21.7 Removing Packages

Packages may be removed once they are installed using the `spm remove` command.

```
spm remove apache
```

If files have been modified, they will not be removed. Empty directories will also be removed.

21.8 Technical Information

Packages are built using BZ2-compressed tarballs. By default, the package database is stored using the `sqlite3` driver (see Loader Modules below).

Support for these are built into Python, and so no external dependencies are needed.

All other files belonging to SPM use YAML, for portability and ease of use and maintainability.
21.9 SPM-Specific Loader Modules

SPM was designed to behave like traditional package managers, which apply files to the filesystem and store package metadata in a local database. However, because modern infrastructures often extend beyond those use cases, certain parts of SPM have been broken out into their own set of modules.

21.9.1 Package Database

By default, the package database is stored using the sqlite3 module. This module was chosen because support for SQLite3 is built into Python itself.

Please see the SPM Development Guide for information on creating new modules for package database management.

21.9.2 Package Files

By default, package files are installed using the local module. This module applies files to the local filesystem, on the machine that the package is installed on.

Please see the SPM Development Guide for information on creating new modules for package file management.

21.10 SPM Configuration

There are a number of options that are specific to SPM. They may be configured in the master configuration file, or in SPM's own spm configuration file (normally located at /etc/salt/spm). If configured in both places, the spm file takes precedence. In general, these values will not need to be changed from the defaults.

21.10.1 spm_logfile

Default: /var/log/salt/spm

Where SPM logs messages.

21.10.2 spm_repos_config

Default: /etc/salt/spm.repos

SPM repositories are configured with this file. There is also a directory which corresponds to it, which ends in .d. For instance, if the filename is /etc/salt/spm.repos, the directory will be /etc/salt/spm.repos.d/.

21.10.3 spm_cache_dir

Default: /var/cache/salt/spm

When SPM updates package repository metadata and downloads packaged, they will be placed in this directory. The package database, normally called packages.db, also lives in this directory.
### 21.10.4 spm_db

Default: /var/cache/salt/spm/packages.db

The location and name of the package database. This database stores the names of all of the SPM packages installed on the system, the files that belong to them, and the metadata for those files.

### 21.10.5 spm_build_dir

Default: /srv/spm

When packages are built, they will be placed in this directory.

### 21.10.6 spm_build_exclude

Default: ['.git']

When SPM builds a package, it normally adds all files in the formula directory to the package. Files listed here will be excluded from that package. This option requires a list to be specified.

```
spm_build_exclude:
  - .git
  - .svn
```

### 21.11 Types of Packages

SPM supports different types of formula packages. The function of each package is denoted by its name. For instance, packages which end in `-formula` are considered to be Salt States (the most common type of formula). Packages which end in `-conf` contain configuration which is to be placed in the `/etc/salt/` directory. Packages which do not contain one of these names are treated as if they have a `-formula` name.

#### 21.11.1 formula

By default, most files from this type of package live in the `/srv/spm/salt/` directory. The exception is the `pillar.example` file, which will be renamed to `<package_name>.sls` and placed in the pillar directory (`/srv/spm/pillar/` by default).

#### 21.11.2 reactor

By default, files from this type of package live in the `/srv/spm/reactor/` directory.

#### 21.11.3 conf

The files in this type of package are configuration files for Salt, which normally live in the `/etc/salt/` directory. Configuration files for packages other than Salt can and should be handled with a Salt State (using a formula type of package).
SPM Development Guide

This document discusses developing additional code for SPM.

SPM-Specific Loader Modules

SPM was designed to behave like traditional package managers, which apply files to the filesystem and store package metadata in a local database. However, because modern infrastructures often extend beyond those use cases, certain parts of SPM have been broken out into their own set of modules.

Each function that accepts arguments has a set of required and optional arguments. Take note that SPM will pass all arguments in, and therefore each function must accept each of those arguments. However, arguments that are marked as required are crucial to SPM's core functionality, while arguments that are marked as optional are provided as a benefit to the module, if it needs to use them.

Package Database

By default, the package database is stored using the sqlite3 module. This module was chosen because support for SQLite3 is built into Python itself.

Modules for managing the package database are stored in the salt/spm/pkgdb/ directory. A number of functions must exist to support database management.

init()

Get a database connection, and initialize the package database if necessary.

This function accepts no arguments. If a database is used which supports a connection object, then that connection object is returned. For instance, the sqlite3 module returns a connect() object from the sqlite3 library:

```python
conn = sqlite3.connect(__opts__['spm_db'], isolation_level=None)
...
return conn
```

SPM itself will not use this connection object; it will be passed in as-is to the other functions in the module. Therefore, when you set up this object, make sure to do so in a way that is easily usable throughout the module.

info()

Return information for a package. This generally consists of the information that is stored in the FORMULA file in the package.

The arguments that are passed in, in order, are package (required) and conn (optional).

package is the name of the package, as specified in the FORMULA. conn is the connection object returned from init().

list_files()

Return a list of files for an installed package. Only the filename should be returned, and no other information.

The arguments that are passed in, in order, are package (required) and conn (optional).
package is the name of the package, as specified in the FORMULA. conn is the connection object returned from init().

register_pkg()

Register a package in the package database. Nothing is expected to be returned from this function.
The arguments that are passed in, in order, are name (required), formula_def (required), and conn (optional).

name is the name of the package, as specified in the FORMULA. formula_def is the contents of the FORMULA file, as a dict. conn is the connection object returned from init().

register_file()

Register a file in the package database. Nothing is expected to be returned from this function.
The arguments that are passed in are name (required), member (required), path (required), digest (optional), and conn (optional).

name is the name of the package.
member is a tarfile object for the package file. It is included, because it contains most of the information for the file.
path is the location of the file on the local filesystem.
digest is the SHA1 checksum of the file.
conn is the connection object returned from init().

unregister_pkg()

Unregister a package from the package database. This usually only involves removing the package's record from the database. Nothing is expected to be returned from this function.
The arguments that are passed in, in order, are name (required) and conn (optional).

name is the name of the package, as specified in the FORMULA. conn is the connection object returned from init().

unregister_file()

Unregister a package from the package database. This usually only involves removing the package's record from the database. Nothing is expected to be returned from this function.
The arguments that are passed in, in order, are name (required), pkg (optional) and conn (optional).

name is the path of the file, as it was installed on the filesystem.
pkg is the name of the package that the file belongs to.
conn is the connection object returned from init().
db_exists()

Check to see whether the package database already exists. This is the path to the package database file. This function will return True or False.

The only argument that is expected is db__, which is the package database file.

Package Files

By default, package files are installed using the local module. This module applies files to the local filesystem, on the machine that the package is installed on.

Modules for managing the package database are stored in the salt/spm/pkgfiles/ directory. A number of functions must exist to support file management.

init()

Initialize the installation location for the package files. Normally these will be directory paths, but other external destinations such as databases can be used. For this reason, this function will return a connection object, which can be a database object. However, in the default local module, this object is a dict containing the paths. This object will be passed into all other functions.

Three directories are used for the destinations: formula_path, pillar_path, and reactor_path.

formula_path is the location of most of the files that will be installed. The default is specific to the operating system, but is normally /srv/salt/.

pillar_path is the location that the pillar.example file will be installed to. The default is specific to the operating system, but is normally /srv/pillar/.

reactor_path is the location that reactor files will be installed to. The default is specific to the operating system, but is normally /srv/reactor/.

check_existing()

Check the filesystem for existing files. All files for the package will be checked, and if any are existing, then this function will normally state that SPM will refuse to install the package.

This function returns a list of the files that exist on the system.

The arguments that are passed into this function are, in order: package (required), pkg_files (required), formula_def (formula_def), and conn (optional).

package is the name of the package that is to be installed.

pkg_files is a list of the files to be checked.

formula_def is a copy of the information that is stored in the FORMULA file.

conn is the file connection object.

install_file()

Install a single file to the destination (normally on the filesystem). Nothing is expected to be returned from this function.
This function returns the final location that the file was installed to.

The arguments that are passed into this function are, in order, `package` (required), `formula_tar` (required), `member` (required), `formula_def` (required), and `conn` (optional).

`package` is the name of the package that is to be installed.

`formula_tar` is the tarfile object for the package. This is passed in so that the function can call `formula_tar.extract()` for the file.

`member` is the tarfile object which represents the individual file. This may be modified as necessary, before being passed into `formula_tar.extract()`.

`formula_def` is a copy of the information from the FORMULA file.

`conn` is the file connection object.

**remove_file()**

Remove a single file from file system. Normally this will be little more than an `os.remove()`. Nothing is expected to be returned from this function.

The arguments that are passed into this function are, in order, `path` (required) and `conn` (optional).

`path` is the absolute path to the file to be removed.

`conn` is the file connection object.

**hash_file()**

Returns the hexdigest hash value of a file.

The arguments that are passed into this function are, in order, `path` (required), `hashobj` (required), and `conn` (optional).

`path` is the absolute path to the file.

`hashobj` is a reference to `hashlib.sha1()`, which is used to pull the `hexdigest()` for the file.

`conn` is the file connection object.

This function will not generally be more complex than:

```python
def hash_file(path, hashobj, conn=None):
    with salt.utils.fopen(path, 'r') as f:
        hashobj.update(f.read())
    return hashobj.hexdigest()
```

**path_exists()**

Check to see whether the file already exists on the filesystem. Returns `True` or `False`.

This function expects a `path` argument, which is the absolute path to the file to be checked.
path_isdir()

Check to see whether the path specified is a directory. Returns True or False.
This function expects a path argument, which is the absolute path to be checked.
One of fundamental features of Salt is remote execution. Salt has two basic "channels" for communicating with minions. Each channel requires a client (minion) and a server (master) implementation to work within Salt. These pairs of channels will work together to implement the specific message passing required by the channel interface.

### 22.1 Pub Channel

The pub channel, or publish channel, is how a master sends a job (payload) to a minion. This is a basic pub/sub paradigm, which has specific targeting semantics. All data which goes across the publish system should be encrypted such that only members of the Salt cluster can decrypt the publishes.

### 22.2 Req Channel

The req channel is how the minions send data to the master. This interface is primarily used for fetching files and returning job returns. The req channels have two basic interfaces when talking to the master. `send` is the basic method that guarantees the message is encrypted at least so that only minions attached to the same master can read it-- but no guarantee of minion-master confidentiality, whereas the `crypted_transfer_decode_dictentry` method does guarantee minion-master confidentiality.

#### 22.2.1 Zeromq Transport

**Note:** Zeromq is the current default transport within Salt

Zeromq is a messaging library with bindings into many languages. Zeromq implements a socket interface for message passing, with specific semantics for the socket type.

**Pub Channel**

The pub channel is implemented using zeromq's pub/sub sockets. By default we don't use zeromq's filtering, which means that all publish jobs are sent to all minions and filtered minion side. Zeromq does have publisher side filtering which can be enabled in salt using `zmq_filtering`.  

---

271
Req Channel

The req channel is implemented using zeromq's req/rep sockets. These sockets enforce a send/recv pattern, which forces salt to serialize messages through these socket pairs. This means that although the interface is asynchronous on the minion we cannot send a second message until we have received the reply of the first message.

### 22.2.2 TCP Transport

The `tcp` transport is an implementation of Salt's channels using raw tcp sockets. Since this isn't using a pre-defined messaging library we will describe the wire protocol, message semantics, etc. in this document.

**Wire Protocol**

This implementation over TCP focuses on flexibility over absolute efficiency. This means we are okay to spend a couple of bytes of wire space for flexibility in the future. That being said, the wire framing is quite efficient and looks like:

```
len(payload) msgpack({'head': SOMEHEADER, 'body': SOMEBODY})
```

The wire protocol is basically two parts, the length of the payload and a payload (which is a msgpack'd dict). Within that payload we have two items `head` and `body`. Head contains header information (such as `message id`). The Body contains the actual message that we are sending. With this flexible wire protocol we can implement any message semantics that we'd like— including multiplexed message passing on a single socket.

**Crypto**

The current implementation uses the same crypto as the zeromq transport.

**Pub Channel**

For the pub channel we send messages without `message ids` which the remote end interprets as a one-way send.

**Note:** As of today we send all publishes to all minions and rely on minion-side filtering.

**Req Channel**

For the req channel we send messages with a `message id`. This `message id` allows us to multiplex messages across the socket.

### 22.2.3 The RAET Transport

**Note:** The RAET transport is in very early development, it is functional but no promises are yet made as to its reliability or security. As for reliability and security, the encryption used has been audited and our tests show that raet is reliable. With this said we are still conducting more security audits and pushing the reliability. This document outlines the encryption used in RAET

New in version 2014.7.0.
The Reliable Asynchronous Event Transport, or RAET, is an alternative transport medium developed specifically with Salt in mind. It has been developed to allow queuing to happen up on the application layer and comes with socket layer encryption. It also abstracts a great deal of control over the socket layer and makes it easy to bubble up errors and exceptions.

RAET also offers very powerful message routing capabilities, allowing for messages to be routed between processes on a single machine all the way up to processes on multiple machines. Messages can also be restricted, allowing processes to be sent messages of specific types from specific sources allowing for trust to be established.

**Using RAET in Salt**

Using RAET in Salt is easy, the main difference is that the core dependencies change, instead of needing pycrypto, M2Crypto, ZeroMQ, and PYZMQ, the packages `libsodium`, `libnacl`, `ioflo`, and raet are required. Encryption is handled very cleanly by libnacl, while the queueing and flow control is handled by ioflo. Distribution packages are forthcoming, but `libsodium` can be easily installed from source, or many distributions do ship packages for it. The libnacl and ioflo packages can be easily installed from pypi, distribution packages are in the works.

Once the new deps are installed the 2014.7 release or higher of Salt needs to be installed.

Once installed, modify the configuration files for the minion and master to set the transport to raet:

```
/etc/salt/master:

transport: raet
```

```
/etc/salt/minion:

transport: raet
```

Now start salt as it would normally be started, the minion will connect to the master and share long term keys, which can then in turn be managed via salt-key. Remote execution and salt states will function in the same way as with Salt over ZeroMQ.

**Limitations**

The 2014.7 release of RAET is not complete! The Syndic and Multi Master have not been completed yet and these are slated for completion in the 2015.5.0 release.

Also, Salt-Raet allows for more control over the client but these hooks have not been implemented yet, therefore the client still uses the same system as the ZeroMQ client. This means that the extra reliability that RAET exposes has not yet been implemented in the CLI client.

**Why?**

**Customer and User Request**

Why make an alternative transport for Salt? There are many reasons, but the primary motivation came from customer requests, many large companies came with requests to run Salt over an alternative transport, the reasoning was varied, from performance and scaling improvements to licensing concerns. These customers have partnered with SaltStack to make RAET a reality.
More Capabilities

RAET has been designed to allow salt to have greater communication capabilities. It has been designed to allow for development into features which out ZeroMQ topologies can't match.

Many of the proposed features are still under development and will be announced as they enter proof of concept phases, but these features include salt-fuse - a filesystem over salt, salt-vt - a parallel api driven shell over the salt transport and many others.

RAET Reliability

RAET is reliable, hence the name (Reliable Asynchronous Event Transport).

The concern posed by some over RAET reliability is based on the fact that RAET uses UDP instead of TCP and UDP does not have built in reliability.

RAET itself implements the needed reliability layers that are not natively present in UDP, this allows RAET to dynamically optimize packet delivery in a way that keeps it both reliable and asynchronous.

RAET and ZeroMQ

When using RAET, ZeroMQ is not required. RAET is a complete networking replacement. It is noteworthy that RAET is not a ZeroMQ replacement in a general sense, the ZeroMQ constructs are not reproduced in RAET, but they are instead implemented in such a way that is specific to Salt’s needs.

RAET is primarily an async communication layer over truly async connections, defaulting to UDP. ZeroMQ is over TCP and abstracts async constructs within the socket layer.

Salt is not dropping ZeroMQ support and has no immediate plans to do so.

Encryption

RAET uses Dan Bernstein's NACL encryption libraries and CurveCP handshake. The libnacl python binding binds to both libsodium and tweetnacl to execute the underlying cryptography. This allows us to completely rely on an externally developed cryptography system.

Programming Intro

Intro to RAET Programming

Note: This page is still under construction

The first thing to cover is that RAET does not present a socket api, it presents, and queueing api, all messages in RAET are made available to via queues. This is the single most differentiating factor with RAET vs other networking libraries, instead of making a socket, a stack is created. Instead of calling send() or recv(), messages are placed on the stack to be sent and messages that are received appear on the stack.

Different kinds of stacks are also available, currently two stacks exist, the UDP stack, and the UXD stack. The UDP stack is used to communicate over udp sockets, and the UXD stack is used to communicate over Unix Domain Sockets.

The UDP stack runs a context for communicating over networks, while the UXD stack has contexts for communicating between processes.
UDP Stack Messages

To create a UDP stack in RAET, simply create the stack, manage the queues, and process messages:

```python
from salt.transport.road.raet import stacking
from salt.transport.road.raet import estating

udp_stack = stacking.StackUdp( ha=('127.0.0.1', 7870))
r_estate = estating.Estate( stack=stack, name='foo', ha=('192.168.42.42', 7870))
msg = {'hello': 'world'}
udp_stack.transmit( msg, udp_stack.estates[r_estate.name])
udp_stack.serviceAll()
```
CHAPTER 23

Windows Software Repository

Note: In 2015.8.0 and later, the Windows Software Repository cache is compiled on the Salt Minion, which enables pillar, grains and other things to be available during compilation time. To support this new functionality, a next-generation (ng) package repository was created. See See the Changes in Version 2015.8.0 for details.

The SaltStack Windows Software Repository provides a package manager and software repository similar to what is provided by yum and apt on Linux. This repository enables the installation of software using the installers on remote Windows systems.

In many senses, the operation is similar to that of the other package managers salt is aware of:

• the pkg.installed and similar states work on Windows.
• the pkg.install and similar module functions work on Windows.

High level differences to yum and apt are:

• The repository metadata (SLS files) is hosted through either salt or git.
• Packages can be downloaded from within the salt repository, a git repository or from http(s) or ftp urls.
• No dependencies are managed. Dependencies between packages needs to be managed manually.

 Requirements:

• GitPython 0.3 or later, or pygit2 0.20.3 with libgit 0.20.0 or later installed on your Salt master. The Windows package definitions are downloaded and updated using Git.

23.1 Configuration

23.1.1 Populate the Repository

The SLS files used to install Windows packages are not distributed by default with Salt. Run the following command to initialize the repository on your Salt master:

```
salt-run winrepo.update_git_repos
```

23.1.2 Sync Repo to Windows Minions

Run pkg.refresh_db on each of your Windows minions to synchronize the package repository.
23.2 Install Windows Software

After completing the configuration steps, you are ready to manage software on your Windows minions.

23.2.1 Show Installed Packages

```
salt -G 'os:windows' pkg.list_pkgs
```

23.2.2 Install a Package

You can query the available version of a package using the Salt pkg module.

```
salt winminion pkg.available_version firefox
```

```
{'firefox': {'15.0.1': 'Mozilla Firefox 15.0.1 (x86 en-US)',
              '16.0.2': 'Mozilla Firefox 16.0.2 (x86 en-US)',
              '17.0.1': 'Mozilla Firefox 17.0.1 (x86 en-US)'}
```

As you can see, there are three versions of Firefox available for installation. You can refer a software package by its name or its full_name surround by single quotes.

```
salt winminion pkg.install 'firefox'
```

The above line will install the latest version of Firefox.

```
salt winminion pkg.install 'firefox' version=16.0.2
```

The above line will install version 16.0.2 of Firefox.

If a different version of the package is already installed it will be replaced with the version in the winrepo (only if the package itself supports live updating).

You can also specify the full name:

```
salt winminion pkg.install 'Mozilla Firefox 17.0.1 (x86 en-US)'
```

23.3 Uninstall Windows Software

Uninstall software using the pkg module:

```
salt winminion pkg.remove firefox
salt winminion pkg.purge firefox
```

Note: pkg.purge just executes pkg.remove on Windows. At some point in the future pkg.purge may direct the installer to remove all configs and settings for software packages that support that option.
23.4 Repository Location

Salt maintains a repository of SLS files to install a large number of Windows packages:

- 2015.8.0 and later minions: https://github.com/saltstack/salt-winrepo-ng
- Earlier releases: https://github.com/saltstack/salt-winrepo

By default, these repositories are mirrored to /srv/salt/win/repo_ng and /srv/salt/win/repo. This location can be changed in the master config file by setting the `winrepo_dir_ng` and `winrepo_dir` options.

23.5 Maintaining Windows Repo Definitions in Git Repositories

Windows software package definitions can be hosted in one or more Git repositories. The default repositories are hosted on GitHub by SaltStack. These include software definition files for various open source software projects. These software definition files are `.sls` files. There are two default repositories: `salt-winrepo` and `salt-winrepo-ng`. `salt-winrepo` contains software definition files for older minions (older than 2015.8.0). `salt-winrepo-ng` is for newer minions (2015.8.0 and newer).

Each software definition file contains all the information salt needs to install that software on a minion including the HTTP or FTP locations of the installer files, required command-line switches for silent install, etc. Anyone is welcome to send a pull request to this repo to add new package definitions. The repos can be browsed here: [salt-winrepo](https://github.com/saltstack/salt-winrepo) [salt-winrepo-ng](https://github.com/saltstack/salt-winrepo-ng)

**Note:** The newer software definition files are run through the salt's parser which allows for the use of Jinja.

Configure which git repositories the master can search for package definitions by modifying or extending the `winrepo_remotes` and `winrepo_remotes_ng` options.

**Important:** `winrepo_remotes` was called `win_gitrepos` in Salt versions earlier than 2015.8.0

Package definitions are pulled down from the online repository by running the `winrepo.update_git_repos` runner. This command is run on the master:

```
salt-run winrepo.update_git_repos
```

This will pull down the software definition files for older minions (salt-winrepo) and new minions (salt-winrepo-ng). They are stored in the `file_roots` under `win/repo/salt-winrepo` and `win/repo-ng/salt-winrepo-ng` respectively.

**Important:** If you have customized software definition files that aren't maintained in a repository, those should be stored under `win/repo` for older minions and `win/repo-ng` for newer minions. The reason for this is that the contents of `win/repo/salt-winrepo` and `win/repo-ng/salt-winrepo-ng` are wiped out every time you run `winrepo.update_git_repos`.

Additionally, when you run `winrepo.genrepo` and `pkg.refresh_db` the entire contents under `win/repo` and `win/repo-ng`, to include all subdirectories, are used to create the msgpack file.

The next step (if you have older minions) is to create the msgpack file for the repo (`winrepo.p`). This is done by running the `winrepo.genrepo` runner. This is also run on the master:
salt-run winrepo.genrepo

**Note:** If you have only 2015.8.0 and newer minions, you no longer need to run `salt-run winrepo.genrepo` on the master.

Finally, you need to refresh the minion database by running the `pkg.refresh_db` command. This is run on the master as well:

```
salt '*' pkg.refresh_db
```

On older minions (older than 2015.8.0) this will copy the winrepo.p file down to the minion. On newer minions (2015.8.0 and newer) this will copy all the software definition files (.sls) down to the minion and then create the msgpack file (winrepo.p) locally. The reason this is done locally is because the Jinja needs to be parsed using the minion's grains.

**Important:** Every time you modify the software definition files on the master, either by running `salt-run winrepo.update_git_repos`, modifying existing files, or by creating your own, you need to refresh the database on your minions. For older minions, that means running `salt-run winrepo.genrepo` and then `salt '*' pkg.refresh_db`. For newer minions (2015.8.0 and newer) it is just `salt '*' pkg.refresh_db`.

**Note:** If the `winrepo.genrepo` or the `pkg.refresh_db` fails, it is likely a problem with the Jinja in one of the software definition files. This will cause the operations to stop. You'll need to fix the syntax in order for the msgpack file to be created successfully.

To disable one of the repos, set it to an empty list `[]` in the master config. For example, to disable `winrepo_remotes` set the following in the master config file:

```
winrepo_remotes: []
```

### 23.6 Creating a Package Definition SLS File

The package definition file is a yaml file that contains all the information needed to install a piece of software using Salt. It defines information about the package to include version, full name, flags required for the installer and uninstaller, whether or not to use the windows task scheduler to install the package, where to find the installation package, etc.

Take a look at this example for Firefox:

```
firefox:
  '17.0.1':
    installer: 'salt://win/repo/firefox/English/Firefox Setup 17.0.1.exe'
    full_name: Mozilla Firefox 17.0.1 (x86 en-US)
    locale: en_US
    reboot: False
    install_flags: '-ms'
    uninstaller: '%ProgramFiles(x86)%/Mozilla Firefox/uninstall/helper.exe'
    uninstall_flags: '/S'
  '16.0.2':
    installer: 'salt://win/repo/firefox/English/Firefox Setup 16.0.2.exe'
```
Each software definition file begins with a package name for the software. As in the example above `firefox`. The next line is indented two spaces and contains the version to be defined. As in the example above, a software definition file can define multiple versions for the same piece of software. The lines following the version are indented two more spaces and contain all the information needed to install that package.

**Warning:** The package name and the `full_name` must be unique to all other packages in the software repository.

The version line is the version for the package to be installed. It is used when you need to install a specific version of a piece of software.

**Warning:** The version must be enclosed in quotes, otherwise the yaml parser will remove trailing zeros.

**Note:** There are unique situations where previous versions are unavailable. Take Google Chrome for example. There is only one url provided for a standalone installation of Google Chrome. ([https://dl.google.com/edgedl/chrome/install/GoogleChromeStandaloneEnterprise.msi](https://dl.google.com/edgedl/chrome/install/GoogleChromeStandaloneEnterprise.msi)) When a new version is released, the url just points to the new version. To handle situations such as these, set the version to `latest`. Salt will install the version of Chrome at the URL and report that version. Here's an example:

```yaml
chrome:
  latest:
    full_name: 'Google Chrome'
    installer: 'https://dl.google.com/edgedl/chrome/install/GoogleChromeStandaloneEnterprise.msi'
    install_flags: '/qn /norestart'
    uninstaller: 'https://dl.google.com/edgedl/chrome/install/GoogleChromeStandaloneEnterprise.msi'
    uninstall_flags: '/qn /norestart'
    msiexec: True
    locale: en_US
    reboot: False
```

Available parameters are as follows:

- **param str full_name**  The Full Name for the software as shown in "Programs and Features" in the control panel. You can also get this information by installing the package manually and then running
pkg.list_pkgs. Here's an example of the output from pkg.list_pkgs:

```
salt 'test-2008' pkg.list_pkgs
test-2008
----------
  7-Zip 9.20 (x64 edition):
    9.20.00.0
  Microsoft .NET Framework 4 Client Profile:
    4.0.30319,4.0.30319
  Microsoft .NET Framework 4 Extended:
    4.0.30319,4.0.30319
  Microsoft Visual C++ 2008 Redistributable - x64 9.0.21022:
    9.0.21022
  Mozilla Firefox 17.0.1 (x86 en-US):
    17.0.1
  Mozilla Maintenance Service:
    17.0.1
  NSClient++ (x64):
    0.3.8.76
  Notepad++:
    6.4.2
  Salt Minion 0.16.0:
    0.16.0
```

Notice the Full Name for Firefox: Mozilla Firefox 17.0.0 (x86 en-US). That's exactly what's in the full_name parameter in the software definition file.

If any of the software installed on the machine matches one of the software definition files in the repository the full_name will be automatically renamed to the package name. The example below shows the pkg.list_pkgs for a machine that already has Mozilla Firefox 17.0.1 installed.

```
test-2008:
----------
  7zip:
    9.20.00.0
  Microsoft .NET Framework 4 Client Profile:
    4.0.30319,4.0.30319
  Microsoft .NET Framework 4 Extended:
    4.0.30319,4.0.30319
  Microsoft Visual C++ 2008 Redistributable - x64 9.0.21022:
    9.0.21022
  Mozilla Maintenance Service:
    17.0.1
  Notepad++:
    6.4.2
  Salt Minion 0.16.0:
    0.16.0
  firefox:
    17.0.1
  nsclient:
    0.3.9.328
```

**Important:** The version number and full_name need to match the output from pkg.list_pkgs so that the status can be verified when running highstate.

**Note:** It is still possible to successfully install packages using pkg.install even if they don't match. This can
make troubleshooting difficult so be careful.

**param str installer** The path to the `.exe` or `.msi` to use to install the package. This can be a path or a URL. If it is a URL or a salt path (salt://), the package will be cached locally and then executed. If it is a path to a file on disk or a file share, it will be executed directly.

**param str install_flags** Any flags that need to be passed to the installer to make it perform a silent install. These can often be found by adding `/?` or `/h` when running the installer from the command-line. A great resource for finding these silent install flags can be found on the WPKG project's wiki. Salt will not return if the installer is waiting for user input so these are important.

**param str uninstaller** The path to the program used to uninstall this software. This can be the path to the same `.exe` or `.msi` used to install the software. It can also be a GUID. You can find this value in the registry under the following keys:

- Software\Microsoft\Windows\CurrentVersion\Uninstall
- Software\Wow6432None\Microsoft\Windows\CurrentVersion\Uninstall

**param str uninstall_flags** Any flags that need to be passed to the uninstaller to make it perform a silent uninstall. These can often be found by adding `/?` or `/h` when running the uninstaller from the command-line. A great resource for finding these silent install flags can be found on the WPKG project's wiki. Salt will not return if the uninstaller is waiting for user input so these are important.

Here are some examples of installer and uninstaller settings:

```
7zip:
'9.20.00.0':
    installer: salt://win/repo/7zip/7z920-x64.msi
    full_name: 7-Zip 9.20 (x64 edition)
    reboot: False
    install_flags: '/qn /norestart'
    msiexec: True
    uninstaller: '{23170F69-40C1-2702-0920-000001000000}'
    uninstall_flags: '/qn /norestart'
```

Alternatively the uninstaller can also simply repeat the URL of the msi file.

```
7zip:
'9.20.00.0':
    installer: salt://win/repo/7zip/7z920-x64.msi
    full_name: 7-Zip 9.20 (x64 edition)
    reboot: False
    install_flags: '/qn /norestart'
    msiexec: True
    uninstaller: salt://win/repo/7zip/7z920-x64.msi
    uninstall_flags: '/qn /norestart'
```

**param bool msiexec** This tells salt to use `msiexec /i` to install the package and `msiexec /x` to uninstall. This is for `.msi` installations.

**param bool allusers** This parameter is specific to `.msi` installations. It tells `msiexec` to install the software for all users. The default is `True`.

**param bool cache_dir** If true, the entire directory where the installer resides will be recursively cached. This is useful for installers that depend on other files in the same directory for installation.
Here's an example for a software package that has dependent files:

```yaml
sqlexpress:
  '12.0.2000.8':
    installer: 'salt://win/repo/sqlexpress/setup.exe'
    full_name: Microsoft SQL Server 2014 Setup (English)
    reboot: False
    install_flags: '/ACTION=install /IACCEPTSQLSERVERLICENSETERMS /Q'
    cache_dir: True

param bool use_scheduler If true, windows will use the task scheduler to run the installation. This is
useful for running the salt installation itself as the installation process kills any currently running
instances of salt.

param bool reboot Not implemented

param str local Not implemented
```

Examples can be found at https://github.com/saltstack/salt-winrepo-ng

### 23.7 Managing Windows Software on a Standalone Windows Minion

The Windows Package Repository functions similar in a standalone environment, with a few differences in the
configuration.

To replace the winrepo runner that is used on the Salt master, an execution module exists to provide the same
functionality to standalone minions. The functions are named the same as the ones in the runner, and are used in
the same way; the only difference is that salt-call is used instead of salt-run:

```
salt-call winrepo.update_git_repos
salt-call winrepo.genrepo
salt-call pkg.refresh_db
```

After executing the previous commands the repository on the standalone system is ready to use.

#### 23.7.1 Custom Location for Repository SLS Files

If `file_roots` has not been modified in the minion configuration, then no additional configuration needs to be
added to the minion configuration. The `winrepo.genrepo` function from the `winrepo` execution module will
by default look for the filename specified by `winrepo_cachefile` within `C:\salt\srv\salt\win\repo`.

If the `file_roots` parameter has been modified, then `winrepo_dir` must be modified to fall within that path,
at the proper relative path. For example, if the `base` environment in `file_roots` points to `D:\foo`, and `win-
repo_source_dir` is `salt://win/repo`, then `winrepo_dir` must be set to `D:\foo\win\repo` to ensure that
`winrepo.genrepo` puts the cachefile into right location.

### 23.8 Config Options for Minions 2015.8.0 and Later

The `winrepo_source_dir` config parameter (default: `salt://win/repo`) controls where
`pkg.refresh_db` looks for the cachefile (default: `winrepo.p`). This means that the default location for
the winrepo cachefile would be `salt://win/repo/winrepo.p`. Both `winrepo_source_dir` and `winrepo_cachefile` can be adjusted to match the actual location of this file on the Salt fileserver.

### 23.9 Config Options for Minions Before 2015.8.0

If connected to a master, the minion will by default look for the winrepo cachefile (the file generated by the `winrepo.genrepo` runner) at `salt://win/repo/winrepo.p`. If the cachefile is in a different path on the salt fileservers, then `win_repo_cachefile` will need to be updated to reflect the proper location.

### 23.10 Changes in Version 2015.8.0

Git repository management for the Windows Software Repository has changed in version 2015.8.0, and several master/minion config parameters have been renamed to make their naming more consistent with each other.

For a list of the winrepo config options, see [here](#) for master config options, and [here](#) for configuration options for masterless Windows minions.

On the master, the `winrepo.update_git_repos` runner has been updated to use either `pygit2` or `GitPython` to checkout the git repositories containing repo data. If `pygit2` or `GitPython` is installed, existing winrepo git checkouts should be removed after upgrading to 2015.8.0, to allow them to be checked out again by running `winrepo.update_git_repos`.

If neither `GitPython` nor `pygit2` are installed, then Salt will fall back to the pre-existing behavior for `winrepo.update_git_repos`, and a warning will be logged in the master log.

**Note:** Standalone Windows minions do not support the new `GitPython/pygit2` functionality, and will instead use the `git.latest` state to keep repositories up-to-date. More information on how to use the Windows Software Repo on a standalone minion can be found [here](#).

#### 23.10.1 Config Parameters Renamed

Many of the legacy winrepo configuration parameters have changed in version 2015.8.0 to make the naming more consistent. The old parameter names will still work, but a warning will be logged indicating that the old name is deprecated.

Below are the parameters which have changed for version 2015.8.0:

**Master Config**

<table>
<thead>
<tr>
<th>Old Name</th>
<th>New Name</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>win_repo</code></td>
<td><code>winrepo_dir</code></td>
</tr>
<tr>
<td><code>win_repo_mastercachefile</code></td>
<td><code>winrepo_cachefile</code></td>
</tr>
<tr>
<td><code>win_gitrepos</code></td>
<td><code>winrepo_remotes</code></td>
</tr>
</tbody>
</table>

**Note:** `winrepo_cachefile` is no longer used by 2015.8.0 and later minions, and the `winrepo_dir` setting is replaced by `winrepo_dir_ng` for 2015.8.0 and later minions.

See [here](#) for detailed information on all master config options for the Windows Repo.
Minion Config

<table>
<thead>
<tr>
<th>Old Name</th>
<th>New Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>win_repo</td>
<td>winrepo_dir</td>
</tr>
<tr>
<td>win_repo_cachefile</td>
<td>winrepo_cachefile</td>
</tr>
<tr>
<td>win_gitrepos</td>
<td>winrepo_remotes</td>
</tr>
</tbody>
</table>

See [here](#) for detailed information on all minion config options for the Windows Repo.

### 23.10.2 pygit2/GitPython Support for Maintaining Git Repos

The `winrepo.update_git_repos` runner (and the corresponding `remote execution function` for standalone minions) now makes use of the same underlying code used by the `Git Fileserver Backend` and `Git External Pillar` to maintain and update its local clones of git repositories. If a compatible version of either `pygit2` (0.20.3 and later) or `GitPython` (0.3.0 or later) is installed, then Salt will use it instead of the old method (which invokes the `git.latest` state).

**Note:** If compatible versions of both `pygit2` and `GitPython` are installed, then Salt will prefer `pygit2`, to override this behavior use the `winrepo_provider` configuration parameter:

```
winrepo_provider: gitpython
```

The `winrepo execution module` (discussed above in the `Managing Windows Software on a Standalone Windows Minion` section) does not yet officially support the new `pygit2/GitPython` functionality, but if either `pygit2` or `GitPython` is installed into Salt's bundled Python then it *should* work. However, it should be considered experimental at this time.

To minimize potential issues, it is a good idea to remove any winrepo git repositories that were checked out by the old (pre-2015.8.0) winrepo code when upgrading the master to 2015.8.0 or later, and run `winrepo.update_git_repos` to clone them anew after the master is started.

Additional added features include the ability to access authenticated git repositories (`NOTE: pygit2` only), and to set per-remote config settings. An example of this would be the following:

```
winrepo_remotes:
  - https://github.com/saltstack/salt-winrepo.git
  - git@github.com:myuser/myrepo.git:
    - pubkey: /path/to/key.pub
    - privkey: /path/to/key
    - passphrase: myaw3s0m3pa$$phr4$$3
  - https://github.com/myuser/privaterepo.git:
    - user: mygithubuser
    - password: CorrectHorseBatteryStaple
```

**Note:** Per-remote configuration settings work in the same fashion as they do in gitfs, with global parameters being overridden by their per-remote counterparts (for instance, setting `winrepo_passphrase` would set a global passphrase for winrepo that would apply to all SSH-based remotes, unless overridden by a `passphrase` per-remote parameter).

See [here](#) for more a more in-depth explanation of how per-remote configuration works in gitfs, the same principles apply to winrepo.
There are a couple other changes in how Salt manages git repos using pygit2/GitPython. First of all, a `clean` argument has been added to the `winrepo.update_git_repos` runner, which (if set to `True`) will tell the runner to dispose of directories under the `winrepo_dir` which are not explicitly configured. This prevents the need to manually remove these directories when a repo is removed from the config file. To clean these old directories, just pass `clean=True`, like so:

```
salt-run winrepo.update_git_repos clean=True
```

However, if a mix of git and non-git Windows Repo definition files are being used, then this should not be used, as it will remove the directories containing non-git definitions.

The other major change is that collisions between repo names are now detected, and the `winrepo.update_git_repos` runner will not proceed if any are detected. Consider the following configuration:

```
winrepo_remotes:
- https://foo.com/bar/baz.git
- https://mydomain.tld/baz.git
- https://github.com/foobar/baz
```

The `winrepo.update_git_repos` runner will refuse to update repos here, as all three of these repos would be checked out to the same directory. To work around this, a per-remote parameter called `name` can be used to resolve these conflicts:

```
winrepo_remotes:
- https://foo.com/bar/baz.git
- https://mydomain.tld/baz.git:
  - name: baz_junior
- https://github.com/foobar/baz:
  - name: baz_the_third
```

## 23.11 Troubleshooting

### 23.11.1 Incorrect name/version

If the package seems to install properly, but salt reports a failure then it is likely you have a version or `full_name` mismatch.

Check the exact `full_name` and version used by the package. Use `pkg.list_pkgs` to check that the names and version exactly match what is installed.

### 23.11.2 Changes to sls files not being picked up

Ensure you have (re)generated the repository cache file (for older minions) and then updated the repository cache on the relevant minions:

```
salt-run winrepo.genrepo
salt winminion pkg.refresh_db
```

### 23.11.3 Packages management under Windows 2003

On Windows server 2003, you need to install optional Windows component `wmi windows installer provider` to have full list of installed packages. If you don’t have this, salt-minion can’t report some installed software.
23.11.4 How Success and Failure are Reported

The install state/module function of the Windows package manager works roughly as follows:

1. Execute `pkg.list_pkgs` and store the result
2. Check if any action needs to be taken. (i.e. compare required package and version against `pkg.list_pkgs` results)
3. If so, run the installer command.
4. Execute `pkg.list_pkgs` and compare to the result stored from before installation.
5. Success/Failure/Changes will be reported based on the differences between the original and final `pkg.list_pkgs` results.

If there are any problems in using the package manager it is likely due to the data in your sls files not matching the difference between the pre and post `pkg.list_pkgs` results.
Salt is capable of managing Windows systems, however due to various differences between the operating systems, there are some things you need to keep in mind.

This document will contain any quirks that apply across Salt or generally across multiple module functions. Any Windows-specific behavior for particular module functions will be documented in the module function documentation. Therefore this document should be read in conjunction with the module function documentation.

### 24.1 Group parameter for files

Salt was originally written for managing Unix-based systems, and therefore the file module functions were designed around that security model. Rather than trying to shoehorn that model on to Windows, Salt ignores these parameters and makes non-applicable module functions unavailable instead.

One of the commonly ignored parameters is the `group` parameter for managing files. Under Windows, while files do have a 'primary group' property, this is rarely used. It generally has no bearing on permissions unless intentionally configured and is most commonly used to provide Unix compatibility (e.g. Services For Unix, NFS services).

Because of this, any file module functions that typically require a group, do not under Windows. Attempts to directly use file module functions that operate on the group (e.g. `file.chgrp`) will return a pseudo-value and cause a log message to appear. No group parameters will be acted on.

If you do want to access and change the 'primary group' property and understand the implications, use the `file.get_pgid` or `file.get_pgroup` functions or the `pgroup` parameter on the `file.chown` module function.

### 24.2 Dealing with case-insensitive but case-preserving names

Windows is case-insensitive, but however preserves the case of names and it is this preserved form that is returned from system functions. This causes some issues with Salt because it assumes case-sensitive names. These issues generally occur in the state functions and can cause bizarre looking errors.

To avoid such issues, always pretend Windows is case-sensitive and use the right case for names, e.g. specify `user=Administrator` instead of `user=administrator`.

Follow issue 11801 for any changes to this behavior.
24.3 Dealing with various username forms

Salt does not understand the various forms that Windows usernames can come in, e.g. username, mydomain\username, username@mydomain.tld can all refer to the same user. In fact, Salt generally only considers the raw username value, i.e. the username without the domain or host information.

Using these alternative forms will likely confuse Salt and cause odd errors to happen. Use only the raw username value in the correct case to avoid problems.

Follow issue 11801 for any changes to this behavior.

24.4 Specifying the None group

Each Windows system has built-in None group. This is the default `primary group' for files for users not on a domain environment.

Unfortunately, the word _None_ has special meaning in Python - it is a special value indicating `nothing', similar to null or nil in other languages.

To specify the None group, it must be specified in quotes, e.g. ./salt '*' file.chgrp C:\path\to\file "'None'".

24.5 Symbolic link loops

Under Windows, if any symbolic link loops are detected or if there are too many levels of symlinks (defaults to 64), an error is always raised.

For some functions, this behavior is different to the behavior on Unix platforms. In general, avoid symlink loops on either platform.

24.6 Modifying security properties (ACLs) on files

There is no support in Salt for modifying ACLs, and therefore no support for changing file permissions, besides modifying the owner/user.
CHAPTER 25

Salt Cloud

25.1 Configuration

Salt Cloud provides a powerful interface to interact with cloud hosts. This interface is tightly integrated with Salt, and new virtual machines are automatically connected to your Salt master after creation.

Since Salt Cloud is designed to be an automated system, most configuration is done using the following YAML configuration files:

- `/etc/salt/cloud`: The main configuration file, contains global settings that apply to all cloud hosts. See `Salt Cloud Configuration`.

- `/etc/salt/cloud.providers.d/*.conf`: Contains settings that configure a specific cloud host, such as credentials, region settings, and so on. Since configuration varies significantly between each cloud host, a separate file should be created for each cloud host. In Salt Cloud, a provider is synonymous with a cloud host (Amazon EC2, Google Compute Engine, Rackspace, and so on). See `Provider Specifics`.

- `/etc/salt/cloud.profiles.d/*.conf`: Contains settings that define a specific VM type. A profile defines the systems specs and image, and any other settings that are specific to this VM type. Each specific VM type is called a profile, and multiple profiles can be defined in a profile file. Each profile references a parent provider that defines the cloud host in which the VM is created (the provider settings are in the provider configuration explained above). Based on your needs, you might define different profiles for web servers, database servers, and so on. See `VM Profiles`.

25.2 Configuration Inheritance

Configuration settings are inherited in order from the cloud config => providers => profile.

For example, if you wanted to use the same image for all virtual machines for a specific provider, the image name could be placed in the provider file. This value is inherited by all profiles that use that provider, but is overridden if a image name is defined in the profile.
Most configuration settings can be defined in any file, the main difference being how that setting is inherited.

### 25.3 QuickStart

The *Salt Cloud Quickstart* walks you through defining a provider, a VM profile, and shows you how to create virtual machines using Salt Cloud.

Note that if you installed Salt via Salt Bootstrap, it may not have automatically installed salt-cloud for you. Use your distribution's package manager to install the `salt-cloud` package from the same repo that you used to install Salt. These repos will automatically be setup by Salt Bootstrap.

If there is no salt-cloud package, install with `pip install salt-cloud`.

### 25.4 Using Salt Cloud

#### 25.4.1 salt-cloud

Provision virtual machines in the cloud with Salt

**Synopsis**

```
salt-cloud -m /etc/salt/cloud.map
salt-cloud -m /etc/salt/cloud.map NAME
salt-cloud -m /etc/salt/cloud.map NAME1 NAME2
salt-cloud -p PROFILE NAME
salt-cloud -p PROFILE NAME1 NAME2 NAME3 NAME4 NAME5 NAME6
```

**Description**

Salt Cloud is the system used to provision virtual machines on various public clouds via a cleanly controlled profile and mapping system.

**Options**

- `-v`, `--version`
  
  Print the version of Salt that is running.

- `-V`, `--versions-report`
  
  Show program's dependencies and version number, and then exit

- `-h`, `--help`
  
  Show the help message and exit

- `-c`, `--config-dir=CONFIG_dir`
  
  The location of the Salt configuration directory. This directory contains the configuration files for Salt master and minions. The default location on most systems is `/etc/salt`.
Execution Options

-L LOCATION, --location=LOCATION
Specify which region to connect to.

-a ACTION, --action=ACTION
Perform an action that may be specific to this cloud provider. This argument requires one or more instance names to be specified.

-f <FUNC-NAME> <PROVIDER>, --function=<FUNC-NAME> <PROVIDER>
Perform an function that may be specific to this cloud provider, that does not apply to an instance. This argument requires a provider to be specified (i.e.: nova).

-p PROFILE, --profile=PROFILE
Select a single profile to build the named cloud VMs from. The profile must be defined in the specified profiles file.

-m MAP, --map=MAP
Specify a map file to use. If used without any other options, this option will ensure that all of the mapped VMs are created. If the named VM already exists then it will be skipped.

-H, --hard
When specifying a map file, the default behavior is to ensure that all of the VMs specified in the map file are created. If the --hard option is set, then any VMs that exist on configured cloud providers that are not specified in the map file will be destroyed. Be advised that this can be a destructive operation and should be used with care.

-d, --destroy
Pass in the name(s) of VMs to destroy, salt-cloud will search the configured cloud providers for the specified names and destroy the VMs. Be advised that this is a destructive operation and should be used with care. Can be used in conjunction with the -m option to specify a map of VMs to be deleted.

-P, --parallel
Normally when building many cloud VMs they are executed serially. The -P option will run each cloud vm build in a separate process allowing for large groups of VMs to be build at once.

Be advised that some cloud provider's systems don't seem to be well suited for this influx of vm creation. When creating large groups of VMs watch the cloud provider carefully.

-u, --update-bootstrap
Update salt-bootstrap to the latest stable bootstrap release.

-y, --assume-yes
Default yes in answer to all confirmation questions.

-k, --keep-tmp
Do not remove files from /tmp/ after deploy.sh finishes.

--show-deploy-args
Include the options used to deploy the minion in the data returned.

--script-args=SCRIPT_ARGS
Script arguments to be fed to the bootstrap script when deploying the VM.

Query Options

-Q, --query
Execute a query and return some information about the nodes running on configured cloud providers.
-F, --full-query
Execute a query and print out all available information about all cloud VMs. Can be used in conjunction with -m to display only information about the specified map.

-S, --select-query
Execute a query and print out selected information about all cloud VMs. Can be used in conjunction with -m to display only information about the specified map.

--list-providers
Display a list of configured providers.

--list-profiles
New in version 2014.7.0.
Display a list of configured profiles. Pass in a cloud provider to view the provider's associated profiles, such as digital_ocean, or pass in all to list all the configured profiles.

Cloud Providers Listings

--list-locations=LIST_LOCATIONS
Display a list of locations available in configured cloud providers. Pass the cloud provider that available locations are desired on, aka ``linode'', or pass ``all'' to list locations for all configured cloud providers

--list-images=LIST_IMAGES
Display a list of images available in configured cloud providers. Pass the cloud provider that available images are desired on, aka ``linode'', or pass ``all'' to list images for all configured cloud providers

--list-sizes=LIST_SIZES
Display a list of sizes available in configured cloud providers. Pass the cloud provider that available sizes are desired on, aka ``AWS'', or pass ``all'' to list sizes for all configured cloud providers

Cloud Credentials

--set-password=<USERNAME> <PROVIDER>
Configure password for a cloud provider and save it to the keyring. PROVIDER can be specified with or without a driver, for example: ``--set-password bob rackspace'' or more specific ``--set-password bob rackspace:openstack'' DEPRECATED!

Output Options

--out
Pass in an alternative outpuer to display the return of data. This outpuer can be any of the available outpuers:
grains, highstate, json, key, overstatestage, pprint, raw, txt, yaml
Some outpuers are formaed only for data returned from specific functions; for instance, the grains outpuer will not work for non-grains data.

If an outpuer is used that does not support the data passed into it, then Salt will fall back on the pprint outpuer and display the return data using the Python pprint standard library module.

Note: If using --out=json, you will probably want --static as well. Without the static option, you will get a separate JSON string per minion which makes JSON output invalid as a whole. This is due to using an
iterative outputter. So if you want to feed it to a JSON parser, use --static as well.

```
--out-indent OUTPUT_INDENT, --output-indent OUTPUT_INDENT
Print the output indented by the provided value in spaces. Negative values disable indentation. Only applicable in outptuters that support indentation.
```

```
--out-file=OUTPUT_FILE, --output-file=OUTPUT_FILE
Write the output to the specified file.
```

```
--no-color
    Disable all colored output
```

```
--force-color
    Force colored output
```

Note: When using colored output the color codes are as follows:

- **green** denotes success,
- **red** denotes failure,
- **blue** denotes changes and success
- **yellow** denotes an expected future change in configuration.

**Examples**

To create 4 VMs named web1, web2, db1, and db2 from specified profiles:

```
salt-cloud -p fedora_rackspace web1 web2 db1 db2
```

To read in a map file and create all VMs specified therein:

```
salt-cloud -m /path/to/cloud.map
```

To read in a map file and create all VMs specified therein in parallel:

```
salt-cloud -m /path/to/cloud.map -P
```

To delete any VMs specified in the map file:

```
salt-cloud -m /path/to/cloud.map -d
```

To delete any VMs NOT specified in the map file:

```
salt-cloud -m /path/to/cloud.map -H
```

To display the status of all VMs specified in the map file:

```
salt-cloud -m /path/to/cloud.map -Q
```

**See also**

```
salt-cloud(7) salt(7) salt-master(1) salt-minion(1)
```

**25.4.2 Salt Cloud basic usage**

Salt Cloud needs, at least, one configured Provider and Profile to be functional.
Creating a VM

To create a VM with salt cloud, use command:

```
salt-cloud -p <profile> name_of_vm
```

Assuming there is a profile configured as following:

```
fedora_rackspace:
    provider: my-rackspace-config
    image: Fedora 17
    size: 256 server
    script: bootstrap-salt
```

Then, the command to create new VM named `fedora_http_01` is:

```
salt-cloud -p fedora_rackspace fedora_http_01
```

Destroying a VM

To destroy a created-by-salt-cloud VM, use command:

```
salt-cloud -d name_of_vm
```

For example, to delete the VM created on above example, use:

```
salt-cloud -d fedora_http_01
```

### 25.4.3 VM Profiles

Salt cloud designates virtual machines inside the profile configuration file. The profile configuration file defaults to `/etc/salt/cloud.profiles` and is a yaml configuration. The syntax for declaring profiles is simple:

```
fedora_rackspace:
    provider: my-rackspace-config
    image: Fedora 17
    size: 256 server
    script: bootstrap-salt
```

It should be noted that the `script` option defaults to `bootstrap-salt`, and does not normally need to be specified. Further examples in this document will not show the `script` option.

A few key pieces of information need to be declared and can change based on the cloud provider. A number of additional parameters can also be inserted:

```
centos_rackspace:
    provider: my-rackspace-config
    image: CentOS 6.2
    size: 1024 server
    minion:
        master: salt.example.com
        append_domain: webs.example.com
        grains:
            role: webserver
```
The image must be selected from available images. Similarly, sizes must be selected from the list of sizes. To get a list of available images and sizes use the following command:

```
salt-cloud --list-images openstack
salt-cloud --list-sizes openstack
```

Some parameters can be specified in the main Salt cloud configuration file and then are applied to all cloud profiles. For instance if only a single cloud provider is being used then the provider option can be declared in the Salt cloud configuration file.

### Multiple Configuration Files

In addition to `/etc/salt/cloud.profiles`, profiles can also be specified in any file matching `cloud.profiles.d/*conf` which is a sub-directory relative to the profiles configuration file(with the above configuration file as an example, `/etc/salt/cloud.profiles.d/*.conf`). This allows for more extensible configuration, and plays nicely with various configuration management tools as well as version control systems.

### Larger Example

```plaintext
rhel_ec2:
  provider: my-ec2-config
  image: ami-e565ba8c
  size: t1.micro
  minion:
    cheese: edam

ubuntu_ec2:
  provider: my-ec2-config
  image: ami-7e2da54e
  size: t1.micro
  minion:
    cheese: edam

ubuntu_rackspace:
  provider: my-rackspace-config
  image: Ubuntu 12.04 LTS
  size: 256 server
  minion:
    cheese: edam

fedora_rackspace:
  provider: my-rackspace-config
  image: Fedora 17
  size: 256 server
  minion:
    cheese: edam

cent_linode:
  provider: my-linode-config
  image: CentOS 6.2 64bit
  size: Linode 512

cent_gogrid:
  provider: my-gogrid-config
  image: 12834
```
A number of options exist when creating virtual machines. They can be managed directly from profiles and the command line execution, or a more complex map file can be created. The map file allows for a number of virtual machines to be created and associated with specific profiles. The map file is designed to be run once to create these more complex scenarios using salt-cloud.

Map files have a simple format, specify a profile and then a list of virtual machines to make from said profile:

```yaml
fedora_small:
  - web1
  - web2
  - web3
fedora_high:
  - redis1
  - redis2
  - redis3
cent_high:
  - riak1
  - riak2
  - riak3
```

This map file can then be called to roll out all of these virtual machines. Map files are called from the salt-cloud command with the `-m` option:

```
$ salt-cloud -m /path/to/mapfile
```

Remember, that as with direct profile provisioning the `-P` option can be passed to create the virtual machines in parallel:

```
$ salt-cloud -m /path/to/mapfile -P
```

**Note:** Due to limitations in the GoGrid API, instances cannot be provisioned in parallel with the GoGrid driver. Map files will work with GoGrid, but the `-P` argument should not be used on maps referencing GoGrid instances.

A map file can also be enforced to represent the total state of a cloud deployment by using the `--hard` option. When using the hard option any vms that exist but are not specified in the map file will be destroyed:

```
$ salt-cloud -m /path/to/mapfile -P -H
```

Be careful with this argument, it is very dangerous! In fact, it is so dangerous that in order to use it, you must explicitly enable it in the main configuration file.

```yaml
enable_hard_maps: True
```

A map file can include grains and minion configuration options:
fedora_small:
- web1:
  minion:
    log_level: debug
  grains:
    cheese: tasty
    omelet: du fromage
- web2:
  minion:
    log_level: warn
  grains:
    cheese: more tasty
    omelet: with peppers

A map file may also be used with the various query options:

```
$ salt-cloud -m /path/to/mapfile -Q
{'ec2': {'web1': {'id': 'i-e6aqfegb',
                     'image': None,
                     'private_ips': [],
                     'public_ips': [],
                     'size': None,
                     'state': 0},
       'web2': {'Absent'}}
```

...or with the delete option:

```
$ salt-cloud -m /path/to/mapfile -d
The following virtual machines are set to be destroyed:
  web1
  web2
Proceed? [N/y]
```

**Warning:** Specifying Nodes with Maps on the Command Line Specifying the name of a node or nodes with the maps options on the command line is not supported. This is especially important to remember when using `--destroy` with maps; `salt-cloud` will ignore any arguments passed in which are not directly relevant to the map file. When using `''--destroy''` with a map, every node in the map file will be deleted! Maps don't provide any useful information for destroying individual nodes, and should not be used to destroy a subset of a map.

### Setting up New Salt Masters

Bootstrapping a new master in the map is as simple as:

```
fedora_small:
  - web1:
    make_master: True
  - web2
  - web3
```

Notice that ALL bootstrapped minions from the map will answer to the newly created salt-master.

To make any of the bootstrapped minions answer to the bootstrapping salt-master as opposed to the newly created salt-master, as an example:
The above says the minion running on the newly created salt-master responds to the local master, ie, the master used to bootstrap these VMs.

Another example:

```
fedora_small:
  - web1:
    make_master: True
    minion:
      master: <the local master ip address>
      local_master: True
  - web2
  - web3
```

The above example makes the web3 minion answer to the local master, not the newly created master.

### 25.4.5 Cloud Actions

Once a VM has been created, there are a number of actions that can be performed on it. The `reboot` action can be used across all providers, but all other actions are specific to the cloud provider. In order to perform an action, you may specify it from the command line, including the name(s) of the VM to perform the action on:

```
$ salt-cloud -a reboot vm_name
$ salt-cloud -a reboot vm1 vm2 vm2
```

Or you may specify a map which includes all VMs to perform the action on:

```
$ salt-cloud -a reboot -m /path/to/mapfile
```

The following is a list of actions currently supported by salt-cloud:

```
all providers:
  - reboot
ec2:
  - start
  - stop
joyent:
  - stop
linode:
  - start
  - stop
```

Another useful reference for viewing more salt-cloud actions is the :ref:`Salt Cloud Feature Matrix <salt-cloud-feature-matrix>`
25.4.6 Cloud Functions

Cloud functions work much the same way as cloud actions, except that they don't perform an operation on a specific instance, and so do not need a machine name to be specified. However, since they perform an operation on a specific cloud provider, that provider must be specified.

```
$ salt-cloud -f show_image ec2 image=ami-fd20ad94
```

There are three universal salt-cloud functions that are extremely useful for gathering information about instances on a provider basis:

- `list_nodes`: Returns some general information about the instances for the given provider.
- `list_nodes_full`: Returns all information about the instances for the given provider.
- `list_nodes_select`: Returns select information about the instances for the given provider.

```
$ salt-cloud -f list_nodes linode
$ salt-cloud -f list_nodes_full linode
$ salt-cloud -f list_nodes_select linode
```

Another useful reference for viewing salt-cloud functions is the :ref:`Salt Cloud Feature Matrix <salt-cloud-feature-matrix>`

25.5 Core Configuration

25.5.1 Install Salt Cloud

Salt Cloud is now part of Salt proper. It was merged in as of Salt version 2014.1.0.

On Ubuntu, install Salt Cloud by using following command:

```
sudo add-apt-repository ppa:saltstack/salt
sudo apt-get update
sudo apt-get install salt-cloud
```

If using Salt Cloud on OS X, `curl-ca-bundle` must be installed. Presently, this package is not available via brew, but it is available using MacPorts:

```
sudo port install curl-ca-bundle
```

Salt Cloud depends on `apache-libcloud`. Libcloud can be installed via pip with `pip install apache-libcloud`.

**Installing Salt Cloud for development**

Installing Salt for development enables Salt Cloud development as well, just make sure `apache-libcloud` is installed as per above paragraph.

See these instructions: `Installing Salt for development`

25.5.2 Core Configuration

A number of core configuration options and some options that are global to the VM profiles can be set in the cloud configuration file. By default this file is located at `/etc/salt/cloud`. 
Thread Pool Size

When salt cloud is operating in parallel mode via the -P argument, you can control the thread pool size by specifying the pool_size parameter with a positive integer value.

By default, the thread pool size will be set to the number of VMs that salt cloud is operating on.

```
pool_size: 10
```

Minion Configuration

The default minion configuration is set up in this file. Minions created by salt-cloud derive their configuration from this file. Almost all parameters found in Configuring the Salt Minion can be used here.

```
minion:
  master: saltmaster.example.com
```

In particular, this is the location to specify the location of the salt master and its listening port, if the port is not set to the default.

Similar to most other settings, Minion configuration settings are inherited across configuration files. For example, the master setting might be contained in the main cloud configuration file as demonstrated above, but additional settings can be placed in the provider or profile:

```
ec2-web:
  size: t1.micro
  minion:
    environment: test
    startup_states: sls
    sls_list:
      - web
```

Cloud Configuration Syntax

The data specific to interacting with public clouds is set up here.

Cloud provider configuration settings can live in several places. The first is in /etc/salt/cloud:

```
# /etc/salt/cloud
providers:
  my-aws-migrated-config:
    id: HJGRYCIJLJKJYG
    key: 'kdjgfsym;woormgl/aserigjksjdasdfgn'
    keyname: test
    securitygroup: quick-start
    private_key: /root/test.pem
    driver: ec2
```

Cloud provider configuration data can also be housed in /etc/salt/cloud.providers or any file matching /etc/salt/cloud.providers.d/*.*.conf. All files in any of these locations will be parsed for cloud provider data.

Using the example configuration above:
# /etc/salt/cloud.providers
# or could be /etc/salt/cloud.providers.d/*.conf
my-aws-config:
  id: HJGRYCILJLKJYG
  key: 'kdjgfsgm;woormgl/aserigjksjdhasdfgn'
  keyname: test
  securitygroup: quick-start
  private_key: /root/test.pem
  driver: ec2

Note: Salt Cloud provider configurations within /etc/cloud.provider.d/ should not specify the
`providers` starting key.

It is also possible to have multiple cloud configuration blocks within the same alias block. For example:

```
production-config:
  - id: HJGRYCILJLKJYG
    key: 'kdjgfsgm;woormgl/aserigjksjdhasdfgn'
    keyname: test
    securitygroup: quick-start
    private_key: /root/test.pem
    driver: ec2

  - user: example_user
    apikey: 123984bjjas87034
    driver: rackspace
```

However, using this configuration method requires a change with profile configuration blocks. The provider alias
needs to have the provider key value appended as in the following example:

```
rhel_aws_dev:
  provider: production-config:ec2
  image: ami-e565ba8c
  size: t1.micro

rhel_aws_prod:
  provider: production-config:ec2
  image: ami-e565ba8c
  size: High-CPU Extra Large Instance

database_prod:
  provider: production-config:rackspace
  image: Ubuntu 12.04 LTS
  size: 256 server
```

Notice that because of the multiple entries, one has to be explicit about the provider alias and name, from the above
example, `production-config: ec2`.

This data interactions with the `salt-cloud` binary regarding its `--list-location`, `--list-images`, and
`--list-sizes` which needs a cloud provider as an argument. The argument used should be the configured cloud
provider alias. If the provider alias has multiple entries, `<provider-alias>`: `<provider-name>` should be
used.

To allow for a more extensible configuration, `--providers-config`, which defaults to
`/etc/salt/cloud.providers`, was added to the cli parser. It allows for the providers' configuration
to be added on a per-file basis.
Pillar Configuration

It is possible to configure cloud providers using pillars. This is only used when inside the cloud module. You can setup a variable called `cloud` that contains your profile and provider to pass that information to the cloud servers instead of having to copy the full configuration to every minion. In your pillar file, you would use something like this:

```yaml
cloud:
  ssh_key_name: saltstack
  ssh_key_file: /root/.ssh/id_rsa
  update_cachedir: True
  diff_cache_events: True
  change_password: True

providers:
  my-nova:
    identity_url: https://identity.api.rackspacecloud.com/v2.0/
    compute_region: IAD
    user: myuser
    api_key: apikey
    tenant: 123456
    driver: nova

  my-openstack:
    identity_url: https://identity.api.rackspacecloud.com/v2.0/tokens
    user: user2
    apikey: apikey2
    tenant: 654321
    compute_region: DFW
    driver: openstack
    compute_name: cloudServersOpenStack

profiles:
  ubuntu-nova:
    provider: my-nova
    size: performance1-8
    image: bb02b1a3-bc77-4d17-ab5b-421d89850fca
    script_args: git develop

  ubuntu-openstack:
    provider: my-openstack
    size: performance1-8
    image: bb02b1a3-bc77-4d17-ab5b-421d89850fca
    script_args: git develop
```

Cloud Configurations

Scaleway

To use Salt Cloud with Scaleway, you need to get an access key and an API token. API tokens are unique identifiers associated with your Scaleway account. To retrieve your access key and API token, log-in to the Scaleway control panel, open the pull-down menu on your account name and click on "My Credentials" link.

If you do not have API token you can create one by clicking the "Create New Token" button on the right corner.
my-scaleway-config:
  access_key: 15cf404d-4560-41b1-9a0c-21c3d5c4ff1f
  token: a7347ec8-5de1-4024-a5e3-24b77d1ba91d
  driver: scaleway

Note: In the cloud profile that uses this provider configuration, the syntax for the provider required field would be provider: my-scaleway-config.

Rackspace

Rackspace cloud requires two configuration options; a user and an apikey:

my-rackspace-config:
  user: example_user
  apikey: 123984bajas87034
  driver: rackspace

Note: In the cloud profile that uses this provider configuration, the syntax for the provider required field would be provider: my-rackspace-config.

Amazon AWS

A number of configuration options are required for Amazon AWS including id, key, keyname, securitygroup, and private_key:

my-aws-quick-start:
  id: HJGRYCILJKJYG
  key: 'kdjgfsmg;woomgls/aserigjksjdhasdfgn'
  keyname: test
  securitygroup: quick-start
  private_key: /root/test.pem
  driver: ec2

my-aws-default:
  id: HJGRYCILJKJYG
  key: 'kdjgfsmg;woomgls/aserigjksjdhasdfgn'
  keyname: test
  securitygroup: default
  private_key: /root/test.pem
  driver: ec2

Note: In the cloud profile that uses this provider configuration, the syntax for the provider required field would be either provider: my-aws-quick-start or provider: my-aws-default.

Linode

Linode requires a single API key, but the default root password also needs to be set:
The password needs to be 8 characters and contain lowercase, uppercase, and numbers.

Note: In the cloud profile that uses this provider configuration, the syntax for the provider required field would be `provider: my-linode-config`

**Joyent Cloud**

The Joyent cloud requires three configuration parameters: The username and password that are used to log into the Joyent system, as well as the location of the private SSH key associated with the Joyent account. The SSH key is needed to send the provisioning commands up to the freshly created virtual machine.

```
my-joyent-config:
  user: fred
  password: saltybacon
  private_key: /root/joyent.pem
  driver: joyent
```

Note: In the cloud profile that uses this provider configuration, the syntax for the provider required field would be `provider: my-joyent-config`

**GoGrid**

To use Salt Cloud with GoGrid, log into the GoGrid web interface and create an API key. Do this by clicking on `My Account` and then going to the API Keys tab.

The apikey and the sharedsecret configuration parameters need to be set in the configuration file to enable interfacing with GoGrid:

```
my-gogrid-config:
  apikey: asdff7896asdh789
  sharedsecret: saltybacon
  driver: gogrid
```

Note: In the cloud profile that uses this provider configuration, the syntax for the provider required field would be `provider: my-gogrid-config`. 
OpenStack

OpenStack configuration differs between providers, and at the moment several options need to be specified. This module has been officially tested against the HP and the Rackspace implementations, and some examples are provided for both.

### For HP

```yaml
my-openstack-hp-config:
  compute_name: Compute
  compute_region: 'az-1.region-a.geo-1'
  tenant: myuser-tenant1
  user: myuser
  ssh_key_name: mykey
  ssh_key_file: '/etc/salt/hpcloud/mykey.pem'
  password: mypass
  driver: openstack
```

### For Rackspace

```yaml
my-openstack-rackspace-config:
  identity_url: 'https://identity.api.rackspacecloud.com/v2.0/tokens'
  compute_name: cloudServersOpenStack
  protocol: ipv4
  compute_region: DFW
  protocol: ipv4
  user: myuser
  tenant: 5555555
  password: mypass
  driver: openstack
```

If you have an API key for your provider, it may be specified instead of a password:

```yaml
my-openstack-hp-config:
  apikey: 901d3f579h23c8v73q9

my-openstack-rackspace-config:
  apikey: 901d3f579h23c8v73q9
```

**Note:** In the cloud profile that uses this provider configuration, the syntax for the `provider` required field would be either `provider: my-openstack-hp-config` or `provider: my-openstack-rackspace-config`.

You will certainly need to configure the `user`, `tenant`, and either `password` or `apikey`.

If your OpenStack instances only have private IP addresses and a CIDR range of private addresses are not reachable from the salt-master, you may set your preference to have Salt ignore it:

```yaml
my-openstack-config:
  ignore_cidr: 192.168.0.0/16
```

For in-house OpenStack Essex installation, libcloud needs the `service_type`:

```yaml
my-openstack-config:
  identity_url: 'http://control.openstack.example.org:5000/v2.0/
  compute_name : Compute Service
  service_type : compute
```
DigitalOcean

Using Salt for DigitalOcean requires a client_key and an api_key. These can be found in the DigitalOcean web interface, in the "My Settings" section, under the API Access tab.

```yaml
my-digitalocean-config:
  driver: digital_ocean
  personal_access_token: xxx
  location: New York 1
```

Note: In the cloud profile that uses this provider configuration, the syntax for the provider required field would be `provider: my-digital-ocean-config`.

Parallels

Using Salt with Parallels requires a user, password and URL. These can be obtained from your cloud provider.

```yaml
my-parallels-config:
  user: myuser
  password: xyzzy
  url: https://api.cloud.xmission.com:4465/paci/v1.0/
  driver: parallels
```

Note: In the cloud profile that uses this provider configuration, the syntax for the provider required field would be `provider: my-parallels-config`.

Proxmox

Using Salt with Proxmox requires a user, password, and URL. These can be obtained from your cloud host. Both PAM and PVE users can be used.

```yaml
my-proxmox-config:
  driver: proxmox
  user: saltcloud@pve
  password: xyzzy
  url: your.proxmox.host
```

Note: In the cloud profile that uses this provider configuration, the syntax for the provider required field would be `provider: my-proxmox-config`.

LXC

The lxc driver uses saltify to install salt and attach the lxc container as a new lxc minion. As soon as we can, we manage baremetal operation over SSH. You can also destroy those containers via this driver.
Devhost10-lxc:
  target: devhost10
  driver: lxc

And in the map file:

Devhost10-lxc:
  provider: devhost10-lxc
  from_container: ubuntu
  backing: lvm
  sudo: True
  size: 3g
  ip: 10.0.3.9
  minion:
    master: 10.5.0.1
    master_port: 4506
  lxc_conf:
    - lxc.utsname: superlxc

Note: In the cloud profile that uses this provider configuration, the syntax for the provider required field would be provider: devhost10-lxc.

Saltify

The Saltify driver is a new, experimental driver designed to install Salt on a remote machine, virtual or bare metal, using SSH. This driver is useful for provisioning machines which are already installed, but not Salted. For more information about using this driver and for configuration examples, please see the Getting Started with Saltify documentation.

Extending Profiles and Cloud Providers Configuration

As of 0.8.7, the option to extend both the profiles and cloud providers configuration and avoid duplication was added. The extends feature works on the current profiles configuration, but, regarding the cloud providers configuration, only works in the new syntax and respective configuration files, i.e. /etc/salt/salt/cloud.providers or /etc/salt/cloud.providers.d/* .conf.

Note: Extending cloud profiles and providers is not recursive. For example, a profile that is extended by a second profile is possible, but the second profile cannot be extended by a third profile.

Also, if a profile (or provider) is extending another profile and each contains a list of values, the lists from the extending profile will override the list from the original profile. The lists are not merged together.

Extending Profiles

Some example usage on how to use extends with profiles. Consider /etc/salt/salt/cloud.profiles containing:

development-instances:
  provider: my-ec2-config
The above configuration, once parsed would generate the following profiles data:

```json
[
    {
        'deploy': False,
        'image': 'ami-08d97e61',
        'profile': 'Fedora-17',
        'provider': 'my-ec2-config',
        'securitygroup': ['default'],
        'size': 't1.micro',
        'ssh_username': 'ec2_user'
    },
    {
        'deploy': False,
        'image': 'ami-09b61d60',
        'profile': 'CentOS-5',
        'provider': 'my-aws-config',
        'securitygroup': ['default'],
        'size': 't1.micro',
        'ssh_username': 'ec2_user'
    },
    {
        'deploy': False,
        'image': 'ami-54cf5c3d',
        'profile': 'Amazon-Linux-AMI-2012.09-64bit',
        'provider': 'my-ec2-config',
        'securitygroup': ['default'],
        'size': 't1.micro',
        'ssh_username': 'ec2_user'
    },
    {
        'deploy': False,
        'profile': 'development-instances',
        'provider': 'my-ec2-config',
        'securitygroup': ['default'],
        'size': 't1.micro',
        'ssh_username': 'ec2_user'
    }
]
```

Pretty cool right?

**Extending Providers**

Some example usage on how to use `extends` within the cloud providers configuration. Consider `/etc/salt/salt/cloud.providers` containing:
The above configuration, once parsed would generate the following providers data:

```json
'providers': {
  'my-develop-envs': [
    {'availability_zone': 'ap-southeast-1b',
     'id': 'HJGRYCIILJKJYG',
     'key': 'kdjgfsgm;woormgl/aserigjksjdhashdfgn',
     'keyname': 'test',
     'location': 'ap-southeast-1',
     'private_key': '/root/test.pem',
     'driver': 'ec2'},
    {'location': 'Raleigh',
     'password': 'mypass',
     'driver': 'ibmsce',
     'ssh_key_file': '/etc/salt/ibm/mykey.pem',
     'ssh_key_name': 'mykey',
     'user': 'myuser@mycorp.com'}
  ],
  'my-productions-envs': [
    {'availability_zone': 'us-east-1',
     'location': 'us-east-1',
     'password': 'mypass',
     'driver': 'ibmsce',
     'ssh_key_file': '/etc/salt/ibm/mykey.pem',
     'ssh_key_name': 'mykey',
     'user': 'my-production-user@mycorp.com'}
  ]
}
```
25.6 Windows Configuration

25.6.1 Spinning up Windows Minions

It is possible to use Salt Cloud to spin up Windows instances, and then install Salt on them. This functionality is available on all cloud providers that are supported by Salt Cloud. However, it may not necessarily be available on all Windows images.

Requirements

Salt Cloud makes use of `impacket` and `winexe` to set up the Windows Salt Minion installer.

`impacket` is usually available as either the `impacket` or the `python-impacket` package, depending on the distribution. More information on `impacket` can be found at the project home:

- `impacket` project home

`winexe` is less commonly available in distribution-specific repositories. However, it is currently being built for various distributions in 3rd party channels:

- RPMs at phone.net
- OpenSuse Build Service

Optionally WinRM can be used instead of `winexe` if the python module `pywinrm` is available and WinRM is supported on the target Windows version. Information on `pywinrm` can be found at the project home:

- `pywinrm` project home

Additionally, a copy of the Salt Minion Windows installer must be present on the system on which Salt Cloud is running. This installer may be downloaded from saltstack.com:

- SaltStack Download Area

Firewall Settings

Because Salt Cloud makes use of `smbclient` and `winexe`, port 445 must be open on the target image. This port is not generally open by default on a standard Windows distribution, and care must be taken to use an image in which this port is open, or the Windows firewall is disabled.

If supported by the cloud provider, a PowerShell script may be used to open up this port automatically, using the cloud provider’s `userdata`. The following script would open up port 445, and apply the changes:

```powershell
<powershell>
New-NetFirewallRule -Name "SMB445" -DisplayName "SMB445" -Protocol TCP -LocalPort 445
Set-Item (dir wsman:\localhost\Listener\*\Port -Recurse).pspath 445 -Force
Restart-Service winrm
</powershell>
```

For EC2, this script may be saved as a file, and specified in the provider or profile configuration as `userdata_file`. For instance:

```
userdata_file: /etc/salt/windows-firewall.ps1
```

If you are using WinRM on EC2 the HTTPS port for the WinRM service must also be enabled in your userdata. By default EC2 Windows images only have insecure HTTP enabled. To enable HTTPS and basic authentication required by `pywinrm` consider the following userdata example:
No certificate store is available by default on EC2 images and creating one does not seem possible without an MMC (cannot be automated). To use the default EC2 Windows images the above copies the RDP store.

**Configuration**

Configuration is set as usual, with some extra configuration settings. The location of the Windows installer on the machine that Salt Cloud is running on must be specified. This may be done in any of the regular configuration files (main, providers, profiles, maps). For example:

Setting the installer in `/etc/salt/cloud.providers`:

```yaml
my-softlayer:
driver: softlayer
user: MYUSER1138
apikey: 'e3b68aa711e6deadc62d5b76355674beef7cc3116062ddbacafe5f7e465bfdc9'
minion:
  master: saltmaster.example.com
win_installer: /root/Salt-Minion-2014.7.0-AMD64-Setup.exe
win_username: Administrator
```
The default Windows user is *Administrator*, and the default Windows password is blank.

If WinRM is to be used `use_winrm` needs to be set to *True*. `winrm_port` can be used to specify a custom port (must be HTTPS listener).

**Auto-Generated Passwords on EC2**

On EC2, when the `win_password` is set to *auto*, Salt Cloud will query EC2 for an auto-generated password. This password is expected to take at least 4 minutes to generate, adding additional time to the deploy process.

When the EC2 API is queried for the auto-generated password, it will be returned in a message encrypted with the specified `keyname`. This requires that the appropriate `private_key` file is also specified. Such a profile configuration might look like:

```yaml
windows-server-2012:
    provider: my-ec2-config
    image: ami-c49c0dac
    size: m1.small
    securitygroup: windows
    keyname: mykey
    private_key: /root/mykey.pem
    userdata_file: /etc/salt/windows-firewall.ps1
    win_installer: /root/Salt-Minion-2014.7.0-AMD64-Setup.exe
    win_username: Administrator
    win_password: auto
```

### 25.7 Cloud Provider Specifics

#### 25.7.1 Getting Started With Aliyun ECS

The Aliyun ECS (Elastic Computer Service) is one of the most popular public cloud hosts in China. This cloud host can be used to manage aliyun instance using salt-cloud.

http://www.aliyun.com/

**Dependencies**

This driver requires the Python `requests` library to be installed.

**Configuration**

Using Salt for Aliyun ECS requires aliyun access key id and key secret. These can be found in the aliyun web interface, in the "User Center" section, under "My Service" tab.

```bash
# Note: This example is for /etc/salt/cloud.providers or any file in the
# /etc/salt/cloud.providers.d/ directory.

my-aliyun-config:
    # aliyun Access Key ID
```
id: wDGEwGrgedg3435gDgxd
# aliyun Access Key Secret
copy: GDd45t43RDBTrkkkg43934t34qT43t4dgegerGEgg
location: cn-qingdao
driver: aliyun

Note: Changed in version 2015.8.0.

The provider parameter in cloud provider definitions was renamed to driver. This change was made to avoid confusion with the provider parameter that is used in cloud profile definitions. Cloud provider definitions now use driver to refer to the Salt cloud module that provides the underlying functionality to connect to a cloud host, while cloud profiles continue to use provider to refer to provider configurations that you define.

Profiles

Cloud Profiles

Set up an initial profile at /etc/salt/cloud.profiles or in the /etc/salt/cloud.profiles.d/ directory:

```plaintext
aliyun_centos:
    provider: my-aliyun-config
    size: ecs.t1.small
    location: cn-qingdao
    securitygroup: G1989096784427999
    image: centos6u3_64_20G_aliaegis_20130816.vhd
```

Sizes can be obtained using the --list-sizes option for the salt-cloud command:

```plaintext
# salt-cloud --list-sizes my-aliyun-config
my-aliyun-config:
    ----------
    aliyun:
        ----------
        ecs.c1.large:
            ----------
            CpuCoreCount: 8
            InstanceTypeId: ecs.c1.large
            MemorySize: 16.0
...SNIP...
```

Images can be obtained using the --list-images option for the salt-cloud command:

```plaintext
# salt-cloud --list-images my-aliyun-config
my-aliyun-config:
    ----------
    aliyun:
        ----------
        centos5u8_64_20G_aliaegis_20131231.vhd:
        ----------
```

25.7. Cloud Provider Specifics
Architecture:
x86_64
Description:

ImageId:
centos5u8_64_20G_aliaegis_20131231.vhd
ImageName:
CentOS 5.8 64
ImageOwnerAlias:
system
ImageVersion:
1.0
OSName:
CentOS 5.8 64
Platform:
CENTOS5
Size:
20
Visibility:
public

Locations can be obtained using the --list-locations option for the salt-cloud command:

```yaml
my-aliyun-config:
----------
aliyun:
----------
  cn-beijing:
  ----------
    LocalName:
    cn-beijing
  cn-hangzhou:
  ----------
    LocalName:
    cn-hangzhou
  cn-hongkong:
  ----------
    LocalName:
    cn-hongkong
  cn-qingdao:
  ----------
    LocalName:
    cn-qingdao
```

Security Group can be obtained using the -f list_securitygroup option for the salt-cloud command:

```
# salt-cloud --location=cn-qingdao -f list_securitygroup my-aliyun-config
```
Note: Aliyun ECS REST API documentation is available from Aliyun ECS API.

### 25.7.2 Getting Started With Azure

New in version 2014.1.0.

Azure is a cloud service by Microsoft providing virtual machines, SQL services, media services, and more. This document describes how to use Salt Cloud to create a virtual machine on Azure, with Salt installed.

#### Dependencies

- The Azure Python SDK $\geq 0.10.2$ and $< 1.0.0$
- The python-requests library, for Python $\leq 2.7.9$.
- A Microsoft Azure account
- OpenSSL (to generate the certificates)
- Salt

**Note:** The Azure driver is currently being updated to work with the new version of the Python Azure SDK, 1.0.0. However until that process is complete, this driver will not work with Azure 1.0.0. Please be sure you’re running on a minimum version of 0.10.2 and less than version 1.0.0.

See Issue #27980 for more information.

#### Configuration

Set up the provider config at `/etc/salt/cloud.providers.d/azure.conf`:

```bash
# Note: This example is for /etc/salt/cloud.providers.d/azure.conf

my-azure-config:
  driver: azure
  subscription_id: 3287abc8-f98a-c678-3bde-326766fd3617
  certificate_path: /etc/salt/azure.pem

# Set up the location of the salt master
#
minion:
  master: saltmaster.example.com
```
The certificate used must be generated by the user. OpenSSL can be used to create the management certificates. Two certificates are needed: a .cer file, which is uploaded to Azure, and a .pem file, which is stored locally.

To create the .pem file, execute the following command:

```
openssl req -x509 -nodes -days 365 -newkey rsa:1024 -keyout /etc/salt/azure.pem -out /etc/salt/azure.pem
```

To create the .cer file, execute the following command:

```
openssl x509 -inform pem -in /etc/salt/azure.pem -outform der -out /etc/salt/azure.cer
```

After creating these files, the .cer file will need to be uploaded to Azure via the ‘Upload a Management Certificate’ action of the ‘Management Certificates’ tab within the ‘Settings’ section of the management portal.

Optionally, a `management_host` may be configured, if necessary for the region.

---

### Note: Changed in version 2015.8.0.

The `provider` parameter in cloud provider definitions was renamed to `driver`. This change was made to avoid confusion with the `provider` parameter that is used in cloud profile definitions. Cloud provider definitions now use `driver` to refer to the Salt cloud module that provides the underlying functionality to connect to a cloud host, while cloud profiles continue to use `provider` to refer to provider configurations that you define.

---

### Cloud Profiles

Set up an initial profile at `/etc/salt/cloud.profiles`:

```
azure-ubuntu:
  provider: my-azure-config
  image: 'b39f27a8b8c64d52b05ec6a62ebad85__Ubuntu-12_04_3-LTS-amd64-server-20131003-en-us-30GB'
  size: Small
  location: 'East US'
  ssh_username: azureuser
  ssh_password: verybadpass
  slot: production
  media_link: 'http://portalvhdabcdefghijklmn.blob.core.windows.net/vhds'
  virtual_network_name: azure-virtual-network
  subnet_name: azure-subnet
```

These options are described in more detail below. Once configured, the profile can be realized with a salt command:

```
salt-cloud -p azure-ubuntu newinstance
```

This will create an salt minion instance named `newinstance` in Azure. If the command was executed on the salt-master, its Salt key will automatically be signed on the master.

Once the instance has been created with salt-minion installed, connectivity to it can be verified with Salt:

```
salt newinstance test.ping
```
Profile Options

The following options are currently available for Azure.

**provider**

The name of the provider as configured in `/etc/salt/cloud.providers.d/azure.conf`.

**image**

The name of the image to use to create a VM. Available images can be viewed using the following command:

```
salt-cloud --list-images my-azure-config
```

**size**

The name of the size to use to create a VM. Available sizes can be viewed using the following command:

```
salt-cloud --list-sizes my-azure-config
```

**location**

The name of the location to create a VM in. Available locations can be viewed using the following command:

```
salt-cloud --list-locations my-azure-config
```

**affinity_group**

The name of the affinity group to create a VM in. Either a location or an affinity_group may be specified, but not both. See Affinity Groups below.

**ssh_username**

The user to use to log into the newly-created VM to install Salt.

**ssh_password**

The password to use to log into the newly-created VM to install Salt.

**slot**

The environment to which the hosted service is deployed. Valid values are staging or production. When set to production, the resulting URL of the new VM will be `<vm_name>.cloudapp.net`. When set to staging, the resulting URL will contain a generated hash instead.
media_link

This is the URL of the container that will store the disk that this VM uses. Currently, this container must already exist. If a VM has previously been created in the associated account, a container should already exist. In the web interface, go into the Storage area and click one of the available storage selections. Click the Containers link, and then copy the URL from the container that will be used. It generally looks like:

```
http://portalvhdabcdefghijklmn.blob.core.windows.net/vhds
```

service_name

The name of the service in which to create the VM. If this is not specified, then a service will be created with the same name as the VM.

virtual_network_name

Optional. The name of the virtual network for the VM to join. If this is not specified, then no virtual network will be joined.

subnet_name

Optional. The name of the subnet in the virtual network for the VM to join. Requires that a `virtual_network_name` is specified.

Show Instance

This action is a thin wrapper around `--full-query`, which displays details on a single instance only. In an environment with several machines, this will save a user from having to sort through all instance data, just to examine a single instance.

```
salt-cloud -a show_instance myinstance
```

Destroying VMs

There are certain options which can be specified in the global cloud configuration file (usually `/etc/salt/cloud`) which affect Salt Cloud's behavior when a VM is destroyed.

cleanup_disks

New in version 2015.8.0.
Default is `False`. When set to `True`, Salt Cloud will wait for the VM to be destroyed, then attempt to destroy the main disk that is associated with the VM.
cleanup_vhds

New in version 2015.8.0.
Default is False. Requires cleanup_disks to be set to True. When also set to True, Salt Cloud will ask Azure to delete the VHD associated with the disk that is also destroyed.

cleanup_services

New in version 2015.8.0.
Default is False. Requires cleanup_disks to be set to True. When also set to True, Salt Cloud will wait for the disk to be destroyed, then attempt to remove the service that is associated with the VM. Because the disk belongs to the service, the disk must be destroyed before the service can be.

Managing Hosted Services

New in version 2015.8.0.
An account can have one or more hosted services. A hosted service is required in order to create a VM. However, as mentioned above, if a hosted service is not specified when a VM is created, then one will automatically be created with the name of the name. The following functions are also available.

create_service

Create a hosted service. The following options are available.

name

Required. The name of the hosted service to create.

label

Required. A label to apply to the hosted service.

description

Optional. A longer description of the hosted service.

location

Required, if affinity_group is not set. The location in which to create the hosted service. Either the location or the affinity_group must be set, but not both.

affinity_group

Required, if location is not set. The affinity group in which to create the hosted service. Either the location or the affinity_group must be set, but not both.
extended_properties

Optional. Dictionary containing name/value pairs of hosted service properties. You can have a maximum of 50 extended property name/value pairs. The maximum length of the Name element is 64 characters, only alphanumeric characters and underscores are valid in the Name, and the name must start with a letter. The value has a maximum length of 255 characters.

CLI Example

The following example illustrates creating a hosted service.

```
salt-cloud -f create_service my-azure name=my-service label=my-service location='West--US'
```

show_service

Return details about a specific hosted service. Can also be called with get_service.

```
salt-cloud -f show_storage my-azure name=my-service
```

list_services

List all hosted services associates with the subscription.

```
salt-cloud -f list_services my-azure-config
```

delete_service

Delete a specific hosted service.

```
salt-cloud -f delete_service my-azure name=my-service
```

Managing Storage Accounts

New in version 2015.8.0.

Salt Cloud can manage storage accounts associated with the account. The following functions are available. Deprecated marked as deprecated are marked as such as per the SDK documentation, but are still included for completeness with the SDK.

create_storage

Create a storage account. The following options are supported.

name

Required. The name of the storage account to create.
label

Required. A label to apply to the storage account.

description

Optional. A longer description of the storage account.

location

Required, if affinity_group is not set. The location in which to create the storage account. Either the location or the affinity_group must be set, but not both.

affinity_group

Required, if location is not set. The affinity group in which to create the storage account. Either the location or the affinity_group must be set, but not both.

extended_properties

Optional. Dictionary containing name/value pairs of storage account properties. You can have a maximum of 50 extended property name/value pairs. The maximum length of the Name element is 64 characters, only alphanumeric characters and underscores are valid in the Name, and the name must start with a letter. The value has a maximum length of 255 characters.

geo_replication_enabled

Deprecated. Replaced by the account_type parameter.

account_type

Specifies whether the account supports locally-redundant storage, geo-redundant storage, zone-redundant storage, or read access geo-redundant storage. Possible values are:

- Standard_LRS
- Standard_ZRS
- Standard_GRS
- Standard_RAGRS

CLI Example

The following example illustrates creating a storage account.

code

```
salt-cloud -f create_storage my-azure name=my-storage label=my-storage location='West US'
```
list_storage

List all storage accounts associates with the subscription.

```
salt-cloud -f list_storage my-azure-config
```

show_storage

Return details about a specific storage account. Can also be called with get_storage.

```
salt-cloud -f show_storage my-azure name=my-storage
```

update_storage

Update details concerning a storage account. Any of the options available in create_storage can be used, but the name cannot be changed.

```
salt-cloud -f update_storage my-azure name=my-storage label=my-storage
```

delete_storage

Delete a specific storage account.

```
salt-cloud -f delete_storage my-azure name=my-storage
```

show_storage_keys

Returns the primary and secondary access keys for the specified storage account.

```
salt-cloud -f show_storage_keys my-azure name=my-storage
```

regenerate_storage_keys

Regenerate storage account keys. Requires a key_type (``primary'' or ``secondary'') to be specified.

```
salt-cloud -f regenerate_storage_keys my-azure name=my-storage key_type=primary
```

Managing Disks

New in version 2015.8.0.

When a VM is created, a disk will also be created for it. The following functions are available for managing disks. Deprecated marked as deprecated are marked as such as per the SDK documentation, but are still included for completeness with the SDK.
show_disk

Return details about a specific disk. Can also be called with get_disk.

```
salt-cloud -f show_disk my-azure name=my-disk
```

list_disks

List all disks associates with the account.

```
salt-cloud -f list_disks my-azure
```

update_disk

Update details for a disk. The following options are available.

**name**

Required. The name of the disk to update.

**has_operating_system**

Deprecated.

**label**

Required. The label for the disk.

**media_link**

Deprecated. The location of the disk in the account, including the storage container that it is in. This should not need to be changed.

**new_name**

Deprecated. If renaming the disk, the new name.

**os**

Deprecated.
CLI Example

The following example illustrates updating a disk.

```
salt-cloud -f update_disk my-azure name=my-disk label=my-disk
```

**delete_disk**

Delete a specific disk.

```
salt-cloud -f delete_disk my-azure name=my-disk
```

**Managing Service Certificates**

New in version 2015.8.0.

Stored at the cloud service level, these certificates are used by your deployed services. For more information on service certificates, see the following link:

- Manage Certificates

The following functions are available.

**list_service_certificates**

List service certificates associated with the account.

```
salt-cloud -f list_service_certificates my-azure
```

**show_service_certificate**

Show the data for a specific service certificate associated with the account. The name, thumbprint, and thumbalgorithm can be obtained from list_service_certificates. Can also be called with get_service_certificate.

```
salt-cloud -f show_service_certificate my-azure name=my_service_certificate \   thumbalgorithm=sha1 thumbprint=0123456789ABCDEF
```

**add_service_certificate**

Add a service certificate to the account. This requires that a certificate already exists, which is then added to the account. For more information on creating the certificate itself, see:

- Create a Service Certificate for Azure

The following options are available.

**name**

Required. The name of the hosted service that the certificate will belong to.
data

Required. The base-64 encoded form of the pfx file.

certificate_format

Required. The service certificate format. The only supported value is pfx.

password

The certificate password.

```
salt-cloud -f add_service_certificate my-azure name=my-cert "
  data='...CERT_DATA...' certificate_format=pfx password=verybadpass"
```

delete_service_certificate

Delete a service certificate from the account. The name, thumbprint, and thumbalgorithm can be obtained from list_service_certificates.

```
salt-cloud -f delete_service_certificate my-azure "
  name=my_service_certificate "
  thumbalgorithm=sha1 thumbprint=0123456789ABCDEF"
```

Managing Management Certificates

New in version 2015.8.0.

A Azure management certificate is an X.509 v3 certificate used to authenticate an agent, such as Visual Studio Tools for Windows Azure or a client application that uses the Service Management API, acting on behalf of the subscription owner to manage subscription resources. Azure management certificates are uploaded to Azure and stored at the subscription level. The management certificate store can hold up to 100 certificates per subscription. These certificates are used to authenticate your Windows Azure deployment.

For more information on management certificates, see the following link.

- Manage Certificates

The following functions are available.

list_management_certificates

List management certificates associated with the account.

```
salt-cloud -f list_management_certificates my-azure
```
show_management_certificate

Show the data for a specific management certificate associated with the account. The name, thumbprint, and thumbalgorithm can be obtained from list_management_certificates. Can also be called with get_management_certificate.

```
salt-cloud -f show_management_certificate my-azure name=my_management_certificate \ 
    thumbalgorithm=sha1 thumbprint=0123456789ABCDEF
```

add_management_certificate

Management certificates must have a key length of at least 2048 bits and should reside in the Personal certificate store. When the certificate is installed on the client, it should contain the private key of the certificate. To upload to the certificate to the Microsoft Azure Management Portal, you must export it as a .cer format file that does not contain the private key. For more information on creating management certificates, see the following link:

- Create and Upload a Management Certificate for Azure

The following options are available.

public_key

A base64 representation of the management certificate public key.

thumbprint

The thumb print that uniquely identifies the management certificate.

data

The certificate's raw data in base-64 encoded .cer format.

```
salt-cloud -f add_management_certificate my-azure public_key='...PUBKEY...' \ 
    thumbprint=0123456789ABCDEF data='...CERT_DATA...'
```

delete_management_certificate

Delete a management certificate from the account. The thumbprint can be obtained from list_management_certificates.

```
salt-cloud -f delete_management_certificate my-azure thumbprint=0123456789ABCDEF
```

Virtual Network Management

New in version 2015.8.0.

The following are functions for managing virtual networks.
list_virtual_networks

List input endpoints associated with the deployment.

```
salt-cloud -f list_virtual_networks my-azure service=myservice deployment=mydeployment
```

Managing Input Endpoints

New in version 2015.8.0.

Input endpoints are used to manage port access for roles. Because endpoints cannot be managed by the Azure Python SDK, Salt Cloud uses the API directly. With versions of Python before 2.7.9, the requests-python package needs to be installed in order for this to work. Additionally, the following needs to be set in the master's configuration file:

```
requests_lib: True
```

The following functions are available.

list_input_endpoints

List input endpoints associated with the deployment

```
salt-cloud -f list_input_endpoints my-azure service=myservice deployment=mydeployment
```

show_input_endpoint

Show an input endpoint associated with the deployment

```
salt-cloud -f show_input_endpoint my-azure service=myservice 
  deployment=mydeployment name=SSH
```

add_input_endpoint

Add an input endpoint to the deployment. Please note that there may be a delay before the changes show up. The following options are available.

service

Required. The name of the hosted service which the VM belongs to.

deployment

Required. The name of the deployment that the VM belongs to. If the VM was created with Salt Cloud, the deployment name probably matches the VM name.
role

Required. The name of the role that the VM belongs to. If the VM was created with Salt Cloud, the role name probably matches the VM name.

name

Required. The name of the input endpoint. This typically matches the port that the endpoint is set to. For instance, port 22 would be called SSH.

port

Required. The public (Internet-facing) port that is used for the endpoint.

local_port

Optional. The private port on the VM itself that will be matched with the port. This is typically the same as the port. If this value is not specified, it will be copied from port.

protocol

Required. Either tcp or udp.

collect_default

Optional. If an internal load balancer exists in the account, it can be used with a direct server return. The default value is False. Please see the following article for an explanation of this option.

- Load Balancing for Azure Infrastructure Services

timeout_for_tcp_idle_connection

Optional. The default value is 4. Please see the following article for an explanation of this option.

- Configurable Idle Timeout for Azure Load Balancer

CLI Example

The following example illustrates adding an input endpoint.

```
salt-cloud -f add_input_endpoint my-azure service=myservice \
    deployment=mydeployment role=myrole name=HTTP local_port=80 \
    port=80 protocol=tcp enable_direct_server_return=False \
    timeout_for_tcp_idle_connection=4
```
update_input_endpoint

Updates the details for a specific input endpoint. All options from add_input_endpoint are supported.

```
salt-cloud -f update_input_endpoint my-azure service=myservice deployment=mydeployment role=myrole name=HTTP local_port=80 port=80 protocol=tcp enable_direct_server_return=False timeout_for_tcp_idle_connection=4
```

delete_input_endpoint

Delete an input endpoint from the deployment. Please note that there may be a delay before the changes show up. The following items are required.

**CLI Example**

The following example illustrates deleting an input endpoint.

```
salt-cloud -f delete_input_endpoint my-azure service=myservice deployment=mydeployment role=myrole name=HTTP
```

**Managing Affinity Groups**

New in version 2015.8.0.

Affinity groups allow you to group your Azure services to optimize performance. All services and VMs within an affinity group will be located in the same region. For more information on Affinity groups, see the following link:

- Create an Affinity Group in the Management Portal
The following functions are available.

**list_affinity_groups**

List input endpoints associated with the account

```bash
salt-cloud -f list_affinity_groups my-azure
```

**show_affinity_group**

Show an affinity group associated with the account

```bash
salt-cloud -f show_affinity_group my-azure service=myservice \
  deployment=mydeployment name=SSH
```

**create_affinity_group**

Create a new affinity group. The following options are supported.

- **name**
  
  Required. The name of the new affinity group.

- **location**
  
  Required. The region in which the affinity group lives.

- **label**
  
  Required. A label describing the new affinity group.

- **description**
  
  Optional. A longer description of the affinity group.

```bash
salt-cloud -f create_affinity_group my-azure name=my_affinity_group \
  label=my-affinity-group location='West US'
```

**update_affinity_group**

Update an affinity group's properties

```bash
salt-cloud -f update_affinity_group my-azure name=my_group label=my_group
```
delete_affinity_group

Delete a specific affinity group associated with the account

```
salt-cloud -f delete_affinity_group my-azure name=my_affinity_group
```

Managing Blob Storage

New in version 2015.8.0.

Azure storage containers and their contents can be managed with Salt Cloud. This is not as elegant as using one of the other available clients in Windows, but it benefits Linux and Unix users, as there are fewer options available on those platforms.

Blob Storage Configuration

Blob storage must be configured differently than the standard Azure configuration. Both a storage_account and a storage_key must be specified either through the Azure provider configuration (in addition to the other Azure configuration) or via the command line.

```
storage_account: mystorage
storage_key: ffhj334fDSGFEGDFDewr34fwfsFSDFwe==
```

storage_account

This is one of the storage accounts that is available via the list_storage function.

storage_key

Both a primary and a secondary storage_key can be obtained by running the show_storage_keys function. Either key may be used.

Blob Functions

The following functions are made available through Salt Cloud for managing blob storage.

make_blob_url

Creates the URL to access a blob

```
salt-cloud -f make_blob_url my-azure container=mycontainer blob=myblob
```

container

Name of the container.
blob

Name of the blob.

account

Name of the storage account. If not specified, derives the host base from the provider configuration.

protocol

Protocol to use: `http` or `https`. If not specified, derives the host base from the provider configuration.

host_base

Live host base URL. If not specified, derives the host base from the provider configuration.

list_storage_containers

List containers associated with the storage account

```
salt-cloud -f list_storage_containers my-azure
```

create_storage_container

Create a storage container

```
salt-cloud -f create_storage_container my-azure name=mycontainer
```

name

Name of container to create.

meta_name_values

Optional. A dict with name_value pairs to associate with the container as metadata. Example:`{'Category':'test'}`

blob_public_access

Optional. Possible values include: container, blob

fail_on_exist

Specify whether to throw an exception when the container exists.
show_storage_container

Show a container associated with the storage account

```
salt-cloud -f show_storage_container my-azure name=myservice
```

name

Name of container to show.

show_storage_container_metadata

Show a storage container's metadata

```
salt-cloud -f show_storage_container_metadata my-azure name=myservice
```

name

Name of container to show.

lease_id

If specified, show_storage_container_metadata only succeeds if the container's lease is active and matches this ID.

set_storage_container_metadata

Set a storage container's metadata

```
salt-cloud -f set_storage_container my-azure name=mycontainer \x_ms_meta_name_values='{"my_name": "my_value"}''
```

name

Name of existing container. meta_name_values A dict containing name, value for metadata. Example: {"category":"test"} lease_id If specified, set_storage_container_metadata only succeeds if the container's lease is active and matches this ID.

show_storage_container_acl

Show a storage container's acl

```
salt-cloud -f show_storage_container_acl my-azure name=myservice
```
**name**

Name of existing container.

**lease_id**

If specified, `show_storage_container_acl` only succeeds if the container's lease is active and matches this ID.

**set_storage_container_acl**

Set a storage container's acl

```
salt-cloud -f set_storage_container my-azure name=mycontainer
```

**name**

Name of existing container.

**signed_identifiers**

SignedIdentifiers instance

**blob_public_access**

Optional. Possible values include: container, blob

**lease_id**

If specified, `set_storage_container_acl` only succeeds if the container's lease is active and matches this ID.

**delete_storage_container**

Delete a container associated with the storage account

```
salt-cloud -f delete_storage_container my-azure name=mycontainer
```

**name**

Name of container to create.

**fail_not_exist**

Specify whether to throw an exception when the container exists.
lease_id

If specified, delete_storage_container only succeeds if the container's lease is active and matches this ID.

lease_storage_container

Lease a container associated with the storage account

```
salt-cloud -f lease_storage_container my-azure name=mycontainer
```

name

Name of container to create.

lease_action

Required. Possible values: acquire|renew|release|break|change

lease_id

Required if the container has an active lease.

lease_duration

Specifies the duration of the lease, in seconds, or negative one (-1) for a lease that never expires. A non-infinite lease can be between 15 and 60 seconds. A lease duration cannot be changed using renew or change. For backwards compatibility, the default is 60, and the value is only used on an acquire operation.

lease_break_period

Optional. For a break operation, this is the proposed duration of seconds that the lease should continue before it is broken, between 0 and 60 seconds. This break period is only used if it is shorter than the time remaining on the lease. If longer, the time remaining on the lease is used. A new lease will not be available before the break period has expired, but the lease may be held for longer than the break period. If this header does not appear with a break operation, a fixed-duration lease breaks after the remaining lease period elapses, and an infinite lease breaks immediately.

proposed_lease_id

Optional for acquire, required for change. Proposed lease ID, in a GUID string format.
list_blobs

List blobs associated with the container

```
salt-cloud -f list_blobs my-azure container=mycontainer
```

container

The name of the storage container

prefix

Optional. Filters the results to return only blobs whose names begin with the specified prefix.

marker

Optional. A string value that identifies the portion of the list to be returned with the next list operation. The operation returns a marker value within the response body if the list returned was not complete. The marker value may then be used in a subsequent call to request the next set of list items. The marker value is opaque to the client.

maxresults

Optional. Specifies the maximum number of blobs to return, including all BlobPrefix elements. If the request does not specify maxresults or specifies a value greater than 5,000, the server will return up to 5,000 items. Setting maxresults to a value less than or equal to zero results in error response code 400 (Bad Request).

include

Optional. Specifies one or more datasets to include in the response. To specify more than one of these options on the URI, you must separate each option with a comma. Valid values are:

<table>
<thead>
<tr>
<th>Dataset</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>snapshots:</td>
<td>Specifies that snapshots should be included in the enumeration. Snapshots are listed from oldest to newest in the response.</td>
</tr>
<tr>
<td>metadata:</td>
<td>Specifies that blob metadata be returned in the response.</td>
</tr>
<tr>
<td>uncommittedblobs:</td>
<td>Specifies that blobs for which blocks have been uploaded, but which have not been committed using Put Block List (REST API), be included in the response.</td>
</tr>
<tr>
<td>copy:</td>
<td>Version 2012-02-12 and newer. Specifies that metadata related to any current or previous Copy Blob operation should be included in the response.</td>
</tr>
</tbody>
</table>
delimiter

Optional. When the request includes this parameter, the operation returns a BlobPrefix element in the response body that acts as a placeholder for all blobs whose names begin with the same substring up to the appearance of the delimiter character. The delimiter may be a single character or a string.

show_blob_service_properties

Show a blob's service properties

```
salt-cloud -f show_blob_service_properties my-azure
```

set_blob_service_properties

Sets the properties of a storage account's Blob service, including Windows Azure Storage Analytics. You can also use this operation to set the default request version for all incoming requests that do not have a version specified.

```
salt-cloud -f set_blob_service_properties my-azure
```

properties

a StorageServiceProperties object.

timeout

Optional. The timeout parameter is expressed in seconds.

show_blob_properties

Returns all user-defined metadata, standard HTTP properties, and system properties for the blob.

```
salt-cloud -f show_blob_properties my-azure container=mycontainer blob=myblob
```

container

Name of existing container.

blob

Name of existing blob.

lease_id

Required if the blob has an active lease.
**set_blob_properties**

Set a blob's properties

```
salt-cloud -f set_blob_properties my-azure
```

**container**

Name of existing container.

**blob**

Name of existing blob.

**blob_cache_control**

Optional. Modifies the cache control string for the blob.

**blob_content_type**

Optional. Sets the blob's content type.

**blob_content_md5**

Optional. Sets the blob's MD5 hash.

**blob_content_encoding**

Optional. Sets the blob's content encoding.

**blob_content_language**

Optional. Sets the blob's content language.

**lease_id**

Required if the blob has an active lease.

**blob_content_disposition**

Optional. Sets the blob's Content-Disposition header. The Content-Disposition response header field conveys additional information about how to process the response payload, and also can be used to attach additional metadata. For example, if set to attachment, it indicates that the user-agent should not display the response, but instead show a Save As dialog with a filename other than the blob name specified.
put_blob

Upload a blob

```bash
salt-cloud -f put_blob my-azure container=base name=top.sls blob_path=/srv/salt/top.sls
salt-cloud -f put_blob my-azure container=base name=content.txt blob_content='Some!

container

Name of existing container.

name

Name of existing blob.

blob_path

The path on the local machine of the file to upload as a blob. Either this or blob_content must be specified.

blob_content

The actual content to be uploaded as a blob. Either this or blob_path must be specified.

cache_control

Optional. The Blob service stores this value but does not use or modify it.

content_language

Optional. Specifies the natural languages used by this resource.

content_md5

Optional. An MD5 hash of the blob content. This hash is used to verify the integrity of the blob during transport. When this header is specified, the storage service checks the hash that has arrived with the one that was sent. If the two hashes do not match, the operation will fail with error code 400 (Bad Request).

blob_content_type

Optional. Set the blob's content type.

blob_content_encoding

Optional. Set the blob's content encoding.
blob_content_language

Optional. Set the blob's content language.

blob_content_md5

Optional. Set the blob's MD5 hash.

blob_cache_control

Optional. Sets the blob's cache control.

meta_name_values

A dict containing name, value for metadata.

lease_id

Required if the blob has an active lease.

get_blob

Download a blob

```
salt-cloud -f get_blob my-azure container=base name=top.sls local_path=/srv/salt/top
        sls
salt-cloud -f get_blob my-azure container=base name=content.txt return_content=True
```

container

Name of existing container.

name

Name of existing blob.

local_path

The path on the local machine to download the blob to. Either this or return_content must be specified.

return_content

Whether or not to return the content directly from the blob. If specified, must be True or False. Either this or the local_path must be specified.
snapshot

Optional. The snapshot parameter is an opaque DateTime value that, when present, specifies the blob snapshot to retrieve.

lease_id

Required if the blob has an active lease.

progress_callback

callback for progress with signature function(current, total) where current is the number of bytes transferred so far, and total is the size of the blob.

max_connections

Maximum number of parallel connections to use when the blob size exceeds 64MB. Set to 1 to download the blob chunks sequentially. Set to 2 or more to download the blob chunks in parallel. This uses more system resources but will download faster.

max_retries

Number of times to retry download of blob chunk if an error occurs.

retry_wait

Sleep time in secs between retries.

25.7.3 Getting Started With DigitalOcean

DigitalOcean is a public cloud host that specializes in Linux instances.

Configuration

Using Salt for DigitalOcean requires a personal_access_token, an ssh_key_file, and at least one SSH key name in ssh_key_names. More ssh_key_names can be added by separating each key with a comma. The personal_access_token can be found in the DigitalOcean web interface in the "Apps & API" section. The SSH key name can be found under the "SSH Keys" section.

```bash
# Note: This example is for /etc/salt/cloud.providers or any file in the
# /etc/salt/cloud.providers.d/ directory.
my-digitalocean-config:
  driver: digital_ocean
  personal_access_token: xxx
  ssh_key_file: /path/to/ssh/key/file
  ssh_key_names: my-key-name,my-key-name-2
  location: New York 1
```
Notes: Changed in version 2015.8.0.

The `provider` parameter in cloud provider definitions was renamed to `driver`. This change was made to avoid confusion with the `provider` parameter that is used in cloud profile definitions. Cloud provider definitions now use `driver` to refer to the Salt cloud module that provides the underlying functionality to connect to a cloud host, while cloud profiles continue to use `provider` to refer to provider configurations that you define.

Profiles

Cloud Profiles

Set up an initial profile at `/etc/salt/cloud.profiles` or in the `/etc/salt/cloud.profiles.d/` directory:

```
digitalocean-ubuntu:
    provider: my-digitalocean-config
    image: 14.04 x64
    size: 512MB
    location: New York 1
    private_networking: True
    backups_enabled: True
    ipv6: True
```

Locations can be obtained using the `--list-locations` option for the `salt-cloud` command:

```
# salt-cloud --list-locations my-digitalocean-config
my-digitalocean-config:
    digitalocean:
        Amsterdam 1:
            available: False
            features: [u'backups']
            name: Amsterdam 1
            sizes: []
            slug: ams1
...SNIP...
```

Sizes can be obtained using the `--list-sizes` option for the `salt-cloud` command:

```
# salt-cloud --list-sizes my-digitalocean-config
my-digitalocean-config:
    digitalocean:
        512MB:
            cost_per_hour: 0.00744
```
Images can be obtained using the `--list-images` option for the `salt-cloud` command:

```bash
# salt-cloud --list-images my-digitalocean-config
my-digitalocean-config:
    digital_ocean:
        10.1:
            created_at: 2015-01-20T20:04:34Z
            distribution: FreeBSD
            id: 10144573
            min_disk_size: 20
            name: 10.1
            public: True
```

Profile Specifics:

**ssh_username**

If using a FreeBSD image from Digital Ocean, you'll need to set the `ssh_username` setting to `freebsd` in your profile configuration.

```yaml
digitalocean-freebsd:
    provider: my-digitalocean-config
    image: 10.2
    size: 512MB
    ssh_username: freebsd
```

Miscellaneous Information
Note: DigitalOcean’s concept of Applications is nothing more than a pre-configured instance (same as a normal Droplet). You will find examples such Docker 0.7 Ubuntu 13.04 x64 and Wordpress on Ubuntu 12.10 when using the --list-images option. These names can be used just like the rest of the standard instances when specifying an image in the cloud profile configuration.

Note: If your domain’s DNS is managed with DigitalOcean, you can automatically create A-records for newly created droplets. Use create_dns_record: True in your config to enable this. Add delete_dns_record: True to also delete records when a droplet is destroyed.

Note: Additional documentation is available from DigitalOcean.

25.7.4 Getting Started With AWS EC2

Amazon EC2 is a very widely used public cloud platform and one of the core platforms Salt Cloud has been built to support.

Previously, the suggested driver for AWS EC2 was the aws driver. This has been deprecated in favor of the ec2 driver. Configuration using the old aws driver will still function, but that driver is no longer in active development.

Dependencies

This driver requires the Python requests library to be installed.

Configuration

The following example illustrates some of the options that can be set. These parameters are discussed in more detail below.

```
# Note: This example is for /etc/salt/cloud.providers or any file in the # /etc/salt/cloud.providers.d/ directory.

my-ec2-southeast-public-ips:
    # Set up the location of the salt master
    #
    minion:
        master: saltmaster.example.com

    # Set up grains information, which will be common for all nodes
    # using this provider
    grains:
        node_type: broker
        release: 1.0.1

    # Specify whether to use public or private IP for deploy script.
    #
    # Valid options are:
    #    private_ips - The salt-cloud command is run inside the EC2
    #    public_ips - The salt-cloud command is run outside of EC2
```
ssh_interface: public_ips

# Optionally configure the Windows credential validation number of
# retries and delay between retries. This defaults to 10 retries
# with a one second delay between retries
win_deploy_auth_retries: 10
win_deploy_auth_retry_delay: 1

# Set the EC2 access credentials (see below)
#
id: 'use-instance-role-credentials'
key: 'use-instance-role-credentials'

# Make sure this key is owned by root with permissions 0400.
#
private_key: /etc/salt/my_test_key.pem
keyname: my_test_key
securitygroup: default

# Optionally configure default region
# Use salt-cloud --list-locations <provider> to obtain valid regions
#
location: ap-southeast-1
availability_zone: ap-southeast-1b

# Configure which user to use to run the deploy script. This setting is
# dependent upon the AMI that is used to deploy. It is usually safer to
# configure this individually in a profile, than globally. Typical users
# are:
#
# Amazon Linux -> ec2-user
# RHEL         -> ec2-user
# CentOS       -> ec2-user
# Ubuntu       -> ubuntu
#
ssh_username: ec2-user

# Optionally add an IAM profile
iam_profile: 'arn:aws:iam::123456789012:instance-profile/ExampleInstanceProfile'

driver: ec2

my-ec2-southeast-private-ips:

# Set up the location of the salt master
#
minion:
  master: saltmaster.example.com

# Specify whether to use public or private IP for deploy script.
#
# Valid options are:
#   private_ips - The salt-master is also hosted with EC2
#   public_ips - The salt-master is hosted outside of EC2
#
ssh_interface: private_ips

# Optionally configure the Windows credential validation number of
Salt Documentation, Release 2015.8.12

```yaml
# retries and delay between retries. This defaults to 10 retries
# with a one second delay between retries
win_deploy_auth_retries: 10
win_deploy_auth_retry_delay: 1

# Set the EC2 access credentials (see below)
#
id: 'use-instance-role-credentials'
key: 'use-instance-role-credentials'

# Make sure this key is owned by root with permissions 0400.
#
private_key: /etc/salt/my_test_key.pem
keyname: my_test_key

# This one should NOT be specified if VPC was not configured in AWS to be
# the default. It might cause an error message which says that network
# interfaces and an instance-level security groups may not be specified
# on the same request.
#
securitygroup: default

# Optionally configure default region
#
location: ap-southeast-1
availability_zone: ap-southeast-1b

# Configure which user to use to run the deploy script. This setting is
# dependent upon the AMI that is used to deploy. It is usually safer to
# configure this individually in a profile, than globally. Typical users
# are:
#
# Amazon Linux -> ec2-user
# RHEL       -> ec2-user
# CentOS     -> ec2-user
# Ubuntu     -> ubuntu
#
ssh_username: ec2-user

# Optionally add an IAM profile
iam_profile: 'my other profile name'

driver: ec2
```

**Note:** Changed in version 2015.8.0.

The `provider` parameter in cloud provider definitions was renamed to `driver`. This change was made to avoid confusion with the `provider` parameter that is used in cloud profile definitions. Cloud provider definitions now use `driver` to refer to the Salt cloud module that provides the underlying functionality to connect to a cloud host, while cloud profiles continue to use `provider` to refer to provider configurations that you define.

**Access Credentials**

The `id` and `key` settings may be found in the Security Credentials area of the AWS Account page:
Both are located in the Access Credentials area of the page, under the Access Keys tab. The id setting is labeled Access Key ID, and the key setting is labeled Secret Access Key.

Note: if either id or key is set to 'use-instance-role-credentials' it is assumed that Salt is running on an AWS instance, and the instance role credentials will be retrieved and used. Since both the id and key are required parameters for the AWS ec2 provider, it is recommended to set both to 'use-instance-role-credentials' for this functionality.

A "static" and "permanent" Access Key ID and Secret Key can be specified, but this is not recommended. Instance role keys are rotated on a regular basis, and are the recommended method of specifying AWS credentials.

Windows Deploy Timeouts

For Windows instances, it may take longer than normal for the instance to be ready. In these circumstances, the provider configuration can be configured with a win_deploy_auth_retries and/or a win_deploy_auth_retry_delay setting, which default to 10 retries and a one second delay between retries. These retries and timeouts relate to validating the Administrator password once AWS provides the credentials via the AWS API.

Key Pairs

In order to create an instance with Salt installed and configured, a key pair will need to be created. This can be done in the EC2 Management Console, in the Key Pairs area. These key pairs are unique to a specific region. Keys in the us-east-1 region can be configured at:

https://console.aws.amazon.com/ec2/home?region=us-east-1#s=KeyPairs

Keys in the us-west-1 region can be configured at

https://console.aws.amazon.com/ec2/home?region=us-west-1#s=KeyPairs

...and so on. When creating a key pair, the browser will prompt to download a pem file. This file must be placed in a directory accessible by Salt Cloud, with permissions set to either 0400 or 0600.

Security Groups

An instance on EC2 needs to belong to a security group. Like key pairs, these are unique to a specific region. These are also configured in the EC2 Management Console. Security groups for the us-east-1 region can be configured at:

https://console.aws.amazon.com/ec2/home?region=us-east-1#s=SecurityGroups

...and so on.

A security group defines firewall rules which an instance will adhere to. If the salt-master is configured outside of EC2, the security group must open the SSH port (usually port 22) in order for Salt Cloud to install Salt.

IAM Profile

Amazon EC2 instances support the concept of an instance profile, which is a logical container for the IAM role. At the time that you launch an EC2 instance, you can associate the instance with an instance profile, which in turn corresponds to the IAM role. Any software that runs on the EC2 instance is able to access AWS using the permissions associated with the IAM role.

Scaffolding the profile is a 2-step configuration process:
1. Configure an IAM Role from the IAM Management Console.

2. Attach this role to a new profile. It can be done with the AWS CLI:

```
> aws iam create-instance-profile --instance-profile-name PROFILE_NAME
> aws iam add-role-to-instance-profile --instance-profile-name PROFILE_NAME --role-name ROLE_NAME
```

Once the profile is created, you can use the PROFILE_NAME to configure your cloud profiles.

Cloud Profiles

Set up an initial profile at /etc/salt/cloud.profiles:

```yaml
base_ec2_private:
  provider: my-ec2-southeast-private-ips
  image: ami-e565ba8c
  size: t2.micro
  ssh_username: ec2-user

base_ec2_public:
  provider: my-ec2-southeast-public-ips
  image: ami-e565ba8c
  size: t2.micro
  ssh_username: ec2-user

base_ec2_db:
  provider: my-ec2-southeast-public-ips
  image: ami-e565ba8c
  size: m1.xlarge
  ssh_username: ec2-user
  volumes:
    - { size: 10, device: /dev/sdf }
    - { size: 10, device: /dev/sdg, type: io1, iops: 1000 }
    - { size: 10, device: /dev/sdh, type: io1, iops: 1000 }
    - { size: 10, device: /dev/sdi, tags: { "Environment": "production" } }

# optionally add tags to profile:

# force grains to sync after install
sync_after_install: grains

del_root_vol_on_destroy: True

del_all_vol_on_destroy: True
```

350 Chapter 25. Salt Cloud
volumes:
- { size: 10, device: /dev/sdf }
- { size: 10, device: /dev/sdg, type: io1, iops: 1000 }
- { size: 10, device: /dev/sdh, type: io1, iops: 1000 }

tag: { 'Environment': 'production', 'Role': 'database' }
sync_after_install: grains

The profile can now be realized with a salt command:

```
# salt-cloud -p base_ec2 ami.example.com
# salt-cloud -p base_ec2_public ami.example.com
# salt-cloud -p base_ec2_private ami.example.com
```

This will create an instance named `ami.example.com` in EC2. The minion that is installed on this instance will have an id of `ami.example.com`. If the command was executed on the salt-master, its Salt key will automatically be signed on the master.

Once the instance has been created with salt-minion installed, connectivity to it can be verified with Salt:

```
# salt 'ami.example.com' test.ping
```

### Required Settings

The following settings are always required for EC2:

```
# Set the EC2 login data
my-ec2-config:
  id: HJGRYCILJLKJYG
  key: 'kdjgfsmg;woormgl/aserigjksjdhasdfgn'
  keyname: test
  securitygroup: quick-start
  private_key: /root/test.pem
  driver: ec2
```

### Optional Settings

EC2 allows a userdata file to be passed to the instance to be created. This functionality was added to Salt in the 2015.5.0 release.

```
my-ec2-config:
  # Pass userdata to the instance to be created
  userdata_file: /etc/salt/my-userdata-file
```

EC2 allows a location to be set for servers to be deployed in. Availability zones exist inside regions, and may be added to increase specificity.

```
my-ec2-config:
  # Optionally configure default region
  location: ap-southeast-1
  availability_zone: ap-southeast-1b
```

EC2 instances can have a public or private IP, or both. When an instance is deployed, Salt Cloud needs to log into it via SSH to run the deploy script. By default, the public IP will be used for this. If the salt-cloud command is run from another EC2 instance, the private IP should be used.
Many EC2 instances do not allow remote access to the root user by default. Instead, another user must be used to run the deploy script using sudo. Some common usernames include ec2-user (for Amazon Linux), ubuntu (for Ubuntu instances), admin (official Debian) and bitnami (for images provided by Bitnami).

Multiple usernames can be provided, in which case Salt Cloud will attempt to guess the correct username. This is mostly useful in the main configuration file:

```
my-ec2-config:
    ssh_username:
      - ec2-user
      - ubuntu
      - admin
      - bitnami
```

Multiple security groups can also be specified in the same fashion:

```
my-ec2-config:
    securitygroup:
      - default
      - extra
```

Your instances may optionally make use of EC2 Spot Instances. The following example will request that spot instances be used and your maximum bid will be $0.10. Keep in mind that different spot prices may be needed based on the current value of the various EC2 instance sizes. You can check current and past spot instance pricing via the EC2 API or AWS Console.

```
my-ec2-config:
    spot_config:
      spot_price: 0.10
```

By default, the spot instance type is set to `one-time', meaning it will be launched and, if it's ever terminated for whatever reason, it will not be recreated. If you would like your spot instances to be relaunched after a termination (by your or AWS), set the `type` to `persistent'.

**NOTE:** Spot instances are a great way to save a bit of money, but you do run the risk of losing your spot instances if the current price for the instance size goes above your maximum bid.

The following parameters may be set in the cloud configuration file to control various aspects of the spot instance launching:

- **wait_for_spot_timeout**: seconds to wait before giving up on spot instance launch (default=600)
- **wait_for_spot_interval**: seconds to wait in between polling requests to determine if a spot instance is available (default=30)
- **wait_for_spot_interval_multiplier**: a multiplier to add to the interval in between requests, which is useful if AWS is throttling your requests (default=1)
- **wait_for_spot_max_failures**: maximum number of failures before giving up on launching your spot instance (default=10)
If you find that you’re being throttled by AWS while polling for spot instances, you can set the following in your core cloud configuration file that will double the polling interval after each request to AWS.

```yaml
wait_for_spot_interval: 1
wait_for_spot_interval_multiplier: 2
```

See the AWS Spot Instances documentation for more information.

Block device mappings enable you to specify additional EBS volumes or instance store volumes when the instance is launched. This setting is also available on each cloud profile. Note that the number of instance stores varies by instance type. If more mappings are provided than are supported by the instance type, mappings will be created in the order provided and additional mappings will be ignored. Consult the AWS documentation for a listing of the available instance stores, and device names.

```yaml
my-ec2-config:
  block_device_mappings:
    - DeviceName: /dev/sdb
      VirtualName: ephemeral0
    - DeviceName: /dev/sdc
      VirtualName: ephemeral1
```

You can also use block device mappings to change the size of the root device at the provisioning time. For example, assuming the root device is `/dev/sda`, you can set its size to 100G by using the following configuration.

```yaml
my-ec2-config:
  block_device_mappings:
    - DeviceName: /dev/sda
      Ebs.VolumeSize: 100
      Ebs.VolumeType: gp2
      Ebs.SnapshotId: dummy0
    - DeviceName: /dev/sdb
      # required for devices > 2TB
      Ebs.VolumeType: gp2
      Ebs.VolumeSize: 3001
```

Existing EBS volumes may also be attached (not created) to your instances or you can create new EBS volumes based on EBS snapshots. To simply attach an existing volume use the `volume_id` parameter.

```yaml
device: /dev/xvdj
volume_id: vol-12345abcd
```

Or, to create a volume from an EBS snapshot, use the `snapshot` parameter.

```yaml
device: /dev/xvdj
snapshot: snap-abcd12345
```

Note that `volume_id` will take precedence over the `snapshot` parameter.

Tags can be set once an instance has been launched.

```yaml
my-ec2-config:
  tag:
    tag0: value
    tag1: value
```
Modify EC2 Tags

One of the features of EC2 is the ability to tag resources. In fact, under the hood, the names given to EC2 instances by salt-cloud are actually just stored as a tag called Name. Salt Cloud has the ability to manage these tags:

```
salt-cloud -a get_tags mymachine
salt-cloud -a set_tags mymachine tag1=somestuff tag2='Other stuff'
salt-cloud -a del_tags mymachine tag1,tag2,tag3
```

It is possible to manage tags on any resource in EC2 with a Resource ID, not just instances:

```
salt-cloud -f get_tags my_ec2 resource_id=af5467ba
salt-cloud -f set_tags my_ec2 resource_id=af5467ba tag1=somestuff
salt-cloud -f del_tags my_ec2 resource_id=af5467ba tag1,tag2,tag3
```

Rename EC2 Instances

As mentioned above, EC2 instances are named via a tag. However, renaming an instance by renaming its tag will cause the salt keys to mismatch. A rename function exists which renames both the instance, and the salt keys.

```
salt-cloud -a rename mymachine newname=yourmachine
```

EC2 Termination Protection

EC2 allows the user to enable and disable termination protection on a specific instance. An instance with this protection enabled cannot be destroyed.

```
salt-cloud -a enable_term_protect mymachine
salt-cloud -a disable_term_protect mymachine
```

Rename on Destroy

When instances on EC2 are destroyed, there will be a lag between the time that the action is sent, and the time that Amazon cleans up the instance. During this time, the instance still retains a Name tag, which will cause a collision if the creation of an instance with the same name is attempted before the cleanup occurs. In order to avoid such collisions, Salt Cloud can be configured to rename instances when they are destroyed. The new name will look something like:

```
myinstance-DEL20f5b8ad4eb64ed88f2c428df80a1a0c
```

In order to enable this, add rename_on_destroy line to the main configuration file:

```
my-ec2-config:
  rename_on_destroy: True
```

Listing Images

Normally, images can be queried on a cloud provider by passing the `--list-images` argument to Salt Cloud. This still holds true for EC2:
salt-cloud --list-images my-ec2-config

However, the full list of images on EC2 is extremely large, and querying all of the available images may cause Salt Cloud to behave as if frozen. Therefore, the default behavior of this option may be modified, by adding an owner argument to the provider configuration:

owner: aws-marketplace

The possible values for this setting are amazon, aws-marketplace, self, <AWS account ID> or all. The default setting is amazon. Take note that all and aws-marketplace may cause Salt Cloud to appear as if it is freezing, as it tries to handle the large amount of data.

It is also possible to perform this query using different settings without modifying the configuration files. To do this, call the avail_images function directly:

salt-cloud -f avail_images my-ec2-config owner=aws-marketplace

EC2 Images

The following are lists of available AMI images, generally sorted by OS. These lists are on 3rd-party websites, are not managed by Salt Stack in any way. They are provided here as a reference for those who are interested, and contain no warranty (express or implied) from anyone affiliated with Salt Stack. Most of them have never been used, much less tested, by the Salt Stack team.

- Arch Linux
- FreeBSD
- Fedora
- CentOS
- Ubuntu
- Debian
- OmniOS
- All Images on Amazon

show_image

This is a function that describes an AMI on EC2. This will give insight as to the defaults that will be applied to an instance using a particular AMI.

$ salt-cloud -f show_image ec2 image=ami-fd20ad94

show_instance

This action is a thin wrapper around --full-query, which displays details on a single instance only. In an environment with several machines, this will save a user from having to sort through all instance data, just to examine a single instance.

$ salt-cloud -a show_instance myinstance
**ebs_optimized**

This argument enables switching of the EbsOptimized setting which default to `false`. Indicates whether the instance is optimized for EBS I/O. This optimization provides dedicated throughput to Amazon EBS and an optimized configuration stack to provide optimal Amazon EBS I/O performance. This optimization isn't available with all instance types. Additional usage charges apply when using an EBS-optimized instance.

This setting can be added to the profile or map file for an instance.

If set to True, this setting will enable an instance to be EbsOptimized

```
ebs_optimized: True
```

This can also be set as a cloud provider setting in the EC2 cloud configuration:

```
my-ec2-config:
  ebs_optimized: True
```

**del_root_vol_on_destroy**

This argument overrides the default DeleteOnTermination setting in the AMI for the EBS root volumes for an instance. Many AMIs contain `false` as a default, resulting in orphaned volumes in the EC2 account, which may unknowingly be charged to the account. This setting can be added to the profile or map file for an instance.

If set, this setting will apply to the root EBS volume

```
del_root_vol_on_destroy: True
```

This can also be set as a cloud provider setting in the EC2 cloud configuration:

```
my-ec2-config:
  del_root_vol_on_destroy: True
```

**del_all_vols_on_destroy**

This argument overrides the default DeleteOnTermination setting in the AMI for the not-root EBS volumes for an instance. Many AMIs contain `false` as a default, resulting in orphaned volumes in the EC2 account, which may unknowingly be charged to the account. This setting can be added to the profile or map file for an instance.

If set, this setting will apply to any (non-root) volumes that were created by salt-cloud using the `volumes` setting.

The volumes will not be deleted under the following conditions:
- If a volume is detached before terminating the instance
- If a volume is created without this setting and attached to the instance

```
del_all_vols_on_destroy: True
```

This can also be set as a cloud provider setting in the EC2 cloud configuration:

```
my-ec2-config:
  del_all_vols_on_destroy: True
```

The setting for this may be changed on all volumes of an existing instance using one of the following commands:

```
salt-cloud -a delvol_on_destroy myinstance
salt-cloud -a keepvol_on_destroy myinstance
salt-cloud -a show_delvol_on_destroy myinstance
```
The setting for this may be changed on a volume on an existing instance using one of the following commands:

```bash
salt-cloud -a delvol_on_destroy myinstance device=/dev/sda1
salt-cloud -a delvol_on_destroy myinstance volume_id=vol-1a2b3c4d
salt-cloud -a keepvol_on_destroy myinstance device=/dev/sda1
salt-cloud -a keepvol_on_destroy myinstance volume_id=vol-1a2b3c4d
salt-cloud -a show_delvol_on_destroy myinstance device=/dev/sda1
salt-cloud -a show_delvol_on_destroy myinstance volume_id=vol-1a2b3c4d
```

**EC2 Termination Protection**

EC2 allows the user to enable and disable termination protection on a specific instance. An instance with this protection enabled cannot be destroyed. The EC2 driver adds a show_term_protect action to the regular EC2 functionality.

```bash
salt-cloud -a show_term_protect mymachine
salt-cloud -a enable_term_protect mymachine
salt-cloud -a disable_term_protect mymachine
```

**Alternate Endpoint**

Normally, EC2 endpoints are built using the region and the service_url. The resulting endpoint would follow this pattern:

```bash
e2.<region>,<service_url>
```

This results in an endpoint that looks like:

```bash
e2.us-east-1.amazonaws.com
```

There are other projects that support an EC2 compatibility layer, which this scheme does not account for. This can be overridden by specifying the endpoint directly in the main cloud configuration file:

```bash
my-ec2-config:
  endpoint: myendpoint.example.com:1138/services/Cloud
```

**Volume Management**

The EC2 driver has several functions and actions for management of EBS volumes.

**Creating Volumes**

A volume may be created, independent of an instance. A zone must be specified. A size or a snapshot may be specified (in GiB). If neither is given, a default size of 10 GiB will be used. If a snapshot is given, the size of the snapshot will be used.

The following parameters may also be set (when providing a snapshot OR size):

- **type**: choose between standard (magnetic disk), gp2 (SSD), or io1 (provisioned IOPS). (default=standard)
- **iops**: the number of IOPS (only applicable to io1 volumes) (default varies on volume size)
- **encrypted**: enable encryption on the volume (default=false)
Attaching Volumes

Unattached volumes may be attached to an instance. The following values are required; name or instance_id, volume_id, and device.

```bash
salt-cloud -a attach_volume myinstance volume_id=vol-12345 device=/dev/sdb1
```

Show a Volume

The details about an existing volume may be retrieved.

```bash
salt-cloud -a show_volume myinstance volume_id=vol-12345
salt-cloud -f show_volume ec2 volume_id=vol-12345
```

Detaching Volumes

An existing volume may be detached from an instance.

```bash
salt-cloud -a detach_volume myinstance volume_id=vol-12345
```

Deleting Volumes

A volume that is not attached to an instance may be deleted.

```bash
salt-cloud -f delete_volume ec2 volume_id=vol-12345
```

Managing Key Pairs

The EC2 driver has the ability to manage key pairs.

Creating a Key Pair

A key pair is required in order to create an instance. When creating a key pair with this function, the return data will contain a copy of the private key. This private key is not stored by Amazon, will not be obtainable past this point, and should be stored immediately.

```bash
salt-cloud -f create_keypair ec2 keyname=mykeypair
```
Importing a Key Pair

```
salt-cloud -f import_keypair ec2 keyname=mykeypair file=/path/to/id_rsa.pub
```

Show a Key Pair

This function will show the details related to a key pair, not including the private key itself (which is not stored by Amazon).

```
salt-cloud -f show_keypair ec2 keyname=mykeypair
```

Delete a Key Pair

This function removes the key pair from Amazon.

```
salt-cloud -f delete_keypair ec2 keyname=mykeypair
```

Launching instances into a VPC

Simple launching into a VPC

In the amazon web interface, identify the id of the subnet into which your image should be created. Then, edit your cloud.profiles file like so:

```
profile-id:
  provider: provider-name
  subnetid: subnet-XXXXXXXX
  image: ami-XXXXXXXX
  size: m1.medium
  ssh_username: ubuntu
  securitygroupid:
    - sg-XXXXXXXX
```

Specifying interface properties

New in version 2014.7.0.

Launching into a VPC allows you to specify more complex configurations for the network interfaces of your virtual machines, for example:

```
profile-id:
  provider: provider-name
  image: ami-XXXXXXXX
  size: m1.medium
  ssh_username: ubuntu

  # Do not include either 'subnetid' or 'securitygroupid' here if you are
  # going to manually specify interface configuration
  #
  network_interfaces:
```

25.7. Cloud Provider Specifics
Note that it is an error to assign a `subnetid' or `securitygroupid' to a profile where the interfaces are manually configured like this. These are both really properties of each network interface, not of the machine itself.

### 25.7.5 Getting Started With GoGrid

GoGrid is a public cloud host that supports Linux and Windows.

#### Configuration

To use Salt Cloud with GoGrid log into the GoGrid web interface and create an API key. Do this by clicking on `My Account" and then going to the API Keys tab.

The apikey and the sharedsecret configuration parameters need to be set in the configuration file to enable interfacing with GoGrid:

```
# Note: This example is for /etc/salt/cloud.providers or any file in the
# /etc/salt/cloud.providers.d/ directory.

my-gogrid-config:
  driver: gogrid
```
Note: A Note about using Map files with GoGrid:

Due to limitations in the GoGrid API, instances cannot be provisioned in parallel with the GoGrid driver. Map files will work with GoGrid, but the \(-P\) argument should not be used on maps referencing GoGrid instances.

Note: Changed in version 2015.8.0.

The `provider` parameter in cloud provider definitions was renamed to `driver`. This change was made to avoid confusion with the `provider` parameter that is used in cloud profile definitions. Cloud provider definitions now use `driver` to refer to the Salt cloud module that provides the underlying functionality to connect to a cloud host, while cloud profiles continue to use `provider` to refer to provider configurations that you define.

Profiles

Cloud Profiles

Set up an initial profile at `/etc/salt/cloud.profiles` or in the `/etc/salt/cloud.profiles.d/` directory:

```
gogrid_512:
  provider: my-gogrid-config
  size: 512MB
  image: CentOS 6.2 (64-bit) w/ None
```

Sizes can be obtained using the `--list-sizes` option for the `salt-cloud` command:

```
# salt-cloud --list-sizes my-gogrid-config
my-gogrid-config:
    --------
gogrid:
    --------
512MB:
    --------
  bandwidth:
  None
disk:
  30
driver:
get_uuid:
id:
  512MB
name:
  512MB
price:
  0.095
ram:
  512
uuid:
  bde1e4d7c3a643536e42a35142c7caac34b060e9
...SNIP...
```
Images can be obtained using the `--list-images` option for the `salt-cloud` command:

```bash
# salt-cloud --list-images my-gogrid-config
my-gogrid-config:
    gogrid:
        CentOS 6.4 (64-bit) w/ None:
            driver:
            extra:
                get_uuid:
                id: 18094
                name: CentOS 6.4 (64-bit) w/ None
                uuid: bfd4055389919e01aa6261828a96cf54c8d2c2c4

...SNIP...
```

### Assigning IPs

New in version 2015.8.0.

The GoGrid API allows IP addresses to be manually assigned. Salt Cloud supports this functionality by allowing an IP address to be specified using the `assign_public_ip` argument. This likely makes the most sense inside a map file, but it may also be used inside a profile.

```yaml
gogrid_512:
    provider: my-gogrid-config
    size: 512MB
    image: CentOS 6.2 (64-bit) w/ None
    assign_public_ip: 11.38.257.42
```

### 25.7.6 Getting Started With Google Compute Engine

Google Compute Engine (GCE) is Google-infrastructure as a service that lets you run your large-scale computing workloads on virtual machines. This document covers how to use Salt Cloud to provision and manage your virtual machines hosted within Google's infrastructure.

You can find out more about GCE and other Google Cloud Platform services at [https://cloud.google.com](https://cloud.google.com).

### Dependencies

- LibCloud >= 0.14.1
- A Google Cloud Platform account with Compute Engine enabled
- A registered Service Account for authorization
- Oh, and obviously you'll need `salt`
Google Compute Engine Setup

1. Sign up for Google Cloud Platform
   
   Go to https://cloud.google.com and use your Google account to sign up for Google Cloud Platform and complete the guided instructions.

2. Create a Project
   
   Next, go to the console at https://cloud.google.com/console and create a new Project. Make sure to select your new Project if you are not automatically directed to the Project.

   Projects are a way of grouping together related users, services, and billing. You may opt to create multiple Projects and the remaining instructions will need to be completed for each Project if you wish to use GCE and Salt Cloud to manage your virtual machines.

3. Enable the Google Compute Engine service
   
   In your Project, either just click Compute Engine to the left, or go to the APIs & auth section and APIs link and enable the Google Compute Engine service.

4. Create a Service Account
   
   To set up authorization, navigate to APIs & auth section and then the Credentials link and click the CREATE NEW CLIENT ID button. Select Service Account and click the Create Client ID button. This will automatically download a .json file, which may or may not be used in later steps, depending on your version of libcloud.

   Look for a new Service Account section in the page and record the generated email address for the matching key/fingerprint. This email address will be used in the service_account_email_address of the /etc/salt/cloud.providers or the /etc/salt/cloud.providers.d/*.conf file.

5. Key Format

   **Note:** If you are using libcloud >= 0.17.0 it is recommended that you use the JSON format file you downloaded above and skip to the Provider Configuration section below, using the JSON file in place of `NEW.pem` in the documentation.

   If you are using an older version of libcloud or are unsure of the version you have, please follow the instructions below to generate and format a new P12 key.

   In the new Service Account section, click Generate new P12 key, which will automatically download a .p12 private key file. The .p12 private key needs to be converted to a format compatible with libcloud. This new Google-generated private key was encrypted using notasecret as a passphrase. Use the following command and record the location of the converted private key and record the location for use in the service_account_private_key of the /etc/salt/cloud file:

   ```
   openssl pkcs12 -in ORIG.p12 -passin pass:notasecret
   -nodes -nocerts | openssl rsa -out NEW.pem
   ```

Provider Configuration

Set up the provider cloud config at /etc/salt/cloud.providers or /etc/salt/cloud.providers.d/*.conf:

```
gce-config:
  # Set up the Project name and Service Account authorization
  project: "your-project-id"
  service_account_email_address: "123-a5gt@developer.gserviceaccount.com"
```
service_account_private_key: "/path/to/your/NEW.pem"

# Set up the location of the salt master
minion:
    master: saltmaster.example.com

# Set up grains information, which will be common for all nodes # using this provider
grains:
    node_type: broker
    release: 1.0.1

driver: gce

Note: The value provided for project must not contain underscores or spaces and is labeled as "Project ID" on the Google Developers Console.

Note: Changed in version 2015.8.0.

The provider parameter in cloud provider definitions was renamed to driver. This change was made to avoid confusion with the provider parameter that is used in cloud profile definitions. Cloud provider definitions now use driver to refer to the Salt cloud module that provides the underlying functionality to connect to a cloud host, while cloud profiles continue to use provider to refer to provider configurations that you define.

Profile Configuration

Set up an initial profile at /etc/salt/cloud.profiles or /etc/salt/cloud.profiles.d/*.conf:

```yaml
my-gce-profile:
    image: centos-6
    size: n1-standard-1
    location: europe-west1-b
    network: default
    tags: ['"one", "two", "three"]
    metadata: {'"one": "1", "2": "two"'}
    use_persistent_disk: True
    delete_boot_pd: False
    deploy: True
    make_master: False
    provider: gce-config
```

The profile can be realized now with a salt command:

```
salt-cloud -p my-gce-profile gce-instance
```

This will create an salt minion instance named gce-instance in GCE. If the command was executed on the salt-master, its Salt key will automatically be signed on the master.

Once the instance has been created with a salt-minion installed, connectivity to it can be verified with Salt:

```
salt gce-instance test.ping
```
GCE Specific Settings

Consult the sample profile below for more information about GCE specific settings. Some of them are mandatory and are properly labeled below but typically also include a hard-coded default.

Initial Profile

Set up an initial profile at `/etc/salt/cloud.profiles` or `/etc/salt/cloud.profiles.d/gce.conf`:

```yaml
my-gce-profile:
  image: centos-6
  size: n1-standard-1
  location: europe-west1-b
  network: default
  tags: ['"one", "two", "three"]'
  metadata: '{"one": "1", "2": "two"}'
  use_persistent_disk: True
  delete_boot_pd: False
  ssh_interface: public_ips
  external_ip: "ephemeral"
```

**image**

Image is used to define what Operating System image should be used to for the instance. Examples are Debian 7 (wheezy) and CentOS 6. Required.

**size**

A `size`, in GCE terms, refers to the instance's `machine type`. See the on-line documentation for a complete list of GCE machine types. Required.

**location**

A `location`, in GCE terms, refers to the instance's `zone`. GCE has the notion of both Regions (e.g. us-central1, europe-west1, etc) and Zones (e.g. us-central1-a, us-central1-b, etc). Required.

**network**

Use this setting to define the network resource for the instance. All GCE projects contain a network named `default` but it’s possible to use this setting to create instances belonging to a different network resource.

**tags**

GCE supports instance/network tags and this setting allows you to set custom tags. It should be a list of strings and must be parse-able by the python ast.literal_eval() function to convert it to a python list.
metadata

GCE supports instance metadata and this setting allows you to set custom metadata. It should be a hash of key/value strings and parse-able by the python ast.literal_eval() function to convert it to a python dictionary.

use_persistent_disk

Use this setting to ensure that when new instances are created, they will use a persistent disk to preserve data between instance terminations and re-creations.

delete_boot_pd

In the event that you wish the boot persistent disk to be permanently deleted when you destroy an instance, set delete_boot_pd to True.

ssh_interface

New in version 2015.5.0.
Specify whether to use public or private IP for deploy script.
Valid options are:
- private_ips: The salt-master is also hosted with GCE
- public_ips: The salt-master is hosted outside of GCE

external_ip

Per instance setting: Used a named fixed IP address to this host.
Valid options are:
- ephemeral: The host will use a GCE ephemeral IP
- None: No external IP will be configured on this host.
Optionally, pass the name of a GCE address to use a fixed IP address. If the address does not already exist, it will be created.

ex_disk_type

GCE supports two different disk types, pd-standard and pd-ssd. The default disk type setting is pd-standard. To specify using an SSD disk, set pd-ssd as the value.
New in version 2014.7.0.

ip_forwarding

GCE instances can be enabled to use IP Forwarding. When set to True, this options allows the instance to send/receive non-matching src/dst packets. Default is False.
Profile with scopes

Scopes can be specified by setting the optional `ex_service_accounts` key in your cloud profile. The following example enables the bigquery scope.

```yaml
my-gce-profile:
  image: centos-6
  ssh_username: salt
  size: f1-micro
  location: us-central1-a
  network: default
  tags: '["one", "two", "three"]'
  metadata: '{"one": "1", "2": "two",
    "sshKeys": ""}
  use_persistent_disk: True
  delete_boot_pd: False
  deploy: False
  make_master: False
  provider: gce-config
  ex_service_accounts:
    - scopes:
      - bigquery
```

Email can also be specified as an (optional) parameter.

```
my-gce-profile:
  ...snip
  ex_service_accounts:
    - scopes:
      - bigquery
    email: default
```

There can be multiple entries for scopes since `ex-service_accounts` accepts a list of dictionaries. For more information refer to the libcloud documentation on specifying service account scopes.

SSH Remote Access

GCE instances do not allow remote access to the root user by default. Instead, another user must be used to run the deploy script using sudo. Append something like this to `/etc/salt/cloud.profiles` or `/etc/salt/cloud.profiles.d/*.conf`:

```
my-gce-profile:
  ...
  # SSH to GCE instances as gceuser
  ssh_username: gceuser

  # Use the local private SSH key file located here
  ssh_keyfile: /etc/cloud/google_compute_engine
```

If you have not already used this SSH key to login to instances in this GCE project you will also need to add the public key to your projects metadata at `https://cloud.google.com/console`. You could also add it via the metadata setting too:

```
my-gce-profile:
  ...
```
Single instance details

This action is a thin wrapper around --full-query, which displays details on a single instance only. In an environment with several machines, this will save a user from having to sort through all instance data, just to examine a single instance.

```
salt-cloud -a show_instance myinstance
```

Destroy, persistent disks, and metadata

As noted in the provider configuration, it’s possible to force the boot persistent disk to be deleted when you destroy the instance. The way that this has been implemented is to use the instance metadata to record the cloud profile used when creating the instance. When destroy is called, if the instance contains a salt-cloud-profile key, it’s value is used to reference the matching profile to determine if delete_boot_pd is set to True.

Be aware that any GCE instances created with salt cloud will contain this custom salt-cloud-profile metadata entry.

List various resources

It’s also possible to list several GCE resources similar to what can be done with other providers. The following commands can be used to list GCE zones (locations), machine types (sizes), and images.

```
salt-cloud --list-locations gce
salt-cloud --list-sizes gce
salt-cloud --list-images gce
```

Persistent Disk

The Compute Engine provider provides functions via salt-cloud to manage your Persistent Disks. You can create and destroy disks as well as attach and detach them from running instances.

Create

When creating a disk, you can create an empty disk and specify its size (in GB), or specify either an `image' or `snapshot'.

```
salt-cloud -f create_disk gce disk_name=pd location=us-central1-b size=200
```

Delete

Deleting a disk only requires the name of the disk to delete
Attach

Attaching a disk to an existing instance is really an `action' and requires both an instance name and disk name. It's possible to use this action to create bootable persistent disks if necessary. Compute Engine also supports attaching a persistent disk in READ_ONLY mode to multiple instances at the same time (but then cannot be attached in READ_WRITE to any instance).

```
salt-cloud -a attach_disk myinstance disk_name=pd mode=READ_WRITE boot=yes
```

Detach

Detaching a disk is also an action against an instance and only requires the name of the disk. Note that this does not safely sync and unmount the disk from the instance. To ensure no data loss, you must first make sure the disk is unmounted from the instance.

```
salt-cloud -a detach_disk myinstance disk_name=pd
```

Show disk

It's also possible to look up the details for an existing disk with either a function or an action.

```
salt-cloud -a show_disk myinstance disk_name=pd
salt-cloud -f show_disk gce disk_name=pd
```

Create snapshot

You can take a snapshot of an existing disk's content. The snapshot can then in turn be used to create other persistent disks. Note that to prevent data corruption, it is strongly suggested that you unmount the disk prior to taking a snapshot. You must name the snapshot and provide the name of the disk.

```
salt-cloud -f create_snapshot gce name=backup-20140226 disk_name=pd
```

Delete snapshot

You can delete a snapshot when it's no longer needed by specifying the name of the snapshot.

```
salt-cloud -f delete_snapshot gce name=backup-20140226
```

Show snapshot

Use this function to look up information about the snapshot.

```
salt-cloud -f show_snapshot gce name=backup-20140226
```
Networking

Compute Engine supports multiple private networks per project. Instances within a private network can easily communicate with each other by an internal DNS service that resolves instance names. Instances within a private network can also communicate with either directly without needing special routing or firewall rules even if they span different regions/zones.

Networks also support custom firewall rules. By default, traffic between instances on the same private network is open to all ports and protocols. Inbound SSH traffic (port 22) is also allowed but all other inbound traffic is blocked.

Create network

New networks require a name and CIDR range. New instances can be created and added to this network by setting the network name during create. It is not possible to add/remove existing instances to a network.

```
salt-cloud -f create_network gce name=mynet cidr=10.10.10.0/24
```

Destroy network

Destroy a network by specifying the name. Make sure that there are no instances associated with the network prior to deleting it or you'll have a bad day.

```
salt-cloud -f delete_network gce name=mynet
```

Show network

Specify the network name to view information about the network.

```
salt-cloud -f show_network gce name=mynet
```

Create address

Create a new named static IP address in a region.

```
salt-cloud -f create_address gce name=my-fixed-ip region=us-central1
```

Delete address

Delete an existing named fixed IP address.

```
salt-cloud -f delete_address gce name=my-fixed-ip region=us-central1
```

Show address

View details on a named address.
Create firewall

You'll need to create custom firewall rules if you want to allow other traffic than what is described above. For instance, if you run a web service on your instances, you'll need to explicitly allow HTTP and/or SSL traffic. The firewall rule must have a name and it will use the 'default' network unless otherwise specified with a 'network' attribute. Firewalls also support instance tags for source/destination.

```bash
salt-cloud -f create_fwrule gce name=web allow=tcp:80,tcp:443,icmp
```

Delete firewall

Deleting a firewall rule will prevent any previously allowed traffic for the named firewall rule.

```bash
salt-cloud -f delete_fwrule gce name=web
```

Show firewall

Use this function to review an existing firewall rule's information.

```bash
salt-cloud -f show_fwrule gce name=web
```

Load Balancer

Compute Engine possess a load-balancer feature for splitting traffic across multiple instances. Please reference the documentation for a more complete discription.

The load-balancer functionality is slightly different than that described in Google's documentation. The concept of TargetPool and ForwardingRule are consolidated in salt-cloud/libcloud. HTTP Health Checks are optional.

HTTP Health Check

HTTP Health Checks can be used as a means to toggle load-balancing across instance members, or to detect if an HTTP site is functioning. A common use-case is to set up a health check URL and if you want to toggle traffic on/off to an instance, you can temporarily have it return a non-200 response. A non-200 response to the load-balancer's health check will keep the LB from sending any new traffic to the "down" instance. Once the instance's health check URL beings returning 200-responses, the LB will again start to send traffic to it. Review Compute Engine's documentation for allowable parameters. You can use the following salt-cloud functions to manage your HTTP health checks.

```bash
salt-cloud -f create_hc gce name=myhc path=/ port=80
salt-cloud -f delete_hc gce name=myhc
salt-cloud -f show_hc gce name=myhc
```
Load-balancer

When creating a new load-balancer, it requires a name, region, port range, and list of members. There are other optional parameters for protocol, and list of health checks. Deleting or showing details about the LB only requires the name.

```
salt-cloud -f create_lb gce name=lb region=... ports=80 members=w1,w2,w3
salt-cloud -f delete_lb gce name=lb
salt-cloud -f show_lb gce name=lb
```

You can also create a load balancer using a named fixed IP address by specifying the name of the address. If the address does not exist yet it will be created.

```
salt-cloud -f create_lb gce name=my-lb region=us-central1 ports=234 members=s1,s2,s3 address=my-lb-ip
```

Attach and Detach LB

It is possible to attach or detach an instance from an existing load-balancer. Both the instance and load-balancer must exist before using these functions.

```
salt-cloud -f attach_lb gce name=lb member=w4
salt-cloud -f detach_lb gce name=lb member=oops
```

25.7.7 Getting Started With HP Cloud

HP Cloud is a major public cloud platform and uses the libcloud openstack driver. The current version of OpenStack that HP Cloud uses is Havana. When an instance is booted, it must have a floating IP added to it in order to connect to it and further below you will see an example that adds context to this statement.

Set up a cloud provider configuration file

To use the openstack driver for HP Cloud, set up the cloud provider configuration file as in the example shown below:

```
/etc/salt/cloud.providers.d/hpcloud.conf:

hpcloud-config:
  # Set the location of the salt-master
  #
  minion:
    master: saltmaster.example.com

  # Configure HP Cloud using the OpenStack plugin
  #
  identity_url: https://region-b.geo-1.identity.hpcloudsvc.com:35357/v2.0/tokens
  compute_name: Compute
  protocol: ipv4

  # Set the compute region:
  #
  compute_region: region-b.geo-1

  # Configure HP Cloud authentication credentials
```
#
user: myname
tenant: myname-project1
password: xxxxxxxxx

# keys to allow connection to the instance launched
#
ssh_key_name: yourkey
ssh_key_file: /path/to/key/yourkey.priv
driver: openstack

The subsequent example that follows is using the openstack driver.

**Note:** Changed in version 2015.8.0.

The *provider* parameter in cloud provider definitions was renamed to *driver*. This change was made to avoid confusion with the *provider* parameter that is used in cloud profile definitions. Cloud provider definitions now use *driver* to refer to the Salt cloud module that provides the underlying functionality to connect to a cloud host, while cloud profiles continue to use *provider* to refer to provider configurations that you define.

**Compute Region**

Originally, HP Cloud, in its OpenStack Essex version (1.0), had 3 availability zones in one region, US West (region-a.geo-1), which each behaved each as a region.

This has since changed, and the current OpenStack Havana version of HP Cloud (1.1) now has simplified this and now has two regions to choose from:

<table>
<thead>
<tr>
<th>Region</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>region-a.geo-1</td>
<td>US West</td>
</tr>
<tr>
<td>region-b.geo-1</td>
<td>US East</td>
</tr>
</tbody>
</table>

**Authentication**

The *user* is the same user as is used to log into the HP Cloud management UI. The *tenant* can be found in the upper left under "Project/Region/Scope". It is often named the same as *user* albeit with a `-project1` appended. The *password* is of course what you created your account with. The management UI also has other information such as being able to select US East or US West.

**Set up a cloud profile config file**

The profile shown below is a know working profile for an Ubuntu instance. The profile configuration file is stored in the following location:

```
/etc/salt/cloud.profiles.d/hp_ae1Ubuntu.conf
```

```yaml
hp_ae1Ubuntu:
  provider: hp_ae1
  image: 9302692b-b787-4b52-a3a6-daebb79cb498
  ignore_cidr: 10.0.0.1/24
  networks:
    - floating: Ext-Net
  size: standard.small
```

25.7. Cloud Provider Specifics 373
### Some important things about the example above:

- The `image` parameter can use either the image name or image ID which you can obtain by running in the example below (this case US East):

  ```
  # salt-cloud --list-images hp_ae1
  ```

- The parameter `ignore_cidr` specifies a range of addresses to ignore when trying to connect to the instance. In this case, it's the range of IP addresses used for a private IP of the instance.

- The parameter `networks` is very important to include. In previous versions of Salt Cloud, this is what made it possible for salt-cloud to be able to attach a floating IP to the instance in order to connect to the instance and set up the minion. The current version of salt-cloud doesn't require it, though having it is of no harm either. Newer versions of salt-cloud will use this, and without it, will attempt to find a list of floating IP addresses to use regardless.

- The `ssh_key_file` and `ssh_key_name` are the keys that will make it possible to connect to the instance to set up the minion

- The `ssh_username` parameter, in this case, being that the image used will be `ubuntu`, will make it possible to not only log in but install the minion

### Launch an instance

To instantiate a machine based on this profile (example):

```
# salt-cloud -p hp_ae1_ubuntu ubuntu_instance_1
```

After several minutes, this will create an instance named `ubuntu_instance_1` running in HP Cloud in the US East region and will set up the minion and then return information about the instance once completed.

### Manage the instance

Once the instance has been created with salt-minion installed, connectivity to it can be verified with Salt:

```
# salt ubuntu_instance_1 ping
```

### SSH to the instance

Additionally, the instance can be accessed via SSH using the floating IP assigned to it

```
# ssh ubuntu@<floating_ip>
```

### Using a private IP

Alternatively, in the cloud profile, using the private IP to log into the instance to set up the minion is another option, particularly if salt-cloud is running within the cloud on an instance that is on the same network with all the other instances (minions)
The example below is a modified version of the previous example. Note the use of `ssh_interface`:

```yaml
hp_ae1_ubuntu:
  provider: hp_ae1
  image: 9302692b-b787-4b52-a3a6-daebb79cb498
  size: standard.small
  ssh_key_file: /root/keys/test.key
  ssh_key_name: test
  ssh_username: ubuntu
  ssh_interface: private_ips
```

With this setup, salt-cloud will use the private IP address to `ssh` into the instance and set up the salt-minion.

### 25.7.8 Getting Started With Joyent

Joyent is a public cloud host that supports SmartOS, Linux, FreeBSD, and Windows.

#### Dependencies

This driver requires the Python `requests` library to be installed.

#### Configuration

The Joyent cloud requires three configuration parameters. The user name and password that are used to log into the Joyent system, and the location of the private ssh key associated with the Joyent account. The ssh key is needed to send the provisioning commands up to the freshly created virtual machine.

```yaml
# Note: This example is for /etc/salt/cloud.providers or any file in the
# /etc/salt/cloud.providers.d/ directory.

my-joyent-config:
  driver: joyent
  user: fred
  password: saltybacon
  private_key: /root/mykey.pem
  keyname: mykey
```

**Note:** Changed in version 2015.8.0.

The `provider` parameter in cloud provider definitions was renamed to `driver`. This change was made to avoid confusion with the `provider` parameter that is used in cloud profile definitions. Cloud provider definitions now use `driver` to refer to the Salt cloud module that provides the underlying functionality to connect to a cloud host, while cloud profiles continue to use `provider` to refer to provider configurations that you define.

#### Profiles

#### Cloud Profiles

Set up an initial profile at `/etc/salt/cloud.profiles` or in the `/etc/salt/cloud.profiles.d/` directory:
joyent_512
  provider: my-joyent-config
  size: Extra Small 512 MB
  image: Arch Linux 2013.06

Sizes can be obtained using the --list-sizes option for the salt-cloud command:

```bash
# salt-cloud --list-sizes my-joyent-config
my-joyent-config:
  --------
  joyent:
    ---------
    Extra Small 512 MB:
      ---------
      default:
        false
disk:
  15360
id:
  Extra Small 512 MB
memory:
  512
name:
  Extra Small 512 MB
swap:
  1024
vcpus:
  1
```

Images can be obtained using the --list-images option for the salt-cloud command:

```bash
# salt-cloud --list-images my-joyent-config
my-joyent-config:
  --------
  joyent:
    ---------
    base:
      -------
      description:
        A 32-bit SmartOS image with just essential packages installed. Ideal for users who are comfortable with setting up their own environment and tools.
disabled:
  False
files:
  --------
  - compression:
    bzip2
  - sha1:
    48cdc6457c237cf6306103c74b5f45f5bf2d9bbe
  - size:
    82492182
name:
  base
os:
  smartos
owner:
```
SmartDataCenter

This driver can also be used with the Joyent SmartDataCenter project. More details can be found at:

Using SDC requires that an api_host_suffix is set. The default value for this is .api.joyentcloud.com. All characters, including the leading ., should be included:

| api_host_suffix: .api.myhostname.com |

Miscellaneous Configuration

The following configuration items can be set in either provider or profile configuration files.

**use_ssl**

When set to True (the default), attach https:// to any URL that does not already have http:// or https:// included at the beginning. The best practice is to leave the protocol out of the URL, and use this setting to manage it.

**verify_ssl**

When set to True (the default), the underlying web library will verify the SSL certificate. This should only be set to False for debugging.

### 25.7.9 Getting Started With LXC

The LXC module is designed to install Salt in an LXC container on a controlled and possibly remote minion.

In other words, Salt will connect to a minion, then from that minion:

- Provision and configure a container for networking access
- Use those modules to deploy salt and re-attach to master.
  - lxc runner
  - lxc module
  - seed

**Limitations**

- You can only act on one minion and one provider at a time.
- Listing images must be targeted to a particular LXC provider (nothing will be outputted with all)
Operation

Salt’s LXC support does use `lxc.init` via the `lxc.cloud_init_interface` and seeds the minion via `seed.mkconfig`.

You can provide to those lxc VMs a profile and a network profile like if you were directly using the minion module.

Order of operation:

- Create the LXC container on the desired minion (clone or template)
- Change LXC config options (if any need to be changed)
- Start container
- Change base passwords if any
- Change base DNS configuration if necessary
- Wait for LXC container to be up and ready for ssh
- Test SSH connection and bailout in error
- Upload deploy script and seeds, then re-attach the minion.

Provider configuration

Here is a simple provider configuration:

```bash
# Note: This example goes in /etc/salt/cloud.providers or any file in the
# /etc/salt/cloud.providers.d/ directory.
devhost10-lxc:
    target: devhost10
    driver: lxc
```

**Note:** Changed in version 2015.8.0.

The `provider` parameter in cloud provider definitions was renamed to `driver`. This change was made to avoid confusion with the `provider` parameter that is used in cloud profile definitions. Cloud provider definitions now use `driver` to refer to the Salt cloud module that provides the underlying functionality to connect to a cloud host, while cloud profiles continue to use `provider` to refer to provider configurations that you define.

Profile configuration

Please read *LXC Management with Salt* before anything else. And specially *Profiles*.

Here are the options to configure your containers:

- **target** Host minion id to install the lxc Container into
- **lxc_profile** Name of the profile or inline options for the LXC vm creation/cloning, please see Container Profiles.
- **network_profile** Name of the profile or inline options for the LXC vm network settings, please see Network Profiles.
- **nic_opts** Totally optional. Per interface new-style configuration options mappings which will override any profile default option:
**eth0**: {
  'mac': '00:16:3e:01:29:40',
  'gateway': None, (default)
  'link': 'br0', (default)
  'gateway': None, (default)
  'netmask': '', (default)
  'ip': '22.1.4.25'}

**password**  password for root and sysadmin users

**dnsservers**  List of DNS servers to use. This is optional.

**minion**  minion configuration (see Minion Configuration in Salt Cloud)

**bootstrap_delay**  specify the time to wait (in seconds) between container creation and salt bootstrap execution. It is useful to ensure that all essential services have started before the bootstrap script is executed. By default there's no wait time between container creation and bootstrap unless you are on systemd where we wait that the system is no more in starting state.

**bootstrap_shell**  shell for bootstraping script (default: /bin/sh)

**script**  defaults to salt-boostrap

**script_args**  arguments which are given to the bootstrap script. the {0} placeholder will be replaced by the path which contains the minion config and key files, eg:

```
script_args="-c {0}"
```

Using profiles:

```
# Note: This example would go in /etc/salt/cloud.profiles or any file in the
# /etc/salt/cloud.profiles.d/ directory.
devhost10-lxc:
  provider: devhost10-lxc
  lxc_profile: foo
  network_profile: bar
  minion:
    master: 10.5.0.1
    master_port: 4506
```

Using inline profiles (eg to override the network bridge):

```
devhost11-lxc:
  provider: devhost10-lxc
  lxc_profile:
    clone_from: foo
  network_profile:
    eth0:
      link: lxcbr0
  minion:
    master: 10.5.0.1
    master_port: 4506
```

Using a lxc template instead of a clone:

```
devhost11-lxc:
  provider: devhost10-lxc
  lxc_profile:
    template: ubuntu
  # options:
  #  release: trusty
```
network_profile:
  etho:
    link: lxcbr0
  minion:
    master: 10.5.0.1
    master_port: 4506

Static ip:

# Note: This example would go in /etc/salt/cloud.profiles or any file in the
# /etc/salt/cloud.profiles.d/ directory.
devhost10-lxc:
  provider: devhost10-lxc
  nic_opts:
    eth0:
      ipv4: 10.0.3.9
  minion:
    master: 10.5.0.1
    master_port: 4506

DHCP:

# Note: This example would go in /etc/salt/cloud.profiles or any file in the
# /etc/salt/cloud.profiles.d/ directory.
devhost10-lxc:
  provider: devhost10-lxc
  minion:
    master: 10.5.0.1
    master_port: 4506

Driver Support

- Container creation
- Image listing (LXC templates)
- Running container information (IP addresses, etc.)

25.7.10 Getting Started With Linode

Linode is a public cloud host with a focus on Linux instances.

Starting with the 2015.8.0 release of Salt, the Linode driver uses Linode's native REST API. There are no external dependencies required to use the Linode driver.

Configuration

Linode requires a single API key, but the default root password for new instances also needs to be set:

# Note: This example is for /etc/salt/cloud.providers or any file in the
# /etc/salt/cloud.providers.d/ directory.
my-linode-config:
  apikey: asldkgfakl;sdfjsjaslfjakldsjf;askldjfaklsljsdjfhasldsdafghdkf
  password: F00barbaz
The password needs to be 8 characters and contain lowercase, uppercase, and numbers.

**Note:** Changed in version 2015.8.0.

The `provider` parameter in cloud provider definitions was renamed to `driver`. This change was made to avoid confusion with the `provider` parameter that is used in cloud profile definitions. Cloud provider definitions now use `driver` to refer to the Salt cloud module that provides the underlying functionality to connect to a cloud host, while cloud profiles continue to use `provider` to refer to provider configurations that you define.

### Profiles

#### Cloud Profiles

Set up an initial profile at `/etc/salt/cloud.profiles` or in the `/etc/salt/cloud.profiles.d/` directory:

```yaml
linode_1024:
  provider: my-linode-config
  size: Linode 2048
  image: CentOS 7
  location: London, England, UK
```

Sizes can be obtained using the `--list-sizes` option for the `salt-cloud` command:

```
# salt-cloud --list-sizes my-linode-config
my-linode-config:
  -------
  linode:
  -------
  Linode 1024:
  -------
    bandwidth: 2000
    disk: 49152
    driver:
      get_uuid:
      id: 1
      name: Linode 1024
      price: 20.0
      ram: 1024
      uuid: 03e18728ce4629e2ac07c9cbb48afffb8cb499c4
...
```

---

25.7. Cloud Provider Specifics
Images can be obtained using the `--list-images` option for the `salt-cloud` command:

```
# salt-cloud --list-images my-linode-config
my-linode-config:
         --------
    linode:
         --------
    Arch Linux 2013.06:
         --------
     driver:
         extra:
         --------
       64bit:
                       1
     pvops:
                       1
   get_uuid:
       id:
               112
   name:
       Arch Linux 2013.06
   uuid:
       8457f92eaffc92b7666b6734a96ad7abe1a8a6dd
...SNIP...
```

Locations can be obtained using the `--list-locations` option for the `salt-cloud` command:

```
# salt-cloud --list-locations my-linode-config
my-linode-config:
         --------
    linode:
         --------
    Atlanta, GA, USA:
         --------
   abbreviation:
         atlanta
   id:
               4
    Dallas, TX, USA:
         --------
   abbreviation:
         dallas
   id:
               2
...SNIP...
```

**Cloning**

When `salt-cloud` accesses Linode via `linode-python` it can clone machines.

It is safest to clone a stopped machine. To stop a machine run

```
salt-cloud -a stop machine_to_clone
```

To create a new machine based on another machine, add an entry to your linode cloud profile that looks like this:
li-clone:
  provider: my-linode-config
  clonefrom: machine_to_clone
  script_args: -C -F

Then run salt-cloud as normal, specifying `-p li-clone`. The profile name can be anything; it doesn't have to be `li-clone`.

`clonefrom:` is the name of an existing machine in Linode from which to clone. `Script_args: -C -F` is necessary to avoid re-deploying Salt via salt-bootstrap. `-C` will just re-deploy keys so the new minion will not have a duplicate key or minion_id on the Master, and `-F` will force a rewrite of the Minion config file on the new Minion. If `-F` isn't provided, the new Minion will have the `machine_to_clone`'s Minion ID, instead of its own Minion ID, which can cause problems.

Note: Pull Request #733 to the salt-bootstrap repo makes the `-F` argument non-necessary. Once that change is released into a stable version of the Bootstrap Script, the `-C` argument will be sufficient for the `script_args` setting.

If the `machine_to_clone` does not have Salt installed on it, refrain from using the `script_args: -C -F` altogether, because the new machine will need to have Salt installed.

### 25.7.11 Getting Started With OpenStack

OpenStack is one of the most popular cloud projects. It's an open source project to build public and/or private clouds. You can use Salt Cloud to launch OpenStack instances.

#### Dependencies

- Libcloud >= 0.13.2

#### Configuration

- Using the new format, set up the cloud configuration at `/etc/salt/cloud.providers` or `/etc/salt/cloud.providers.d/openstack.conf`:

```yaml
my-openstack-config:
  # Set the location of the salt-master
  #
  minion:
    master: saltmaster.example.com

  # Configure the OpenStack driver
  #
  identity_url: http://identity.youopenstack.com/v2.0/tokens
  compute_name: nova
  protocol: ipv4

  compute_region: RegionOne

  # Configure Openstack authentication credentials
  #
  user: myname
```

25.7. Cloud Provider Specifics
### Using nova client to get information from OpenStack

One of the best ways to get information about OpenStack is using the novaclient python package (available in pypi as python-novaclient). The client configuration is a set of environment variables that you can get from the Dashboard. Log in and then go to Project -> Access & security -> API Access and download the "OpenStack RC file". Then:

```
source /path/to/your/rcfile
nova credentials
nova endpoints
```

In the `nova endpoints` output you can see the information about `compute_region` and `compute_name`.

### Compute Region

It depends on the OpenStack cluster that you are using. Please, have a look at the previous sections.

### Authentication

The `user` and `password` is the same user as is used to log into the OpenStack Dashboard.

### Profiles

Here is an example of a profile:

```
openstack_512:
  provider: my-openstack-config
  size: m1.tiny
  image: cirros-0.3.1-x86_64-uec
  ssh_key_file: /tmp/test.pem
  ssh_key_name: test
  ssh_interface: private_ips
```

The following list explains some of the important properties.

`size` can be one of the options listed in the output of `nova flavor-list`. 

---

**Note:** Changed in version 2015.8.0.

The `provider` parameter in cloud provider definitions was renamed to `driver`. This change was made to avoid confusion with the `provider` parameter that is used in cloud profile definitions. Cloud provider definitions now use `driver` to refer to the Salt cloud module that provides the underlying functionality to connect to a cloud host, while cloud profiles continue to use `provider` to refer to provider configurations that you define.
image can be one of the options listed in the output of nova image-list.

**ssh_key_file** The SSH private key that the salt-cloud uses to SSH into the VM after its first booted in order to execute a command or script. This private key's public key must be the openstack public key inserted into the authorized_key's file of the VM's root user account.

**ssh_key_name** The name of the openstack SSH public key that is inserted into the authorized_keys file of the VM's root user account. Prior to using this public key, you must use openstack commands or the horizon web UI to load that key into the tenant's account. Note that this openstack tenant must be the one you defined in the cloud provider.

**ssh_interface** This option allows you to create a VM without a public IP. If this option is omitted and the VM does not have a public IP, then the salt-cloud waits for a certain period of time and then destroys the VM. With the nova drive, private cloud networks can be defined here.

For more information concerning cloud profiles, see [here](#).

**change_password**

If no ssh_key_file is provided, and the server already exists, change_password will use the api to change the root password of the server so that it can be bootstrapped.

```
change_password: True
```

**userdata_file**

Use `userdata_file` to specify the userdata file to upload for use with cloud-init if available.

```
userdata_file: /etc/salt/cloud-init/packages.yml
```

### 25.7.12 Getting Started With Parallels

Parallels Cloud Server is a product by Parallels that delivers a cloud hosting solution. The PARALLELS module for Salt Cloud enables you to manage instances hosted using PCS. Further information can be found at:

http://www.parallels.com/products/pcs/

- Using the old format, set up the cloud configuration at `/etc/salt/cloud`:

```
# Set up the location of the salt master
#
minion:
    master: saltmaster.example.com

# Set the PARALLELS access credentials (see below)
#
PARALLELS.user: myuser
PARALLELS.password: badpass

# Set the access URL for your PARALLELS host
#
PARALLELS.url: https://api.cloud.xmission.com:4465/paci/v1.0/
```

- Using the new format, set up the cloud configuration at `/etc/salt/cloud.providers` or `/etc/salt/cloud.providers.d/parallels.conf`:
my-parallels-config:

# Set up the location of the salt master
#
minion:
  master: saltmaster.example.com

# Set the PARALLELS access credentials (see below)
#
user: myuser
password: badpass

# Set the access URL for your PARALLELS provider
#
url: https://api.cloud.xmission.com:4465/paci/v1.0/
driver: parallels

Note: Changed in version 2015.8.0.

The `provider` parameter in cloud provider definitions was renamed to `driver`. This change was made to avoid confusion with the `provider` parameter that is used in cloud profile definitions. Cloud provider definitions now use `driver` to refer to the Salt cloud module that provides the underlying functionality to connect to a cloud host, while cloud profiles continue to use `provider` to refer to provider configurations that you define.

Access Credentials

The `user`, `password`, and `url` will be provided to you by your cloud host. These are all required in order for the PARALLELS driver to work.

Cloud Profiles

Set up an initial profile at `/etc/salt/cloud.profiles` or `/etc/salt/cloud.profiles.d/parallels.conf`:

```
parallels-ubuntu:
  provider: my-parallels-config
  image: ubuntu-12.04-x86_64
```

The profile can be realized now with a salt command:

```
# salt-cloud -p parallels-ubuntu myubuntu
```

This will create an instance named `myubuntu` on the cloud host. The minion that is installed on this instance will have an `id` of `myubuntu`. If the command was executed on the salt-master, its Salt key will automatically be signed on the master.

Once the instance has been created with salt-minion installed, connectivity to it can be verified with Salt:

```
# salt myubuntu test.ping
```

Required Settings

The following settings are always required for PARALLELS:

- Using the old cloud configuration format:
PARALLELS.user: myuser
PARALLELS.password: badpass
PARALLELS.url: https://api.cloud.xmission.com:4465/paci/v1.0/

- Using the new cloud configuration format:

```yaml
my-parallels-config:
  user: myuser
  password: badpass
  url: https://api.cloud.xmission.com:4465/paci/v1.0/
  driver: parallels
```

### Optional Settings

Unlike other cloud providers in Salt Cloud, Parallels does not utilize a size setting. This is because Parallels allows the end-user to specify a more detailed configuration for their instances than is allowed by many other cloud hosts. The following options are available to be used in a profile, with their default settings listed.

```yaml
# Description of the instance. Defaults to the instance name.
desc: <instance_name>

# How many CPU cores, and how fast they are (in MHz)
cpu_number: 1
cpu_power: 1000

# How many megabytes of RAM
ram: 256

# Bandwidth available, in kbps
bandwidth: 100

# How many public IPs will be assigned to this instance
ip_num: 1

# Size of the instance disk (in GiB)
disk_size: 10

# Username and password
ssh_username: root
password: <value from PARALLELS.password>

# The name of the image, from `salt-cloud --list-images parallels`
image: ubuntu-12.04-x86_64
```

#### 25.7.13 Getting Started With Proxmox

Proxmox Virtual Environment is a complete server virtualization management solution, based on LXC and full virtualization with KVM. Further information can be found at:

http://www.proxmox.org/

### Dependencies

- IPy >= 0.81
requests >= 2.2.1

Please note: This module allows you to create both OpenVZ and KVM but installing Salt on it will only be done when the VM is an OpenVZ container rather than a KVM virtual machine.

Set up the cloud configuration at /etc/salt/cloud.providers or /etc/salt/cloud.providers.d/proxmox.conf:

```yaml
my-proxmox-config:
  # Set up the location of the salt master
  #
  minion:
    master: saltmaster.example.com

  # Set the PROXMOX access credentials (see below)
  #
  user: myuser@pve
  password: badpass

  # Set the access URL for your PROXMOX host
  #
  url: your.proxmox.host
  driver: proxmox
```

**Note:** Changed in version 2015.8.0.

The `provider` parameter in cloud provider definitions was renamed to `driver`. This change was made to avoid confusion with the `provider` parameter that is used in cloud profile definitions. Cloud provider definitions now use `driver` to refer to the Salt cloud module that provides the underlying functionality to connect to a cloud host, while cloud profiles continue to use `provider` to refer to provider configurations that you define.

**Access Credentials**

The `user`, `password`, and `url` will be provided to you by your cloud host. These are all required in order for the PROXMOX driver to work.

**Cloud Profiles**

Set up an initial profile at `/etc/salt/cloud.profiles` or `/etc/salt/cloud.profiles.d/proxmox.conf`:

- Configure a profile to be used:

```yaml
proxmox-ubuntu:
  provider: my-proxmox-config
  image: local:vztmpl/ubuntu-12.04-standard_12.04-1_amd64.tar.gz
  technology: openvz

  # host needs to be set to the configured name of the proxmox host
  # and not the ip address or FQDN of the server
  host: myvmhost
  ip_address: 192.168.100.155
  password: topsecret
```

The profile can be realized now with a salt command:
This will create an instance named `myubuntu` on the cloud host. The minion that is installed on this instance will have a `hostname` of `myubuntu`. If the command was executed on the salt-master, its Salt key will automatically be signed on the master.

Once the instance has been created with salt-minion installed, connectivity to it can be verified with Salt:

```bash
# salt myubuntu test.ping
```

### Required Settings

The following settings are always required for PROXMOX:

- Using the new cloud configuration format:

```yaml
my-proxmox-config:
    driver: proxmox
    user: saltcloud@pve
    password: xyzzy
    url: your.proxmox.host
```

### Optional Settings

Unlike other cloud providers in Salt Cloud, Proxmox does not utilize a `size` setting. This is because Proxmox allows the end-user to specify a more detailed configuration for their instances, than is allowed by many other cloud providers. The following options are available to be used in a profile, with their default settings listed.

```yaml
# Description of the instance.
desc: <instance_name>

# How many CPU cores, and how fast they are (in MHz)
cpus: 1
cpuunits: 1000

# How many megabytes of RAM
memory: 256

# How much swap space in MB
swap: 256

# Whether to auto boot the vm after the host reboots
onboot: 1

# Size of the instance disk (in GiB)
disk: 10

# Host to create this vm on
host: myvmhost

# Nameservers. Defaults to host
nameserver: 8.8.8.8 8.8.4.4

# Username and password
ssh_username: root
```
25.7.14 Getting Started With Rackspace

Rackspace is a major public cloud platform which may be configured using either the rackspace or the openstack driver, depending on your needs.

Please note that the rackspace driver is intended only for 1st gen instances, aka, ``the old cloud'' at Rackspace. It is required for 1st gen instances, but will not work with OpenStack-based instances. Unless you explicitly have a reason to use it, it is highly recommended that you use the openstack driver instead.

Dependencies

- Libcloud >= 0.13.2

Configuration

To use the openstack driver (recommended), set up the cloud configuration at /etc/salt/cloud.providers or /etc/salt/cloud.providers.d/rackspace.conf:

```yaml
my-rackspace-config:
  # Set the location of the salt-master
  #
  minion:
    master: saltmaster.example.com

  # Configure Rackspace using the OpenStack plugin
  #
  identity_url: 'https://identity.api.rackspacecloud.com/v2.0/tokens'
  compute_name: cloudServersOpenStack
  protocol: ipv4

  # Set the compute region:
  #
  compute_region: DFW

  # Configure Rackspace authentication credentials
  #
  user: myname
  tenant: 123456
  apikey: xxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

  driver: openstack
```

To use the rackspace driver, set up the cloud configuration at /etc/salt/cloud.providers or /etc/salt/cloud.providers.d/rackspace.conf:

```yaml
my-rackspace-config:
  driver: rackspace
  # The Rackspace login user
  user: fred
```
The settings that follow are for using Rackspace with the `openstack` driver, and will not work with the `rackspace` driver.

**Note:** Changed in version 2015.8.0.

The `provider` parameter in cloud provider definitions was renamed to `driver`. This change was made to avoid confusion with the `provider` parameter that is used in cloud profile definitions. Cloud provider definitions now use `driver` to refer to the Salt cloud module that provides the underlying functionality to connect to a cloud host, while cloud profiles continue to use `provider` to refer to provider configurations that you define.

### Compute Region

Rackspace currently has six compute regions which may be used:

<table>
<thead>
<tr>
<th>Region</th>
<th>Location</th>
</tr>
</thead>
<tbody>
<tr>
<td>DFW</td>
<td>Dallas/Forth Worth</td>
</tr>
<tr>
<td>ORD</td>
<td>Chicago</td>
</tr>
<tr>
<td>SYD</td>
<td>Sydney</td>
</tr>
<tr>
<td>LON</td>
<td>London</td>
</tr>
<tr>
<td>IAD</td>
<td>Northern Virginia</td>
</tr>
<tr>
<td>HKG</td>
<td>Hong Kong</td>
</tr>
</tbody>
</table>

Note: Currently the LON region is only available with a UK account, and UK accounts cannot access other regions.

### Authentication

The `user` is the same user as is used to log into the Rackspace Control Panel. The `tenant` and `apikey` can be found in the API Keys area of the Control Panel. The `apikey` will be labeled as API Key (and may need to be generated), and `tenant` will be labeled as Cloud Account Number.

An initial profile can be configured in `/etc/salt/cloud.profiles` or `/etc/salt/cloud.profiles.d/rackspace.conf`:

```yaml
openstack_512:
    provider: my-rackspace-config
    size: 512 MB Standard
    image: Ubuntu 12.04 LTS (Precise Pangolin)
```

To instantiate a machine based on this profile:

```bash
# salt-cloud -p openstack_512 myinstance
```

This will create a virtual machine at Rackspace with the name `myinstance`. This operation may take several minutes to complete, depending on the current load at the Rackspace data center.

Once the instance has been created with salt-minion installed, connectivity to it can be verified with Salt:

```bash
# salt myinstance test.ping
```
RackConnect Environments

Rackspace offers a hybrid hosting configuration option called RackConnect that allows you to use a physical firewall appliance with your cloud servers. When this service is in use the public_ip assigned by nova will be replaced by a NAT ip on the firewall. For salt-cloud to work properly it must use the newly assigned ``access ip" instead of the Nova assigned public ip. You can enable that capability by adding this to your profiles:

```yaml
openstack_512:
  provider: my-openstack-config
  size: 512 MB Standard
  image: Ubuntu 12.04 LTS (Precise Pangolin)
  rackconnect: True
```

Managed Cloud Environments

Rackspace offers a managed service level of hosting. As part of the managed service level you have the ability to choose from base of lamp installations on cloud server images. The post build process for both the base and the lamp installations used Chef to install things such as the cloud monitoring agent and the cloud backup agent. It also takes care of installing the lamp stack if selected. In order to prevent the post installation process from stomping over the bootstrapping you can add the below to your profiles.

```yaml
openstack_512:
  provider: my-rackspace-config
  size: 512 MB Standard
  image: Ubuntu 12.04 LTS (Precise Pangolin)
  managedcloud: True
```

First and Next Generation Images

Rackspace provides two sets of virtual machine images, first, and next generation. As of 0.8.9 salt-cloud will default to using the next generation images. To force the use of first generation images, on the profile configuration please add:

```yaml
FreeBSD-9.0-512:
  provider: my-rackspace-config
  size: 512 MB Standard
  image: FreeBSD 9.0
  force_first_gen: True
```

Private Subnets

By default salt-cloud will not add Rackspace private networks to new servers. To enable a private network to a server instantiated by salt cloud, add the following section to the provider file (typically /etc/salt/cloud.providers.d/rackspace.conf)

```yaml
networks:
  - fixed:
      # This is the private network
      - private-network-id
      # This is Rackspace's "PublicNet"
      - 00000000-0000-0000-0000-000000000000
```
To get the Rackspace private network ID, go to Networking, Networks and hover over the private network name. The order of the networks in the above code block does not map to the order of the ethernet devices on newly created servers. Public IP will always be first (eth0) followed by servicenet (eth1) and then private networks.

Enabling the private network per above gives the option of using the private subnet for all master-minion communication, including the bootstrap install of salt-minion. To enable the minion to use the private subnet, update the master: line in the minion: section of the providers file. To configure the master to only listen on the private subnet IP, update the interface: line in the /etc/salt/master file to be the private subnet IP of the salt master.

### 25.7.15 Getting Started With Saltify

The Saltify driver is a new, experimental driver for installing Salt on existing machines (virtual or bare metal).

**Dependencies**

The Saltify driver has no external dependencies.

**Configuration**

Because the Saltify driver does not use an actual cloud provider host, it has a simple provider configuration. The only thing that is required to be set is the driver name, and any other potentially useful information, like the location of the salt-master:

```
# Note: This example is for /etc/salt/cloud.providers file or any file in
# the /etc/salt/cloud.providers.d/ directory.

my-saltify-config:
    minion:
        master: 111.222.333.444
        provider: saltify
```

**Profiles**

Saltify requires a profile to be configured for each machine that needs Salt installed. The initial profile can be set up at /etc/salt/cloud.profiles or in the /etc/salt/cloud.profiles.d/ directory. Each profile requires both an ssh_host and an ssh_username key parameter as well as either an key_filename or a password.

Profile configuration example:

```
# /etc/salt/cloud.profiles.d/saltify.conf

salt-this-machine:
    ssh_host: 12.34.56.78
    ssh_username: root
    key_filename: '/etc/salt/mysshkey.pem'
    provider: my-saltify-config
```

The machine can now be ``Salted`` with the following command:
salt-cloud -p salt-this-machine my-machine

This will install salt on the machine specified by the cloud profile, \texttt{salt-this-machine}, and will give the machine the minion id of \texttt{my-machine}. If the command was executed on the salt-master, its Salt key will automatically be signed on the master.

Once a salt-minion has been successfully installed on the instance, connectivity to it can be verified with Salt:

\begin{verbatim}
salt my-machine test.ping
\end{verbatim}

Using Map Files

The settings explained in the section above may also be set in a map file. An example of how to use the Saltify driver with a map file follows:

\begin{verbatim}
# /etc/salt/saltify-map
make_salty:
  - my-instance-0:
    ssh_host: 12.34.56.78
    ssh_username: root
    password: very-bad-password
  - my-instance-1:
    ssh_host: 44.33.22.11
    ssh_username: root
    password: another-bad-pass
\end{verbatim}

Note: When using a cloud map with the Saltify driver, the name of the profile to use, in this case \texttt{make_salty}, must be defined in a profile config. For example:

\begin{verbatim}
# /etc/salt/cloud.profiles.d/saltify.conf
make_salty:
  provider: my-saltify-config
\end{verbatim}

The machines listed in the map file can now be `Salted` by applying the following salt map command:

\begin{verbatim}
salt-cloud -m /etc/salt/saltify-map
\end{verbatim}

This command will install salt on the machines specified in the map and will give each machine their minion id of \texttt{my-instance-0} and \texttt{my-instance-1}, respectively. If the command was executed on the salt-master, its Salt key will automatically be signed on the master.

Connectivity to the new `Salted` instances can now be verified with Salt:

\begin{verbatim}
salt 'my-instance-*' test.ping
\end{verbatim}

\section*{25.7.16 Getting Started With Scaleway}

Scaleway is the first IaaS host worldwide to offer an ARM based cloud. It’s the ideal platform for horizontal scaling with BareMetal SSD servers. The solution provides on demand resources: it comes with on-demand SSD storage, movable IPs, images, security group and an Object Storage solution. \url{https://scaleway.com}
**Configuration**

Using Salt for Scaleway, requires an **access key** and an **API token**. **API tokens** are unique identifiers associated with your Scaleway account. To retrieve your **access key** and **API token**, log-in to the Scaleway control panel, open the pull-down menu on your account name and click on ```My Credentials``` link.

If you do not have API token you can create one by clicking the ```Create New Token``` button on the right corner.

```bash
# Note: This example is for /etc/salt/cloud.providers or any file in the
# /etc/salt/cloud.providers.d/ directory.
my-scaleway-config:
    access_key: 15cf404d-4560-41b1-9a0c-21c3d5c4ff1f
    token: a7347ec8-5de1-4024-a5e3-24b77d1ba91d
    driver: scaleway
```

**Note:** Changed in version 2015.8.0.

The **provider** parameter in cloud provider definitions was renamed to **driver**. This change was made to avoid confusion with the **provider** parameter that is used in cloud profile definitions. Cloud provider definitions now use **driver** to refer to the Salt cloud module that provides the underlying functionality to connect to a cloud host, while cloud profiles continue to use **provider** to refer to provider configurations that you define.

**Profiles**

**Cloud Profiles**

Set up an initial profile at `/etc/salt/cloud.profiles` or in the `/etc/salt/cloud.profiles.d/` directory:

```yaml
scalewa-ubuntu:
    provider: my-scaleway-config
    image: Ubuntu Trusty (14.04 LTS)
```

Images can be obtained using the ```--list-images``` option for the `salt-cloud` command:

```bash
#salt-cloud --list-images my-scaleway-config
my-scaleway-config:
    ------------
    scaleway:
        -----------
        069fd876-eb04-44ab-a9cd-47e2fa3e5309:
            arch: arm
            creation_date: 2015-03-12T09:35:45.764477+00:00
            default_bootscript:
                {u'kernel': {u'dtb': u'', u'title': u'Pimouss 3.2.34-30-std', u'id': u'cfda4308-cd6f-4e51-9744-905fc0da370f'}, u'path': u'kernel/pimouss-uImage-3.2.34-30-std'}, u'title': u'3.2.34-std #30 (stable)', u'id': u'c5af0215-2516-4316-be5f-5da1cfd699c', u'initrd': {u'path': u'initrd/c1-uInitrd', u'id': u'1be14b1b-e24c-48e5-b6b6-7ba452e42b92', u'title': u'C1 initrd'}, u'bootcmdargs': {u'id': u'd22c4d8e-6a4-47ad-abb9-d23b54d542ff', u'value': u'ip=dhcp boot=local root=/dev/nbd0 USE_XNBD=1 nbd.max_parts=8'}, u'organization': u'11111111-1111-4111-8111-111111111111', u'public': True}
```
Execute a query and return all information about the nodes running on configured cloud providers using the \texttt{-Q} option for the \texttt{salt-cloud} command:

```
# salt-cloud -F
[INFO]   ] salt-cloud starting
my-scaleway-config:
   ------------
scaleway:
   ---------
salt-manager:
   ---------
   creation_date: 2015-06-03T08:17:38.818068+00:00
   hostname: salt-manager
   ...
```

\begin{footnote}{Note: Additional documentation about Scaleway can be found at \url{https://www.scaleway.com/docs}.}

\end{footnote}

**25.7.17 Getting Started With SoftLayer**

SoftLayer is a public cloud host, and baremetal hardware hosting service.

\section*{Dependencies}

The SoftLayer driver for Salt Cloud requires the softlayer package, which is available at PyPI:

\url{https://pypi.python.org/pypi/SoftLayer}

This package can be installed using \texttt{pip} or \texttt{easy_install}:

```
# pip install softlayer
# easy_install softlayer
```

396 Chapter 25. Salt Cloud
Configuration

Set up the cloud config at /etc/salt/cloud.providers:

```yaml
# Note: These examples are for /etc/salt/cloud.providers

my-softlayer:
    # Set up the location of the salt master
    minion:
        master: saltmaster.example.com

    # Set the SoftLayer access credentials (see below)
    user: MYUSER1138
    apikey: 'e3b68aa711e6deadc62d5b76355674beef7cc3116062ddbacafe5f7e465bfdc9'

    driver: softlayer

my-softlayer-hw:
    # Set up the location of the salt master
    minion:
        master: saltmaster.example.com

    # Set the SoftLayer access credentials (see below)
    user: MYUSER1138
    apikey: 'e3b68aa711e6deadc62d5b76355674beef7cc3116062ddbacafe5f7e465bfdc9'

    driver: softlayer_hw
```

Note: Changed in version 2015.8.0.

The provider parameter in cloud provider definitions was renamed to driver. This change was made to avoid confusion with the provider parameter that is used in cloud profile definitions. Cloud provider definitions now use driver to refer to the Salt cloud module that provides the underlying functionality to connect to a cloud host, while cloud profiles continue to use provider to refer to provider configurations that you define.

Access Credentials

The user setting is the same user as is used to log into the SoftLayer Administration area. The apikey setting is found inside the Admin area after logging in:

- Hover over the Account menu item.
- Click the Users link.
- Find the API Key column and click View.

Profiles

Cloud Profiles

Set up an initial profile at /etc/salt/cloud.profiles:
base_softlayer_ubuntu:
  provider: my-softlayer
  image: UBUNTU_LATEST
  cpu_number: 1
  ram: 1024
  disk_size: 100
  local_disk: True
  hourly_billing: True
  domain: example.com
  location: sjc01
  # Optional
  max_net_speed: 1000
  private_vlan: 396
  private_network: True
  private_ssh: True
  # May be used _instead_of_ image
  global_identifier: 320d8be5-46c0-dead-cafe-13e3c51

Most of the above items are required; optional items are specified below.

**image**

Images to build an instance can be found using the `--list-images` option:

```
# salt-cloud --list-images my-softlayer
```

The setting used will be labeled as template.

**cpu_number**

This is the number of CPU cores that will be used for this instance. This number may be dependent upon the image that is used. For instance:

```
Red Hat Enterprise Linux 6 - Minimal Install (64 bit) (1 - 4 Core):
  name: Red Hat Enterprise Linux 6 - Minimal Install (64 bit) (1 - 4 Core)
  template: REDHAT_6_64

Red Hat Enterprise Linux 6 - Minimal Install (64 bit) (5 - 100 Core):
  name: Red Hat Enterprise Linux 6 - Minimal Install (64 bit) (5 - 100 Core)
  template: REDHAT_6_64
```

Note that the template (meaning, the `image` option) for both of these is the same, but the names suggest how many CPU cores are supported.

**ram**

This is the amount of memory, in megabytes, that will be allocated to this instance.
disk_size

The amount of disk space that will be allocated to this image, in gigabytes.

```
base_softlayer_ubuntu:
  disk_size: 100
```

Using Multiple Disks

SoftLayer allows up to 5 disks to be specified for a virtual machine upon creation. Multiple disks can be specified either as a list or a comma-delimited string. The first disk size specified in the string or list will be the first disk size assigned to the VM.

List Example: .. code-block:: yaml

```
  base_softlayer_ubuntu: disk_size: ['100', '20', '20']
```

String Example: .. code-block:: yaml

```
  base_softlayer_ubuntu: disk_size: '100, 20, 20'
```

local_disk

When true the disks for the computing instance will be provisioned on the host which it runs, otherwise SAN disks will be provisioned.

hourly_billing

When true the computing instance will be billed on hourly usage, otherwise it will be billed on a monthly basis.

domain

The domain name that will be used in the FQDN (Fully Qualified Domain Name) for this instance. The domain setting will be used in conjunction with the instance name to form the FQDN.

location

Images to build an instance can be found using the --list-locations option:

```
# salt-cloud --list-location my-softlayer
```

max_net_speed

Specifies the connection speed for the instance's network components. This setting is optional. By default, this is set to 10.
**post_uri**

Specifies the uri location of the script to be downloaded and run after the instance is provisioned.

Example: .. code-block:: yaml

**public_vlan**

If it is necessary for an instance to be created within a specific frontend VLAN, the ID for that VLAN can be specified in either the provider or profile configuration.

This ID can be queried using the `list_vlans` function, as described below. This setting is optional.

**private_vlan**

If it is necessary for an instance to be created within a specific backend VLAN, the ID for that VLAN can be specified in either the provider or profile configuration.

This ID can be queried using the `list_vlans` function, as described below. This setting is optional.

**private_network**

If a server is to only be used internally, meaning it does not have a public VLAN associated with it, this value would be set to True. This setting is optional. The default is False.

**private_ssh**

Whether to run the deploy script on the server using the public IP address or the private IP address. If set to True, Salt Cloud will attempt to SSH into the new server using the private IP address. The default is False. This setting is optional.

**global_identifier**

When creating an instance using a custom template, this option is set to the corresponding value obtained using the `list_custom_images` function. This option will not be used if an image is set, and if an image is not set, it is required.

The profile can be realized now with a salt command:

```
# salt-cloud -p base_softlayer_ubuntu myserver
```

Using the above configuration, this will create `myserver.example.com`.

Once the instance has been created with salt-minion installed, connectivity to it can be verified with Salt:

```
# salt 'myserver.example.com' test.ping
```
Cloud Profiles

Set up an initial profile at /etc/salt/cloud.profiles:

```
base_softlayer_hw_centos:
  provider: my-softlayer-hw
  # CentOS 6.0 - Minimal Install (64 bit)
  image: 13963
  # 2 x 2.0 GHz Core Bare Metal Instance - 2 GB Ram
  size: 1921
  # 500GB SATA II
  hdd: 1267
  # San Jose 01
  location: 168642
  domain: example.com
  # Optional
  vlan: 396
  port_speed: 273
  bandwidth: 248
```

Most of the above items are required; optional items are specified below.

**image**

Images to build an instance can be found using the --list-images option:

```
# salt-cloud --list-images my-softlayer-hw
```

A list of id's and names will be provided. The `name` will describe the operating system and architecture. The id will be the setting to be used in the profile.

**size**

Sizes to build an instance can be found using the --list-sizes option:

```
# salt-cloud --list-sizes my-softlayer-hw
```

A list of id's and names will be provided. The `name` will describe the speed and quantity of CPU cores, and the amount of memory that the hardware will contain. The id will be the setting to be used in the profile.

**hdd**

There is currently only one size of hard disk drive (HDD) that is available for hardware instances on SoftLayer:

```
1267: 500GB SATA II
```

The hdd setting in the profile should be 1267. Other sizes may be added in the future.

**location**

Locations to build an instance can be found using the --list-images option:
# salt-cloud --list-locations my-softlayer-hw

A list of IDs and names will be provided. The location will describe the location in human terms. The id will be the setting to be used in the profile.

**domain**

The domain name that will be used in the FQDN (Fully Qualified Domain Name) for this instance. The domain setting will be used in conjunction with the instance name to form the FQDN.

**vlan**

If it is necessary for an instance to be created within a specific VLAN, the ID for that VLAN can be specified in either the provider or profile configuration.

This ID can be queried using the list_vlans function, as described below.

**port_speed**

Specifies the speed for the instance's network port. This setting refers to an ID within the SoftLayer API, which sets the port speed. This setting is optional. The default is 273, or, 100 Mbps Public & Private Networks. The following settings are available:

- 273: 100 Mbps Public & Private Networks
- 274: 1 Gbps Public & Private Networks
- 21509: 10 Mbps Dual Public & Private Networks (up to 20 Mbps)
- 21513: 100 Mbps Dual Public & Private Networks (up to 200 Mbps)
- 2314: 1 Gbps Dual Public & Private Networks (up to 2 Gbps)
- 272: 10 Mbps Public & Private Networks

**bandwidth**

Specifies the network bandwidth available for the instance. This setting refers to an ID within the SoftLayer API, which sets the bandwidth. This setting is optional. The default is 248, or, 5000 GB Bandwidth. The following settings are available:

- 248: 5000 GB Bandwidth
- 129: 6000 GB Bandwidth
- 130: 8000 GB Bandwidth
- 131: 10000 GB Bandwidth
- 36: Unlimited Bandwidth (10 Mbps Uplink)
- 125: Unlimited Bandwidth (100 Mbps Uplink)
Actions

The following actions are currently supported by the SoftLayer Salt Cloud driver.

show_instance

This action is a thin wrapper around `--full-query`, which displays details on a single instance only. In an environment with several machines, this will save a user from having to sort through all instance data, just to examine a single instance.

```
$ salt-cloud -a show_instance myinstance
```

Functions

The following functions are currently supported by the SoftLayer Salt Cloud driver.

list_vlans

This function lists all VLANs associated with the account, and all known data from the SoftLayer API concerning those VLANs.

```
$ salt-cloud -f list_vlans my-softlayer
$ salt-cloud -f list_vlans my-softlayer-hw
```

The id returned in this list is necessary for the vlan option when creating an instance.

list_custom_images

This function lists any custom templates associated with the account, that can be used to create a new instance.

```
$ salt-cloud -f list_custom_images my-softlayer
```

The globalIdentifier returned in this list is necessary for the global_identifier option when creating an image using a custom template.

Optional Products for SoftLayer HW

The softlayer_hw driver supports the ability to add optional products, which are supported by SoftLayer's API. These products each have an ID associated with them, that can be passed into Salt Cloud with the optional_products option:

```
softlayer_hw_test:
    provider: my-softlayer-hw
    # CentOS 6.0 - Minimal Install (64 bit)
    image: 13963
    # 2 x 2.0 GHz Core Bare Metal Instance - 2 GB Ram
    size: 1921
    # 500GB SATA II
    hdd: 1267
    # San Jose 01
    location: 168642
    domain: example.com
```
optional_products:
  # MySQL for Linux
  - id: 28
    # Business Continuance Insurance
    - id: 184

These values can be manually obtained by looking at the source of an order page on the SoftLayer web interface. For convenience, many of these values are listed here:

**Public Secondary IP Addresses**

- 22: 4 Public IP Addresses
- 23: 8 Public IP Addresses

**Primary IPv6 Addresses**

- 17129: 1 IPv6 Address

**Public Static IPv6 Addresses**

- 1481: /64 Block Static Public IPv6 Addresses

**OS-Specific Addon**

- 17139: XenServer Advanced for XenServer 6.x
- 17141: XenServer Enterprise for XenServer 6.x
- 2334: XenServer Advanced for XenServer 5.6
- 2335: XenServer Enterprise for XenServer 5.6
- 13915: Microsoft WebMatrix
- 21276: VMware vCenter 5.1 Standard

**Control Panel Software**

- 121: cPanel/WHM with Fantastico and RVskin
- 20778: Parallels Plesk Panel 11 (Linux) 100 Domain w/ Power Pack
- 20786: Parallels Plesk Panel 11 (Windows) 100 Domain w/ Power Pack
- 20787: Parallels Plesk Panel 11 (Linux) Unlimited Domain w/ Power Pack
- 20792: Parallels Plesk Panel 11 (Windows) Unlimited Domain w/ Power Pack
- 2340: Parallels Plesk Panel 10 (Linux) 100 Domain w/ Power Pack
- 2339: Parallels Plesk Panel 10 (Linux) Unlimited Domain w/ Power Pack
- 13704: Parallels Plesk Panel 10 (Windows) Unlimited Domain w/ Power Pack
Database Software

- 29: MySQL 5.0 for Windows
- 28: MySQL for Linux
- 21501: Riak 1.x
- 20893: MongoDB
- 30: Microsoft SQL Server 2005 Express
- 92: Microsoft SQL Server 2005 Workgroup
- 90: Microsoft SQL Server 2005 Standard
- 94: Microsoft SQL Server 2005 Enterprise
- 1330: Microsoft SQL Server 2008 Express
- 1340: Microsoft SQL Server 2008 Web
- 1337: Microsoft SQL Server 2008 Workgroup
- 1334: Microsoft SQL Server 2008 Standard
- 1331: Microsoft SQL Server 2008 Enterprise
- 2179: Microsoft SQL Server 2008 Express R2
- 2173: Microsoft SQL Server 2008 Web R2
- 2183: Microsoft SQL Server 2008 Workgroup R2
- 2180: Microsoft SQL Server 2008 Standard R2
- 2176: Microsoft SQL Server 2008 Enterprise R2

Anti-Virus & Spyware Protection

- 594: McAfee VirusScan Anti-Virus - Windows
- 414: McAfee Total Protection - Windows

Insurance

- 104: Business Continuance Insurance

Monitoring

- 55: Host Ping
- 56: Host Ping and TCP Service Monitoring

Notification

- 57: Email and Ticket
Advanced Monitoring

• 2302: Monitoring Package - Basic
• 2303: Monitoring Package - Advanced
• 2304: Monitoring Package - Premium Application

Response

• 58: Automated Notification
• 59: Automated Reboot from Monitoring
• 60: 24x7x365 NOC Monitoring, Notification, and Response

Intrusion Detection & Protection

• 413: McAfee Host Intrusion Protection w/Reporting

Hardware & Software Firewalls

• 411: APF Software Firewall for Linux
• 894: Microsoft Windows Firewall
• 410: 10Mbps Hardware Firewall
• 409: 100Mbps Hardware Firewall
• 408: 1000Mbps Hardware Firewall

25.7.18 Getting Started with VEXXHOST

VEXXHOST is a cloud computing host which provides Canadian cloud computing services which are based in Montreal and use the libcloud OpenStack driver. VEXXHOST currently runs the Havana release of OpenStack. When provisioning new instances, they automatically get a public IP and private IP address. Therefore, you do not need to assign a floating IP to access your instance after it’s booted.

Cloud Provider Configuration

To use the openstack driver for the VEXXHOST public cloud, you will need to set up the cloud provider configuration file as in the example below:

/etc/salt/cloud.providers.d/vexxhost.conf: In order to use the VEXXHOST public cloud, you will need to setup a cloud provider configuration file as in the example below which uses the OpenStack driver.

```
my-vexxhost-config:
  # Set the location of the salt-master
  #
  minion:
    master: saltmaster.example.com

  # Configure VEXXHOST using the OpenStack plugin
```
```
# identity_url: http://auth.api.thenebacloud.com:5000/v2.0/tokens
compute_name: nova

# Set the compute region:
# compute_region: na-yul-nhs1

# Configure VEXXHOST authentication credentials
# user: your-tenant-id
password: your-api-key
tenant: your-tenant-name

# keys to allow connection to the instance launched
# ssh_key_name: yourkey
ssh_key_file: /path/to/key/yourkey.priv
driver: openstack
```

**Note:** Changed in version 2015.8.0.

The `provider` parameter in cloud provider definitions was renamed to `driver`. This change was made to avoid confusion with the `provider` parameter that is used in cloud profile definitions. Cloud provider definitions now use `driver` to refer to the Salt cloud module that provides the underlying functionality to connect to a cloud host, while cloud profiles continue to use `provider` to refer to provider configurations that you define.

**Authentication**

All of the authentication fields that you need can be found by logging into your VEXXHOST customer center. Once you’ve logged in, you will need to click on `CloudConsole` and then click on `API Credentials`.

**Cloud Profile Configuration**

In order to get the correct image UUID and the instance type to use in the cloud profile, you can run the following command respectively:

```
# salt-cloud --list-images=vexxhost-config
# salt-cloud --list-sizes=vexxhost-config
```

Once you have that, you can go ahead and create a new cloud profile. This profile will build an Ubuntu 12.04 LTS `nb.2G` instance.

```
/etc/salt/cloud.profiles.d/vh_ubuntu1204_2G.conf:

vh_ubuntu1204_2G:
  provider: my-vexxhost-config
  image: 4051139f-750d-4d72-8ef0-074f2c6c7e5a
  size: nb.2G
```
Provision an instance

To create an instance based on the sample profile that we created above, you can run the following `salt-cloud` command.

```
# salt-cloud -p vh_ubuntu1204_2G vh_instance1
```

Typically, instances are provisioned in under 30 seconds on the VEXXHOST public cloud. After the instance provisions, it will be set up a minion and then return all the instance information once it's complete.

Once the instance has been setup, you can test connectivity to it by running the following command:

```
# salt vh_instance1 test.ping
```

You can now continue to provision new instances and they will all automatically be set up as minions of the master you've defined in the configuration file.

### 25.7.19 Getting Started With VMware

New in version 2015.5.4.

**Author:** Nitin Madhok &lt;nmadhok@clemson.edu&gt;

The VMware cloud module allows you to manage VMware ESX, ESXi, and vCenter.

#### Dependencies

The vmware module for Salt Cloud requires the `pyVmomi` package, which is available at PyPI:

[https://pypi.python.org/pypi/pyvmomi](https://pypi.python.org/pypi/pyvmomi)

This package can be installed using `pip` or `easy_install`:

```
pip install pyvmomi
easy_install pyvmomi
```

**Note:** Version 6.0 of pyVmomi has some problems with SSL error handling on certain versions of Python. If using version 6.0 of pyVmomi, the machine that you are running the proxy minion process from must have either Python 2.7.9 or newer. This is due to an upstream dependency in pyVmomi 6.0 that is not supported in Python version 2.6 to 2.7.8. If the version of Python running the salt-cloud command is not in the supported range, you will need to install an earlier version of pyVmomi. See [Issue #29537](https://github.com/saltstack/salt/issues/29537) for more information.

#### Configuration

The VMware cloud module needs the vCenter URL, username and password to be set up in the cloud configuration at `/etc/salt/cloud.providers` or `/etc/salt/cloud.providers.d/vmware.conf`:

```
my-vmware-config:
  driver: vmware
  user: 'DOMAIN\user'
  password: 'verybadpass'
  url: '10.20.30.40'

vcenter01:
```

408 Chapter 25. Salt Cloud
driver: vmware
user: 'DOMAIN\user'
password: 'verybadpass'
url: 'vcenter01.domain.com'
protocol: 'https'
port: 443

vcenter02:
driver: vmware
user: 'DOMAIN\user'
password: 'verybadpass'
url: 'vcenter02.domain.com'
protocol: 'http'
port: 80

Note: Optionally, protocol and port can be specified if the vCenter server is not using the defaults. Default is protocol: https and port: 443.

Note: Changed in version 2015.8.0.
The provider parameter in cloud provider definitions was renamed to driver. This change was made to avoid confusion with the provider parameter that is used in cloud profile definitions. Cloud provider definitions now use driver to refer to the Salt cloud module that provides the underlying functionality to connect to a cloud host, while cloud profiles continue to use provider to refer to provider configurations that you define.

Profiles

Set up an initial profile at /etc/salt/cloud.profiles or /etc/salt/cloud.profiles.d/vmware.conf:

vmware-centos6.5:
  provider: vcenter01
  clonefrom: test-vm

## Optional arguments
num_cpus: 4
memory: 8GB
devices:
  cd:
    CD/DVD drive 1:
    device_type: datastore_iso_file
    iso_path: "[nap004-1] vmimages/tools-isoimages/linux.iso"
    CD/DVD drive 2:
    device_type: client_device
    mode: atapi
    CD/DVD drive 3:
    device_type: client_device
    mode: passthrough
disk:
  Hard disk 1:
    size: 30
  Hard disk 2:
    size: 20
  Hard disk 3:
size: 5

network:
  Network adapter 1:

  guestinfo.domain: foobar.com
  guestinfo.customVariable: customValue

deploy: True
private_key: /root/.ssh/mykey.pem
ssh_username: cloud-user
password: veryVeryBadPassword
minion:
master: 123.127.193.105

file_map:
/path/to/local/custom/script: /path/to/remote/script
/path/to/local/file: /path/to/remote/file
/srv/salt/yum/epel.repo: /etc/yum.repos.d/epel.repo

hardware_version: 10

**provider** Enter the name that was specified when the cloud provider config was created.

**clonefrom** Enter the name of the VM/template to clone from.

**num_cpus** Enter the number of vCPUs that you want the VM/template to have. If not specified, the current VM/template’s vCPU count is used.

**memory** Enter the memory size (in MB or GB) that you want the VM/template to have. If not specified, the current VM/template’s memory size is used. Example memory: 8GB or memory: 8192MB.

**devices** Enter the device specifications here. Currently, the following devices can be created or reconfigured:

- **cd** Enter the CD/DVD drive specification here. If the CD/DVD drive doesn’t exist, it will be created with the specified configuration. If the CD/DVD drive already exists, it will be reconfigured with the specifications. The following options can be specified per CD/DVD drive:
  - **device_type** Specify how the CD/DVD drive should be used. Currently supported types are `client_device` and `datastore_iso_file`. Default is `device_type: client_device`
  - **iso_path** Enter the path to the iso file present on the datastore only if `device_type: datastore_iso_file`. The syntax to specify this is `iso_path: "[datastoreName] vmimages/tools-isoimages/linux.iso"`. This field is ignored if `device_type: client_device`
  - **mode** Enter the mode of connection only if `device_type: client_device`. Currently supported modes are `passthrough` and `atapi`. This field is ignored if `device_type: datastore_iso_file`. Default is `mode: passthrough`

- **disk** Enter the disk specification here. If the hard disk doesn’t exist, it will be created with the provided size. If the hard disk already exists, it will be expanded if the provided size is greater than the current size of the disk.

- **network** Enter the network adapter specification here. If the network adapter doesn’t exist, a new network adapter will be created with the specified network name, type and other configuration. If the network adapter already exists, it will be reconfigured with the specifications. The following additional options can be specified per network adapter (See example above):
  - **name** Enter the network name you want the network adapter to be mapped to.
  - **adapter_type** Enter the network adapter type you want to create. Currently supported types are `vmxnet`, `vmxnet2`, `vmxnet3`, `e1000` and `e1000e`. If no type is specified, by default `vmxnet3` will be used.
  - **switch_type** Enter the type of switch to use. This decides whether to use a standard switch network or a distributed virtual portgroup. Currently supported types are `standard` for standard portgroups and `distributed` for distributed virtual portgroups.
  - **ip** Enter the static IP you want the network adapter to be mapped to. If the network specified is DHCP enabled, you do not have to specify this.
gateway  Enter the gateway for the network as a list. If the network specified is DHCP enabled, you do not have to specify this.

subnet_mask  Enter the subnet mask for the network. If the network specified is DHCP enabled, you do not have to specify this.

domain  Enter the domain to be used with the network adapter. If the network specified is DHCP enabled, you do not have to specify this.

scsi  Enter the SCSI adapter specification here. If the SCSI adapter doesn’t exist, a new SCSI adapter will be created of the specified type. If the SCSI adapter already exists, it will be reconfigured with the specifications. The following additional options can be specified per SCSI adapter:

type  Enter the SCSI adapter type you want to create. Currently supported types are lsilogic, lsi-logic_sas and paravirtual. Type must be specified when creating a new SCSI adapter.

bus_sharing  Specify this if sharing of virtual disks between virtual machines is desired. The following can be specified:

  virtual  Virtual disks can be shared between virtual machines on the same server.

  physical  Virtual disks can be shared between virtual machines on any server.

  no  Virtual disks cannot be shared between virtual machines.

domain  Enter the global domain name to be used for DNS. If not specified and if the VM name is a FQDN, domain is set to the domain from the VM name. Default is local.

dns_servers  Enter the list of DNS servers to use in order of priority.

resourcepool  Enter the name of the resourcepool to which the new virtual machine should be attached. This determines what compute resources will be available to the clone.

Note:

• For a clone operation from a virtual machine, it will use the same resourcepool as the original virtual machine unless specified.

• For a clone operation from a template to a virtual machine, specifying either this or cluster is required. If both are specified, the resourcepool value will be used.

• For a clone operation to a template, this argument is ignored.

cluster  Enter the name of the cluster whose resource pool the new virtual machine should be attached to.

Note:

• For a clone operation from a virtual machine, it will use the same cluster’s resourcepool as the original virtual machine unless specified.

• For a clone operation from a template to a virtual machine, specifying either this or resourcepool is required. If both are specified, the resourcepool value will be used.

• For a clone operation to a template, this argument is ignored.

datastore  Enter the name of the datastore or the datastore cluster where the virtual machine should be located on physical storage. If not specified, the current datastore is used.

Note:
- If you specify a datastore cluster name, DRS Storage recommendation is automatically applied.
- If you specify a datastore name, DRS Storage recommendation is disabled.

folder Enter the name of the folder that will contain the new virtual machine.

Note:
- For a clone operation from a VM/template, the new VM/template will be added to the same folder that the original VM/template belongs to unless specified.
- If both folder and datacenter are specified, the folder value will be used.

datacenter Enter the name of the datacenter that will contain the new virtual machine.

Note:
- For a clone operation from a VM/template, the new VM/template will be added to the same folder that the original VM/template belongs to unless specified.
- If both folder and datacenter are specified, the folder value will be used.

host Enter the name of the target host where the virtual machine should be registered.

If not specified:

Note:
- If resource pool is not specified, current host is used.
- If resource pool is specified, and the target pool represents a stand-alone host, the host is used.
- If resource pool is specified, and the target pool represents a DRS-enabled cluster, a host selected by DRS is used.
- If resource pool is specified and the target pool represents a cluster without DRS enabled, an InvalidArgument exception be thrown.

template Specifies whether the new virtual machine should be marked as a template or not. Default is template: False.

power_on Specifies whether the new virtual machine should be powered on or not. If template: True is set, this field is ignored. Default is power_on: True.

extra_config Specifies the additional configuration information for the virtual machine. This describes a set of modifications to the additional options. If the key is already present, it will be reset with the new value provided. Otherwise, a new option is added. Keys with empty values will be removed.

deploy Specifies if salt should be installed on the newly created VM. Default is True so salt will be installed using the bootstrap script. If template: True or power_on: False is set, this field is ignored and salt will not be installed.

private_key Specify the path to the private key to use to be able to ssh to the VM.

ssh_username Specify the username to use in order to ssh to the VM. Default is root

password Specify a password to use in order to ssh to the VM. If private_key is specified, you do not need to specify this.
minion Specify custom minion configuration you want the salt minion to have. A good example would be to specify the master as the IP/DNS name of the master.

file_map Specify file/files you want to copy to the VM before the bootstrap script is run and salt is installed. A good example of using this would be if you need to put custom repo files on the server in case your server will be in a private network and cannot reach external networks.

hardware_version Specify the virtual hardware version for the vm/template that is supported by the host.

customization Specify whether the new virtual machine should be customized or not. If customization: False is set, the new virtual machine will not be customized. Default is customization: True.

25.7.20 Getting Started With vSphere

Note: Deprecated since version Carbon: The vsphere cloud driver has been deprecated in favor of the vmware cloud driver and will be removed in Salt Carbon. Please refer to Getting started with VMware instead to get started with the configuration.

VMware vSphere is a management platform for virtual infrastructure and cloud computing.

Dependencies

The vsphere module for Salt Cloud requires the PySphere package, which is available at PyPI:

https://pypi.python.org/pypi/pysphere

This package can be installed using pip or easy_install:

```
# pip install pysphere
# easy_install pysphere
```

Configuration

Set up the cloud config at /etc/salt/cloud.providers or in the /etc/salt/cloud.providers.d/ directory:

```
my-vsphere-config:
  driver: vsphere
  # Set the vSphere access credentials
  user: marco
  password: polo
  # Set the URL of your vSphere server
  url: 'vsphere.example.com'
```

Note: Changed in version 2015.8.0.

The provider parameter in cloud provider definitions was renamed to driver. This change was made to avoid confusion with the provider parameter that is used in cloud profile definitions. Cloud provider definitions now use driver to refer to the Salt cloud module that provides the underlying functionality to connect to a cloud host, while cloud profiles continue to use provider to refer to provider configurations that you define.
Profiles

Cloud Profiles

vSphere uses a Managed Object Reference to identify objects located in vCenter. The MOR ID’s are used when configuring a vSphere cloud profile. Use the following reference when locating the MOR’s for the cloud profile.

http://kb.vmware.com/selfservice/microsites/search.do?cmd=displayKC&docType=kc&externalId=1017126&sliceId=1&docTypeID=DT_KB_1_1&dialogID=520386078&stateId=1%200%20520388386

Set up an initial profile at /etc/salt/cloud.profiles or in the /etc/salt/cloud.profiles.d directory:

```
vsphere-centos:
  provider: my-vsphere-config
  image: centos
  # Optional
datastore: datastore-15
  resourcepool: resgroup-8
  folder: salt-cloud
  host: host-9
  template: False
```

provider

Enter the name that was specified when the cloud provider profile was created.

image

Images available to build an instance can be found using the `--list-images` option:

```
# salt-cloud --list-images my-vsphere-config
```

datastore

The MOR of the datastore where the virtual machine should be located. If not specified, the current datastore is used.

resourcepool

The MOR of the resourcepool to be used for the new vm. If not set, it will use the same resourcepool as the original vm.

folder

Name of the folder that will contain the new VM. If not set, the VM will be added to the folder the original VM belongs to.
**host**

The MOR of the host where the VM should be registered.

If not specified:

- if resourcepool is not specified, the current host is used.
- if resourcepool is specified, and the target pool represents a stand-alone host, the host is used.
- if resourcepool is specified, and the target pool represents a DRS-enabled cluster, a host selected by DRS is used.
- if resourcepool is specified, and the target pool represents a cluster without DRS enabled, an InvalidArgument exception will be thrown.

**template**

Specifies whether or not the new virtual machine should be marked as a template. Default is False.

### 25.8 Miscellaneous Options

#### 25.8.1 Miscellaneous Salt Cloud Options

This page describes various miscellaneous options available in Salt Cloud

**Deploy Script Arguments**

Custom deploy scripts are unlikely to need custom arguments to be passed to them, but salt-bootstrap has been extended quite a bit, and this may be necessary. script_args can be specified in either the profile or the map file, to pass arguments to the deploy script:

```yaml
ec2-amazon:
    provider: my-ec2-config
    image: ami-1624987f
    size: t1.micro
    ssh_username: ec2-user
    script: bootstrap-salt
    script_args: -c /tmp/
```

This has also been tested to work with pipes, if needed:

```bash
script_args: | head
```

**Selecting the File Transport**

By default, Salt Cloud uses SFTP to transfer files to Linux hosts. However, if SFTP is not available, or specific SCP functionality is needed, Salt Cloud can be configured to use SCP instead.

```yaml
file_transport: sftp
file_transport: scp
```
Sync After Install

Salt allows users to create custom modules, grains, and states which can be synchronised to minions to extend Salt with further functionality.

This option will inform Salt Cloud to synchronise your custom modules, grains, states or all these to the minion just after it has been created. For this to happen, the following line needs to be added to the main cloud configuration file:

```makefile
sync_after_install: all
```

The available options for this setting are:

```plaintext
modules
grains
states
all
```

Setting Up New Salt Masters

It has become increasingly common for users to set up multi-hierarchal infrastructures using Salt Cloud. This sometimes involves setting up an instance to be a master in addition to a minion. With that in mind, you can now lay down master configuration on a machine by specifying master options in the profile or map file.

```makefile
make_master: True
```

This will cause Salt Cloud to generate master keys for the instance, and tell salt-bootstrap to install the salt-master package, in addition to the salt-minion package.

The default master configuration is usually appropriate for most users, and will not be changed unless specific master configuration has been added to the profile or map:

```plaintext
master:
  user: root
  interface: 0.0.0.0
```

Setting Up a Salt Syndic with Salt Cloud

In addition to setting up new Salt Masters, syndic’s can also be provisioned using Salt Cloud. In order to set up a Salt Syndic via Salt Cloud, a Salt Master needs to be installed on the new machine and a master configuration file needs to be set up using the `make_master` setting. This setting can be defined either in a profile config file or in a map file:

```makefile
make_master: True
```

To install the Salt Syndic, the only other specification that needs to be configured is the `syndic_master` key to specify the location of the master that the syndic will be reporting to. This modification needs to be placed in the master setting, which can be configured either in the profile, provider, or `/etc/salt/cloud` config file:

```plaintext
master:
  syndic_master: 123.456.789  # may be either an IP address or a hostname
```

Many other Salt Syndic configuration settings and specifications can be passed through to the new syndic machine via the `master` configuration setting. See the Salt Syndic documentation for more information.
SSH Port

By default ssh port is set to port 22. If you want to use a custom port in provider, profile, or map blocks use ssh_port option.

New in version 2015.5.0.

| ssh_port: 2222 |

Delete SSH Keys

When Salt Cloud deploys an instance, the SSH pub key for the instance is added to the known_hosts file for the user that ran the salt-cloud command. When an instance is deployed, a cloud host generally recycles the IP address for the instance. When Salt Cloud attempts to deploy an instance using a recycled IP address that has previously been accessed from the same machine, the old key in the known_hosts file will cause a conflict.

In order to mitigate this issue, Salt Cloud can be configured to remove old keys from the known_hosts file when destroying the node. In order to do this, the following line needs to be added to the main cloud configuration file:

| delete_sshkeys: True |

Keeping /tmp/ Files

When Salt Cloud deploys an instance, it uploads temporary files to /tmp/ for salt-bootstrap to put in place. After the script has run, they are deleted. To keep these files around (mostly for debugging purposes), the --keep-tmp option can be added:

```
salt-cloud -p myprofile mymachine --keep-tmp
```

For those wondering why /tmp/ was used instead of /root/, this had to be done for images which require the use of sudo, and therefore do not allow remote root logins, even for file transfers (which makes /root/ unavailable).

Hide Output From Minion Install

By default Salt Cloud will stream the output from the minion deploy script directly to STDOUT. Although this can been very useful, in certain cases you may wish to switch this off. The following config option is there to enable or disable this output:

| display_ssh_output: False |

Connection Timeout

There are several stages when deploying Salt where Salt Cloud needs to wait for something to happen. The VM getting it's IP address, the VM's SSH port is available, etc.

If you find that the Salt Cloud defaults are not enough and your deployment fails because Salt Cloud did not wait log enough, there are some settings you can tweak.

---

**Note**

All settings should be provided in lowercase All values should be provided in seconds
You can tweak these settings globally, per cloud provider, or event per profile definition.

**wait_for_ip_timeout**

The amount of time Salt Cloud should wait for a VM to start and get an IP back from the cloud host. Default: varies by cloud provider (between 5 and 25 minutes)

**wait_for_ip_interval**

The amount of time Salt Cloud should sleep while querying for the VM's IP. Default: varies by cloud provider (between .5 and 10 seconds)

**ssh_connect_timeout**

The amount of time Salt Cloud should wait for a successful SSH connection to the VM. Default: varies by cloud provider (between 5 and 15 minutes)

**wait_for_passwd_timeout**

The amount of time until an ssh connection can be established via password or ssh key. Default: varies by cloud provider (mostly 15 seconds)

**wait_for_passwd_maxtries**

The number of attempts to connect to the VM until we abandon. Default: 15 attempts

**wait_for_fun_timeout**

Some cloud drivers check for an available IP or a successful SSH connection using a function, namely, SoftLayer, and SoftLayer-HW. So, the amount of time Salt Cloud should retry such functions before failing. Default: 15 minutes.

**wait_for_spot_timeout**

The amount of time Salt Cloud should wait before an EC2 Spot instance is available. This setting is only available for the EC2 cloud driver. Default: 10 minutes

**Salt Cloud Cache**

Salt Cloud can maintain a cache of node data, for supported providers. The following options manage this functionality.
update_cachedir

On supported cloud providers, whether or not to maintain a cache of nodes returned from a --full-query. The data will be stored in msgpack format under `<SALT_CACHEDIR>/cloud/active/<DRIVER>/<PROVIDER>/<NODE_NAME>.p`. This setting can be True or False.

diff_cache_events

When the cloud cachedir is being managed, if differences are encountered between the data that is returned live from the cloud host and the data in the cache, fire events which describe the changes. This setting can be True or False.

Some of these events will contain data which describe a node. Because some of the fields returned may contain sensitive data, the cache_event_strip_fields configuration option exists to strip those fields from the event return.

```
cache_event_strip_fields:
    - password
    - priv_key
```

The following are events that can be fired based on this data.

salt/cloud/minionid/cache_node_new

A new node was found on the cloud host which was not listed in the cloud cachedir. A dict describing the new node will be contained in the event.

salt/cloud/minionid/cache_node_missing

A node that was previously listed in the cloud cachedir is no longer available on the cloud host.

salt/cloud/minionid/cache_node_diff

One or more pieces of data in the cloud cachedir has changed on the cloud host. A dict containing both the old and the new data will be contained in the event.

SSH Known Hosts

Normally when bootstrapping a VM, salt-cloud will ignore the SSH host key. This is because it does not know what the host key is before starting (because it doesn't exist yet). If strict host key checking is turned on without the key in the known_hosts file, then the host will never be available, and cannot be bootstrapped.

If a provider is able to determine the host key before trying to bootstrap it, that provider's driver can add it to the known_hosts file, and then turn on strict host key checking. This can be set up in the main cloud configuration file (normally /etc/salt/cloud) or in the provider-specific configuration file:

```
known_hosts_file: /path/to/.ssh/known_hosts
```
If this is not set, it will default to /dev/null, and strict host key checking will be turned off.

It is highly recommended that this option is not set, unless the user has verified that the provider supports this functionality, and that the image being used is capable of providing the necessary information. At this time, only the EC2 driver supports this functionality.

### SSH Agent

New in version 2015.5.0.

If the ssh key is not stored on the server salt-cloud is being run on, set ssh_agent, and salt-cloud will use the forwarded ssh-agent to authenticate.

```yaml
sshd_agent: True
```

### File Map Upload

New in version 2014.7.0.

The file_map option allows an arbitrary group of files to be uploaded to the target system before running the deploy script. This functionality requires a provider uses salt.utils.cloud.bootstrap(), which is currently limited to the ec2, gce, openstack and nova drivers.

The file_map can be configured globally in /etc/salt/cloud, or in any cloud provider or profile file. For example, to upload an extra package or a custom deploy script, a cloud profile using file_map might look like:

```yaml
ubuntu14:
  provider: ec2-config
  image: ami-98aa1cf0
  size: t1.micro
  ssh_username: root
  securitygroup: default
  file_map:
    /local/path/to/custom/script: /remote/path/to/use/custom/script
    /local/path/to/package: /remote/path/to/store/package
```

### 25.9 Troubleshooting Steps

#### 25.9.1 Troubleshooting Salt Cloud

This page describes various steps for troubleshooting problems that may arise while using Salt Cloud.

**Virtual Machines Are Created, But Do Not Respond**

Are TCP ports 4505 and 4506 open on the master? This is easy to overlook on new masters. Information on how to open firewall ports on various platforms can be found [here](#).

**Generic Troubleshooting Steps**

This section describes a set of instructions that are useful to a large number of situations, and are likely to solve most issues that arise.
Version Compatibility

One of the most common issues that Salt Cloud users run into is import errors. These are often caused by version compatibility issues with Salt.

- Salt 0.16.x works with Salt Cloud 0.8.9 or greater.
- Salt 0.17.x requires Salt Cloud 0.8.11.

Releases after 0.17.x (0.18 or greater) should not encounter issues as Salt Cloud has been merged into Salt itself.

Debug Mode

Frequently, running Salt Cloud in debug mode will reveal information about a deployment which would otherwise not be obvious:

```
salt-cloud -p myprofile myinstance -l debug
```

Keep in mind that a number of messages will appear that look at first like errors, but are in fact intended to give developers factual information to assist in debugging. A number of messages that appear will be for cloud providers that you do not have configured; in these cases, the message usually is intended to confirm that they are not configured.

Salt Bootstrap

By default, Salt Cloud uses the Salt Bootstrap script to provision instances:

This script is packaged with Salt Cloud, but may be updated without updating the Salt package:

```
salt-cloud -u
```

The Bootstrap Log

If the default deploy script was used, there should be a file in the `/tmp/` directory called `bootstrap-salt.log`. This file contains the full output from the deployment, including any errors that may have occurred.

Keeping Temp Files

Salt Cloud uploads minion-specific files to instances once they are available via SSH, and then executes a deploy script to put them into the correct place and install Salt. The `--keep-tmp` option will instruct Salt Cloud not to remove those files when finished with them, so that the user may inspect them for problems:

```
salt-cloud -p myprofile myinstance --keep-tmp
```

By default, Salt Cloud will create a directory on the target instance called `/tmp/.saltcloud/`. This directory should be owned by the user that is to execute the deploy script, and should have permissions of `0700`.

Most cloud hosts are configured to use `root` as the default initial user for deployment, and as such, this directory and all files in it should be owned by the `root` user.

The `/tmp/.saltcloud/` directory should the following files:

- A `deploy.sh` script. This script should have permissions of `0755`. 
- A .pem and .pub key named after the minion. The .pem file should have permissions of 0600. Ensure that the .pem and .pub files have been properly copied to the /etc/salt/pki/minion/ directory.

- A file called minion. This file should have been copied to the /etc/salt/ directory.

- Optionally, a file called grains. This file, if present, should have been copied to the /etc/salt/ directory.

**Unprivileged Primary Users**

Some cloud hosts, most notably EC2, are configured with a different primary user. Some common examples are ec2-user, ubuntu, fedora, and bitnami. In these cases, the /tmp/.saltcloud/ directory and all files in it should be owned by this user.

Some cloud hosts, such as EC2, are configured to not require these users to provide a password when using the sudo command. Because it is more secure to require sudo users to provide a password, other hosts are configured that way.

If this instance is required to provide a password, it needs to be configured in Salt Cloud. A password for sudo to use may be added to either the provider configuration or the profile configuration:

```
sudo_password: mypassword
```

**/tmp/ is Mounted as noexec**

It is more secure to mount the /tmp/ directory with a noexec option. This is uncommon on most cloud hosts, but very common in private environments. To see if the /tmp/ directory is mounted this way, run the following command:

```
mount | grep tmp
```

The if the output of this command includes a line that looks like this, then the /tmp/ directory is mounted as noexec:

```
tmpfs on /tmp type tmpfs (rw,noexec)
```

If this is the case, then the deploy_command will need to be changed in order to run the deploy script through the sh command, rather than trying to execute it directly. This may be specified in either the provider or the profile config:

```
deploy_command: sh /tmp/.saltcloud/deploy.sh
```

Please note that by default, Salt Cloud will place its files in a directory called /tmp/.saltcloud/. This may be also be changed in the provider or profile configuration:

```
tmp_dir: /tmp/.saltcloud/
```

If this directory is changed, then the deploy_command need to be changed in order to reflect the tmp_dir configuration.

**Executing the Deploy Script Manually**

If all of the files needed for deployment were successfully uploaded to the correct locations, and contain the correct permissions and ownerships, the deploy script may be executed manually in order to check for other issues:
25.10 Extending Salt Cloud

25.10.1 Writing Cloud Driver Modules

Salt Cloud runs on a module system similar to the main Salt project. The modules inside saltcloud exist in the `salt/cloud/clouds` directory of the salt source.

There are two basic types of cloud modules. If a cloud host is supported by libcloud, then using it is the fastest route to getting a module written. The Apache Libcloud project is located at:

http://libcloud.apache.org/

Not every cloud host is supported by libcloud. Additionally, not every feature in a supported cloud host is necessarily supported by libcloud. In either of these cases, a module can be created which does not rely on libcloud.

All Driver Modules

The following functions are required by all driver modules, whether or not they are based on libcloud.

The `__virtual__`() Function

This function determines whether or not to make this cloud module available upon execution. Most often, it uses `get_configured_provider()` to determine if the necessary configuration has been set up. It may also check for necessary imports, to decide whether to load the module. In most cases, it will return a `True` or `False` value. If the name of the driver used does not match the filename, then that name should be returned instead of `True`. An example of this may be seen in the Azure module:

https://github.com/saltstack/salt/tree/develop/salt/cloud/clouds/msazure.py

The `get_configured_provider()` Function

This function uses `config.is_provider_configured()` to determine whether all required information for this driver has been configured. The last value in the list of required settings should be followed by a comma.

Libcloud Based Modules

Writing a cloud module based on libcloud has two major advantages. First of all, much of the work has already been done by the libcloud project. Second, most of the functions necessary to Salt have already been added to the Salt Cloud project.

The `create()` Function

The most important function that does need to be manually written is the `create()` function. This is what is used to request a virtual machine to be created by the cloud host, wait for it to become available, and then (optionally) log in and install Salt on it.
A good example to follow for writing a cloud driver module based on libcloud is the module provided for Linode:
https://github.com/saltstack/salt/tree/develop/salt/cloud/clouds/linode.py

The basic flow of a `create()` function is as follows:

- Send a request to the cloud host to create a virtual machine.
- Wait for the virtual machine to become available.
- Generate kwargs to be used to deploy Salt.
- Log into the virtual machine and deploy Salt.
- Return a data structure that describes the newly-created virtual machine.

At various points throughout this function, events may be fired on the Salt event bus. Four of these events, which are described below, are required. Other events may be added by the user, where appropriate.

When the `create()` function is called, it is passed a data structure called `vm_`. This dict contains a composite of information describing the virtual machine to be created. A dict called `__opts__` is also provided by Salt, which contains the options used to run Salt Cloud, as well as a set of configuration and environment variables.

The first thing the `create()` function must do is fire an event stating that it has started the create process. This event is tagged `salt/cloud/<vm name>/creating`. The payload contains the names of the VM, profile, and provider.

A set of kwargs is then usually created, to describe the parameters required by the cloud host to request the virtual machine.

An event is then fired to state that a virtual machine is about to be requested. It is tagged as `salt/cloud/<vm name>/requesting`. The payload contains most or all of the parameters that will be sent to the cloud host. Any private information (such as passwords) should not be sent in the event.

After a request is made, a set of deploy kwargs will be generated. These will be used to install Salt on the target machine. Windows options are supported at this point, and should be generated, even if the cloud host does not currently support Windows. This will save time in the future if the host does eventually decide to support Windows.

An event is then fired to state that the deploy process is about to begin. This event is tagged `salt/cloud/<vm name>/deploying`. The payload for the event will contain a set of deploy kwargs, useful for debugging purposes. Any private data, including passwords and keys (including public keys) should be stripped from the deploy kwargs before the event is fired.

If any Windows options have been passed in, the `salt.utils.cloud.deploy_windows()` function will be called. Otherwise, it will be assumed that the target is a Linux or Unix machine, and the `salt.utils.cloud.deploy_script()` will be called.

Both of these functions will wait for the target machine to become available, then the necessary port to log in, then a successful login that can be used to install Salt. Minion configuration and keys will then be uploaded to a temporary directory on the target by the appropriate function. On a Windows target, the Windows Minion Installer will be run in silent mode. On a Linux/Unix target, a deploy script (`bootstrap-salt.sh`, by default) will be run, which will auto-detect the operating system, and install Salt using its native package manager. These do not need to be handled by the developer in the cloud module.

The `salt.utils.cloud.validate_windows_creds()` function has been extended to take the number of retries and retry_delay parameters in case a specific cloud host has a delay between providing the Windows credentials and the credentials being available for use. In their `create()` function, or as a a sub-function called during the creation process, developers should use the `win_deploy_auth_retries` and `win_deploy_auth_retry_delay` parameters from the provider configuration to allow the end-user the ability to customize the number of tries and delay between tries for their particular host.
After the appropriate deploy function completes, a final event is fired which describes the virtual machine that has just been created. This event is tagged `salt/cloud/<vm name>/created`. The payload contains the names of the VM, profile, and provider.

Finally, a dict (queried from the provider) which describes the new virtual machine is returned to the user. Because this data is not fired on the event bus it can, and should, return any passwords that were returned by the cloud host. In some cases (for example, Rackspace), this is the only time that the password can be queried by the user; post-creation queries may not contain password information (depending upon the host).

**The libcloudfuncs Functions**

A number of other functions are required for all cloud hosts. However, with libcloud-based modules, these are all provided for free by the libcloudfuncs library. The following two lines set up the imports:

```python
from salt.cloud.libcloudfuncs import *  # pylint: disable=W0614,W0401
from salt.utils import namespaced_function
```

And then a series of declarations will make the necessary functions available within the cloud module.

```python
get_size = namespaced_function(get_size, globals())
get_image = namespaced_function(get_image, globals())
avail_locations = namespaced_function(avail_locations, globals())
avail_images = namespaced_function(avail_images, globals())
avail_sizes = namespaced_function(avail_sizes, globals())
script = namespaced_function(script, globals())
destroy = namespaced_function(destroy, globals())
list_nodes = namespaced_function(list_nodes, globals())
list_nodes_full = namespaced_function(list_nodes_full, globals())
list_nodes_select = namespaced_function(list_nodes_select, globals())
show_instance = namespaced_function(show_instance, globals())
```

If necessary, these functions may be replaced by removing the appropriate declaration line, and then adding the function as normal.

These functions are required for all cloud modules, and are described in detail in the next section.

**Non-Libcloud Based Modules**

In some cases, using libcloud is not an option. This may be because libcloud has not yet included the necessary driver itself, or it may be that the driver that is included with libcloud does not contain all of the necessary features required by the developer. When this is the case, some or all of the functions in `libcloudfuncs` may be replaced. If they are all replaced, the libcloud imports should be absent from the Salt Cloud module.

A good example of a non-libcloud driver is the DigitalOcean driver:

https://github.com/saltstack/salt/tree/develop/salt/cloud/clouds/digital_ocean.py

**The create() Function**

The `create()` function must be created as described in the libcloud-based module documentation.

**The get_size() Function**

This function is only necessary for libcloud-based modules, and does not need to exist otherwise.
The `get_image()` Function

This function is only necessary for libcloud-based modules, and does not need to exist otherwise.

The `avail_locations()` Function

This function returns a list of locations available, if the cloud host uses multiple data centers. It is not necessary if the cloud host uses only one data center. It is normally called using the `--list-locations` option.

```
salt-cloud --list-locations my-cloud-provider
```

The `avail_images()` Function

This function returns a list of images available for this cloud provider. There are not currently any known cloud providers that do not provide this functionality, though they may refer to images by a different name (for example, `templates`). It is normally called using the `--list-images` option.

```
salt-cloud --list-images my-cloud-provider
```

The `avail_sizes()` Function

This function returns a list of sizes available for this cloud provider. Generally, this refers to a combination of RAM, CPU, and/or disk space. This functionality may not be present on some cloud providers. For example, the Parallels module breaks down RAM, CPU, and disk space into separate options, whereas in other providers, these options are baked into the image. It is normally called using the `--list-sizes` option.

```
salt-cloud --list-sizes my-cloud-provider
```

The `script()` Function

This function builds the deploy script to be used on the remote machine. It is likely to be moved into the `salt.utils.cloud` library in the near future, as it is very generic and can usually be copied wholesale from another module. An excellent example is in the Azure driver.

The `destroy()` Function

This function irreversibly destroys a virtual machine on the cloud provider. Before doing so, it should fire an event on the Salt event bus. The tag for this event is `salt/cloud/<vm name>/destroying`. Once the virtual machine has been destroyed, another event is fired. The tag for that event is `salt/cloud/<vm name>/destroyed`. This function is normally called with the `-d` options:

```
salt-cloud -d myinstance
```

The `list_nodes()` Function

This function returns a list of nodes available on this cloud provider, using the following fields:
- id (str)
- image (str)
- size (str)
- state (str)
- private_ips (list)
- public_ips (list)

No other fields should be returned in this function, and all of these fields should be returned, even if empty. The private_ips and public_ips fields should always be of a list type, even if empty, and the other fields should always be of a str type. This function is normally called with the -Q option:

salt-cloud -Q

The list_nodes_full() Function

All information available about all nodes should be returned in this function. The fields in the list_nodes() function should also be returned, even if they would not normally be provided by the cloud provider. This is because some functions both within Salt and 3rd party will break if an expected field is not present. This function is normally called with the -F option:

salt-cloud -F

The list_nodes_select() Function

This function returns only the fields specified in the query.selection option in /etc/salt/cloud. Because this function is so generic, all of the heavy lifting has been moved into the salt.utils.cloud library.

A function to call list_nodes_select() still needs to be present. In general, the following code can be used as-is:

```python
def list_nodes_select(call=None):
    '''
    Return a list of the VMs that are on the provider, with select fields
    '''
    return salt.utils.cloud.list_nodes_select(
        list_nodes_full('function'), __opts__['query.selection'], call,
    )
```

However, depending on the cloud provider, additional variables may be required. For instance, some modules use a conn object, or may need to pass other options into list_nodes_full(). In this case, be sure to update the function appropriately:

```python
def list_nodes_select(conn=None, call=None):
    '''
    Return a list of the VMs that are on the provider, with select fields
    '''
    if not conn:
        conn = get_conn()  # pylint: disable=E0602

    return salt.utils.cloud.list_nodes_select(
        list_nodes_full(conn, 'function'),
        __opts__['query.selection'],
    )
```
The show_instance() Function

This function is used to display all of the information about a single node that is available from the cloud provider. The simplest way to provide this is usually to call `list_nodes_full()`, and return just the data for the requested node. It is normally called as an action:

```
salt-cloud -a show_instance myinstance
```

Actions and Functions

Extra functionality may be added to a cloud provider in the form of an `--action` or a `--function`. Actions are performed against a cloud instance/virtual machine, and functions are performed against a cloud provider.

Actions

Actions are calls that are performed against a specific instance or virtual machine. The `show_instance` action should be available in all cloud modules. Actions are normally called with the `-a` option:

```
salt-cloud -a show_instance myinstance
```

Actions must accept a `name` as a first argument, may optionally support any number of `kwargs` as appropriate, and must accept an argument of `call`, with a default of `None`.

Before performing any other work, an action should normally verify that it has been called correctly. It may then perform the desired feature, and return useful information to the user. A basic action looks like:

```python
def show_instance(name, call=None):
    
    '''Show the details from EC2 concerning an AMI'''
    
    if call != 'action':
        raise SaltCloudSystemExit(
            'The show_instance action must be called with -a or --action.'
        )
    
    return _get_node(name)
```

Please note that generic `kwargs`, if used, are passed through to actions as `kwargs` and not `**kwargs`. An example of this is seen in the Functions section.

Functions

Functions are called that are performed against a specific cloud provider. An optional function that is often useful is `show_image`, which describes an image in detail. Functions are normally called with the `-f` option:
A function may accept any number of kwargs as appropriate, and must accept an argument of call with a default of None.

Before performing any other work, a function should normally verify that it has been called correctly. It may then perform the desired feature, and return useful information to the user. A basic function looks like:

```python
def show_image(kwargs, call=None):
    '''Show the details from EC2 concerning an AMI
    '''
    if call != 'function':
        raise SaltCloudSystemExit('The show_image action must be called with -f or --function.'
    )
    params = {'ImageId.1': kwargs['image'],
              'Action': 'DescribeImages'}
    result = query(params)
    log.info(result)
    return result
```

Take note that generic kwargs are passed through to functions as kwargs and not **kwargs.

### 25.10.2 Cloud deployment scripts

Salt Cloud works primarily by executing a script on the virtual machines as soon as they become available. The script that is executed is referenced in the cloud profile as the `script`. In older versions, this was the `os` argument. This was changed in 0.8.2.

A number of legacy scripts exist in the deploy directory in the saltcloud source tree. The preferred method is currently to use the salt-bootstrap script. A stable version is included with each release tarball starting with 0.8.4. The most updated version can be found at:

https://github.com/saltstack/salt-bootstrap

Note that, somewhat counter-intuitively, this script is referenced as `bootstrap-salt` in the configuration.

You can specify a deploy script in the cloud configuration file (`/etc/salt/cloud` by default):

```
script: bootstrap-salt
```

Or in a provider:

```
my-provider:
    # snip...
    script: bootstrap-salt
```

Or in a profile:

```
my-profile:
    provider: my-provider
    # snip...
    script: bootstrap-salt
```
If you do not specify a script argument in your cloud configuration file, provider configuration or profile configuration, the `bootstrap-salt` script will be used by default.

**Other Generic Deploy Scripts**

If you want to be assured of always using the latest Salt Bootstrap script, there are a few generic templates available in the deploy directory of your saltcloud source tree:

<table>
<thead>
<tr>
<th>Script</th>
</tr>
</thead>
<tbody>
<tr>
<td>curl-bootstrap</td>
</tr>
<tr>
<td>curl-bootstrap-git</td>
</tr>
<tr>
<td>python-bootstrap</td>
</tr>
<tr>
<td>wget-bootstrap</td>
</tr>
<tr>
<td>wget-bootstrap-git</td>
</tr>
</tbody>
</table>

These are example scripts which were designed to be customized, adapted, and refit to meet your needs. One important use of them is to pass options to the salt-bootstrap script, such as updating to specific git tags.

**Custom Deploy Scripts**

If the Salt Bootstrap script does not meet your needs, you may write your own. The script should be written in shell and is a Jinja template. Deploy scripts need to execute a number of functions to do a complete salt setup. These functions include:

1. Install the salt minion. If this can be done via system packages this method is HIGHLY preferred.
2. Add the salt minion keys before the minion is started for the first time. The minion keys are available as strings that can be copied into place in the Jinja template under the dict named `vm`.
3. Start the salt-minion daemon and enable it at startup time.
4. Set up the minion configuration file from the `minion` data available in the Jinja template.

A good, well commented example of this process is the Fedora deployment script:

https://github.com/saltstack/salt-cloud/blob/master/saltcloud/deploy/Fedora.sh

A number of legacy deploy scripts are included with the release tarball. None of them are as functional or complete as Salt Bootstrap, and are still included for academic purposes.

Custom deploy scripts are picked up from `/etc/salt/cloud.deploy.d` by default, but you can change the location of deploy scripts with the cloud configuration `deploy_scripts_search_path`. Additionally, if your deploy script has the extension `.sh`, you can leave out the extension in your configuration.

For example, if your custom deploy script is located in `/etc/salt/cloud.deploy.d/my_deploy.sh`, you could specify it in a cloud profile like this:

```yaml
my-profile:
  provider: my-provider
  # snip...
  script: my_deploy
```

You're also free to use the full path to the script if you like. Using full paths, your script doesn't have to live inside `/etc/salt/cloud.deploy.d` or whatever you've configured with `deploy_scripts_search_path`.

25.10. Extending Salt Cloud 431
Post-Deploy Commands

Once a minion has been deployed, it has the option to run a salt command. Normally, this would be the `state.apply`, which would finish provisioning the VM. Another common option (for testing) is to use `test.ping`. This is configured in the main cloud config file:

```
start_action: state.apply
```

This is currently considered to be experimental functionality, and may not work well with all cloud hosts. If you experience problems with Salt Cloud hanging after Salt is deployed, consider using Startup States instead:

http://docs.saltstack.com/ref/states/startup.html

Skipping the Deploy Script

For whatever reason, you may want to skip the deploy script altogether. This results in a VM being spun up much faster, with absolutely no configuration. This can be set from the command line:

```
salt-cloud --no-deploy -p micro_aws my_instance
```

Or it can be set from the main cloud config file:

```
deploy: False
```

Or it can be set from the provider's configuration:

```
RACKSPACE.user: example_user
RACKSPACE.apikey: 123984bjjas87034
RACKSPACE.deploy: False
```

Or even on the VM's profile settings:

```
ubuntu_aws:
  provider: my-ec2-config
  image: ami-7e2da54e
  size: t1.micro
  deploy: False
```

The default for deploy is True.

In the profile, you may also set the script option to `None`:

```
script: None
```

This is the slowest option, since it still uploads the None deploy script and executes it.

Updating Salt Bootstrap

Salt Bootstrap can be updated automatically with `salt-cloud`:

```
salt-cloud -u
salt-cloud --update-bootstrap
```

Bear in mind that this updates to the latest `stable` version from:

To update Salt Bootstrap script to the `develop` version, run the following command on the Salt minion host with `salt-cloud` installed:

```shell
salt-call config.gather_bootstrap_script 'https://bootstrap.saltstack.com/develop/bootstrap-salt.sh'
```

Or just download the file manually:

```shell
curl -L 'https://bootstrap.saltstack.com/develop' > /etc/salt/cloud.deploy.d/bootstrap-salt.sh
```

### Keeping `/tmp/` Files

When Salt Cloud deploys an instance, it uploads temporary files to `/tmp/` for salt-bootstrap to put in place. After the script has run, they are deleted. To keep these files around (mostly for debugging purposes), the `--keep-tmp` option can be added:

```
salt-cloud -p myprofile mymachine --keep-tmp
```

For those wondering why `/tmp/` was used instead of `/root/`, this had to be done for images which require the use of `sudo`, and therefore do not allow remote root logins, even for file transfers (which makes `/root/` unavailable).

### Deploy Script Arguments

Custom deploy scripts are unlikely to need custom arguments to be passed to them, but salt-bootstrap has been extended quite a bit, and this may be necessary. `script_args` can be specified in either the profile or the map file, to pass arguments to the deploy script:

```yaml
aws-amazon:
  provider: my-ec2-config
  image: ami-1624987f
  size: t1.micro
  ssh_username: ec2-user
  script: bootstrap-salt
  script_args: -c /tmp/
```

This has also been tested to work with pipes, if needed:

```
script_args: | head
```

## 25.11 Using Salt Cloud from Salt

### 25.11.1 Using the Salt Modules for Cloud

In addition to the `salt-cloud` command, Salt Cloud can be called from Salt, in a variety of different ways. Most users will be interested in either the execution module or the state module, but it is also possible to call Salt Cloud as a runner.

Because the actual work will be performed on a remote minion, the normal Salt Cloud configuration must exist on any target minion that needs to execute a Salt Cloud command. Because Salt Cloud now supports breaking out configuration into individual files, the configuration is easily managed using Salt’s own `file.managed` state function. For example, the following directories allow this configuration to be managed easily:
Minion Keys

Keep in mind that when creating minions, Salt Cloud will create public and private minion keys, upload them to the minion, and place the public key on the machine that created the minion. It will not attempt to place any public minion keys on the master, unless the minion which was used to create the instance is also the Salt Master. This is because granting arbitrary minions access to modify keys on the master is a serious security risk, and must be avoided.

Execution Module

The cloud module is available to use from the command line. At the moment, almost every standard Salt Cloud feature is available to use. The following commands are available:

**list_images**

This command is designed to show images that are available to be used to create an instance using Salt Cloud. In general they are used in the creation of profiles, but may also be used to create an instance directly (see below). Listing images requires a provider to be configured, and specified:

```
salt myminion cloud.list_images my-cloud-provider
```

**list_sizes**

This command is designed to show sizes that are available to be used to create an instance using Salt Cloud. In general they are used in the creation of profiles, but may also be used to create an instance directly (see below). This command is not available for all cloud providers; see the provider-specific documentation for details. Listing sizes requires a provider to be configured, and specified:

```
salt myminion cloud.list_sizes my-cloud-provider
```

**list_locations**

This command is designed to show locations that are available to be used to create an instance using Salt Cloud. In general they are used in the creation of profiles, but may also be used to create an instance directly (see below). This command is not available for all cloud providers; see the provider-specific documentation for details. Listing locations requires a provider to be configured, and specified:

```
salt myminion cloud.list_locations my-cloud-provider
```

**query**

This command is used to query all configured cloud providers, and display all instances associated with those accounts. By default, it will run a standard query, returning the following fields:

**id** The name or ID of the instance, as used by the cloud provider.
image  The disk image that was used to create this instance.

private_ips  Any public IP addresses currently assigned to this instance.

current_ips  Any private IP addresses currently assigned to this instance.

size  The size of the instance; can refer to RAM, CPU(s), disk space, etc., depending on the cloud provider.

state  The running state of the instance; for example, running, stopped, pending, etc. This state is dependent upon the provider.

This command may also be used to perform a full query or a select query, as described below. The following usages are available:

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>salt myminion cloud.query</td>
<td>Performs a query on all cloud providers.</td>
</tr>
<tr>
<td>salt myminion cloud.query list_nodes</td>
<td>Lists all nodes in the cloud.</td>
</tr>
<tr>
<td>salt myminion cloud.query list_nodes_full</td>
<td>Lists all fields for the cloud provider.</td>
</tr>
</tbody>
</table>

full_query

This command behaves like the query command, but lists all information concerning each instance as provided by the cloud provider, in addition to the fields returned by the query command.

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>salt myminion cloud.full_query</td>
<td>Lists all information for all instances.</td>
</tr>
</tbody>
</table>

select_query

This command behaves like the query command, but only returned select fields as defined in the /etc/salt/cloud configuration file. A sample configuration for this section of the file might look like:

```yaml
query.selection:
  - id
  - key_name
```

This configuration would only return the id and key_name fields, for those cloud providers that support those two fields. This would be called using the following command:

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>salt myminion cloud.select_query</td>
<td>Returns only select fields.</td>
</tr>
</tbody>
</table>

profile

This command is used to create an instance using a profile that is configured on the target minion. Please note that the profile must be configured before this command can be used with it.

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>salt myminion cloud.profile ec2-centos64-x64 my-new-instance</td>
<td>Creates an instance using a specified profile.</td>
</tr>
</tbody>
</table>

Please note that the execution module does not run in parallel mode. Using multiple minions to create instances can effectively perform parallel instance creation.
create

This command is similar to the profile command, in that it is used to create a new instance. However, it does not require a profile to be pre-configured. Instead, all of the options that are normally configured in a profile are passed directly to Salt Cloud to create the instance:

```
salt myminion cloud.create my-ec2-config my-new-instance \
    image=ami-1624987f size='t1.micro' ssh_username=ec2-user \
    securitygroup=default delvol_on_destroy=True
```

Please note that the execution module does not run in parallel mode. Using multiple minions to create instances can effectively perform parallel instance creation.

destroy

This command is used to destroy an instance or instances. This command will search all configured providers and remove any instance(s) which matches the name(s) passed in here. The results of this command are non-reversible and should be used with caution.

```
salt myminion cloud.destroy myinstance
salt myminion cloud.destroy myinstance1,myinstance2
```

action

This command implements both the action and the function commands used in the standard salt-cloud command. If one of the standard action commands is used, an instance name must be provided. If one of the standard function commands is used, a provider configuration must be named.

```
salt myminion cloud.action start instance=myinstance
salt myminion cloud.action show_image provider=my-ec2-config \
    image=ami-1624987f
```

The actions available are largely dependent upon the module for the specific cloud provider. The following actions are available for all cloud providers:

- **list_nodes**  This is a direct call to the query function as described above, but is only performed against a single cloud provider. A provider configuration must be included.

- **list_nodes_select**  This is a direct call to the full_query function as described above, but is only performed against a single cloud provider. A provider configuration must be included.

- **list_nodes_select**  This is a direct call to the select_query function as described above, but is only performed against a single cloud provider. A provider configuration must be included.

- **show_instance**  This is a thin wrapper around list_nodes, which returns the full information about a single instance. An instance name must be provided.

State Module

A subset of the execution module is available through the cloud state module. Not all functions are currently included, because there is currently insufficient code for them to perform statefully. For example, a command to create an instance may be issued with a series of options, but those options cannot currently be statefully managed. Additional states to manage these options will be released at a later time.
cloud.present

This state will ensure that an instance is present inside a particular cloud provider. Any option that is normally specified in the \texttt{cloud.create} execution module and function may be declared here, but only the actual presence of the instance will be managed statefully.

```yaml
my-instance-name:
  cloud.present:
    - provider: my-ec2-config
    - image: ami-1624987f
    - size: 't1.micro'
    - ssh_username: ec2-user
    - securitygroup: default
    - delvol_on_destroy: True
```

cloud.profile

This state will ensure that an instance is present inside a particular cloud provider. This function calls the \texttt{cloud.profile} execution module and function, but as with \texttt{cloud.present}, only the actual presence of the instance will be managed statefully.

```yaml
my-instance-name:
  cloud.profile:
    - profile: ec2-centos64-x64
```

cloud.absent

This state will ensure that an instance (identified by name) does not exist in any of the cloud providers configured on the target minion. Please note that this state is \textit{non-reversable} and may be considered especially destructive when issued as a cloud state.

```yaml
my-instance-name:
  cloud.absent
```

Runner Module

The \texttt{cloud} runner module is executed on the master, and performs actions using the configuration and Salt modules on the master itself. This means that any public minion keys will also be properly accepted by the master.

Using the functions in the runner module is no different than using those in the execution module, outside of the behavior described in the above paragraph. The following functions are available inside the runner:

- \texttt{list_images}
- \texttt{list_sizes}
- \texttt{list_locations}
- \texttt{query}
- \texttt{full_query}
- \texttt{select_query}
- \texttt{profile}
Outside of the standard usage of `salt-run` itself, commands are executed as usual:

```
salt-run cloud.profile ec2-centos64-x86_64 my-instance-name
```

### CloudClient

The execution, state, and runner modules ultimately all use the CloudClient library that ships with Salt. To use the CloudClient library locally (either on the master or a minion), create a client object and issue a command against it:

```python
import salt.cloud
import pprint
client = salt.cloud.CloudClient('/etc/salt/cloud')
nodes = client.query()
pprint.pprint(nodes)
```

### Reactor

Examples of using the reactor with Salt Cloud are available in the `ec2-autoscale-reactor` and `salt-cloud-reactor` formulas.

## 25.12 Feature Comparison

### 25.12.1 Feature Matrix

A number of features are available in most cloud hosts, but not all are available everywhere. This may be because the feature isn’t supported by the cloud host itself, or it may only be that the feature has not yet been added to Salt Cloud. In a handful of cases, it is because the feature does not make sense for a particular cloud provider (Saltify, for instance).

This matrix shows which features are available in which cloud hosts, as far as Salt Cloud is concerned. This is not a comprehensive list of all features available in all cloud hosts, and should not be used to make business decisions concerning choosing a cloud host. In most cases, adding support for a feature to Salt Cloud requires only a little effort.

### Legacy Drivers

Both AWS and Rackspace are listed as `Legacy`. This is because those drivers have been replaced by other drivers, which are generally the preferred method for working with those hosts.

The EC2 driver should be used instead of the AWS driver, when possible. The OpenStack driver should be used instead of the Rackspace driver, unless the user is dealing with instances in ```the old cloud``` in Rackspace.

### Note for Developers

When adding new features to a particular cloud host, please make sure to add the feature to this table. Additionally, if you notice a feature that is not properly listed here, pull requests to fix them is appreciated.
Standard Features

These are features that are available for almost every cloud host.

<table>
<thead>
<tr>

Actions

These are features that are performed on a specific instance, and require an instance name to be passed in. For example:

```
# salt-cloud -a attach_volume ami.example.com
```
These are features that are performed against a specific cloud provider, and require the name of the provider to be passed in. For example:

```
# salt-cloud -f list_images my_digitalocean
```

### 25.13 Tutorials

#### 25.13.1 Salt Cloud Quickstart

Salt Cloud is built-in to Salt, and the easiest way to run Salt Cloud is directly from your Salt Master.

Note that if you installed Salt via Salt Bootstrap, it may not have automatically installed salt-cloud for you. Use your distribution’s package manager to install the `salt-cloud` package from the same repo that you used to install Salt. These repos will automatically be setup by Salt Bootstrap.

If there is no salt-cloud package, install with `pip install salt-cloud`.

This quickstart walks you through the basic steps of setting up a cloud host and defining some virtual machines to create.

Note: Salt Cloud has its own process and does not rely on the Salt Master, so it can be installed on a standalone minion instead of your Salt Master.

#### Define a Provider

The first step is to add the credentials for your cloud host. Credentials and other settings provided by the cloud host are stored in provider configuration files. Provider configurations contain the details needed to connect to a cloud host such as EC2, GCE, Rackspace, etc., and any global options that you want set on your cloud minions (such as the location of your Salt Master).
On your Salt Master, browse to /etc/salt/cloud.providers.d/ and create a file called <provider>.conf, replacing <provider> with ec2, softlayer, and so on. The name helps you identify the contents, and is not important as long as the file ends in .conf.

Next, browse to the Provider specifics and add any required settings for your cloud host to this file. Here is an example for Amazon EC2:

```yaml
my-ec2:
    driver: ec2
    # Set the EC2 access credentials (see below)
    #
    id: 'HJGRYCIILJKJYG'
    key: 'kdjgfsgm;woormgl/aseregjksjdhasdfgn'
    # Make sure this key is owned by root with permissions 0400.
    #
    private_key: /etc/salt/my_test_key.pem
    keyname: my_test_key
    securitygroup: default
    # Optional: Set up the location of the Salt Master
    #
    minion:
        master: saltmaster.example.com
```

The required configuration varies between cloud hosts so make sure you read the provider specifics.

### List Cloud Provider Options

You can now query the cloud provider you configured for available locations, images, and sizes. This information is used when you set up VM profiles.

```bash
salt-cloud --list-locations <provider_name>  # my-ec2 in the previous example
salt-cloud --list-images <provider_name>
salt-cloud --list-sizes <provider_name>
```

Replace <provider_name> with the name of the provider configuration you defined.

### Create VM Profiles

On your Salt Master, browse to /etc/salt/cloud.profiles.d/ and create a file called <profile>.conf, replacing <profile> with ec2, softlayer, and so on. The file must end in .conf.

You can now add any custom profiles you’d like to define to this file. Here are a few examples:

```yaml
micro_ec2:
    provider: my-ec2
    image: ami-d514f291
    size: t1.micro

medium_ec2:
    provider: my-ec2
    image: ami-d514f291
    size: m3.medium

large_ec2:
    provider: my-ec2
    image: ami-d514f291
    size: m3.large
```
Notice that the provider in our profile matches the provider name that we defined? That is how Salt Cloud knows how to connect to a cloud host to create a VM with these attributes.

**Create VMs**

VMs are created by calling `salt-cloud` with the following options:

```
salt-cloud -p <profile> <name1> <name2> ...
```

For example:

```
salt-cloud -p micro_ec2 minion1 minion2
```

**Destroy VMs**

Add a `-d` and the minion name you provided to destroy:

```
salt-cloud -d minion1 minion2
```

**Query VMs**

You can view details about the VMs you've created using `--query`:

```
salt-cloud --query
```

**Cloud Map**

Now that you know how to create and destroy individual VMs, next you should learn how to use a cloud map to create a number of VMs at once.

Cloud maps let you define a map of your infrastructure and quickly provision any number of VMs. On subsequent runs, any VMs that do not exist are created, and VMs that are already configured are left unmodified.

See [Cloud Map File](#).

### 25.13.2 Using Salt Cloud with the Event Reactor

One of the most powerful features of the Salt framework is the Event Reactor. As the Reactor was in development, Salt Cloud was regularly updated to take advantage of the Reactor upon completion. As such, various aspects of both the creation and destruction of instances with Salt Cloud fire events to the Salt Master, which can be used by the Event Reactor.

**Event Structure**

As of this writing, all events in Salt Cloud have a tag, which includes the ID of the instance being managed, and a payload which describes the task that is currently being handled. A Salt Cloud tag looks like:

```text
salt/cloud/<minion_id>/<task>
```
For instance, the first event fired when creating an instance named `web1` would look like:

```
salt/cloud/web1/creating
```

Assuming this instance is using the `ec2-centos` profile, which is in turn using the `ec2-config` provider, the payload for this tag would look like:

```
{"name": "web1",
 'profile': 'ec2-centos',
 'provider': 'ec2-config:ec2'}
```

### Available Events

When an instance is created in Salt Cloud, whether by map, profile, or directly through an API, a minimum of five events are normally fired. More may be available, depending upon the cloud provider being used. Some of the common events are described below.

**salt/cloud/<minion_id>/creating**

This event states simply that the process to create an instance has begun. At this point in time, no actual work has begun. The payload for this event includes:

- name
- profile
- provider

**salt/cloud/<minion_id>/requesting**

Salt Cloud is about to make a request to the cloud provider to create an instance. At this point, all of the variables required to make the request have been gathered, and the payload of the event will reflect those variables which do not normally pose a security risk. What is returned here is dependent upon the cloud provider. Some common variables are:

- name
- image
- size
- location

**salt/cloud/<minion_id>/querying**

The instance has been successfully requested, but the necessary information to log into the instance (such as IP address) is not yet available. This event marks the beginning of the process to wait for this information.

The payload for this event normally only includes the `instance_id`.

**salt/cloud/<minion_id>/waiting_for_ssh**

The information required to log into the instance has been retrieved, but the instance is not necessarily ready to be accessed. Following this event, Salt Cloud will wait for the IP address to respond to a ping, then wait for the specified port (usually 22) to respond to a connection, and on Linux systems, for SSH to become available. Salt Cloud will attempt to issue the `date` command on the remote system, as a means to check for availability. If no `ssh_username` has been specified, a list of usernames (starting with `root`) will be attempted. If one or more usernames was configured for `ssh_username`, they will be added to the beginning of the list, in order.

The payload for this event normally only includes the `ip_address`. 
salt/cloud/<minion_id>/deploying

The necessary port has been detected as available, and now Salt Cloud can log into the instance, upload any files used for deployment, and run the deploy script. Once the script has completed, Salt Cloud will log back into the instance and remove any remaining files.

A number of variables are used to deploy instances, and the majority of these will be available in the payload. Any keys, passwords or other sensitive data will be scraped from the payload. Most of the variables returned will be related to the profile or provider config, and any default values that could have been changed in the profile or provider, but weren't.

salt/cloud/<minion_id>/created

The deploy sequence has completed, and the instance is now available, Salted, and ready for use. This event is the final task for Salt Cloud, before returning instance information to the user and exiting.

The payload for this event contains little more than the initial creating event. This event is required in all cloud providers.

Configuring the Event Reactor

The Event Reactor is built into the Salt Master process, and as such is configured via the master configuration file. Normally this will be a YAML file located at /etc/salt/master. Additionally, master configuration items can be stored, in YAML format, inside the /etc/salt/master.d/ directory.

These configuration items may be stored in either location; however, they may only be stored in one location. For organizational and security purposes, it may be best to create a single configuration file, which contains only Event Reactor configuration, at /etc/salt/master.d/reactor.

The Event Reactor uses a top-level configuration item called reactor. This block contains a list of tags to be watched for, each of which also includes a list of sls files. For instance:

```
reactor:
  - 'salt/minion/*/start':
    - '/srv/reactor/custom-reactor.sls'
  - 'salt/cloud/*/created':
    - '/srv/reactor/cloud-alert.sls'
  - 'salt/cloud/*/destroyed':
    - '/srv/reactor/cloud-destroy-alert.sls'
```

The above configuration configures reactors for three different tags: one which is fired when a minion process has started and is available to receive commands, one which is fired when a cloud instance has been created, and one which is fired when a cloud instance is destroyed.

Note that each tag contains a wildcard (*) in it. For each of these tags, this will normally refer to a minion_id. This is not required of event tags, but is very common.

Reactor SLS Files

Reactor sls files should be placed in the /srv/reactor/ directory for consistency between environments, but this is not currently enforced by Salt.

Reactor sls files follow a similar format to other sls files in Salt. By default they are written in YAML and can be templated using Jinja, but since they are processed through Salt's rendering system, any available renderer (JSON, Mako, Cheetah, etc.) can be used.
As with other sls files, each stanza will start with a declaration ID, followed by the function to run, and then any arguments for that function. For example:

```
# /srv/reactor/cloud-alert.sls
new_instance_alert:
cmd.pagerduty.create_event:
  - tgt: alertserver
  - kwarg:
    description: "New instance: {{ data['name'] }}"
    details: "New cloud instance created on {{ data['provider'] }}"
    service_key: 1626dead5ecafe46231e968eb1be29c4
    profile: my-pagerduty-account
```

When the Event Reactor receives an event notifying it that a new instance has been created, this sls will create a new incident in PagerDuty, using the configured PagerDuty account.

The declaration ID in this example is **new_instance_alert**. The function called is `cmd.pagerduty.create_event`. The **cmd** portion of this function specifies that an execution module and function will be called, in this case, the `pagerduty.create_event` function.

Because an execution module is specified, a target (tgt) must be specified on which to call the function. In this case, a minion called `alertserver` has been used. Any arguments passed through to the function are declared in the **kwarg** block.

**Example: Reactor-Based Highstate**

When Salt Cloud creates an instance, by default it will install the Salt Minion onto the instance, along with any specified minion configuration, and automatically accept that minion's keys on the master. One of the configuration options that can be specified is **startup_states**, which is commonly set to **highstate**. This will tell the minion to immediately apply a **highstate**, as soon as it is able to do so.

This can present a problem with some system images on some cloud hosts. For instance, Salt Cloud can be configured to log in as either the root user, or a user with sudo access. While some hosts commonly use images that lock out remote root access and require a user with sudo privileges to log in (notably EC2, with their ec2-user login), most cloud hosts fall back to root as the default login on all images, including for operating systems (such as Ubuntu) which normally disallow remote root login.

For users of these operating systems, it is understandable that a **highstate** would include configuration to block remote root logins again. However, Salt Cloud may not have finished cleaning up its deployment files by the time the minion process has started, and kicked off a **highstate** run. Users have reported errors from Salt Cloud getting locked out while trying to clean up after itself.

The goal of a startup state may be achieved using the Event Reactor. Because a minion fires an event when it is able to receive commands, this event can effectively be used inside the reactor system instead. The following will point the reactor system to the right sls file:

```
reactor:
  - 'salt/cloud/*/created':
    - '/srv/reactor/startup_highstate.sls'
```

And the following sls file will start a **highstate** run on the target minion:

```
# /srv/reactor/startup_highstate.sls
reactor_highstate:
cmd.state.apply:
  - tgt: {{ data['name'] }}
```
Because this event will not be fired until Salt Cloud has cleaned up after itself, the `highstate` run will not step on salt-cloud’s toes. And because every file on the minion is configurable, including `/etc/salt/minion`, the `startup_states` can still be configured for future minion restarts, if desired.
26.1 Writing netapi modules

netapi modules, put simply, bind a port and start a service. They are purposefully open-ended and can be used to present a variety of external interfaces to Salt, and even present multiple interfaces at once.

See also:
The full list of netapi modules

26.1.1 Configuration

All netapi configuration is done in the Salt master config and takes a form similar to the following:

```python
rest_cherrypy:
  port: 8000
  debug: True
  ssl_crt: /etc/pki/tls/certs/localhost.crt
  ssl_key: /etc/pki/tls/certs/localhost.key
```

26.1.2 The __virtual__ function

Like all module types in Salt, netapi modules go through Salt’s loader interface to determine if they should be loaded into memory and then executed.

The __virtual__ function in the module makes this determination and should return False or a string that will serve as the name of the module. If the module raises an ImportError or any other errors, it will not be loaded.

26.1.3 The start function

The start() function will be called for each netapi module that is loaded. This function should contain the server loop that actually starts the service. This is started in a multiprocess.

26.1.4 Inline documentation

As with the rest of Salt, it is a best-practice to include liberal inline documentation in the form of a module docstring and docstrings on any classes, methods, and functions in your netapi module.
26.1.5 Loader “magic” methods

The loader makes the __opts__ data structure available to any function in a netapi module.

26.2 Introduction to netapi modules

netapi modules provide API-centric access to Salt. Usually externally-facing services such as REST or WebSockets, XMPP, XMLRPC, etc.

In general netapi modules bind to a port and start a service. They are purposefully open-ended. A single module can be configured to run as well as multiple modules simultaneously.

netapi modules are enabled by adding configuration to your Salt Master config file and then starting the salt-api daemon. Check the docs for each module to see external requirements and configuration settings.

Communication with Salt and Salt satellite projects is done using Salt's own Python API. A list of available client interfaces is below.

26.3 Client interfaces

Salt's client interfaces expose executing functions by crafting a dictionary of values that are mapped to function arguments. This allows calling functions simply by creating a data structure. (And this is exactly how much of Salt's own internals work!)

class salt.netapi.NetapiClient(opts)

Provide a uniform method of accessing the various client interfaces in Salt in the form of low-data data structures. For example:

```python
>>> client = NetapiClient(__opts__)
>>> lowstate = {'client': 'local', 'tgt': '*', 'fun': 'test.ping', 'arg': ''}
>>> client.run(lowstate)
```

**local**(*args, **kwargs*)

Run execution modules synchronously

See salt.client.LocalClient.cmd() for all available parameters.

Sends a command from the master to the targeted minions. This is the same interface that Salt's own CLI uses. Note the arg and kwarg parameters are sent down to the minion(s) and the given function, fun, is called with those parameters.

**Returns** Returns the result from the execution module

**local_async**(*args, **kwargs*)

Run execution modules asynchronously

Wraps salt.client.LocalClient.run_job().
Returns job ID

**local_batch**(*args, **kwargs*)

Run execution modules against batches of minions

New in version 0.8.4.

Wraps `salt.client.LocalClient.cmd_batch()`

Returns Returns the result from the execution module for each batch of returns

**runner**(*fun, timeout=None, **kwargs*)

Run runner modules `<all-salt.runners>` synchronously

Wraps `salt.runner.RunnerClient.cmd_sync()`.

Note that runner functions must be called using keyword arguments. Positional arguments are not supported.

Returns Returns the result from the runner module

**runner_async**(*fun, **kwargs*)

Run runner modules `<all-salt.runners>` asynchronously

Wraps `salt.runner.RunnerClient.cmd_async()`.

Note that runner functions must be called using keyword arguments. Positional arguments are not supported.

Returns event data and a job ID for the executed function.

**ssh**(*args, **kwargs*)

Run salt-ssh commands synchronously

Wraps `salt.client.ssh.client.SSHClient.cmd_sync()`.

Returns Returns the result from the salt-ssh command

**ssh_async**(*fun, timeout=None, **kwargs*)

Run salt-ssh commands asynchronously

Wraps `salt.client.ssh.client.SSHClient.cmd_async()`.

Returns Returns the JID to check for results on

**wheel**(*fun, **kwargs*)

Run wheel modules synchronously

Wraps `salt.wheel.WheelClient.master_call()`.

Note that wheel functions must be called using keyword arguments. Positional arguments are not supported.

Returns Returns the result from the wheel module

**wheel_async**(*fun, **kwargs*)

Run wheel modules asynchronously

Wraps `salt.wheel.WheelClient.master_call()`.

Note that wheel functions must be called using keyword arguments. Positional arguments are not supported.

Returns Returns the result from the wheel module
The Salt Virt cloud controller capability was initially added to Salt in version 0.14.0 as an alpha technology.

The initial Salt Virt system supports core cloud operations:

- Virtual machine deployment
- Inspection of deployed VMs
- Virtual machine migration
- Network profiling
- Automatic VM integration with all aspects of Salt
- Image Pre-seeding

Many features are currently under development to enhance the capabilities of the Salt Virt systems.

**Note:** It is noteworthy that Salt was originally developed with the intent of using the Salt communication system as the backbone to a cloud controller. This means that the Salt Virt system is not an afterthought, simply a system that took the back seat to other development. The original attempt to develop the cloud control aspects of Salt was a project called butter. This project never took off, but was functional and proves the early viability of Salt to be a cloud controller.

**Warning:** Salt Virt does not work with KVM that is running in a VM. KVM must be running on the base hardware.

### 27.1 Salt Virt Tutorial

A tutorial about how to get Salt Virt up and running has been added to the tutorial section:

*Cloud Controller Tutorial*

### 27.2 The Salt Virt Runner

The point of interaction with the cloud controller is the virt runner. The virt runner comes with routines to execute specific virtual machine routines.
Reference documentation for the virt runner is available with the runner module documentation:

Virt Runner Reference

27.3 Based on Live State Data

The Salt Virt system is based on using Salt to query live data about hypervisors and then using the data gathered to make decisions about cloud operations. This means that no external resources are required to run Salt Virt, and that the information gathered about the cloud is live and accurate.

27.4 Deploy from Network or Disk

27.4.1 Virtual Machine Disk Profiles

Salt Virt allows for the disks created for deployed virtual machines to be finely configured. The configuration is a simple data structure which is read from the config.option function, meaning that the configuration can be stored in the minion config file, the master config file, or the minion's pillar.

This configuration option is called virt.disk. The default virt.disk data structure looks like this:

```yaml
virt.disk:
  default:
    - system:
      size: 8192
      format: qcow2
      model: virtio
```

Note: The format and model does not need to be defined, Salt will default to the optimal format used by the underlying hypervisor, in the case of kvm this it is qcow2 and virtio.

This configuration sets up a disk profile called default. The default profile creates a single system disk on the virtual machine.

Define More Profiles

Many environments will require more complex disk profiles and may require more than one profile, this can be easily accomplished:

```yaml
virt.disk:
  default:
    - system:
      size: 8192
  database:
    - system:
      size: 8192
    - data:
      size: 30720
  web:
    - system:
      size: 1024
```
This configuration allows for one of three profiles to be selected, allowing virtual machines to be created with different storage needs of the deployed vm.

### 27.4.2 Virtual Machine Network Profiles

Salt Virt allows for the network devices created for deployed virtual machines to be finely configured. The configuration is a simple data structure which is read from the `config.option` function, meaning that the configuration can be stored in the minion config file, the master config file, or the minion’s pillar.

This configuration option is called `virt.nic`. By default the `virt.nic` option is empty but defaults to a data structure which looks like this:

```
virt.nic:
  default:
    eth0:
      bridge: br0
      model: virtio
```

**Note:** The model does not need to be defined, Salt will default to the optimal model used by the underlying hypervisor, in the case of kvm this model is `virtio`.

This configuration sets up a network profile called default. The default profile creates a single Ethernet device on the virtual machine that is bridged to the hypervisor’s `br0` interface. This default setup does not require setting up the `virt.nic` configuration, and is the reason why a default install only requires setting up the `br0` bridge device on the hypervisor.

### Define More Profiles

Many environments will require more complex network profiles and may require more than one profile, this can be easily accomplished:

```
virt.nic:
  dual:
    eth0:
      bridge: service_br
    eth1:
      bridge: storage_br
  single:
    eth0:
      bridge: service_br
  triple:
    eth0:
      bridge: service_br
    eth1:
      bridge: storage_br
    eth2:
      bridge: dmz_br
  all:
    eth0:
      bridge: service_br
```

27.4. Deploy from Network or Disk
This configuration allows for one of six profiles to be selected, allowing virtual machines to be created which attach to different network depending on the needs of the deployed vm.
The default renderer for SLS files is the YAML renderer. YAML is a markup language with many powerful features. However, Salt uses a small subset of YAML that maps over very commonly used data structures, like lists and dictionaries. It is the job of the YAML renderer to take the YAML data structure and compile it into a Python data structure for use by Salt.

Though YAML syntax may seem daunting and terse at first, there are only three very simple rules to remember when writing YAML for SLS files.

### 28.1 Rule One: Indentation

YAML uses a fixed indentation scheme to represent relationships between data layers. Salt requires that the indentation for each level consists of exactly two spaces. Do not use tabs.

### 28.2 Rule Two: Colons

Python dictionaries are, of course, simply key-value pairs. Users from other languages may recognize this data type as hashes or associative arrays.

Dictionary keys are represented in YAML as strings terminated by a trailing colon. Values are represented by either a string following the colon, separated by a space:

```
my_key: my_value
```

In Python, the above maps to:

```python
{'my_key': 'my_value'}
```

Alternatively, a value can be associated with a key through indentation.

```
my_key:
  my_value
```

**Note:** The above syntax is valid YAML but is uncommon in SLS files because most often, the value for a key is not singular but instead is a list of values.

In Python, the above maps to:
Dictionaries can be nested:

```
first_level_dict_key:
  second_level_dict_key: value_in_second_level_dict
```

And in Python:

```
{  
  'first_level_dict_key': {  
    'second_level_dict_key': 'value_in_second_level_dict'  
  }  
}
```

## 28.3 Rule Three: Dashes

To represent lists of items, a single dash followed by a space is used. Multiple items are a part of the same list as a function of their having the same level of indentation.

```
- list_value_one
- list_value_two
- list_value_three
```

Lists can be the value of a key-value pair. This is quite common in Salt:

```
my_dictionary:
  - list_value_one
  - list_value_two
  - list_value_three
```

In Python, the above maps to:

```
{'my_dictionary': ['list_value_one', 'list_value_two', 'list_value_three']}
```

## 28.4 Learning More

One easy way to learn more about how YAML gets rendered into Python data structures is to use an online YAML parser to see the Python output.

One excellent choice for experimenting with YAML parsing is: [http://yaml-online-parser.appspot.com/](http://yaml-online-parser.appspot.com/)
CHAPTER 29

Master Tops System

In 0.10.4 the external_nodes system was upgraded to allow for modular subsystems to be used to generate the top file data for a highstate run on the master.

The old external_nodes option has been removed. The master tops system contains a number of subsystems that are loaded via the Salt loader interfaces like modules, states, returners, runners, etc.

Using the new master_tops option is simple:

```yaml
master_tops:
  ext_nodes: cobbler-external-nodes
```

for Cobbler or:

```yaml
master_tops:
  reclass:
    inventory_base_uri: /etc/reclass
    classes_uri: roles
```

for Reclass.

It's also possible to create custom master_tops modules. These modules must go in a subdirectory called tops in the extension_modules directory. The extension_modules directory is not defined by default (the default /srv/salt/_modules will NOT work as of this release)

Custom tops modules are written like any other execution module, see the source for the two modules above for examples of fully functional ones. Below is a degenerate example:

/etc/salt/master:

```yaml
extension_modules: /srv/salt/modules
master_tops:
  customtop: True
```

/srv/salt/modules/tops/customtop.py:

```python
import logging
import sys
# Define the module's virtual name
__virtualname__ = 'customtop'

log = logging.getLogger(__name__)

def __virtual__():
    return __virtualname__
```
```python
def top(**kwargs):
    log.debug('Calling top in customtop')
    return {'base': ['test']}
```

`salt minion state.show_top` should then display something like:

```
$ salt minion state.show_top

minion
      --------
    base:
        - test
```
30.1 Getting Started

Salt SSH is very easy to use, simply set up a basic roster file of the systems to connect to and run salt-ssh commands in a similar way as standard salt commands.

- Salt ssh is considered production ready in version 2014.7.0
- Python is required on the remote system (unless using the -r option to send raw ssh commands)
- On many systems, the salt-ssh executable will be in its own package, usually named salt-ssh
- The Salt SSH system does not supercede the standard Salt communication systems, it simply offers an SSH-based alternative that does not require ZeroMQ and a remote agent. Be aware that since all communication with Salt SSH is executed via SSH it is substantially slower than standard Salt with ZeroMQ.
- At the moment fileserver operations must be wrapped to ensure that the relevant files are delivered with the salt-ssh commands. The state module is an exception, which compiles the state run on the master, and in the process finds all the references to salt:// paths and copies those files down in the same tarball as the state run. However, needed fileserver wrappers are still under development.

30.2 Salt SSH Roster

The roster system in Salt allows for remote minions to be easily defined.

**Note:** See the Roster documentation for more details.

Simply create the roster file, the default location is /etc/salt/roster:

```shell
web1: 192.168.42.1
```

This is a very basic roster file where a Salt ID is being assigned to an IP address. A more elaborate roster can be created:

```shell
table:
  host: 192.168.42.1  # The IP addr or DNS hostname
  user: fred          # Remote executions will be executed as user fred
  passwd: foobaz      # The password to use for login, if omitted, keys are used
  sudo: True          # Whether to sudo to root, not enabled by default
```
web2:
  host: 192.168.42.2

Note: sudo works only if NOPASSWD is set for user in /etc/sudoers: fred ALL=(ALL) NOPASSWD: ALL

### 30.3 Deploy ssh key for salt-ssh

By default, salt-ssh will generate key pairs for ssh, the default path will be /etc/salt/pki/master/ssh/salt-ssh.rsa
You can use ssh-copy-id, (the OpenSSH key deployment tool) to deploy keys to your servers.

```sh
ssh-copy-id -i /etc/salt/pki/master/ssh/salt-ssh.rsa.pub user@server.demo.com
```

One could also create a simple shell script, named salt-ssh-copy-id.sh as follows:

```bash
#!/bin/bash
if [ -z $1 ]; then
  echo $0 user@host.com
  exit 0
fi
ssh-copy-id -i /etc/salt/pki/master/ssh/salt-ssh.rsa.pub $1
```

Note: Be certain to chmod +x salt-ssh-copy-id.sh.

```sh
./salt-ssh-copy-id.sh user@server1.host.com
./salt-ssh-copy-id.sh user@server2.host.com
```

Once keys are successfully deployed, salt-ssh can be used to control them.

### 30.4 Calling Salt SSH

Note: salt-ssh on RHEL/CentOS 5

The salt-ssh command requires at least python 2.6, which is not installed by default on RHEL/CentOS 5. An easy workaround in this situation is to use the -r option to run a raw shell command that installs python26:

```sh
salt-ssh centos-5-minion -r 'yum -y install epel-release ; yum -y install python26'
```

The salt-ssh command can be easily executed in the same way as a salt command:

```sh
salt-ssh '*' test.ping
```

Commands with salt-ssh follow the same syntax as the salt command.

The standard salt functions are available! The output is the same as salt and many of the same flags are available. Please see http://docs.saltstack.com/ref/cli/salt-ssh.html for all of the available options.
30.4.1 Raw Shell Calls

By default salt-ssh runs Salt execution modules on the remote system, but salt-ssh can also execute raw shell commands:

```
salt-ssh '*' -r 'ifconfig'
```

30.5 States Via Salt SSH

The Salt State system can also be used with salt-ssh. The state system abstracts the same interface to the user in salt-ssh as it does when using standard salt. The intent is that Salt Formulas defined for standard salt will work seamlessly with salt-ssh and vice-versa.

The standard Salt States walkthroughs function by simply replacing salt commands with salt-ssh.

30.6 Targeting with Salt SSH

Due to the fact that the targeting approach differs in salt-ssh, only glob and regex targets are supported as of this writing, the remaining target systems still need to be implemented.

**Note:** By default, Grains are settable through salt-ssh. By default, these grains will *not* be persisted across reboots.

See the `"thin_dir"` setting in Roster documentation for more details.

30.7 Configuring Salt SSH

Salt SSH takes its configuration from a master configuration file. Normally, this file is in `/etc/salt/master`. If one wishes to use a customized configuration file, the `-c` option to Salt SSH facilitates passing in a directory to look inside for a configuration file named `master`.

30.7.1 Minion Config

New in version 2015.5.1.

Minion config options can be defined globally using the master configuration option `ssh_minion_opts`. It can also be defined on a per-minion basis with the `minion_opts` entry in the roster.

30.8 Running Salt SSH as non-root user

By default, Salt read all the configuration from `/etc/salt/`. If you are running Salt SSH with a regular user you have to modify some paths or you will get "Permission denied" messages. You have to modify two parameters: `pki_dir` and `cachedir`. Those should point to a full path writable for the user.

It's recommended not to modify `/etc/salt` for this purpose. Create a private copy of `/etc/salt` for the user and run the command with `-c /new/config/path`.
30.9 Define CLI Options with Saltfile

If you are commonly passing in CLI options to `salt-ssh`, you can create a Saltfile to automatically use these options. This is common if you’re managing several different salt projects on the same server.

So you can `cd` into a directory that has a Saltfile with the following YAML contents:

```yaml
salt-ssh:
  config_dir: path/to/config/dir
  max_procs: 30
  wipe_ssh: True
```

Instead of having to call `salt-ssh --config-dir=path/to/config/dir --max-procs=30 --wipe \* test.ping` you can call `salt-ssh \* test.ping`.

Boolean-style options should be specified in their YAML representation.

**Note:** The option keys specified must match the destination attributes for the options specified in the parser `salt.utils.parsers.SaltSSHOptionParser`. For example, in the case of the `--wipe` command line option, its `dest` is configured to be `wipe_ssh` and thus this is what should be configured in the Saltfile. Using the names of flags for this option, being `wipe: True` or `w: True`, will not work.

30.10 Debugging salt-ssh

One common approach for debugging `salt-ssh` is to simply use the tarball that salt ships to the remote machine and call `salt-call` directly.

To determine the location of `salt-call`, simply run `salt-ssh` with the `-ldebug` flag and look for a line containing the string, `SALT_ARGV`. This contains the `salt-call` command that `salt-ssh` attempted to execute.

It is recommended that one modify this command a bit by removing the `-l quiet`, `--metadata` and `--output json` to get a better idea of what’s going on on the target system.
Salt Rosters

Salt rosters are pluggable systems added in Salt 0.17.0 to facilitate the `salt-ssh` system. The roster system was created because `salt-ssh` needs a means to identify which systems need to be targeted for execution.

See also:

*Full list of builtin roster modules*

**Note:** The Roster System is not needed or used in standard Salt because the master does not need to be initially aware of target systems, since the Salt Minion checks itself into the master.

Since the roster system is pluggable, it can be easily augmented to attach to any existing systems to gather information about what servers are presently available and should be attached to by `salt-ssh`. By default the roster file is located at `/etc/salt/roster`.

### 31.1 How Rosters Work

The roster system compiles a data structure internally referred to as `targets`. The `targets` is a list of target systems and attributes about how to connect to said systems. The only requirement for a roster module in Salt is to return the `targets` data structure.

#### 31.1.1 Targets Data

The information which can be stored in a roster `target` is the following:

```
<Salt ID>:     # The id to reference the target system with
host:         # The IP address or DNS name of the remote host
user:         # The user to log in as
passwd:       # The password to log in with

# Optional parameters
port:         # The target system's ssh port number
sudo:         # Boolean to run command via sudo
sudo_user:    # Str: Set this to execute Salt as a sudo user other than root.
              # This user must be in the same system group as the remote user
              # that is used to login and is specified above. Alternatively,
              # the user must be a super-user.
tty:          # Boolean: Set this option to True if sudo is also set to
              # True and requiretty is also set on the target system
```
Salt needs to upload a standalone environment to the target system, and this defaults to /tmp/salt-<hash>. This directory will be cleaned up per normal systems operation.

If you need a persistent Salt environment, for instance to set persistent grains, this value will need to be changed.
32.1 Full list of builtin auth modules

<table>
<thead>
<tr>
<th>auth</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>auto</td>
<td>An &quot;Always Approved&quot; eauth interface to test against, not intended for production use.</td>
</tr>
<tr>
<td>django</td>
<td>Provide authentication using Django Web Framework.</td>
</tr>
<tr>
<td>keystone</td>
<td>Provide authentication using OpenStack Keystone.</td>
</tr>
<tr>
<td>ldap</td>
<td>Provide authentication using simple LDAP binds.</td>
</tr>
<tr>
<td>mysql</td>
<td>Provide authentication using MySQL.</td>
</tr>
<tr>
<td>pam</td>
<td>Authenticate against PAM.</td>
</tr>
<tr>
<td>pki</td>
<td>Authenticate via a PKI certificate.</td>
</tr>
<tr>
<td>rest</td>
<td>Provide authentication using a REST call.</td>
</tr>
<tr>
<td>stormpath</td>
<td>Provide authentication using Stormpath.</td>
</tr>
<tr>
<td>yubico</td>
<td>Provide authentication using YubiKey.</td>
</tr>
</tbody>
</table>

32.1.1 salt.auth.auto

An "Always Approved" eauth interface to test against, not intended for production use.

```python
salt.auth.auto.auth(username, password)
```

Authenticate!

32.1.2 salt.auth.django

Provide authentication using Django Web Framework.

```python
def depends
    """Django Web Framework"
```

Django authentication depends on the presence of the django framework in the PYTHONPATH, the Django project's settings.py file being in the PYTHONPATH and accessible via the DJANGO_SETTINGS_MODULE environment variable.

Django auth can be defined like any other eauth module:

```python
external_auth:
    django:
        fred:
```
This will authenticate Fred via Django and allow him to run any execution module and all runners.

The authorization details can optionally be located inside the Django database. The relevant entry in the models.py file would look like this:

```python
class SaltExternalAuthModel(models.Model):
    user_fk = models.ForeignKey(auth.User)
    minion_matcher = models.CharField()
    minion_fn = models.CharField()
```

The `external_auth` clause in the master config would then look like this:

```yaml
external_auth:
    django:
        ^model: <fully-qualified reference to model class>
```

When a user attempts to authenticate via Django, Salt will import the package indicated via the keyword `^model`. That model must have the fields indicated above, though the model DOES NOT have to be named `SaltExternalAuthModel`.

```python
salt.auth.django.auth(username, password)
    Simple Django auth

salt.auth.django.django_auth_setup()
    Prepare the connection to the Django authentication framework

salt.auth.django.retrieve_auth_entries(u=None)
    Parameters u -- Username to filter for

    Returns Dictionary that can be slotted into the __opts__ structure for eauth that designates the user associated ACL
```

Database records such as:

<table>
<thead>
<tr>
<th>username</th>
<th>minion_or_fn_matcher</th>
<th>minion_fn</th>
</tr>
</thead>
<tbody>
<tr>
<td>fred</td>
<td>test.ping</td>
<td></td>
</tr>
<tr>
<td>fred</td>
<td>server1</td>
<td>network.interfaces</td>
</tr>
<tr>
<td>fred</td>
<td>server1</td>
<td>raid.list</td>
</tr>
<tr>
<td>fred</td>
<td>server2</td>
<td>*</td>
</tr>
<tr>
<td>guru</td>
<td>*</td>
<td></td>
</tr>
<tr>
<td>smartadmin</td>
<td>server1</td>
<td>*</td>
</tr>
</tbody>
</table>

Should result in an eauth config such as:

```yaml
fred:
    - test.ping
    - server1:
        - network.interfaces
        - raid.list
    - server2:
        - *

guru:
    - *

smartadmin:
    - server1:
        - *
```
32.1.3 salt.auth.keystone

Provide authentication using OpenStack Keystone

dependencies
- keystoneclient Python module

salt.auth.keystone.auth(username, password)
Try and authenticate

salt.auth.keystone.get_auth_url()
Try and get the URL from the config, else return localhost

32.1.4 salt.auth.ldap

Provide authentication using simple LDAP binds

dependencies
- ldap Python module

salt.auth.ldap.auth(username, password)
Simple LDAP auth

salt.auth.ldap.groups(username, **kwargs)
Authenticate against an LDAP group

Behavior is highly dependent on if Active Directory is in use.

AD handles group membership very differently than OpenLDAP. See the External Authentication documentation for a thorough discussion of available parameters for customizing the search.

OpenLDAP allows you to search for all groups in the directory and returns members of those groups. Then we check against the username entered.

32.1.5 salt.auth.mysql

Provide authentication using MySQL.

When using MySQL as an authentication backend, you will need to create or use an existing table that has a username and a password column.

To get started, create a simple table that holds just a username and a password. The password field will hold a SHA256 checksum.

```sql
CREATE TABLE `users` (  `id` int(11) NOT NULL AUTO_INCREMENT,  `username` varchar(25) DEFAULT NULL,  `password` varchar(70) DEFAULT NULL,  PRIMARY KEY (`id`) ) ENGINE=InnoDB AUTO_INCREMENT=2 DEFAULT CHARSET=latin1;
```

To create a user within MySQL, execute the following statement.

```sql
INSERT INTO users VALUES (NULL, 'diana', SHA2('secret', 256))
```
The `auth_sql` contains the SQL that will validate a user to ensure they are correctly authenticated. This is where you can specify other SQL queries to authenticate users.

Enable MySQL authentication.

```
depend
  • MySQL-python Python module
salt.auth.mysql.auth(username, password)
  Authenticate using a MySQL user table
```

### 32.1.6 salt.auth.pam

Authenticate against PAM

Provides an authenticate function that will allow the caller to authenticate a user against the Pluggable Authentication Modules (PAM) on the system.

Implemented using ctypes, so no compilation is necessary.

There is one extra configuration option for pam. The `pam_service` that is authenticated against. This defaults to `login`

```
auth.pam.service: login
```

**Note:** PAM authentication will not work for the `root` user.

The Python interface to PAM does not support authenticating as `root`.

```
class salt.auth.pam.PamConv
  Wrapper class for pam_conv structure
  appdata_ptr
    Structure/Union member
  conv
    Structure/Union member

class salt.auth.pam.PamHandle
  Wrapper class for pam_handle_t
  handle
    Structure/Union member
```
class salt.auth.pam.PamMessage
    Wrapper class for pam_message structure
    
    msg
        Structure/Union member
    msg_style
        Structure/Union member

class salt.auth.pam.PamResponse
    Wrapper class for pam_response structure
    
    resp
        Structure/Union member
    resp_retcode
        Structure/Union member

salt.auth.pam.auth(username, password, **kwargs)
    Authenticate via pam

salt.auth.pam.authenticate(username, password)
    Returns True if the given username and password authenticate for the given service. Returns False otherwise
        username: the username to authenticate
        password: the password in plain text

salt.auth.pam.groups(username, *args, **kwargs)
    Retrieve groups for a given user for this auth provider
    Uses system groups

32.1.7 salt.auth.pki

Authenticate via a PKI certificate.

Note: This module is Experimental and should be used with caution

Provides an authenticate function that will allow the caller to authenticate a user via their public cert against a pre-defined Certificate Authority.

TODO: Add a `ca_dir` option to configure a directory of CA files, a la Apache.

    depends
        * pyOpenSSL module

salt.auth.pki.auth(pem, **kwargs)
    Returns True if the given user cert was issued by the CA. Returns False otherwise.
        pem: a pem-encoded user public key (certificate)

Configure the CA cert in the master config file:

    external_auth:
        pki:
            ca_file: /etc/pki/tls/ca_certs/trusted-ca.crt
### 32.1.8 salt.auth.rest module

Provide authentication using a REST call

Django auth can be defined like any other eauth module:

```yaml
external_auth:
  rest:
    ^url: https://url/for/rest/call
    fred:
    - .*
    - '@runner'
```

If there are entries underneath the `^url` entry then they are merged with any responses from the REST call. In the above example, assuming the REST call does not return any additional ACLs, this will authenticate Fred via a REST call and allow him to run any execution module and all runners.

The REST call should return a JSON object that maps to a regular eauth YAML structure as above.

```python
salt.auth.rest.auth(username, password)
```

### 32.1.9 salt.auth.stormpath

Provide authentication using Stormpath.

This driver requires some extra configuration beyond that which Stormpath normally requires.

```yaml
stormpath:
  apiid: 1234567890
  apikey: 1234567890/ABCDEF
  # Can use an application ID
  application: 6789012345
  # Or can use a directory ID
  directory: 3456789012
  # But not both
```

New in version 2015.8.0.

```python
salt.auth.stormpath.auth(username, password)
```

Authenticate using a Stormpath directory or application

### 32.1.10 salt.auth.yubico

Provide authentication using YubiKey.

New in version 2015.5.0.

```python
depends  yubico-client Python module
```

To get your YubiKey API key you will need to visit the website below.

https://upgrade.yubico.com/getapikey/

The resulting page will show the generated Client ID (aka AuthID or API ID) and the generated API key (Secret Key). Make a note of both and use these two values in your /etc/salt/master configuration.
Please wait five to ten minutes after generating the key before testing so that the API key will be updated on all the YubiCloud servers.

salt.auth.yubico.auth(username, password)

Authenticate against yubico server

### 32.2 Command Line Reference

Salt can be controlled by a command line client by the root user on the Salt master. The Salt command line client uses the Salt client API to communicate with the Salt master server. The Salt client is straightforward and simple to use.

Using the Salt client commands can be easily sent to the minions.

Each of these commands accepts an explicit --config option to point to either the master or minion configuration file. If this option is not provided and the default configuration file does not exist then Salt falls back to use the environment variables SALT_MASTER_CONFIG and SALT_MINION_CONFIG.

See also:

*Configuration*

### 32.2.1 Using the Salt Command

The Salt command needs a few components to send information to the Salt minions. The target minions need to be defined, the function to call and any arguments the function requires.

**Defining the Target Minions**

The first argument passed to salt, defines the target minions, the target minions are accessed via their hostname. The default target type is a bash glob:

```
salt '*foo.com' sys.doc
```

Salt can also define the target minions with regular expressions:

```
salt -E '.*' cmd.run 'ls -l | grep foo'
```

Or to explicitly list hosts, salt can take a list:

```
salt -L foo.bar.baz,quo.qux cmd.run 'ps aux | grep foo'
```
More Powerful Targets

The simple target specifications, glob, regex, and list will cover many use cases, and for some will cover all use cases, but more powerful options exist.

Targeting with Grains

The Grains interface was built into Salt to allow minions to be targeted by system properties. So minions running on a particular operating system can be called to execute a function, or a specific kernel.

Calling via a grain is done by passing the -G option to salt, specifying a grain and a glob expression to match the value of the grain. The syntax for the target is the grain key followed by a glob expression: ``os:Arch*``.

```
salt -G 'os:Fedora' test.ping
```

Will return True from all of the minions running Fedora.

To discover what grains are available and what the values are, execute the grains.item salt function:

```
salt '*' grains.items
```

more info on using targeting with grains can be found here.

Compound Targeting

New in version 0.9.5.

Multiple target interfaces can be used in conjunction to determine the command targets. These targets can then be combined using and or or statements. This is well defined with an example:

```
salt -C 'G@os:Debian and webser* or E@db.*' test.ping
```

In this example any minion who's id starts with webser and is running Debian, or any minion who's id starts with db will be matched.

The type of matcher defaults to glob, but can be specified with the corresponding letter followed by the @ symbol. In the above example a grain is used with G@ as well as a regular expression with E@. The webser* target does not need to be prefaced with a target type specifier because it is a glob.

more info on using compound targeting can be found here.

Node Group Targeting

New in version 0.9.5.

For certain cases, it can be convenient to have a predefined group of minions on which to execute commands. This can be accomplished using what are called nodegroups. Nodegroups allow for predefined compound targets to be declared in the master configuration file, as a sort of shorthand for having to type out complicated compound expressions.

```
nodegroups:
  group1: 'L@foo.domain.com,bar.domain.com,baz.domain.com and bl*.domain.com'
  group2: 'G@os:Debian and foo.domain.com'
  group3: 'G@os:Debian and N@group1'
```
Calling the Function

The function to call on the specified target is placed after the target specification.
New in version 0.9.8.

Functions may also accept arguments, space-delimited:

```
salt '*' cmd.exec_code python 'import sys; print sys.version'
```

Optional, keyword arguments are also supported:

```
salt '*' pip.install salt timeout=5 upgrade=True
```

They are always in the form of `kwarg=argument`.

Arguments are formatted as YAML:

```
salt '*' cmd.run 'echo "Hello: $FIRST_NAME"' env='{{FIRST_NAME: "Joe"}}'
```

Note: dictionaries must have curly braces around them (like the `env` keyword argument above). This was changed in 0.15.1: in the above example, the first argument used to be parsed as the dictionary `{'echo "Hello": "$FIRST_NAME"'}. This was generally not the expected behavior.

If you want to test what parameters are actually passed to a module, use the `test.arg_repr` command:

```
salt '*' test.arg_repr 'echo "Hello: $FIRST_NAME"' env='{{FIRST_NAME: "Joe"}}'
```

Finding available minion functions

The Salt functions are self documenting, all of the function documentation can be retrieved from the minions via the `sys.doc()` function:

```
salt '*' sys.doc
```

Compound Command Execution

If a series of commands needs to be sent to a single target specification then the commands can be sent in a single publish. This can make gathering groups of information faster, and lowers the stress on the network for repeated commands.

Compound command execution works by sending a list of functions and arguments instead of sending a single function and argument. The functions are executed on the minion in the order they are defined on the command line, and then the data from all of the commands are returned in a dictionary. This means that the set of commands are called in a predictable way, and the returned data can be easily interpreted.

Executing compound commands if done by passing a comma delimited list of functions, followed by a comma delimited list of arguments:

```
salt '*' cmd.run,test.ping,test.echo 'cat /proc/cpuinfo',,foo
```

The trick to look out for here, is that if a function is being passed no arguments, then there needs to be a placeholder for the absent arguments. This is why in the above example, there are two commas right next to each other `test.ping` takes no arguments, so we need to add another comma, otherwise Salt would attempt to pass `''foo''` to `test.ping`. 
If you need to pass arguments that include commas, then make sure you add spaces around the commas that separate arguments. For example:

```
salt '*' cmd.run,test.ping,test.echo 'echo "1,2,3"' , , foo
```

You may change the arguments separator using the `--args-separator` option:

```
salt --args-separator=:: '*!' some.fun,test.echo params with , comma :: foo
```

### 32.2.2 CLI Completion

Shell completion scripts for the Salt CLI are available in the `pkg` Salt source directory.

### 32.2.3 salt-call

**salt-call**

**Synopsis**

```
salt-call [options]
```

**Description**

The `salt-call` command is used to run module functions locally on a minion instead of executing them from the master. `salt-call` is used to run a *Standalone Minion*, and was originally created for *troubleshooting*.

The Salt Master is contacted to retrieve state files and other resources during execution unless the `--local` option is specified.

**Note:** `salt-call` commands execute from the current user's shell context, while `salt` commands execute from the system's default context.

**Options**

`--version`

Print the version of Salt that is running.

`--versions-report`

Show program's dependencies and version number, and then exit.

`-h, --help`

Show the help message and exit.

`-c CONFIG_DIR, --config-dir=CONFIG_dir`

The location of the Salt configuration directory. This directory contains the configuration files for Salt master and minions. The default location on most systems is `/etc/salt`.

`--hard-crash`

Raise any original exception rather than exiting gracefully Default: False
-g, --grains
Return the information generated by the Salt grains

-m MODULE_DIRS, --module-dirs=MODULE_DIRS
Specify an additional directory to pull modules from. Multiple directories can be provided by passing -m
--module-dirs multiple times.

-d, --doc, --documentation
Return the documentation for the specified module or for all modules if none are specified

--master=MASTER
Specify the master to use. The minion must be authenticated with the master. If this option is omitted, the
master options from the minion config will be used. If multi masters are set up the first listed master that
responds will be used.

--return RETURNER
Set salt-call to pass the return data to one or many returner interfaces. To use many returner interfaces specify
a comma delimited list of returners.

--local
Run salt-call locally, as if there was no master running.

--file-root=FILE_ROOT
Set this directory as the base file root.

--pillar-root=PIILLAR_ROOT
Set this directory as the base pillar root.

--retcode-passthrough
Exit with the salt call retcode and not the salt binary retcode

--metadata
Print out the execution metadata as well as the return. This will print out the outputter data, the return code,
etc.

--id=ID
Specify the minion id to use. If this option is omitted, the id option from the minion config will be used.

--skip-grains
Do not load grains.

--refresh-grains-cache
Force a refresh of the grains cache

Logging Options

Logging options which override any settings defined on the configuration files.

-l LOG_LEVEL, --log-level=LOG_LEVEL
Console logging log level. One of all, garbage, trace, debug, info, warning, error, quiet. Default: info.

--log-file=LOG_FILE
Log file path. Default: /var/log/salt/minion.

--log-file-level=LOG_LEVEL_LOGFILE
Log file logging log level. One of all, garbage, trace, debug, info, warning, error, quiet. Default: info.
Output Options

--out
   Pass in an alternative outpuer to display the return of data. This outpuer can be any of the available out-
   putters:
   
   grains, highstate, json, key, overstatestage, pprint, raw, txt, yaml
   
   Some outputters are formatted only for data returned from specific functions; for instance, the grains out-
   putter will not work for non-grains data.
   
   If an outpuer is used that does not support the data passed into it, then Salt will fall back on the pprint
   outpuer and display the return data using the Python pprint standard library module.

   Note: If using --out=json, you will probably want --static as well. Without the static option, you will
   get a separate JSON string per minion which makes JSON output invalid as a whole. This is due to using an
   iterative outpuer. So if you want to feed it to a JSON parser, use --static as well.

--out-indent OUTPUT_INDENT, --output-indent OUTPUT_INDENT
   Print the output indented by the provided value in spaces. Negative values disable indentation. Only applicable
   in outputters that support indentation.

--out-file=OUTPUT_FILE, --output-file=OUTPUT_FILE
   Write the output to the specified file.

--no-color
   Disable all colored output

--force-color
   Force colored output

   Note: When using colored output the color codes are as follows:
   green denotes success, red denotes failure, blue denotes changes and success and yellow denotes a
   expected future change in configuration.

See also

salt(1) salt-master(1) salt-minion(1)

32.2.4 salt

salt

Synopsis

   salt "" [ options ] sys.doc
   salt -E "" [ options ] sys.doc cmd
   salt -G `os:Arch."" [ options ] test.ping
   salt -C `G@os:Arch." and webserv" or G@kernel:FreeBSD' [ options ] test.ping
Description

Salt allows for commands to be executed across a swath of remote systems in parallel. This means that remote systems can be both controlled and queried with ease.

Options

--)version
Print the version of Salt that is running.

--)versions-report
Show program's dependencies and version number, and then exit

-h, --help
Show the help message and exit

-c CONFIG_DIR, --config-dir=CONFIG_dir
The location of the Salt configuration directory. This directory contains the configuration files for Salt master and minions. The default location on most systems is /etc/salt.

-t TIMEOUT, --timeout=TIMEOUT
The timeout in seconds to wait for replies from the Salt minions. The timeout number specifies how long the command line client will wait to query the minions and check on running jobs. Default: 5

-s, --static
By default as of version 0.9.8 the salt command returns data to the console as it is received from minions, but previous releases would return data only after all data was received. Use the static option to only return the data with a hard timeout and after all minions have returned. Without the static option, you will get a separate JSON string per minion which makes JSON output invalid as a whole.

--)async
Instead of waiting for the job to run on minions only print the job id of the started execution and complete.

--)state-output=STATE_OUTPUT
New in version 0.17.
Override the configured state_output value for minion output. One of full, terse, mixed, changes or filter. Default: full.

--)subset=SUBSET
Execute the routine on a random subset of the targeted minions. The minions will be verified that they have the named function before executing.

-v VERBOSE, --verbose
Turn on verbosity for the salt call, this will cause the salt command to print out extra data like the job id.

--)hide-timeout
Instead of showing the return data for all minions. This option prints only the online minions which could be reached.

-b BATCH, --batch-size=BATCH
Instead of executing on all targeted minions at once, execute on a progressive set of minions. This option takes an argument in the form of an explicit number of minions to execute at once, or a percentage of minions to execute on.

-a EAUTH, --auth=EAUTH
Pass in an external authentication medium to validate against. The credentials will be prompted for. The options are auto, keystone, ldap, pam, and stormpath. Can be used with the -T option.
-T, --make-token
Used in conjunction with the -a option. This creates a token that allows for the authenticated user to send
commands without needing to re-authenticate.

--return=RETURNER
Choose an alternative returner to call on the minion, if an alternative returner is used then the return will
not come back to the command line but will be sent to the specified return system. The options are carbon,
cassandra, couchbase, couchdb, elasticsearch, etcd, hipchat, local, local_cache, memcache, mongo, mysql, odbc,
postgres, redis, sentry, slack, sms, smtp, sqlite3, syslog, and xmpp.

-d, --doc, --documentation
Return the documentation for the module functions available on the minions

--args-separator=ARGS_SEPARATOR
Set the special argument used as a delimiter between command arguments of compound commands. This is
useful when one wants to pass commas as arguments to some of the commands in a compound command.

Logging Options

Logging options which override any settings defined on the configuration files.

-l LOG_LEVEL, --log-level=LOG_LEVEL
Console logging log level. One of all, garbage, trace, debug, info, warning, error, quiet. Default: warning.

--log-file=LOG_FILE

--log-file-level=LOG_LEVEL_LOGFILE
Logfile logging log level. One of all, garbage, trace, debug, info, warning, error, quiet. Default: warning.

Target Selection

The default matching that Salt utilizes is shell-style globbing around the minion id. See https://docs.python.org/2/
library/fnmatch.html#module-fnmatch.

-E, --pcre
The target expression will be interpreted as a PCRE regular expression rather than a shell glob.

-L, --list
The target expression will be interpreted as a comma-delimited list; example: server1.foo.bar,server2.foo.bar,example7.quo.qux

-G, --grain
The target expression matches values returned by the Salt grains system on the minions. The target expression
is in the format of `<grain value>:<glob expression>'; example: `os:Arch`
This was changed in version 0.9.8 to accept glob expressions instead of regular expression. To use regular
expression matching with grains, use the --grain-pcre option.

--grain-pcre
The target expression matches values returned by the Salt grains system on the minions. The target expression
is in the format of `<grain value>:< regular expression>'; example: `os:Arch`.

-N, --nodegroup
Use a predefined compound target defined in the Salt master configuration file.
--R, --range
Instead of using shell globs to evaluate the target, use a range expression to identify targets. Range expressions look like %cluster.

Using the Range option requires that a range server is set up and the location of the range server is referenced in the master configuration file.

--C, --compound
Utilize many target definitions to make the call very granular. This option takes a group of targets separated by and or or. The default matcher is a glob as usual. If something other than a glob is used, preface it with the letter denoting the type; example: `webserv* and G@os:Debian or E@db*` Make sure that the compound target is encapsulated in quotes.

--I, --pillar
Instead of using shell globs to evaluate the target, use a pillar value to identify targets. The syntax for the target is the pillar key followed by a glob expression: "role:production"

--S, --ipcidr
Match based on Subnet (CIDR notation) or IPv4 address.

Output Options

--out
Pass in an alternative outpuuter to display the return of data. This outpuuter can be any of the available outputers:

grains, highstate, json, key, overstatestage, pprint, raw, txt, yaml

Some outputers are formatted only for data returned from specific functions; for instance, the grains outpuuter will not work for non-grains data.

If an outpuuter is used that does not support the data passed into it, then Salt will fall back on the pprint outpuuter and display the return data using the Python pprint standard library module.

Note: If using --out=json, you will probably want --static as well. Without the static option, you will get a separate JSON string per minion which makes JSON output invalid as a whole. This is due to using an iterative outpuuter. So if you want to feed it to a JSON parser, use --static as well.

--out-indent OUTPUT_INDENT, --output-indent OUTPUT_INDENT
Print the output indented by the provided value in spaces. Negative values disable indentation. Only applicable in outputers that support indentation.

--out-file=OUTPUT_FILE, --output-file=OUTPUT_FILE
Write the output to the specified file.

--no-color
Disable all colored output

--force-color
Force colored output

Note: When using colored output the color codes are as follows:
green denotes success, red denotes failure, blue denotes changes and success and yellow denotes a expected future change in configuration.
32.2.5 salt-cloud

32.2.6 salt-cp

salt-cp

Copy a file to a set of systems

Synopsis

salt-cp '.*' [ options ] SOURCE DEST
salt-cp -E '.*' [ options ] SOURCE DEST
salt-cp -G 'os:Arch.*' [ options ] SOURCE DEST

Description

Salt copy copies a local file out to all of the Salt minions matched by the given target.

Note: salt-cp uses salt's publishing mechanism. This means the privacy of the contents of the file on the wire is completely dependent upon the transport in use. In addition, if the salt-master is running with debug logging it is possible that the contents of the file will be logged to disk.

Options

--version
   Print the version of Salt that is running.

--version-report
   Show program's dependencies and version number, and then exit

-h, --help
   Show the help message and exit

-c CONFIG_DIR, --config-dir=CONFIG_dir
   The location of the Salt configuration directory. This directory contains the configuration files for Salt master and minions. The default location on most systems is /etc/salt.

-t TIMEOUT, --timeout=TIMEOUT
   The timeout in seconds to wait for replies from the Salt minions. The timeout number specifies how long the command line client will wait to query the minions and check on running jobs. Default: 5
Logging Options

Logging options which override any settings defined on the configuration files.

-\texttt{\textbf{\texttt{-l}} \ LOG\_LEVEL, \ --log-level=LOG\_LEVEL}
  Console logging log level. One of all, garbage, trace, debug, info, warning, error, quiet. Default: warning.

-\texttt{\textbf{\texttt{--log-file}}=LOG\_FILE}

-\texttt{\textbf{\texttt{--log-file-level}}=LOG\_LEVEL\_LOGFILE}
  Logfile logging log level. One of all, garbage, trace, debug, info, warning, error, quiet. Default: warning.

Target Selection

The default matching that Salt utilizes is shell-style globbing around the minion id. See \url{https://docs.python.org/2/library/fnmatch.html#module-fnmatch}.

-\texttt{\textbf{\texttt{--pcre}}}
  The target expression will be interpreted as a PCRE regular expression rather than a shell glob.

-\texttt{\textbf{\texttt{-L}} \ --list}
  The target expression will be interpreted as a comma-delimited list; example: server1.foo.bar,server2.foo.bar,example7.quo.qux

-\texttt{\textbf{\texttt{-G}} \ --grain}
  The target expression matches values returned by the Salt grains system on the minions. The target expression is in the format of `\texttt{<grain value>:<glob expression>}`; example: `os:Arch`

  This was changed in version 0.9.8 to accept glob expressions instead of regular expression. To use regular expression matching with grains, use the --grain-pcre option.

-\texttt{\textbf{\texttt{--grain-pcre}}}
  The target expression matches values returned by the Salt grains system on the minions. The target expression is in the format of `\texttt{<grain value>:< regular expression>}`; example: `os:Arch`

-\texttt{\textbf{\texttt{-N}} \ --nodegroup}
  Use a predefined compound target defined in the Salt master configuration file.

-\texttt{\textbf{\texttt{-R}} \ --range}
  Instead of using shell globs to evaluate the target, use a range expression to identify targets. Range expressions look like %cluster.

  Using the Range option requires that a range server is set up and the location of the range server is referenced in the master configuration file.

\texttt{salt(1) salt-master(1) salt-minion(1)}
32.2.7 salt-key

salt-key

Synopsis

salt-key [ options ]

Description

Salt-key executes simple management of Salt server public keys used for authentication.

On initial connection, a Salt minion sends its public key to the Salt master. This key must be accepted using the salt-key command on the Salt master.

Salt minion keys can be in one of the following states:

- **unaccepted**: key is waiting to be accepted.
- **accepted**: key was accepted and the minion can communicate with the Salt master.
- **rejected**: key was rejected using the salt-key command. In this state the minion does not receive any communication from the Salt master.
- **denied**: key was rejected automatically by the Salt master. This occurs when a minion has a duplicate ID, or when a minion was rebuilt or had new keys generated and the previous key was not deleted from the Salt master. In this state the minion does not receive any communication from the Salt master.

To change the state of a minion key, use -d to delete the key and then accept or reject the key.

Options

```
--version
Print the version of Salt that is running.

--versions-report
Show program's dependencies and version number, and then exit

-h, --help
Show the help message and exit

-c CONFIG_DIR, --config-dir=CONFIG_dir
The location of the Salt configuration directory. This directory contains the configuration files for Salt master and minions. The default location on most systems is /etc/salt.

-u USER, --user=USER
Specify user to run salt-key

--hard-crash
Raise any original exception rather than exiting gracefully. Default is False.

-q, --quiet
Suppress output

-y, --yes
Answer 'Yes' to all questions presented, defaults to False
```
`--rotate-aes-key=ROTATE_AES_KEY`

Setting this to False prevents the master from refreshing the key session when keys are deleted or rejected, this lowers the security of the key deletion/rejection operation. Default is True.

Logging Options

Logging options which override any settings defined on the configuration files.

`--log-file=LOG_FILE`

Log file path. Default: /var/log/salt/minion.

`--log-file-level=LOG_LEVEL_LOGFILE`

Logfile logging log level. One of all, garbage, trace, debug, info, warning, error, quiet. Default: warning.

Output Options

`--out`

Pass in an alternative outpuer to display the return of data. This outpuer can be any of the available out-putters:

*grains*, *highstate*, *json*, *key*, *overstatestage*, *pprint*, *raw*, *txt*, *yaml*

Some outpuers are formatted only for data returned from specific functions; for instance, the grains out-putter will not work for non-grains data.

If an outpuer is used that does not support the data passed into it, then Salt will fall back on the pprint outpuer and display the return data using the Python pprint standard library module.

**Note:** If using `--out=json`, you will probably want `--static` as well. Without the static option, you will get a separate JSON string per minion which makes JSON output invalid as a whole. This is due to using an iterative outpuer. So if you want to feed it to a JSON parser, use `--static` as well.

`--out-indent OUTPUT_INDENT, --output-indent OUTPUT_INDENT`

Print the output indented by the provided value in spaces. Negative values disable indentation. Only applicable in outpuers that support indentation.

`--out-file=OUTPUT_FILE, --output-file=OUTPUT_FILE`

Write the output to the specified file.

`--no-color`

Disable all colored output

`--force-color`

Force colored output

**Note:** When using colored output the color codes are as follows:

green denotes success, red denotes failure, blue denotes changes and success and yellow denotes a expected future change in configuration.
Actions

-l ARG, --list=ARG
List the public keys. The args pre, un, and unaccepted will list unaccepted/unsigned keys. acc or accepted will list accepted/signed keys. rej or rejected will list rejected keys. Finally, all will list all keys.

-L, --list-all
List all public keys. (Deprecated: use --list all)

-a ACCEPT, --accept=ACCEPT
Accept the specified public key (use --include-all to match rejected keys in addition to pending keys). Globs are supported.

-A, --accept-all
Accepts all pending keys.

-r REJECT, --reject=REJECT
Reject the specified public key (use --include-all to match accepted keys in addition to pending keys). Globs are supported.

-R, --reject-all
Rejects all pending keys.

--include-all
Include non-pending keys when accepting/rejecting.

-p PRINT, --print=PRINT
Print the specified public key.

-P, --print-all
Print all public keys

-d DELETE, --delete=DELETE
Delete the specified key. Globs are supported.

-D, --delete-all
Delete all keys.

-f FINGER, --finger=FINGER
Print the specified key's fingerprint.

-F, --finger-all
Print all keys' fingerprints.

Key Generation Options

--gen-keys=GEN_KEYS
Set a name to generate a keypair for use with salt

--gen-keys-dir=GEN_KEYS_DIR
Set the directory to save the generated keypair. Only works with `gen_keys_dir' option; default is the current directory.

--keysize=KEYSIZE
Set the keysize for the generated key, only works with the `--gen-keys' option, the key size must be 2048 or higher, otherwise it will be rounded up to 2048. The default is 2048.

--gen-signature
Create a signature file of the master's public-key named master_pubkey_signature. The signature can be sent to
a minion in the master’s auth-reply and enables the minion to verify the master’s public-key cryptographically. This requires a new signing-key-pair which can be auto-created with the --auto-create parameter.

`--priv=PRIV`

The private-key file to create a signature with

`--signature-path=SIGNATURE_PATH`

The path where the signature file should be written

`--pub=PUB`

The public-key file to create a signature for

`--auto-create`

Auto-create a signing key-pair if it does not yet exist

See also

`salt(7) salt-master(1) salt-minion(1)`

32.2.8 salt-master

`salt-master`

The Salt master daemon, used to control the Salt minions

Synopsis

```
salt-master [ options ]
```

Description

The master daemon controls the Salt minions

Options

`--version`

Print the version of Salt that is running.

`--versions-report`

Show program’s dependencies and version number, and then exit

`-h, --help`

Show the help message and exit

`-c CONFIG_DIR, --config-dir=CONFIG_dir`

The location of the Salt configuration directory. This directory contains the configuration files for Salt master and minions. The default location on most systems is `/etc/salt`.

`-u USER, --user=USER`

Specify user to run salt-master

`-d, --daemon`

Run salt-master as a daemon
--pid-file  PIDFILE
    Specify the location of the pidfile. Default: /var/run/salt-master.pid

Logging Options

Logging options which override any settings defined on the configuration files.

-l  LOG_LEVEL,  --log-level=LOG_LEVEL
    Console logging log level. One of all, garbage, trace, debug, info, warning, error, quiet. Default: warning.

--log-file=LOG_FILE

--log-file-level=LOG_LEVEL_LOGFILE
    Logfile logging log level. One of all, garbage, trace, debug, info, warning, error, quiet. Default: warning.

salt(1) salt(7) salt-minion(1)

32.2.9  salt-minion

salt-minion

The Salt minion daemon, receives commands from a remote Salt master.

Synopsis

    salt-minion [ options ]

Description

The Salt minion receives commands from the central Salt master and replies with the results of said commands.

Options

--version
    Print the version of Salt that is running.

--versions-report
    Show program's dependencies and version number, and then exit

-h,  --help
    Show the help message and exit

-c  CONFIG_DIR,  --config-dir=CONFIG_dir
    The location of the Salt configuration directory. This directory contains the configuration files for Salt master
    and minions. The default location on most systems is /etc/salt.
-u USER, --user=USER
   Specify user to run salt-minion

-d, --daemon
   Run salt-minion as a daemon

--pid-file PIDFILE
   Specify the location of the pidfile. Default: /var/run/salt-minion.pid

Logging Options

Logging options which override any settings defined on the configuration files.

-l LOG_LEVEL, --log-level=LOG_LEVEL
   Console logging log level. One of all, garbage, trace, debug, info, warning, error, quiet. Default: warning.

--log-file=LOG_FILE
   Log file path. Default: /var/log/salt/minion.

--log-file-level=LOG_LEVEL_LOGFILE
   Logfile logging log level. One of all, garbage, trace, debug, info, warning, error, quiet. Default: warning.

salt(1) salt(7) salt-master(1)

32.2.10 salt-proxy

salt-proxy

Receives commands from a Salt master and proxies these commands to devices that are unable to run a full minion.

Synopsis

salt-proxy [ options ]

Description

The Salt proxy minion receives commands from a Salt master, transmits appropriate commands to devices that are unable to run a minion, and replies with the results of said commands.

Options

--proxyid
   The minion id that this proxy will assume. This is required.

--version
   Print the version of Salt that is running.
--versions-report
    Show program's dependencies and version number, and then exit

-h, --help
    Show the help message and exit

c CONFIG_DIR, --config-dir=CONFIG_dir
    The location of the Salt configuration directory. This directory contains the configuration files for Salt master and minions. The default location on most systems is /etc/salt.

-u USER, --user=USER
    Specify user to run salt-proxy

d, --daemon
    Run salt-proxy as a daemon

--pid-file PIDFILE
    Specify the location of the pidfile. Default: /var/run/salt-proxy-<id>.pid

Logging Options

Logging options which override any settings defined on the configuration files.

-l LOG_LEVEL, --log-level=LOG_LEVEL
    Console logging log level. One of all, garbage, trace, debug, info, warning, error, quiet. Default: warning.

--log-file=LOG_FILE
    Log file path. Default: /var/log/salt/minion.

--log-file-level=LOG_LEVEL_LOGFILE
    Logfile logging log level. One of all, garbage, trace, debug, info, warning, error, quiet. Default: warning.

salt(1) salt(7) salt-master(1) salt-minion(1)

32.2.11 salt-run

salt-run

Execute a Salt runner

Synopsis

salt-run RUNNER

Description

salt-run is the frontend command for executing Salt Runners. Salt runners are simple modules used to execute convenience functions on the master
Options

--version
Print the version of Salt that is running.

--versions-report
Show program’s dependencies and version number, and then exit

-h, --help
Show the help message and exit

-c CONFIG_DIR, --config-dir=CONFIG_dir
The location of the Salt configuration directory. This directory contains the configuration files for Salt master and minions. The default location on most systems is /etc/salt.

-t TIMEOUT, --timeout=TIMEOUT
The timeout in seconds to wait for replies from the Salt minions. The timeout number specifies how long the command line client will wait to query the minions and check on running jobs. Default: 1

--hard-crash
Raise any original exception rather than exiting gracefully. Default is False.

-d, --doc, --documentation
Display documentation for runners, pass a module or a runner to see documentation on only that module/runner.

Logging Options

Logging options which override any settings defined on the configuration files.

-l LOG_LEVEL, --log-level=LOG_LEVEL
Console logging log level. One of all, garbage, trace, debug, info, warning, error, quiet. Default: warning.

--log-file=LOG_FILE

--log-file-level=LOG_LEVEL_LOGFILE
Logfile logging log level. One of all, garbage, trace, debug, info, warning, error, quiet. Default: warning.

salt(1) salt-master(1) salt-minion(1)

32.2.12 salt-ssh

salt-ssh

Synopsis

salt-ssh 'x' [ options ] sys.doc
salt-ssh -E ',x' [ options ] sys.doc cmd
Description

Salt SSH allows for salt routines to be executed using only SSH for transport

Options

- **-r, --raw, --raw-shell**
  Execute a raw shell command.

- **--priv**
  Specify the SSH private key file to be used for authentication.

- **--roster**
  Define which roster system to use, this defines if a database backend, scanner, or custom roster system is used.
  Default is the flat file roster.

- **--roster-file**
  Define an alternative location for the default roster file location. The default roster file is called roster and is found in the same directory as the master config file.
  New in version 2014.1.0.

- **--refresh, --refresh-cache**
  Force a refresh of the master side data cache of the target's data. This is needed if a target's grains have been changed and the auto refresh timeframe has not been reached.

- **--max-procs**
  Set the number of concurrent minions to communicate with. This value defines how many processes are opened up at a time to manage connections, the more running process the faster communication should be, default is 25.

- **-i, --ignore-host-keys**
  Ignore the ssh host keys which by default are honored and connections would ask for approval.

- **--passwd**
  Set the default password to attempt to use when authenticating.

- **--key-deploy**
  Set this flag to attempt to deploy the authorized ssh key with all minions. This combined with --passwd can make initial deployment of keys very fast and easy.

- **--version**
  Print the version of Salt that is running.

- **--versions-report**
  Show program's dependencies and version number, and then exit

- **-h, --help**
  Show the help message and exit

- **-c CONFIG_DIR, --config-dir=CONFIG_dir**
  The location of the Salt configuration directory. This directory contains the configuration files for Salt master and minions. The default location on most systems is /etc/salt.

Target Selection

The default matching that Salt utilizes is shell-style globbing around the minion id. See https://docs.python.org/2/library/fnmatch.html#module-fnmatch.
-E, --pcre
The target expression will be interpreted as a PCRE regular expression rather than a shell glob.

Logging Options

Logging options which override any settings defined on the configuration files.

-Il LOG_LEVEL, --log-level=LOG_LEVEL
  Console logging log level. One of all, garbage, trace, debug, info, warning, error, quiet. Default: warning.

--log-file=LOG_FILE

--log-file-level=LOG_LEVEL_LOGFILE
  Logfile logging log level. One of all, garbage, trace, debug, info, warning, error, quiet. Default: warning.

Output Options

--out
  Pass in an alternative outpunter to display the return of data. This outpunter can be any of the available outpuuters:

  grains, highstate, json, key, overstatestage, pprint, raw, txt, yaml

  Some outpuuters are formatted only for data returned from specific functions; for instance, the grains outpunter will not work for non-grains data.

  If an outpunter is used that does not support the data passed into it, then Salt will fall back on the pprint outpunter and display the return data using the Python pprint standard library module.

  **Note:** If using --out=json, you will probably want --static as well. Without the static option, you will get a separate JSON string per minion which makes JSON output invalid as a whole. This is due to using an iterative outpunter. So if you want to feed it to a JSON parser, use --static as well.

--out-indent OUTPUT_INDENT, --output-indent OUTPUT_INDENT
  Print the output indented by the provided value in spaces. Negative values disable indentation. Only applicable in outpuuters that support indentation.

--out-file=OUTPUT_FILE, --output-file=OUTPUT_FILE
  Write the output to the specified file.

--no-color
  Disable all colored output

--force-color
  Force colored output

  **Note:** When using colored output the color codes are as follows:

  * green denotes success, red denotes failure, blue denotes changes and success and yellow denotes a expected future change in configuration.

salt(7) salt-master(1) salt-minion(1)

32.2.13 salt-syndic

**salt-syndic**

The Salt syndic daemon, a special minion that passes through commands from a higher master

**Synopsis**

```
salt-syndic [ options ]
```

**Description**

The Salt syndic daemon, a special minion that passes through commands from a higher master.

**Options**

```
--version
  Print the version of Salt that is running.
--versions-report
  Show program's dependencies and version number, and then exit
-h, --help
  Show the help message and exit
-c CONFIG_DIR, --config-dir=CONFIG_dir
  The location of the Salt configuration directory. This directory contains the configuration files for Salt master and minions. The default location on most systems is /etc/salt.
-u USER, --user=USER
  Specify user to run salt-syndic
-d, --daemon
  Run salt-syndic as a daemon
--pid-file PIDFILE
  Specify the location of the pidfile. Default: /var/run/salt-syndic.pid
```

**Logging Options**

Logging options which override any settings defined on the configuration files.

```
-l LOG_LEVEL, --log-level=LOG_LEVEL
  Console logging log level. One of all, garbage, trace, debug, info, warning, error, quiet. Default: warning.
--log-file=LOG_FILE
```
---log-file-level=LOG_LEVEL_LOGFILE
    Logfile logging log level. One of all, garbage, trace, debug, info, warning, error, quiet. Default: warning.

salt(1) salt-master(1) salt-minion(1)

32.2.14 salt-api

salt-api

Start interfaces used to remotely connect to the salt master

Synopsis

salt-api

Description

The Salt API system manages network api connectors for the Salt Master

Options

--version
    Print the version of Salt that is running.

--versions-report
    Show program's dependencies and version number, and then exit

-h, --help
    Show the help message and exit

-c CONFIG_DIR, --config-dir=CONFIG_dir
    The location of the Salt configuration directory. This directory contains the configuration files for Salt master and minions. The default location on most systems is /etc/salt.

-d, --daemon
    Run the salt-api as a daemon

--pid-file=PIDFILE
    Specify the location of the pidfile. Default: /var/run/salt-api.pid

Logging Options

Logging options which override any settings defined on the configuration files.

-l LOG_LEVEL, --log-level=LOG_LEVEL
    Console logging log level. One of all, garbage, trace, debug, info, warning, error, quiet. Default: warning.
--log-file=LOG_FILE

--log-file-level=LOG_LEVEL_LOGFILE
Logfile logging log level. One of all, garbage, trace, debug, info, warning, error, quiet. Default: warning.

salt-api(7) salt(7) salt-master(1)

32.2.15 spm

spm

Salt Package Manager

Synopsis

ssp <command> [argument]

Description

spm is the frontend command for managing Salt packages. Packages normally only include formulas, meaning a group of SLS files that install into the file_roots on the Salt Master, but Salt modules can also be installed.

Options

-y, --assume-yes
Assume yes instead of prompting the other whether or not to proceed with a particular command. Default is False.

-f, --force
When presented with a course of action that spm would normally refuse to perform, that action will be performed anyway. This is often destructive, and should be used with caution.

Logging Options

Logging options which override any settings defined on the configuration files.

-l LOG_LEVEL, --log-level=LOG_LEVEL
Console logging log level. One of all, garbage, trace, debug, info, warning, error, quiet. Default: warning.

--log-file=LOG_FILE

--log-file-level=LOG_LEVEL_LOGFILE
Logfile logging log level. One of all, garbage, trace, debug, info, warning, error, quiet. Default: warning.
Commands

update_repo
   Connect to remote repositories locally configured on the system and download their metadata.

install
   Install a package from a configured SPM repository. Requires a package name.

remove
   Remove an installed package from the system. Requires a package name.

info
   List information about an installed package. Requires a package name.

current
   List files belonging to an installed package. Requires a package name.

local
   Perform one of the above options (except for remove) on a package file, instead of on a package in a repository, or an installed package. Requires a valid path to a local file on the system.

build
   Build a package from a directory containing a FORMULA file. Requires a valid path to a local directory on the system.

create_repo
   Scan a directory for valid SPM package files and build an SPM-METADATA file in that directory which describes them.

See also

salt(1) salt-master(1) salt-minion(1)

32.3 Client ACL system

The salt client ACL system is a means to allow system users other than root to have access to execute select salt commands on minions from the master.

The client ACL system is configured in the master configuration file via the client_acl configuration option. Under the client_acl configuration option the users open to send commands are specified and then a list of regular expressions which specify the minion functions which will be made available to specified user. This configuration is much like the peer configuration:

```text
client_acl:
    # Allow thatch to execute anything.
    thatch:
        - .*
    # Allow fred to use test and pkg, but only on "web*" minions.
    fred:
        - web*:
        - test.*
        - pkg.*
```

32.3. Client ACL system
32.3.1 Permission Issues

Directories required for client_acl must be modified to be readable by the users specified:

```
chmod 755 /var/cache/salt /var/cache/salt/master /var/cache/salt/master/jobs /var/run/
       ->salt /var/run/salt/master
```

Note: In addition to the changes above you will also need to modify the permissions of /var/log/salt and the existing log file to be writable by the user(s) which will be running the commands. If you do not wish to do this then you must disable logging or Salt will generate errors as it cannot write to the logs as the system users.

If you are upgrading from earlier versions of salt you must also remove any existing user keys and re-start the Salt master:

```
rm /var/cache/salt/.*key
service salt-master restart
```

32.4 Python client API

Salt provides several entry points for interfacing with Python applications. These entry points are often referred to as *Client() APIs. Each client accesses different parts of Salt, either from the master or from a minion. Each client is detailed below.

See also:

There are many ways to access Salt programmatically.

Salt can be used from CLI scripts as well as via a REST interface.

See Salt’s outputter system to retrieve structured data from Salt as JSON, or as shell-friendly text, or many other formats.

See the state.event runner to utilize Salt’s event bus from shell scripts.

Salt’s netapi module provides access to Salt externally via a REST interface. Review the netapi module documentation for more information.

32.4.1 Salt’s opts dictionary

Some clients require access to Salt’s opts dictionary. (The dictionary representation of the master or minion config files.)

A common pattern for fetching the opts dictionary is to defer to environment variables if they exist or otherwise fetch the config from the default location.

```
salt.config.client_config(path, env_var='SALT_CLIENT_CONFIG', defaults=None)
```

Load Master configuration data

Usage:

```
import salt.config
master_opts = salt.config.client_config('/etc/salt/master')
```
Returns a dictionary of the Salt Master configuration file with necessary options needed to communicate with a locally-running Salt Master daemon. This function searches for client specific configurations and adds them to the data from the master configuration.

This is useful for master-side operations like `LocalClient`.

salt.config.minion_config(path, env_var='SALT_MINION_CONFIG', defaults=None, cache_minion_id=False, ignore_config_errors=True)

Reads in the minion configuration file and sets up special options

This is useful for Minion-side operations, such as the `Caller` class, and manually running the loader interface.

```python
import salt.client
minion_opts = salt.config.minion_config('/etc/salt/minion')
```

### 32.4.2 Salt’s Loader Interface

Modules in the Salt ecosystem are loaded into memory using a custom loader system. This allows modules to have conditional requirements (OS, OS version, installed libraries, etc) and allows Salt to inject special variables (`__salt__`, `__opts__`, etc).

Most modules can be manually loaded. This is often useful in third-party Python apps or when writing tests. However some modules require and expect a full, running Salt system underneath. Notably modules that facilitate master-to-minion communication such as the `mine`, `publish`, and `peer` execution modules. The error `KeyError: 'master_uri'` is a likely indicator for this situation. In those instances use the `Caller` class to execute those modules instead.

Each module type has a corresponding loader function.

```python
salt.loader.minion_mods(opts, context=None, utils=None, whitelist=None, include_errors=False, initial_load=False, loaded_base_name=None, notify=False, proxy=None)
```

Load execution modules

Returns a dictionary of execution modules appropriate for the current system by evaluating the `__virtual__()` function in each module.

**Parameters**

- `opts (dict)` -- The Salt options dictionary
- `context (dict)` -- A Salt context that should be made present inside generated modules in `__context__`
- `utils (dict)` -- Utility functions which should be made available to Salt modules in `__utils__`. See `utils_dir` in `salt.config` for additional information about configuration.
- `whitelist (list)` -- A list of modules which should be whitelisted.
- `include_errors (bool)` -- Deprecated flag! Unused.
- `initial_load (bool)` -- Deprecated flag! Unused.
- `loaded_base_name (str)` -- A string marker for the loaded base name.
- `notify (bool)` -- Flag indicating that an event should be fired upon completion of module loading.

```python
import salt.config
import salt.loader

__opts__ = salt.config.minion_config('/etc/salt/minion')
__grains__ = salt.loader.grains(__opts__)
```
__opts__['grains'] = __grains__
__utils__ = salt.loader.utils(__opts__)
__salt__ = salt.loader.minion_mods(__opts__, utils=__utils__)

salt.loader.raw_mod(opts, name, functions, mod='modules')
Returns a single module loaded raw and bypassing the __virtual__ function

```python
import salt.config
import salt.loader

__opts__ = salt.config.minion_config('/etc/salt/minion')
testmod = salt.loader.raw_mod(__opts__, 'test', None)
testmod['test.ping']()
```

salt.loader.states(opts, functions, utils, whitelist=None)
Returns the state modules

Parameters
- **opts** (dict) -- The Salt options dictionary
- **functions** (dict) -- A dictionary of minion modules, with module names as keys and funcs as values.

```python
import salt.config
import salt.loader

__opts__ = salt.config.minion_config('/etc/salt/minion')
statemods = salt.loader.states(__opts__, None, None)
```

salt.loader.grains(opts, force_refresh=False, proxy=None)
Return the functions for the dynamic grains and the values for the static grains.

```python
import salt.config
import salt.loader

__opts__ = salt.config.minion_config('/etc/salt/minion')
__grains__ = salt.loader.grains(__opts__)
print __grains__['id']
```

salt.loader.grain_funcs(opts)
Returns the grain functions

```python
import salt.config
import salt.loader

__opts__ = salt.config.minion_config('/etc/salt/minion')
grainfuncs = salt.loader.grain_funcs(__opts__)
```

32.4.3 Salt's Client Interfaces

**LocalClient**

class salt.client.LocalClient(c_path='/etc/salt/master', mopts=None, skip_perm_errors=False)
The interface used by the salt CLI tool on the Salt Master
LocalClient is used to send a command to Salt minions to execute execution modules and return the results to the Salt Master.

Importing and using LocalClient must be done on the same machine as the Salt Master and it must be done using the same user that the Salt Master is running as. (Unless external_auth is configured and authentication credentials are included in the execution).

```python
import salt.client
local = salt.client.LocalClient()
local.cmd('*', 'test.fib', [10])
```

**cmd(tgt, fun, arg=(), timeout=None, expr_form='glob', ret='`', jid='`, kwarg=None, **kwargs)**

Synchronously execute a command on targeted minions

The cmd method will execute and wait for the timeout period for all minions to reply, then it will return all minion data at once.

```python
>>> import salt.client
>>> local = salt.client.LocalClient()
>>> local.cmd('*','cmd.run', ['whoami'])
{'jerry': 'root'}
```

With extra keyword arguments for the command function to be run:

```python
local.cmd('*','test.arg', ['arg1', 'arg2'], kwarg={'foo': 'bar'})
```

Compound commands can be used for multiple executions in a single publish. Function names and function arguments are provided in separate lists but the index values must correlate and an empty list must be used if no arguments are required.

```python
>>> local.cmd('*',[ 'grains.items','sys.doc','cmd.run'],
                          [],
                          [],
                          ['uptime'],
                          )
```

**Parameters**

- **tgt**(string or list) -- Which minions to target for the execution. Default is shell glob. Modified by the expr_form option.
- **fun**(string or list of strings) -- The module and function to call on the specified minions of the form module.function. For example test.ping or grains.items.

**Compound commands** Multiple functions may be called in a single publish by passing a list of commands. This can dramatically lower overhead and speed up the application communicating with Salt.

This requires that the arg param is a list of lists. The fun list and the arg list must correlate by index meaning a function that does not take arguments must still have a corresponding empty list at the expected index.
- **arg** *(list or list-of-lists)* -- A list of arguments to pass to the remote function. If the function takes no arguments `arg` may be omitted except when executing a compound command.

- **timeout** -- Seconds to wait after the last minion returns but before all minions return.

- **expr_form** -- The type of `tgt`. Allowed values:
  - glob - Bash glob completion - Default
  - pcre - Perl style regular expression
  - list - Python list of hosts
  - grain - Match based on a grain comparison
  - grain_pcre - Grain comparison with a regex
  - pillar - Pillar data comparison
  - pillar_pcre - Pillar data comparison with a regex
  - nodegroup - Match on nodegroup
  - range - Use a Range server for matching
  - compound - Pass a compound match string

- **ret** -- The returner to use. The value passed can be single returner, or a comma delimited list of returners to call in order on the minions

- **kwarg** -- A dictionary with keyword arguments for the function.

- **kwargs** -- Optional keyword arguments. Authentication credentials may be passed when using `external_auth`.

  For example: `local.cmd('*', 'test.ping', username='saltdev', password='saltdev', eauth='pam')`

  Or: `local.cmd('*', 'test.ping', token='5871821ea51754fdcea8153c1c745433')`

  **Returns** A dictionary with the result of the execution, keyed by minion ID. A compound command will return a sub-dictionary keyed by function name.

  ```python
  cmd_async(tgt, fun, arg=(), expr_form='glob', ret='', kwarg=None, **kwargs)
  
  Asynchronously send a command to connected minions
  
  The function signature is the same as `cmd()` with the following exceptions.
  
  **Returns** A job ID or 0 on failure.
  ```

  ```python
  >>> local.cmd_async('*', 'test.sleep', [300])
  '20131219215921857715'
  ```

  ```python
  cmd_batch(tgt, fun, arg=(), expr_form='glob', ret='', kwarg=None, batch='10%', **kwargs)
  
  Iteratively execute a command on subsets of minions at a time
  
  The function signature is the same as `cmd()` with the following exceptions.
  
  **Parameters** `batch` -- The batch identifier of systems to execute on
  
  **Returns** A generator of minion returns
  ```

  ```python
  >>> returns = local.cmd_batch('*', 'state.highstate', batch='10%')
  >>> for ret in returns:
  ...     print(ret)
  {'jerry': {...}}
  ```
**cmd_iter**(tgt, fun=(), timeout=None, expr_form='glob', ret='`, kwarg=None, **kwargs)

Yields the individual minion returns as they come in.

Returns: A generator yielding the individual minion returns.

```python
cmd_iter('*', 'test.ping')
for i in ret:
    print(i)
{'jerry': {'ret': True}}
{'dave': {'ret': True}}
{'stewart': {'ret': True}}
```

**cmd_iter_no_block**(tgt, fun=(), timeout=None, expr_form='glob', ret='`, kwarg=None, show_jid=False, verbose=False, **kwargs)

Yields the individual minion returns as they come in, or None when no returns are available.

Returns: A generator yielding the individual minion returns, or None when no returns are available. This allows for actions to be injected in between minion returns.

```python
for i in cmd_iter_no_block('*', 'test.ping'):
    print(i)
None
{'jerry': {'ret': True}}
{'dave': {'ret': True}}
None
{'stewart': {'ret': True}}
```

**cmd_subset**(tgt, fun=(), expr_form='glob', ret='`, kwarg=None, sub=3, cli=False, progress=False, **kwargs)

Execute a command on a random subset of the targeted systems.

The function signature is the same as `cmd()` with the following exceptions.

Parameters:

---

**sub** -- The number of systems to execute on.

```python
SLC.cmd_subset('*', 'test.ping', sub=1)
{'jerry': True}
```

**get_cli_returns**(jid, minions, timeout=None, tgt='*', tgt_type='glob', verbose=False, show_jid=False, **kwargs)

Starts a watcher looking at the return data for a specified JID.

Returns: all of the information for the JID.

```python
get_cli_returns('jerry', minions, timeout=None, tgt='*', tgt_type='glob', verbose=False, show_jid=False)
```

**get_event_iter_returns**(jid, minions, timeout=None)

Gather the return data from the event system, break hard when timeout is reached.

**run_job**(tgt, fun=(), expr_form='glob', ret='`, timeout=None, jid='`, kwarg=None, **kwargs)

Asynchronously send a command to connected minions.

Prep the job directory and publish a command to any targeted minions.
Returns A dictionary of (validated) `pub_data` or an empty dictionary on failure. The `pub_data` contains the job ID and a list of all minions that are expected to return data.

```python
>>> local.run_job('*', 'test.sleep', [300])
{'jid': '20131219215650131543', 'minions': ['jerry']}
```

Salt Caller

class salt.client.Caller(c_path='/etc/salt/minion', mopts=None)

`Caller` is the same interface used by the `salt-call` command-line tool on the Salt Minion.

Changed in version 2015.8.0: Added the `cmd` method for consistency with the other Salt clients. The existing `function` and `sminion.functions` interfaces still exist but have been removed from the docs.

Importing and using `Caller` must be done on the same machine as a Salt Minion and it must be done using the same user that the Salt Minion is running as.

Usage:

```python
import salt.client
caller = salt.client.Caller()
caller.cmd('test.ping')
```

Note, a running master or minion daemon is not required to use this class. Running `salt-call --local` simply sets `file_client` to `local`. The same can be achieved at the Python level by including that setting in a minion config file.

New in version 2014.7.0: Pass the minion config as the `mopts` dictionary.

```python
import salt.client

__opts__ = salt.config.minion_config('/etc/salt/minion')
__opts__['file_client'] = 'local'
caller = salt.client.Caller(mopts=__opts__)

```

```python
caller.cmd('test.arg', 'Foo', 'Bar', baz='Baz')

caller.cmd('event.send', 'myco/myevent/something',
           data={'foo': 'Foo'}, with_env=['GIT_COMMIT'], with_grains=True)
```

RunnerClient

class salt.runner.RunnerClient(opts)

The interface used by the `salt-run` CLI tool on the Salt Master

It executes `runner modules` which run on the Salt Master.

Importing and using `RunnerClient` must be done on the same machine as the Salt Master and it must be done using the same user that the Salt Master is running as.
Salt’s `external_auth` can be used to authenticate calls. The eauth user must be authorized to execute runner modules: `@runner`. Only the `master_call()` below supports eauth.

```python
async(fun, low, user='UNKNOWN')
```
Execute the function in a multiprocess and return the event tag to use to watch for the return

```python
cmd(fun, arg=None, pub_data=None, kwarg=None, print_event=True)
```
Execute a function

```python
cmd_async(low)
```
Execute a runner function asynchronously; eauth is respected

This function requires that `external_auth` is configured and the user is authorized to execute runner functions: `@runner`.

```python
runner.eauth_async({
    'fun': 'jobs.list_jobs',
    'username': 'saltdev',
    'password': 'saltdev',
    'eauth': 'pam',
})
```

```python
cmd_sync(low, timeout=None)
```
Execute a runner function synchronously; eauth is respected

This function requires that `external_auth` is configured and the user is authorized to execute runner functions: `@runner`.

```python
runner.eauth_sync({
    'fun': 'jobs.list_jobs',
    'username': 'saltdev',
    'password': 'saltdev',
    'eauth': 'pam',
})
```

### WheelClient

```python
class salt.wheel.WheelClient(opts=None)
```
An interface to Salt’s wheel modules

Wheel modules interact with various parts of the Salt Master.

Importing and using `WheelClient` must be done on the same machine as the Salt Master and it must be done using the same user that the Salt Master is running as. Unless `external_auth` is configured and the user is authorized to execute wheel functions: `@wheel`.

Usage:

```python
import salt.config
import salt.wheel
opts = salt.config.master_config('/etc/salt/master')
wheel = salt.wheel.WheelClient(opts)
```

```python
async(fun, low, user='UNKNOWN')
```
Execute the function in a multiprocess and return the event tag to use to watch for the return

```python
cmd(fun, arg=None, pub_data=None, kwarg=None, print_event=True)
```
Execute a function
wheel.cmd('key.finger', ['jerry'])

**cmd_async** *(low)*
Execute a function asynchronously; eauth is respected

This function requires that `external_auth` is configured and the user is authorized

```python
>>> wheel.cmd_async(
    'fun': 'key.finger',
    'match': 'jerry',
    'eauth': 'auto',
    'username': 'saltdev',
    'password': 'saltdev',
)
{'jid': '20131219224744416681', 'tag': 'salt/wheel/20131219224744416681'}
```

**cmd_sync** *(low, timeout=None)*
Execute a wheel function synchronously; eauth is respected

This function requires that `external_auth` is configured and the user is authorized to execute runner functions: (`@wheel`).

```python
>>> wheel.cmd_sync(
    'fun': 'key.finger',
    'match': 'jerry',
    'eauth': 'auto',
    'username': 'saltdev',
    'password': 'saltdev',
)
```

### CloudClient

class `salt.cloud.CloudClient(path=None, opts=None, config_dir=None, pillars=None)`
The client class to wrap cloud interactions

**action** *(fun=None, cloudmap=None, names=None, provider=None, instance=None, kwars=None)*
Execute a single action via the cloud plugin backend

Examples:

```python
client.action(fun='show_instance', names=['myinstance'])
client.action(fun='show_image', provider='my-ec2-config',
    kwars={'image': 'ami-10314d79'})
```

**create** *(provider, names, **kwars)*
Create the named VMs, without using a profile

Example:

```python
client.create(names=['myinstance'], provider='my-ec2-config',
    kwars={'image': 'ami-1624987f', 'size': 't1.micro',
        'ssh_username': 'ec2-user', 'securitygroup': 'default',
        'delvol_on_destroy': True})
```
**destroy**(names)
Destroy the named VMs

**extra_action**(names, provider, action, **kwargs)
Perform actions with block storage devices

Example:

```python
client.extra_action(names=['myblock'], action='volume_create',
                  provider='my-nova', kwargs={'voltype': 'SSD', 'size': 1000})
client.extra_action(names=['salt-net'], action='network_create',
                  provider='my-nova', kwargs={'cidr': '192.168.100.0/24'})
```

**full_query**(query_type='list_nodes_full')
Query all instance information

**list_images**(provider=None)
List all available images in configured cloud systems

**list_locations**(provider=None)
List all available locations in configured cloud systems

**list_sizes**(provider=None)
List all available sizes in configured cloud systems

**low**(fun, low)
Pass the cloud function and low data structure to run

**map_run**(path, **kwargs)
Pass in a location for a map to execute

**min_query**(query_type='list_nodes_min')
Query select instance information

**profile**(profile, names, vm_overrides=None, **kwargs)
Pass in a profile to create, names is a list of vm names to allocate

  vm_overrides is a special dict that will be per node options overrides

Example:

```python
>>> client = salt.cloud.CloudClient(path='/etc/salt/cloud')
>>> client.profile('do_512git', names=['minion01',])
{'minion01': {u'backups_active': 'False',
             u'created_at': '2014-09-04T18:10:15Z',
             u'droplet': {u'event_id': 31000502,
                          u'id': 2530006,
                          u'image_id': 5140006,
                          u'name': u'minion01',
                          u'size_id': 66},
             u'id': '2530006',
             u'image_id': '5140006',
             u'ip_address': '107.XXX.XXX.XXX',
             u'locked': 'True',
             u'name': 'minion01',
             u'private_ip_address': None,
             u'region_id': '4',
             u'size_id': '66',
             u'status': 'new'}}
```
query(query_type='list_nodes')
Query basic instance information

select_query(query_type='list_nodes_select')
Query select instance information

SSHClient

class salt.client.ssh.client.SSHClient(c_path='/etc/salt/master', mopts=None)
Create a client object for executing routines via the salt-ssh backend

New in version 2015.5.0.

cmd(tgt, fun, arg=(), timeout=None, expr_form='glob', kwarg=None, **kwargs)
Execute a single command via the salt-ssh subsystem and return all routines at once

New in version 2015.5.0.

cmd_iter(tgt, fun, arg=(), timeout=None, expr_form='glob', ret='`', kwarg=None, **kwargs)
Execute a single command via the salt-ssh subsystem and return a generator

New in version 2015.5.0.

32.5.1 salt.cloud.clouds.aliyun

AliYun ECS Cloud Module

New in version 2014.7.0.

The Aliyun cloud module is used to control access to the aliyun ECS. http://www.aliyun.com/

Use of this module requires the id and key parameter to be set. Set up the cloud configuration at /etc/salt/cloud.providers or /etc/salt/cloud.providers.d/aliyun.conf:

```yaml
my-aliyun-config:
  # aliyun Access Key ID
  id: wFGEwgregeqw3435gDger
  # aliyun Access Key Secret
  key: GDE43t43REGTrkilg43934t34qT43t4dgegerGEGg
  location: cn-qingdao
  driver: aliyun
```

```
depends requests
salt.cloud.clouds.aliyun.avail_images(kwars=\None, call=\None)
  Return a list of the images that are on the provider
salt.cloud.clouds.aliyun.avail_locations(call=\None)
  Return a dict of all available VM locations on the cloud provider with relevant data
salt.cloud.clouds.aliyun.avail_sizes(call=\None)
  Return a list of the image sizes that are on the provider
salt.cloud.clouds.aliyun.create(vm_)
  Create a single VM from a data dict
salt.cloud.clouds.aliyun.create_node(kwarg)
  Convenience function to make the rest api call for node creation.
salt.cloud.clouds.aliyun.destroy(name, call=\None)
  Destroy a node.
  CLI Example:
    salt-cloud -a destroy myinstance
    salt-cloud -d myinstance
salt.cloud.clouds.aliyun.get_configured_provider()
  Return the first configured instance.
salt.cloud.clouds.aliyun.get_dependencies()
  Warn if dependencies aren't met.
salt.cloud.clouds.aliyun.get_image(vm_)
  Return the image object to use
salt.cloud.clouds.aliyun.get_location(vm_=\None)
  Return the aliyun region to use, in this order:
  - CLI parameter
  - VM parameter
  - Cloud profile setting
```
salt.cloud.clouds.aliyun.get_securitygroup(vm_)
    Return the security group

salt.cloud.clouds.aliyun.get_size(vm_)
    Return the VM's size. Used by create_node().

salt.cloud.clouds.aliyun.list_availability_zones(call=None)
    List all availability zones in the current region

salt.cloud.clouds.aliyun.list_monitor_data(kwars=call, call=None)
    Get monitor data of the instance. If instance name is missing, will show all the instance monitor data on the
    region.

    CLI Examples:
    salt-cloud -f list_monitor_data aliyun
    salt-cloud -f list_monitor_data aliyun name=AY14051311071990225bd

salt.cloud.clouds.aliyun.list_nodes(call=None)
    Return a list of the VMs that are on the provider

salt.cloud.clouds.aliyun.list_nodes_full(call=None)
    Return a list of the VMs that are on the provider

salt.cloud.clouds.aliyun.list_nodes_min(call=None)
    Return a list of the VMs that are on the provider. Only a list of VM names, and their state, is returned. This is
    the minimum amount of information needed to check for existing VMs.

salt.cloud.clouds.aliyun.list_nodes_select(call=None)
    Return a list of the VMs that are on the provider, with select fields

salt.cloud.clouds.aliyun.list_securitygroup(call=None)
    Return a list of security group

salt.cloud.clouds.aliyun.query(params=None)
    Make a web call to aliyun ECS REST API

salt.cloud.clouds.aliyun.reboot(name, call=None)
    Reboot a node

    CLI Examples:
    salt-cloud -a reboot myinstance

salt.cloud.clouds.aliyun.script(vm_)
    Return the script deployment object

salt.cloud.clouds.aliyun.show_disk(name, call=None)
    Show the disk details of the instance

    CLI Examples:
    salt-cloud -a show_disk aliyun myinstance

salt.cloud.clouds.aliyun.show_image(kwars, call=None)
    Show the details from aliyun image

salt.cloud.clouds.aliyun.show_instance(name, call=None)
    Show the details from aliyun instance

salt.cloud.clouds.aliyun.start(name, call=None)
    Start a node
CLI Examples:

```
salt-cloud -a start myinstance
```

`salt.cloud.clouds.aliyun.stop(name, force=False, call=None)`

Stop a node

CLI Examples:

```
salt-cloud -a stop myinstance
salt-cloud -a stop myinstance force=True
```

### 32.5.2 `salt.cloud.clouds.botocore_aws`

**The AWS Cloud Module**

The AWS cloud module is used to interact with the Amazon Web Services system.

This module has been replaced by the EC2 cloud module, and is no longer supported. The documentation shown here is for reference only; it is highly recommended to change all usages of this driver over to the EC2 driver.

If this driver is still needed, set up the cloud configuration at `/etc/salt/cloud.providers` or `/etc/salt/cloud.providers.d/aws.conf`:

```
my-aws-botocore-config:
    # The AWS API authentication id
    id: GKTADJGHEIQSXMKKRBJ08H
    # The AWS API authentication key
    key: askdjghsdfjkgWupUjasdflkdfklgjsdfjajkggh
    # The ssh keyname to use
    keyname: default
    # The amazon security group
    securitygroup: ssh_open
    # The location of the private key which corresponds to the keyname
    private_key: /root/default.pem
    driver: aws
```

`salt.cloud.clouds.botocore_aws.disable_term_protect(name, call=None)`

Disable termination protection on a node

CLI Example:

```
salt-cloud -a disable_term_protect mymachine
```

`salt.cloud.clouds.botocore_aws.enable_term_protect(name, call=None)`

Enable termination protection on a node

CLI Example:

```
salt-cloud -a enable_term_protect mymachine
```

`salt.cloud.clouds.botocore_aws.get_configured_provider()`

Return the first configured instance.

`salt.cloud.clouds.botocore_aws.get_dependencies()`

Warn if dependencies aren’t met.
32.5.3  salt.cloud.clouds.cloudstack

CloudStack Cloud Module

The CloudStack cloud module is used to control access to a CloudStack based Public Cloud.

    depends  libcloud >= 0.15

Use of this module requires the apikey, secretkey, host and path parameters.

```yaml
my-cloudstack-cloud-config:
  apikey: <your api key >
  secretkey: <your secret key >
  host: localhost
  path: /client/api
  driver: cloudstack
```

salt.cloud.clouds.cloudstack.avail_images(conn=None, call=None)
Return a dict of all available VM images on the cloud provider with relevant data

salt.cloud.clouds.cloudstack.avail_locations(conn=None, call=None)
Return a dict of all available VM locations on the cloud provider with relevant data

salt.cloud.clouds.cloudstack.avail_sizes(conn=None, call=None)
Return a dict of all available VM images on the cloud provider with relevant data

salt.cloud.clouds.cloudstack.block_device_mappings(vm_)
Return the block device mapping:

```
[{'DeviceName': '/dev/sdb', 'VirtualName': 'ephemeral0'},
 {'DeviceName': '/dev/sdc', 'VirtualName': 'ephemeral1'}]
```

salt.cloud.clouds.cloudstack.cloudstack_displayname(vm_)
Return display name of VM:

```
\"minion1\"
```

salt.cloud.clouds.cloudstack.create(vm_)
Create a single VM from a data dict

salt.cloud.clouds.cloudstack.destroy(name, conn=None, call=None)
Delete a single VM, and all of its volumes

salt.cloud.clouds.cloudstack.get_configured_provider()
Return the first configured instance.

salt.cloud.clouds.cloudstack.get_conn()
Return a conn object for the passed VM data

salt.cloud.clouds.cloudstack.get_dependencies()
Warn if dependencies aren't met.

salt.cloud.clouds.cloudstack.get_image(conn, vm_)
Return the image object to use

salt.cloud.clouds.cloudstack.get_ip(data)
Return the IP address of the VM If the VM has public IP as defined by libcloud module then use it Otherwise try to extract the private IP and use that one.

salt.cloud.clouds.cloudstack.get_key()
Returns the ssh private key for VM access
salt.cloud.clouds.cloudstack.get_keypair(vm_)
    Return the keypair to use
salt.cloud.clouds.cloudstack.get_location(conn, vm_)
    Return the node location to use
salt.cloud.clouds.cloudstack.get_networkid(vm_)
    Return the networkid to use, only valid for Advanced Zone
salt.cloud.clouds.cloudstack.get_node(conn, name)
    Return a libcloud node for the named VM
salt.cloud.clouds.cloudstack.get_password(vm_)
    Return the password to use
salt.cloud.clouds.cloudstack.get_project(conn, vm_)
    Return the project to use.
salt.cloud.clouds.cloudstack.get_size(conn, vm_)
    Return the VM’s size object
salt.cloud.clouds.cloudstack.list_nodes(conn=None, call=None)
    Return a list of the VMs that are on the provider
salt.cloud.clouds.cloudstack.list_nodes_full(conn=None, call=None)
    Return a list of the VMs that are on the provider, with all fields
salt.cloud.clouds.cloudstack.list_nodes_select(conn=None, call=None)
    Return a list of the VMs that are on the provider, with select fields
salt.cloud.clouds.cloudstack.script(vm_)
    Return the script deployment object
salt.cloud.clouds.cloudstack.show_instance(name, call=None)
    Show the details from the provider concerning an instance

32.5.4 salt.cloud.clouds.digital_ocean

DigitalOcean Cloud Module

The DigitalOcean cloud module is used to control access to the DigitalOcean VPS system.

Use of this module requires a requires a personal_access_token, an ssh_key_file, and at least one SSH key name in ssh_key_names. More ssh_key_names can be added by separating each key with a comma. The personal_access_token can be found in the DigitalOcean web interface in the ``Apps & API'' section. The SSH key name can be found under the ``SSH Keys'' section.

```yaml
# Note: This example is for /etc/salt/cloud.providers or any file in the # /etc/salt/cloud.providers.d/ directory.

my-digital-ocean-config:
    personal_access_token: xxx
    ssh_key_file: /path/to/ssh/key/file
    ssh_key_names: my-key-name,my-key-name-2
    driver: digital_ocean
```

depends requests

salt.cloud.clouds.digital_ocean.avail_images(call=None)
    Return a list of the images that are on the provider
salt.cloud.clouds.digital_ocean.avail_locations(call=None)
    Return a dict of all available VM locations on the cloud provider with relevant data

salt.cloud.clouds.digital_ocean.avail_sizes(call=None)
    Return a list of the image sizes that are on the provider

salt.cloud.clouds.digital_ocean.create(vm_)
    Create a single VM from a data dict

salt.cloud.clouds.digital_ocean.create_dns_record(hostname, ip_address)
    Creates a DNS record for the given hostname if the domain is managed with DO.

salt.cloud.clouds.digital_ocean.create_key(kwargs=None, call=None)
    Upload a public key

salt.cloud.clouds.digital_ocean.create_node(args)
    Create a node

salt.cloud.clouds.digital_ocean.delete_dns_record(hostname)
    Deletes a DNS for the given hostname if the domain is managed with DO.

salt.cloud.clouds.digital_ocean.destroy(name, call=None)
    Destroy a node. Will check termination protection and warn if enabled.
    CLI Example:

    salt-cloud --destroy mymachine

salt.cloud.clouds.digital_ocean.get_configured_provider()
    Return the first configured instance.

salt.cloud.clouds.digital_ocean.get_dependencies()
    Warn if dependencies aren't met.

salt.cloud.clouds.digital_ocean.get_image(vm_)
    Return the image object to use

salt.cloud.clouds.digital_ocean.get_keyid(keyname)
    Return the ID of the keyname

salt.cloud.clouds.digital_ocean.get_location(vm_)
    Return the VM's location

salt.cloud.clouds.digital_ocean.get_size(vm_)
    Return the VM's size. Used by create_node().

salt.cloud.clouds.digital_ocean.list_keypairs(call=None)
    Return a dict of all available VM locations on the cloud provider with relevant data

salt.cloud.clouds.digital_ocean.list_nodes(call=None)
    Return a list of the VMs that are on the provider

salt.cloud.clouds.digital_ocean.list_nodes_full(call=None, for_output=True)
    Return a list of the VMs that are on the provider

salt.cloud.clouds.digital_ocean.list_nodes_select(call=None)
    Return a list of the VMs that are on the provider, with select fields

salt.cloud.clouds.digital_ocean.query(method='droplets', droplet_id=None, command=None, args=None, http_method='get')
    Make a web call to DigitalOcean
salt.cloud.clouds.digital_ocean.reboot(name, call=\None)
    Reboot a droplet in DigitalOcean.
    name The name of the droplet to restart.
    CLI Example:
    \[\text{salt-cloud -a reboot droplet_name}\]

salt.cloud.clouds.digital_ocean.remove_key(kwargs=None, call=\None)
    Delete public key

salt.cloud.clouds.digital_ocean.script(vm_)
    Return the script deployment object

salt.cloud.clouds.digital_ocean.show_instance(name, call=\None)
    Show the details from DigitalOcean concerning a droplet

salt.cloud.clouds.digital_ocean.show_keypair(kwargs=None, call=\None)
    Show the details of an SSH keypair

salt.cloud.clouds.digital_ocean.show_pricing(kwargs=None, call=\None)
    Show pricing for a particular profile. This is only an estimate, based on unofficial pricing sources.
    New in version 2015.8.0.
    CLI Examples:
    \[\text{salt-cloud -f show_pricing my-digitalocean-config profile=my-profile}\]

salt.cloud.clouds.digital_ocean.start(name, call=\None)
    Start a droplet in DigitalOcean.
    name The name of the droplet to start.
    CLI Example:
    \[\text{salt-cloud -a start droplet_name}\]

salt.cloud.clouds.digital_ocean.stop(name, call=\None)
    Stop a droplet in DigitalOcean.
    name The name of the droplet to stop.
    CLI Example:
    \[\text{salt-cloud -a stop droplet_name}\]

32.5.5 salt.cloud.clouds.ec2

The EC2 Cloud Module

The EC2 cloud module is used to interact with the Amazon Elastic Cloud Computing.

To use the EC2 cloud module, set up the cloud configuration at \(\text{/etc/salt/cloud.providers}\) or \(\text{/etc/salt/cloud.providers.d/ec2.conf}\):
my-ec2-config:

# EC2 API credentials: Access Key ID and Secret Access Key.
# Alternatively, to use IAM Instance Role credentials available via
# EC2 metadata set both id and key to 'use-instance-role-credentials'
id: GKTADJGHEIQSXMKKRBJ08H
key: askdjghsdfjkgWupUjasdfklgjsdfjajkghs
# The ssh keyname to use
keyname: default
# The amazon security group
securitygroup: ssh_open
# The location of the private key which corresponds to the keyname
private_key: /root/default.pem

# Be default, service_url is set to amazonaws.com. If you are using this
driver for something other than Amazon EC2, change it here:
service_url: amazonaws.com

# The endpoint that is ultimately used is usually formed using the region
# and the service_url. If you would like to override that entirely, you
# can explicitly define the endpoint:
endpoint: myendpoint.example.com:1138/services/Cloud

# SSH Gateways can be used with this provider. Gateways can be used
# when a salt-master is not on the same private network as the instance
# that is being deployed.

# Defaults to None
# Required
ssh_gateway: gateway.example.com

# Defaults to port 22
# Optional
ssh_gateway_port: 22

# Defaults to root
# Optional
ssh_gateway_username: root

# One authentication method is required. If both
# are specified, Private key wins.

# Private key defaults to None
ssh_gateway_private_key: /path/to/key.pem

# Password defaults to None
ssh_gateway_password: ExamplePasswordHere

driver: ec2

# Pass userdata to the instance to be created
userdata_file: /etc/salt/my-userdata-file

depends requests

salt.cloud.clouds.ec2.attach_volume(name=None, kwargs=None, instance_id=None, call=None)

Attach a volume to an instance

salt.cloud.clouds.ec2.avail_images(kwargs=None, call=None)
Return a dict of all available VM images on the cloud provider.

```
salt.cloud.clouds.ec2.avail_locations(call=None)
```
List all available locations

```
salt.cloud.clouds.ec2.avail_sizes(call=None)
```
Return a dict of all available VM sizes on the cloud provider with relevant data. Latest version can be found at:

```
```

```
salt.cloud.clouds.ec2.block_device_mappings(vm_)
```
Return the block device mapping:

```
[{
    'DeviceName': '/dev/sdb',
    'VirtualName': 'ephemeral0',
},
{
    'DeviceName': '/dev/sdc',
    'VirtualName': 'ephemeral1'
}]
```

```
salt.cloud.clouds.ec2.copy_snapshot(kwargs=None, call=None)
```
Copy a snapshot

```
salt.cloud.clouds.ec2.create(vm_=None, call=None)
```
Create a single VM from a data dict

```
salt.cloud.clouds.ec2.create_attach_volumes(name, kwargs, call=None, wait_to_finish=True)
```
Create and attach volumes to created node

```
salt.cloud.clouds.ec2.create_keypair(kwargs=None, call=None)
```
Create an SSH keypair

```
salt.cloud.clouds.ec2.create_snapshot(kwargs=None, call=None, wait_to_finish=False)
```
Create a snapshot.

- `volume_id` The ID of the Volume from which to create a snapshot.
- `description` The optional description of the snapshot.

CLI Example:
```
salt-cloud -f create_snapshot my-ec2-config volume_id=vol-351d8826
salt-cloud -f create_snapshot my-ec2-config volume_id=vol-351d8826 description="My Snapshot Description"
```

```
salt.cloud.clouds.ec2.create_volume(kwargs=None, call=None, wait_to_finish=False)
```
Create a volume

CLI Examples:
```
salt-cloud -f create_volume my-ec2-config zone=us-east-1b
salt-cloud -f create_volume my-ec2-config zone=us-east-1b tags='{"tag1": "val1",
  "tag2": "val2"}''
```

```
salt.cloud.clouds.ec2.del_tags(name=None, kwargs=None, call=None, instance_id=None, resource_id=None)
```
Delete tags for a resource. Normally a VM name or instance_id is passed in, but a resource_id may be passed instead. If both are passed in, the instance_id will be used.

CLI Examples:
```
salt-cloud -a del_tags mymachine tags="mytag",
salt-cloud -a del_tags mymachine tags=tag1,tag2,tag3
salt-cloud -a del_tags resource_id=vol-3267ab32 tags=tag1,tag2,tag3
```
salt.cloud.clouds.ec2.delete_keypair(*kwargs=None, call=None*)
Delete an SSH keypair

salt.cloud.clouds.ec2.delete_snapshot(*kwargs=None, call=None*)
Delete a snapshot

salt.cloud.clouds.ec2.delete_volume(*name=None, kwargs=None, instance_id=None, call=None*)
Delete a volume

salt.cloud.clouds.ec2.delvol_on_destroy(*name, kwargs=None, call=None*)
Delete all/specified EBS volumes upon instance termination

CLI Example:
```
salt-cloud -a delvol_on_destroy mymachine
```

salt.cloud.clouds.ec2.describe_snapshots(*kwargs=None, call=None*)
Describe a snapshot (or snapshots)

- **snapshot_id** One or more snapshot IDs. Multiple IDs must be separated by ",".
- **owner** Return the snapshots owned by the specified owner. Valid values include: self, amazon, <AWS Account ID>. Multiple values must be separated by ",".
- **restorable_by** One or more AWS accounts IDs that can create volumes from the snapshot. Multiple aws account IDs must be separated by ",".

TODO: Add all of the filters.

salt.cloud.clouds.ec2.describe_volumes(*kwargs=None, call=None*)
Describe a volume (or volumes)

- **volume_id** One or more volume IDs. Multiple IDs must be separated by ",".

TODO: Add all of the filters.

salt.cloud.clouds.ec2.destroy(*name, call=None*)
Destroy a node. Will check termination protection and warn if enabled.

CLI Example:
```
salt-cloud --destroy mymachine
```

salt.cloud.clouds.ec2.detach_volume(*name=None, kwargs=None, instance_id=None, call=None*)
Detach a volume from an instance

salt.cloud.clouds.ec2.disable_term_protect(*name, call=None*)
Disable termination protection on a node

CLI Example:
```
salt-cloud -a disable_term_protect mymachine
```

salt.cloud.clouds.ec2.enable_term_protect(*name, call=None*)
Enable termination protection on a node

CLI Example:
```
salt-cloud -a enable_term_protect mymachine
```

salt.cloud.clouds.ec2.get_availability_zone(*vm_*)
Return the availability zone to use
salt.cloud.clouds.ec2.get_configured_provider()
Return the first configured instance.

salt.cloud.clouds.ec2.get_console_output(name=None, location=None, instance_id=None, call=None, kwargs=None)
Show the console output from the instance.
By default, returns decoded data, not the Base64-encoded data that is actually returned from the EC2 API.

salt.cloud.clouds.ec2.get_dependencies()
Warn if dependencies aren't met.

salt.cloud.clouds.ec2.get_location(vm_=None)
Return the EC2 region to use, in this order:
• CLI parameter
• VM parameter
• Cloud profile setting

salt.cloud.clouds.ec2.get_password_data(name=None, kwargs=None, instance_id=None, call=None)
Return password data for a Windows instance.
By default only the encrypted password data will be returned. However, if a key_file is passed in, then a decrypted password will also be returned.

Note that the key_file references the private key that was used to generate the keypair associated with this instance. This private key will _not_ be transmitted to Amazon; it is only used internally inside of Salt Cloud to decrypt data _after_ it has been received from Amazon.

CLI Examples:
salt-cloud -a get_password_data mymachine
salt-cloud -a get_password_data mymachine key_file=/root/ec2key.pem

Note: PKCS1_v1_5 was added in PyCrypto 2.5

salt.cloud.clouds.ec2.get_placementgroup(vm_)
Returns the PlacementGroup to use

salt.cloud.clouds.ec2.get_provider(vm_=None)
Extract the provider name from vm

salt.cloud.clouds.ec2.get_spot_config(vm_)
Returns the spot instance configuration for the provided vm

salt.cloud.clouds.ec2.get_ssh_gateway_config(vm_)
Return the ssh_gateway configuration.

salt.cloud.clouds.ec2.get_subnetid(vm_)
Returns the SubnetId to use

salt.cloud.clouds.ec2.get_tags(name=None, instance_id=None, call=None, location=None, kwargs=None, resource_id=None)
Retrieve tags for a resource. Normally a VM name or instance_id is passed in, but a resource_id may be passed instead. If both are passed in, the instance_id will be used.

CLI Examples:
salt-cloud -a get_tags mymachine
salt-cloud -a get_tags resource_id=vol-3267ab32
salt.cloud.clouds.ec2.get_tenancy(vm_)
    Returns the Tenancy to use.
    Can be `"dedicated"` or `"default"`. Cannot be present for spot instances.

salt.cloud.clouds.ec2.iam_profile(vm_)
    Return the IAM profile.
    The IAM instance profile to associate with the instances. This is either the Amazon Resource Name (ARN) of
    the instance profile or the name of the role.
    Type: String
    Default: None
    Required: No
    Example: arn:aws:iam::111111111111:instance-profile/s3access
    Example: s3access

salt.cloud.clouds.ec2.import_keypair(kwargs=None, call=None)
    Import an SSH public key

salt.cloud.clouds.ec2.keepvol_on_destroy(name, kwargs=None, call=None)
    Do not delete all/specified EBS volumes upon instance termination
    CLI Example:

    salt-cloud -a keepvol_on_destroy mymachine

salt.cloud.clouds.ec2.keyname(vm_)
    Return the keyname

salt.cloud.clouds.ec2.list_nodes(call=None)
    Return a list of the VMs that are on the provider

salt.cloud.clouds.ec2.list_nodes_full(location=None, call=None)
    Return a list of the VMs that are on the provider

salt.cloud.clouds.ec2.list_nodes_min(location=None, call=None)
    Return a list of the VMs that are on the provider. Only a list of VM names, and their state, is returned. This is
    the minimum amount of information needed to check for existing VMs.

salt.cloud.clouds.ec2.list_nodes_select(call=None)
    Return a list of the VMs that are on the provider, with select fields

salt.cloud.clouds.ec2.optimize_providers(providers)
    Return an optimized list of providers.
    We want to reduce the duplication of querying the same region.
    If a provider is using the same credentials for the same region the same data will be returned for each provider,
    thus causing un-wanted duplicate data and API calls to EC2.

salt.cloud.clouds.ec2.query(params=None, setname=None, requesturl=None, location=None, return_url=False, return_root=False)

salt.cloud.clouds.ec2.query_instance(vm_=None, call=None)
    Query an instance upon creation from the EC2 API

salt.cloud.clouds.ec2.queue_instances(instances)
    Queue a set of instances to be provisioned later. Expects a list.
Currently this only queries node data, and then places it in the cloud cache (if configured). If the salt-cloud-reactor is being used, these instances will be automatically provisioned using that.

For more information about the salt-cloud-reactor, see:
https://github.com/saltstack-formulas/salt-cloud-reactor

salt.cloud.clouds.ec2.reboot(name, call=None)
Reboot a node.

CLI Example:
```
salt-cloud -a reboot mymachine
```

salt.cloud.clouds.ec2.rename(name, kwargs, call=None)
Properly rename a node. Pass in the new name as `new name`.

CLI Example:
```
salt-cloud -a rename mymachine newname=yourmachine
```

salt.cloud.clouds.ec2.request_instance(vm_=None, call=None)
Put together all of the information necessary to request an instance on EC2, and then fire off the request the instance.

Returns data about the instance

salt.cloud.clouds.ec2.script(vm_)
Return the script deployment object

salt.cloud.clouds.ec2.securitygroup(vm_)
Return the security group

salt.cloud.clouds.ec2.securitygroupid(vm_)
Returns the SecurityGroupId

salt.cloud.clouds.ec2.set_tags(name=None, tags=None, call=None, location=None, instance_id=None, resource_id=None, kwargs=None)
Set tags for a resource. Normally a VM name or instance_id is passed in, but a resource_id may be passed instead. If both are passed in, the instance_id will be used.

CLI Examples:
```
salt-cloud -a set_tags mymachine tag1=somestuff tag2='Other stuff'
```

salt.cloud.clouds.ec2.show_delvol_on_destroy(name, kwargs=None, call=None)
Do not delete all/specified EBS volumes upon instance termination

CLI Example:
```
salt-cloud -a show_delvol_on_destroy mymachine
```

salt.cloud.clouds.ec2.show_image(kwargs, call=None)
Show the details from EC2 concerning an AMI

salt.cloud.clouds.ec2.show_instance(name=None, instance_id=None, call=None, kwargs=None)
Show the details from EC2 concerning an AMI.

Can be called as an action (which requires a name):
salt-cloud -a show_instance myinstance

...or as a function (which requires either a name or instance_id):
salt-cloud -f show_instance my-ec2 name=myinstance
salt-cloud -f show_instance my-ec2 instance_id=i-d34db33f

salt.cloud.clouds.ec2.show_keypair(kwags=None, call=None)
    Show the details of an SSH keypair

salt.cloud.clouds.ec2.show_pricing(kwags=None, call=None)
    Show pricing for a particular profile. This is only an estimate, based on unofficial pricing sources.
    CLI Examples:
salt-cloud -f show_pricing my-ec2-config profile=my-profile

    If pricing sources have not been cached, they will be downloaded. Once they have been cached, they will not
    be updated automatically. To manually update all prices, use the following command:
salt-cloud -f update_pricing <provider>

    New in version 2015.8.0.

salt.cloud.clouds.ec2.show_term_protect(name=None, instance_id=None, call=None, quiet=False)
    Show the details from EC2 concerning an AMI

salt.cloud.clouds.ec2.show_volume(kwags=None, call=None)
    Wrapper around describe_volumes. Here just to keep functionality. Might be deprecated later.

salt.cloud.clouds.ec2.sign(key, msg)

salt.cloud.clouds.ec2.ssh_interface(vm_)
    Return the ssh_interface type to connect to. Either 'public_ips' (default) or 'private_ips'.

salt.cloud.clouds.ec2.start(name, call=None)
    Start a node

salt.cloud.clouds.ec2.stop(name, call=None)
    Stop a node

salt.cloud.clouds.ec2.update_pricing(kwags=None, call=None)
    Download most recent pricing information from AWS and convert to a local JSON file.
    CLI Examples:
salt-cloud -f update_pricing my-ec2-config
salt-cloud -f update_pricing my-ec2-config type=linux

    New in version 2015.8.0.

salt.cloud.clouds.ec2.wait_for_instance(vm_=None, data=None, ip_address=None, display_ssh_output=True, call=None)
    Wait for an instance upon creation from the EC2 API, to become available

32.5.6 salt.cloud.clouds.gce

Copyright 2013 Google Inc. All Rights Reserved.
Google Compute Engine Module

The Google Compute Engine module. This module interfaces with Google Compute Engine (GCE). To authenticate to GCE, you will need to create a Service Account. To set up Service Account Authentication, follow the Google Compute Engine Setup instructions.

Example Provider Configuration

```
my-gce-config:
  # The Google Cloud Platform Project ID
  project: "my-project-id"
  # The Service Account client ID
  service_account_email_address: 1234567890@developer.gserviceaccount.com
  # The location of the private key (PEM format)
  service_account_private_key: /home/erjohnso/PRIVKEY.pem
  driver: gce
    # Specify whether to use public or private IP for deploy script.
    # Valid options are:
    #  private_ips - The salt-master is also hosted with GCE
    #  public_ips - The salt-master is hosted outside of GCE
  ssh_interface: public_ips

  maintainer  Eric Johnson <erjohnso@google.com>
  depends    libcloud >= 0.14.1

salt.cloud.clouds.gce.attach_disk(name=None, kwargs=None, call=None)
  Attach an existing disk to an existing instance.
  CLI Example:
  
  salt-cloud -a attach_disk myinstance disk_name=mydisk mode=READ_WRITE

salt.cloud.clouds.gce.attach_lb(kwargs=None, call=None)
  Add an existing node/member to an existing load-balancer configuration.
  CLI Example:
  
  salt-cloud -f attach_lb gce name=lb member=myinstance

salt.cloud.clouds.gce.avail_images(conn=None)
  Return a dict of all available VM images on the cloud provider with relevant data
  Note that for GCE, there are custom images within the project, but the generic images are in other projects.
  This returns a dict of images in the project plus images in `debian-cloud' and `centos-cloud' (If there is overlap in names, the one in the current project is used.)

salt.cloud.clouds.gce.avail_locations(conn=None, call=None)
  Return a dict of all available VM locations on the cloud provider with relevant data
```
salt.cloud.clouds.gce.avail_sizes(conn=None)
    Return a dict of available instances sizes (a.k.a machine types) and convert them to something more serializable.

salt.cloud.clouds.gce.create(vm_=None, call=None)
    Create a single GCE instance from a data dict.

salt.cloud.clouds.gce.create_address(kwargs=None, call=None)
    Create a static address in a region.
    CLI Example:
    ```
salt-cloud -f create_address gce name=my-ip region=us-central1 address=IP
    ```

salt.cloud.clouds.gce.create_disk(kwargs=None, call=None)
    Create a new persistent disk. Must specify `disk_name` and `location`. Can also specify an `image` or `snapshot` but if neither of those are specified, a `size` (in GB) is required.
    CLI Example:
    ```
salt-cloud -f create_disk gce disk_name=pd size=300 location=us-central1-b
    ```

salt.cloud.clouds.gce.create_fwrule(kwargs=None, call=None)
    Create a GCE firewall rule. The `default` network is used if not specified.
    CLI Example:
    ```
salt-cloud -f create_fwrule gce name=allow-http allow=tcp:80
    ```

salt.cloud.clouds.gce.create_hc(kwargs=None, call=None)
    Create an HTTP health check configuration.
    CLI Example:
    ```
salt-cloud -f create_hc gce name=hc path=/healthy port=80
    ```

salt.cloud.clouds.gce.create_lb(kwargs=None, call=None)
    Create a load-balancer configuration.
    CLI Example:
    ```
salt-cloud -f create_lb gce name=lb region=us-central1 ports=80
    ```

salt.cloud.clouds.gce.create_network(kwargs=None, call=None)
    Create a GCE network.
    CLI Example:
    ```
salt-cloud -f create_network gce name=mynet cidr=10.10.10.0/24
    ```

salt.cloud.clouds.gce.create_snapshot(kwargs=None, call=None)
    Create a new disk snapshot. Must specify name and `disk_name`.
    CLI Example:
    ```
salt-cloud -f create_snapshot gce name=snap1 disk_name=pd
    ```

salt.cloud.clouds.gce.delete_address(kwargs=None, call=None)
    Permanently delete a static address.
    CLI Example:
salt-cloud -f delete_address gce name=my-ip

salt.cloud.clouds.gce.delete_disk(kwargs=None, call=None)
Permanently delete a persistent disk.

CLI Example:
salt-cloud -f delete_disk gce disk_name=pd

salt.cloud.clouds.gce.delete_fwrule(kwargs=None, call=None)
Permanently delete a firewall rule.

CLI Example:
salt-cloud -f delete_fwrule gce name=allow-http

salt.cloud.clouds.gce.delete_hc(kwargs=None, call=None)
Permanently delete a health check.

CLI Example:
salt-cloud -f delete_hc gce name=hc

salt.cloud.clouds.gce.delete_lb(kwargs=None, call=None)
Permanently delete a load-balancer.

CLI Example:
salt-cloud -f delete_lb gce name=lb

salt.cloud.clouds.gce.delete_network(kwargs=None, call=None)
Permanently delete a network.

CLI Example:
salt-cloud -f delete_network gce name=mynet

salt.cloud.clouds.gce.delete_snapshot(kwargs=None, call=None)
Permanently delete a disk snapshot.

CLI Example:
salt-cloud -f delete_snapshot gce name=disk-snap-1

salt.cloud.clouds.gce.destroy(vm_name, call=None)
Call `destroy' on the instance. Can be called with ``-a destroy'' or -d

CLI Example:
salt-cloud -a destroy myinstance1 myinstance2 ...
salt-cloud -d myinstance1 myinstance2 ...

salt.cloud.clouds.gce.detach_disk(name=None, kwargs=None, call=None)
Detach a disk from an instance.

CLI Example:
salt-cloud -a detach_disk myinstance disk_name=mydisk
salt.cloud.clouds.gce.detach_lb(**kwargs=None, call=None)**

Remove an existing node/member from an existing load-balancer configuration.

CLI Example:

```
salt-cloud -f detach_lb gce name=lb member=myinstance
```

salt.cloud.clouds.gce.get_configured_provider()  
Return the first configured instance.

salt.cloud.clouds.gce.get_conn()  
Return a conn object for the passed VM data

salt.cloud.clouds.gce.get_dependencies()  
Warn if dependencies aren’t met.

salt.cloud.clouds.gce.get_lb_conn(**kwargs=None, call=None)**  
Return a load-balancer conn object

salt.cloud.clouds.gce.list_nodes(**conn=None, call=None)**  
Return a list of the VMs that are on the provider

salt.cloud.clouds.gce.list_nodes_full(**conn=None, call=None)**  
Return a list of the VMs that are on the provider, with all fields

salt.cloud.clouds.gce.list_nodes_select(**conn=None, call=None)**  
Return a list of the VMs that are on the provider, with select fields

salt.cloud.clouds.gce.reboot(vm_name, call=None)**  
Call GCE `reset` on the instance.

CLI Example:

```
salt-cloud -a reboot myinstance
```

salt.cloud.clouds.gce.script(vm_)
Return the script deployment object

salt.cloud.clouds.gce.show_address(**kwargs=None, call=None)**  
Show the details of an existing static address.

CLI Example:

```
salt-cloud -f show_address gce name=mysnapshot region=us-central1
```

salt.cloud.clouds.gce.show_disk(name=None, **kwargs=None, call=None)**  
Show the details of an existing disk.

CLI Example:

```
salt-cloud -a show_disk myinstance disk_name=mydisk
salt-cloud -f show_disk gce disk_name=mydisk
```

salt.cloud.clouds.gce.show_fwrule(**kwargs=None, call=None)**  
Show the details of an existing firewall rule.

CLI Example:

```
salt-cloud -f show_fwrule gce name=allow-http
```

salt.cloud.clouds.gce.show_hc(**kwargs=None, call=None)**  
Show the details of an existing health check.
CLI Example:
```
salt-cloud -f show_hc gce name=hc
```

salt.cloud.clouds.gce.show_instance(vm_name, call=None)
Show the details of the existing instance.

salt.cloud.clouds.gce.show_lb(kwargs=None, call=None)
Show the details of an existing load-balancer.

CLI Example:
```
salt-cloud -f show_lb gce name=lb
```

salt.cloud.clouds.gce.show_network(kwargs=None, call=None)
Show the details of an existing network.

CLI Example:
```
salt-cloud -f show_network gce name=mynet
```

salt.cloud.clouds.gce.show_pricing(kwargs=None, call=None)
Show pricing for a particular profile. This is only an estimate, based on unofficial pricing sources.
New in version 2015.8.0.

CLI Examples:
```
salt-cloud -f show_pricing my-gce-config profile=my-profile
```

salt.cloud.clouds.gce.show_snapshot(kwargs=None, call=None)
Show the details of an existing snapshot.

CLI Example:
```
salt-cloud -f show_snapshot gce name=mysnapshot
```

salt.cloud.clouds.gce.update_pricing(kwargs=None, call=None)
Download most recent pricing information from GCE and save locally

CLI Examples:
```
salt-cloud -f update_pricing my-gce-config
```

New in version 2015.8.0.

### 32.5.7 salt.cloud.clouds.gogrid

**GoGrid Cloud Module**

The GoGrid cloud module. This module interfaces with the gogrid public cloud service. To use Salt Cloud with GoGrid log into the GoGrid web interface and create an api key. Do this by clicking on "My Account" and then going to the API Keys tab.

Set up the cloud configuration at /etc/salt/cloud.providers or /etc/salt/cloud.providers.d/gogrid.conf:
my-gogrid-config:
# The generated api key to use
apikey: asdff7896asdh789
# The apikey's shared secret
sharedsecret: saltybacon
driver: gogrid

Note: A Note about using Map files with GoGrid:

Due to limitations in the GoGrid API, instances cannot be provisioned in parallel with the GoGrid driver. Map files will work with GoGrid, but the `-P` argument should not be used on maps referencing GoGrid instances.

salt.cloud.clouds.gogrid.avail_images()
Available images
salt.cloud.clouds.gogrid.avail_locations()
Available locations
salt.cloud.clouds.gogrid.avail_sizes()
Available sizes
salt.cloud.clouds.gogrid.create(vm_)
Create a single VM from a data dict
salt.cloud.clouds.gogrid.destroy(name, call=None)
Destroy a machine by name

CLI Example:
```bash
salt-cloud -d vm_name
```

salt.cloud.clouds.gogrid.get_configured_provider()
Return the first configured instance.

salt.cloud.clouds.gogrid.list_common_lookups(kwarg=kwargs, call=None)
List common lookups for a particular type of item

New in version 2015.8.0.

salt.cloud.clouds.gogrid.list_nodes(full=False, call=None)
List of nodes, keeping only a brief listing

CLI Example:
```bash
call=-Q
```

salt.cloud.clouds.gogrid.list_nodes_full(call=None)
List nodes, with all available information

CLI Example:
```bash
call=-F
```
salt.cloud.clouds.gogrid.list_nodes_select(call=None)
Return a list of the VMs that are on the provider, with select fields

CLI Example:
```
salt-cloud -S
```

salt.cloud.clouds.gogrid.list_passwords(kwargs=None, call=None)
List all password on the account
New in version 2015.8.0.

salt.cloud.clouds.gogrid.list_public_ips(kwargs=None, call=None)
List all available public IPs.

CLI Example: .. code-block:: bash
```
salt-cloud -f list_public_ips <provider>
```
To list unavailable (assigned) IPs, use:

CLI Example: .. code-block:: bash
```
salt-cloud -f list_public_ips <provider> state=assigned
```
New in version 2015.8.0.

salt.cloud.clouds.gogrid.reboot(name, call=None)
Reboot a machine by name

CLI Example:
```
salt-cloud -a reboot vm_name
```
New in version 2015.8.0.

salt.cloud.clouds.gogrid.show_instance(name, call=None)
Start a machine by name

CLI Example:
```
salt-cloud -a show_instance vm_name
```
New in version 2015.8.0.

salt.cloud.clouds.gogrid.start(name, call=None)
Start a machine by name

CLI Example:
```
salt-cloud -a start vm_name
```
New in version 2015.8.0.

salt.cloud.clouds.gogrid.stop(name, call=None)
Stop a machine by name

CLI Example:
```
salt-cloud -a stop vm_name
```
New in version 2015.8.0.
32.5.8 salt.cloud.clouds.joyent

Joyent Cloud Module

The Joyent Cloud module is used to interact with the Joyent cloud system.

Set up the cloud configuration at `/etc/salt/cloud.providers` or `/etc/salt/cloud.providers.d/joyent.conf`:

```yaml
my-joyent-config:
  driver: joyent
  # The Joyent login user
  user: fred
  # The Joyent user's password
  password: saltybacon
  # The location of the ssh private key that can log into the new VM
  private_key: /root/mykey.pem
  # The name of the private key
  private_key: mykey
```

When creating your profiles for the joyent cloud, add the location attribute to the profile, this will automatically get picked up when performing tasks associated with that vm. An example profile might look like:

```yaml
joyent_512:
  provider: my-joyent-config
  size: Extra Small 512 MB
  image: centos-6
  location: us-east-1
```

This driver can also be used with the Joyent SmartDataCenter project. More details can be found at:

Using SDC requires that an `api_host_suffix` is set. The default value for this is `.api.joyentcloud.com`. All characters, including the leading `.`, should be included:

```yaml
api_host_suffix: .api.myhostname.com
```

**depends** PyCrypto

**salt.cloud.clouds.joyent.avail_images**(call=None)
Get list of available images

CLI Example:
```bash
salt-cloud --list-images
```

Can use a custom URL for images. Default is:

```yaml
image_url: images.joyent.com/image
```

**salt.cloud.clouds.joyent.avail_locations**(call=None)
List all available locations

**salt.cloud.clouds.joyent.avail_sizes**(call=None)
Get list of available packages

CLI Example:
```bash
salt-cloud --list-sizes
```

**salt.cloud.clouds.joyent.create**(vm_)
Create a single VM from a data dict
CLI Example:

```
salt-cloud -p profile_name vm_name
```

```
salt.cloud.clouds.joyent.create_node(**kwargs)
```
convenience function to make the rest api call for node creation.

```
salt.cloud.clouds.joyent.delete_key(kwargs=None, call=None)
```
List the keys available

CLI Example:

```
salt-cloud -f delete_key joyent keyname=mykey
```

```
salt.cloud.clouds.joyent.destroy(name, call=None)
```
destroy a machine by name

**Parameters**

- **name** -- name given to the machine
- **call** -- call value in this case is `action`

**Returns**  array of booleans , true if successfully stopped and true if successfully removed

CLI Example:

```
salt-cloud -d vm_name
```

```
salt.cloud.clouds.joyent.get_configured_provider()
```
Return the first configured instance.

```
salt.cloud.clouds.joyent.get_image(vm_)
```
Return the image object to use

```
salt.cloud.clouds.joyent.get_location(vm_=None)
```
Return the joyent data center to use, in this order:

- CLI parameter
- VM parameter
- Cloud profile setting

```
salt.cloud.clouds.joyent.get_location_path(location='us-east-1', api_host_suffix='api.joyentcloud.com')
```
create url from location variable :param location: joyent data center location :return: url

```
salt.cloud.clouds.joyent.get_node(name)
```
gets the node from the full node list by name :param name: name of the vm :return: node object

```
salt.cloud.clouds.joyent.get_size(vm_)
```
Return the VM's size object

```
salt.cloud.clouds.joyent.has_method(obj, method_name)
```
Find if the provided object has a specific method

```
salt.cloud.clouds.joyent.import_key(kwargs=None, call=None)
```
List the keys available

CLI Example:

```
salt-cloud -f import_key joyent keyname=mykey keyfile=/tmp/mykey.pub
```
salt.cloud.clouds.joyent.joyent_node_state(id_)
    Convert joyent returned state to state common to other data center return values for consistency
    
    Parameters
    id -- joyent state value
    
    Returns
    state value

salt.cloud.clouds.joyent.key_list(items=None)
    convert list to dictionary using the key as the identifier
    :param items: array to iterate over
    :return: dictionary

salt.cloud.clouds.joyent.list_keys(kwargs=None, call=None)
    List the keys available

salt.cloud.clouds.joyent.list_nodes(full=False, call=None)
    list of nodes, keeping only a brief listing
    
    CLI Example:
    
    salt-cloud -Q

salt.cloud.clouds.joyent.list_nodes_full(call=None)
    list of nodes, maintaining all content provided from joyent listings
    
    CLI Example:
    
    salt-cloud -F

salt.cloud.clouds.joyent.list_nodes_select(call=None)
    Return a list of the VMs that are on the provider, with select fields

salt.cloud.clouds.joyent.query(action=None, command=None, args=None, method='GET', location=None, data=None)
    Make a web call to Joyent

salt.cloud.clouds.joyent.query_instance(vm_=None, call=None)
    Query an instance upon creation from the Joyent API

salt.cloud.clouds.joyent.reboot(name, call=None)
    reboot a machine by name
    :param name: name given to the machine
    :param call: call value in this case is 'action'
    :return: true if successful
    
    CLI Example:
    
    salt-cloud -a reboot vm_name

salt.cloud.clouds.joyent.reformat_node(item=None, full=False)
    Reformat the returned data from joyent, determine public/private IPs and strip out fields if necessary to provide
    either full or brief content.
    
    Parameters
    - item -- node dictionary
    - full -- full or brief output
    
    Returns dict

salt.cloud.clouds.joyent.show_instance(name, call=None)
    get details about a machine
    :param name: name given to the machine
    :param call: call value in this case is 'action'
    :return: machine information
    
    CLI Example:
salt documentation -a show_instance vm_name

salt.cloud.clouds.joyent.show_key(kwargs=None, call=None)
List the keys available

salt.cloud.clouds.joyent.ssh_interface(vm_)
Return the ssh_interface type to connect to. Either `public_ips' (default) or `private_ips'.

salt.cloud.clouds.joyent.start(name, call=None)
start a machine by name :param name: name given to the machine :param call: call value in this case is `action'
:return: true if successful

CLI Example:
salt-cloud -a start vm_name

salt.cloud.clouds.joyent.stop(name, call=None)
stop a machine by name :param name: name given to the machine :param call: call value in this case is `action'
:return: true if successful

CLI Example:
salt-cloud -a stop vm_name

salt.cloud.clouds.joyent.take_action(name=None, call=None, command=None, data=None, method='GET', location='us-east-1')
take action call used by start,stop, reboot :param name: name given to the machine :param call: call value in this case is `action' :command: api path :data: any data to be passed to the api, must be in json format :method: GET,POST,or DELETE :location: data center to execute the command on :return: true if successful

32.5.9 salt.cloud.clouds.libcloud_aws

The AWS Cloud Module

The AWS cloud module is used to interact with the Amazon Web Services system.

This module has been replaced by the EC2 cloud module, and is no longer supported. The documentation shown here is for reference only; it is highly recommended to change all usages of this driver over to the EC2 driver.

If this driver is still needed, set up the cloud configuration at /etc/salt/cloud.providers or /etc/salt/cloud.providers.d/aws.conf:

```
my-aws-config:
  # The AWS API authentication id
  id: GKTADJGHEIQSXMKKRBJ08H
  # The AWS API authentication key
  key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
  # The ssh keyname to use
  keyname: default
  # The amazon security group
  securitygroup: ssh_open
  # The location of the private key which corresponds to the keyname
  private_key: /root/default.pem
  driver: aws
```

32.5. Full list of Salt Cloud modules
salt.cloud.clouds.libcloud_aws.block_device_mappings(vm_)
Return the block device mapping:

```python
[{
    'DeviceName': '/dev/sdb', 'VirtualName': 'ephemeral0'},
    {'DeviceName': '/dev/sdc', 'VirtualName': 'ephemeral1'}]
```

salt.cloud.clouds.libcloud_aws.create(vm_)
Create a single VM from a data dict

salt.cloud.clouds.libcloud_aws.create_attach_volumes(volumes, location, data)
Create and attach volumes to created node

salt.cloud.clouds.libcloud_aws.del_tags(name, kwargs, call=None)
Delete tags for a node

CLI Example:
```
salt-cloud -a del_tags mymachine tag1,tag2,tag3
```

salt.cloud.clouds.libcloud_aws.destroy(name)
Wrap core libcloudfuncs destroy method, adding check for termination protection

salt.cloud.clouds.libcloud_aws.get_availability_zone(conn, vm_)
Return the availability zone to use

salt.cloud.clouds.libcloud_aws.get_configured_provider()
Return the first configured instance.

salt.cloud.clouds.libcloud_aws.get_conn(**kwargs)
Return a conn object for the passed VM data

salt.cloud.clouds.libcloud_aws.get_dependencies()
Warn if dependencies aren't met.

salt.cloud.clouds.libcloud_aws.get_location(vm_=None)
Return the AWS region to use, in this order:
- CLI parameter
- Cloud profile setting
- Global salt-cloud config

salt.cloud.clouds.libcloud_aws.get_tags(name, call=None)
Retrieve tags for a node

salt.cloud.clouds.libcloud_aws.iam_profile(vm_)
Return the IAM role

salt.cloud.clouds.libcloud_aws.keyname(vm_)
Return the keyname

salt.cloud.clouds.libcloud_aws.rename(name, kwargs, call=None)
Properly rename a node. Pass in the new name as `new name`.

CLI Example:
```
salt-cloud -a rename mymachine newname=yourmachine
```

salt.cloud.clouds.libcloud_aws.securitygroup(vm_)
Return the security group
salt.cloud.clouds.libcloud_aws.set_tags(name, tags, call=None)
Set tags for a node

CLI Example:
salt-cloud -a set_tags mymachine tag1=somestuff tag2='Other stuff'

salt.cloud.clouds.libcloud_aws.ssh_interface(vm_)
Return the ssh_interface type to connect to. Either 'public_ips' (default) or 'private_ips'.

salt.cloud.clouds.libcloud_aws.ssh_username(vm_)
Return the ssh_username. Defaults to 'ec2-user'.

salt.cloud.clouds.libcloud_aws.start(name, call=None)
Start a node

salt.cloud.clouds.libcloud_aws.stop(name, call=None)
Stop a node

32.5.10 salt.cloud.clouds.linode

Linode Cloud Module using Linode's REST API

The Linode cloud module is used to control access to the Linode VPS system.

Use of this module only requires the apikey parameter. However, the default root password for new instances also needs to be set. The password needs to be 8 characters and contain lowercase, uppercase, and numbers.

Set up the cloud configuration at /etc/salt/cloud.providers or /etc/salt/cloud.providers.d/linode.conf:

```
my-linode-provider:
    apikey: f4ZsmwtB1c7f85Jdu43RgXVDFlNjuJaeIYV80QMtTqKScEB2vSosFSr...
    password: F00barbaz
    driver: linode
    ssh_key_file: /tmp/salt-cloud_pubkey
    ssh_pubkey: ssh-rsa AAAAB3NzaC1yc2EA...

linode-profile:
    provider: my-linode-provider
    size: Linode 1024
    image: CentOS 7
    location: London, England, UK
    private_ip: true
```

To clone, add a profile with a clonefrom key, and a script_args: -C clonefrom should be the name of the VM (linode) that is the source for the clone. script_args: -C passes a -C to the bootstrap script, which only configures the minion and doesn’t try to install a new copy of salt-minion. This way the minion gets new keys and the keys get pre-seeded on the master, and the /etc/salt/minion file has the right `id:' declaration.

Cloning requires a post 2015-02-01 salt-bootstrap.

salt.cloud.clouds.linode.avail_images(call=None)
Return available Linode images.

CLI Example:
salt-cloud --list-images my-linode-config
salt-cloud -f avail_images my-linode-config
salt.cloud.clouds.linode.avail_locations(call=None)
  Return available Linode datacenter locations.
  CLI Example:
  
  salt-cloud --list-locations my-linode-config
  salt-cloud -f avail_locations my-linode-config

salt.cloud.clouds.linode.avail_sizes(call=None)
  Return available Linode sizes.
  CLI Example:
  
  salt-cloud --list-sizes my-linode-config
  salt-cloud -f avail_sizes my-linode-config

salt.cloud.clouds.linode.boot(name=None, kwags=None, call=None)
  Boot a Linode.
  
  name  The name of the Linode to boot. Can be used instead of linode_id.
  linode_id  The ID of the Linode to boot. If provided, will be used as an alternative to name and reduces the number of API calls to Linode by one. Will be preferred over name.
  config_id  The ID of the Config to boot. Required.
  
  check_running  Defaults to True. If set to False, overrides the call to check if the VM is running before calling the linode.boot API call. Change check_running to True is useful during the boot call in the create function, since the new VM will not be running yet.

  Can be called as an action (which requires a name):
  
  salt-cloud -a boot my-instance config_id=10

  ...or as a function (which requires either a name or linode_id):
  
  salt-cloud -f boot my-linode-config name=my-instance config_id=10
  salt-cloud -f boot my-linode-config linode_id=1225876 config_id=10

salt.cloud.clouds.linode.clone(kwags=None, call=None)
  Clone a Linode.
  
  linode_id  The ID of the Linode to clone. Required.
  datacenter_id  The ID of the Datacenter where the Linode will be placed. Required.
  plan_id  The ID of the plan (size) of the Linode. Required.

  CLI Example:
  
  salt-cloud -f clone my-linode-config linode_id=1234567 datacenter_id=2 plan_id=5

salt.cloud.clouds.linode.create(vm_)
  Create a single Linode VM.

salt.cloud.clouds.linode.create_config(kwags=None, call=None)
  Creates a Linode Configuration Profile.
  
  name  The name of the VM to create the config for.
  linode_id  The ID of the Linode to create the configuration for.
  root_disk_id  The Root Disk ID to be used for this config.
swap_disk_id  The Swap Disk ID to be used for this config.

kernel_id  The ID of the kernel to use for this configuration profile.

salt.cloud.clouds.linode.create_disk_from_distro(vm_, linode_id, swap_size=None)
Creates the disk for the Linode from the distribution.

vm_  The VM profile to create the disk for.

linode_id  The ID of the Linode to create the distribution disk for. Required.

swap_size  The size of the disk, in MB.

salt.cloud.clouds.linode.create_private_ip(vm_, linode_id)
Creates a private IP for the specified Linode.

vm_  The VM profile to create the swap disk for.

linode_id  The ID of the Linode to create the IP address for.

salt.cloud.clouds.linode.create_swap_disk(vm_, linode_id, swap_size=None)
Creates the disk for the specified Linode.

vm_  The VM profile to create the swap disk for.

linode_id  The ID of the Linode to create the swap disk for.

swap_size  The size of the disk, in MB.

salt.cloud.clouds.linode.destroy(name, call=None)
Destroys a Linode by name.

name  The name of VM to be be destroyed.

CLI Example:
salt-cloud -d vm_name

salt.cloud.clouds.linode.get_config_id(kwargs=None, call=None)
Returns a config_id for a given linode.

New in version 2015.8.0.

name  The name of the Linode for which to get the config_id. Can be used instead of linode_id.

linode_id  The ID of the Linode for which to get the config_id. Can be used instead of name.

CLI Example:
salt-cloud -f get_config_id my-linode-config
salt-cloud -f get_config_id my-linode-config name=my-linode
salt-cloud -f get_config_id my-linode-config linode_id=1234567

salt.cloud.clouds.linode.get_configured_provider()
Return the first configured instance.

salt.cloud.clouds.linode.get_datacenter_id(location)
Returns the Linode Datacenter ID.

location  The location, or name, of the datacenter to get the ID from.

salt.cloud.clouds.linode.get_disk_size(vm_, swap, linode_id)
Returns the size of of the root disk in MB.

vm_  The VM to get the disk size for.

salt.cloud.clouds.linode.get_distribution_id(vm_)
Returns the distribution ID for a VM

32.5.  Full list of Salt Cloud modules 537
`vm_` The VM to get the distribution ID for

```python
salt.cloud.clouds.linode.get_ips(linode_id=None)
```

Returns public and private IP addresses.

- `linode_id` Limits the IP addresses returned to the specified Linode ID.

```python
salt.cloud.clouds.linode.get_linode(kwargs=None, call=None)
```

Returns data for a single named Linode.

- `name` The name of the Linode for which to get data. Can be used instead of `linode_id`. Note this will induce an additional API call compared to using `linode_id`.
- `linode_id` The ID of the Linode for which to get data. Can be used instead of `name`.

CLI Example:

```bash
salt-cloud -f get_linode my-linode-config name=my-instance
salt-cloud -f get_linode my-linode-config linode_id=1234567
```

```python
salt.cloud.clouds.linode.get_linode_id_from_name(name)
```

Returns the Linode ID for a VM from the provided name.

- `name` The name of the Linode from which to get the Linode ID. Required.

```python
salt.cloud.clouds.linode.get_password(vm_)
```

Return the password to use for a VM.

- `vm_` The configuration to obtain the password from.

```python
salt.cloud.clouds.linode.get_plan_id(kwargs=None, call=None)
```

Returns the Linode Plan ID.

- `label` The label, or name, of the plan to get the ID from.

CLI Example:

```bash
salt-cloud -f get_plan_id linode label="Linode 1024"
```

```python
salt.cloud.clouds.linode.get_private_ip(vm_)
```

Return True if a private ip address is requested

```python
salt.cloud.clouds.linode.get_pub_key(vm_)
```

Return the SSH pubkey.

- `vm_` The configuration to obtain the public key from.

```python
salt.cloud.clouds.linode.get_swap_size(vm_)
```

Returns the amount of swap space to be used in MB.

- `vm_` The VM profile to obtain the swap size from.

```python
salt.cloud.clouds.linode.get_vm_size(vm_)
```

Returns the VM's size.

- `vm_` The VM to get the size for.

```python
salt.cloud.clouds.linode.list_nodes(call=None)
```

Returns a list of linodes, keeping only a brief listing.

CLI Example:

```bash
salt-cloud -Q
salt-cloud --query
salt-cloud -f list_nodes my-linode-config
```
Note: The `image` label only displays information about the VM’s distribution vendor, such as ‘Debian’ or ‘RHEL’ and does not display the actual image name. This is due to a limitation of the Linode API.

```python
salt.cloud.clouds.linode.list_nodes_full(call=none)
```

List linodes, with all available information.

CLI Example:

```
salt-cloud -F
salt-cloud --full-query
salt-cloud -f list_nodes_full my-linode-config
```

Note: The `image` label only displays information about the VM’s distribution vendor, such as ‘Debian’ or ‘RHEL’ and does not display the actual image name. This is due to a limitation of the Linode API.

```python
salt.cloud.clouds.linode.list_nodes_min(call=none)
```

Return a list of the VMs that are on the provider. Only a list of VM names and their state is returned. This is the minimum amount of information needed to check for existing VMs.

New in version 2015.8.0.

CLI Example:

```
salt-cloud -f list_nodes_min my-linode-config
salt-cloud --function list_nodes_min my-linode-config
```

```python
salt.cloud.clouds.linode.list_nodes_select(call=none)
```

Return a list of the VMs that are on the provider, with select fields.

```python
salt.cloud.clouds.linode.reboot(name, call=none)
```

Reboot a linode.

New in version 2015.8.0.

```python
name  The name of the VM to reboot.
```

CLI Example:

```
salt-cloud -a reboot vm_name
```

```python
salt.cloud.clouds.linode.show_instance(name, call=none)
```

Displays details about a particular Linode VM. Either a name or a linode_id must be provided.

New in version 2015.8.0.

```python
name  The name of the VM for which to display details.
```

CLI Example:

```
salt-cloud -a show_instance vm_name
```

Note: The `image` label only displays information about the VM’s distribution vendor, such as ‘Debian’ or ‘RHEL’ and does not display the actual image name. This is due to a limitation of the Linode API.

```python
salt.cloud.clouds.linode.show_pricing(kwargs=None, call=none)
```

Show pricing for a particular profile. This is only an estimate, based on unofficial pricing sources.
New in version 2015.8.0.

CLI Example:
```
salt-cloud -f show_pricing my-linode-config profile=my-linode-profile
```

```python
salt.cloud.clouds.linode.start(name, call=None)
```
Start a VM in Linode.

- **name** The name of the VM to start.

CLI Example:
```
salt-cloud -a stop vm_name
```

```python
salt.cloud.clouds.linode.stop(name, call=None)
```
Stop a VM in Linode.

- **name** The name of the VM to stop.

CLI Example:
```
salt-cloud -a stop vm_name
```

```python
salt.cloud.clouds.linode.update_linode(linode_id, update_args=None)
```
Updates a Linode's properties.

- **linode_id** The ID of the Linode to shutdown. Required.
- **update_args** The args to update the Linode with. Must be in dictionary form.

### 32.5.11 salt.cloud.clouds.lxc

**Install Salt on an LXC Container**

New in version 2014.7.0.

Please read [core config documentation](#).

```python
salt.cloud.clouds.lxc.avail_images()
```

```python
salt.cloud.clouds.lxc.create(vm_, call=None)
```
Create an lxc Container. This function is idempotent and will try to either provision or finish the provision of an lxc container.

- **vm_**
- **call**

NOTE: Most of the initialization code has been moved and merged with the lxc runner and lxc.init functions

```python
salt.cloud.clouds.lxc.destroy(vm_, call=None)
```
Destroy a lxc container

```python
salt.cloud.clouds.lxc.get_configured_provider(vm_=None)
```
Return the contextual provider of None if no configured one can be found.

```python
salt.cloud.clouds.lxc.get_provider(name)
```

```python
salt.cloud.clouds.lxc.list_nodes(conn=None, call=None)
```

```python
salt.cloud.clouds.lxc.list_nodes_full(conn=None, call=None)
```

```python
salt.cloud.clouds.lxc.list_nodes_select(call=None)
```
Return a list of the VMs that are on the provider, with select fields
32.5.12 salt.cloud.clouds.msazure

Azure Cloud Module

The Azure cloud module is used to control access to Microsoft Azure.

**depends**
- Microsoft Azure SDK for Python >= 0.11.1
- python-requests, for Python < 2.7.9

**configuration** Required provider parameters:
- apikey
- certificate_path
- subscription_id
- requests_lib

A Management Certificate (.pem and .crt files) must be created and the .pem file placed on the same machine that salt-cloud is run from. Information on creating the pem file to use, and uploading the associated cer file can be found at:

For users with Python < 2.7.9, requests_lib must currently be set to True.

Example /etc/salt/cloud.providers or /etc/salt/cloud.providers.d/azure.conf configuration:

```yaml
my-azure-config:
  driver: azure
  subscription_id: 3287abc8-f98a-c678-3bde-326766fd3617
  certificate_path: /etc/salt/azure.pem
  management_host: management.core.windows.net
```

salt.cloud.clouds.msazure.add_input_endpoint(**kwargs=None**, **conn=None**, **call=None**)  
New in version 2015.8.0.

Add an input endpoint to the deployment. Please note that there may be a delay before the changes show up.

CLI Example:

```
salt-cloud -f add_input_endpoint my-azure service=myservice \ 
  deployment=mydeployment role=myrole name=HTTP local_port=80 \ 
  port=80 protocol=tcp enable_direct_server_return=False \ 
  timeout_for_tcp_idle_connection=4
```

salt.cloud.clouds.msazure.add_management_certificate(**kwargs=None**, **conn=None**, **call=None**)  
New in version 2015.8.0.

Add a new management certificate.

CLI Example:
salt-cloud \[-f\] add_management_certificate my-azure public_key='...PUBKEY...'
thumbprint=0123456789ABCDEF data='...CERT_DATA...'

```
salt.cloud.clouds.msazure.add_service_certificate

New in version 2015.8.0.
Add a new service certificate
CLI Example:
```
salt-cloud -f add_service_certificate my-azure name=my_service_certificate 
data='...CERT_DATA...'
certificate_format=sha1 password=verybadpass

```
salt.cloud.clouds.msazure.avail_images

List available images for Azure
```
salt.cloud.clouds.msazure.avail_locations

List available locations for Azure
```
salt.cloud.clouds.msazure.avail_sizes

Return a list of sizes from Azure
```
salt.cloud.clouds.msazure.cleanup_unattached_disks

New in version 2015.8.0.
Cleans up all disks associated with the account, which are not attached.
* CAUTION * This is a destructive function with no undo button, and no ```Are you sure?``` confirmation!
CLI Examples:
```
salt-cloud -f cleanup_unattached_disks my-azure name=my_disk
salt-cloud -f cleanup_unattached_disks my-azure name=my_disk delete_vhd=True

```
salt.cloud.clouds.msazure.create

Create a single VM from a data dict
```
salt.cloud.clouds.msazure.create_affinity_group

New in version 2015.8.0.
Create a new affinity group
CLI Example:
```
salt-cloud -f create_affinity_group my-azure name=my_affinity_group

```
salt.cloud.clouds.msazure.create_attach_volumes

Create and attach volumes to created node
```
salt.cloud.clouds.msazure.create_service

New in version 2015.8.0.
Create a new hosted service
CLI Example:
```
salt-cloud -f create_service my-azure name=my_service label=my_service location=

← 'West US'```
salt.cloud.clouds.msazure.create_storage(**kwargs=None, conn=None, call=None)**
New in version 2015.8.0.
Create a new storage account

CLI Example:

```
salt-cloud -f create_storage my-azure name=my_storage label=my_storage location='
  "West US"'
```

salt.cloud.clouds.msazure.create_storage_container(**kwargs=None, storage_conn=None,
call=None)**
New in version 2015.8.0.
Create a storage container

CLI Example:

```
salt-cloud -f create_storage_container my-azure name=mycontainer
```

- **name**: Name of container to create.
- **meta_name_values**: Optional. A dict with name_value pairs to associate with the container as metadata. Example: `{Category: 'test'}`
- **blob_public_access**: Optional. Possible values include: container, blob
- **fail_on_exist**: Specify whether to throw an exception when the container exists.

salt.cloud.clouds.msazure.delete_affinity_group(**kwargs=None, conn=None, call=None)**
New in version 2015.8.0.
Delete a specific affinity group associated with the account

CLI Examples:

```
salt-cloud -f delete_affinity_group my-azure name=my_affinity_group
```

salt.cloud.clouds.msazure.delete_disk(**kwargs=None, conn=None, call=None)**
New in version 2015.8.0.
Delete a specific disk associated with the account

CLI Examples:

```
salt-cloud -f delete_disk my-azure name=my_disk
salt-cloud -f delete_disk my-azure name=my_disk delete_vhd=True
```

salt.cloud.clouds.msazure.delete_input_endpoint(**kwargs=None, conn=None, call=None)**
New in version 2015.8.0.
Delete an input endpoint from the deployment. Please note that there may be a delay before the changes show up.

CLI Example:

```
salt-cloud -f delete_input_endpoint my-azure service=myservice \
  deployment=mydeployment role=myrole name=HTTP
```

salt.cloud.clouds.msazure.delete_management_certificate(**kwargs=None, conn=None,
call=None)**
New in version 2015.8.0.
Delete a specific certificate associated with the management

CLI Examples:

```
salt-cloud -f delete_management_certificate my-azure name=my_management_certificate \
    thumbalgorithm=sha1 thumbprint=0123456789ABCDEF
```

```
salt.cloud.clouds.msazure.delete_service(kwargs=None, conn=None, call=None)
```

New in version 2015.8.0.

Delete a specific service associated with the account

CLI Examples:

```
salt-cloud -f delete_service my-azure name=my_service
```

```
salt.cloud.clouds.msazure.delete_service_certificate(kwargs=None, conn=None, call=None)
```

New in version 2015.8.0.

Delete a specific certificate associated with the service

CLI Examples:

```
salt-cloud -f delete_service_certificate my-azure name=my_service_certificate \
    thumbalgorithm=sha1 thumbprint=0123456789ABCDEF
```

```
salt.cloud.clouds.msazure.delete_storage(kwargs=None, conn=None, call=None)
```

New in version 2015.8.0.

Delete a specific storage account

CLI Examples:

```
salt-cloud -f delete_storage my-azure name=my_storage
```

```
salt.cloud.clouds.msazure.delete_storage_container(kwargs=None, storage_conn=None, call=None)
```

New in version 2015.8.0.

Delete a container associated with the storage account

CLI Example:

```
salt-cloud -f delete_storage_container my-azure name=mycontainer
```

name: Name of container to create.

fail_not_exist: Specify whether to throw an exception when the container exists.

lease_id: If specified, delete_storage_container only succeeds if the container's lease is active and matches this ID.

```
salt.cloud.clouds.msazure.destroy(name, conn=None, call=None, kwargs=None)
```

Destroy a VM

CLI Examples:

```
salt-cloud -d myminion
salt-cloud -a destroy myminion service_name=myservice
```
salt.cloud.clouds.msazure.get_affinity_group(kwargs=None, conn=None, call=None)

New in version 2015.8.0.
Show an affinity group associated with the account

CLI Example:
```
salt-cloud -f show_affinity_group my-azure service=myservice \ 
    deployment=mydeployment name=SSH
```

salt.cloud.clouds.msazure.get_blob(kwargs=None, storage_conn=None, call=None)

New in version 2015.8.0.
Download a blob

CLI Example:
```
salt-cloud -f get_blob my-azure container=base name=top.sls local_path=/srv/salt/ →top.sls
salt-cloud -f get_blob my-azure container=base name=content.txt return_content=True
```

- **container**: Name of existing container.
- **name**: Name of existing blob.
- **local_path**: The path on the local machine to download the blob to. Either this or return_content must be specified.
- **return_content**: Whether or not to return the content directly from the blob. If specified, must be True or False. Either this or the local_path must be specified.
- **snapshot**: Optional. The snapshot parameter is an opaque DateTime value that, when present, specifies the blob snapshot to retrieve.
- **lease_id**: Required if the blob has an active lease.
- **progress_callback**: callback for progress with signature function(current, total) where current is the number of bytes transferred so far, and total is the size of the blob.
- **max_connections**: Maximum number of parallel connections to use when the blob size exceeds 64MB. Set to 1 to download the blob chunks sequentially. Set to 2 or more to download the blob chunks in parallel. This uses more system resources but will download faster.
- **max_retries**: Number of times to retry download of blob chunk if an error occurs.
- **retry_wait**: Sleep time in secs between retries.

salt.cloud.clouds.msazure.get_blob_properties(kwargs=None, storage_conn=None, call=None)

New in version 2015.8.0.
Returns all user-defined metadata, standard HTTP properties, and system properties for the blob.

CLI Example:
```
salt-cloud -f show_blob_properties my-azure container=mycontainer blob=myblob
```

- **container**: Name of existing container.
- **blob**: Name of existing blob.
- **lease_id**: Required if the blob has an active lease.
salt.cloud.clouds.msazure.get_blob_service_properties(kwargs=None, storage_conn=None, call=None)

New in version 2015.8.0.
Show a blob's service properties
CLI Example:

```
salt-cloud -f show_blob_service_properties my-azure
```

salt.cloud.clouds.msazure.get_configured_provider()
Return the first configured instance.

salt.cloud.clouds.msazure.get_conn()
Return a conn object for the passed VM data

salt.cloud.clouds.msazure.get_dependencies()
Warn if dependencies aren't met.

salt.cloud.clouds.msazure.get_deployment(kwargs=None, conn=None, call=None)
New in version 2015.8.0.
Return information about a deployment
CLI Example:

```
salt-cloud -f show_deployment my-azure name=my_deployment
```

salt.cloud.clouds.msazure.get_disk(kwargs=None, conn=None, call=None)
New in version 2015.8.0.
Return information about a disk
CLI Example:

```
salt-cloud -f show_disk my-azure name=my_disk
```

salt.cloud.clouds.msazure.get_input_endpoint(kwargs=None, conn=None, call=None)
New in version 2015.8.0.
Show an input endpoint associated with the deployment
CLI Example:

```
salt-cloud -f show_input_endpoint my-azure service=myservice \ 
    deployment=mydeployment name=SSH
```

salt.cloud.clouds.msazure.get_management_certificate(kwargs=None, conn=None, call=None)
New in version 2015.8.0.
Return information about a management_certificate
CLI Example:

```
salt-cloud -f get_management_certificate my-azure name=my_management_certificate \ 
    thumbalgorithm=sha1 thumbprint=0123456789ABCDEF
```

salt.cloud.clouds.msazure.get_operation_status(kwargs=None, conn=None, call=None)
New in version 2015.8.0.
Get Operation Status, based on a request ID
CLI Example:

```
salt-cloud -f get_operation_status my-azure id=0123456789abcdef0123456789abcdef
```

```
salt.cloud.clouds.msazure.get_service_certificate(kwargs=None, conn=None, call=None)
```

New in version 2015.8.0.

Return information about a service certificate

CLI Example:

```
salt-cloud -f show_service_certificate my-azure name=my_service_certificate thumbalgorithm=sha1 thumbprint=0123456789ABCDEF
```

```
salt.cloud.clouds.msazure.get_storage(kwargs=None, conn=None, call=None)
```

New in version 2015.8.0.

List storage service properties

CLI Example:

```
salt-cloud -f show_storage my-azure name=my_storage
```

```
salt.cloud.clouds.msazure.get_storage_conn(storage_account=None, storage_key=None, conn_kwargs=None)
```

New in version 2015.8.0.

Return a storage_conn object for the storage account

```
salt.cloud.clouds.msazure.get_storage_container(kwargs=None, storage_conn=None, call=None)
```

New in version 2015.8.0.

Show a container associated with the storage account

CLI Example:

```
salt-cloud -f show_storage_container my-azure name=myservice
```

name: Name of container to show.

```
salt.cloud.clouds.msazure.get_storage_container_acl(kwargs=None, storage_conn=None, call=None)
```

New in version 2015.8.0.

Show a storage container's acl

CLI Example:

```
salt-cloud -f show_storage_container_acl my-azure name=myservice
```

name: Name of existing container.

lease_id: If specified, show_storage_container_acl only succeeds if the container's lease is active and matches this ID.

```
salt.cloud.clouds.msazure.get_storage_container_metadata(kwargs=None, storage_conn=None, call=None)
```

New in version 2015.8.0.
Show a storage container's metadata

CLI Example:

```
salt-cloud -f show_storage_container_metadata my-azure name=myservice
```

**name**: Name of container to show.

**lease_id**: If specified, show_storage_container_metadata only succeeds if the container's lease is active and matches this ID.

salt.cloud.clouds.msazure.get_storage_keys(*kwargs=None, conn=None, call=None*)

New in version 2015.8.0.

Show storage account keys

CLI Example:

```
salt-cloud -f show_storage_keys my-azure name=my_storage
```

salt.cloud.clouds.msazure.lease_storage_container(*kwargs=None, storage_conn=None, call=None*)

New in version 2015.8.0.

Lease a container associated with the storage account

CLI Example:

```
salt-cloud -f lease_storage_container my-azure name=mycontainer
```

**name**: Name of container to create.

**lease_action**: Required. Possible values: acquire|renew|release|break|change

**lease_id**: Required if the container has an active lease.

**lease_duration**: Specifies the duration of the lease, in seconds, or negative one (-1) for a lease that never expires. A non-infinite lease can be between 15 and 60 seconds. A lease duration cannot be changed using renew or change. For backwards compatibility, the default is 60, and the value is only used on an acquire operation.

**lease_break_period**: Optional. For a break operation, this is the proposed duration of seconds that the lease should continue before it is broken, between 0 and 60 seconds. This break period is only used if it is shorter than the time remaining on the lease. If longer, the time remaining on the lease is used. A new lease will not be available before the break period has expired, but the lease may be held for longer than the break period. If this header does not appear with a break operation, a fixed-duration lease breaks after the remaining lease period elapses, and an infinite lease breaks immediately.

**proposed_lease_id**: Optional for acquire, required for change. Proposed lease ID, in a GUID string format.

salt.cloud.clouds.msazure.list_affinity_groups(*kwargs=None, conn=None, call=None*)

New in version 2015.8.0.

List input endpoints associated with the deployment

CLI Example:

```
salt-cloud -f list_affinity_groups my-azure
```
salt.cloud.clouds.msazure.list_blobs(\texttt{kwargs=None, storage\_conn=None, call=None})

New in version 2015.8.0.

List blobs associated with the container

CLI Example:

```
salt-cloud \-f list\_blobs my-azure container=mycontainer
```

\texttt{container}: The name of the storage container

\texttt{prefix}: Optional. Filters the results to return only blobs whose names begin with the specified prefix.

\texttt{marker}: Optional. A string value that identifies the portion of the list to be returned with the next list operation. The operation returns a marker value within the response body if the list returned was not complete. The marker value may then be used in a subsequent call to request the next set of list items. The marker value is opaque to the client.

\texttt{maxresults}: Optional. Specifies the maximum number of blobs to return, including all BlobPrefix elements. If the request does not specify maxresults or specifies a value greater than 5,000, the server will return up to 5,000 items. Setting maxresults to a value less than or equal to zero results in error response code 400 (Bad Request).

\texttt{include}: Optional. Specifies one or more datasets to include in the response. To specify more than one of these options on the URI, you must separate each option with a comma. Valid values are:

\texttt{snapshots}: Specifies that snapshots should be included in the enumeration. Snapshots are listed from oldest to newest in the response.

\texttt{metadata}: Specifies that blob metadata be returned in the response.

\texttt{uncommittedblobs}: Specifies that blobs for which blocks have been uploaded, but which have not been committed using Put Block List (REST API), be included in the response.

\texttt{copy}: Version 2012-02-12 and newer. Specifies that metadata related to any current or previous Copy Blob operation should be included in the response.

\texttt{delimiter}: Optional. When the request includes this parameter, the operation returns a BlobPrefix element in the response body that acts as a placeholder for all blobs whose names begin with the same substring up to the appearance of the delimiter character. The delimiter may be a single character or a string.

salt.cloud.clouds.msazure.list_disks(\texttt{kwargs=None, conn=None, call=None})

New in version 2015.8.0.

List disks associated with the account

CLI Example:

```
salt-cloud \-f list\_disks my-azure
```

salt.cloud.clouds.msazure.list_hosted_services(\texttt{conn=None, call=None})

List VMs on this Azure account, with full information

salt.cloud.clouds.msazure.list_input_endpoints(\texttt{kwargs=None, conn=None, call=None})

New in version 2015.8.0.

List input endpoints associated with the deployment

CLI Example:

```
salt-cloud \-f list\_input\_endpoints my-azure service=myservice\&deployment=mydeployment
```
salt.cloud.clouds.msazure.list_management_certificates(kwarg=None, conn=None, call=None)

New in version 2015.8.0.
List management certificates associated with the subscription

CLI Example:
```
salt-cloud -f list_management_certificates my-azure name=my_management
```

salt.cloud.clouds.msazure.list_nodes(conn=None, call=None)
List VMs on this Azure account

salt.cloud.clouds.msazure.list_nodes_full(conn=None, call=None)
List VMs on this Azure account, with full information

salt.cloud.clouds.msazure.list_nodes_select(conn=None, call=None)
Return a list of the VMs that are on the provider, with select fields

salt.cloud.clouds.msazure.list_service_certificates(kwarg=None, conn=None, call=None)

New in version 2015.8.0.
List certificates associated with the service

CLI Example:
```
salt-cloud -f list_service_certificates my-azure name=my_service
```

salt.cloud.clouds.msazure.list_services(kwarg=None, conn=None, call=None)

New in version 2015.8.0.
List hosted services associated with the account

CLI Example:
```
salt-cloud -f list_services my-azure
```

salt.cloud.clouds.msazure.list_storage(kwarg=None, conn=None, call=None)

New in version 2015.8.0.
List storage accounts associated with the account

CLI Example:
```
salt-cloud -f list_storage my-azure
```

salt.cloud.clouds.msazure.list_storage_containers(kwarg=None, storage_conn=None, call=None)

New in version 2015.8.0.
List containers associated with the storage account

CLI Example:
```
salt-cloud -f list_storage_containers my-azure
```

salt.cloud.clouds.msazure.list_storage_services(conn=None, call=None)
List VMs on this Azure account, with full information

salt.cloud.clouds.msazure.list_virtual_networks(kwarg=None, conn=None, call=None)

New in version 2015.8.0.
List input endpoints associated with the deployment
CLI Example:
```
salt-cloud -f list_virtual_networks my-azure service=myservice deployment=mydeployment
```

salt.cloud.clouds.msazure.make_blob_url(**kwargs=None, storage_conn=None, call=None)**

New in version 2015.8.0.

Creates the URL to access a blob

CLI Example:
```
salt-cloud -f make_blob_url my-azure container=mycontainer blob=myblob
```

container: Name of the container.
blob: Name of the blob.
account: Name of the storage account. If not specified, derives the host base from the provider configuration.
protocol: Protocol to use: 'http' or 'https'. If not specified, derives the host base from the provider configuration.
host_base: Live host base URL. If not specified, derives the host base from the provider configuration.

salt.cloud.clouds.msazure.put_blob(**kwargs=None, storage_conn=None, call=None)**

New in version 2015.8.0.

Upload a blob

CLI Examples:
```
salt-cloud -f put_blob my-azure container=base name=top.sls blob_path=/srv/salt/
top.sls
salt-cloud -f put_blob my-azure container=base name=content.txt blob_content=
'Some content'
```

container: Name of existing container.
name: Name of existing blob.
blob_path: The path on the local machine of the file to upload as a blob. Either this or blob_content must be specified.
blob_content: The actual content to be uploaded as a blob. Either this or blob_path must be specified.
cache_control: Optional. The Blob service stores this value but does not use or modify it.
content_language: Optional. Specifies the natural languages used by this resource.
content_md5: Optional. An MD5 hash of the blob content. This hash is used to verify the integrity of the blob during transport. When this header is specified, the storage service checks the hash that has arrived with the one that was sent. If the two hashes do not match, the operation will fail with error code 400 (Bad Request).
blob_content_type: Optional. Set the blob's content type.
blob_content_encoding: Optional. Set the blob's content encoding.
blob_content_language: Optional. Set the blob's content language.
blob_content_md5: Optional. Set the blob's MD5 hash.
blob_cache_control: Optional. Sets the blob's cache control.
meta_name_values: A dict containing name, value for metadata.

lease_id: Required if the blob has an active lease.

salt.cloud.clouds.msazure.query(path, method='GET', data=None, params=None, header_dict=None, decode=True)
Perform a query directly against the Azure REST API

salt.cloud.clouds.msazure.regenerate_storage_keys(kwags=None, conn=None, call=None)
New in version 2015.8.0.
Regenerate storage account keys. Requires a key_type (``primary'' or `secondary'') to be specified.
CLI Example:

```
salt-cloud -f regenerate_storage_keys my-azure name=my_storage key_type=primary
```

salt.cloud.clouds.msazure.script(vm_)
Return the script deployment object

salt.cloud.clouds.msazure.set_blob_properties(kwags=None, storage_conn=None, call=None)
New in version 2015.8.0.
Set a blob's properties
CLI Example:

```
salt-cloud -f set_blob_properties my-azure
```

container: Name of existing container.
blob: Name of existing blob.
blob_cache_control: Optional. Modifies the cache control string for the blob.
blob_content_type: Optional. Sets the blob's content type.
blob_content_md5: Optional. Sets the blob's MD5 hash.
blob_content_encoding: Optional. Sets the blob's content encoding.
blob_content_language: Optional. Sets the blob's content language.
 lease_id: Required if the blob has an active lease.
blob_content_disposition: Optional. Sets the blob's Content-Disposition header. The Content-Disposition response header field conveys additional information about how to process the response payload, and also can be used to attach additional metadata. For example, if set to attachment, it indicates that the user-agent should not display the response, but instead show a Save As dialog with a filename other than the blob name specified.

salt.cloud.clouds.msazure.set_blob_service_properties(kwags=None, storage_conn=None, call=None)
New in version 2015.8.0.
Sets the properties of a storage account's Blob service, including Windows Azure Storage Analytics. You can also use this operation to set the default request version for all incoming requests that do not have a version specified.

CLI Example:
salt-cloud -f set_blob_service_properties my-azure

properties: a StorageServiceProperties object.
timeout: Optional. The timeout parameter is expressed in seconds.
salt.cloud.clouds.msazure.set_storage_container_acl(kwargs=None, storage_conn=None, call=None)
New in version 2015.8.0.
Set a storage container's acl
CLI Example:
salt-cloud -f set_storage_container my-azure name=mycontainer

name: Name of existing container.
signed_identifiers: SignedIdentifiers instance
blob_public_access: Optional. Possible values include: container, blob
lease_id: If specified, set_storage_container_acl only succeeds if the container's lease is active and matches this ID.
salt.cloud.clouds.msazure.set_storage_container_metadata(kwargs=None, storage_conn=None, call=None)
New in version 2015.8.0.
Set a storage container's metadata
CLI Example:
salt-cloud -f set_storage_container my-azure name=mycontainer \  
x_ms_meta_name_values='{"my_name": "my_value"}"

name: Name of existing container.
meta_name_values: A dict containing name, value for metadata. Example: {'category': 'test'}
lease_id: If specified, set_storage_container_metadata only succeeds if the container's lease is active and matches this ID.
salt.cloud.clouds.msazure.show_affinity_group(kwargs=None, conn=None, call=None)
New in version 2015.8.0.
Show an affinity group associated with the account
CLI Example:
salt-cloud -f show_affinity_group my-azure service=myservice \  
deployment=mydeployment name=SSH

salt.cloud.clouds.msazure.show_blob_properties(kwargs=None, storage_conn=None, call=None)
New in version 2015.8.0.
Returns all user-defined metadata, standard HTTP properties, and system properties for the blob.
CLI Example:
salt-cloud -f show_blob_properties my-azure container=mycontainer blob=myblob

container: Name of existing container.
blob: Name of existing blob.
lease_id: Required if the blob has an active lease.

salt.cloud.clouds.msazure.show_blob_service_properties(kwars=None, storage_conn=None, call=None)

New in version 2015.8.0.
Show a blob's service properties
CLI Example:
salt-cloud -f show_blob_service_properties my-azure

salt.cloud.clouds.msazure.show_deployment(kwars=None, conn=None, call=None)

New in version 2015.8.0.
Return information about a deployment
CLI Example:
salt-cloud -f show_deployment my-azure name=my_deployment

salt.cloud.clouds.msazure.show_disk(kwars=None, conn=None, call=None)

New in version 2015.8.0.
Return information about a disk
CLI Example:
salt-cloud -f show_disk my-azure name=my_disk

salt.cloud.clouds.msazure.show_input_endpoint(kwars=None, conn=None, call=None)

New in version 2015.8.0.
Show an input endpoint associated with the deployment
CLI Example:
salt-cloud -f show_input_endpoint my-azure service=myservice 
  deployment=mydeployment name=SSH

salt.cloud.clouds.msazure.show_instance(name, call=None)

Show the details from the provider concerning an instance

salt.cloud.clouds.msazure.show_management_certificate(kwars=None, conn=None, call=None)

New in version 2015.8.0.
Return information about a management_certificate
CLI Example:
salt-cloud -f get_management_certificate my-azure name=my_management_certificate 
  thumbalgorithm=sha1 thumbprint=0123456789ABCDEF
salt.cloud.clouds.msazure.show_service(kwargs=None, conn=None, call=None)
New in version 2015.8.0.
List hosted service properties
CLI Example:
salt-cloud -f show_service my-azure name=my_service

salt.cloud.clouds.msazure.show_service_certificate(kwargs=None, conn=None, call=None)
New in version 2015.8.0.
Return information about a service certificate
CLI Example:
salt-cloud -f show_service_certificate my-azure name=my_service_certificate \thumbalgorithm=sha1 thumbprint=0123456789ABCDEF

salt.cloud.clouds.msazure.show_storage(kwargs=None, conn=None, call=None)
New in version 2015.8.0.
List storage service properties
CLI Example:
salt-cloud -f show_storage my-azure name=my_storage

salt.cloud.clouds.msazure.show_storage_container(kwargs=None, storage_conn=None, call=None)
New in version 2015.8.0.
Show a container associated with the storage account
CLI Example:
salt-cloud -f show_storage_container my-azure name=myservice

name: Name of container to show.

salt.cloud.clouds.msazure.show_storage_container_acl(kwargs=None, storage_conn=None, call=None)
New in version 2015.8.0.
Show a storage container's acl
CLI Example:
salt-cloud -f show_storage_container_acl my-azure name=myservice

name: Name of existing container.

lease_id: If specified, show_storage_container_acl only succeeds if the container's lease is active and matches this ID.

salt.cloud.clouds.msazure.show_storage_container_metadata(kwargs=None, storage_conn=None, call=None)
New in version 2015.8.0.
Show a storage container's metadata

CLI Example:
```
salt-cloud -f show_storage_container_metadata my-azure name=myservice
```

**name**: Name of container to show.

**lease_id**: If specified, `show_storage_container_metadata` only succeeds if the container's lease is active and matches this ID.

salt.cloud.clouds.msazure.show_storage_keys(*kwargs=None, conn=None, call=None*)
New in version 2015.8.0.
Show storage account keys

CLI Example:
```
salt-cloud -f show_storage_keys my-azure name=my_storage
```

salt.cloud.clouds.msazure.update_affinity_group(*kwargs=None, conn=None, call=None*)
New in version 2015.8.0.
Update an affinity group's properties

CLI Example:
```
salt-cloud -f update_affinity_group my-azure name=my_group label=my_group
```

salt.cloud.clouds.msazure.update_disk(*kwargs=None, conn=None, call=None*)
New in version 2015.8.0.
Update a disk's properties

CLI Example:
```
salt-cloud -f update_disk my-azure name=my_disk label=my_disk
salt-cloud -f update_disk my-azure name=my_disk new_name=another_disk
```

salt.cloud.clouds.msazure.update_input_endpoint(*kwargs=None, conn=None, call=None, activity='update', port=None, protocol=None, enable_direct_server_return=None, timeout_for_tcp_idle_connection=None*)
New in version 2015.8.0.
Update an input endpoint associated with the deployment. Please note that there may be a delay before the changes show up.

CLI Example:
```
salt-cloud -f update_input_endpoint my-azure service=myservice \ 
   deployment=mydeployment role=myrole name=HTTP local_port=80 \ 
   port=80 protocol=tcp enable_direct_server_return=False \ 
   timeout_for_tcp_idle_connection=4
```

salt.cloud.clouds.msazure.update_storage(*kwargs=None, conn=None, call=None*)
New in version 2015.8.0.
Update a storage account's properties

CLI Example:
32.5.13  salt.cloud.clouds.nova

OpenStack Nova Cloud Module

OpenStack is an open source project that is in use by a number of cloud providers, each of which have their own ways of using it.

The OpenStack Nova module for Salt Cloud was bootstrapped from the OpenStack module for Salt Cloud, which uses a libcloud-based connection. The Nova module is designed to use the nova and glance modules already built into Salt.

These modules use the Python novaclient and glanceclient libraries, respectively. In order to use this module, the proper salt configuration must also be in place. This can be specified in the master config, the minion config, a set of grains or a set of pillars.

```
my_openstack_profile:
  keystone.user: admin
  keystone.password: verybadpass
  keystone.tenant: admin
  keystone.auth_url: 'http://127.0.0.1:5000/v2.0/
```

Note that there is currently a dependency upon netaddr. This can be installed on Debian-based systems by means of the python-netaddr package.

This module currently requires the latest develop branch of Salt to be installed.

This module has been tested to work with HP Cloud and Rackspace. See the documentation for specific options for either of these providers. These examples could be set up in the cloud configuration at /etc/salt/cloud.providers or /etc/salt/cloud.providers.d/openstack.conf:

```
my-openstack-config:
  # The ID of the minion that will execute the salt nova functions
  auth_minion: myminion
  # The name of the configuration profile to use on said minion
  config_profile: my_openstack_profile
  ssh_key_name: mykey
  driver: nova
  userdata_file: /tmp/userdata.txt
```

For local installations that only use private IP address ranges, the following option may be useful. Using the old syntax:

Note: For api use, you will need an auth plugin. The base novaclient does not support apikeys, but some providers such as rackspace have extended keystone to accept them

```
my-openstack-config:
  # Ignore IP addresses on this network for bootstrap
  ignore_cidr: 192.168.50.0/24

my-nova:
  identity_url: 'https://identity.api.rackspacecloud.com/v2.0/
  compute_region: IAD
  user: myusername
```
```yaml
password: mypassword
tenant: <userid>
driver: nova

my-api:
  identity_url: 'https://identity.api.rackspacecloud.com/v2.0/
  compute_region: IAD
  user: myusername
  api_key: <api_key>
  os_auth_plugin: rackspace
tenant: <userid>
driver: nova
networks:
  - net-id: 47a38ff2-fe21-4800-8604-42bd1848e743
  - net-id: 00000000-0000-0000-0000-000000000000
  - net-id: 11111111-1111-1111-1111-111111111111

This is an example profile.

debian8-2-iad-cloudqe4:
  provider: cloudqe4-iad
  size: performance1-2
  image: Debian 8 (Jessie) (PVHVM)
  script_args: -UP -p python-zmq git 2015.8

and one using cinder volumes already attached

```
```
# create the block storage device
centos7-2-iad-rackspace:
  provider: rackspace-iad
  size: general1-2
  block_device:
    - source: image
      id: <image_id>
      dest: volume
      size: 100
      shutdown: <preserve/remove>
      bootindex: 0

# with the volume already created
centos7-2-iad-rackspace:
  provider: rackspace-iad
  size: general1-2
  boot_volume: <volume id>

# create the volume from a snapshot
centos7-2-iad-rackspace:
  provider: rackspace-iad
  size: general1-2
  snapshot: <cinder snapshot id>

# create the create an extra ephemeral disk
centos7-2-iad-rackspace:
  provider: rackspace-iad
  size: general1-2
  ephemeral:
    - size: 100
      format: <swap/ext4>

```
# create the create an extra ephemeral disk

```
centos7-2-iad-rackspace:
    provider: rackspace-iad
    size: general1-2
    swap: <size>
```

Block Device can also be used for having more than one block storage device attached

```
centos7-2-iad-rackspace:
    provider: rackspace-iad
    size: general1-2
    block_device:
        - source: image
          id: <image_id>
          dest: volume
          size: 100
          shutdown: <preserve/remove>
          bootindex: 0
        - source: blank
          dest: volume
          device: xvdc
          size: 100
          shutdown: <preserve/remove>
```

Note: You must include the default net-ids when setting networks or the server will be created without the rest of the interfaces

Note: For rackconnect v3, rackconnectv3 needs to be specified with the rackconnect v3 cloud network as its variable.

```python
salt.cloud.clouds.nova.attach_volume(name, server_name, device='/dev/xvdb', **kwargs)

Attach block volume

salt.cloud.clouds.nova.avail_images()

Return a dict of all available VM images on the cloud provider.

salt.cloud.clouds.nova.avail_locations(conn=None, call=None)

Return a list of locations

salt.cloud.clouds.nova.avail_sizes()

Return a dict of all available VM sizes on the cloud provider.

salt.cloud.clouds.nova.cloudnetwork(vm_)

Determine if we should use an extra network to bootstrap Either 'False' (default) or 'True'.

salt.cloud.clouds.nova.create(vm_)

Create a single VM from a data dict

salt.cloud.clouds.nova.create_attach_volumes(name, call=None, **kwargs)

Create and attach volumes to created node

salt.cloud.clouds.nova.create_volume(name, size=100, snapshot=None, voltype=None, **kwargs)

Create block storage device

salt.cloud.clouds.nova.destroy(name, conn=None, call=None)

Delete a single VM

salt.cloud.clouds.nova.get_block_mapping_opts(vm_)
```
salt.cloud.clouds.nova.get_configured_provider()
    Return the first configured instance.

salt.cloud.clouds.nova.get_conn()
    Return a conn object for the passed VM data
salt.cloud.clouds.nova.get_dependencies()
    Warn if dependencies aren't met.
salt.cloud.clouds.nova.get_image(conn, vm_)
    Return the image object to use
salt.cloud.clouds.nova.get_size(conn, vm_)
    Return the VM's size object
salt.cloud.clouds.nova.ignore_cidr(vm_, ip)
    Return True if we are to ignore the specified IP. Compatible with IPv4.
salt.cloud.clouds.nova.list_nodes(call=None, **kwargs)
    Return a list of the VMs that in this location
salt.cloud.clouds.nova.list_nodes_full(call=None, **kwargs)
    Return a list of the VMs that in this location
salt.cloud.clouds.nova.list_nodes_select(call=None)
    Return a list of the VMs that are on the provider, with select fields
salt.cloud.clouds.nova.managedcloud(vm_)
    Determine if we should wait for the managed cloud automation before running. Either 'False' (default) or 'True'.
salt.cloud.clouds.nova.network_create(name, **kwargs)
    Create private networks
salt.cloud.clouds.nova.network_list(call=None, **kwargs)
    List private networks
salt.cloud.clouds.nova.preferred_ip(vm_, ips)
    Return the preferred Internet protocol. Either 'ipv4' (default) or 'ipv6'.
salt.cloud.clouds.nova.rackconnect(vm_)
    Determine if we should wait for rackconnect automation before running. Either 'False' (default) or 'True'.
salt.cloud.clouds.nova.rackconnectv3(vm_)
    Determine if server is using rackconnectv3 or not Return the rackconnect network name or False
salt.cloud.clouds.nova.reboot(name, conn=None)
    Reboot a single VM
salt.cloud.clouds.nova.request_instance(vm_=None, call=None)
    Put together all of the information necessary to request an instance through Novaclient and then fire off the request the instance.
    Returns data about the instance
salt.cloud.clouds.nova.script(vm_)
    Return the script deployment object
salt.cloud.clouds.nova.show_instance(name, call=None)
    Show the details from the provider concerning an instance
salt.cloud.clouds.nova.ssh_interface(vm_)
    Return the ssh_interface type to connect to. Either 'public_ips' (default) or 'private_ips'.
salt.cloud.clouds.nova.virtual_interface_create(name, net_name, **kwargs)
    Create private networks
salt.cloud.clouds.nova.virtual_interface_list(name, **kwargs)
    Create private networks
salt.cloud.clouds.nova.volume_attach(name, server_name, device='/dev/xvdb', **kwargs)
    Attach block volume
salt.cloud.clouds.nova.volume_create(name, size=100, snapshot=None, voltype=None, **kwargs)
    Create block storage device
salt.cloud.clouds.nova.volume_createAttach(name, call=None, **kwargs)
    Create and attach volumes to created node
salt.cloud.clouds.nova.volume_delete(name, **kwargs)
    Delete block storage device
salt.cloud.clouds.nova.volume_detach(name, **kwargs)
    Detach block volume
salt.cloud.clouds.nova.volume_list(**kwargs)
    List block devices

32.5.14 salt.cloud.clouds.opennebula

OpenNebula Cloud Module

The OpenNebula cloud module is used to control access to an OpenNebula cloud.

    depends lxml

Use of this module requires the xml_rpc, user and password parameter to be set. Set up the cloud configuration at /etc/salt/cloud.providers or /etc/salt/cloud.providers.d/opennebula.conf:

```
my-opennebula-config:
    xml_rpc: http://localhost:2633/RPC2
    user: oneadmin
    password: JHGhgsayu32jsa
    driver: opennebula
```

salt.cloud.clouds.opennebula.avail_images(call=None)
    Return a list of the templates that are on the provider
salt.cloud.clouds.opennebula.avail_locations(call=None)
    Return a dict of all available VM locations on the cloud provider with relevant data
salt.cloud.clouds.opennebula.avail_sizes(call=None)
    Because sizes are built into templates with OpenNebula, there will be no sizes to return here
salt.cloud.clouds.opennebula.create(vm_)
    Create a single VM from a data dict
salt.cloud.clouds.opennebula.destroy(name, call=None)
    Destroy a node. Will check termination protection and warn if enabled.

CLI Example:

```
salt-cloud --destroy mymachine
```
32.5.15 salt.cloud.clouds.openstack

OpenStack Cloud Module

OpenStack is an open source project that is in use by a number a cloud providers, each of which have their own ways of using it.

```
[OpenStack auth]
identity_url: https://region-b.geo-1.identity.hpcloudsvc.com:35357/v2.0/
compute_region: region-b.geo-1
compute_name: Compute

[OpenStack tenant]
tenant: myuser-tenant1
user: myuser
keypair: mykeypair
```

Note that there is currently a dependency upon netaddr. This can be installed on Debian-based systems by means of the python-netaddr package.

This module has been tested to work with HP Cloud and Rackspace. See the documentation for specific options for either of these providers. Some examples, using the old configuration syntax, are provided below:

Set up in the cloud configuration at /etc/salt/cloud.providers or /etc/salt/cloud.providers.d/openstack.conf:
ssh_key_name: mykey
# Skip SSL certificate validation
insecure: false
# The ssh key file
ssh_key_file: /path/to/keyfile/test.pem
# The OpenStack network UUIDs
networks:
  - fixed:
    - 4402cd51-37ee-435e-a966-8245956dc0e6
  - floating:
    - Ext-Net
files:
  /path/to/dest.txt:
  /local/path/to/src.txt
# Skips the service catalog API endpoint, and uses the following
driver: openstack
userdata_file: /tmp/userdata.txt
# config_drive is required for userdata at rackspace
config_drive: True

For in-house Openstack Essex installation, libcloud needs the service_type:

my-openstack-config:
  identity_url: 'http://control.openstack.example.org:5000/v2.0/
  compute_name : Compute Service
  service_type : compute

Either a password or an API key must also be specified:

my-openstack-password-or-api-config:
  # The OpenStack password
  password: letmein
  # The OpenStack API key
  apikey: 901d3f579h23c8v73q9

Optionally, if you don’t want to save plain-text password in your configuration file, you can use keyring:

my-openstack-keyring-config:
  # The OpenStack password is stored in keyring
  # don’t forget to set the password by running something like:
  # salt-cloud --set-password=myuser my-openstack-keyring-config
  password: USE_KEYRING

For local installations that only use private IP address ranges, the following option may be useful. Using the old syntax:

my-openstack-config:
  # Ignore IP addresses on this network for bootstrap
  ignore_cidr: 192.168.50.0/24

It is possible to upload a small set of files (no more than 5, and nothing too large) to the remote server. Generally this should not be needed, as salt itself can upload to the server after it is spun up, with nowhere near the same restrictions.

my-openstack-config:
  files:
Alternatively, one could use the private IP to connect by specifying:

```
my-openstack-config:
  ssh_interface: private_ips
```

Salt provides several functions for working with OpenStack:

- `salt.cloud.clouds.openstack.avail_images(conn=None, call=None)`: Returns a dict of all available VM images on the cloud provider with relevant data.
- `salt.cloud.clouds.openstack.avail_locations(conn=None, call=None)`: Returns a dict of all available VM locations on the cloud provider with relevant data.
- `salt.cloud.clouds.openstack.avail_sizes(conn=None, call=None)`: Returns a dict of all available VM images on the cloud provider with relevant data.
- `salt.cloud.clouds.openstack.create(vm_)`: Creates a single VM from a data dict.
- `salt.cloud.clouds.openstack.destroy(name, conn=None, call=None)`: Deletes a single VM.
- `salt.cloud.clouds.openstack.get_configured_provider()`: Returns the first configured instance.
- `salt.cloud.clouds.openstack.get_conn()`: Returns a conn object for the passed VM data.
- `salt.cloud.clouds.openstack.get_dependencies()`: Warns if dependencies aren’t met.
- `salt.cloud.clouds.openstack.get_image(conn, vm_)`: Returns the image object to use.
- `salt.cloud.clouds.openstack.get_node(conn, name)`: Returns a libcloud node for the named VM.
- `salt.cloud.clouds.openstack.get_size(conn, vm_)`: Returns the VM’s size object.
- `salt.cloud.clouds.openstack.ignore_cidr(vm_, ip)`: Returns True if we are to ignore the specified IP. Compatible with IPv4.
- `salt.cloud.clouds.openstack.list_nodes(conn=None, call=None)`: Returns a list of the VMs that are on the provider.
- `salt.cloud.clouds.openstack.list_nodes_full(conn=None, call=None)`: Returns a list of the VMs that are on the provider, with all fields.
- `salt.cloud.clouds.openstack.list_nodes_select(conn=None, call=None)`: Returns a list of the VMs that are on the provider, with select fields.
- `salt.cloud.clouds.openstack.managedcloud(vm_)`: Determines if we should wait for the managed cloud automation before running. Either ‘False’ (default) or ‘True’.
- `salt.cloud.clouds.openstack.networks(vm_, kwargs=None)`: Returns the preferred Internet protocol. Either ‘ipv4’ (default) or ‘ipv6’.

```
salt.cloud.clouds.openstack.rackconnect(vm_)
    Determine if we should wait for rackconnect automation before running. Either 'False' (default) or 'True'.

salt.cloud.clouds.openstack.reboot(name, conn=None)
    Reboot a single VM

salt.cloud.clouds.openstack.request_instance(vm_=None, call=None)
    Put together all of the information necessary to request an instance on Openstack and then fire off the request
    the instance.
    Returns data about the instance

salt.cloud.clouds.openstack.script(vm_)
    Return the script deployment object

salt.cloud.clouds.openstack.show_instance(name, call=None)
    Show the details from the provider concerning an instance

salt.cloud.clouds.openstack.ssh_interface(vm_)
    Return the ssh_interface type to connect to. Either 'public_ips' (default) or 'private_ips'.

32.5.16 salt.cloud.clouds.parallels

Parallels Cloud Module

The Parallels cloud module is used to control access to cloud providers using the Parallels VPS system.

Set up the cloud configuration at /etc/salt/cloud.providers or /etc/salt/cloud.providers.d/parallels.conf:

```
my-parallels-config:
    # Parallels account information
    user: myuser
    password: mypassword
    url: https://api.cloud.xmission.com:4465/paci/v1.0/
    driver: parallels
```

salt.cloud.clouds.parallels.avail_images(call=None)
    Return a list of the images that are on the provider

salt.cloud.clouds.parallels.create(vm_)
    Create a single VM from a data dict

salt.cloud.clouds.parallels.create_node(vm_)
    Build and submit the XML to create a node

salt.cloud.clouds.parallels.destroy(name, call=None)
    Destroy a node.
    CLI Example:

```
salt-cloud --destroy mymachine
```

salt.cloud.clouds.parallels.get_configured_provider()
    Return the first configured instance.

salt.cloud.clouds.parallels.get_image(vm_)
    Return the image object to use

salt.cloud.clouds.parallels.list_nodes(call=None)
    Return a list of the VMs that are on the provider
salt.cloud.clouds.parallels.list_nodes_full(call=None)
    Return a list of the VMs that are on the provider

salt.cloud.clouds.parallels.list_nodes_select(call=None)
    Return a list of the VMs that are on the provider, with select fields

salt.cloud.clouds.parallels.query(action=None, command=None, args=None, method='GET', data=None)
    Make a web call to a Parallels provider

salt.cloud.clouds.parallels.script(vm_)
    Return the script deployment object

salt.cloud.clouds.parallels.show_image(kwars, call=None)
    Show the details from Parallels concerning an image

salt.cloud.clouds.parallels.show_instance(name, call=None)
    Show the details from Parallels concerning an instance

salt.cloud.clouds.parallels.start(name, call=None)
    Start a node.
    CLI Example:
    ```
    salt-cloud -a start mymachine
    ```

salt.cloud.clouds.parallels.stop(name, call=None)
    Stop a node.
    CLI Example:
    ```
    salt-cloud -a stop mymachine
    ```

salt.cloud.clouds.parallels.wait_until(name, state, timeout=300)
    Wait until a specific state has been reached on a node

### 32.5.17 salt.cloud.clouds.proxmox

**Proxmox Cloud Module**

New in version 2014.7.0.

The Proxmox cloud module is used to control access to cloud providers using the Proxmox system (KVM / OpenVZ).

Set up the cloud configuration at `/etc/salt/cloud.providers` or `/etc/salt/cloud.providers.d/proxmox.conf`

```yaml
my-proxmox-config:
    # Proxmox account information
    user: myuser@pam or myuser@pve
    password: mypassword
    url: hypervisor.domain.tld
    driver: proxmox
    verify_ssl: True
```

*maintainer* Frank Klaassen `<frank@cloudright.nl>`

*depends* requests >= 2.2.1

*depends* IPy >= 0.81
salt.cloud.clouds.proxmox.avail_images(call=None, location='local')
  Return a list of the images that are on the provider
  CLI Example:
  ```
salt-cloud --list-images my-proxmox-config
  ```

salt.cloud.clouds.proxmox.avail_locations(call=None)
  Return a list of the hypervisors (nodes) which this Proxmox PVE machine manages
  CLI Example:
  ```
salt-cloud --list-locations my-proxmox-config
  ```

salt.cloud.clouds.proxmox.create(vm_)
  Create a single VM from a data dict
  CLI Example:
  ```
salt-cloud -p proxmox-ubuntu vmhostname
  ```

salt.cloud.clouds.proxmox.create_node(vm_)
  Build and submit the requestdata to create a new node

salt.cloud.clouds.proxmox.destroy(name, call=None)
  Destroy a node.
  CLI Example:
  ```
salt-cloud --destroy mymachine
  ```

salt.cloud.clouds.proxmox.get_configured_provider()
  Return the first configured instance.

salt.cloud.clouds.proxmox.get_dependencies()
  Warn if dependencies aren't met.

salt.cloud.clouds.proxmox.get_resources_nodes(call=None, resFilter=None)
  Retrieve all hypervisors (nodes) available on this environment
  CLI Example:
  ```
salt-cloud -f get_resources_nodes my-proxmox-config
  ```

salt.cloud.clouds.proxmox.get_resources_vms(call=None, resFilter=None, includeConfig=True)
  Retrieve all VMs available on this environment
  CLI Example:
  ```
salt-cloud -f get_resources_vms my-proxmox-config
  ```

salt.cloud.clouds.proxmox.get_vm_status(vmid=None, name=None)
  Get the status for a VM, either via the ID or the hostname

salt.cloud.clouds.proxmox.get_vmconfig(vmid, node=None, node_type='openvz')
  Get VM configuration

salt.cloud.clouds.proxmox.list_nodes(call=None)
  Return a list of the VMs that are managed by the provider
  CLI Example:
salt-cloud -Q my-proxmox-config

salt.cloud.clouds.proxmox.list_nodes_full(call=None)
Return a list of the VMs that are on the provider

CLI Example:
salt-cloud -F my-proxmox-config

salt.cloud.clouds.proxmox.list_nodes_select(call=None)
Return a list of the VMs that are on the provider, with select fields

CLI Example:
salt-cloud -S my-proxmox-config

salt.cloud.clouds.proxmox.query(conn_type, option, post_data=None)
Execute the HTTP request to the API

salt.cloud.clouds.proxmox.script(vm_)
Return the script deployment object

salt.cloud.clouds.proxmox.set_vm_status(status, name=None, vmid=None)
Convenience function for setting VM status

salt.cloud.clouds.proxmox.show_instance(name, call=None)
Show the details from Proxmox concerning an instance

salt.cloud.clouds.proxmox.shutdown(name=None, vmid=None, call=None)
Shutdown a node via ACPI.

CLI Example:
salt-cloud -a shutdown mymachine

salt.cloud.clouds.proxmox.start(name, vmid=None, call=None)
Start a node.

CLI Example:
salt-cloud -a start mymachine

salt.cloud.clouds.proxmox.stop(name, vmid=None, call=None)
Stop a node ("pulling the plug").

CLI Example:
salt-cloud -a stop mymachine

salt.cloud.clouds.proxmox.wait_for_created(upid, timeout=300)
Wait until the vm has been created successfully

salt.cloud.clouds.proxmox.wait_for_state(vmid, state, timeout=300)
Wait until a specific state has been reached on a node
32.5.18 salt.cloud.clouds.pyrax

Pyrax Cloud Module

PLEASE NOTE: This module is currently in early development, and considered to be experimental and unstable. It is not recommended for production use. Unless you are actively developing code in this module, you should use the OpenStack module instead.

salt.cloud.clouds.pyrax.get_configured_provider()
    Return the first configured instance.

salt.cloud.clouds.pyrax.get_conn(conn_type)
    Return a conn object for the passed VM data

salt.cloud.clouds.pyrax.get_dependencies()
    Warn if dependencies aren't met.

salt.cloud.clouds.pyrax.queues_create(call, kwargs)

salt.cloud.clouds.pyrax.queues_delete(call, kwargs)

salt.cloud.clouds.pyrax.queues_exists(call, kwargs)

salt.cloud.clouds.pyrax.queues_show(call, kwargs)

32.5.19 salt.cloud.clouds.rackspace

Rackspace Cloud Module

The Rackspace cloud module. This module uses the preferred means to set up a libcloud based cloud module and should be used as the general template for setting up additional libcloud based modules.

    depends libcloud >= 0.13.2

Please note that the rackspace driver is only intended for 1st gen instances, aka, `the old cloud' at Rackspace. It is required for 1st gen instances, but will not work with OpenStack-based instances. Unless you explicitly have a reason to use it, it is highly recommended that you use the openstack driver instead.

The rackspace cloud module interfaces with the Rackspace public cloud service and requires that two configuration parameters be set for use, user and apikey.

Set up the cloud configuration at /etc/salt/cloud.providers or /etc/salt/cloud.providers.d/rackspace.conf:

```
my-rackspace-config:
  driver: rackspace
  # The Rackspace login user
  user: fred
  # The Rackspace user's apikey
  apikey: 901d3f579h23c8v73q9
```

salt.cloud.clouds.rackspace.avail_images(conn=None, call=None)
    Return a dict of all available VM images on the cloud provider with relevant data

salt.cloud.clouds.rackspace.avail_locations(conn=None, call=None)
    Return a dict of all available VM locations on the cloud provider with relevant data

salt.cloud.clouds.rackspace.avail_sizes(conn=None, call=None)
    Return a dict of all available VM images on the cloud provider with relevant data
salt.cloud.clouds.rackspace.create(vm_)
    Create a single VM from a data dict

salt.cloud.clouds.rackspace.destroy(name, conn=None, call=None)
    Delete a single VM

salt.cloud.clouds.rackspace.get_configured_provider()
    Return the first configured instance.

salt.cloud.clouds.rackspace.get_conn()
    Return a conn object for the passed VM data

salt.cloud.clouds.rackspace.get_dependencies()
    Warn if dependencies aren't met.

salt.cloud.clouds.rackspace.get_image(conn, vm_)
    Return the image object to use

salt.cloud.clouds.rackspace.get_size(conn, vm_)
    Return the VM's size object

salt.cloud.clouds.rackspace.list_nodes(conn=None, call=None)
    Return a list of the VMs that are on the provider

salt.cloud.clouds.rackspace.list_nodes_full(conn=None, call=None)
    Return a list of the VMs that are on the provider, with all fields

salt.cloud.clouds.rackspace.list_nodes_select(conn=None, call=None)
    Return a list of the VMs that are on the provider, with select fields

salt.cloud.clouds.rackspace.preferred_ip(vm_, ips)
    Return the preferred Internet protocol. Either `ipv4` (default) or `ipv6`.

salt.cloud.clouds.rackspace.script(vm_)
    Return the script deployment object

salt.cloud.clouds.rackspace.show_instance(name, call=None)
    Show the details from the provider concerning an instance

salt.cloud.clouds.rackspace.ssh_interface(vm_)
    Return the ssh_interface type to connect to. Either `public_ips` (default) or `private_ips`.

32.5.20 salt.cloud.clouds.saltify

Saltify Module

The Saltify module is designed to install Salt on a remote machine, virtual or bare metal, using SSH. This module is useful for provisioning machines which are already installed, but not Salted.

Use of this module requires some configuration in cloud profile and provider files as described in the Getting Started with Saltify documentation.

salt.cloud.clouds.saltify.create(vm_)
    Provision a single machine

salt.cloud.clouds.saltify.get_configured_provider()
    Return the first configured instance.

salt.cloud.clouds.saltify.list_nodes()
    Because this module is not specific to any cloud providers, there will be no nodes to list.
Because this module is not specific to any cloud providers, there will be no nodes to list.

Because this module is not specific to any cloud providers, there will be no nodes to list.

### 32.5.21 salt.cloud.clouds.softlayer

**SoftLayer Cloud Module**

The SoftLayer cloud module is used to control access to the SoftLayer VPS system.

Use of this module only requires the apikey parameter. Set up the cloud configuration at:

```bash
/etc/salt/cloud.providers or /etc/salt/cloud.providers.d/softlayer.conf
```

```yaml
my-softlayer-config:
    # SoftLayer account api key
    user: MYLOGIN
    apikey: JVkbSJDGHSDKUKSDJfhsdklfjgsjdkgflhjlsdfffhgjkenrtuinv
    driver: softlayer
```

The SoftLayer Python Library needs to be installed in order to use the SoftLayer salt.cloud modules. See: [https://pypi.python.org/pypi/SoftLayer](https://pypi.python.org/pypi/SoftLayer)

```python
depends softlayer
```

```python
salt.cloud.clouds.softlayer.avail_images(call=None)
```

Return a dict of all available VM images on the cloud provider.

```python
salt.cloud.clouds.softlayer.avail_locations(call=None)
```

List all available locations

```python
salt.cloud.clouds.softlayer.avail_sizes(call=None)
```

Return a dict of all available VM sizes on the cloud provider with relevant data. This data is provided in three dicts.

```python
salt.cloud.clouds.softlayer.create(vm_)
```

Create a single VM from a data dict

```python
salt.cloud.clouds.softlayer.destroy(name, call=None)
```

Destroy a node.

CLI Example:

```bash
salt-cloud --destroy mymachine
```

```python
salt.cloud.clouds.softlayer.get_configured_provider()
```

Return the first configured instance.

```python
salt.cloud.clouds.softlayer.get_conn(service='SoftLayer_Virtual_Guest')
```

Return a conn object for the passed VM data

```python
salt.cloud.clouds.softlayer.get_dependencies()
```

Warn if dependencies aren’t met.

```python
salt.cloud.clouds.softlayer.get_location(vm_=None)
```

Return the location to use, in this order:

- CLI parameter
• VM parameter
• Cloud profile setting

```python
class Clouds:
    # Return a dict of all custom VM images on the cloud provider.
    list_custom_images(call=None)

    # Return a list of the VMs that are on the provider.
    list_nodes(call=None)

    # Return a list of the VMs that are on the provider.
    list_nodes_full(mask='mask[id]', call=None)

    # Return a list of the VMs that are on the provider, with select fields.
    list_nodes_select(call=None)

    # List all VLANs associated with the account.
    list_vlans(call=None)

    # Return the script deployment object.
    script(vm_)

    # Show the details from SoftLayer concerning a guest.
    show_instance(name, call=None)
```

### 32.5.22 salt.cloud.clouds.softlayer_hw

**SoftLayer HW Cloud Module**

The SoftLayer HW cloud module is used to control access to the SoftLayer hardware cloud system.

Use of this module only requires the `apikey` parameter. Set up the cloud configuration at:

```
/etc/salt/cloud.providers or /etc/salt/cloud.providers.d/softlayer.conf:
```

```
my-softlayer-config:
  # SoftLayer account api key
  user: MYLOGIN
  apikey: JVkbSJJDGHSDKUKSDJfhsdklfjgsjdjkflhjlsdffffhgdgjkenrtuin
  driver: softlayer_hw
```

The SoftLayer Python Library needs to be installed in order to use the SoftLayer salt.cloud modules. See: [https://pypi.python.org/pypi/SoftLayer](https://pypi.python.org/pypi/SoftLayer)

```
depends softlayer
```

```python
class Clouds:
    # Return a dict of all available VM images on the cloud provider.
    avail_images(call=None)

    # List all available locations.
    avail_locations(call=None)

    # Return a dict of all available VM sizes on the cloud provider with relevant data. This data is provided in three
dicts.
    avail_sizes(call=None)

    # Create a single VM from a data dict.
    create(vm_)

    # Destroy a node.
    destroy(name, call=None)
```

572 Chapter 32. Reference
CLI Example:

```
salt-cloud --destroy mymachine
```

```
salt.cloud.clouds.softlayer_hw.get_configured_provider()
```

Return the first configured instance.

```
salt.cloud.clouds.softlayer_hw.get_conn(service='SoftLayer_Hardware')
```

Return a conn object for the passed VM data.

```
salt.cloud.clouds.softlayer_hw.get_dependencies()
```

Warn if dependencies aren’t met.

```
salt.cloud.clouds.softlayer_hw.get_location(vm_=None)
```

Return the location to use, in this order:

- CLI parameter
- VM parameter
- Cloud profile setting

```
salt.cloud.clouds.softlayer_hw.list_nodes(call=None)
```

Return a list of the VMs that are on the provider.

```
salt.cloud.clouds.softlayer_hw.list_nodes_full(mask='mask[id, hostname, primaryIpAddress, primaryBackendIpAddress, processorPhysicalCoreAmount, memoryCount]', call=None)
```

Return a list of the VMs that are on the provider.

```
salt.cloud.clouds.softlayer_hw.list_nodes_select(call=None)
```

Return a list of the VMs that are on the provider, with select fields.

```
salt.cloud.clouds.softlayer_hw.list_vlans(call=None)
```

List all VLANs associated with the account.

```
salt.cloud.clouds.softlayer_hw.script(vm_)
```

Return the script deployment object.

```
salt.cloud.clouds.softlayer_hw.show_all_prices(call=None, kwarg=kwarg)
```

Return a dict of all available VM images on the cloud provider.

```
salt.cloud.clouds.softlayer_hw.show_instance(name, call=None)
```

Show the details from SoftLayer concerning a guest.

```
salt.cloud.clouds.softlayer_hw.show_pricing(kwarg=kwarg, call=None)
```

Show pricing for a particular profile. This is only an estimate, based on unofficial pricing sources.

CLI Examples:

```
salt-cloud -f show_pricing my-softlayerhw-config profile=my-profile
```

If pricing sources have not been cached, they will be downloaded. Once they have been cached, they will not be updated automatically. To manually update all prices, use the following command:

```
salt-cloud -f update_pricing <provider>
```

New in version 2015.8.0.
32.5.23  salt.cloud.clouds.vmware

VMware Cloud Module

New in version 2015.5.4.

The VMware cloud module allows you to manage VMware ESX, ESXi, and vCenter.

See Getting started with VMware to get started.

   codeauthor  Nitin Madhok <nmadhok@clemson.edu>

Dependencies

- pyVmomi Python Module

pyVmomi

PyVmomi can be installed via pip:

```
pip install pyVmomi
```

**Note:** Version 6.0 of pyVmomi has some problems with SSL error handling on certain versions of Python. If using version 6.0 of pyVmomi, Python 2.6, Python 2.7.9, or newer must be present. This is due to an upstream dependency in pyVmomi 6.0 that is not supported in Python versions 2.7 to 2.7.8. If the version of Python is not in the supported range, you will need to install an earlier version of pyVmomi. See Issue #29537 for more information.

Based on the note above, to install an earlier version of pyVmomi than the version currently listed in PyPi, run the following:

```
pip install pyVmomi==5.5.0.2014.1.1
```

The 5.5.0.2014.1.1 is a known stable version that this original VMware cloud driver was developed against.

**Note:** Ensure python pyVmomi module is installed by running following one-liner check. The output should be 0.

```
python -c "import pyVmomi" ; echo $?
```

Configuration

To use this module, set up the vCenter URL, username and password in the cloud configuration at
/etc/salt/cloud.providers or /etc/salt/cloud.providers.d/vmware.conf:

```
my-vmware-config:
  driver: vmware
  user: 'DOMAIN\user'
  password: 'verybadpass'
  url: '10.20.30.40'

vcenter01:
  driver: vmware
```
user: 'DOMAIN\user'
password: 'verybadpass'
url: 'vcenter01.domain.com'
protocol: 'https'
port: 443

vcenter02:
driver: vmware
user: 'DOMAIN\user'
password: 'verybadpass'
url: 'vcenter02.domain.com'
protocol: 'http'
port: 80

Note: Optionally, protocol and port can be specified if the vCenter server is not using the defaults. Default is protocol: https and port: 443.

To test the connection for my-vmware-config specified in the cloud configuration, run test_vcenter_connection()

click云集云.clouds.vmware.add_host(kwargs=None, call=None)

Add a host system to the specified cluster or datacenter in this VMware environment

Note: To use this function, you need to specify esxi_host_user and esxi_host_password under your provider configuration set up at /etc/salt/cloud.providers or /etc/salt/cloud.providers.d/vmware.conf:

vcenter01:
driver: vmware
user: 'DOMAIN\user'
password: 'verybadpass'
url: 'vcenter01.domain.com'

# Required when adding a host system
esxi_host_user: 'root'
esxi_host_password: 'myhostpassword'
# Optional fields that can be specified when adding a host system
              2B:34:CD'

The SSL thumbprint of the host system can be optionally specified by setting esxi_host_ssl_thumbprint under your provider configuration. To get the SSL thumbprint of the host system, execute the following command from a remote server:

echo -n | openssl s_client -connect <YOUR-HOSTSYSTEM-DNS/IP>:443 2>/dev/null | openssl x509 -noout -fingerprint -sha1

CLI Example:
salt-cloud -f add_host my-vmware-config host="myHostSystemName" cluster="myClusterName"
salt-cloud -f add_host my-vmware-config host="myHostSystemName" datacenter="myDatacenterName"
salt.cloud.clouds.vmware.avail_images(call=None)
Return a list of all the templates present in this VMware environment with basic details

CLI Example:
salt-cloud --list-images my-vmware-config

salt.cloud.clouds.vmware.avail_locations(call=None)
Return a list of all the available locations/datacenters in this VMware environment

CLI Example:
salt-cloud --list-locations my-vmware-config

call=None)

salt.cloud.clouds.vmware.avail_sizes(call=None)
Return a list of all the available sizes in this VMware environment.

CLI Example:
salt-cloud --list-sizes my-vmware-config

Note: Since sizes are built into templates, this function will return an empty dictionary.

salt.cloud.clouds.vmware.connect_host(kwargs=None, call=None)
Connect the specified host system in this VMware environment

CLI Example:
salt-cloud -f connect_host my-vmware-config host="myHostSystemName"

salt.cloud.clouds.vmware.create(vm_)  
To create a single VM in the VMware environment.
Sample profile and arguments that can be specified in it can be found here.

CLI Example:
salt-cloud -p vmware-centos6.5 vmname

salt.cloud.clouds.vmware.create_cluster(kwargs=None, call=None)
Create a new cluster under the specified datacenter in this VMware environment

CLI Example:
salt-cloud -f create_cluster my-vmware-config name="myNewCluster" datacenter="datacenterName"

salt.cloud.clouds.vmware.create_datacenter(kwargs=None, call=None)
Create a new data center in this VMware environment

CLI Example:
salt-cloud -f create_datacenter my-vmware-config name="MyNewDatacenter"

salt.cloud.clouds.vmware.create_datastore_cluster(kwargs=None, call=None)
Create a new datastore cluster for the specified datacenter in this VMware environment

CLI Example:
salt-cloud -f create_datastore_cluster my-vmware-config name="datastoreClusterName", datacenter="datacenterName"

salt.cloud.clouds.vmware.create_folder(kwargs=None, call=None)
Create the specified folder path in this VMware environment

Note: To create a Host and Cluster Folder under a Datacenter, specify path="/yourDatacenterName/host/yourFolderName"
To create a Network Folder under a Datacenter, specify path="/yourDatacenterName/network/yourFolderName"
To create a Storage Folder under a Datacenter, specify path="/yourDatacenterName/datastore/yourFolderName"
To create a VM and Template Folder under a Datacenter, specify path="/yourDatacenterName/vm/yourFolderName"

CLI Example:
salt-cloud -f create_folder my-vmware-config path="/Local/a/b/c"
salt-cloud -f create_folder my-vmware-config path="/MyDatacenter/vm/MyVMFolder"
salt-cloud -f create_folder my-vmware-config path="/MyDatacenter/host/MyHostFolder"
salt-cloud -f create_folder my-vmware-config path="/MyDatacenter/network/MyNetworkFolder"
salt-cloud -f create_folder my-vmware-config path="/MyDatacenter/storage/MyStorageFolder"

salt.cloud.clouds.vmware.create_snapshot(name, kwargs=None, call=None)
Create a snapshot of the specified virtual machine in this VMware environment

Note: If the VM is powered on, the internal state of the VM (memory dump) is included in the snapshot by default which will also set the power state of the snapshot to `powered on`. You can set memdump=False to override this. This field is ignored if the virtual machine is powered off or if the VM does not support snapshots with memory dumps. Default is memdump=True

Note: If the VM is powered on when the snapshot is taken, VMware Tools can be used to quiesce the file system in the virtual machine by setting quiesce=True. This field is ignored if the virtual machine is powered off; if VMware Tools are not available or if memdump=True. Default is quiesce=False

CLI Example:
salt-cloud -a create_snapshot vmname snapshot_name="mySnapshot" snapshot_name="mySnapshot" [description="MySnapshot"] [memdump=False] [quiesce=True]

salt.cloud.clouds.vmware.destroy(name, call=None)
To destroy a VM from the VMware environment

CLI Example:
salt-cloud -d vmname
salt-cloud --destroy vmname
salt-cloud -a destroy vmname

32.5. Full list of Salt Cloud modules 577
salt.cloud.clouds.vmware.disconnect_host(kwags=None, call=None)
   Disconnect the specified host system in this VMware environment
   CLI Example:
   
   ```
   salt-cloud -f disconnect_host my-vmware-config host="myHostSystemName"
   ```

salt.cloud.clouds.vmware.enter_maintenance_mode(kwags=None, call=None)
   To put the specified host system in maintenance mode in this VMware environment
   CLI Example:
   
   ```
   salt-cloud -f enter_maintenance_mode my-vmware-config host="myHostSystemName"
   ```

salt.cloud.clouds.vmware.exit_maintenance_mode(kwags=None, call=None)
   To take the specified host system out of maintenance mode in this VMware environment
   CLI Example:
   
   ```
   salt-cloud -f exit_maintenance_mode my-vmware-config host="myHostSystemName"
   ```

salt.cloud.clouds.vmware.get_dependencies()
   Warn if dependencies aren’t met.

salt.cloud.clouds.vmware.get_vcenter_version(kwags=None, call=None)
   Show the vCenter Server version with build number.
   CLI Example:
   
   ```
   salt-cloud -f get_vcenter_version my-vmware-config
   ```

salt.cloud.clouds.vmware.list_clusters(kwags=None, call=None)
   List all the clusters for this VMware environment
   CLI Example:
   
   ```
   salt-cloud -f list_clusters my-vmware-config
   ```

salt.cloud.clouds.vmware.list_clusters_by_datacenter(kwags=None, call=None)
   List clusters for each datacenter; or clusters for a specified datacenter in this VMware environment
   
   To list clusters for each datacenter:
   
   CLI Example:
   
   ```
   salt-cloud -f list_clusters_by_datacenter my-vmware-config
   ```

   To list clusters for a specified datacenter:
   
   CLI Example:
   
   ```
   salt-cloud -f list_clusters_by_datacenter my-vmware-config datacenter="datacenterName"
   ```

salt.cloud.clouds.vmware.list_datacenters(kwags=None, call=None)
   List all the data centers for this VMware environment
   CLI Example:
   
   ```
   salt-cloud -f list_datacenters my-vmware-config
   ```
salt.cloud.clouds.vmware.list_datastore_clusters(**kwargs=None, call=None)
List all the datastore clusters for this VMware environment

CLI Example:
```
salt-cloud -f list_datastore_clusters my-vmware-config
```

salt.cloud.clouds.vmware.list_datastores(**kwargs=None, call=None)
List all the datastores for this VMware environment

CLI Example:
```
salt-cloud -f list_datastores my-vmware-config
```

salt.cloud.clouds.vmware.list_dvs(**kwargs=None, call=None)
List all the distributed virtual switches for this VMware environment

CLI Example:
```
salt-cloud -f list_dvs my-vmware-config
```

salt.cloud.clouds.vmware.list_folders(**kwargs=None, call=None)
List all the folders for this VMware environment

CLI Example:
```
salt-cloud -f list_folders my-vmware-config
```

salt.cloud.clouds.vmware.list_hbas(**kwargs=None, call=None)
List all HBAs for each host system; or all HBAs for a specified host system; or HBAs of specified type for each host system; or HBAs of specified type for a specified host system in this VMware environment

Note: You can specify type as either parallel, iscsi, block or fibre.

To list all HBAs for each host system:

CLI Example:
```
salt-cloud -f list_hbas my-vmware-config
```

To list all HBAs for a specified host system:

CLI Example:
```
salt-cloud -f list_hbas my-vmware-config host="hostSystemName"
```

To list HBAs of specified type for each host system:

CLI Example:
```
salt-cloud -f list_hbas my-vmware-config type="HBAtype"
```

To list HBAs of specified type for a specified host system:

CLI Example:
```
salt-cloud -f list_hbas my-vmware-config host="hostSystemName" type="HBAtype"
```
salt.cloud.clouds.vmware.list_hosts(kwargs=None, call=None)
List all the hosts for this VMware environment

CLI Example:
```
salt-cloud -f list_hosts my-vmware-config
```

salt.cloud.clouds.vmware.list_hosts_by_cluster(kwargs=None, call=None)
List hosts for each cluster; or hosts for a specified cluster in this VMware environment

To list hosts for each cluster:
CLI Example:
```
salt-cloud -f list_hosts_by_cluster my-vmware-config
```

To list hosts for a specified cluster:
CLI Example:
```
salt-cloud -f list_hosts_by_cluster my-vmware-config cluster="clusterName"
```

salt.cloud.clouds.vmware.list_hosts_by_datacenter(kwargs=None, call=None)
List hosts for each datacenter; or hosts for a specified datacenter in this VMware environment

To list hosts for each datacenter:
CLI Example:
```
salt-cloud -f list_hosts_by_datacenter my-vmware-config
```

To list hosts for a specified datacenter:
CLI Example:
```
salt-cloud -f list_hosts_by_datacenter my-vmware-config datacenter="datacenterName"
```

salt.cloud.clouds.vmware.list_networks(kwargs=None, call=None)
List all the standard networks for this VMware environment

CLI Example:
```
salt-cloud -f list_networks my-vmware-config
```

salt.cloud.clouds.vmware.list_nodes(kwargs=None, call=None)
Return a list of all VMs and templates that are on the specified provider, with basic fields

CLI Example:
```
salt-cloud -f list_nodes my-vmware-config
```

To return a list of all VMs and templates present on ALL configured providers, with basic fields:
CLI Example:
```
salt-cloud -Q
```

salt.cloud.clouds.vmware.list_nodes_full(kwargs=None, call=None)
Return a list of all VMs and templates that are on the specified provider, with full details

CLI Example:
<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>salt-cloud -f list_nodes_full my-vmware-config</code></td>
<td>To return a list of all VMs and templates present on ALL configured providers, with full details:</td>
</tr>
<tr>
<td><code>salt-cloud -F</code></td>
<td>CLI Example:</td>
</tr>
<tr>
<td><code>salt.cloud.clouds.vmware.list_nodes_min(kwargs=None, call=None)</code></td>
<td>Return a list of all VMs and templates that are on the specified provider, with no details</td>
</tr>
<tr>
<td><code>salt-cloud -f list_nodes_min my-vmware-config</code></td>
<td>CLI Example:</td>
</tr>
<tr>
<td><code>salt.cloud.clouds.vmware.list_nodes_select(call=None)</code></td>
<td>Return a list of all VMs and templates that are on the specified provider, with fields specified under query.selection in /etc/salt/cloud</td>
</tr>
<tr>
<td><code>salt-cloud -f list_nodes_select my-vmware-config</code></td>
<td>CLI Example:</td>
</tr>
<tr>
<td><code>salt.cloud.clouds.vmware.list_resourcepools(kwargs=None, call=None)</code></td>
<td>List all the resource pools for this VMware environment</td>
</tr>
<tr>
<td><code>salt-cloud -f list_resourcepools my-vmware-config</code></td>
<td>CLI Example:</td>
</tr>
<tr>
<td><code>salt.cloud.clouds.vmware.list_snapshots(kwargs=None, call=None)</code></td>
<td>List snapshots either for all VMs and templates or for a specific VM/template in this VMware environment</td>
</tr>
<tr>
<td><code>salt-cloud -f list_snapshots my-vmware-config</code></td>
<td>To list snapshots for all VMs and templates:</td>
</tr>
<tr>
<td><code>salt-cloud -f list_snapshots my-vmware-config name=&quot;vmname&quot;</code></td>
<td>CLI Example:</td>
</tr>
<tr>
<td><code>salt.cloud.clouds.vmware.list_templates(kwargs=None, call=None)</code></td>
<td>List all the templates present in this VMware environment</td>
</tr>
<tr>
<td><code>salt-cloud -f list_templates my-vmware-config</code></td>
<td>CLI Example:</td>
</tr>
</tbody>
</table>
salt.cloud.clouds.vmware.list_vapps(**kwargs=None, call=None)**

List all the vApps for this VMware environment

CLI Example:

```
salt-cloud -f list_vapps my-vmware-config
```

salt.cloud.clouds.vmware.reboot_host(**kwargs=None, call=None)**

Reboot the specified host system in this VMware environment

**Note:** If the host system is not in maintenance mode, it will not be rebooted. If you want to reboot the host system regardless of whether it is in maintenance mode, set `force=True`. Default is `force=False`

CLI Example:

```
salt-cloud -f reboot_host my-vmware-config host="myHostSystemName" [force=True]
```

salt.cloud.clouds.vmware.remove_all_snapshots(name, **kwargs=None, call=None)**

Remove all the snapshots present for the specified virtual machine.

**Note:** All the snapshots higher up in the hierarchy of the current snapshot tree are consolidated and their virtual disks are merged. To override this behavior and only remove all snapshots, set `merge_snapshots=False`. Default is `merge_snapshots=True`

CLI Example:

```
salt-cloud -a remove_all_snapshots vmname [merge_snapshots=False]
```

salt.cloud.clouds.vmware.remove_host(**kwargs=None, call=None)**

Remove the specified host system from this VMware environment

CLI Example:

```
salt-cloud -f remove_host my-vmware-config host="hostSystemName"
```

salt.cloud.clouds.vmware.rescan_hba(**kwargs=None, call=None)**

To rescan a specified HBA or all the HBAs on the Host System

CLI Example:

```
salt-cloud -f rescan_hba my-vmware-config host="hostSystemName"
```

salt.cloud.clouds.vmware.reset(name, call=None)**

To reset a VM using its name

CLI Example:

```
salt-cloud -a reset vmname
```

salt.cloud.clouds.vmware.revert_to_snapshot(name, **kwargs=None, call=None)**

Revert virtual machine to it’s current snapshot. If no snapshot exists, the state of the virtual machine remains unchanged
Note: The virtual machine will be powered on if the power state of the snapshot when it was created was set to `Powered On`. Set `power_off=True` so that the virtual machine stays powered off regardless of the power state of the snapshot when it was created. Default is `power_off=False`.

If the power state of the snapshot when it was created was `Powered On` and if `power_off=True`, the VM will be put in suspended state after it has been reverted to the snapshot.

CLI Example:
```bash
salt-cloud -a revert_to_snapshot vmname [power_off=True]
```

```python
salt.cloud.clouds.vmware.show_instance(name, call=None)
List all available details of the specified VM
```

CLI Example:
```bash
salt-cloud -a show_instance vmname
```

```python
salt.cloud.clouds.vmware.start(name, call=None)
To start/power on a VM using its name
```

CLI Example:
```bash
salt-cloud -a start vmname
```

```python
salt.cloud.clouds.vmware.stop(name, call=None)
To stop/power off a VM using its name
```

CLI Example:
```bash
salt-cloud -a stop vmname
```

```python
salt.cloud.clouds.vmware.suspend(name, call=None)
To suspend a VM using its name
```

CLI Example:
```bash
salt-cloud -a suspend vmname
```

```python
salt.cloud.clouds.vmware.terminate(name, call=None)
To do an immediate power off of a VM using its name. A SIGKILL is issued to the vmx process of the VM
```

CLI Example:
```bash
salt-cloud -a terminate vmname
```

```python
salt.cloud.clouds.vmware.test_vcenter_connection(kwargs=None, call=None)
Test if the connection can be made to the vCenter server using the specified credentials inside /etc/salt/cloud.providers or /etc/salt/cloud.providers.d/vmware.conf
```

CLI Example:
```bash
salt-cloud -f test_vcenter_connection my-vmware-config
```

```python
salt.cloud.clouds.vmware.upgrade_tools(name, reboot=False, call=None)
To upgrade VMware Tools on a specified virtual machine.
```

32.5. Full list of Salt Cloud modules
Note: If the virtual machine is running Windows OS, use `reboot=True` to reboot the virtual machine after VMware tools upgrade. Default is `reboot=False`.

CLI Example:

```
salt-cloud -a upgrade_tools vmname
salt-cloud -a upgrade_tools vmname reboot=True
```

**salt.cloud.clouds.vmware.upgrade_tools_all** *(call=None)*  
To upgrade VMware Tools on all virtual machines present in the specified provider.

Note: If the virtual machine is running Windows OS, this function will attempt to suppress the automatic reboot caused by a VMware Tools upgrade.

CLI Example:

```
salt-cloud -f upgrade_tools_all my-vmware-config
```

### 32.5.24 salt.cloud.clouds.vsphere

**vSphere Cloud Module**

Note: Deprecated since version Carbon: The `vsphere` cloud driver has been deprecated in favor of the `vmware` cloud driver and will be removed in Salt Carbon. Please refer to [Getting started with VMware](#) to get started and convert your vsphere provider configurations to use the vmware driver.

The vSphere cloud module is used to control access to VMWare vSphere.

**depends**  
PySphere Python module >= 0.1.8

Note: Ensure python pysphere module is installed by running following one-liner check. The output should be 0.

```
python -c "import pysphere" ; echo $?  
# if this fails install using
pip install https://pysphere.googlecode.com/files/pysphere-0.1.8.zip
```

Use of this module only requires a URL, username and password. Set up the cloud configuration at:

```
/etc/salt/cloud.providers or /etc/salt/cloud.providers.d/vsphere.conf:
```

```
my-vsphere-config:
  driver: vsphere
  user: myuser
  password: verybadpass
  template_user: root
  template_password: mybadVMpassword
  url: 'https://10.1.1.1:443'
```

Note: Your URL may or may not look like any of the following, depending on how your VMWare installation is configured:
folder  Name of the folder that will contain the new VM. If not set, the VM will be added to the folder the original VM belongs to.

resourcepool  MOR of the resourcepool to be used for the new vm. If not set, it uses the same resourcepool than the original vm.

datastore  MOR of the datastore where the virtual machine should be located. If not specified, the current datastore is used.

host  MOR of the host where the virtual machine should be registered.

  Id not specified:
  • if resourcepool is not specified, current host is used.
  • if resourcepool is specified, and the target pool represents a stand-alone host, the host is used.
  • if resourcepool is specified, and the target pool represents a DRS-enabled cluster, a host selected by DRS is used.
  • if resourcepool is specified and the target pool represents a cluster without DRS enabled, an InvalidArgument exception will be thrown.

template  Specifies whether or not the new virtual machine should be marked as a template. Default is False.

template_user  Specifies the user to access the VM. Should be

template_password  The password with which to access the VM.

sudo  The user to access the VM with sudo privileges.

  New in version 2015.5.2.

sudo_password  The password corresponding to the sudo user to access the VM with sudo privileges.

  New in version 2015.5.2.

salt.cloud.clouds.vsphere.avail_images()  
Return a dict of all available VM images on the cloud provider.

salt.cloud.clouds.vsphere.avail_locations()  
Return a dict of all available VM locations on the cloud provider with relevant data

salt.cloud.clouds.vsphere.create(vm_)  
Create a single VM from a data dict

salt.cloud.clouds.vsphere.create_snapshot(kwags=None, call=None)  
Create a snapshot

  @name: Name of the virtual machine to snapshot @snapshot: Name of the snapshot @description: Description of the snapshot (optional) @memory: Dump of the internal state of the virtual machine (optional)

  New in version 2015.8.0.

  CLI Example:

salt-cloud -f create_snapshot [PROVIDER] name=myvm.example.com snapshot=mysnapshot
salt-cloud -f create_snapshot [PROVIDER] name=myvm.example.com snapshot=mysnapshot description='My Snapshot' memory=True
salt.cloud.clouds.vsphere.delete_snapshot(kwarg=None, call=None)
Delete snapshot
New in version 2015.8.0.
CLI Example:

    salt-cloud -f delete_snapshot [PROVIDER] name=myvm.example.com snapshot=mysnapshot

salt.cloud.clouds.vsphere.destroy(name, call=None)
Destroy a node.
CLI Example:

    salt-cloud --destroy mymachine

salt.cloud.clouds.vsphere.get_configured_provider()
Return the first configured instance.
salt.cloud.clouds.vsphere.get_conn()
Return a conn object for the passed VM data
salt.cloud.clouds.vsphere.get_dependencies()
Warn if dependencies aren’t met.
salt.cloud.clouds.vsphere.list_clusters(kwarg=None, call=None)
List the clusters for this VMware environment
salt.cloud.clouds.vsphere.list_datacenters(kwarg=None, call=None)
List the data centers for this VMware environment
salt.cloud.clouds.vsphere.list_datastores(kwarg=None, call=None)
List the datastores for this VMware environment
salt.cloud.clouds.vsphere.list_folders(kwarg=None, call=None)
List the folders for this VMWare environment
salt.cloud.clouds.vsphere.list_hosts(kwarg=None, call=None)
List the hosts for this VMware environment
salt.cloud.clouds.vsphere.list_nodes(kwarg=None, call=None)
Return a list of the VMs that are on the provider, with basic fields
salt.cloud.clouds.vsphere.list_nodes_full(kwarg=None, call=None)
Return a list of the VMs that are on the provider with full details
salt.cloud.clouds.vsphere.list_nodes_min(kwarg=None, call=None)
Return a list of the nodes in the provider, with no details
salt.cloud.clouds.vsphere.list_nodes_select()
Return a list of the VMs that are on the provider, with select fields
salt.cloud.clouds.vsphere.list_resourcepools(kwarg=None, call=None)
List the hosts for this VMware environment
salt.cloud.clouds.vsphere.reset(name, call=None)
To reset a VM using its name
CLI Example:

    salt-cloud -a reset vmname
salt.cloud.clouds.vsphere.script(vm_)
   Return the script deployment object

salt.cloud.clouds.vsphere.show_instance(name, call=None)
   Show the details from vSphere concerning a guest

salt.cloud.clouds.vsphere.snapshot_list(**kwargs, call=None)
   List virtual machines with snapshots
   New in version 2015.8.0.
   CLI Example:
   
   ```
   salt-cloud -f snapshot_list
   ```

salt.cloud.clouds.vsphere.start(name, call=None)
   To start/power on a VM using its name
   CLI Example:
   
   ```
   salt-cloud -a start vmname
   ```

salt.cloud.clouds.vsphere.status(name, call=None)
   To check the status of a VM using its name
   CLI Example:
   
   ```
   salt-cloud -a status vmname
   ```

salt.cloud.clouds.vsphere.stop(name, call=None)
   To stop/power off a VM using its name
   CLI Example:
   
   ```
   salt-cloud -a stop vmname
   ```

salt.cloud.clouds.vsphere.suspend(name, call=None)
   To suspend a VM using its name
   CLI Example:
   
   ```
   salt-cloud -a suspend vmname
   ```

salt.cloud.clouds.vsphere.wait_for_ip(vm_)

### 32.6 Configuration file examples

- Example master configuration file
- Example minion configuration file

#### 32.6.1 Example master configuration file
##### Primary configuration settings #####

This configuration file is used to manage the behavior of the Salt Master. Values that are commented out but have an empty line after the comment are defaults that do not need to be set in the config. If there is no blank line after the comment then the value is presented as an example and is not the default.

Per default, the master will automatically include all config files from master.d/*.conf (master.d is a directory in the same directory as the main master config file).

default_include: master.d/*.conf

The address of the interface to bind to:
@interface: 0.0.0.0

Whether the master should listen for IPv6 connections. If this is set to True, the interface option must be adjusted, too. (For example: "interface: '::'"

ipv6: False

The tcp port used by the publisher:
publish_port: 4505

The user under which the salt master will run. Salt will update all permissions to allow the specified user to run the master. The exception is the job cache, which must be deleted if this user is changed. If the modified files cause conflicts, set verify_env to False.

user: root

The port used by the communication interface. The ret (return) port is the interface used for the file server, authentication, job returns, etc.

ret_port: 4506

Specify the location of the daemon process ID file:
pidfile: /var/run/salt-master.pid

The root directory prepended to these options: pki_dir, cachedir, sock_dir, log_file, autosign_file, autoreject_file, extension_modules, key_logfile, pidfile:

root_dir: /

The path to the master's configuration file.
conf_file: /etc/salt/master

Directory used to store public key data:
pki_dir: /etc/salt/pki/master

Directory to store job and cache data:
# This directory may contain sensitive data and should be protected accordingly.
cachedir: /var/cache/salt/master

Directory for custom modules. This directory can contain subdirectories for each of Salt's module types such as "runners", "output", "wheel", "modules", "states", "returners", etc.

extension_modules: <no default>

Directory for custom modules. This directory can contain subdirectories for
# each of Salt's module types such as "runners", "output", "wheel", "modules", # "states", "returners", etc. # Like 'extension_modules' but can take an array of paths #module_dirs: <no default> # - /var/cache/salt/minion/extmods #
# Verify and set permissions on configuration directories at startup: #verify_env: True
#
# Set the number of hours to keep old job information in the job cache: #keep_jobs: 24
#
# The number of seconds to wait when the client is requesting information # about running jobs. #gather_job_timeout: 10
#
# Set the default timeout for the salt command and api. The default is 5 # seconds. #timeout: 5
#
# The loop_interval option controls the seconds for the master's maintenance # process check cycle. This process updates file server backends, cleans the # job cache and executes the scheduler. #loop_interval: 60
#
# Set the default outputter used by the salt command. The default is "nested". #output: nested
#
# Set the default output file used by the salt command. Default is to output # to the CLI and not to a file. Functions the same way as the "--out-file" # CLI option, only sets this to a single file for all salt commands. #output_file: None
#
# Return minions that timeout when running commands like test.ping #show_timeout: True
#
# By default, output is colored. To disable colored output, set the color value # to False. #color: True
#
# Do not strip off the colored output from nested results and state outputs # (true by default). #strip_colors: False
#
# To display a summary of the number of minions targeted, the number of # minions returned, and the number of minions that did not return, set the # cli_summary value to True. (False by default.) # #cli_summary: False
#
# Set the directory used to hold unix sockets: #sock_dir: /var/run/salt/master
#
# The master can take a while to start up when lspci and/or dmidecode is used # to populate the grains for the master. Enable if you want to see GPU hardware # data for your master. #enable_gpu_grains: False
The master maintains a job cache. While this is a great addition, it can be
a burden on the master for larger deployments (over 5000 minions).
Disabling the job cache will make previously executed jobs unavailable to
the jobs system and is not generally recommended.

```
#job_cache: True
```

Cache minion grains and pillar data in the cachedir.

```
#minion_data_cache: True
```

Store all returns in the given returner.

```
#event_return: mysql
```

On busy systems, enabling event_returns can cause a considerable load on
the storage system for returners. Events can be queued on the master and
stored in a batched fashion using a single transaction for multiple events.

```
#event_return_queue: 0
```

Only return events matching tags in a whitelist,

```
#event_return_whitelist:
  - salt/master/a_tag
  - salt/master/another_tag
```

Store all event returns except the tags in a blacklist.

```
#event_return_blacklist:
  - salt/master/not_this_tag
  - salt/master/or_this_one
```

Passing very large events can cause the minion to consume large amounts of
memory. This value tunes the maximum size of a message allowed onto the
master event bus. The value is expressed in bytes.

```
#max_event_size: 1048576
```

By default, the master AES key rotates every 24 hours. The next command
following a key rotation will trigger a key refresh from the minion which may
result in minions which do not respond to the first command after a key refresh.

```
# ping_on_rotate to True. This should mitigate the issue where a minion does not
# appear to initially respond after a key is rotated.
```

Note that ping_on_rotate may cause high load on the master immediately after
the key rotation event as minions reconnect. Consider this carefully if this
salt master is managing a large number of minions.

```
# If disabled, it is recommended to handle this event by listening for the
# 'aes_key_rotate' event with the 'key' tag and acting appropriately.
```

By default, the master deletes its cache of minion data when the key for that
minion is removed. To preserve the cache after key deletion, set

```
# 'preserve_minion_cache' to True.
```

WARNING: This may have security implications if compromised minions auth with
# a previous deleted minion ID.
#preserve_minion_cache: False

# If max_minions is used in large installations, the master might experience
# high-load situations because of having to check the number of connected
# minions for every authentication. This cache provides the minion-ids of
# all connected minions to all Worker-processes and greatly improves the
# performance of max_minions.
#con_cache: False

# The master can include configuration from other files. To enable this,
# pass a list of paths to this option. The paths can be either relative or
# absolute; if relative, they are considered to be relative to the directory
# the main master configuration file lives in (this file). Paths can make use
# of shell-style globbing. If no files are matched by a path passed to this
# option, then the master will log a warning message.
#
# Include a config file from some other path:
#include: /etc/salt/extra_config
#
# Include config from several files and directories:
#include:
# - /etc/salt/extra_config

####### Large-scale tuning settings #######
############################################
# Max open files
#
# Each minion connecting to the master uses AT LEAST one file descriptor, the
# master subscription connection. If enough minions connect you might start
# seeing on the console (and then salt-master crashes):
# Too many open files (tcp_listener.cpp:335)
# Aborted (core dumped)
#
# By default this value will be the one of `ulimit -Hn`, ie, the hard limit for
# max open files.
#
# If you wish to set a different value than the default one, uncomment and
# configure this setting. Remember that this value CANNOT be higher than the
# hard limit. Raising the hard limit depends on your OS and/or distribution,
# a good way to find the limit is to search the internet. For example:
# raise max open files hard limit debian
#
#max_open_files: 100000

# The number of worker threads to start. These threads are used to manage
# return calls made from minions to the master. If the master seems to be
# running slowly, increase the number of threads. This setting can not be
# set lower than 3.
#worker_threads: 5

# Set the ZeroMQ high water marks
# http://api.zeromq.org/3-2:zmq-setsockopt
#
# The publisher interface ZeroMQPubServerChannel
#pub_hwm: 1000
These two ZMQ HWM settings, `salt_event_pub_hwm` and `event_publisher_pub_hwm`, are significant for masters with thousands of minions. When these are insufficiently high, it will manifest in random responses missing in the CLI and even missing from the job cache. Masters that have fast CPUs and many cores with appropriate worker_threads will not need these set as high.

On deployment with 8,000 minions, 2.4GHz CPUs, 24 cores, 32GiB memory has these settings:

```yaml
# salt_event_pub_hwm: 128000
# event_publisher_pub_hwm: 64000

# ZMQ high-water-mark for SaltEvent pub socket
#salt_event_pub_hwm: 20000

# ZMQ high-water-mark for EventPublisher pub socket
#event_publisher_pub_hwm: 10000
```

### Security settings

Enable "open mode", this mode still maintains encryption, but turns off authentication, this is only intended for highly secure environments or for the situation where your keys end up in a bad state. If you run in open mode you do so at your own risk!

```yaml
#open_mode: False
```

Enable auto_accept, this setting will automatically accept all incoming public keys from the minions. Note that this is insecure.

```yaml
#auto_accept: False
```

Time in minutes that a public key with a matching name found in `pki_dir/minion_autosign/keyid` is automatically accepted. Expired autosign keys are removed when the master checks the minion_autosign directory.

```yaml
# autosign_timeout: 120
```

If the `autosign_file` is specified, incoming keys specified in the `autosign_file` will be automatically accepted. This is insecure. Regular expressions as well as globbing lines are supported.

```yaml
#autosign_file: /etc/salt/autosign.conf
```

Works like `autosign_file`, but instead allows you to specify minion IDs for which keys will automatically be rejected. Will override both membership in the `autosign_file` and the auto_accept setting.

```yaml
#autoreject_file: /etc/salt/autoreject.conf
```

Enable permissive access to the salt keys. This allows you to run the master or minion as root, but have a non-root group be given access to your `pki_dir`. To make the access explicit, root must belong to the group you've given access to. This is potentially quite insecure. If an `autosign_file` is specified, enabling permissive_pki_access will allow group access to that specific file.

```yaml
#permissive_pki_access: False
```

Allow users on the master access to execute specific commands on minions. This setting should be treated with care since it opens up execution.
Salt Documentation, Release 2015.8.12

# capabilities to non root users. By default this capability is completely # disabled.
#client_acl:
#  larry:
#    - test.ping
#    - network.*
#
# Blacklist any of the following users or modules
#
# This example would blacklist all non sudo users, including root from # running any commands. It would also blacklist any use of the "cmd" # module. This is completely disabled by default.
#
# Check the list of configured users in client ACL against users on the # system and throw errors if they do not exist.
#client_acl_verify: True
#
#client_acl_blacklist:
#  users:
#    - root
#    - '^(?!sudo_).*$' # all non sudo users
#  modules:
#    - cmd

# Enforce client_acl & client_acl_blacklist when users have sudo # access to the salt command.
#sudo_acl: False

# The external auth system uses the Salt auth modules to authenticate and # validate users to access areas of the Salt system.
#external_auth:
#  pam:
#    fred:
#    - test.*
#
# Time (in seconds) for a newly generated token to live. Default: 12 hours #token_expire: 43200

# Allow minions to push files to the master. This is disabled by default, for # security purposes.
#file_recv: False

# Set a hard-limit on the size of the files that can be pushed to the master. # It will be interpreted as megabytes. Default: 100 #file_recv_max_size: 100

# Signature verification on messages published from the master. # This causes the master to cryptographically sign all messages published to its event # bus, and minions then verify that signature before acting on the message. # # This is False by default.
#
# Note that to facilitate interoperability with masters and minions that are different # versions, if sign_pub_messages is True but a message is received by a minion with # no signature, it will still be accepted, and a warning message will be logged. # Conversely, if sign_pub_messages is False, but a minion receives a signed
# message it will be accepted, the signature will not be checked, and a warning message
# will be logged. This behavior went away in Salt 2014.1.0 and these two situations
# will cause minion to throw an exception and drop the message.
# sign_pub_messages: False

##### Salt-SSH Configuration #####
###################################
# Pass in an alternative location for the salt-ssh roster file
#roster_file: /etc/salt/roster

# Pass in minion option overrides that will be inserted into the SHIM for
# salt-ssh calls. The local minion config is not used for salt-ssh. Can be
# overridden on a per-minion basis in the roster ('minion_opts')
#ssh_minion_opts:
#  gpg_keydir: /root/gpg

##### Master Module Management #####
#####################################
# Manage how master side modules are loaded.

# Add any additional locations to look for master runners:
#runner_dirs: []

# Enable Cython for master side modules:
#cython_enable: False

##### State System settings #####
###################################
# The state system uses a "top" file to tell the minions what environment to
# use and what modules to use. The state_top file is defined relative to the
# root of the base environment as defined in "File Server settings" below.
#state_top: top.sls

# The master_tops option replaces the external_nodes option by creating
# a plugable system for the generation of external top data. The external_nodes
# option is deprecated by the master_tops option.
#
# To gain the capabilities of the classic external_nodes system, use the
# following configuration:
#master_tops:
#  ext_nodes: <Shell command which returns yaml>
#
#master_tops: {}

# The external_nodes option allows Salt to gather data that would normally be
# placed in a top file. The external_nodes option is the executable that will
# return the ENC data. Remember that Salt will look for external nodes AND top
# files and combine the results if both are enabled.
#external_nodes: None

# The renderer to use on the minions to render the state data
#renderer: yaml_jinja

# The Jinja renderer can strip extra carriage returns and whitespace
# See http://jinja.pocoo.org/docs/api/#high-level-api
# If this is set to True the first newline after a Jinja block is removed
# (block, not variable tag!). Defaults to False, corresponds to the Jinja
# environment init variable "trim_blocks".
#jinja_trim_blocks: False
#
# If this is set to True leading spaces and tabs are stripped from the start
# of a line to a block. Defaults to False, corresponds to the Jinja
# environment init variable "lstrip_blocks".
#jinja_lstrip_blocks: False
#
# The failhard option tells the minions to stop immediately after the first
# failure detected in the state execution, defaults to False
#failhard: False
#
# The state_verbose and state_output settings can be used to change the way
# state system data is printed to the display. By default all data is printed.
# The state_verbose setting can be set to True or False, when set to False
# all data that has a result of True and no changes will be suppressed.
#state_verbose: True
#
# The state_output setting changes if the output is the full multi line
# output for each changed state if set to 'full', but if set to 'terse'
# the output will be shortened to a single line. If set to 'mixed', the output
# will be terse unless a state failed, in which case that output will be full.
# If set to 'changes', the output will be full unless the state didn't change.
#state_output: full
#
# Automatically aggregate all states that have support for mod_aggregate by
# setting to 'True'. Or pass a list of state module names to automatically
# aggregate just those types.
#
# state_aggregate:
#  - pkg
#
#state_aggregate: False
#
# Send progress events as each function in a state run completes execution
# by setting to 'True'. Progress events are in the format
# 'salt/job/<JID>/prog/<MID>/<RUN NUM>'.
#state_events: False

##### File Server settings #####
##########################################
# Salt runs a lightweight file server written in zeromq to deliver files to
# minions. This file server is built into the master daemon and does not
# require a dedicated port.
#
# The file server works on environments passed to the master, each environment
# can have multiple root directories, the subdirectories in the multiple file
# roots cannot match, otherwise the downloaded files will not be able to be
# reliably ensured. A base environment is required to house the top file.
#
# Example:
# file_roots:
#  - /srv/salt/
#  - /srv/salt/dev/services
#  - /srv/salt/dev/states

32.6. Configuration file examples 595
# prod:
# - /srv/salt/prod/services
# - /srv/salt/prod/states
#
#file_roots:
# base:
# - /srv/salt
#
# When using multiple environments, each with their own top file, the
default behaviour is an unordered merge. To prevent top files from
# being merged together and instead to only use the top file from the
# requested environment, set this value to `same`.
#top_file_merging_strategy: merge
#
# To specify the order in which environments are merged, set the ordering
# in the env_order option. Given a conflict, the last matching value will
# win.
#env_order: ['base', 'dev', 'prod']
#
# If top_file_merging_strategy is set to `same` and an environment does not
# contain a top file, the top file in the environment specified by default_top
# will be used instead.
#default_top: base

# The hash_type is the hash to use when discovering the hash of a file on
# the master server. The default is md5 but sha1, sha224, sha256, sha384
# and sha512 are also supported.
# WARNING: While md5 is supported, do not use it due to the high chance
# of possible collisions and thus security breach.
#hash_type: md5

# The buffer size in the file server can be adjusted here:
#file_buffer_size: 1048576
#
# A regular expression (or a list of expressions) that will be matched
# against the file path before syncing the modules and states to the minions.
# This includes files affected by the file.recurse state.
# For example, if you manage your custom modules and states in subversion
# and don't want all the '.svn' folders and content synced to your minions,
# you could set this to '/\.svn\$(\//)'. By default nothing is ignored.
#file_ignore_regex:
# - '/\.svn\$(\//)'
# - '/\..git\$(\//)'

# A file glob (or list of file globs) that will be matched against the file
# path before syncing the modules and states to the minions. This is similar
# to file_ignore_regex above, but works on globs instead of regex. By default
# nothing is ignored.
#file_ignore_glob:
# - '*.pyc'
# - '*.somefolder/*.bak'
# - '*.swp'
# File Server Backend
#
# Salt supports a modular fileserver backend system, this system allows
# the salt master to link directly to third party systems to gather and
# manage the files available to minions. Multiple backends can be
# configured and will be searched for the requested file in the order in which
# they are defined here. The default setting only enables the standard backend
# "roots" which uses the "file_roots" option.
#fileserver_backend:
# - roots
#
# To use multiple backends list them in the order they are searched:
#fileserver_backend:
# - git
# - roots
#
# Uncomment the line below if you do not want the file_server to follow
# symlinks when walking the filesystem tree. This is set to True
# by default. Currently this only applies to the default roots
# fileserver_backend.
#fileserver_followsymlinks: False
#
# Uncomment the line below if you do not want symlinks to be
# treated as the files they are pointing to. By default this is set to
# False. By uncommenting the line below, any detected symlink while listing
# files on the Master will not be returned to the Minion.
#fileserver_ignoresymlinks: True
#
# By default, the Salt fileserver recurses fully into all defined environments
# to attempt to find files. To limit this behavior so that the fileserver only
# traverses directories with SLS files and special Salt directories like _modules,
# enable the option below. This might be useful for installations where a file root
# has a very large number of files and performance is impacted. Default is False.
# fileserver_limit_traversal: False
#
# The fileserver can fire events off every time the fileserver is updated,
# these are disabled by default, but can be easily turned on by setting this
# flag to True
#fileserver_events: False
#
# Git File Server Backend Configuration
#
# Optional parameter used to specify the provider to be used for gitfs. Must
# be one of the following: pygit2, gitpython, or dulwich. If unset, then each
# will be tried in that same order, and the first one with a compatible
# version installed will be the provider that is used.
#gitfs_provider: pygit2
#
# Along with gitfs_password, is used to authenticate to HTTPS remotes.
# gitfs_user: ''
#
# Along with gitfs_user, is used to authenticate to HTTPS remotes.
# This parameter is not required if the repository does not use authentication.
#gitfs_password: ''
#
# By default, Salt will not authenticate to an HTTP (non-HTTPS) remote.
# This parameter enables authentication over HTTP. Enable this at your own risk.
#gitfs_insecure_auth: False
Along with `gitfs_privkey` (and optionally `gitfs_passphrase`), is used to authenticate to SSH remotes. This parameter (or its per-remote counterpart) is required for SSH remotes.

```
#gitfs_pubkey: ''
```

Along with `gitfs_pubkey` (and optionally `gitfs_passphrase`), is used to authenticate to SSH remotes. This parameter (or its per-remote counterpart) is required for SSH remotes.

```
#gitfs_privkey: ''
```

This parameter is optional, required only when the SSH key being used to authenticate is protected by a passphrase.

```
#gitfs_passphrase: ''
```

When using the git fileserver backend at least one git remote needs to be defined. The user running the salt master will need read access to the repo.

```
# The repos will be searched in order to find the file requested by a client and the first repo to have the file will return it.
# When using the git backend branches and tags are translated into salt environments.
# Note: file:// repos will be treated as a remote, so refs you want used must exist in that repo as *local* refs.
#gitfs_remotes:
#  - git://github.com/saltstack/salt-states.git
#  - file:///var/git/saltmaster
#
# The gitfs_ssl_verify option specifies whether to ignore ssl certificate errors when contacting the gitfs backend. You might want to set this to false if you're using a git backend that uses a self-signed certificate but keep in mind that setting this flag to anything other than the default of True is a security concern, you may want to try using the ssh transport.
#gitfs_ssl_verify: True
#
# The gitfs_root option gives the ability to serve files from a subdirectory within the repository. The path is defined relative to the root of the repository and defaults to the repository root.
#gitfs_root: somefolder/otherfolder
#
```

### Pillar settings

Pillar settings allow for the building of global data that can be made selectively available to different minions based on minion grain filtering. The Salt Pillar is laid out in the same fashion as the file server, with environments, a top file and sls files. However, pillar data does not need to be in the highstate format, and is generally just key/value pairs.

```
#pillar_roots:
#  base:
#    - /srv/pillar
#
#ext_pillar:
#  - hiera: /etc/hiera.yaml
#  - cmd_yaml: cat /etc/salt/yaml
#
```

The `ext_pillar_first` option allows for external pillar sources to populate before file system pillar. This allows for targeting file system pillar from
# ext_pillar.
#ext_pillar_first: False

# The pillar_gitfs_ssl_verify option specifies whether to ignore ssl certificate
# errors when contacting the pillar gitfs backend. You might want to set this to
# false if you're using a git backend that uses a self-signed certificate but
# keep in mind that setting this flag to anything other than the default of True
# is a security concern, you may want to try using the ssh transport.
pillar_gitfs_ssl_verify: True

# The pillar_opts option adds the master configuration file data to a dict in
# the pillar called "master". This is used to set simple configurations in the
# master config file that can then be used on minions.
pillar_opts: False

# The pillar_safe_render_error option prevents the master from passing pillar
# render errors to the minion. This is set on by default because the error could
# contain templating data which would give that minion information it shouldn't
# have, like a password! When set true the error message will only show:
#  Rendering SLS 'my.sls' failed. Please see master log for details.
pillar_safe_render_error: True

# The pillar_source_merging_strategy option allows you to configure merging strategy
# between different sources. It accepts four values: recurse, aggregate, overwrite,
# or smart. Recurse will merge recursively mapping of data. Aggregate instructs
# aggregation of elements between sources that use the #!yamlex renderer. Overwrite
# will overwrite elements according the order in which they are processed. This is
# behavior of the 2014.1 branch and earlier. Smart guesses the best strategy based
# on the "renderer" setting and is the default value.
pillar_source_merging_strategy: smart

# Recursively merge lists by aggregating them instead of replacing them.
pillar_merge_lists: False

# Git External Pillar (git_pillar) Configuration Options
#
# Specify the provider to be used for git_pillar. Must be either pygit2 or
# gitpython. If unset, then both will be tried in that same order, and the
# first one with a compatible version installed will be the provider that
# is used.
git_pillar_provider: pygit2

# If the desired branch matches this value, and the environment is omitted
# from the git_pillar configuration, then the environment for that git_pillar
# remote will be base.
git_pillar_base: master

# If the branch is omitted from a git_pillar remote, then this branch will
# be used instead.
git_pillar_branch: master

# Environment to use for git_pillar remotes. This is normally derived from
# the branch/tag (or from a per-remote env parameter), but if set this will
# override the process of deriving the env from the branch/tag name.
git_pillar_env: ''

# Path relative to the root of the repository where the git_pillar top file
# and SLS files are located.

32.6. Configuration file examples 599
#git_pillar_root: ''

# Specifies whether or not to ignore SSL certificate errors when contacting
# the remote repository.
#git_pillar_ssl_verify: False

# When set to False, if there is an update/checkout lock for a git_pillar
# remote and the pid written to it is not running on the master, the lock
# file will be automatically cleared and a new lock will be obtained.
#git_pillar_global_lock: True

# Git External Pillar Authentication Options
#
# Along with git_pillar_password, is used to authenticate to HTTPS remotes.
#git_pillar_user: ''

# Along with git_pillar_user, is used to authenticate to HTTPS remotes.
# This parameter is not required if the repository does not use authentication.
#git_pillar_password: ''

# By default, Salt will not authenticate to an HTTP (non-HTTPS) remote.
# This parameter enables authentication over HTTP.
#git_pillar_insecure_auth: False

# Along with git_pillar_privkey (and optionally git_pillar_passphrase),
# is used to authenticate to SSH remotes.
#git_pillar_pubkey: ''

# Along with git_pillar_passkey (and optionally git_pillar_passphrase),
# is used to authenticate to SSH remotes.
#git_pillar_privkey: ''

# This parameter is optional, required only when the SSH key being used
# to authenticate is protected by a passphrase.
#git_pillar_passphrase: ''

# A master can cache pillars locally to bypass the expense of having to render them
# for each minion on every request. This feature should only be enabled in cases
# where pillar rendering time is known to be unsatisfactory and any attendant security
# concerns about storing pillars in a master cache have been addressed.
#
# When enabling this feature, be certain to read through the additional `pillar_cache_
# *` configuration options to fully understand the tunable parameters and their
# implications.
#
# Note: setting `pillar_cache: True` has no effect on targeting Minions with Pillars.
# See https://docs.saltstack.com/en/latest/topics/targeting/pillar.html
#pillar_cache: False

# If and only if a master has set `pillar_cache: True`, the cache TTL controls the
# amount
# of time, in seconds, before the cache is considered invalid by a master and a fresh
# pillar is recompiled and stored.
#pillar_cache_ttl: 3600

# If an only if a master has set `pillar_cache: True`, one of several storage
# providers
# can be utilized:
#
# disk: The default storage backend. This caches rendered pillars to the master cache. Rendered pillars are serialized and deserialized as `msgpack` structures for speed. Note that pillars are stored UNENCRYPTED. Ensure that the master cache has permissions set appropriately (sane defaults are provided).
#
# memory: [EXPERIMENTAL] An optional backend for pillar caches which uses a pure-Python in-memory data structure for maximal performance. There are several caveats, however. First, because each master worker contains its own in-memory cache, there is no guarantee of cache consistency between minion requests. This works best in situations where the pillar rarely if ever changes. Secondly, and perhaps more importantly, this means that unencrypted pillars will be accessible to any process which can examine the memory of the `salt-master`!
#
# This may represent a substantial security risk.
#
# pillow_cache_backend: disk

##### Syndic settings #####
##########################################
# The Salt syndic is used to pass commands through a master from a higher master. Using the syndic is simple. If this is a master that will have syndic servers(s) below it, then set the "order_masters" setting to True.
#
# If this is a master that will be running a syndic daemon for passthrough, then the "syndic_master" setting needs to be set to the location of the master server to receive commands from.
#
# Set the order_masters setting to True if this master will command lower masters' syndic interfaces.
#order_masters: False
#
# If this master will be running a salt syndic daemon, syndic_master tells this master where to receive commands from.
#syndic_master: masterofmaster
#
# This is the 'ret_port' of the MasterOfMaster:
#syndic_master_port: 4506
#
# PID file of the syndic daemon:
#syndic_pidfile: /var/run/salt-syndic.pid
#
# LOG file of the syndic daemon:
#syndic_log_file: syndic.log

##### Peer Publish settings #####
##########################################
# Salt minions can send commands to other minions, but only if the minion is allowed to. By default "Peer Publication" is disabled, and when enabled it is enabled for specific minions and specific commands. This allows secure compartmentalization of commands based on individual minions.
#
# The configuration uses regular expressions to match minions and then a list of regular expressions to match functions. The following will allow the minion authenticated as foo.example.com to execute functions from the test
# and pkg modules.
#peer:
# foo.example.com:
#   - test.*
#   - pkg.*
#
# This will allow all minions to execute all commands:
#peer:
#   .*:
#     - .*
#
# This is not recommended, since it would allow anyone who gets root on any
# single minion to instantly have root on all of the minions!
#
# Minions can also be allowed to execute runners from the salt master.
# Since executing a runner from the minion could be considered a security risk,
# it needs to be enabled. This setting functions just like the peer setting
# except that it opens up runners instead of module functions.
#
# All peer runner support is turned off by default and must be enabled before
# using. This will enable all peer runners for all minions:
#peer_run:
#   .*:
#     - .*
#
# To enable just the manage.up runner for the minion foo.example.com:
#peer_run:
#   foo.example.com:
#     - manage.up
#
##### Mine settings #####
#####################################
# Restrict mine.get access from minions. By default any minion has a full access
# to get all mine data from master cache. In acl definition below, only pcre matches
# are allowed.
#mine_get:
#   .*:
#     - .*
#
# The example below enables minion foo.example.com to get 'network.interfaces' mine
# data only, minions web* to get all network.* and disk.* mine data and all other
# minions won't get any mine data.
#mine_get:
#   foo.example.com:
#     - network.interfaces
#   web.*:
#     - network.*
#     - disk.*

##### Logging settings #####
########################################
# The location of the master log file
# The master log can be sent to a regular file, local path name, or network
# location. Remote logging works best when configured to use rsyslogd(8) (e.g.:
# `file:///dev/log`), with rsyslogd(8) configured for network logging. The URI
# format is: <file|udp|tcp>://<host|socketpath>:<port-if-required>/<log-facility>
#log_file: /var/log/salt/master
#log_file: file:///dev/log
#log_file: udp://loghost:10514

#log_file: /var/log/salt/master
#key_logfile: /var/log/salt/key

# The level of messages to send to the console.
# One of 'garbage', 'trace', 'debug', 'info', 'warning', 'error', 'critical'.
# The following log levels are considered INSECURE and may log sensitive data:
# ['garbage', 'trace', 'debug']
#log_level: warning

# The level of messages to send to the log file.
# One of 'garbage', 'trace', 'debug', 'info', 'warning', 'error', 'critical'.
# If using 'log_granular_levels' this must be set to the highest desired level.
#log_level_logfile: warning

# The date and time format used in log messages. Allowed date/time formatting
# can be seen here: http://docs.python.org/library/time.html#time.strftime
#log_datefmt: '%H:%M:%S'
#log_datefmt_logfile: '%Y-%m-%d %H:%M:%S'

# The format of the console logging messages. Allowed formatting options can
# be seen here: http://docs.python.org/library/logging.html#logrecord-attributes
#
# Console log colors are specified by these additional formatters:
#
# %(colorlevel)s
# %(colormsg)s
#%(colorprocess)s
# Since it is desirable to include the surrounding brackets, '[' and ']', in
# the coloring of the messages, these color formatters also include padding as
# well. Color LogRecord attributes are only available for console logging.
#log_fmt_console: '%(colorlevel)s %(colormsg)s'
#log_fmt_console: '(%(levelname)-8s) %(message)s'
#log_fmt_logfile: '%(asctime)s,%(msecs)03.0f [%(name)-17s][%(levelname)-8s] %(message)s'
#
# This can be used to control logging levels more specifically. This
# example sets the main salt library at the 'warning' level, but sets
# 'salt.modules' to log at the 'debug' level:
#log_granular_levels:
# 'salt': 'warning'
# 'salt.modules': 'debug'
#log_granular_levels: {}

##### Node Groups ######
##########################################
# Node groups allow for logical groupings of minion nodes. A group consists of

---

32.6. Configuration file examples 603
# a group name and a compound target. Nodegroups can reference other nodegroups
# with 'N@' classifier. Ensure that you do not have circular references.

#nodegroups:
# group1: 'L@foo.domain.com,bar.domain.com,baz.domain.com or bl*.domain.com'
# group2: 'G@os:Debian and foo.domain.com'
# group3: 'G@os:Debian and N@group1'
# group4:
#  - 'G@foo:bar'
#  - 'or'
#  - 'G@foo:baz'

##### Range Cluster settings #####
##########################################
# The range server (and optional port) that serves your cluster information
# https://github.com/ytoolshed/range/wiki/%22yamlfile%22-module-file-spec
#
#range_server: range:80

##### Windows Software Repo settings #####
###########################################
# Location of the repo on the master:
#winrepo_dir_ng: '/srv/salt/win/repo-ng'
#
# List of git repositories to include with the local repo:
#winrepo_remotes_ng:
#  - 'https://github.com/saltstack/salt-winrepo-ng.git'

##### Windows Software Repo settings - Pre 2015.8 #####
########################################################
# Legacy repo settings for pre-2015.8 Windows minions.
#
# Location of the repo on the master:
#winrepo_dir: '/srv/salt/win/repo'
#
# Location of the master's repo cache file:
#winrepo_mastercachefile: '/srv/salt/win/repo/winrepo.p'
#
# List of git repositories to include with the local repo:
#winrepo_remotes:
#  - 'https://github.com/saltstack/salt-winrepo.git'

##### Returner settings ######
############################################
# Which returner(s) will be used for minion's result:
#return: mysql

##### Miscellaneous settings ######
############################################
# Default match type for filtering events tags: startswith, endswith, find, regex,
#  → fnmatch
#event_match_type: startswith
# Permanently include any available Python 3rd party modules into Salt Thin
# when they are generated for Salt-SSH or other purposes.
# The modules should be named by the names they are actually imported inside the Python.
# The value of the parameters can be either one module or a comma separated list of them.
#thin_extra_mods: foo,bar

32.6.2 Example minion configuration file

```
##### Primary configuration settings #####
# This configuration file is used to manage the behavior of the Salt Minion.
# With the exception of the location of the Salt Master Server, values that are
# commented out but have an empty line after the comment are defaults that need
# not be set in the config. If there is no blank line after the comment, the
# value is presented as an example and is not the default.

# Per default the minion will automatically include all config files
# from minion.d/*.conf (minion.d is a directory in the same directory
# as the main minion config file).
default_include: minion.d/*.conf

# Set the location of the salt master server. If the master server cannot be
# resolved, then the minion will fail to start.
master: salt

# Set http proxy information for the minion when doing requests
proxy_host:
proxy_port:
proxy_username:
proxy_password:

# If multiple masters are specified in the 'master' setting, the default behavior
# is to always try to connect to them in the order they are listed. If random_master is
# set to True, the order will be randomized instead. This can be helpful in distributing
# the load of many minions executing salt-call requests, for example, from a cron job.
# If only one master is listed, this setting is ignored and a warning will be logged.
# NOTE: If master_type is set to failover, use master_shuffle instead.
#random_master: False

# Use if master_type is set to failover.
master_shuffle: False

# Minions can connect to multiple masters simultaneously (all masters
# are "hot"), or can be configured to failover if a master becomes
# unavailable. Multiple hot masters are configured by setting this
# value to "str". Failover masters can be requested by setting
# to "failover". MAKE SURE TO SET master_alive_interval if you are
# using failover.
master_type: str

# Poll interval in seconds for checking if the master is still there. Only
# respected if master_type above is "failover". To disable the interval entirely,
# set the value to -1. (This may be necessary on machines which have high numbers
# of TCP connections, such as load balancers.)
master_alive_interval: 30
```
# Set whether the minion should connect to the master via IPv6:
#ipv6: False

# Set the number of seconds to wait before attempting to resolve
# the master hostname if name resolution fails. Defaults to 30 seconds.
# Set to zero if the minion should shutdown and not retry.
# retry_dns: 30

# Set the port used by the master reply and authentication server.
#master_port: 4506

# The user to run salt.
#user: root

# The user to run salt remote execution commands as via sudo. If this option is
# enabled then sudo will be used to change the active user executing the remote
# command. If enabled the user will need to be allowed access via the sudoers
# file for the user that the salt minion is configured to run as. The most
# common option would be to use the root user. If this option is set the user
# option should also be set to a non-root user. If migrating from a root minion
# to a non root minion the minion cache should be cleared and the minion pki
# directory will need to be changed to the ownership of the new user.
#sudo_user: root

# Specify the location of the daemon process ID file.
#pidfile: /var/run/salt-minion.pid

# The root directory prepended to these options: pki_dir, cachedir, log_file,
# sock_dir, pidfile.
#root_dir: /

# The path to the minion's configuration file.
#conf_file: /etc/salt/minion

# The directory to store the pki information in
#pki_dir: /etc/salt/pki/minion

# Explicitly declare the id for this minion to use, if left commented the id
# will be the hostname as returned by the python call: socket.getfqdn()
# Since salt uses detached ids it is possible to run multiple minions on the
# same machine but with different ids, this can be useful for salt compute
# clusters.
#id:

# Cache the minion id to a file when the minion's id is not statically defined
# in the minion config. Defaults to "True". This setting prevents potential
# problems when automatic minion id resolution changes, which can cause the
# minion to lose connection with the master. To turn off minion id caching,
# set this config to `False`.
#minion_id_caching: True

# Append a domain to a hostname in the event that it does not exist. This is
# useful for systems where socket.getfqdn() does not actually result in a
# FQDN (for instance, Solaris).
#append_domain:

# Custom static grains for this minion can be specified here and used in SLS
# files just like all other grains. This example sets 4 custom grains, with
# the 'roles' grain having two values that can be matched against.
grains:
  roles:
    - webserver
    - memcache
  deployment: datacenter4
  cabinet: 13
  cab_u: 14-15

# Where cache data goes.
# This data may contain sensitive data and should be protected accordingly.
cachedir: /var/cache/salt/minion

# Verify and set permissions on configuration directories at startup.
verify_env: True

# The minion can locally cache the return data from jobs sent to it, this
# can be a good way to keep track of jobs the minion has executed
# (on the minion side). By default this feature is disabled, to enable, set
# cache_jobs to True.
cache_jobs: False

# Set the directory used to hold unix sockets.
sock_dir: /var/run/salt/minion

# Set the default outputter used by the salt-call command. The default is
# "nested".
output: nested

# By default output is colored. To disable colored output, set the color value
# to False.
color: True

# Do not strip off the colored output from nested results and state outputs
# (true by default).
strip_colors: False

# Backup files that are replaced by file.managed and file.recurse under
# 'cachedir'/file_backups relative to their original location and appended
# with a timestamp. The only valid setting is "minion". Disabled by default.
backup_mode: minion

# Alternatively this can be specified for each file in state files:
# /etc/ssh/sshd_config:
#   file.managed:
#     - source: salt://ssh/sshd_config
#     - backup: minion
#   backup_mode: minion

# When waiting for a master to accept the minion's public key, salt will
# continuously attempt to reconnect until successful. This is the time, in
# seconds, between those reconnection attempts.
acceptance_wait_time: 10

# If this is nonzero, the time between reconnection attempts will increase by
# acceptance_wait_time seconds per iteration, up to this maximum. If this is
# set to zero, the time between reconnection attempts will stay constant.
acceptance_wait_time_max: 0
# If the master rejects the minion's public key, retry instead of exiting.
# Rejected keys will be handled the same as waiting on acceptance.
# rejected_retry: False

# When the master key changes, the minion will try to re-auth itself to receive
# the new master key. In larger environments this can cause a SYN flood on the
# master because all minions try to re-auth immediately. To prevent this and
# have a minion wait for a random amount of time, use this optional parameter.
# The wait-time will be a random number of seconds between 0 and the defined value.
# random_reauth_delay: 60

# When waiting for a master to accept the minion's public key, salt will
# continuously attempt to reconnect until successful. This is the timeout value,
# in seconds, for each individual attempt. After this timeout expires, the minion
# will wait for acceptance_wait_time seconds before trying again. Unless your master
# is under unusually heavy load, this should be left at the default.
# auth_timeout: 60

# Number of consecutive SaltReqTimeoutError that are acceptable when trying to
# authenticate.
# auth_tries: 7

# If authentication fails due to SaltReqTimeoutError during a ping_interval,
# cause sub minion process to restart.
# auth_safemode: False

# Ping Master to ensure connection is alive (minutes).
# ping_interval: 0

# To auto recover minions if master changes IP address (DDNS)
# auth_tries: 10
# auth_safemode: False
# ping_interval: 90

# Minions won't know master is missing until a ping fails. After the ping fail,
# the minion will attempt authentication and likely fails out and cause a restart.
# When the minion restarts it will resolve the masters IP and attempt to reconnect.

# If you don't have any problems with syn-floods, don't bother with the
# three recon_* settings described below, just leave the defaults!
# The ZeroMQ pull-socket that binds to the masters publishing interface tries
# to reconnect immediately, if the socket is disconnected (for example if
# the master processes are restarted). In large setups this will have all
# minions reconnect immediately which might flood the master (the ZeroMQ-default
# is usually a 100ms delay). To prevent this, these three recon_* settings
# can be used.
# recon_default: the interval in milliseconds that the socket should wait before
# trying to reconnect to the master (1000ms = 1 second)
# recon_max: the maximum time a socket should wait. each interval the time to wait
# is calculated by doubling the previous time. if recon_max is reached,
# it starts again at recon_default. Short example:
#
# reconnect 1: the socket will wait 'recon_default' milliseconds
# reconnect 2: 'recon_default' * 2
# reconnect 3: ('recon_default' * 2) * 2
# reconnect 4: value from previous interval * 2
# reconnect 5: value from previous interval * 2
# reconnect x: if value >= recon_max, it starts again with recon_default
#
# recon_randomize: generate a random wait time on minion start. The wait time will
# be a random value between recon_default and recon_default + recon_max. Having all minions reconnect with the same recon_default
# and recon_max value kind of defeats the purpose of being able to
# change these settings. If all minions have the same values and your
# setup is quite large (several thousand minions), they will still
# flood the master. The desired behavior is to have timeframe within
# all minions try to reconnect.
#
# Example on how to use these settings. The goal: have all minions reconnect within a
# 60 second timeframe on a disconnect.
# recon_default: 1000
# recon_max: 59000
# recon_randomize: True
#
# Each minion will have a randomized reconnect value between 'recon_default'
# and 'recon_default + recon_max', which in this example means between 1000ms
# 60000ms (or between 1 and 60 seconds). The generated random-value will be
# doubled after each attempt to reconnect. Lets say the generated random
# value is 11 seconds (or 11000ms).
# reconnect 1: wait 11 seconds
# reconnect 2: wait 22 seconds
# reconnect 3: wait 33 seconds
# reconnect 4: wait 44 seconds
# reconnect 5: wait 55 seconds
# reconnect 6: wait time is bigger than 60 seconds (recon_default + recon_max)
# reconnect 7: wait 11 seconds
# reconnect 8: wait 22 seconds
# reconnect 9: wait 33 seconds
# reconnect x: etc.
#
# In a setup with ~6000 thousand hosts these settings would average the reconnects
# to about 100 per second and all hosts would be reconnected within 60 seconds.
# recon_default: 100
# recon_max: 5000
# recon_randomize: False
#
# The loop_interval sets how long in seconds the minion will wait between
# evaluating the scheduler and running cleanup tasks. This defaults to a
# sane 60 seconds, but if the minion scheduler needs to be evaluated more
# often lower this value
#loop_interval: 60
#
# The grains_refresh_every setting allows for a minion to periodically check
# its grains to see if they have changed and, if so, to inform the master
# of the new grains. This operation is moderately expensive, therefore
# care should be taken not to set this value too low.
#
# Note: This value is expressed in _minutes_!
#
# A value of 10 minutes is a reasonable default.
#
# If the value is set to zero, this check is disabled.
#grains_refresh_every: 1

# Cache grains on the minion. Default is False.
#grains_cache: False

# Grains cache expiration, in seconds. If the cache file is older than this
# number of seconds then the grains cache will be dumped and fully re-populated
# with fresh data. Defaults to 5 minutes. Will have no effect if 'grains_cache'
# is not enabled.
# grains_cache_expiration: 300

# Determines whether or not the salt minion should run scheduled mine updates.
# Defaults to "True". Set to "False" to disable the scheduled mine updates.
#mine_enabled: True

# Determines whether or not scheduled mine updates should be accompanied by a job
# return for the job cache. Defaults to "False". Set to "True" to include job
# returns in the job cache for mine updates.
#mine_return_job: False

# Example functions that can be run via the mine facility
# NO mine functions are established by default.
# Note these can be defined in the minion's pillar as well.
#mine_functions:
#   test.ping: []
#   network.ip_addrs:
#     interface: eth0
#     cidr: '10.0.0.0/8'

# Windows platforms lack posix IPC and must rely on slower TCP based inter-
# process communications. Set ipc_mode to 'tcp' on such systems
#ipc_mode: ipc

# Overwrite the default tcp ports used by the minion when in tcp mode
#tcp_pub_port: 4510
#tcp_pull_port: 4511

# Passing very large events can cause the minion to consume large amounts of
# memory. This value tunes the maximum size of a message allowed onto the
# minion event bus. The value is expressed in bytes.
#max_event_size: 1048576

# To detect failed master(s) and fire events on connect/disconnect, set
# master_alive_interval to the number of seconds to poll the masters for
# connection events.
#
# master_alive_interval: 30

# The minion can include configuration from other files. To enable this,
# pass a list of paths to this option. The paths can be either relative or
# absolute; if relative, they are considered to be relative to the directory
# the main minion configuration file lives in (this file). Paths can make use
# of shell-style globbing. If no files are matched by a path passed to this
# option then the minion will log a warning message.
#
# Include a config file from some other path:
# include: /etc/salt/extra_config
#
# Include config from several files and directories:
#include:
# - /etc/salt/extra_config
# - /etc/roles/webserver

# The syndic minion can verify that it is talking to the correct master via the
# key fingerprint of the higher-level master with the "syndic_finger" config.
#syndic_finger: ''
#
#
##### Minion module management #####
##########################################
# Disable specific modules. This allows the admin to limit the level of
# access the master has to the minion.
#disable_modules: [cmd,test]
#disable_returners: []

# This is the reverse of disable_modules. The default, like disable_modules, is the
# empty list,
# but if this option is set to *anything* then *only* those modules will load.
# Note that this is a very large hammer and it can be quite difficult to keep the
# minion working
# the way you think it should since Salt uses many modules internally itself. At a
# bare minimum
# you need the following enabled or else the minion won't start.
#whitelist_modules:
# - cmdmod
# - test
# - config

# Modules can be loaded from arbitrary paths. This enables the easy deployment
# of third party modules. Modules for returners and minions can be loaded.
# Specify a list of extra directories to search for minion modules and
# returners. These paths must be fully qualified!
#module_dirs: []
#returner_dirs: []
#states_dirs: []
#render_dirs: []
#utils_dirs: []

# A module provider can be statically overwritten or extended for the minion
# via the providers option, in this case the default module will be
# overwritten by the specified module. In this example the pkg module will
# be provided by the yumpkg5 module instead of the system default.
#providers:
# pkg: yumpkg5
#
# Enable Cython modules searching and loading. (Default: False)
#cython_enable: False
#
# Specify a max size (in bytes) for modules on import. This feature is currently
# only supported on *nix operating systems and requires psutil.
#modules_max_memory: -1

##### State Management Settings #####
###########################################
The state management system executes all of the state templates on the minion to enable more granular control of system state management. The type of template and serialization used for state management needs to be configured on the minion, the default renderer is yaml_jinja. This is a yaml file rendered from a jinja template, the available options are:

- yaml_jinja
- yaml_mako
- yaml_wempy
- json_jinja
- json_mako
- json_wempy

```yaml
#renderer: yaml_jinja
```

The failhard option tells the minions to stop immediately after the first failure detected in the state execution. Defaults to False.

```yaml
#failhard: False
```

Reload the modules prior to a highstate run.

```yaml
#autoload_dynamic_modules: True
```

Clean_dynamic_modules keeps the dynamic modules on the minion in sync with the dynamic modules on the master, this means that if a dynamic module is not on the master it will be deleted from the minion. By default, this is enabled and can be disabled by changing this value to False.

```yaml
#clean_dynamic_modules: True
```

Normally, the minion is not isolated to any single environment on the master when running states, but the environment can be isolated on the minion side by statically setting it. Remember that the recommended way to manage environments is to isolate via the top file.

```yaml
#environment: None
```

Isolates the pillar environment on the minion side. This functions the same as the environment setting, but for pillar instead of states.

```yaml
#pillarenv: None
```

If using the local file directory, then the state top file name needs to be defined, by default this is top.sls.

```yaml
#state_top: top.sls
```

Run states when the minion daemon starts. To enable, set startup_states to:

- 'highstate' -- Execute state.highstate
- 'sls' -- Read in the sls_list option and execute the named sls files
- 'top' -- Read top_file option and execute based on that file on the Master

```yaml
#startup_states: ''
```

List of states to run when the minion starts up if startup_states is 'sls':

```yaml
#sls_list:
#  - edit.vim
#  - hyper
```

Top file to execute if startup_states is 'top':

```yaml
#top_file: ''
```

Automatically aggregate all states that have support for mod_aggregate by setting to True. Or pass a list of state module names to automatically aggregate just those types.
# state_aggregate:
# - pkg
# state_aggregate: False

##### File Directory Settings #####
##########################################
# The Salt Minion can redirect all file server operations to a local directory,
# this allows for the same state tree that is on the master to be used if
# copied completely onto the minion. This is a literal copy of the settings on
# the master but used to reference a local directory on the minion.

# Set the file client. The client defaults to looking on the master server for
# files, but can be directed to look at the local file directory setting
# defined below by setting it to "local". Setting a local file_client runs the
# minion in masterless mode.
#file_client: remote

# The file directory works on environments passed to the minion, each environment
# can have multiple root directories, the subdirectories in the multiple file
# roots cannot match, otherwise the downloaded files will not be able to be
# reliably ensured. A base environment is required to house the top file.
# Example:
# file_roots:
#  base:
#   - /srv/salt/
#  dev:
#   - /srv/salt/dev/services
#   - /srv/salt/dev/states
#  prod:
#   - /srv/salt/prod/services
#   - /srv/salt/prod/states
#
#file_roots:
#  base:
#   - /srv/salt

# Uncomment the line below if you do not want the file_server to follow
# symlinks when walking the filesystem tree. This is set to True
# by default. Currently this only applies to the default roots
# fileserver_backend.
#fileserver_followsymlinks: False

# Uncomment the line below if you do not want symlinks to be
# treated as the files they are pointing to. By default this is set to
# False. By uncommenting the line below, any detected symlink while listing
# files on the Master will not be returned to the Minion.
#fileserver_ignoresymlinks: True

# By default, the Salt fileserver recurses fully into all defined environments
# to attempt to find files. To limit this behavior so that the fileserver only
# traverses directories with SLS files and special Salt directories like _modules,
# enable the option below. This might be useful for installations where a file root
# has a very large number of files and performance is negatively impacted. Default
# is False.
#fileserver_limit_traversal: False
The hash_type is the hash to use when discovering the hash of a file in the local fileserver. The default is sha256, sha224, sha384 and sha512 are also supported.

WARNING: While md5 and sha1 are also supported, do not use it due to the high chance of possible collisions and thus security breach.

Warning: Prior to changing this value, the minion should be stopped and all Salt caches should be cleared.

hash_type: sha256

The Salt pillar is searched for locally if file_client is set to local. If this is the case, and pillar data is defined, then the pillar_roots need to also be configured on the minion:
pillar_roots:
  base:
    - /srv/pillar

Set a hard-limit on the size of the files that can be pushed to the master. It will be interpreted as megabytes. Default: 100
file_recv_max_size: 100

# Security settings

Enable "open mode", this mode still maintains encryption, but turns off authentication, this is only intended for highly secure environments or for the situation where your keys end up in a bad state. If you run in open mode you do so at your own risk!
open_mode: False

Enable permissive access to the salt keys. This allows you to run the master or minion as root, but have a non-root group be given access to your pki_dir. To make the access explicit, root must belong to the group you've given access to. This is potentially quite insecure.
permissive_pki_access: False

The state_verbose and state_output settings can be used to change the way state system data is printed to the display. By default all data is printed. The state_verbose setting can be set to True or False, when set to False all data that has a result of True and no changes will be suppressed.
state_verbose: True
state_output: full

The state_output_diff setting changes whether or not the output from successful states is returned. Useful when even the terse output of these states is cluttering the logs. Set it to True to ignore them.
state_output_diff: False

The state_output_profile setting changes whether profile information will be shown for each state run.
state_output_profile: True

Fingerprint of the master public key to validate the identity of your Salt master
# before the initial key exchange. The master fingerprint can be found by running
# "salt-key -F master" on the Salt master.

# master_finger: ''

# Thread settings
###########################################
# Disable multiprocessing support, by default when a minion receives a
# publication a new process is spawned and the command is executed therein.
# multiprocessing: True

# Logging settings
##########################################
# The location of the minion log file
# The minion log can be sent to a regular file, local path name, or network
# location. Remote logging works best when configured to use rsyslogd(8) (e.g.:
# `file:///dev/log`), with rsyslogd(8) configured for network logging. The URI
# format is: `<file|udp|tcp>://<host|socketpath>:<port-if-required>/<log-facility>
# log_file: /var/log/salt/minion
# log_file: file:///dev/log
# log_file: udp://loghost:10514
# log_file: /var/log/salt/minion
# key_logfile: /var/log/salt/key

# The level of messages to send to the console.
# One of 'garbage', 'trace', 'debug', info', 'warning', 'error', 'critical'.
# The following log levels are considered INSECURE and may log sensitive data:
# ['garbage', 'trace', 'debug']
# Default: 'warning'
# log_level: warning

# The level of messages to send to the log file.
# One of 'garbage', 'trace', 'debug', info', 'warning', 'error', 'critical'.
# If using 'log_granular_levels' this must be set to the highest desired level.
# Default: 'warning'
# log_level_logfile:

# The date and time format used in log messages. Allowed date/time formatting
# can be seen here: http://docs.python.org/library/time.html#time.strftime
# log_datefmt: '%H:%M:%S'
# log_datefmt_logfile: '%Y-%m-%d %H:%M:%S'

# The format of the console logging messages. Allowed formatting options can
# be seen here: http://docs.python.org/library/logging.html#logrecord-attributes
# Console log colors are specified by these additional formatters:
# %%(colorlevel)s
# %%(colormsg)s
# %%(colormsg)s
# Since it is desirable to include the surrounding brackets, '[' and ']', in
# the coloring of the messages, these color formatters also include padding as
# well. Color LogRecord attributes are only available for console logging.
#
#log_fmt_console: '%(colorlevel)s %(colormsg)s'
#log_fmt_console: '[%(levelname)-8s] %(message)s'
#
#log_fmt_logfile: '%(asctime)s,%(msecs)03.0f [%(name)-17s][%(levelname)-8s] %(message)s'
#
# This can be used to control logging levels more specifically. This example sets the main salt library at the 'warning' level, but sets 'salt.modules' to log at the 'debug' level:
#log_granular_levels:
#  'salt': 'warning'
#  'salt.modules': 'debug'
#
#log_granular_levels: {}
#
# To diagnose issues with minions disconnecting or missing returns, ZeroMQ supports the use of monitor sockets to log connection events. This feature requires ZeroMQ 4.0 or higher.
#
# To enable ZeroMQ monitor sockets, set 'zmq_monitor' to 'True' and log at a debug level or higher.
#
# A sample log event is as follows:
#[DEBUG ] ZeroMQ event: {'endpoint': 'tcp://127.0.0.1:4505', 'event': 512, 'value': 27, 'description': 'EVENT_DISCONNECTED'}
#
# All events logged will include the string 'ZeroMQ event'. A connection event should be logged as the minion starts up and initially connects to the master. If not, check for debug log level and that the necessary version of ZeroMQ is installed.
#
#zmq_monitor: False

####### Module configuration #######
###########################################
# Salt allows for modules to be passed arbitrary configuration data, any data passed here in valid yaml format will be passed on to the salt minion modules for use. It is STRONGLY recommended that a naming convention be used in which the module name is followed by a . and then the value. Also, all top level data must be applied via the yaml dict construct, some examples:
#
# You can specify that all modules should run in test mode:
#test: True
#
# A simple value for the test module:
#test.foo: foo
#
# A list for the test module:
#test.bar: [baz,quo]
#
# A dict for the test module:
#test.baz: {spam: sausage, cheese: bread}
#
# Update settings

616 Chapter 32. Reference
Using the features in Esky, a salt minion can both run as a frozen app and be updated on the fly. These options control how the update process (saltutil.update()) behaves.

The url for finding and downloading updates. Disabled by default.
update_url: False

The list of services to restart after a successful update. Empty by default.
update_restart_services: []

Keepalive settings

ZeroMQ now includes support for configuring SO_KEEPALIVE if supported by the OS. If connections between the minion and the master pass through a state tracking device such as a firewall or VPN gateway, there is the risk that it could tear down the connection the master and minion without informing either party that their connection has been taken away. Enabling TCP Keepalives prevents this from happening.

Overall state of TCP Keepalives, enable (1 or True), disable (0 or False) or leave to the OS defaults (-1), on Linux, typically disabled. Default True, enabled.
tcp_keepalive: True

How long before the first keepalive should be sent in seconds. Default 300 to send the first keepalive after 5 minutes, OS default (-1) is typically 7200 seconds on Linux see /proc/sys/net/ipv4/tcp_keepalive_time.
tcp_keepalive_idle: 300

How many lost probes are needed to consider the connection lost. Default -1 to use OS defaults, typically 9 on Linux, see /proc/sys/net/ipv4/tcp_keepalive_probes.
tcp_keepalive_cnt: -1

How often, in seconds, to send keepalives after the first one. Default -1 to use OS defaults, typically 75 seconds on Linux, see /proc/sys/net/ipv4/tcp_keepalive_intvl.
tcp_keepalive_intvl: -1

Windows Software settings

Location of the repository cache file on the master:
win_repo_cachefile: 'salt://win/repo/winrepo.p'

Returner settings

Which returner(s) will be used for minion's result:
return: mysql

Miscellaneous settings

Default match type for filtering events tags: startswith, endswith, find, regex, fnmatch
#event_match_type: startswith
32.7 Configuring Salt

Salt configuration is very simple. The default configuration for the master will work for most installations and the only requirement for setting up a minion is to set the location of the master in the minion configuration file.

The configuration files will be installed to /etc/salt and are named after the respective components, /etc/salt/master, and /etc/salt/minion.

32.7.1 Master Configuration

By default the Salt master listens on ports 4505 and 4506 on all interfaces (0.0.0.0). To bind Salt to a specific IP, redefine the `interface` directive in the master configuration file, typically /etc/salt/master, as follows:

```plaintext
- #interface: 0.0.0.0
+ interface: 10.0.0.1
```

After updating the configuration file, restart the Salt master. See the master configuration reference for more details about other configurable options.

32.7.2 Minion Configuration

Although there are many Salt Minion configuration options, configuring a Salt Minion is very simple. By default a Salt Minion will try to connect to the DNS name `salt`; if the Minion is able to resolve that name correctly, no configuration is needed.

If the DNS name `salt` does not resolve to point to the correct location of the Master, redefine the `master` directive in the minion configuration file, typically /etc/salt/minion, as follows:

```plaintext
- #master: salt
+ master: 10.0.0.1
```

After updating the configuration file, restart the Salt minion. See the minion configuration reference for more details about other configurable options.

32.7.3 Running Salt

1. Start the master in the foreground (to daemonize the process, pass the `-d` flag):

   ```shell
   salt-master
   ```

2. Start the minion in the foreground (to daemonize the process, pass the `-d` flag):

   ```shell
   salt-minion
   ```

Having trouble?

The simplest way to troubleshoot Salt is to run the master and minion in the foreground with log level set to debug:

```shell
salt-master --log-level=debug
```
For information on salt's logging system please see the *logging document*.

---

**Run as an unprivileged (non-root) user**

To run Salt as another user, set the `user` parameter in the master config file.

Additionally, ownership, and permissions need to be set such that the desired user can read from and write to the following directories (and their subdirectories, where applicable):

- `/etc/salt`
- `/var/cache/salt`
- `/var/log/salt`
- `/var/run/salt`

More information about running salt as a non-privileged user can be found here.

There is also a full *troubleshooting guide* available.

### 32.7.4 Key Identity

Salt provides commands to validate the identity of your Salt master and Salt minions before the initial key exchange. Validating key identity helps avoid inadvertently connecting to the wrong Salt master, and helps prevent a potential MiTM attack when establishing the initial connection.

**Master Key Fingerprint**

Print the master key fingerprint by running the following command on the Salt master:

```
salt-key -F master
```

Copy the `master.pub` fingerprint from the *Local Keys* section, and then set this value as the `master_finger` in the minion configuration file. Save the configuration file and then restart the Salt minion.

**Minion Key Fingerprint**

Run the following command on each Salt minion to view the minion key fingerprint:

```
salt-call --local key.finger
```

Compare this value to the value that is displayed when you run the `salt-key --finger <MINION_ID>` command on the Salt master.

### 32.7.5 Key Management

Salt uses AES encryption for all communication between the Master and the Minion. This ensures that the commands sent to the Minions cannot be tampered with, and that communication between Master and Minion is authenticated through trusted, accepted keys.

Before commands can be sent to a Minion, its key must be accepted on the Master. Run the `salt-key` command to list the keys known to the Salt Master:
This example shows that the Salt Master is aware of four Minions, but none of the keys has been accepted. To accept the keys and allow the Minions to be controlled by the Master, again use the `salt-key` command:

```
[root@master ~]# salt-key -A
Unaccepted Keys:
Accepte Keys:
```

The `salt-key` command allows for signing keys individually or in bulk. The example above, using `-A` bulk-accepts all pending keys. To accept keys individually use the lowercase of the same option, `-a keyname`.

See also:

`salt-key manpage`

### 32.7.6 Sending Commands

Communication between the Master and a Minion may be verified by running the `test.ping` command:

```
[root@master ~]# salt alpha test.ping
alpha:
    True
```

Communication between the Master and all Minions may be tested in a similar way:

```
[root@master ~]# salt '*' test.ping
alpha:
    True
bravo:
    True
charlie:
    True
delta:
    True
```

Each of the Minions should send a `True` response as shown above.

### 32.7.7 What's Next?

Understanding `targeting` is important. From there, depending on the way you wish to use Salt, you should also proceed to learn about `States` and `Execution Modules`. 
32.8 Configuring the Salt Master

The Salt system is amazingly simple and easy to configure, the two components of the Salt system each have a respective configuration file. The **salt-master** is configured via the master configuration file, and the **salt-minion** is configured via the minion configuration file.

See also:

*Example master configuration file.*

The configuration file for the salt-master is located at `/etc/salt/master` by default. A notable exception is FreeBSD, where the configuration file is located at `/usr/local/etc/salt`. The available options are as follows:

### 32.8.1 Primary Master Configuration

**interface**

Default: `0.0.0.0` (all interfaces)

The local interface to bind to.

```
interface: 192.168.0.1
```

**ipv6**

Default: `False`

Whether the master should listen for IPv6 connections. If this is set to True, the interface option must be adjusted too (for example: `interface: '::'`)

```
ipv6: True
```

**publish_port**

Default: `4505`

The network port to set up the publication interface.

```
publish_port: 4505
```

**master_id**

Default: `None`

The id to be passed in the publish job to minions. This is used for MultiSyndics to return the job to the requesting master.

**Note:** This must be the same string as the syndic is configured with.

```
master_id: MasterOfMaster
```
user
Default: root
The user to run the Salt processes

user: root

max_open_files
Default: 100000
Each minion connecting to the master uses AT LEAST one file descriptor, the master subscription connection. If enough minions connect you might start seeing on the console(and then salt-master crashes):

Too many open files (tcp_listener.cpp:335)
Aborted (core dumped)

max_open_files: 100000
By default this value will be the one of ulimit -Hn, i.e., the hard limit for max open files.
To set a different value than the default one, uncomment, and configure this setting. Remember that this value CANNOT be higher than the hard limit. Raising the hard limit depends on the OS and/or distribution, a good way to find the limit is to search the internet for something like this:

raise max open files hard limit debian

worker_threads
Default: 5
The number of threads to start for receiving commands and replies from minions. If minions are stalling on replies because you have many minions, raise the worker_threads value.

Worker threads should not be put below 3 when using the peer system, but can drop down to 1 worker otherwise.

Note: When the master daemon starts, it is expected behaviour to see multiple salt-master processes, even if `worker_threads' is set to `1'. At a minimum, a controlling process will start along with a Publisher, an EventPublisher, and a number of MWorker processes will be started. The number of MWorker processes is tuneable by the `worker_threads' configuration value while the others are not.

worker_threads: 5

ret_port
Default: 4506
The port used by the return server, this is the server used by Salt to receive execution returns and command executions.

ret_port: 4506
### pidfile
Default: /var/run/salt-master.pid
Specify the location of the master pidfile.

```bash
pidfile: /var/run/salt-master.pid
```

### root_dir
Default: /
The system root directory to operate from, change this to make Salt run from an alternative root.

```bash
root_dir: /
```

**Note:** This directory is prepended to the following options: `pki_dir, cachedir, sock_dir, log_file, autosign_file, autoreject_file, pidfile`.

### conf_file
Default: /etc/salt/master
The path to the master's configuration file.

```bash
conf_file: /etc/salt/master
```

### pki_dir
Default: /etc/salt/pki/master
The directory to store the pki authentication keys.

```bash
pki_dir: /etc/salt/pki/master
```

### extension_modules
Directory for custom modules. This directory can contain subdirectories for each of Salt's module types such as `runners`, `output`, `wheel`, `modules`, `states`, `returners`, etc. This path is appended to `root_dir`.

```bash
extension_modules: srv/modules
```

### module_dirs
Default: []
Like `extension_modules`, but a list of extra directories to search for Salt modules.

```bash
module_dirs:
  - /var/cache/salt/minion/extmods
```
cachedir

Default: /var/cache/salt/master

The location used to store cache information, particularly the job information for executed salt commands.
This directory may contain sensitive data and should be protected accordingly.

cachedir: /var/cache/salt/master

verify_env

Default: True

Verify and set permissions on configuration directories at startup.

verify_env: True

keep_jobs

Default: 24

Set the number of hours to keep old job information. Note that setting this option to 0 disables the cache cleaner.

keep_jobs: 24

gather_job_timeout

New in version 2014.7.0.

Default: 10

The number of seconds to wait when the client is requesting information about running jobs.

gather_job_timeout: 10

timeout

Default: 5

Set the default timeout for the salt command and api.

loop_interval

Default: 60

The loop_interval option controls the seconds for the master's maintenance process check cycle. This process updates
file server backends, cleans the job cache and executes the scheduler.

output

Default: nested

Set the default outputter used by the salt command.
**output_file**

Default: None

Set the default output file used by the salt command. Default is to output to the CLI and not to a file. Functions the same way as the ``--out-file`` CLI option, only sets this to a single file for all salt commands.

```plaintext
output_file: /path/output/file
```

**color**

Default: True

By default output is colored, to disable colored output set the color value to False.

```plaintext
color: False
```

**cli_summary**

Default: False

When set to True, displays a summary of the number of minions targeted, the number of minions returned, and the number of minions that did not return.

```plaintext
cli_summary: False
```

**sock_dir**

Default: /var/run/salt/master

Set the location to use for creating Unix sockets for master process communication.

```plaintext
sock_dir: /var/run/salt/master
```

**enable_gpu_grains**

Default: True

Enable GPU hardware data for your master. Be aware that the master can take a while to start up when lspci and/or dmidecode is used to populate the grains for the master.

**job_cache**

Default: True

The master maintains a temporary job cache. While this is a great addition, it can be a burden on the master for larger deployments (over 5000 minions). Disabling the job cache will make previously executed jobs unavailable to the jobs system and is not generally recommended. Normally it is wise to make sure the master has access to a faster IO system or a tmpfs is mounted to the jobs dir.

```plaintext
job_cache: True
```
Note: Setting the `job_cache` to `False` will not cache minion returns, but the JID directory for each job is still created. The creation of the JID directories is necessary because Salt uses those directories to check for JID collisions. By setting this option to `False`, the job cache directory, which is `/var/cache/salt/master/jobs/` by default, will be smaller, but the JID directories will still be present.

Note that the `keep_jobs` option can be set to a lower value, such as 1, to limit the number of hours jobs are stored in the job cache. (The default is 24 hours.)

Please see the *Managing the Job Cache* documentation for more information.

**minion_data_cache**

Default: `True`

The minion data cache is a cache of information about the minions stored on the master, this information is primarily the pillar and grains data. The data is cached in the Master cachedir under the name of the minion and used to predetermine what minions are expected to reply from executions.

```yaml
minion_data_cache: True
```

**ext_job_cache**

Default: `'`

Used to specify a default returner for all minions. When this option is set, the specified returner needs to be properly configured and the minions will always default to sending returns to this returner. This will also disable the local job cache on the master.

```yaml
ext_job_cache: redis
```

**event_return**

New in version 2015.5.0.

Default: `'`

Specify the returner to use to log events. A returner may have installation and configuration requirements. Read the returner’s documentation.

Note: Not all returners support event returns. Verify that a returner has an `event_return()` function before configuring this option with a returner.

```yaml
event_return: cassandra_cql
```

**event_return_queue**

New in version 2015.5.0.

Default: `0`
On busy systems, enabling event_returns can cause a considerable load on the storage system for returners. Events can be queued on the master and stored in a batched fashion using a single transaction for multiple events. By default, events are not queued.

```yaml
event_return_queue: 0
```

**event_return_whitelist**

New in version 2015.5.0.

Default: []

Only return events matching tags in a whitelist.

```yaml
event_return_whitelist:
  - salt/master/a_tag
  - salt/master/another_tag
```

**event_return_blacklist**

New in version 2015.5.0.

Default: []

Store all event returns _except_ the tags in a blacklist.

```yaml
event_return_blacklist:
  - salt/master/not_this_tag
  - salt/master/or_this_one
```

**max_event_size**

New in version 2014.7.0.

Default: 1048576

Passing very large events can cause the minion to consume large amounts of memory. This value tunes the maximum size of a message allowed onto the master event bus. The value is expressed in bytes.

```yaml
max_event_size: 1048576
```

**master_job_cache**

New in version 2014.7.0.

Default: local_cache

Specify the returner to use for the job cache. The job cache will only be interacted with from the salt master and therefore does not need to be accessible from the minions.

```yaml
master_job_cache: redis
```
**enforce_mine_cache**

Default: False

By-default when disabling the minion_data_cache mine will stop working since it is based on cached data, by enabling this option we explicitly enabling only the cache for the mine system.

```
enforce_mine_cache: False
```

**max_minions**

Default: 0

The maximum number of minion connections allowed by the master. Use this to accommodate the number of minions per master if you have different types of hardware serving your minions. The default of 0 means unlimited connections. Please note that this can slow down the authentication process a bit in large setups.

```
max_minions: 100
```

**con_cache**

Default: False

If max_minions is used in large installations, the master might experience high-load situations because of having to check the number of connected minions for every authentication. This cache provides the minion-ids of all connected minions to all MWorker-processes and greatly improves the performance of max_minions.

```
con_cache: True
```

**presence_events**

Default: False

Causes the master to periodically look for actively connected minions. Presence events are fired on the event bus on a regular interval with a list of connected minions, as well as events with lists of newly connected or disconnected minions. This is a master-only operation that does not send executions to minions. Note, this does not detect minions that connect to a master via localhost.

```
presence_events: False
```

**transport**

Default: zeromq

Changes the underlying transport layer. ZeroMQ is the recommended transport while additional transport layers are under development. Supported values are zeromq, raet (experimental), and tcp (experimental). This setting has a significant impact on performance and should not be changed unless you know what you are doing! Transports are explained in Salt Transports.

```
transport: zeromq
```
32.8.2 Salt-SSH Configuration

**roster_file**

Default: `/etc/salt/roster`

Pass in an alternative location for the salt-ssh roster file.

```
roster_file: /root/roster
```

**ssh_minion_opts**

Default: None

Pass in minion option overrides that will be inserted into the SHIM for salt-ssh calls. The local minion config is not used for salt-ssh. Can be overridden on a per-minion basis in the roster (minion_opts)

```
minion_opts:
  gpg_keydir: /root/gpg
```

**thin_extra_mods**

Default: None

List of additional modules, needed to be included into the Salt Thin. Pass a list of importable Python modules that are typically located in the *site-packages* Python directory so they will be also always included into the Salt Thin, once generated.

32.8.3 Master Security Settings

**open_mode**

Default: False

Open mode is a dangerous security feature. One problem encountered with pki authentication systems is that keys can become ‘‘mixed up’’ and authentication begins to fail. Open mode turns off authentication and tells the master to accept all authentication. This will clean up the pki keys received from the minions. Open mode should not be turned on for general use. Open mode should only be used for a short period of time to clean up pki keys. To turn on open mode set this value to True.

```
open_mode: False
```

**auto_accept**

Default: False

Enable auto_accept. This setting will automatically accept all incoming public keys from minions.

```
auto_accept: False
```
**autosign_timeout**

New in version 2014.7.0.

Default: 120

Time in minutes that a incoming public key with a matching name found in pki_dir/minion_autosign/keyid is automatically accepted. Expired autosign keys are removed when the master checks the minion_autosign directory. This method to auto accept minions can be safer than an autosign_file because the keyid record can expire and is limited to being an exact name match. This should still be considered a less than secure option, due to the fact that trust is based on just the requesting minion id.

**autosign_file**

Default: not defined

If the autosign_file is specified incoming keys specified in the autosign_file will be automatically accepted. Matches will be searched for first by string comparison, then by globbing, then by full-string regex matching. This should still be considered a less than secure option, due to the fact that trust is based on just the requesting minion id.

**autoreject_file**

New in version 2014.1.0.

Default: not defined

Works like autosign_file, but instead allows you to specify minion IDs for which keys will automatically be rejected. Will override both membership in the autosign_file and the auto_accept setting.

**client_acl**

Default: {}  
Enable user accounts on the master to execute specific modules. These modules can be expressed as regular expressions.

```python
client_acl:
    fred:
        - test.ping
        - pkg.*
```

**client_acl_blacklist**

Default: {}

Blacklist users or modules

This example would blacklist all non sudo users, including root from running any commands. It would also blacklist any use of the `cmd` module.

This is completely disabled by default.
client_acl_blacklist:
  users:
    - root
    - ^([^sudo_].*)$  # all non sudo users
modules:
  - cmd

external_auth

Default: {}

The external auth system uses the Salt auth modules to authenticate and validate users to access areas of the Salt system.

external_auth:
  pam:
    fred:
      - test.*

token_expire

Default: 43200

Time (in seconds) for a newly generated token to live.
Default: 12 hours

token_expire: 43200

file_recv

Default: False

Allow minions to push files to the master. This is disabled by default, for security purposes.

file_recv: False

file_recv_max_size

New in version 2014.7.0.

Default: 100

Set a hard-limit on the size of the files that can be pushed to the master. It will be interpreted as megabytes.

file_recv_max_size: 100

master_sign_pubkey

Default: False

Sign the master auth-replies with a cryptographic signature of the master's public key. Please see the tutorial how to use these settings in the Multimaster-PKI with Failover Tutorial

32.8. Configuring the Salt Master
**master_sign_pubkey**: True

**master_sign_key_name**

Default: master_sign

The customizable name of the signing-key-pair without suffix.

**master_sign_key_name**: <filename_without_suffix>

**master_pubkey_signature**

Default: master_pubkey_signature

The name of the file in the master’s pki-directory that holds the pre-calculated signature of the master’s public-key.

**master_pubkey_signature**: <filename>

**master_use_pubkey_signature**

Default: False

Instead of computing the signature for each auth-reply, use a pre-calculated signature. The **master_pubkey_signature** must also be set for this.

**master_use_pubkey_signature**: True

**rotate_aes_key**

Default: True

Rotate the salt-masters AES-key when a minion-public is deleted with salt-key. This is a very important security-setting. Disabling it will enable deleted minions to still listen in on the messages published by the salt-master. Do not disable this unless it is absolutely clear what this does.

**rotate_aes_key**: True

### 32.8.4 Master Module Management

**runner_dirs**

Default: []

Set additional directories to search for runner modules.

**runner_dirs**: - /var/lib/salt/runners
**cython_enable**

Default: False

Set to true to enable Cython modules (.pyx files) to be compiled on the fly on the Salt master.

```
cython_enable: False
```

### 32.8.5 Master State System Settings

#### state_top

Default: top.sls

The state system uses a `top` file to tell the minions what environment to use and what modules to use. The state_top file is defined relative to the root of the base environment.

```
state_top: top.sls
```

#### master_tops

Default: {}

The master_tops option replaces the external_nodes option by creating a pluggable system for the generation of external top data. The external_nodes option is deprecated by the master_tops option. To gain the capabilities of the classic external_nodes system, use the following configuration:

```
master_tops:
  ext_nodes: <Shell command which returns yaml>
```

#### external_nodes

Default: None

The external_nodes option allows Salt to gather data that would normally be placed in a top file from and external node controller. The external_nodes option is the executable that will return the ENC data. Remember that Salt will look for external nodes AND top files and combine the results if both are enabled and available!

```
external_nodes: cobbler-ext-nodes
```

#### renderer

Default: yaml_jinja

The renderer to use on the minions to render the state data.

```
renderer: yaml_jinja
```
**jinja_trim_blocks**

New in version 2014.1.0.
Default: False

If this is set to True, the first newline after a Jinja block is removed (block, not variable tag!). Defaults to False and corresponds to the Jinja environment init variable `trim_blocks`.

```
jinja_trim_blocks: False
```

**jinja_lstrip_blocks**

New in version 2014.1.0.
Default: False

If this is set to True, leading spaces and tabs are stripped from the start of a line to a block. Defaults to False and corresponds to the Jinja environment init variable `lstrip_blocks`.

```
jinja_lstrip_blocks: False
```

**failhard**

Default: False

Set the global failhard flag. This informs all states to stop running states at the moment a single state fails.

```
failhard: False
```

**state_verbose**

Default: True

Controls the verbosity of state runs. By default, the results of all states are returned, but setting this value to False will cause salt to only display output for states that failed or states that have changes.

```
state_verbose: False
```

**state_output**

Default: full

The state_output setting changes if the output is the full multi line output for each changed state if set to `full`, but if set to `terse` the output will be shortened to a single line. If set to `mixed`, the output will be terse unless a state failed, in which case that output will be full. If set to `changes`, the output will be full unless the state didn’t change.

```
state_output: full
```
**state_aggregate**

Default: False

Automatically aggregate all states that have support for mod_aggregate by setting to True. Or pass a list of state module names to automatically aggregate just those types.

```
state_aggregate:
    - pkg

state_aggregate: True
```

**state_events**

Default: False

Send progress events as each function in a state run completes execution by setting to True. Progress events are in the format `salt/job/<JID>/prog/<MID>/<RUN_NUM>`.

```
state_events: True
```

**yaml_utf8**

Default: False

Enable extra routines for YAML renderer used states containing UTF characters.

```
yaml_utf8: False
```

**test**

Default: False

Set all state calls to only test if they are going to actually make changes or just post what changes are going to be made.

```
test: False
```

### 32.8.6 Master File Server Settings

**filesaherver_backend**

Default: ['roots']

Salt supports a modular fileserver backend system, this system allows the salt master to link directly to third party systems to gather and manage the files available to minions. Multiple backends can be configured and will be searched for the requested file in the order in which they are defined here. The default setting only enables the standard backend roots, which is configured using the `file_roots` option.

Example:
fileserver_backend:
  - roots
  - git

Note: For masterless Salt, this parameter must be specified in the minion config file.

fileserver_followsymlinks

New in version 2014.1.0.
Default: True
By default, the file_server follows symlinks when walking the filesystem tree. Currently this only applies to the default roots fileserver_backend.

fileserver_followsymlinks: True

fileserver_ignoresymlinks

New in version 2014.1.0.
Default: False
If you do not want symlinks to be treated as the files they are pointing to, set fileserver_ignoresymlinks to True. By default this is set to False. When set to True, any detected symlink while listing files on the Master will not be returned to the Minion.

fileserver_ignoresymlinks: False

fileserver_limit_traversal

New in version 2014.1.0.
Default: False
By default, the Salt fileserver recurses fully into all defined environments to attempt to find files. To limit this behavior so that the fileserver only traverses directories with SLS files and special Salt directories like _modules, set fileserver_limit_traversal to True. This might be useful for installations where a file root has a very large number of files and performance is impacted.

fileserver_limit_traversal: False

hash_type

Default: md5
The hash_type is the hash to use when discovering the hash of a file on the master server. The default is md5, but sha1, sha224, sha256, sha384, and sha512 are also supported.

hash_type: md5
**file_buffer_size**

Default: 1048576

The buffer size in the file server in bytes.

| file_buffer_size: 1048576 |

**file_ignore_regex**

Default: ''

A regular expression (or a list of expressions) that will be matched against the file path before syncing the modules and states to the minions. This includes files affected by the file.recurse state. For example, if you manage your custom modules and states in subversion and don't want all the `.svn` folders and content synced to your minions, you could set this to ` /.svn($|/)`. By default nothing is ignored.

| file_ignore_regex: |
| - ' /.svn($|/) ' |
| - ' /.git($|/) ' |

**file_ignore_glob**

Default: ''

A file glob (or list of file globs) that will be matched against the file path before syncing the modules and states to the minions. This is similar to file_ignore_regex above, but works on globs instead of regex. By default nothing is ignored.

| file_ignore_glob: |
| - '*.pyc' |
| - '*/somefolder/*.bak' |
| - '*.swp' |

**Note:** Vim's .swp files are a common cause of Unicode errors in file.recurse states which use templating. Unless there is a good reason to distribute them via the fileserver, it is good practice to include `'* .swp'` in the file_ignore_glob.

**roots: Master's Local File Server**

**file_roots**

Default:

| base: |
| - /srv/salt |

Salt runs a lightweight file server written in ZeroMQ to deliver files to minions. This file server is built into the master daemon and does not require a dedicated port.
The file server works on environments passed to the master. Each environment can have multiple root directories. The subdirectories in the multiple file roots cannot match, otherwise the downloaded files will not be able to be reliably ensured. A base environment is required to house the top file.

Example:

```yaml
file_roots:
  base:
    - /srv/salt
  dev:
    - /srv/salt/dev/services
    - /srv/salt/dev/states
  prod:
    - /srv/salt/prod/services
    - /srv/salt/prod/states
```

Note: For masterless Salt, this parameter must be specified in the minion config file.

**git**: Git Remote File Server Backend

**gitfs_remotes**

Default: []

When using the `git` fileserver backend at least one git remote needs to be defined. The user running the salt master will need read access to the repo.

The repos will be searched in order to find the file requested by a client and the first repo to have the file will return it. Branches and tags are translated into salt environments.

```yaml
gitfs_remotes:
  - git://github.com/saltstack/salt-states.git
  - file:///var/git/saltmaster
```

Note: `file://` repos will be treated as a remote and copied into the master's gitfs cache, so only the `local` refs for those repos will be exposed as fileserver environments.

As of 2014.7.0, it is possible to have per-repo versions of several of the gitfs configuration parameters. For more information, see the *GitFS Walkthrough*.

**gitfs_provider**

New in version 2014.7.0.

Optional parameter used to specify the provider to be used for gitfs. More information can be found in the *GitFS Walkthrough*.

Must be one of the following: `pygit2`, `gitpython`, or `dulwich`. If unset, then each will be tried in that same order, and the first one with a compatible version installed will be the provider that is used.

```yaml
gitfs_provider: dulwich
```
**gitfs_ssl_verify**

Default: False

Specifies whether or not to ignore SSL certificate errors when contacting the remote repository. The False setting is useful if you’re using a git repo that uses a self-signed certificate. However, keep in mind that setting this to anything other True is considered insecure, and using an SSH-based transport (if available) may be a better option.

```
gitfs_ssl_verify: True
```

**gitfs_mountpoint**

New in version 2014.7.0.

Default: ''

Specifies a path on the salt fileserver which will be prepended to all files served by gitfs. This option can be used in conjunction with gitfs_root. It can also be configured on a per-remote basis, see here for more info.

```
gitfs_mountpoint: salt://foo/bar
```

**Note:** The salt:// protocol designation can be left off (in other words, foo/bar and salt://foo/bar are equivalent). Assuming a file baz.sh in the root of a gitfs remote, and the above example mountpoint, this file would be served up via salt://foo/bar/baz.sh.

**gitfs_root**

Default: ''

Relative path to a subdirectory within the repository from which Salt should begin to serve files. This is useful when there are files in the repository that should not be available to the Salt fileserver. Can be used in conjunction with gitfs_mountpoint. If used, then from Salt’s perspective the directories above the one specified will be ignored and the relative path will (for the purposes of gitfs) be considered as the root of the repo.

```
gitfs_root: somefolder/otherfolder
```

Changed in version 2014.7.0: Ability to specify gitfs roots on a per-remote basis was added. See here for more info.

**gitfs_base**

Default: master

Defines which branch/tag should be used as the base environment.

```
gitfs_base: salt
```

Changed in version 2014.7.0: Ability to specify the base on a per-remote basis was added. See here for more info.
**gitfs_env_whitelist**

New in version 2014.7.0.

Default: `[]`

Used to restrict which environments are made available. Can speed up state runs if the repos in `gitfs_remotes` contain many branches/tags. More information can be found in the *GitFS Walkthrough*.

```
| gitfs_env_whitelist:
|   - base
|   - v1.*
|   - 'mybranch\d+
```

**gitfs_env_blacklist**

New in version 2014.7.0.

Default: `[]`

Used to restrict which environments are made available. Can speed up state runs if the repos in `gitfs_remotes` contain many branches/tags. More information can be found in the *GitFS Walkthrough*.

```
| gitfs_env_blacklist:
|   - base
|   - v1.*
|   - 'mybranch\d+
```

**gitfs_global_lock**

New in version 2015.8.9.

Default: `True`

When set to `False`, if there is an update lock for a gitfs remote and the pid written to it is not running on the master, the lock file will be automatically cleared and a new lock will be obtained. When set to `True`, Salt will simply log a warning when there is an update lock present.

On single-master deployments, disabling this option can help automatically deal with instances where the master was shutdown/restarted during the middle of a gitfs update, leaving a update lock in place.

However, on multi-master deployments with the gitfs cachedir shared via *GlusterFS*, *nfs*, or another network filesystem, it is strongly recommended not to disable this option as doing so will cause lock files to be removed if they were created by a different master.

```
# Disable global lock
gitfs_global_lock: False
```

**GitFS Authentication Options**

These parameters only currently apply to the pygit2 gitfs provider. Examples of how to use these can be found in the *GitFS Walkthrough*. 
**gitfs_user**

New in version 2014.7.0.
Default: ''
Along with `gitfs_password`, is used to authenticate to HTTPS remotes.

```shell
gitfs_user: git
```

**gitfs_password**

New in version 2014.7.0.
Default: ''
Along with `gitfs_user`, is used to authenticate to HTTPS remotes. This parameter is not required if the repository does not use authentication.

```shell
gitfs_password: mypassword
```

**gitfs_insecure_auth**

New in version 2014.7.0.
Default: False
By default, Salt will not authenticate to an HTTP (non-HTTPS) remote. This parameter enables authentication over HTTP. **Enable this at your own risk.**

```shell
gitfs_insecure_auth: True
```

**gitfs_pubkey**

New in version 2014.7.0.
Default: ''
Along with `gitfs_privkey` (and optionally `gitfs_passphrase`), is used to authenticate to SSH remotes. This parameter (or its per-remote counterpart) is required for SSH remotes.

```shell
gitfs_pubkey: /path/to/key.pub
```

**gitfs_privkey**

New in version 2014.7.0.
Default: ''
Along with `gitfs_pubkey` (and optionally `gitfs_passphrase`), is used to authenticate to SSH remotes. This parameter (or its per-remote counterpart) is required for SSH remotes.

```shell
gitfs_privkey: /path/to/key
```
gitfs_passphrase

New in version 2014.7.0.
Default: ''
This parameter is optional, required only when the SSH key being used to authenticate is protected by a passphrase.

| gitfs_passphrase: mypassphrase |

hg: Mercurial Remote File Server Backend

hgfs_remotes

New in version 0.17.0.
Default: []
When using the hg fileserver backend at least one mercurial remote needs to be defined. The user running the salt master will need read access to the repo.
The repos will be searched in order to find the file requested by a client and the first repo to have the file will return it. Branches and/or bookmarks are translated into salt environments, as defined by the hgfs_branch_method parameter.

| hgfs_remotes: |
| - https://username@bitbucket.org/username/reponame |

Note: As of 2014.7.0, it is possible to have per-repo versions of the hgfs_root, hgfs_mountpoint, hgfs_base, and hgfs_branch_method parameters. For example:

| hgfs_remotes: |
| - https://username@bitbucket.org/username/repo1 |
| - base: saltstates |
| - https://username@bitbucket.org/username/repo2: |
| - root: salt |
| - mountpoint: salt://foo/bar/baz |
| - https://username@bitbucket.org/username/repo3: |
| - root: salt/states |
| - branch_method: mixed |

hgfs_branch_method

New in version 0.17.0.
Default: branches
Defines the objects that will be used as fileserver environments.

- branches - Only branches and tags will be used
- bookmarks - Only bookmarks and tags will be used
- mixed - Branches, bookmarks, and tags will be used
**hgfs_branch_method**: mixed

Note: Starting in version 2014.1.0, the value of the `hgfs_base` parameter defines which branch is used as the base environment, allowing for a base environment to be used with an `hgfs_branch_method` of bookmarks.

Prior to this release, the default branch will be used as the base environment.

---

**hgfs_mountpoint**

New in version 2014.7.0.

Default: ''

Specifies a path on the salt fileserver which will be prepended to all files served by hgfs. This option can be used in conjunction with `hgfs_root`. It can also be configured on a per-remote basis, see here for more info.

```python
hgfs_mountpoint: salt://foo/bar
```

Note: The `salt://` protocol designation can be left off (in other words, `foo/bar` and `salt://foo/bar` are equivalent). Assuming a file `baz.sh` in the root of an hgfs remote, this file would be served up via `salt://foo/bar/baz.sh`.

---

**hgfs_root**

New in version 0.17.0.

Default: ''

Relative path to a subdirectory within the repository from which Salt should begin to serve files. This is useful when there are files in the repository that should not be available to the Salt fileserver. Can be used in conjunction with `hgfs_mountpoint`. If used, then from Salt’s perspective the directories above the one specified will be ignored and the relative path will (for the purposes of hgfs) be considered as the root of the repo.

```python
hgfs_root: somefolder/otherfolder
```

Changed in version 2014.7.0: Ability to specify hgfs roots on a per-remote basis was added. See here for more info.

---

**hgfs_base**

New in version 2014.1.0.

Default: default

Defines which branch should be used as the base environment. Change this if `hgfs_branch_method` is set to bookmarks to specify which bookmark should be used as the base environment.

```python
hgfs_base: salt
```
**hgfs_env_whitelist**

New in version 2014.7.0.
Default: []

Used to restrict which environments are made available. Can speed up state runs if your hgfs remotes contain many branches/bookmarks/tags. Full names, globs, and regular expressions are supported. If using a regular expression, the expression must match the entire minion ID.

If used, only branches/bookmarks/tags which match one of the specified expressions will be exposed as fileserver environments.

If used in conjunction with `hgfs_env_blacklist`, then the subset of branches/bookmarks/tags which match the whitelist but do not match the blacklist will be exposed as fileserver environments.

```
hgfs_env_whitelist:
  - base
  - v1.*
  - 'mybranch\d+'
```

**hgfs_env_blacklist**

New in version 2014.7.0.
Default: []

Used to restrict which environments are made available. Can speed up state runs if your hgfs remotes contain many branches/bookmarks/tags. Full names, globs, and regular expressions are supported. If using a regular expression, the expression must match the entire minion ID.

If used, branches/bookmarks/tags which match one of the specified expressions will not be exposed as fileserver environments.

If used in conjunction with `hgfs_env_whitelist`, then the subset of branches/bookmarks/tags which match the whitelist but do not match the blacklist will be exposed as fileserver environments.

```
hgfs_env_blacklist:
  - base
  - v1.*
  - 'mybranch\d+'
```

**svn: Subversion Remote File Server Backend**

**svnfs_remotes**

New in version 0.17.0.
Default: []

When using the `svn` fileserver backend at least one subversion remote needs to be defined. The user running the salt master will need read access to the repo.

The repos will be searched in order to find the file requested by a client and the first repo to have the file will return it. The trunk, branches, and tags become environments, with the trunk being the `base` environment.
svnfs_remotes:
  - svn://foo.com/svn/myproject

Note: As of 2014.7.0, it is possible to have per-repo versions of the following configuration parameters:

- svnfs_root
- svnfs_mountpoint
- svnfs_trunk
- svnfs_branches
- svnfs_tags

For example:

svnfs_remotes:
  - svn://foo.com/svn/project1
  - svn://foo.com/svn/project2:
    - root: salt
    - mountpoint: salt://foo/bar/baz
  - svn://foo.com/svn/project3:
    - root: salt/states
    - branches: branch
    - tags: tag

svnfs_mountpoint

New in version 2014.7.0.
Default: ''

Specifies a path on the salt fileserver which will be prepended to all files served by hgfs. This option can be used in conjunction with svnfs_root. It can also be configured on a per-remote basis, see here for more info.

svnfs_mountpoint: salt://foo/bar

Note: The salt:// protocol designation can be left off (in other words, foo/bar and salt://foo/bar are equivalent). Assuming a file baz.sh in the root of an svnfs remote, this file would be served up via salt://foo/bar/baz.sh.

svnfs_root

New in version 0.17.0.
Default: ''

Relative path to a subdirectory within the repository from which Salt should begin to serve files. This is useful when there are files in the repository that should not be available to the Salt fileserver. Can be used in conjunction with svnfs_mountpoint. If used, then from Salt’s perspective the directories above the one specified will be ignored and the relative path will (for the purposes of svnfs) be considered as the root of the repo.
svnfs_root: somefolder/otherfolder

Changed in version 2014.7.0: Ability to specify svnfs roots on a per-remote basis was added. See here for more info.

**svnfs_trunk**

New in version 2014.7.0.
Default: trunk
Path relative to the root of the repository where the trunk is located. Can also be configured on a per-remote basis, see here for more info.

```
svnfs_trunk: trunk
```

**svnfs_branches**

New in version 2014.7.0.
Default: branches
Path relative to the root of the repository where the branches are located. Can also be configured on a per-remote basis, see here for more info.

```
svnfs_branches: branches
```

**svnfs_tags**

New in version 2014.7.0.
Default: tags
Path relative to the root of the repository where the tags are located. Can also be configured on a per-remote basis, see here for more info.

```
svnfs_tags: tags
```

**svnfs_env_whitelist**

New in version 2014.7.0.
Default: []
Used to restrict which environments are made available. Can speed up state runs if your svnfs remotes contain many branches/tags. Full names, globs, and regular expressions are supported. If using a regular expression, the expression must match the entire minion ID.

If used, only branches/tags which match one of the specified expressions will be exposed as fileserver environments.

If used in conjunction with **svnfs_env_blacklist**, then the subset of branches/tags which match the whitelist but do not match the blacklist will be exposed as fileserver environments.
`svnfs_env_whitelist`:
- base
- v1.*
- 'mybranch\d+'

**svnfs_env_blacklist**

New in version 2014.7.0.

Default: []

Used to restrict which environments are made available. Can speed up state runs if your svnfs remotes contain many branches/tags. Full names, globs, and regular expressions are supported. If using a regular expression, the expression must match the entire minion ID.

If used, branches/tags which match one of the specified expressions will not be exposed as fileserver environments.

If used in conjunction with `svnfs_env_whitelist`, then the subset of branches/tags which match the whitelist but do not match the blacklist will be exposed as fileserver environments.

`svnfs_env_blacklist`:
- base
- v1.*
- 'mybranch\d+'

**minion**: MinionFS Remote File Server Backend

**minionfs_env**

New in version 2014.7.0.

Default: `base`

Environment from which MinionFS files are made available.

`minionfs_env: minionfs`

**minionfs_mountpoint**

New in version 2014.7.0.

Default: ''

Specifies a path on the salt fileserver from which minionfs files are served.

`minionfs_mountpoint: salt://foo/bar`

**Note**: The `salt://` protocol designation can be left off (in other words, `foo/bar` and `salt://foo/bar` are equivalent).
**minionfs_whitelist**

New in version 2014.7.0.

Default: `[]`

Used to restrict which minions’ pushed files are exposed via minionfs. If using a regular expression, the expression must match the entire minion ID.

If used, only the pushed files from minions which match one of the specified expressions will be exposed.

If used in conjunction with `minionfs_blacklist`, then the subset of hosts which match the whitelist but do not match the blacklist will be exposed.

```
minionfs_whitelist:
  - base
  - v1.*
  - 'mybranch\d+'
```

**minionfs_blacklist**

New in version 2014.7.0.

Default: `[]`

Used to restrict which minions’ pushed files are exposed via minionfs. If using a regular expression, the expression must match the entire minion ID.

If used, only the pushed files from minions which match one of the specified expressions will not be exposed.

If used in conjunction with `minionfs_whitelist`, then the subset of hosts which match the whitelist but do not match the blacklist will be exposed.

```
minionfs_blacklist:
  - base
  - v1.*
  - 'mybranch\d+'
```

### 32.8.7 Pillar Configuration

**pillar_roots**

Default:

```
pillar_roots:
  base:
    - /srv/pillar
```

Set the environments and directories used to hold pillar sls data. This configuration is the same as `file_roots`:
pillar_opts

Default: False

The pillar_opts option adds the master configuration file data to a dict in the pillar called master. This can be used to set simple configurations in the master config file that can then be used on minions.

Note that setting this option to True means the master config file will be included in all minion's pillars. While this makes global configuration of services and systems easy, it may not be desired if sensitive data is stored in the master configuration.

```
pillar_opts: False
```

ext_pillar

The ext_pillar option allows for any number of external pillar interfaces to be called when populating pillar data. The configuration is based on ext_pillar functions. The available ext_pillar functions can be found herein:

https://github.com/saltstack/salt/blob/develop/salt/pillar

By default, the ext_pillar interface is not configured to run.

Default: []

```
ext_pillar:
  - hiera: /etc/hiera.yaml
  - cmd_yaml: cat /etc/salt/yaml
  - reclass:
      inventory_base_uri: /etc/reclass
```

There are additional details at Pillars

ext_pillar_first

New in version 2015.5.0.

Default: False

This option allows for external pillar sources to be evaluated before pillar_roots. This allows for targeting file system pillar from ext_pillar.

```
ext_pillar_first: False
```

Git External Pillar (git_pillar) Configuration Options

git_pillar_provider

New in version 2015.8.0.

Specify the provider to be used for git_pillar. Must be either pygit2 or gitpython. If unset, then both will be tried in that same order, and the first one with a compatible version installed will be the provider that is used.

```
git_pillar_provider: gitpython
```
**git_pillar_base**

New in version 2015.8.0.

Default: `master`

If the desired branch matches this value, and the environment is omitted from the `git_pillar` configuration, then the environment for that `git_pillar` remote will be `base`. For example, in the configuration below, the `foo` branch/tag would be assigned to the `base` environment, while `bar` would be mapped to the `bar` environment.

```yaml
git_pillar_base: foo
ext_pillar:
  - git:
    - foo https://mygitserver/git-pillar.git
    - bar https://mygitserver/git-pillar.git
```

**git_pillar_branch**

New in version 2015.8.0.

Default: `master`

If the branch is omitted from a `git_pillar` remote, then this branch will be used instead. For example, in the configuration below, the first two remotes would use the `pillardata` branch/tag, while the third would use the `foo` branch/tag.

```yaml
git_pillar_branch: pillardata
ext_pillar:
  - git:
    - https://mygitserver/pillar1.git
    - https://mygitserver/pillar2.git:
      - root: pillar
    - foo https://mygitserver/pillar3.git
```

**git_pillar_env**

New in version 2015.8.0.

Default: `'` (unset)

Environment to use for `git_pillar` remotes. This is normally derived from the branch/tag (or from a per-remote `env` parameter), but if set this will override the process of deriving the `env` from the branch/tag name. For example, in the configuration below the `foo` branch would be assigned to the `base` environment, while the `bar` branch would need to explicitly have `bar` configured as it's environment to keep it from also being mapped to the `base` environment.

```yaml
git_pillar_env: base
ext_pillar:
  - git:
    - foo https://mygitserver/git-pillar.git
    - bar https://mygitserver/git-pillar.git:
      - env: bar
```
For this reason, this option is recommended to be left unset, unless the use case calls for all (or almost all) of the git_pillar remotes to use the same environment irrespective of the branch/tag being used.

**git_pillar_root**

New in version 2015.8.0.

Default: ''

Path relative to the root of the repository where the git_pillar top file and SLS files are located. In the below configuration, the pillar top file and SLS files would be looked for in a subdirectory called *pillar*.

```yaml
git_pillar_root: pillar

ext_pillar:
  - git:
      - master https://mygitserver/pillar1.git
      - master https://mygitserver/pillar2.git
```

**Note:** This is a global option. If only one or two repos need to have their files sourced from a subdirectory, then *git_pillar_root* can be omitted and the root can be specified on a per-remote basis, like so:

```yaml
ext_pillar:
  - git:
      - master https://mygitserver/pillar1.git
      - master https://mygitserver/pillar2.git:
        - root: pillar
```

In this example, for the first remote the top file and SLS files would be looked for in the root of the repository, while in the second remote the pillar data would be retrieved from the *pillar* subdirectory.

**git_pillar_ssl_verify**

New in version 2015.8.0.

Default: False

Specifies whether or not to ignore SSL certificate errors when contacting the remote repository. The False setting is useful if you’re using a git repo that uses a self-signed certificate. However, keep in mind that setting this to anything other True is a considered insecure, and using an SSH-based transport (if available) may be a better option.

```yaml
git_pillar_ssl_verify: True
```

**git_pillar_global_lock**

New in version 2015.8.9.

Default: True

When set to False, if there is an update/checkout lock for a git_pillar remote and the pid written to it is not running on the master, the lock file will be automatically cleared and a new lock will be obtained. When set to True, Salt will simply log a warning when there is an lock present.
On single-master deployments, disabling this option can help automatically deal with instances where the master was shutdown/restarted during the middle of a git_pillar update/checkout, leaving a lock in place.

However, on multi-master deployments with the git_pillar cachedir shared via GlusterFS, nfs, or another network filesystem, it is strongly recommended not to disable this option as doing so will cause lock files to be removed if they were created by a different master.

```
# Disable global lock
git_pillar_global_lock: False
```

**Git External Pillar Authentication Options**

These parameters only currently apply to the pygit2 git_pillar_provider. Authentication works the same as it does in gitfs, as outlined in the *GitFS Walkthrough*, though the global configuration options are named differently to reflect that they are for git_pillar instead of gitfs.

**git_pillar_user**

New in version 2015.8.0.
Default: ''
Along with `git_pillar_password`, is used to authenticate to HTTPS remotes.

```
git_pillar_user: git
```

**git_pillar_password**

New in version 2015.8.0.
Default: ''
Along with `git_pillar_user`, is used to authenticate to HTTPS remotes. This parameter is not required if the repository does not use authentication.

```
git_pillar_password: mypassword
```

**git_pillar_insecure_auth**

New in version 2015.8.0.
Default: False
By default, Salt will not authenticate to an HTTP (non-HTTPS) remote. This parameter enables authentication over HTTP. **Enable this at your own risk.**

```
git_pillar_insecure_auth: True
```
**git_pillar_pubkey**

New in version 2015.8.0.
Default: ''
Along with `git_pillar_privkey` (and optionally `git_pillar_passphrase`), is used to authenticate to SSH remotes.

```
git_pillar_pubkey: /path/to/key.pub
```

**git_pillar_privkey**

New in version 2015.8.0.
Default: ''
Along with `git_pillar_pubkey` (and optionally `git_pillar_passphrase`), is used to authenticate to SSH remotes.

```
git_pillar_privkey: /path/to/key
```

**git_pillar_passphrase**

New in version 2015.8.0.
Default: ''
This parameter is optional, required only when the SSH key being used to authenticate is protected by a passphrase.

```
git_pillar_passphrase: mypassphrase
```

Pillar Merging Options

**pillar_source_merging_strategy**

New in version 2014.7.0.
Default: smart
The `pillar_source_merging_strategy` option allows you to configure merging strategy between different sources. It accepts 4 values:

- **recurse**:
  it will merge recursively mapping of data. For example, theses 2 sources:

  ```
  foo: 42
  bar:
      element1: True
  
  bar:
      element2: True
  baz: quux
  ```
will be merged as:

```yaml
foo: 42
bar:
  element1: True
  element2: True
baz: quux
```

- **aggregate:**

  instructs aggregation of elements between sources that use the `#!yamlex` renderer.

  For example, these two documents:

  ```yaml
  #!yamlex
  foo: 42
  bar: !aggregate {
      element1: True
    }
  baz: !aggregate quux
  ```

  ```yaml
  #!yamlex
  bar: !aggregate {
      element2: True
    }
  baz: !aggregate quux2
  ```

  will be merged as:

  ```yaml
  foo: 42
  bar:
      element1: True
      element2: True
  baz:
      - quux
      - quux2
  ```

- **overwrite:**

  Will use the behaviour of the 2014.1 branch and earlier.

  Overwrites elements according the order in which they are processed.

  First pillar processed:

  ```yaml
  A:
      first_key: blah
      second_key: blah
  ```

  Second pillar processed:

  ```yaml
  A:
      third_key: blah
      fourth_key: blah
  ```

  will be merged as:

  ```yaml
  A:
      third_key: blah
      fourth_key: blah
  ```
- **smart** (default):
  
  Guesses the best strategy based on the `renderer` setting.

**pillar_merge_lists**

New in version 2015.8.0.
Default: False

Recursively merge lists by aggregating them instead of replacing them.

```
pillar_merge_lists: False
```

**Pillar Cache Options**

**pillar_cache**

Default: False

A master can cache pillars locally to bypass the expense of having to render them for each minion on every request. This feature should only be enabled in cases where pillar rendering time is known to be unsatisfactory and any attendant security concerns about storing pillars in a master cache have been addressed.

When enabling this feature, be certain to read through the additional `pillar_cache_*` configuration options to fully understand the tunable parameters and their implications.

```
pillar_cache: False
```

**Note**: Setting `pillar_cache: True` has no effect on targeting minions with pillar.

**pillar_cache_ttl**

Default: 3600

If and only if a master has set `pillar_cache: True`, the cache TTL controls the amount of time, in seconds, before the cache is considered invalid by a master and a fresh pillar is recompiled and stored.

**pillar_cache_backend**

Default: disk

If an only if a master has set `pillar_cache: True`, one of several storage providers can be utilized:
• disk (default):

  The default storage backend. This caches rendered pillars to the master cache. Rendered pillars are serialized and deserialized as msgpack structures for speed. Note that pillars are stored UNENCRYPTED. Ensure that the master cache has permissions set appropriately (sane defaults are provided).

• memory [EXPERIMENTAL]:

  An optional backend for pillar caches which uses a pure-Python in-memory data structure for maximal performance. There are several caveats, however. First, because each master worker contains its own in-memory cache, there is no guarantee of cache consistency between minion requests. This works best in situations where the pillar rarely if ever changes. Secondly, and perhaps more importantly, this means that unencrypted pillars will be accessible to any process which can examine the memory of the salt-master! This may represent a substantial security risk.

```
pillar_cache_backend: disk
```

### 32.8.8 Syndic Server Settings

A Salt syndic is a Salt master used to pass commands from a higher Salt master to minions below the syndic. Using the syndic is simple. If this is a master that will have syndic servers(s) below it, set the `order_masters` setting to True.

If this is a master that will be running a syndic daemon for passthrough the `syndic_master` setting needs to be set to the location of the master server.

Do not forget that, in other words, it means that it shares with the local minion its ID and PKI_DIR.

**order_masters**

Default: False

Extra data needs to be sent with publications if the master is controlling a lower level master via a syndic minion. If this is the case the order_masters value must be set to True

```
order_masters: False
```

**syndic_master**

Default: ''

If this master will be running a salt-syndic to connect to a higher level master, specify the higher level master with this configuration value.

```
syndic_master: masterofmasters
```

You can optionally connect a syndic to multiple higher level masters by setting the `syndic_master` value to a list:

```
syndic_master:
  - masterofmasters1
  - masterofmasters2
```

Each higher level master must be set up in a multimaster configuration.
**syndic_master_port**

Default: 4506

If this master will be running a salt-syndic to connect to a higher level master, specify the higher level master port with this configuration value.

```
syndic_master_port: 4506
```

**syndic_pidfile**

Default: salt-syndic.pid

If this master will be running a salt-syndic to connect to a higher level master, specify the pidfile of the syndic daemon.

```
syndic_pidfile: syndic.pid
```

**syndic_log_file**

Default: syndic.log

If this master will be running a salt-syndic to connect to a higher level master, specify the log_file of the syndic daemon.

```
syndic_log_file: salt-syndic.log
```

### 32.8.9 Peer Publish Settings

Salt minions can send commands to other minions, but only if the minion is allowed to. By default "Peer Publication" is disabled, and when enabled it is enabled for specific minions and specific commands. This allows secure compartmentalization of commands based on individual minions.

**peer**

Default: {}

The configuration uses regular expressions to match minions and then a list of regular expressions to match functions. The following will allow the minion authenticated as foo.example.com to execute functions from the test and pkg modules.

```
peer:
  foo.example.com:
    - test.*
    - pkg.*
```

This will allow all minions to execute all commands:

```
peer:
  .*:
    - *
```
This is not recommended, since it would allow anyone who gets root on any single minion to instantly have root on all of the minions!

By adding an additional layer you can limit the target hosts in addition to the accessible commands:

```yaml
peer:
  foo.example.com:
    'db*':
      - test.*
      - pkg.*
```

**peer_run**

Default: {}

The peer_run option is used to open up runners on the master to access from the minions. The peer_run configuration matches the format of the peer configuration.

The following example would allow foo.example.com to execute the manage.up runner:

```yaml
peer_run:
  foo.example.com:
    - manage.up
```

### 32.8.10 Master Logging Settings

**log_file**

Default: /var/log/salt/master

The master log can be sent to a regular file, local path name, or network location. See also `log_file`.

Examples:

```
log_file: /var/log/salt/master
```

```
log_file: file:///dev/log
```

```
log_file: udp://loghost:10514
```

**log_level**

Default: warning

The level of messages to send to the console. See also `log_level`.

```
log_level: warning
```

**log_level_logfile**

Default: warning

The level of messages to send to the log file. See also `log_level_logfile`. When it is not set explicitly it will inherit the level set by `log_level` option.
log_level_logfile: warning

**log_datefmt**

Default: %H:%M:%S

The date and time format used in console log messages. See also *log_datefmt*.

```
log_datefmt: '%H:%M:%S'
```

**log_datefmt_logfile**

Default: %Y-%m-%d %H:%M:%S

The date and time format used in log file messages. See also *log_datefmt_logfile*.

```
log_datefmt_logfile: '%Y-%m-%d %H:%M:%S'
```

**log_fmt_console**

Default: [%((levelname)-8s) %message

The format of the console logging messages. See also *log_fmt_console*.

**Note:** Log colors are enabled in *log_fmt_console* rather than the *color* config since the logging system is loaded before the master config.

Console log colors are specified by these additional formatters:

%(colorlevel)s %(colorname)s %(colorprocess)s %(colormsg)s

Since it is desirable to include the surrounding brackets, `[` and `]`, in the coloring of the messages, these color formatters also include padding as well. Color LogRecord attributes are only available for console logging.

```
log_fmt_console: '
log_fmt_console: '[(levelname)-8s] %message''
```

**log_fmt_logfile**

Default: %asctime,%(msecs)03.0f [%(name)-17s][%(levelname)-8s] %message

The format of the log file logging messages. See also *log_fmt_logfile*.

```
log_fmt_logfile: '%asctime,%(msecs)03.0f [%(name)-17s][%(levelname)-8s] %message'
```

**log_granular_levels**

Default: {}

This can be used to control logging levels more specifically. See also *log_granular_levels*. 

---

32.8. Configuring the Salt Master
### 32.8.11 Node Groups

Default: `{}`

Node groups allow for logical groupings of minion nodes. A group consists of a group name and a compound target.

```yaml
nodegroups:
    group1: 'L@foo.domain.com,bar.domain.com,baz.domain.com or bl*.domain.com'
    group2: 'G@os:Debian and foo.domain.com'
    group3: 'G@os:Debian and N@group1'
    group4:
        - 'G@foo:bar'
        - 'or'
        - 'G@foo:baz'
```

More information on using nodegroups can be found [here](#).

### 32.8.12 Range Cluster Settings

**range_server**

Default: `'range:80'`

The range server (and optional port) that serves your cluster information [https://github.com/ytoolshed/range/wiki/%22yamlfile%22-module-file-spec](https://github.com/ytoolshed/range/wiki/%22yamlfile%22-module-file-spec)

```yaml
range_server: range:80
```

### 32.8.13 Include Configuration

**default_include**

Default: `master.d/* .conf`

The master can include configuration from other files. Per default the master will automatically include all config files from `master.d/* .conf` where `master.d` is relative to the directory of the master configuration file.

**include**

Default: not defined

The master can include configuration from other files. To enable this, pass a list of paths to this option. The paths can be either relative or absolute; if relative, they are considered to be relative to the directory the main minion configuration file lives in. Paths can make use of shell-style globbing. If no files are matched by a path passed to this option then the master will log a warning message.

```bash
# Include files from a master.d directory in the same directory as the master config file
include: master.d/*
```
# Include a single extra file into the configuration
include: /etc/roles/webserver

# Include several files and the master.d directory
include:
  - extra_config
  - master.d/*
  - /etc/roles/webserver

32.8.14 Windows Software Repo Settings

**winrepo_provider**

New in version 2015.8.0.

Specify the provider to be used for winrepo. Must be either pygit2 or gitpython. If unset, then both will be tried in that same order, and the first one with a compatible version installed will be the provider that is used.

```bash
winrepo_provider: gitpython
```

**winrepo_dir**

Changed in version 2015.8.0: Renamed from win_repo to winrepo_dir.

Default: /srv/salt/win/repo

Location on the master where the winrepo_remotes are checked out for pre-2015.8.0 minions. 2015.8.0 and later minions use winrepo_remotes_ng instead.

```bash
winrepo_dir: /srv/salt/win/repo
```

**winrepo_dir_ng**

New in version 2015.8.0: A new ng repo was added.

Default: /srv/salt/win/repo-ng

Location on the master where the winrepo_remotes_ng are checked out for 2015.8.0 and later minions.

```bash
winrepo_dir_ng: /srv/salt/win/repo-ng
```

**winrepo_cachefile**

Changed in version 2015.8.0: Renamed from win_repo_mastercachefile to winrepo_cachefile

Note: 2015.8.0 and later minions do not use this setting since the cachefile is now located on the minion.

Default: winrepo.p

Path relative to `winrepo_dir` where the winrepo cache should be created.
**winrepo_cachefile**

`winrepo.p`

---

**winrepo_remotes**

Changed in version 2015.8.0: Renamed from `win_gitrepos` to `winrepo_remotes`.

Default: `['https://github.com/saltstack/salt-winrepo.git']`

List of git repositories to checkout and include in the winrepo for pre-2015.8.0 minions. 2015.8.0 and later minions use `winrepo_remotes_ng` instead.

```
winrepo_remotes:
  - https://github.com/saltstack/salt-winrepo.git
```

To specify a specific revision of the repository, prepend a commit ID to the URL of the repository:

```
winrepo_remotes:
  - '<commit_id> https://github.com/saltstack/salt-winrepo.git'
```

Replace `<commit_id>` with the SHA1 hash of a commit ID. Specifying a commit ID is useful in that it allows one to revert back to a previous version in the event that an error is introduced in the latest revision of the repo.

**winrepo_remotes-ng**

New in version 2015.8.0: A new `ng` repo was added.

Default: `['https://github.com/saltstack/salt-winrepo-ng.git']`

List of git repositories to checkout and include in the winrepo for 2015.8.0 and later minions.

```
winrepo_remotes-ng:
  - https://github.com/saltstack/salt-winrepo-ng.git
```

To specify a specific revision of the repository, prepend a commit ID to the URL of the repository:

```
winrepo_remotes-ng:
  - '<commit_id> https://github.com/saltstack/salt-winrepo-ng.git'
```

Replace `<commit_id>` with the SHA1 hash of a commit ID. Specifying a commit ID is useful in that it allows one to revert back to a previous version in the event that an error is introduced in the latest revision of the repo.

**winrepo_branch**

New in version 2015.8.0.

Default: `master`

If the branch is omitted from a winrepo remote, then this branch will be used instead. For example, in the configuration below, the first two remotes would use the `winrepo` branch/tag, while the third would use the `foo` branch/tag.

```
winrepo_branch: winrepo
ext_pillar:
  - git:
    - https://mygitserver/winrepo1.git
```
- https://mygitserver/winrepo2.git:
- foo https://mygitserver/winrepo3.git

**winrepo_ssl_verify**

New in version 2015.8.0.
Default: False

Specifies whether or not to ignore SSL certificate errors when contacting the remote repository. The False setting is useful if you're using a git repo that uses a self-signed certificate. However, keep in mind that setting this to anything other than True is considered insecure, and using an SSH-based transport (if available) may be a better option.

```yaml
winrepo_ssl_verify: True
```

**Winrepo Authentication Options**

These parameters only currently apply to the pygit2 winrepo_provider. Authentication works the same as it does in gitfs, as outlined in the GitFS Walkthrough, though the global configuration options are named differently to reflect that they are for winrepo instead of gitfs.

**winrepo_user**

New in version 2015.8.0.
Default: ''

Along with winrepo_password, is used to authenticate to HTTPS remotes.

```yaml
winrepo_user: git
```

**winrepo_password**

New in version 2015.8.0.
Default: ''

Along with winrepo_user, is used to authenticate to HTTPS remotes. This parameter is not required if the repository does not use authentication.

```yaml
winrepo_password: mypassword
```

**winrepo_insecure_auth**

New in version 2015.8.0.
Default: False

By default, Salt will not authenticate to an HTTP (non-HTTPS) remote. This parameter enables authentication over HTTP. Enable this at your own risk.
winrepo_insecure_auth: True

winrepo_pubkey

New in version 2015.8.0.
Default: ''
Along with winrepo_privkey (and optionally winrepo_passphrase), is used to authenticate to SSH remotes.

winrepo_pubkey: /path/to/key.pub

winrepo_privkey

New in version 2015.8.0.
Default: ''
Along with winrepo_pubkey (and optionally winrepo_passphrase), is used to authenticate to SSH remotes.

winrepo_privkey: /path/to/key

winrepo_passphrase

New in version 2015.8.0.
Default: ''
This parameter is optional, required only when the SSH key being used to authenticate is protected by a passphrase.

winrepo_passphrase: mypassphrase

32.9 Configuring the Salt Minion

The Salt system is amazingly simple and easy to configure. The two components of the Salt system each have a respective configuration file. The salt-master is configured via the master configuration file, and the salt-minion is configured via the minion configuration file.

See also:
example minion configuration file

The Salt Minion configuration is very simple. Typically, the only value that needs to be set is the master value so the minion knows where to locate its master.

By default, the salt-minion configuration will be in /etc/salt/minion. A notable exception is FreeBSD, where the configuration will be in /usr/local/etc/salt/minion.
32.9.1 Minion Primary Configuration

**master**

Default: salt
The hostname or ipv4 of the master.
Default: salt

```yaml
master: salt
```

The option can also be set to a list of masters, enabling *multi-master* mode.

```yaml
master:
  - address1
  - address2
```

Changed in version 2014.7.0: The master can be dynamically configured. The *master* value can be set to an module function which will be executed and will assume that the returning value is the ip or hostname of the desired master. If a function is being specified, then the *master_type* option must be set to *func*, to tell the minion that the value is a function to be run and not a fully-qualified domain name.

```yaml
master: module.function
master_type: func
```

In addition, instead of using multi-master mode, the minion can be configured to use the list of master addresses as a failover list, trying the first address, then the second, etc. until the minion successfully connects. To enable this behavior, set *master_type* to *failover*:

```yaml
master:
  - address1
  - address2
master_type: failover
```

**master_type**

New in version 2014.7.0.
Default: str
The type of the *master* variable. Can be *str*, *failover* or *func*.

```yaml
master_type: failover
```

If this option is set to *failover*, *master* must be a list of master addresses. The minion will then try each master in the order specified in the list until it successfully connects. *master_alive_interval* must also be set, this determines how often the minion will verify the presence of the master.

```yaml
master_type: func
```

If the master needs to be dynamically assigned by executing a function instead of reading in the static master value, set this to *func*. This can be used to manage the minion's master setting from an execution module. By simply changing the algorithm in the module to return a new master ip/fqdn, restart the minion and it will connect to the new master.
max_event_size

New in version 2014.7.0.
Default: 1048576
Passing very large events can cause the minion to consume large amounts of memory. This value tunes the maximum size of a message allowed onto the minion event bus. The value is expressed in bytes.

```
max_event_size: 1048576
```

master_alive_interval

Default: 0
Configures how often, in seconds, the minion will verify that the current master is alive and responding. The minion will try to establish a connection to the next master in the list if it finds the existing one is dead.

```
master_alive_interval: 30
```

master_shuffle

New in version 2014.7.0.
Default: False
If `master` is a list of addresses and `conf_minion` `master_type` is `failover`, shuffle them before trying to connect to distribute the minions over all available masters. This uses Python's `random.shuffle` method.

```
master_shuffle: True
```

random_master

Default: False
If `master` is a list of addresses, shuffle them before trying to connect to distribute the minions over all available masters. This uses Python's `random.randint` method.

```
random_master: True
```

retry_dns

Default: 30
Set the number of seconds to wait before attempting to resolve the master hostname if name resolution fails. Defaults to 30 seconds. Set to zero if the minion should shutdown and not retry.

```
retry_dns: 30
```
**master_port**

Default: 4506

The port of the master ret server, this needs to coincide with the ret_port option on the Salt master.

```
master_port: 4506
```

**user**

Default: root

The user to run the Salt processes

```
user: root
```

**sudo_user**

Default: ''

The user to run salt remote execution commands as via sudo. If this option is enabled then sudo will be used to change the active user executing the remote command. If enabled the user will need to be allowed access via the sudoers file for the user that the salt minion is configured to run as. The most common option would be to use the root user. If this option is set the `user` option should also be set to a non-root user. If migrating from a root minion to a non root minion the minion cache should be cleared and the minion pki directory will need to be changed to the ownership of the new user.

```
sudo_user: root
```

**pidfile**

Default: /var/run/salt-minion.pid

The location of the daemon's process ID file

```
pidfile: /var/run/salt-minion.pid
```

**root_dir**

Default: /

This directory is prepended to the following options: `pki_dir`, `cachedir`, `log_file`, `sock_dir`, and `pidfile`.

```
root_dir: /
```

**conf_file**

Default: /etc/salt/minion

The path to the minion's configuration file.
conf_file: /etc/salt/minion

pki_dir
Default: /etc/salt/pki/minion
The directory used to store the minion's public and private keys.
pki_dir: /etc/salt/pki/minion

id
Default: the system's hostname
See also:
Salt Walkthrough
The Setting up a Salt Minion section contains detailed information on how the hostname is determined.
Explicitly declare the id for this minion to use. Since Salt uses detached ids it is possible to run multiple minions on
the same machine but with different ids.
id: foo.bar.com

minion_id_caching
New in version 0.17.2.
Default: True
Caches the minion id to a file when the minion's `id` is not statically defined in the minion config.
This setting prevents potential problems when automatic minion id resolution changes, which can cause the minion
to lose connection with the master. To turn off minion id caching, set this config to False.
For more information, please see Issue #7558 and Pull Request #8488.
minion_id_caching: True

append_domain
Default: None
Append a domain to a hostname in the event that it does not exist. This is useful for systems where
socket.getfqdn() does not actually result in a FQDN (for instance, Solaris).
append_domain: foo.org

cachedir
Default: /var/cache/salt/minion
The location for minion cache data.
This directory may contain sensitive data and should be protected accordingly.

```
cachedir: /var/cache/salt/minion
```

**verify_env**

Default: True

Verify and set permissions on configuration directories at startup.

```
verify_env: True
```

*Note:* When set to True the verify_env option requires WRITE access to the configuration directory (/etc/salt/). In certain situations such as mounting /etc/salt/ as read-only for templating this will create a stack trace when state.apply is called.

**cache_jobs**

Default: False

The minion can locally cache the return data from jobs sent to it, this can be a good way to keep track of the minion side of the jobs the minion has executed. By default this feature is disabled, to enable set cache_jobs to True.

```
cache_jobs: False
```

**grains**

Default: (empty)

*See also:*

*Grains in the Minion Config*

Statically assigns grains to the minion.

```
grains:
  roles:
    - webserver
    - memcache
  deployment: datacenter4
  cabinet: 13
  cab_u: 14-15
```

**grains_cache**

Default: False

The minion can locally cache grain data instead of refreshing the data each time the grain is referenced. By default this feature is disabled, to enable set grains_cache to True.

```
grains_cache: False
```
**mine_enabled**

New in version 2015.8.10.
Default: True
Determines whether or not the salt minion should run scheduled mine updates.

```
mine_enabled: True
```

**mine_return_job**

New in version 2015.8.10.
Default: False
Determines whether or not scheduled mine updates should be accompanied by a job return for the job cache.

```
mine_return_job: False
```

**mine_functions**

Default: Empty
Designate which functions should be executed at mine_interval intervals on each minion. See this documentation on the Salt Mine for more information. Note these can be defined in the pillar for a minion as well.

```
example minion configuration file
```

```
mine_functions:
    test.ping: []
    network.ip_addrs:
        interface: eth0
        cidr: '10.0.0.0/8'
```

**sock_dir**

Default: /var/run/salt/minion
The directory where Unix sockets will be kept.

```
sock_dir: /var/run/salt/minion
```

**backup_mode**

Default: ''
Backup files replaced by file.managed and file.recurse under cachedir.

```
backup_mode: minion
```
**acceptance_wait_time**

Default: 10

The number of seconds to wait until attempting to re-authenticate with the master.

```
acceptance_wait_time: 10
```

**acceptance_wait_time_max**

Default: 0

The maximum number of seconds to wait until attempting to re-authenticate with the master. If set, the wait will increase by `acceptance_wait_time` seconds each iteration.

```
acceptance_wait_time_max: 0
```

**random_reauth_delay**

Default: 10

When the master key changes, the minion will try to re-auth itself to receive the new master key. In larger environments this can cause a syn-flood on the master because all minions try to re-auth immediately. To prevent this and have a minion wait for a random amount of time, use this optional parameter. The wait-time will be a random number of seconds between 0 and the defined value.

```
random_reauth_delay: 60
```

**auth_tries**

New in version 2014.7.0.

Default: 7

The number of attempts to authenticate to a master before giving up. Or, more technically, the number of consecutive SaltReqTimeoutErrors that are acceptable when trying to authenticate to the master.

```
auth_tries: 7
```

**auth_timeout**

New in version 2014.7.0.

Default: 60

When waiting for a master to accept the minion’s public key, salt will continuously attempt to reconnect until successful. This is the timeout value, in seconds, for each individual attempt. After this timeout expires, the minion will wait for `acceptance_wait_time` seconds before trying again. Unless your master is under unusually heavy load, this should be left at the default.

```
auth_timeout: 60
```
auth_safemode

New in version 2014.7.0.
Default: False
If authentication fails due to SaltReqTimeoutError during a ping_interval, this setting, when set to True, will cause a sub-minion process to restart.

| auth_safemode: False |

recon_default

Default: 1000
The interval in milliseconds that the socket should wait before trying to reconnect to the master (1000ms = 1 second).

| recon_default: 1000 |

recon_max

Default: 10000
The maximum time a socket should wait. Each interval the time to wait is calculated by doubling the previous time. If recon_max is reached, it starts again at the recon_default.

**Short example:**
- reconnect 1: the socket will wait `recon_default` milliseconds
- reconnect 2: `recon_default` * 2
- reconnect 3: (`recon_default` * 2) * 2
- reconnect 4: value from previous interval * 2
- reconnect 5: value from previous interval * 2
- reconnect x: if value >= recon_max, it starts again with recon_default

| recon_max: 10000 |

recon_randomize

Default: True
Generate a random wait time on minion start. The wait time will be a random value between recon_default and recon_default + recon_max. Having all minions reconnect with the same recon_default and recon_max value kind of defeats the purpose of being able to change these settings. If all minions have the same values and the setup is quite large (several thousand minions), they will still flood the master. The desired behavior is to have time-frame within all minions try to reconnect.

| recon_randomize: True |
**return_retry_timer**

Default: 5
The default timeout for a minion return attempt.

```yaml
return_retry_timer: 5
```

**return_retry_timer_max**

Default: 10
The maximum timeout for a minion return attempt. If non-zero the minion return retry timeout will be a random int between `return_retry_timer` and `return Retry_timer_max`.

```yaml
return_retry_timer_max: 10
```

**cache_sreqs**

Default: True
The connection to the master ret_port is kept open. When set to False, the minion creates a new connection for every return to the master.

```yaml
cache_sreqs: True
```

**ipc_mode**

Default: ipc
Windows platforms lack POSIX IPC and must rely on slower TCP based inter-process communications. Set `ipc_mode` to `tcp` on such systems.

```yaml
ipc_mode: ipc
```

**tcp_pub_port**

Default: 4510
Publish port used when `ipc_mode` is set to `tcp`.

```yaml
tcp_pub_port: 4510
```

**tcp_pull_port**

Default: 4511
Pull port used when `ipc_mode` is set to `tcp`.

```yaml
tcp_pull_port: 4511
```
transport

Default: `zeromq`

Changes the underlying transport layer. ZeroMQ is the recommended transport while additional transport layers are under development. Supported values are `zeromq`, `raet` (experimental), and `tcp` (experimental). This setting has a significant impact on performance and should not be changed unless you know what you are doing! Transports are explained in Salt Transports.

```
transport: zeromq
```

syndic_finger

Default: `'`

The key fingerprint of the higher-level master for the syndic to verify it is talking to the intended master.

```
```

32.9.2 Minion Module Management

disable_modules

Default: `[]` (all modules are enabled by default)

The event may occur in which the administrator desires that a minion should not be able to execute a certain module. The `sys` module is built into the minion and cannot be disabled.

This setting can also tune the minion. Because all modules are loaded into system memory, disabling modules will lower the minion’s memory footprint.

Modules should be specified according to their file name on the system and not by their virtual name. For example, to disable `cmd`, use the string `cmdmod` which corresponds to `salt.modules.cmdmod`.

```
disable_modules:
  - test
  - solr
```

disable_returners

Default: `[]` (all returners are enabled by default)

If certain returners should be disabled, this is the place

```
disable_returners:
  - mongo_return
```

module_dirs

Default: `[]`

A list of extra directories to search for Salt modules
module_dirs:
    - /var/lib/salt/modules

**returner_dirs**

Default: []
A list of extra directories to search for Salt returners

```python
returner_dirs:
    - /var/lib/salt/returners
```

**states_dirs**

Default: []
A list of extra directories to search for Salt states

```python
states_dirs:
    - /var/lib/salt/states
```

**grains_dirs**

Default: []
A list of extra directories to search for Salt grains

```python
grains_dirs:
    - /var/lib/salt/grains
```

**render_dirs**

Default: []
A list of extra directories to search for Salt renderers

```python
render_dirs:
    - /var/lib/salt/renderers
```

**cython_enable**

Default: False
Set this value to true to enable auto-loading and compiling of .pyx modules. This setting requires that gcc and cython are installed on the minion.

```python
cython_enable: False
```
**enable_zip_modules**

New in version 2015.8.0.
Default: False

Set this value to true to enable loading of zip archives as extension modules. This allows for packing module code with specific dependencies to avoid conflicts and/or having to install specific modules' dependencies in system libraries.

```
enable_zip_modules: False
```

**providers**

Default: (empty)

A module provider can be statically overwritten or extended for the minion via the `providers` option. This can be done on an individual basis in an SLS file, or globally here in the minion config, like below.

```
providers:
  service: systemd
```

### 32.9.3 State Management Settings

**renderer**

Default: yaml_jinja

The default renderer used for local state executions

```
renderer: yaml_jinja
```

**state_verbose**

Default: True

Controls the verbosity of runs. By default, the results of all states are returned, but setting this value to False will cause salt to only display output for states that failed or states that have changes.

```
state_verbose: True
```

**state_output**

Default: full

The state_output setting changes if the output is the full multi line output for each changed state if set to 'full', but if set to 'terse' the output will be shortened to a single line.

```
state_output: full
```
**autoload_dynamic_modules**

Default: True

autoload_dynamic_modules turns on automatic loading of modules found in the environments on the master. This is turned on by default. To turn off auto-loading modules when states run, set this value to False.

```
autoload_dynamic_modules: True
```

Default: True

clean_dynamic_modules keeps the dynamic modules on the minion in sync with the dynamic modules on the master. This means that if a dynamic module is not on the master it will be deleted from the minion. By default this is enabled and can be disabled by changing this value to False.

```
clean_dynamic_modules: True
```

**environment**

Normally the minion is not isolated to any single environment on the master when running states, but the environment can be isolated on the minion side by statically setting it. Remember that the recommended way to manage environments is to isolate via the top file.

```
environment: dev
```

**state_top_saltenv**

This option has no default value. Set it to an environment name to ensure that only the top file from that environment is considered during a `highstate`.

**Note:** Using this value does not change the merging strategy. For instance, if `top_file_merging_strategy` is left at its default, and `state_top_saltenv` is set to `foo`, then any sections for environments other than `foo` in the top file for the `foo` environment will be ignored. With `state_top_saltenv` set to `base`, all states from all environments in the `base` top file will be applied, while all other top files are ignored.

```
state_top_saltenv: dev
```

**top_file_merging_strategy**

Default: merge

When no specific fileserver environment (a.k.a. saltenv) has been specified for a `highstate`, all environments' top files are inspected. This config option determines how the SLS targets in those top files are handled.

When set to the default value of `merge`, all SLS files are interpreted. The first target expression for a given environment is kept, and when the same target expression is used in a different top file evaluated later, it is ignored. The environments will be evaluated in no specific order, for greater control over the order in which the environments are evaluated use `env_order`.

When set to `same`, then for each environment, only that environment's top file is processed, with the others being ignored. For example, only the `dev` environment's top file will be processed for the `dev` environment, and any SLS targets defined for `dev` in the `base` environment's (or any other environment's) top file will be ignored. If an
environment does not have a top file, then the top file from the `default_top` config parameter will be used as a fallback.

```yaml
top_file_merging_strategy: same
```

**env_order**

Default: `[]`

When `top_file_merging_strategy` is set to `merge`, and no environment is specified for a `highstate`, this config option allows for the order in which top files are evaluated to be explicitly defined.

```yaml
env_order:
  - base
  - dev
  - qa
```

**default_top**

Default: `base`

When `top_file_merging_strategy` is set to `same`, and no environment is specified for a `highstate`, this config option specifies a fallback environment in which to look for a top file if an environment lacks one.

```yaml
default_top: dev
```

### 32.9.4 File Directory Settings

**file_client**

Default: `remote`

The client defaults to looking on the master server for files, but can be directed to look on the minion by setting this parameter to `local`.

```yaml
file_client: remote
```

**use_master_when_local**

Default: `False`

When using a local `file_client`, this parameter is used to allow the client to connect to a master for remote execution.

```yaml
use_master_when_local: False
```

**file_roots**

Default:
When using a local `file_client`, this parameter is used to setup the fileserver's environments. This parameter operates identically to the `master config parameter` of the same name.

```
file_roots:
  base:
    - /srv/salt
  dev:
    - /srv/salt/dev/services
    - /srv/salt/dev/states
  prod:
    - /srv/salt/prod/services
    - /srv/salt/prod/states
```

### fileserver_followsymlinks

New in version 2014.1.0.

Default: True

By default, the file_server follows symlinks when walking the filesystem tree. Currently this only applies to the default roots fileserver_backend.

```
fileserver_followsymlinks: True
```

### fileserver_ignoresymlinks

New in version 2014.1.0.

Default: False

If you do not want symlinks to be treated as the files they are pointing to, set `fileserver_ignoresymlinks` to True. By default this is set to False. When set to True, any detected symlink while listing files on the Master will not be returned to the Minion.

```
fileserver_ignoresymlinks: False
```

### fileserver_limit_traversal

New in version 2014.1.0.

Default: False

By default, the Salt fileserver recurses fully into all defined environments to attempt to find files. To limit this behavior so that the fileserver only traverses directories with SLS files and special Salt directories like _modules, set `fileserver_limit_traversal` to True. This might be useful for installations where a file root has a very large number of files and performance is impacted.

```
fileserver_limit_traversal: False
```
hash_type

Default: md5

The hash_type is the hash to use when discovering the hash of a file on the local fileserver. The default is md5, but sha1, sha224, sha256, sha384, and sha512 are also supported.

```plaintext
hash_type: md5
```

### 32.9.5 Pillar Settings

**pillar_roots**

Default:

```plaintext
pillar_roots:
  base:
    - /srv/pillar
```

When using a local `file_client`, this parameter is used to setup the pillar environments.

```plaintext
pillar_roots:
  base:
    - /srv/pillar
  dev:
    - /srv/pillar/dev
  prod:
    - /srv/pillar/prod
```

**pillarenv**

Default: None

Isolates the pillar environment on the minion side. This functions the same as the environment setting, but for pillar instead of states.

```plaintext
pillarenv: None
```

**file_recv_max_size**

New in version 2014.7.0.

Default: 100

Set a hard-limit on the size of the files that can be pushed to the master. It will be interpreted as megabytes.

```plaintext
file_recv_max_size: 100
```

### 32.9.6 Security Settings

**open_mode**

Default: False
Open mode can be used to clean out the PKI key received from the Salt master, turn on open mode, restart the minion, then turn off open mode and restart the minion to clean the keys.

`open_mode: False`

**master_finger**

Default: ''
Fingerprint of the master public key to validate the identity of your Salt master before the initial key exchange. The master fingerprint can be found by running `salt-key -F master` on the Salt master.

**verify_master_pubkey_sign**

Default: False
Enables verification of the master-public-signature returned by the master in auth-replies. Please see the tutorial on how to configure this properly [Multimaster-PKI with Failover Tutorial](#).

New in version 2014.7.0.

`verify_master_pubkey_sign: True`

If this is set to True, `master_sign_pubkey` must be also set to True in the master configuration file.

**master_sign_key_name**

Default: master_sign
The filename without the .pub suffix of the public key that should be used for verifying the signature from the master. The file must be located in the minion's pki directory.

New in version 2014.7.0.

`master_sign_key_name: <filename_without_suffix>`

**always_verify_signature**

Default: False
If `verify_master_pubkey_sign` is enabled, the signature is only verified if the public-key of the master changes. If the signature should always be verified, this can be set to True.

New in version 2014.7.0.

`always_verify_signature: True`
32.9.7 Thread Settings

Default: True

Disable multiprocessing support by default when a minion receives a publication a new process is spawned and the command is executed therein.

```yaml
multiprocessing: True
```

32.9.8 Minion Logging Settings

**log_file**

Default: /var/log/salt/minion

The minion log can be sent to a regular file, local path name, or network location. See also `log_file`.

Examples:

```yaml
log_file: /var/log/salt/minion
log_file: file:///dev/log
log_file: udp://loghost:10514
```

**log_level**

Default: warning

The level of messages to send to the console. See also `log_level`.

```yaml
log_level: warning
```

**log_level_logfile**

Default: warning

The level of messages to send to the log file. See also `log_level_logfile`. When it is not set explicitly it will inherit the level set by `log_level` option.

```yaml
log_level_logfile: warning
```

**log_datefmt**

Default: %H:%M:%S

The date and time format used in console log messages. See also `log_datefmt`.

```yaml
log_datefmt: '%H:%M:%S'
```
**log_datefmt_logfile**

Default: `%Y-%m-%d %H:%M:%S`

The date and time format used in log file messages. See also `log_datefmt_logfile`.

| log_datefmt_logfile: '%%Y-%%m-%%d %H:%%M:%%S' |

**log_fmt_console**

Default: `%(levelname)-8s %(message)s`

The format of the console logging messages. See also `log_fmt_console`.

**Note:** Log colors are enabled in `log_fmt_console` rather than the `color` config since the logging system is loaded before the minion config.

Console log colors are specified by these additional formatters:

`%(colorlevel)s %(colorname)s %(colorprocess)s %(colormsg)s`

Since it is desirable to include the surrounding brackets, `[` and `]`, in the coloring of the messages, these color formatters also include padding as well. Color LogRecord attributes are only available for console logging.

| log_fmt_console: '%%(colorlevel)s %%(colormsg)s' |
| log_fmt_console: '%%(%(levelname)-8s) %%(message)s' |

**log_fmt_logfile**

Default: `%(asctime)s,%(msecs)03.0f [%%(name)-17s][%(levelname)-8s] %(message)s`

The format of the log file logging messages. See also `log_fmt_logfile`.

| log_fmt_logfile: '%%(asctime)s,%(msecs)03.0f [%%(name)-17s][%(levelname)-8s] %(message)s' |

**log_granular_levels**

Default: `{}`

This can be used to control logging levels more specifically. See also `log_granular_levels`.

**zmq_monitor**

Default: False

To diagnose issues with minions disconnecting or missing returns, ZeroMQ supports the use of monitor sockets to log connection events. This feature requires ZeroMQ 4.0 or higher.

To enable ZeroMQ monitor sockets, set `zmq_monitor` to `True` and log at a debug level or higher.

A sample log event is as follows:

```
[DEBUG ] ZeroMQ event: {'endpoint': 'tcp://127.0.0.1:4505', 'event': 512, 'value': 27, 'description': 'EVENT_DISCONNECTED'}
```
Salt Documentation, Release 2015.8.12

All events logged will include the string ZeroMQ event. A connection event should be logged as the minion starts up and initially connects to the master. If not, check for debug log level and that the necessary version of ZeroMQ is installed.

**failhard**

Default: False

Set the global failhard flag. This informs all states to stop running states at the moment a single state fails

```makefile
failhard: False
```

### 32.9.9 Include Configuration

**default_include**

Default: minion.d/*.conf

The minion can include configuration from other files. Per default the minion will automatically include all config files from `minion.d/*.conf` where minion.d is relative to the directory of the minion configuration file.

**Note:** Salt creates files in the `minion.d` directory for its own use. These files are prefixed with an underscore. A common example of this is the `_schedule.conf` file.

**include**

Default: not defined

The minion can include configuration from other files. To enable this, pass a list of paths to this option. The paths can be either relative or absolute; if relative, they are considered to be relative to the directory the main minion configuration file lives in. Paths can make use of shell-style globbing. If no files are matched by a path passed to this option then the minion will log a warning message.

```makefile
# Include files from a minion.d directory in the same directory as the minion config file
include: minion.d/*.conf

# Include a single extra file into the configuration
include: /etc/roles/webserver

# Include several files and the minion.d directory
include:
  - extra_config
  - minion.d/*
  - /etc/roles/webserver
```

### 32.9.10 Frozen Build Update Settings

These options control how `salt.modules.saltutil.update()` works with esky frozen apps. For more information look at https://github.com/cloudmatrix/esky/.
**update_url**

Default: False (Update feature is disabled)

The url to use when looking for application updates. Esky depends on directory listings to search for new versions. A webserver running on your Master is a good starting point for most setups.

```yaml
update_url: 'http://salt.example.com/minion-updates'
```

**update_restart_services**

Default: [] (service restarting on update is disabled)

A list of services to restart when the minion software is updated. This would typically just be a list containing the minion's service name, but you may have other services that need to go with it.

```yaml
update_restart_services: ['salt-minion']
```

### 32.9.11 Standalone Minion Windows Software Repo Settings

**Important:** To use these config options, the minion must be running in masterless mode (set `file_client` to `local`).

**winrepo_dir**

Changed in version 2015.8.0: Renamed from `win_repo` to `winrepo_dir`. Also, this option did not have a default value until this version.

Default: C:\salt\srv\salt\win\repo

Location on the minion where the `winrepo_remotes` are checked out.

```yaml
winrepo_dir: 'D:\winrepo'
```

**winrepo_cachefile**

Changed in version 2015.8.0: Renamed from `win_repo_cachefile` to `winrepo_cachefile`. Also, this option did not have a default value until this version.

Default: `winrepo.p`

Path relative to `winrepo_dir` where the winrepo cache should be created.

```yaml
winrepo_cachefile: winrepo.p
```

**winrepo_remotes**

Changed in version 2015.8.0: Renamed from `win_gitrepos` to `winrepo_remotes`. Also, this option did not have a default value until this version.

New in version 2015.8.0.
Default: ['https://github.com/saltstack/salt-winrepo.git']

List of git repositories to checkout and include in the winrepo

```
winrepo_remotes:
    - https://github.com/saltstack/salt-winrepo.git
```

To specify a specific revision of the repository, prepend a commit ID to the URL of the repository:

```
winrepo_remotes:
    - '<commit_id> https://github.com/saltstack/salt-winrepo.git'
```

Replace `<commit_id>` with the SHA1 hash of a commit ID. Specifying a commit ID is useful in that it allows one to revert back to a previous version in the event that an error is introduced in the latest revision of the repo.

### 32.10 Running the Salt Master/Minion as an Unprivileged User

While the default setup runs the master and minion as the root user, some may consider it an extra measure of security to run the master as a non-root user. Keep in mind that doing so does not change the master’s capability to access minions as the user they are running as. Due to this many feel that running the master as a non-root user does not grant any real security advantage which is why the master has remained as root by default.

**Note:** Some of Salt’s operations cannot execute correctly when the master is not running as root, specifically the pam external auth system, as this system needs root access to check authentication.

As of Salt 0.9.10 it is possible to run Salt as a non-root user. This can be done by setting the `user` parameter in the master configuration file, and restarting the `salt-master` service.

The minion has its own `user` parameter as well, but running the minion as an unprivileged user will keep it from making changes to things like users, installed packages, etc. unless access controls (sudo, etc.) are setup on the minion to permit the non-root user to make the needed changes.

In order to allow Salt to successfully run as a non-root user, ownership, and permissions need to be set such that the desired user can read from and write to the following directories (and their subdirectories, where applicable):

- `/etc/salt`
- `/var/cache/salt`
- `/var/log/salt`
- `/var/run/salt`

Ownership can be easily changed with `chown`, like so:

```
# chown -R user /etc/salt /var/cache/salt /var/log/salt /var/run/salt
```

**Warning:** Running either the master or minion with the `root_dir` parameter specified will affect these paths, as well setting options like `pki_dir, cachedir, log_file`, and other options that normally live in the above directories.
32.11 Logging

The salt project tries to get the logging to work for you and help us solve any issues you might find along the way. If you want to get some more information on the nitty-gritty of salt’s logging system, please head over to the logging development document, if all you’re after is salt’s logging configurations, please continue reading.

32.11.1 Available Configuration Settings

log_file

The log records can be sent to a regular file, local path name, or network location. Remote logging works best when configured to use rsyslogd(8) (e.g., file:///dev/log), with rsyslogd(8) configured for network logging. The format for remote addresses is: <file|udp|tcp>://<host|socketpath>:[port-if-required]/<log-facility>.

Default: Dependent of the binary being executed, for example, for salt-master, /var/log/salt/master.

Examples:

| log_file: /var/log/salt/master |
| log_file: /var/log/salt/minion |
| log_file: file:///dev/log |
| log_file: udp://loghost:10514 |

log_level

Default: warning

The level of log record messages to send to the console. One of all, garbage, trace, debug, profile, info, warning, error, critical, quiet.

log_level: warning

log_level_logfile

Default: warning

The level of messages to send to the log file. One of all, garbage, trace, debug, profile, info, warning, error, critical, quiet.

log_level_logfile: warning

log_datefmt

Default: %H:%M:%S

The date and time format used in console log messages. Allowed date/time formatting can be seen on time.strftime.
log_datefmt: '

log_datefmt_logfile
Default: %Y-%m-%d %H:%M:%S
The date and time format used in log file messages. Allowed date/time formatting can be seen on time.strftime.

log_datefmt_logfile: '%Y-%m-%d %H:%M:%S'

log_fmt_console
Default: [%levelname]-8s %(message)s
The format of the console logging messages. All standard python logging LogRecord attributes can be used. Salt also provides these custom LogRecord attributes to colorize console log output:

'\%(colorlevel)s' # log level name colorized by level
'\%(colormodule)s' # colorized module name
'\%(colorprocess)s' # colorized process number
'\%(colormsg)s' # log message colorized by level

Note: The %colorlevel)s, %colormodule)s, and %colorprocess)s LogRecord attributes also include padding and enclosing brackets, [ and ] to match the default values of their collateral non-colorized LogRecord attributes.

log_fmt_console: '[%(levelname)-8s] %(message)s'

log_fmt_logfile
Default: %(asctime)s,%(msecs)03.0f [%(name)-17s] [%(levelname)-8s] %(message)s
The format of the log file logging messages. All standard python logging LogRecord attributes can be used. Salt also provides these custom LogRecord attributes that include padding and enclosing brackets [ and ]:

'\%(bracketlevel)s' # equivalent to [%(levelname)-8s]
'\%(bracketmodule)s' # equivalent to [%(name)-17s]
'\%(bracketprocess)s' # equivalent to [%(process)5s]

log_fmt_logfile: '%(asctime)s,%(msecs)03.0f [%(name)-17s] [%(levelname)-8s] %(message)s'

log_granular_levels
Default: {}
This can be used to control logging levels more specifically. The example sets the main salt library at the `warning` level, but sets salt.modules to log at the debug level:
log_granular_levels:
    'salt': 'warning'
    'salt.modules': 'debug'

External Logging Handlers

Besides the internal logging handlers used by salt, there are some external which can be used, see the external logging handlers document.

32.12 External Logging Handlers

<table>
<thead>
<tr>
<th>logstash_mod</th>
<th>Logstash Logging Handler</th>
</tr>
</thead>
<tbody>
<tr>
<td>sentry_mod</td>
<td>Sentry Logging Handler</td>
</tr>
</tbody>
</table>

32.12.1 Logstash Logging Handler

New in version 0.17.0.
This module provides some Logstash logging handlers.

UDP Logging Handler

For versions of Logstash before 1.2.0:
In the salt configuration file:

```python
logstash_udp_handler:
    host: 127.0.0.1
    port: 9999
    version: 0
```

In the Logstash configuration file:

```ini
input {
    udp {
        type => "udp-type"
        format => "json_event"
    }
}
```

For version 1.2.0 of Logstash and newer:
In the salt configuration file:

```python
logstash_udp_handler:
    host: 127.0.0.1
    port: 9999
    version: 1
```

In the Logstash configuration file:
input {
    udp {
        port => 9999
        codec => json
    }
}

Please read the **UDP input** configuration page for additional information.

ZeroMQ Logging Handler

For versions of Logstash before 1.2.0:

In the salt configuration file:

```yaml
logstash_zmq_handler:
    address: tcp://127.0.0.1:2021
    version: 0
```

In the **Logstash** configuration file:

```yaml
input {
    zeromq {
        type => "zeromq-type"
        mode => "server"
        topology => "pubsub"
        address => "tcp://0.0.0.0:2021"
        charset => "UTF-8"
        format => "json_event"
    }
}
```

For version 1.2.0 of Logstash and newer:

In the salt configuration file:

```yaml
logstash_zmq_handler:
    address: tcp://127.0.0.1:2021
    version: 1
```

In the **Logstash** configuration file:

```yaml
input {
    zeromq {
        topology => "pubsub"
        address => "tcp://0.0.0.0:2021"
        codec => json
    }
}
```

Please read the **ZeroMQ input** configuration page for additional information.

Important Logstash Setting

One of the most important settings that you should not forget on your Logstash configuration file regarding these logging handlers is **format**. Both the **UDP** and ZeroMQ inputs need to have **format** as **json_event** which is
what we send over the wire.

Log Level

Both the logstash_udp_handler and the logstash_zmq_handler configuration sections accept an additional setting log_level. If not set, the logging level used will be the one defined for log_level in the global configuration file section.

HWM

The high water mark for the ZMQ socket setting. Only applicable for the logstash_zmq_handler.

Inspiration

This work was inspired in pylogstash, python-logstash, canary and the PyZMQ logging handler.

32.12.2 Sentry Logging Handler

New in version 0.17.0.

This module provides a Sentry logging handler.

Note

The Raven library needs to be installed on the system for this logging handler to be available.

Configuring the python Sentry client, Raven, should be done under the sentry_handler configuration key. Additional context may be provided for corresponding grain item(s). At the bare minimum, you need to define the DSN. As an example:

```
sentry_handler:
    dsn: https://pub-key:secret-key@app.getsentry.com/app-id
```

More complex configurations can be achieved, for example:

```yaml
sentry_handler:
    servers:
        - https://sentry.example.com
        - http://192.168.1.1
    project: app-id
    public_key: deadbeefdeadbeefdeadbeefdeadbeef
    secret_key: beefdeadbeefdeadbeefdeadbeefdead
    context:
        - os
        - master
        - saltversion
        - cpuarch
        - ec2.tags.environment
```
All the client configuration keys are supported, please see the Raven client documentation.

The default logging level for the sentry handler is ERROR. If you wish to define a different one, define `log_level` under the `sentry_handler` configuration key:

```
sentry_handler:
  dsn: https://pub-key:secret-key@app.getsentry.com/app-id
  log_level: warning
```

The available log levels are those also available for the salt cli tools and configuration; `salt --help` should give you the required information.

### Threaded Transports

Raven's documents rightly suggest using its threaded transport for critical applications. However, don't forget that if you start having troubles with Salt after enabling the threaded transport, please try switching to a non-threaded transport to see if that fixes your problem.

### 32.13 Salt File Server

Salt comes with a simple file server suitable for distributing files to the Salt minions. The file server is a stateless ZeroMQ server that is built into the Salt master.

The main intent of the Salt file server is to present files for use in the Salt state system. With this said, the Salt file server can be used for any general file transfer from the master to the minions.

#### 32.13.1 File Server Backends

In Salt 0.12.0, the modular fileserver was introduced. This feature added the ability for the Salt Master to integrate different file server backends. File server backends allow the Salt file server to act as a transparent bridge to external resources. A good example of this is the git backend, which allows Salt to serve files sourced from one or more git repositories, but there are several others as well. Click [here](#) for a full list of Salt's fileserver backends.

### Enabling a Fileserver Backend

Fileserver backends can be enabled with the `fileserver_backend` option.

```
fileserver_backend:
  - git
```

See the [documentation](#) for each backend to find the correct value to add to `fileserver_backend` in order to enable them.

### Using Multiple Backends

If `fileserver_backend` is not defined in the Master config file, Salt will use the `roots` backend, but the `fileserver_backend` option supports multiple backends. When more than one backend is in use, the files from the enabled backends are merged into a single virtual filesystem. When a file is requested, the backends will be searched in order for that file, and the first backend to match will be the one which returns the file.
fileserver_backend:
  - roots
  - git

With this configuration, the environments and files defined in the file_roots parameter will be searched first, and if the file is not found then the git repositories defined in gitfs_remotes will be searched.

Defining Environments

Just as the order of the values in fileserver_backend matters, so too does the order in which different sources are defined within a fileserver environment. For example, given the below file_roots configuration, if both /srv/salt/dev/foo.txt and /srv/salt/prod/foo.txt exist on the Master, then salt://foo.txt would point to /srv/salt/dev/foo.txt in the dev environment, but it would point to /srv/salt/prod/foo.txt in the base environment.

```yaml
class_roots:
  base:
  - /srv/salt/prod
  qa:
  - /srv/salt/qa
  - /srv/salt/prod
  dev:
  - /srv/salt/dev
  - /srv/salt/qa
  - /srv/salt/prod
```

Similarly, when using the git backend, if both repositories defined below have a hotfix23 branch/tag, and both of them also contain the file bar.txt in the root of the repository at that branch/tag, then salt://bar.txt in the hotfix23 environment would be served from the first repository.

```yaml
gitfs_remotes:
  - https://mydomain.tld/repos/first.git
  - https://mydomain.tld/repos/second.git
```

Note: Environments map differently based on the fileserver backend. For instance, the mappings are explicitly defined in roots backend, while in the VCS backends (git, hg, svn) the environments are created from branches/tags/bookmarks/etc. For the minion backend, the files are all in a single environment, which is specified by the minionfs_env option.

See the documentation for each backend for a more detailed explanation of how environments are mapped.

32.13.2 Dynamic Module Distribution

New in version 0.9.5.

Custom Salt execution, state, and other modules can be distributed to Salt minions using the Salt file server.

Under the root of any environment defined via the file_roots option on the master server directories corresponding to the type of module can be used.

The directories are prepended with an underscore:

- _beacons
- _modules
The contents of these directories need to be synced over to the minions after Python modules have been created in them. There are a number of ways to sync the modules.

**Sync Via States**

The minion configuration contains an option `autoload_dynamic_modules` which defaults to `True`. This option makes the state system refresh all dynamic modules when states are run. To disable this behavior set `autoload_dynamic_modules` to `False` in the minion config.

When dynamic modules are autoloaded via states, modules only pertinent to the environments matched in the master's top file are downloaded.

This is important to remember, because modules can be manually loaded from any specific environment that environment specific modules will be loaded when a state run is executed.

**Sync Via the saltutil Module**

The saltutil module has a number of functions that can be used to sync all or specific dynamic modules. The saltutil module function `saltutil.sync_all` will sync all module types over to a minion. For more information see: `salt.modules.saltutil`

### 32.13.3 Requesting Files from Specific Environments

The Salt fileserver supports multiple environments, allowing for SLS files and other files to be isolated for better organization.

For the default backend (called `roots`), environments are defined using the `roots` option. Other backends (such as `gitfs`) define environments in their own ways. For a list of available fileserver backends, see `here`.

**Querystring Syntax**

Any `salt://` file URL can specify its fileserver environment using a querystring syntax, like so:

```plaintext
salt://path/to/file?saltenv=foo
```

In *Reactor* configurations, this method must be used to pull files from an environment other than `base`.

**In States**

Minions can be instructed which environment to use both globally, and for a single state, and multiple methods for each are available:
Globally

A minion can be pinned to an environment using the `environment` option in the minion config file. Additionally, the environment can be set for a single call to the following functions:

- `state.apply`
- `state.highstate`
- `state.sls`
- `state.top`

Note: When the `saltenv` parameter is used to trigger a `highstate` using either `state.apply` or `state.highstate`, only states from that environment will be applied.

On a Per-State Basis

Within an individual state, there are two ways of specifying the environment. The first is to add a `saltenv` argument to the state. This example will pull the file from the `config` environment:

```
/etc/foo/bar.conf:
  file.managed:
    - source: salt://foo/bar.conf
    - user: foo
    - mode: 600
    - saltenv: config
```

Another way of doing the same thing is to use the `querystring syntax` described above:

```
/etc/foo/bar.conf:
  file.managed:
    - source: salt://foo/bar.conf?saltenv=config
    - user: foo
    - mode: 600
```

Note: Specifying the environment using either of the above methods is only necessary in cases where a state from one environment needs to access files from another environment. If the SLS file containing this state was in the `config` environment, then it would look in that environment by default.

32.13.4 File Server Configuration

The Salt file server is a high performance file server written in ZeroMQ. It manages large files quickly and with little overhead, and has been optimized to handle small files in an extremely efficient manner.

The Salt file server is an environment aware file server. This means that files can be allocated within many root directories and accessed by specifying both the file path and the environment to search. The individual environments can span across multiple directory roots to create overlays and to allow for files to be organized in many flexible ways.
Environments

The Salt file server defaults to the mandatory base environment. This environment **MUST** be defined and is used to download files when no environment is specified.

Environments allow for files and sls data to be logically separated, but environments are not isolated from each other. This allows for logical isolation of environments by the engineer using Salt, but also allows for information to be used in multiple environments.

Directory Overlay

The environment setting is a list of directories to publish files from. These directories are searched in order to find the specified file and the first file found is returned.

This means that directory data is prioritized based on the order in which they are listed. In the case of this file_roots configuration:

```yaml
file_roots:
  base:
    - /srv/salt/base
    - /srv/salt/failover
```

If a file's URI is `salt://httpd/httpd.conf`, it will first search for the file at `/srv/salt/base/httpd/httpd.conf`. If the file is found there it will be returned. If the file is not found there, then `/srv/salt/failover/httpd/httpd.conf` will be used for the source.

This allows for directories to be overlaid and prioritized based on the order they are defined in the configuration.

It is also possible to have file_roots which supports multiple environments:

```yaml
file_roots:
  base:
    - /srv/salt/base
  dev:
    - /srv/salt/dev
    - /srv/salt/base
  prod:
    - /srv/salt/prod
    - /srv/salt/base
```

This example ensures that each environment will check the associated environment directory for files first. If a file is not found in the appropriate directory, the system will default to using the base directory.

Local File Server

New in version 0.9.8.

The file server can be rerouted to run from the minion. This is primarily to enable running Salt states without a Salt master. To use the local file server interface, copy the file server data to the minion and set the file_roots option on the minion to point to the directories copied from the master. Once the minion file_roots option has been set, change the file_client option to local to make sure that the local file server interface is used.

32.13.5 The cp Module

The cp module is the home of minion side file server operations. The cp module is used by the Salt state system, salt-cp, and can be used to distribute files presented by the Salt file server.
Escaping Special Characters

The salt:// url format can potentially contain a query string, for example salt://dir/file.txt?saltenv=base. You can prevent the fileclient/fileserver from interpreting ? as the initial token of a query string by referencing the file with salt://| rather than salt://.

```
/etc/marathon/conf/?checkpoint:
  file.managed:
    - source: salt://|hw/config/?checkpoint
    - makedirs: True
```

Environments

Since the file server is made to work with the Salt state system, it supports environments. The environments are defined in the master config file and when referencing an environment the file specified will be based on the root directory of the environment.

**get_file**

The cp.get_file function can be used on the minion to download a file from the master, the syntax looks like this:

```
# salt '*' cp.get_file salt://vimrc /etc/vimrc
```

This will instruct all Salt minions to download the vimrc file and copy it to /etc/vimrc

Template rendering can be enabled on both the source and destination file names like so:

```
# salt '*' cp.get_file "salt://{{grains.os}}/vimrc" /etc/vimrc template=jinja
```

This example would instruct all Salt minions to download the vimrc from a directory with the same name as their OS grain and copy it to /etc/vimrc

For larger files, the cp.get_file module also supports gzip compression. Because gzip is CPU-intensive, this should only be used in scenarios where the compression ratio is very high (e.g. pretty-printed JSON or YAML files).

To use compression, use the gzip named argument. Valid values are integers from 1 to 9, where 1 is the lightest compression and 9 the heaviest. In other words, 1 uses the least CPU on the master (and minion), while 9 uses the most.

```
# salt '*' cp.get_file salt://vimrc /etc/vimrc gzip=5
```

Finally, note that by default cp.get_file does *not* create new destination directories if they do not exist. To change this, use the makedirs argument:

```
# salt '*' cp.get_file salt://vimrc /etc/vim/vimrc makedirs=True
```

In this example, /etc/vim/ would be created if it didn’t already exist.

**get_dir**

The cp.get_dir function can be used on the minion to download an entire directory from the master. The syntax is very similar to get_file:

```
# salt '*' cp.get_dir salt://etc/apache2 /etc
```
cp.get_dir supports template rendering and gzip compression arguments just like get_file:

```
# salt '*' cp.get_dir salt://etc/{{pillar.webserver}} /etc gzip=5 template=jinja
```

### 32.13.6 File Server Client Instance

A client instance is available which allows for modules and applications to be written which make use of the Salt file server.

The file server uses the same authentication and encryption used by the rest of the Salt system for network communication.

**fileclient Module**

The `salt/fileclient.py` module is used to set up the communication from the minion to the master. When creating a client instance using the fileclient module, the minion configuration needs to be passed in. When using the fileclient module from within a minion module the built in `__opts__` data can be passed:

```python
import salt.minion
import salt.fileclient

def get_file(path, dest, env='base'):
    '''
    Used to get a single file from the Salt master
    
    CLI Example:
salt '*' cp.get_file salt://vimrc /etc/vimrc
    '''
    # Get the fileclient object
    client = salt.fileclient.get_file_client(__opts__)
    # Call get_file
    return client.get_file(path, dest, False, env)
```

Creating a fileclient instance outside of a minion module where the `__opts__` data is not available, it needs to be generated:

```python
import salt.fileclient
import salt.config

def get_file(path, dest, env='base'):
    '''
    Used to get a single file from the Salt master
    '''
    # Get the configuration data
    opts = salt.config.minion_config('/etc/salt/minion')
    # Get the fileclient object
    client = salt.fileclient.get_file_client(opts)
    # Call get_file
    return client.get_file(path, dest, False, env)
```

### 32.14 Full list of builtin fileserver modules
<table>
<thead>
<tr>
<th>Module</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>azurefs</td>
<td>The backend for serving files from the Azure blob storage service.</td>
</tr>

</tr>
<tr>
<td>s3fs</td>
<td>Amazon S3 Fileserver Backend</td>
</tr>
<tr>
<td>svnfs</td>
<td>Subversion Fileserver Backend</td>
</tr>
</tbody>
</table>

### 32.14.1 salt.fileserver.azurefs

The backend for serving files from the Azure blob storage service.

To enable, add `azurefs` to the `fileserver_backend` option in the Master config file.

```yaml
fileserver_backend:
  - azurefs
```

Each environment is configured as a storage container. The name of the container must match the name of the environment. The `storage_account` is the name of the storage account inside Azure where the container lives, and the `storage_key` is the access key used for that storage account:

```yaml
azurefs_envs:
  base:
    storage_account: my_storage
    storage_key: frehgfw34fWGeG07fwswf343tGFDSDGDFD==
```

With this configuration, multiple storage accounts can be used with a single salt infrastructure.

### 32.14.2 salt.fileserver.gitfs

Git Fileserver Backend

With this backend, branches and tags in a remote git repository are exposed to salt as different environments.

To enable, add `git` to the `fileserver_backend` option in the Master config file.

```yaml
fileserver_backend:
  - git
```

As of Salt 2014.7.0, the Git fileserver backend supports `GitPython`, `pygit2`, and `dulwich` to provide the Python interface to git. If more than one of these are present, the order of preference for which one will be chosen is the same as the order in which they were listed: `pygit2`, `GitPython`, `dulwich` (keep in mind, this order is subject to change).

An optional master config parameter (`gitfs_provider`) can be used to specify which provider should be used.

More detailed information on how to use gitfs can be found in the [Gitfs Walkthrough](#).  

**Note:** Minimum requirements

To use `GitPython` for gitfs requires a minimum `GitPython` version of 0.3.0, as well as the `git` CLI utility. Instructions for installing `GitPython` can be found [here](#).

To use `pygit2` for gitfs requires a minimum `pygit2` version of 0.20.3. `pygit2` 0.20.3 requires `libgit2` 0.20.0. `pygit2` and `libgit2` are developed alongside one another, so it is recommended to keep them both at the same major release to

---

**32.14. Full list of builtin fileserver modules**

---
avoid unexpected behavior. For example, pygit2 0.21.x requires libgit2 0.21.x, pygit2 0.22.x will require libgit2 0.22.x, etc.

To find stale refs, pygit2 additionally requires the git CLI utility to be installed.

### 32.14.3 salt.fileserver.hgfs

Mercurial Fileserver Backend

To enable, add hg to the `fileserver_backend` option in the Master config file.

```yaml
fileserver_backend:
  - hg
```

After enabling this backend, branches, bookmarks, and tags in a remote mercurial repository are exposed to salt as different environments. This feature is managed by the `fileserver_backend` option in the salt master config file.

This fileserver has an additional option `hgfs_branch_method` that will set the desired branch method. Possible values are: branches, bookmarks, or mixed. If using branches or mixed, the default branch will be mapped to `base`.

Changed in version 2014.1.0: The `hgfs_base` master config parameter was added, allowing for a branch other than default to be used for the `base` environment, and allowing for a `base` environment to be specified when using an `hgfs_branch_method` of bookmarks.

- depends
  - mercurial
  - python bindings for mercurial (python-hglib)

### 32.14.4 salt.fileserver.minionfs

Fileserver backend which serves files pushed to the Master

The `cp.push` function allows Minions to push files up to the Master. Using this backend, these pushed files are exposed to other Minions via the Salt fileserver.

To enable minionfs, `file_recv` needs to be set to `True` in the master config file (otherwise `cp.push` will not be allowed to push files to the Master), and `minion` must be added to the `fileserver_backends` list.

```yaml
fileserver_backend:
  - minion
```

Other minionfs settings include: `minionfs_whitelist`, `minionfs_blacklist`, `minionfs_mountpoint`, and `minionfs_env`.

See also:

* MinionFS Backend Walkthrough

### 32.14.5 salt.fileserver.roots

The default file server backend
This filesaver backend serves files from the Master's local filesystem. If `fileserver_backend` is not defined in the Master config file, then this backend is enabled by default. If it is defined then `roots` must be in the `fileserver_backend` list to enable this backend.

```
fileserver_backend:
  - roots
```

Filesaver environments are defined using the `file_roots` configuration option.

### 32.14.6 salt.fileserver.s3fs

Amazon S3 Filesaver Backend

This backend exposes directories in S3 buckets as Salt environments. To enable this backend, add `s3fs` to the `fileserver_backend` option in the Master config file.

```
fileserver_backend:
  - s3fs
```

S3 credentials must also be set in the master config file:

```
s3.keyid: GKTADJGHEIQXSXMKKRBJ08H
s3.key: askdjghsdfjkg HwupUjasdfklgjsdfjakghs
```

Alternatively, if on EC2 these credentials can be automatically loaded from instance metadata.

This filesaver supports two modes of operation for the buckets:

1. **A single bucket per environment**

   ```
s3.buckets:
    production:
      - bucket1
      - bucket2
    staging:
      - bucket3
      - bucket4
   ```

2. **Multiple environments per bucket**

   ```
s3.buckets:
      - bucket1
      - bucket2
      - bucket3
      - bucket4
   ```

Note that bucket names must be all lowercase both in the AWS console and in Salt, otherwise you may encounter `SignatureDoesNotMatch` errors.

A multiple-environment bucket must adhere to the following root directory structure:

```
s3://<bucket name>/<environment>/<files>
```

**Note:** This filesaver back-end requires the use of the MD5 hashing algorithm. MD5 may not be compliant with all security policies.
32.14.7 salt.fileserver.svnfs

Subversion Fileserver Backend

After enabling this backend, branches, and tags in a remote subversion repository are exposed to salt as different environments. To enable this backend, add `svn` to the `fileserver_backend` option in the Master config file.

```
fileserver_backend:
  - svn
```

This backend assumes a standard svn layout with directories for branches, tags, and trunk, at the repository root.

```
depends
  - subversion
  - pysvn
```

Changed in version 2014.7.0: The paths to the trunk, branches, and tags have been made configurable, via the config options `svnfs_trunk`, `svnfs_branches`, and `svnfs_tags`. `svnfs_mountpoint` was also added. Finally, support for per-remote configuration parameters was added. See the documentation for more information.

32.15 Full list of builtin grains modules

<table>
<thead>
<tr>
<th>Module</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>chronos</td>
<td>Generate chronos proxy minion grains.</td>
</tr>
<tr>
<td>core</td>
<td>The static grains, these are the core, or built in grains.</td>
</tr>
<tr>
<td>disks</td>
<td>Detect disks</td>
</tr>
<tr>
<td>esxi</td>
<td>Generate baseline proxy minion grains for ESXi hosts.</td>

</tr>
<tr>
<td>philips_hue</td>
<td>Static grains for the Philips HUE lamps</td>
</tr>
<tr>
<td>rest_sample</td>
<td>Generate baseline proxy minion grains</td>
</tr>
</tbody>
</table>

32.15.1 salt.grains.chronos

Generate chronos proxy minion grains.

New in version 2015.8.2.

```
salt.grains.chronos.kernel()
salt.grains.chronos.os()
salt.grains.chronos.os_data()
salt.grains.chronos.os_family()
```
32.15.2 salt.grains.core

The static grains, these are the core, or built in grains.

When grains are loaded they are not loaded in the same way that modules are loaded, grain functions are detected and executed, the functions MUST return a dict which will be applied to the main grains dict. This module will always be executed first, so that any grains loaded here in the core module can be overwritten just by returning dict keys with the same value as those returned here

salt.grains.core.append_domain()
  Return append_domain if set

salt.grains.core.get_machine_id()
  Provide the machine-id

salt.grains.core.get_master()
  Provides the minion with the name of its master. This is useful in states to target other services running on the master.

salt.grains.core.get_server_id()
  Provides an integer based on the FQDN of a machine. Useful as server-id in MySQL replication or anywhere else you'll need an ID like this.

salt.grains.core.hostname()
  Return fqdn, hostname, domainname

salt.grains.core.hwaddr_interfaces()
  Provide a dict of the connected interfaces and their hw addresses (Mac Address)

salt.grains.core.id_()
  Return the id

salt.grains.core.ip4_interfaces()
  Provide a dict of the connected interfaces and their ip4 addresses The addresses will be passed as a list for each interface

salt.grains.core.ip6_interfaces()
  Provide a dict of the connected interfaces and their ip6 addresses The addresses will be passed as a list for each interface

salt.grains.core.ip_fqdn()
  Return ip address and FQDN grains

salt.grains.core.ip_interfaces()
  Provide a dict of the connected interfaces and their ip addresses The addresses will be passed as a list for each interface

salt.grains.core.locale_info()
  Provides defaultlanguage defaultencoding

salt.grains.core.os_data()
  Return grains pertaining to the operating system

salt.grains.core.path()
  Return the path

salt.grains.core.pythonexecutable()
  Return the python executable in use

salt.grains.core.pythonpath()
  Return the Python path
salt.grains.core.pythonversion()
  Return the Python version
	salt.grains.core.saltpath()
  Return the path of the salt module
	salt.grains.core.saltversion()
  Return the version of salt
	salt.grains.core.saltversioninfo()
  Return the version_info of salt
    New in version 0.17.0.
	salt.grains.core.zmqversion()
  Return the zeromq version

32.15.3 salt.grains.disks

Detect disks
	salt.grains.disks.disks()
  Return list of disk devices

32.15.4 salt.grains.esxi

Generate baseline proxy minion grains for ESXi hosts.
  ,, versionadded:: 2015.8.4
	salt.grains.esxi.esxi()
	salt.grains.esxi.kernel()
	salt.grains.esxi.os()
	salt.grains.esxi.os_family()

32.15.5 salt.grains.extra

salt.grains.extra.config()
  Return the grains set in the grains file
	salt.grains.extra.shell()
  Return the default shell to use on this system

32.15.6 salt.grains.fx2

Generate baseline proxy minion grains for Dell FX2 chassis. The challenge is that most of Salt isn't bootstrapped yet, so we need to repeat a bunch of things that would normally happen in proxy/fx2.py--just enough to get data from the chassis to include in grains.
	salt.grains.fx2.fx2()
	salt.grains.fx2.kernel()
	salt.grains.fx2.location()
salt.grains.fx2.os_data()
salt.grains.fx2.os_family()

### 32.15.7 salt.grains.junos

Grains for junos. NOTE this is a little complicated--junos can only be accessed via salt-proxy-minion. Thus, some grains make sense to get them from the minion (PYTHONPATH), but others don't (ip_interfaces)

salt.grains.junos.defaults()
salt.grains.junos.facts()
salt.grains.junos.os_family()

### 32.15.8 salt.grains.marathon

Generate marathon proxy minion grains.
New in version 2015.8.2.

salt.grains.marathon.kernel()
salt.grains.marathon.marathon()
salt.grains.marathon.os()
salt.grains.marathon.os_data()
salt.grains.marathon.os_family()

### 32.15.9 salt.grains.mdadm

Detect MDADM RAIDs

salt.grains.mdadm.mdadm()
    Return list of mdadm devices

### 32.15.10 salt.grains.opts

Simple grain to merge the opts into the grains directly if the grain_opts configuration value is set

salt.grains.opts.opts()
    Return the minion configuration settings

### 32.15.11 salt.grains.philips_hue

Static grains for the Philips HUE lamps

New in version 2015.8.3.

salt.grains.philips_hue.kernel()
salt.grains.philips_hue.os()
salt.grains.philips_hue.os_family()
salt.grains.philips_hue.product()
32.15.12 salt.grains.rest_sample

Generate baseline proxy minion grains

salt.grains.rest_sample.kern()l
salt.grains.rest_sample.loc()ation()

32.16 Salt code and internals

Reference documentation on Salt’s internal code.

32.16.1 Contents

salt.aggregation

salt.utils.aggregation

This library makes it possible to introspect dataset and aggregate nodes when it is instructed.

---

Note: The following examples will be expressed in YAML for convenience's sake:

- !aggr-scalar will refer to Scalar python function
- !aggr-map will refer to Map python object
- !aggr-seq will refer for Sequence python object

---

How to instructs merging

This yaml document has duplicate keys:

```
foo: !aggr-scalar first
foo: !aggr-scalar second
bar: !aggr-map {first: foo}
bar: !aggr-map {second: bar}
baz: !aggr-scalar 42
```

but tagged values instruct Salt that overlapping values they can be merged together:

```
foo: !aggr-seq [first, second]
bar: !aggr-map {first: foo, second: bar}
baz: !aggr-seq [42]
```
Default merge strategy is keep untouched

For example, this yaml document still has duplicate keys, but does not instruct aggregation:

```
foo: first
foo: second
bar: {first: foo}
bar: {second: bar}
baz: 42
```

So the late found values prevail:

```
foo: second
bar: {second: bar}
baz: 42
```

Limitations

Aggregation is permitted between tagged objects that share the same type. If not, the default merge strategy prevails. For example, these examples:

```
foo: {first: value}
foo: !aggr-map {second: value}
bar: !aggr-map {first: value}
bar: 42
baz: !aggr-seq [42]
baz: [fail]
qux: 42
qux: !aggr-scalar fail
```

are interpreted like this:

```
foo: !aggr-map {second: value}
bar: 42
baz: [fail]
qux: !aggr-seq [fail]
```

Introspection

TODO: write this part

```
salt.utils.aggregation.aggregate(obj_a, obj_b, level=False, map_class=<class 'salt.utils.aggregation.Map'>, sequence_class=<class 'salt.utils.aggregation.Sequence'>)
```

Merge obj_b into obj_a.

```
>>> aggregate('first', 'second', True) == ['first', 'second']
True
```
class salt.utils.aggregation.Aggregate
    Aggregation base.

class salt.utils.aggregation.Map(*args, **kwds)
    Map aggregation.

salt.utils.aggregation.Scalar(obj)
    Shortcut for Sequence creation

    >>> Scalar('foo') == Sequence(['foo'])
    True

class salt.utils.aggregation.Sequence
    Sequence aggregation.

Exceptions

Salt-specific exceptions should be thrown as often as possible so the various interfaces to Salt (CLI, API, etc) can handle those errors appropriately and display error messages appropriately.

<table>
<thead>
<tr>
<th>salt.exceptions</th>
<th>This module is a central location for all salt exceptions</th>
</tr>
</thead>
</table>

salt.exceptions

This module is a central location for all salt exceptions

exception salt.exceptions.AuthenticationError(message=''
    If sha256 signature fails during decryption

exception salt.exceptions.AuthorizationError(message=''
    Thrown when runner or wheel execution fails due to permissions

exception salt.exceptions.CommandExecutionError(message=''
    Used when a module runs a command which returns an error and wants to show the user the output gracefully instead of dying

exception salt.exceptions.CommandNotFoundError(message=''
    Used in modules or grains when a required binary is not available

exception salt.exceptions.EauthAuthenticationError(message=''
    Thrown when eauth authentication fails

exception salt.exceptions.FileLockError(msg, time_start=None, *args, **kwargs)
    Used when an error occurs obtaining a file lock

exception salt.exceptions.FileserverConfigError(message=''
    Used when invalid fileserver settings are detected

exception salt.exceptions.GitLockError(erno, strerror, *args, **kwargs)
    Raised when an uncaught error occurs in the midst of obtaining an update/checkout lock in salt.utils.gitfs.

    NOTE: While this uses the errno param similar to an OSError, this exception class is not as subclass of OSError.
    This is done intentionally, so that this exception class can be caught in a try/except without being caught as an OSError.

exception salt.exceptions.LoaderError(message=''
    Problems loading the right renderer
exception salt.exceptions.MasterExit
    Rise when the master exits

exception salt.exceptions.MinionError(message='')
    Minion problems reading uris such as salt:// or http://

exception salt.exceptions.NotImplemented(message='')
    Used when a module runs a command which returns an error and wants to show the user the output gracefully instead of dying

exception salt.exceptions.PkgParseError(message='')
    Used when of the pkg modules cannot correctly parse the output from the CLI tool (pacman, yum, apt, aptitude, etc)

exception salt.exceptions.PublishError(message='')
    Problems encountered when trying to publish a command

exception salt.exceptions.SaltCacheError(message='')
    Thrown when a problem was encountered trying to read or write from the salt cache

exception salt.exceptions.SaltClientError(message='')
    Problem reading the master root key

exception salt.exceptions.SaltClientTimeout(msg, jid=None, *args, **kwargs)
    Thrown when a job sent through one of the Client interfaces times out
    Takes the jid as a parameter

exception salt.exceptions.SaltCloudConfigError(message='')
    Raised when a configuration setting is not found and should exist.

exception salt.exceptions.SaltCloudException(message='')
    Generic Salt Cloud Exception

exception salt.exceptions.SaltCloudExecutionFailure(message='')
    Raised when too much failures have occurred while querying/waiting for data.

exception salt.exceptions.SaltCloudExecutionTimeout(message='')
    Raised when too much time has passed while querying/waiting for data.

exception salt.exceptions.SaltCloudNotFound(message='')
    Raised when some cloud provider function cannot find what's being searched.

exception salt.exceptions.SaltCloudPasswordError(message='')
    Raise when virtual terminal password input failed

exception salt.exceptions.SaltCloudSystemExit(message, exit_code=1)
    This exception is raised when the execution should be stopped.

exception salt.exceptions.SaltConfigurationException(message='')
    Configuration error

exception salt.exceptions.SaltDaemonNotRunning(message='')
    Throw when a running master/minion/syndic is not running but is needed to perform the requested operation (e.g., eauth).

exception salt.exceptions.SaltException(message='')
    Base exception class; all Salt-specific exceptions should subclass this

    pack()
        Pack this exception into a serializable dictionary that is safe for transport via msgpack
exception salt.exceptions.SaltInvocationError(message='')
    Used when the wrong number of arguments are sent to modules or invalid arguments are specified on the command line

exception salt.exceptions.SaltMasterError(message='')
    Problem reading the master root key

exception salt.exceptions.SaltNoMinsionsFound(message='')
    An attempt to retrieve a list of minions failed

exception salt.exceptions.SaltRenderError(message=None, line_num=None, buf='', marker='<<<<<<<', trace=None)
    Used when a render needs to raise an explicit error. If a line number and buffer string are passed, get_context will be invoked to get the location of the error.

exception salt.exceptions.SaltReqTimeoutError(message='')
    Thrown when a salt master request call fails to return within the timeout

exception salt.exceptions.SaltRunnerError(message='')
    Problem in runner

exception salt.exceptions.SaltSyndicMasterError(message='')
    Problem while proxying a request in the syndication master

exception salt.exceptions.SaltSystemExit(code=0, msg=None)
    This exception is raised when an unsolvable problem is found. There's nothing else to do, salt should just exit.

exception salt.exceptions.SaltWheelError(message='')
    Problem in wheel

exception salt.exceptions.TimedProcTimeoutError(message='')
    Thrown when a timed subprocess does not terminate within the timeout, or if the specified timeout is not an int or a float

exception salt.exceptions.TokenAuthenticationError(message='')
    Thrown when token authentication fails

salt.exceptions.get_error_message(error)
    Get human readable message from Python Exception

Salt opts dictionary

It is very common in the Salt codebase to see opts referred to in a number of contexts.
For example, it can be seen as __opts__ in certain cases, or simply as opts as an argument to a function in others.

Simply put, this data structure is a dictionary of Salt's runtime configuration information that's passed around in order for functions to know how Salt is configured.

When writing Python code to use specific parts of Salt, it may become necessary to initialize a copy of opts from scratch in order to have it available for a given function.

To do so, use the utility functions available in salt.config.

As an example, here is how one might generate and print an options dictionary for a minion instance:

```python
import salt.config
opts = salt.config.minion_config('/etc/salt/minion')
print(opts)
```

To generate and display opts for a master, the process is similar:
```python
import salt.config
opts = salt.config.master_config('/etc/salt/master')
print(opts)
```

32.17 Full list of builtin execution modules

Virtual modules

32.17.1 salt.modules.pkg

`pkg` is a virtual module that is fulfilled by one of the following modules:

<table>
<thead>
<tr>
<th>Execution Module</th>
<th>Used for</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>aptpkg</code></td>
<td>Debian/Ubuntu-based distros which use <code>apt-get(8)</code> for package management</td>

<tr>
<td></td>
<td>use launchd/lunchctl</td>
</tr>
<tr>
<td>layman</td>
<td>Support for Layman</td>
</tr>
<tr>
<td>ldapmod</td>
<td>Salt interface to LDAP commands</td>
</tr>
<tr>
<td>linux_acl</td>
<td>Support for Linux File Access Control Lists</td>
</tr>
<tr>
<td>linux_lvm</td>
<td>Support for Linux LVM2</td>
</tr>
<tr>
<td>linux_sysctl</td>
<td>Module for viewing and modifying sysctl parameters</td>
</tr>
<tr>
<td>localemod</td>
<td>Module for managing locales on POSIX-like systems.</td>
</tr>
<tr>
<td>locate</td>
<td>Module for using the locate utilities</td>
</tr>
<tr>
<td>logadm</td>
<td>Module for managing Solaris logadm based log</td>
</tr>
<tr>
<td></td>
<td>rotations.</td>
</tr>
<tr>
<td>logrotate</td>
<td>Module for managing logrotate.</td>
</tr>
<tr>
<td>lvs</td>
<td>Support for LVS (Linux Virtual Server)</td>
</tr>
<tr>
<td>lxc</td>
<td>Control Linux Containers via Salt</td>
</tr>
<tr>
<td>mac_group</td>
<td>Manage groups on Mac OS 10.7+</td>
</tr>
<tr>
<td>mac_user</td>
<td>Manage users on Mac OS 10.7+</td>
</tr>
<tr>
<td>macports</td>
<td>Support for MacPorts under Mac OSX.</td>
</tr>
<tr>
<td>makeconf</td>
<td>Support for modifying make.conf under Gentoo</td>
</tr>
<tr>
<td>Module</td>
<td>Description</td>
</tr>
<tr>
<td>------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td><code>match</code></td>
<td>The match module allows for match routines to be run and determine target specs</td>
</tr>
<tr>
<td><code>mdadm</code></td>
<td>Salt module to manage RAID arrays with mdadm</td>
</tr>
<tr>
<td><code>memcached</code></td>
<td>Module for Management of Memcached Keys</td>
</tr>
<tr>
<td><code>mine</code></td>
<td>The function cache system allows for data to be stored on the master so it can be easily read by other minions</td>
</tr>
<tr>
<td><code>mod_random</code></td>
<td>Provides access to randomness generators.</td>
</tr>
<tr>
<td><code>modjk</code></td>
<td>Control Modjk via the Apache Tomcat <code>Status</code> worker</td>
</tr>
<tr>
<td><code>mongodb</code></td>
<td>Module to provide MongoDB functionality to Salt</td>
</tr>
<tr>
<td><code>monit</code></td>
<td>Monit service module.</td>
</tr>
<tr>
<td><code>moosefs</code></td>
<td>Module for gathering and managing information about MooseFS</td>
</tr>
<tr>
<td><code>mount</code></td>
<td>Salt module to manage Unix mounts and the fstab file</td>
</tr>
<tr>
<td><code>mysql</code></td>
<td>Module to provide MySQL compatibility to salt</td>
</tr>
<tr>
<td><code>nagios</code></td>
<td>Run nagios plugins/checks from salt and get the return as data.</td>
</tr>
<tr>
<td><code>nagios_rpc</code></td>
<td>Check Host &amp; Service status from Nagios via JSON RPC.</td>
</tr>
<tr>
<td><code>netbsd_sysctl</code></td>
<td>Module for viewing and modifying sysctl parameters</td>
</tr>
<tr>
<td><code>netbsdservice</code></td>
<td>The service module for NetBSD</td>
</tr>
<tr>
<td><code>netscaler</code></td>
<td>Module to provide Citrix Netscaler compatibility to Salt (compatible with netscaler 9.2+)</td>
</tr>
<tr>
<td><code>network</code></td>
<td>Module for gathering and managing network information</td>
</tr>
<tr>
<td><code>neutron</code></td>
<td>Module for handling OpenStack Neutron calls</td>
</tr>
<tr>
<td><code>nfs3</code></td>
<td>Module for managing NFS version 3.</td>
</tr>
<tr>
<td><code>nftables</code></td>
<td>Support for nftables</td>
</tr>
<tr>
<td><code>nginx</code></td>
<td>Support for nginx</td>
</tr>
<tr>
<td><code>node</code></td>
<td>Module for full system inspection.</td>
</tr>
<tr>
<td><code>nova</code></td>
<td>Module for handling OpenStack Nova calls</td>
</tr>
<tr>
<td><code>npm</code></td>
<td>Manage and query NPM packages.</td>
</tr>
<tr>
<td><code>nspawn</code></td>
<td>Manage nspawn containers</td>
</tr>
<tr>
<td><code>omapi</code></td>
<td>This module interacts with an ISC DHCP Server via OMAPI.</td>
</tr>
<tr>
<td><code>openssl</code></td>
<td>Module for viewing and modifying OpenSSL sysctl parameters</td>
</tr>
<tr>
<td><code>openssldpkg</code></td>
<td>Package support for OpenBSD</td>
</tr>
<tr>
<td><code>opensslrcctl</code></td>
<td>The rcctl service module for OpenBSD</td>
</tr>
<tr>
<td><code>opensslservice</code></td>
<td>The service module for OpenBSD</td>
</tr>
<tr>
<td><code>openstack_config</code></td>
<td>Modify, retrieve, or delete values from OpenStack configuration files.</td>
</tr>
<tr>
<td><code>oracle</code></td>
<td>Oracle DataBase connection module</td>
</tr>
<tr>
<td><code>osxdesktop</code></td>
<td>Mac OS X implementations of various commands in the <code>desktop</code> interface</td>
</tr>
<tr>
<td><code>pacman</code></td>
<td>A module to wrap pacman calls, since Arch is the best</td>
</tr>
<tr>
<td><code>pagerduty</code></td>
<td>Module for Firing Events via PagerDuty</td>
</tr>
</tbody>
</table>

32.17. Full list of builtin execution modules
<table>
<thead>
<tr>
<th>Module</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pagerduty_util</td>
<td>Module for managing PagerDuty resource</td>
</tr>
<tr>
<td>pam</td>
<td>Support for pam</td>
</tr>
<tr>
<td>parted</td>
<td>Module for managing partitions on POSIX-like systems.</td>
</tr>
<tr>
<td>pecl</td>
<td>Manage PHP pecl extensions.</td>
</tr>
<tr>
<td>pillar</td>
<td>Extract the pillar data for this minion</td>
</tr>
<tr>
<td>pip</td>
<td>Install Python packages with pip to either the system or a virtualenv</td>
</tr>
<tr>
<td>pkg_resource</td>
<td>Resources needed by pkg providers</td>
</tr>
<tr>
<td>pkgin</td>
<td>Package support for pkgin based systems, inspired from freebsdpkg module</td>
</tr>
<tr>
<td>pkgng</td>
<td>Support for pkgng, the new package manager for FreeBSD</td>
</tr>
<tr>
<td>pkgutil</td>
<td>Pkgutil support for Solaris</td>
</tr>
<tr>
<td>portage_config</td>
<td>Configure portage(5)</td>
</tr>
<tr>
<td>postfix</td>
<td>Support for Postfix</td>
</tr>
<tr>
<td>postgres</td>
<td>Module to provide Postgres compatibility to salt.</td>
</tr>
<tr>
<td>poudriere</td>
<td>Support for poudriere</td>
</tr>
<tr>
<td>powerpath</td>
<td>powerpath support.</td>
</tr>
<tr>
<td>ps</td>
<td>A salt interface to psutil, a system and process library.</td>
</tr>
<tr>
<td>publish</td>
<td>Publish a command from a minion to a target</td>
</tr>
<tr>
<td>puppet</td>
<td>Execute puppet routines</td>
</tr>
<tr>
<td>pushover_notify</td>
<td>Module for sending messages to Pushover (<a href="https://www.pushover.net">https://www.pushover.net</a>)</td>
</tr>
<tr>
<td>pw_group</td>
<td>Manage groups on FreeBSD</td>
</tr>
<tr>
<td>pw_user</td>
<td>Manage users with the useradd command</td>
</tr>
<tr>
<td>pyenv</td>
<td>Manage python installations with pyenv.</td>
</tr>
<tr>
<td>qemu_img</td>
<td>Qemu-img Command Wrapper</td>
</tr>
<tr>
<td>qemu_nbd</td>
<td>Qemu Command Wrapper</td>
</tr>
<tr>
<td>quota</td>
<td>Module for managing quotas on POSIX-like systems.</td>
</tr>
<tr>
<td>rabbitmq</td>
<td>Module to provide RabbitMQ compatibility to Salt.</td>
</tr>
<tr>
<td>raet_publish</td>
<td>Publish a command from a minion to a target</td>
</tr>
<tr>
<td>rallydev</td>
<td>Support for RallyDev</td>
</tr>
<tr>
<td>random_org</td>
<td>Module for retrieving random information from Random.org</td>
</tr>
<tr>
<td>rbenv</td>
<td>Manage ruby installations with rbenv.</td>
</tr>
<tr>
<td>rdp</td>
<td>Manage RDP Service on Windows servers</td>
</tr>
<tr>
<td>redismod</td>
<td>Module to provide redis functionality to Salt</td>
</tr>
<tr>
<td>reg</td>
<td>Package support for the REST example</td>
</tr>
<tr>
<td>rest_package</td>
<td>Provide the service module for the proxy-minion REST sample</td>
</tr>
<tr>
<td>rest_service</td>
<td>Provide the service module for the proxy-minion REST sample</td>
</tr>
<tr>
<td>ret</td>
<td>Module to integrate with the returner system and retrieve data sent to a salt returner</td>
</tr>
<tr>
<td>rh_ip</td>
<td>The networking module for RHEL/Fedora based distros</td>
</tr>
<tr>
<td>rh_service</td>
<td>Service support for RHEL-based systems, including support for both upstart and sysvinit</td>
</tr>
<tr>
<td>riak</td>
<td>Riak Salt Module</td>
</tr>
<tr>
<td>rpm</td>
<td>Support for rpm</td>
</tr>
<tr>
<td>rpmbuild</td>
<td>RPM Package builder system</td>
</tr>
<tr>
<td>rsync</td>
<td>Wrapper for rsync</td>
</tr>
</tbody>
</table>

<tr>
<td>scsi</td>
<td>SCSI administration module</td>
</tr>
<tr>
<td>sdb</td>
<td>Module for Manipulating Data via the Salt DB API</td>
</tr>
<tr>
<td>seed</td>
<td>Execute calls on selinux</td>
</tr>
<tr>
<td>sensors</td>
<td>Read lm-sensors</td>
</tr>
<tr>
<td>serverdensity_device</td>
<td>Wrapper around Server Density API</td>
</tr>
<tr>
<td>service</td>
<td>If Salt’s OS detection does not identify a different virtual service module, the minion will fall back to using this basic module, which simply wraps sysvinit scripts.</td>
</tr>
<tr>
<td>shadow</td>
<td>Manage the shadow file on Linux systems</td>
</tr>
<tr>
<td>slack_notify</td>
<td>Module for sending messages to Slack</td>
</tr>
<tr>
<td>sisutil</td>
<td>Utility functions for use with or in SLS files</td>
</tr>
<tr>
<td>smartos_imgadm</td>
<td>Module for running imgadm command on SmartOS</td>
</tr>
<tr>
<td>smartos_virt</td>
<td>Module for managing VMs on SmartOS</td>
</tr>
<tr>
<td>smartos_vmadm</td>
<td>Module for running vmadm command on SmartOS</td>
</tr>
<tr>
<td>smbios</td>
<td>Interface to SMBIOS/DMI</td>
</tr>
<tr>
<td>smf</td>
<td>Service support for Solaris 10 and 11, should work with other systems that use SMF also.</td>
</tr>
<tr>
<td>smtp</td>
<td>Module for Sending Messages via SMTP</td>
</tr>
<tr>
<td>softwareupdate</td>
<td>Support for the softwareupdate command on MacOS.</td>
</tr>
<tr>
<td>solaris_group</td>
<td>Manage groups on Solaris</td>

<tr>
<td>solaris_shadow</td>
<td>Manage the password database on Solaris systems</td>
</tr>
<tr>
<td>solaris_user</td>
<td>Manage users with the useradd command</td>
</tr>
<tr>
<td>solarisips</td>
<td>IPS pkg support for Solaris</td>
</tr>
<tr>
<td>solarispkg</td>
<td>Package support for Solaris</td>
</tr>
<tr>
<td>solr</td>
<td>Apache Solr Salt Module</td>
</tr>
<tr>
<td>splay</td>
<td>Splay function calls across targeted minions</td>
</tr>
<tr>
<td>splunk_search</td>
<td>Module for interop with the Splunk API</td>
</tr>
<tr>
<td>sqlite3</td>
<td>Support for SQLite3</td>
</tr>
<tr>
<td>ssh</td>
<td>Manage client ssh components</td>
</tr>
<tr>
<td>state</td>
<td>Control the state system on the minion.</td>
</tr>
<tr>
<td>status</td>
<td>Module for returning various status data about a minion.</td>
</tr>
<tr>
<td>stormpath</td>
<td>Support for Stormpath</td>
</tr>
<tr>
<td>sudo</td>
<td>Allow for the calling of execution modules via sudo.</td>
</tr>
<tr>
<td>supervisord</td>
<td>Provide the service module for system supervisord or supervisord in a</td>
</tr>
<tr>
<td>svn</td>
<td>Subversion SCM</td>
</tr>
<tr>
<td>swift</td>
<td>Module for handling OpenStack Swift calls</td>
</tr>
<tr>
<td>sysbench</td>
<td>The <code>sysbench</code> module is used to analyze the performance of the minions, right from the master! It measures various system parameters such as CPU, Memory, File I/O, Threads and Mutex.</td>
</tr>
</tbody>
</table>

<tr>
<td>zypper</td>
<td>Package support for openSUSE via the zypper package manager</td>
</tr>
</tbody>
</table>

32.17.2 salt.modules.aliases

Manage the information in the aliases file

**salt.modules.aliases.get_target(alias)**
Return the target associated with an alias

CLI Example:

```
salt '*' aliases.get_target alias
```

**salt.modules.aliases.has_target(alias, target)**
Return true if the alias/target is set

CLI Example:

```
salt '*' aliases.has_target alias target
```

**salt.modules.aliases.list_aliases()**
Return the aliases found in the aliases file in this format:

```
{'alias': 'target'}
```

CLI Example:

```
salt '*' aliases.list_aliases
```

**salt.modules.aliases.rm_alias(alias)**
Remove an entry from the aliases file

CLI Example:
salt '*/' aliases.rm_alias alias

```python
salt.modules.aliases.set_target(alias, target)
```

Set the entry in the aliases file for the given alias, this will overwrite any previous entry for the given alias or create a new one if it does not exist.

CLI Example:

```bash
salt '*/' aliases.set_target alias target
```

### 32.17.3 salt.modules.alternatives

Support for Alternatives system

**codeauthor** Radek Rada <radek.rada@gmail.com>

```python
salt.modules.alternatives.auto(name)
```

Trigger alternatives to set the path for `<name>` as specified by priority.

CLI Example:

```bash
salt '*/' alternatives.auto name
```

```python
salt.modules.alternatives.check_exists(name, path)
```

Check if the given path is an alternative for a name.

New in version 2015.8.4.

CLI Example:

```bash
salt '*/' alternatives.check_exists name path
```

```python
salt.modules.alternatives.check_installed(name, path)
```

Check if the current highest-priority match for a given alternatives link is set to the desired path

CLI Example:

```bash
salt '*/' alternatives.check_installed name path
```

```python
salt.modules.alternatives.display(name)
```

Display alternatives settings for defined command name

CLI Example:

```bash
salt '*/' alternatives.display editor
```

```python
salt.modules.alternatives.install(name, link, path, priority)
```

Install symbolic links determining default commands

CLI Example:

```bash
salt '*/' alternatives.install editor /usr/bin/editor /usr/bin/emacs23 50
```

```python
salt.modules.alternatives.remove(name, path)
```

Remove symbolic links determining the default commands.

CLI Example:
salt '* alternatives.remove name path

salt.modules.alternatives.set(name, path)
Manually set the alternative <path> for <name>.

CLI Example:
salt '* alternatives.set name path

salt.modules.alternatives.show_current(name)
Display the current highest-priority alternative for a given alternatives link

CLI Example:
salt '* alternatives.show_current editor

salt.modules.alternatives.show_link(name)
Display master link for the alternative

CLI Example:
salt '* alternatives.show_link editor

32.17.4 salt.modules.apache

Support for Apache

Note: The functions in here are generic functions designed to work with all implementations of Apache. Debian-specific functions have been moved into deb_apache.py, but will still load under the apache namespace when a Debian-based system is detected.

salt.modules.apache.config(name, config, edit=True)
Create VirtualHost configuration files

name File for the virtual host
config VirtualHost configurations

Note: This function is not meant to be used from the command line. Config is meant to be an ordered dict of all of the apache configs.

CLI Example:
salt '* apache.config /etc/httpd/conf.d/ports.conf config="[{'Listen': '22'}]"

salt.modules.apache.directives()
Return list of directives together with expected arguments and places where the directive is valid (apachectl -L)

CLI Example:
salt '* apache.directives

32.17. Full list of builtin execution modules
salt.modules.apache.fullversion()  
Return server version (apachectl -V)  

CLI Example:  
```
salt '*' apache.fullversion
```

salt.modules.apache.modules()  
Return list of static and shared modules (apachectl -M)  

CLI Example:  
```
salt '*' apache.modules
```

salt.modules.apache.server_status(profile='default')  
Get Information from the Apache server-status handler  

**Note:** The server-status handler is disabled by default. In order for this function to work it needs to be enabled. See [http://httpd.apache.org/docs/2.2/mod/mod_status.html](http://httpd.apache.org/docs/2.2/mod/mod_status.html)  

The following configuration needs to exists in pillar/grains. Each entry nested in `apache.server-status` is a profile of a vhost/server. This would give support for multiple apache servers/vhosts.  

```
apache.server-status:  
    default:  
        url: http://localhost/server-status  
        user: someuser  
        pass: password  
        realm: 'authentication realm for digest passwords'  
        timeout: 5
```

CLI Examples:  
```
salt '*' apache.server_status
salt '*' apache.server_status other-profile
```

salt.modules.apache.servermods()  
Return list of modules compiled into the server (apachectl -l)  

CLI Example:  
```
salt '*' apache.servermods
```

salt.modules.apache.signal(signal=None)  
Signals httpd to start, restart, or stop.  

CLI Example:  
```
salt '*' apache.signal restart
```

salt.modules.apache.useradd(pwfile, user, password, opts='')  
Add HTTP user using the htpasswd command. If the htpasswd file does not exist, it will be created. Valid options that can be passed are:  

- `n` Don't update file; display results on stdout.  
- `m` Force MD5 hashing of the password (default).  
- `d` Force CRYPT(3) hashing of the password.
p  Do not hash the password (plaintext).
s  Force SHA1 hashing of the password.

CLI Examples:
```
salt '*' apache.useradd /etc/httpd/htpasswd larry badpassword
salt '*' apache.useradd /etc/httpd/htpasswd larry badpass opts=ns
```

```
salt.modules.apache.userdel(pwfile, user)
  Delete HTTP user from the specified htpasswd file.
  CLI Example:
  salt '*' apache.userdel /etc/httpd/htpasswd larry
```

```
salt.modules.apache.version()
  Return server version (apachectl -v)
  CLI Example:
  salt '*' apache.version
```

```
salt.modules.apache.vhosts()
  Show the settings as parsed from the config file (currently only shows the virtualhost settings) (apachectl -S). Because each additional virtual host adds to the execution time, this command may require a long timeout be specified by using -t 10.
  CLI Example:
  salt -t 10 '*' apache.vhosts
```

32.17.5  **salt.modules.aptpkg**

Support for APT (Advanced Packaging Tool)

**Important:** If you feel that Salt should be using this module to manage packages on a minion, and it is using a different module (or gives an error similar to `pkg.install' is not available), see [here](#).

**Note:** For virtual package support, either the `python-apt` or `dctrl-tools` package must be installed.

For repository management, the `python-apt` package must be installed.

```
salt.modules.aptpkg.autoremove(list_only=False, purge=False)
  New in version 2015.5.0.
  Remove packages not required by another package using `apt-get autoremove`.
  list_only [False] Only retrieve the list of packages to be auto-removed, do not actually perform the auto-removal.
  purge [False] Also remove package config data when autoremoving packages.
```

New in version 2015.8.0.

CLI Example:
salt.modules.aptpkg.del_repo(repo, **kwargs)
Delete a repo from the sources.list / sources.list.d

If the .list file is in the sources.list.d directory and the file that the repo exists in does not contain any other
repo configuration, the file itself will be deleted.

The repo passed in must be a fully formed repository definition string.

CLI Examples:
```
salt '*' pkg.del_repo "myrepo definition"
```

salt.modules.aptpkg.del_repo_key(name=None, **kwargs)
New in version 2015.8.0.

Remove a repo key using apt-key del

name  Repo from which to remove the key. Unnecessary if keyid is passed.

keyid  The KeyID of the GPG key to remove

keyid_ppa [False] If set to True, the repo's GPG key ID will be looked up from ppa.launchpad.net and re-

Note: Setting this option to True requires that the name param also be passed.

CLI Examples:
```
salt '*' pkg.del_repo_key keyid=0123ABCD
salt '*' pkg.del_repo_key name='ppa:foo/bar' keyid_ppa=True
```

salt.modules.aptpkg.expand_repo_def(**kwargs)
Take a repository definition and expand it to the full pkg repository dict that can be used for comparison. This
is a helper function to make the Debian/Ubuntu apt sources sane for comparison in the pkgrepo states.

This is designed to be called from pkgrepo states and will have little use being called on the CLI.

salt.modules.aptpkg.file_dict(*packages)
List the files that belong to a package, grouped by package. Not specifying any packages will return a list of
_every_file on the system's package database (not generally recommended).

CLI Examples:
```
salt '*' pkg.file_dict httpd
salt '*' pkg.file_dict httpd postfix
salt '*' pkg.file_dict
```

salt.modules.aptpkg.file_list(*packages)
List the files that belong to a package. Not specifying any packages will return a list of _every_file on the
system's package database (not generally recommended).

CLI Examples:
```
salt '*' pkg.file_list httpd
salt '*' pkg.file_list httpd postfix
salt '*' pkg.file_list
```
**salt.modules.aptpkg.get_repo(repo, **kwargs)**

Display a repo from the sources.list / sources.list.d

The repo passed in needs to be a complete repo entry.

CLI Examples:

```bash
salt '*' pkg.get_repo "myrepo definition"
```

**salt.modules.aptpkg.get_selections(pattern=None, state=None)**

View package state from the dpkg database.

Returns a dict of dicts containing the state, and package names:

```python
{
    '<host>': {
        '<state>': ['pkg1',
                    ...
        ],
        ...
    }
}
```

CLI Example:

```bash
salt '*' pkg.get_selections
salt '*' pkg.get_selections 'python-'
salt '*' pkg.get_selections state=hold
salt '*' pkg.get_selections 'openssh' state=hold
```

**salt.modules.aptpkg.hold(name=None, pkgs=None, sources=None, **kwargs)**

New in version 2014.7.0.

Set package in `hold` state, meaning it will not be upgraded.

- **name** The name of the package, e.g., `tmux`

  CLI Example:

  ```bash
  salt '*' pkg.hold <package name>
  ```

- **pkgs** A list of packages to hold. Must be passed as a python list.

  CLI Example:

  ```bash
  salt '*' pkg.hold pkgs=['"foo", "bar"]'
  ```

**salt.modules.aptpkg.info_installed(*names)**

Return the information of the named package(s) installed on the system.

- **names** The names of the packages for which to return information.

  CLI example:

  ```bash
  salt '*' pkg.info_installed <package1>
salt '*' pkg.info_installed <package1> <package2> <package3> ...
  ```
salt.modules.aptpkg.install(name=None, refresh=False, fromrepo=None, skip_verify=False, debconf=None, pkgs=None, sources=None, reinstall=False, **kwargs)

Changed in version 2015.8.12, 2016.3.3, Carbon: On minions running systemd>=205, systemd-run(1) is now used to isolate commands which modify installed packages from the salt-minion daemon's control group. This is done to keep systemd from killing any apt-get/dpkg commands spawned by Salt when the salt-minion service is restarted. (see KillMode in the systemd.kill(5) manpage for more information). If desired, usage of systemd-run(1) can be suppressed by setting a config option called systemd.scope, with a value of False (no quotes).

Install the passed package, add refresh=True to update the dpkg database.

**name** The name of the package to be installed. Note that this parameter is ignored if either ``pkgs`` or ``sources`` is passed. Additionally, please note that this option can only be used to install packages from a software repository. To install a package file manually, use the ``sources`` option.

32-bit packages can be installed on 64-bit systems by appending the architecture designation (:i386, etc.) to the end of the package name.

CLI Example:

```
salt '*' pkg.install <package name>
```

**refresh** Whether or not to refresh the package database before installing.

**fromrepo** Specify a package repository to install from (e.g., apt-get -t unstable install somepackage)

**skip_verify** Skip the GPG verification check (e.g., --allow-unauthenticated, or --force-bad-verify for install from package file).

**debconf** Provide the path to a debconf answers file, processed before installation.

**version** Install a specific version of the package, e.g. 1.2.3-0ubuntu0. Ignored if ``pkgs`` or ``sources`` is passed.

**reinstall** [False] Specifying reinstall=True will use apt-get install --reinstall rather than simply apt-get install for requested packages that are already installed.

If a version is specified with the requested package, then apt-get install --reinstall will only be used if the installed version matches the requested version.

New in version 2015.8.0.

Multiple Package Installation Options:

**pkgs** A list of packages to install from a software repository. Must be passed as a python list.

CLI Example:

```
salt '*' pkg.install pkgs='["foo", "bar"]'
salt '*' pkg.install pkgs='["foo", {"bar": "1.2.3-0ubuntu0"}]'
```

**sources** A list of DEB packages to install. Must be passed as a list of dicts, with the keys being package names, and the values being the source URI or local path to the package. Dependencies are automatically resolved and marked as auto-installed.

32-bit packages can be installed on 64-bit systems by appending the architecture designation (:i386, etc.) to the end of the package name.

Changed in version 2014.7.0.

CLI Example:
force_yes  Passes --force-yes to the apt-get command. Don't use this unless you know what you're doing.

New in version 0.17.4.

install_recommends Whether to install the packages marked as recommended. Default is True.

New in version 2015.5.0.

only_upgrade Only upgrade the packages, if they are already installed. Default is False.

New in version 2015.5.0.

force_conf_new Always install the new version of any configuration files.

New in version 2015.8.0.

Returns a dict containing the new package names and versions:

```python
{'<package>': {'old': '<old-version>', 'new': '<new-version>'}}
```

salt.modules.aptpkg.latest_version(names, **kwargs)

Return the latest version of the named package available for upgrade or installation. If more than one package
name is specified, a dict of name/version pairs is returned.

If the latest version of a given package is already installed, an empty string will be returned for that package.

A specific repo can be requested using the fromrepo keyword argument.

CLI Example:

```bash
salt '*' pkg.latest_version <package name>
salt '*' pkg.latest_version <package name> fromrepo=unstable
class='*': pkg.latest_version <package1> <package2> <package3> ...
```

salt.modules.aptpkg.list_pkgs(versions_as_list=False, removed=False, purge_desired=False, **kwargs)

List the packages currently installed in a dict:

```python
{'<package_name>': '<version>'}
```

removed  If True, then only packages which have been removed (but not purged) will be returned.

purge_desired  If True, then only packages which have been marked to be purged, but can't be purged due
to their status as dependencies for other installed packages, will be returned. Note that these packages
will appear in installed

Changed in version 2014.1.1: Packages in this state now correctly show up in the output of this function.

---

Note: External dependencies

Virtual package resolution requires the dctrl-tools package to be installed. Virtual packages will show a
version of 1.

---

CLI Example:
salt '*' pkg.list_pkgs
salt '*' pkg.list_pkgs versions_as_list=True

salt.modules.aptpkg.list_repos()
    Lists all repos in the sources.list (and sources.lists.d) files

    CLI Example:
    salt '*' pkg.list_repos
    salt '*' pkg.list_repos disabled=True

salt.modules.aptpkg.list_upgrades(refresh=True, dist_upgrade=True, **kwargs)
    List all available package upgrades.
    
    refresh  Whether to refresh the package database before listing upgrades. Default: True.
    
    dist_upgrade  Whether to list the upgrades using dist-upgrade vs upgrade. Default is to use dist-upgrade.

    CLI Example:
    salt '*' pkg.list_upgrades

salt.modules.aptpkg.mod_repo(repo, saltenv='base', **kwargs)
    Modify one or more values for a repo. If the repo does not exist, it will be created, so long as the definition is well formed. For Ubuntu the ppa:<project>/repo format is acceptable. ppa: format can only be used to create a new repository.

    The following options are available to modify a repo definition:
    
    comps  a comma separated list of components for the repo, e.g. main
    file  a file name to be used
    keyserver  keyserver to get gpg key from
    keyid  key id to load with the keyserver argument
    key_url  URL to a GPG key to add to the APT GPG keyring
    consolidate  if True, will attempt to de-dup and consolidate sources
    comments  Sometimes you want to supply additional information, but not as enabled configuration. Anything supplied for this list will be saved in the repo configuration with a comment marker (#) in front.

    New in version 2015.8.9.

    Note:  Due to the way keys are stored for APT, there is a known issue where the key won't be updated unless another change is made at the same time. Keys should be properly added on initial configuration.

    CLI Examples:
    
    salt '*' pkg.mod_repo 'myrepo definition' uri=http://new/url
    salt '*' pkg.mod_repo 'myrepo definition' comps=main,universe

salt.modules.aptpkg.owner('paths')
    New in version 2014.7.0.
Return the name of the package that owns the file. Multiple file paths can be passed. Like `pkg.version`, if a single path is passed, a string will be returned, and if multiple paths are passed, a dictionary of file/package name pairs will be returned.

If the file is not owned by a package, or is not present on the minion, then an empty string will be returned for that path.

CLI Example:

```shell
salt '*' pkg.owner /usr/bin/apachectl
salt '*' pkg.owner /usr/bin/apachectl /usr/bin/basename
```

salt.modules.aptpkg.purge(name=None, pkgs=None, **kwargs)

Changed in version 2015.8.12,2016.3.3,Carbon: On minions running systemd>=205, `systemd-run(1)` is now used to isolate commands which modify installed packages from the salt-minion daemon’s control group. This is done to keep systemd from killing any apt-get/dpkg commands spawned by Salt when the salt-minion service is restarted. (see KillMode in the `systemd.kill(5)` manpage for more information). If desired, usage of `systemd-run(1)` can be suppressed by setting a config option called systemd.scope, with a value of False (no quotes).

Remove packages via `apt-get purge` along with all configuration files.

**name** The name of the package to be deleted.

Multiple Package Options:

**pkgs** A list of packages to delete. Must be passed as a python list. The name parameter will be ignored if this option is passed.

New in version 0.16.0.

Returns a dict containing the changes.

CLI Example:

```shell
salt '*' pkg.purge <package name>
salt '*' pkg.purge <package1>,<package2>,<package3>
salt '*' pkg.purge pkgs='["foo", "bar"]'
```

salt.modules.aptpkg.refresh_db()

Updates the APT database to latest packages based upon repositories

Returns a dict, with the keys being package databases and the values being the result of the update attempt. Values can be one of the following:

- True: Database updated successfully
- False: Problem updating database
- None: Database already up-to-date

CLI Example:

```shell
salt '*' pkg.refresh_db
```

salt.modules.aptpkg.remove(name=None, pkgs=None, **kwargs)

Changed in version 2015.8.12,2016.3.3,Carbon: On minions running systemd>=205, `systemd-run(1)` is now used to isolate commands which modify installed packages from the salt-minion daemon’s control group. This is done to keep systemd from killing any apt-get/dpkg commands spawned by Salt when the salt-minion service is restarted. (see KillMode in the `systemd.kill(5)` manpage for more information). If desired, usage of `systemd-run(1)` can be suppressed by setting a config option called systemd.scope, with a value of False (no quotes).
Remove packages using `apt-get remove`.

**name** The name of the package to be deleted.

**Multiple Package Options:**

**pkgs** A list of packages to delete. Must be passed as a python list. The **name** parameter will be ignored if this option is passed.

New in version 0.16.0.

Returns a dict containing the changes.

**CLI Example:**

```bash
salt '*' pkg.remove <package name>
salt '*' pkg.remove <package1>,<package2>,<package3>
salt '*' pkg.remove pkgs='["foo", "bar"]'
```

salt.modules.aptpkg.set_selections(*path=None, selection=None, clear=False, saltenv='base*)

Change package state in the dpkg database.

The state can be any one of, documented in `dpkg(1)`:

- install
- hold
- deinstall
- purge

This command is commonly used to mark specific packages to be held from being upgraded, that is, to be kept at a certain version. When a state is changed to anything but being held, then it is typically followed by `apt-get -u dselect-upgrade`.

**Note:** Be careful with the **clear** argument, since it will start with setting all packages to deinstall state.

Returns a dict of dicts containing the package names, and the new and old versions:

```python
{
    '<host>': {
        '<package>': {
            'new': '<new-state>',
            'old': '<old-state>'
        },
        ...  
    }
}
```

**CLI Example:**

```bash
salt '*' pkg.set_selections selection='{"install": ["netcat"]}'
salt '*' pkg.set_selections selection='{"hold": ["openssh-server", "openssh-client"]}'
salt '*' pkg.set_selections salt://path/to/file
salt '*' pkg.set_selections salt://path/to/file clear=True
```

salt.modules.aptpkg.unhold(*name=None, pkgs=None, sources=None, **kwargs*)

New in version 2014.7.0.

Set package current in `hold` state to install state, meaning it will be upgraded.

**name** The name of the package, e.g., `tmux`

**CLI Example:**
pkg.unhold <package name>

**pkgs** A list of packages to hold. Must be passed as a python list.

CLI Example:

```
salt '*' pkg.unhold pkgs=['foo', 'bar']
```

salt.modules.aptpkg.upgrade(refresh=True, dist_upgrade=False, **kwargs)

Changed in version 2015.8.12, 2016.3.3, Carbon: On minions running systemd>=205, systemd-run(1) is now used to isolate commands which modify installed packages from the salt-minion daemon's control group. This is done to keep systemd from killing any apt-get/dpkg commands spawned by Salt when the salt-minion service is restarted. (see KillMode in the systemd.kill(5) manpage for more information). If desired, usage of systemd-run(1) can be suppressed by setting a config option called systemd.scope, with a value of False (no quotes).

Upgrades all packages via apt-get upgrade or apt-get dist-upgrade if dist_upgrade is True. Returns a dict containing the changes:

```
{'<package>': {'old': '<old-version>', 'new': '<new-version>'}}
```

dist_upgrade Whether to perform the upgrade using dist-upgrade vs upgrade. Default is to use upgrade.

New in version 2014.7.0.

force_conf_new Always install the new version of any configuration files.

New in version 2015.8.0.

CLI Example:

```
salt '*' pkg.upgrade
```

salt.modules.aptpkg.upgrade_available(name)

Check whether or not an upgrade is available for a given package

CLI Example:

```
salt '*' pkg.upgrade_available <package name>
```

salt.modules.aptpkg.version(*names, **kwargs)

Returns a string representing the package version or an empty string if not installed. If more than one package name is specified, a dict of name/version pairs is returned.

CLI Example:

```
salt '*' pkg.version <package name>
salt '*' pkg.version <package1> <package2> <package3> ...
```

salt.modules.aptpkg.version_cmp(pkg1, pkg2, ignore_epoch=False)

Do a cmp-style comparison on two packages. Return -1 if pkg1 < pkg2, 0 if pkg1 == pkg2, and 1 if pkg1 > pkg2. Return None if there was a problem making the comparison.

ignore_epoch [False] Set to True to ignore the epoch when comparing versions

New in version 2015.8.10, 2016.3.2.

CLI Example:
32.17.6 salt.modules.archive

A module to wrap (non-Windows) archive calls

New in version 2014.1.0.

cmd_unzip

```
salt '*' archive.cmd_unzip (zip_file, dest, excludes=None, template=None, options=None, runas=None)
```

New in version 2015.5.0: In versions 2014.7.x and earlier, this function was known as archive.unzip.

Uses the `unzip` command to unpack zip files. This command is part of the `Info-ZIP` suite of tools, and is typically packaged as simply `unzip`.

- **zip_file** Path of zip file to be unpacked
- **dest** The destination directory into which the file should be unpacked
- **excludes** [None] Comma-separated list of files not to unpack. Can also be passed in a Python list.
- **template** [None] Can be set to `jinja` or another supported template engine to render the command arguments before execution:
  ```
salt '*' archive.cmd_unzip template=jinja /tmp/zipfile.zip /tmp/{{grains.id}}/!
  excludes=file_1,file_2
  ```
- **options** [None] Additional command-line options to pass to the `unzip` binary.

  Changed in version 2015.8.0: The mandatory `-` prefixing has been removed. An options string beginning with a `--long-option`, would have uncharacteristically needed its first `-` removed under the former scheme.

- **runas** [None] Unpack the zip file as the specified user. Defaults to the user under which the minion is running.

New in version 2015.5.0.

CLI Example:
```
salt '*' archive.cmd_unzip /tmp/zipfile.zip /home/strongbad/ excludes=file_1,file_2
```

cmd_zip

```
salt '*' archive.cmd_zip (zip_file, sources, template=None, cwd=None, runas=None)
```

New in version 2015.5.0: In versions 2014.7.x and earlier, this function was known as archive.zip.

Uses the `zip` command to create zip files. This command is part of the `Info-ZIP` suite of tools, and is typically packaged as simply `zip`.

- **zip_file** Path of zip file to be created
- **sources** Comma-separated list of sources to include in the zip file. Sources can also be passed in a Python list.
- **template** [None] Can be set to `jinja` or another supported template engine to render the command arguments before execution:
  ```
salt '*' archive.cmd_zip template=jinja /tmp/zipfile.zip /tmp/sourcefile1,/tmp/!{grains.id}.txt
  ```
- **cwd** [None] Use this argument along with relative paths in `sources` to create zip files which do not contain the leading directories. If not specified, the zip file will be created as if the `cwd` was `/`, and creating a zip file of `/foo/bar/baz.txt` will contain the parent directories `foo` and `bar`. To create a zip file containing just `baz.txt`, the following command would be used:
New in version 2014.7.1.

runas  [None] Create the zip file as the specified user. Defaults to the user under which the minion is running.

New in version 2015.5.0.

CLI Example:

```plaintext
salt '*' archive.cmd_zip /tmp/zipfile.zip /tmp/sourcefile1,/tmp/sourcefile2
```

salt.modules.archive.gunzip(gzipfile, template=None, runas=None)

Uses the gunzip command to unpack gzip files

**template**  [None] Can be set to `jinja` or another supported template engine to render the command arguments before execution:

```plaintext
salt '*' archive.gunzip template=jinja /tmp/{{grains.id}}.txt.gz
```

CLI Example:

```plaintext
# Create /tmp/sourcefile.txt
salt '*' archive.gunzip /tmp/sourcefile.txt.gz
```

salt.modules.archive.gzip(sourcefile, template=None, runas=None)

Uses the gzip command to create gzip files

**template**  [None] Can be set to `jinja` or another supported template engine to render the command arguments before execution:

```plaintext
salt '*' archive.gzip template=jinja /tmp/{{grains.id}}.txt
```

CLI Example:

```plaintext
# Create /tmp/sourcefile.txt.gz
salt '*' archive.gzip /tmp/sourcefile.txt
```

salt.modules.archive.rar(rarfile, sources, template=None, cwd=None, runas=None)

Uses `rar` for Linux to create rar files

**rarfile**  Path of rar file to be created

**sources**  Comma-separated list of sources to include in the rar file. Sources can also be passed in a Python list.

**cwd**  [None] Run the rar command from the specified directory. Use this argument along with relative file paths to create rar files which do not contain the leading directories. If not specified, this will default to the home directory of the user under which the salt minion process is running.

New in version 2014.7.1.

**template**  [None] Can be set to `jinja` or another supported template engine to render the command arguments before execution:

```plaintext
salt '*' archive.rar template= Jinja /tmp/rarfile.rar '/tmp/sourcefile1,/tmp/{{grains.id}}.txt'
```

CLI Example:
salt.modules.archive.tar(options, tarfile, sources=None, dest=None, cwd=None, template=None, runas=None)

Note: This function has changed for version 0.17.0. In prior versions, the cwd and template arguments must be specified, with the source directories/files coming as a space-separated list at the end of the command. Beginning with 0.17.0, sources must be a comma-separated list, and the cwd and template arguments are optional.

Uses the tar command to pack, unpack, etc. tar files

**options** Options to pass to the tar command

Changed in version 2015.8.0: The mandatory - prefixing has been removed. An options string beginning with a --long-option, would have uncharacteristically needed its first - removed under the former scheme.

Also, tar will parse its options differently if short options are used with or without a preceding -, so it is better to not confuse the user into thinking they’re using the non-- format, when really they are using the with-- format.

**tarfile** The filename of the tar archive to pack/unpack

**sources** Comma delimited list of files to pack into the tarfile. Can also be passed as a Python list.

**dest** The destination directory into which to unpack the tarfile

**cwd** [None] The directory in which the tar command should be executed. If not specified, will default to the home directory of the user under which the salt minion process is running.

**template** [None] Can be set to 'jinja' or another supported template engine to render the command arguments before execution:

```
salt '*' archive.tar -cjvf /tmp/salt.tar.bz2 {{grains.saltpath}} template=jinja
```

CLI Examples:

```
# Create a tarfile
salt '*' archive.tar -cjvf /tmp/tarfile.tar.bz2 /tmp/file_1,/tmp/file_2
# Unpack a tarfile
salt '*' archive.tar xf foo.tar dest=/target/directory
```

salt.modules.archive.unrar(rarfile, dest, excludes=None, template=None, runas=None)

Uses *rar* for Linux to unpack *rar* files

**rarfile** Name of rar file to be unpacked

**dest** The destination directory into which to unpack the rar file

**template** [None] Can be set to 'jinja' or another supported template engine to render the command arguments before execution:

```
salt '*' archive.unrar template=jinja /tmp/rarfile.rar /tmp/{{grains.id}}/!@#excludes=file_1,file_2
```

CLI Example:

```
salt '*' archive.unrar /tmp/rarfile.rar /home/strongbad/ excludes=file_1,file_2
```
salt.modules.archive.unzip(zip_file, dest, excludes=None, template=None, runas=None)

Uses the zipfile Python module to unpack zip files

Changed in version 2015.5.0: This function was rewritten to use Python's native zip file support. The old functionality has been preserved in the new function archive.cmd_unzip. For versions 2014.7.x and earlier, see the archive.cmd_zip documentation.

zip_file Path of zip file to be unpacked

dest The destination directory into which the file should be unpacked

excludes [None] Comma-separated list of files not to unpack. Can also be passed in a Python list.

template [None] Can be set to 'jinja' or another supported template engine to render the command arguments before execution:

```bash
salt '*' archive.unzip template=jinja /tmp/ziupfile.zip /tmp/{{grains.id}}/{{
  @excludes=file_1,file_2
}
```

runas [None] Unpack the zip file as the specified user. Defaults to the user under which the minion is running.

CLI Example:

```bash
salt '*' archive.unzip /tmp/ziupfile.zip /home/strongbad/ excludes=file_1,file_2
```

salt.modules.archive.zip(zip_file, sources, template=None, cwd=None, runas=None)

Uses the zipfile Python module to create zip files

Changed in version 2015.5.0: This function was rewritten to use Python's native zip file support. The old functionality has been preserved in the new function archive.cmd_zip. For versions 2014.7.x and earlier, see the archive.cmd_zip documentation.

zip_file Path of zip file to be created

sources Comma-separated list of sources to include in the zip file. Sources can also be passed in a Python list.

template [None] Can be set to 'jinja' or another supported template engine to render the command arguments before execution:

```bash
salt '*' archive.zip template=jinja /tmp/ziupfile.zip /tmp/sourcefile1,/tmp/
  @{{grains.id}}}.txt
```

cwd [None] Use this argument along with relative paths in sources to create zip files which do not contain the leading directories. If not specified, the zip file will be created as if the cwd was /, and creating a zip file of /foo/bar/baz.txt will contain the parent directories foo and bar. To create a zip file containing just baz.txt, the following command would be used:

```bash
salt '*' archive.zip /tmp/baz.zip baz.txt cwd=/foo/bar
```

runas [None] Create the zip file as the specified user. Defaults to the user under which the minion is running.

CLI Example:

```bash
salt '*' archive.zip /tmp/ziupfile.zip /tmp/sourcefile1,/tmp/sourcefile2
```

32.17.7 salt.modules.artifactory

Module for fetching artifacts from Artifactory

exception salt.modules.artifactory.ArtifactoryError(value)
salt.modules.artifactory.get_latest_snapshot(artifactory_url, repository, group_id, artifact_id, packaging, target_dir='/tmp', target_file=None, classifier=None, username=None, password=None)

Gets latest snapshot of the given artifact

artifactory_url URL of artifactory instance
repository Snapshot repository in artifactory to retrieve artifact from, for example: libs-snapshots
group_id Group Id of the artifact
artifact_id Artifact Id of the artifact
packaging Packaging type (jar,war,ear,etc)
target_dir Target directory to download artifact to (default: /tmp)
target_file Target file to download artifact to (by default it is target_dir/artifact_id-snapshot_version.packaging)
classifier Artifact classifier name (ex: sources,javadoc,etc). Optional parameter.
username Artifactory username. Optional parameter.
password Artifactory password. Optional parameter.

salt.modules.artifactory.get_release(artifactory_url, repository, group_id, artifact_id, packaging, version, target_dir='/tmp', target_file=None, classifier=None, username=None, password=None)

Gets the specified release of the artifact

artifactory_url URL of artifactory instance
repository Release repository in artifactory to retrieve artifact from, for example: libs-releases
group_id Group Id of the artifact
artifact_id Artifact Id of the artifact
packaging Packaging type (jar,war,ear,etc)
version Version of the artifact
target_dir Target directory to download artifact to (default: /tmp)
target_file Target file to download artifact to (by default it is target_dir/artifact_id-version.packaging)
classifier Artifact classifier name (ex: sources,javadoc,etc). Optional parameter.
username Artifactory username. Optional parameter.
password Artifactory password. Optional parameter.

salt.modules.artifactory.get_snapshot(artifactory_url, repository, group_id, artifact_id, packaging, version, snapshot_version=None, target_dir='/tmp', target_file=None, classifier=None, username=None, password=None)

Gets snapshot of the desired version of the artifact

artifactory_url URL of artifactory instance
repository Snapshot repository in artifactory to retrieve artifact from, for example: libs-snapshots
group_id Group Id of the artifact
artifact_id Artifact Id of the artifact

Chapter 32. Reference
packaging  Packaging type (jar,war,ear,etc)
version  Version of the artifact
target_dir  Target directory to download artifact to (default: /tmp)
target_file  Target file to download artifact to (by default it is target_dir/artifact_id-snapshot_version.packaging)
classifier  Artifact classifier name (ex: sources,javadoc,etc). Optional parameter.
username  Artifactory username. Optional parameter.
password  Artifactory password. Optional parameter.

32.17.8  salt.modules.at

Wrapper module for at(1)

Also, a `tag' feature has been added to more easily tag jobs.

salt.modules.at.at("args", **"kwrags")
Add a job to the queue.

The `timespec' follows the format documented in the at(1) manpage.

CLI Example:

```
salt '*' at.at <timespec> <cmd> [tag=<tag>] [runas=<user>]
salt '*' at.at 12:05am '/sbin/reboot' tag=reboot
salt '*' at.at '3:05am +3 days' 'bin/myscript' tag=nightly runas=jim
```

salt.modules.at.atc(jobid)
Print the at(1) script that will run for the passed job id. This is mostly for debugging so the output will just be text.

CLI Example:

```
salt '*' at.atc <jobid>
```

salt.modules.at.atq(tag=None)
List all queued and running jobs or only those with an optional `tag'.

CLI Example:

```
salt '*' at.atq
salt '*' at.atq [tag]
salt '*' at.atq [job number]
```

salt.modules.at.atrm(*args)
Remove jobs from the queue.

CLI Example:

```
salt '*' at.atrm <jobid> <jobid> .. <jobid>
salt '*' at.atrm all
salt '*' at.atrm all [tag]
```

salt.modules.at.jobcheck(**kwargs)
Check the job from queue. The kwargs dict include `hour minute day month year tag runas' Other parameters will be ignored.
CLI Example:

```
salt '*' at.jobcheck runas=jam day=13
salt '*' at.jobcheck day=13 month=12 year=13 tag=rose
```

### 32.17.9 `salt.modules.augeas_cfg`

Manages configuration files via augeas

This module requires the `augeas` Python module.

**Warning:** Minimal installations of Debian and Ubuntu have been seen to have packaging bugs with python-augeas, causing the augeas module to fail to import. If the minion has the augeas module installed, but the functions in this execution module fail to run due to being unavailable, first restart the salt-minion service. If the problem persists past that, the following command can be run from the master to determine what is causing the import to fail:

```
salt minion-id cmd.run 'python -c "from augeas import Augeas"'
```

For affected Debian/Ubuntu hosts, installing `libpython2.7` has been known to resolve the issue.

**salt.modules.augeas_cfg.execute** *(context=None, lens=None, commands=())*

Execute Augeas commands

New in version 2014.7.0.

CLI Example:

```
salt '*' augeas.execute /files/etc/redis/redis.conf commands='["set bind 0.0.0.0 \-_"], "set maxmemory 1G"]'
```

**salt.modules.augeas_cfg.get** *(path, value='')*

Get a value for a specific augeas path

CLI Example:

```
salt '*' augeas.get /files/etc/hosts/1/ ipaddr
```

**salt.modules.augeas_cfg.ls** *(path)*

List the direct children of a node

CLI Example:

```
salt '*' augeas.ls /files/etc/passwd
```

**salt.modules.augeas_cfg.match** *(path, value='')*

Get matches for path expression

CLI Example:

```
salt '*' augeas.match /files/etc/services/service-name ssh
```

**salt.modules.augeas_cfg.remove** *(path)*

Get matches for path expression

CLI Example:
salt '*' augeas.remove /files/etc/sysctl.conf/net.ipv4.conf.all.log_martians

salt.modules.augeas_cfg.setvalue('args')
Set a value for a specific augeas path

CLI Example:
```
salt '*' augeas.setvalue /files/etc/hosts/1/canonical localhost
```

This will set the first entry in /etc/hosts to localhost

CLI Example:
```
salt '*' augeas.setvalue /files/etc/hosts/01/ipaddr 192.168.1.1 \n/files/etc/hosts/01/canonical test
```

Adds a new host to /etc/hosts the ip address 192.168.1.1 and hostname test

CLI Example:
```
salt '*' augeas.setvalue prefix=/files/etc/sudoers/ \ "spec[user = '%wheel']/user" "%wheel" \ "spec[user = '%wheel']/host_group/host" 'ALL' \ "spec[user = '%wheel']/host_group/command[1]" 'ALL' \ "spec[user = '%wheel']/host_group/command[1]/tag" 'PASSWD' \ "spec[user = '%wheel']/host_group/command[2]" '/usr/bin/apt-get' \ "spec[user = '%wheel']/host_group/command[2]/tag" NOPASSWD
```

Ensures that the following line is present in /etc/sudoers:
```
%wheel ALL = PASSWD : ALL , NOPASSWD : /usr/bin/apt-get , /usr/bin/aptitude
```

salt.modules.augeas_cfg.tree(path)
Returns recursively the complete tree of a node

CLI Example:
```
salt '*' augeas.tree /files/etc/
```

32.17.10 salt.modules.aws_sqs
Support for the Amazon Simple Queue Service.

salt.modules.aws_sqs.create_queue(name, region, opts=None, user=None)
Creates a queue with the correct name.

- **name** Name of the SQS queue to create
- **region** Region to create the SQS queue in
- **opts** [None] Any additional options to add to the command line
- **user** [None] Run hg as a user other than what the minion runs as

CLI Example:
```
salt '*' aws_sqs.create_queue <sqs queue> <region>
```

salt.modules.aws_sqs.delete_message(queue, region, receipthandle, opts=None, user=None)
Delete one or more messages from a queue in a region
queue The name of the queue to delete messages from
region Region where SQS queues exists
receiptHandle The ReceiptHandle of the message to delete. The ReceiptHandle is obtained in the return from receive_message
opts [None] Any additional options to add to the command line
user [None] Run as a user other than what the minion runs as

CLI Example:
```bash
salt '*' aws_sqs.delete_message <sqs queue> <region> receiptHandle=''<sqs.environ.ReceiptHandle>'
```

New in version 2014.7.0.
salt.modules.aws_sqs.delete_queue(name, region, opts=None, user=None)
Deletes a queue in the region.
name Name of the SQS queue to deletes
region Name of the region to delete the queue from
opts [None] Any additional options to add to the command line
user [None] Run as a user other than what the minion runs as

CLI Example:
```bash
salt '*' aws_sqs.delete_queue <sqs queue> <region>
```

salt.modules.aws_sqs.list_queues(region, opts=None, user=None)
List the queues in the selected region.
region Region to list SQS queues for
opts [None] Any additional options to add to the command line
user [None] Run as a user other than what the minion runs as

CLI Example:
```bash
salt '*' aws_sqs.list_queues <region>
```

salt.modules.aws_sqs.queue_exists(name, region, opts=None, user=None)
Returns True or False on whether the queue exists in the region
name Name of the SQS queue to search for
region Name of the region to search for the queue in
opts [None] Any additional options to add to the command line
user [None] Run as a user other than what the minion runs as

CLI Example:
```bash
salt '*' aws_sqs.queue_exists <sqs queue> <region>
```

salt.modules.aws_sqs.receive_message(queue, region, num=1, opts=None, user=None)
Receive one or more messages from a queue in a region
queue The name of the queue to receive messages from
region Region where SQS queues exists
num [1] The max number of messages to receive
**opts** [None] Any additional options to add to the command line

**user** [None] Run as a user other than what the minion runs as

CLI Example:

```
salt '*' aws_sqs.receive_message <sqs queue> <region>
salt '*' aws_sqs.receive_message <sqs queue> <region> num=10
```

New in version 2014.7.0.

### 32.17.11 salt.modules.bamboohr

Support for BambooHR

New in version 2015.8.0.

Requires a subdomain and an apikey in /etc/salt/minion:

```
salt.modules.bamboohr.list_employees(order_by='id')
```

Show all employees for this company.

CLI Example:

```
salt myminion bamboohr.list_employees
```

By default, the return data will be keyed by ID. However, it can be ordered by any other field. Keep in mind that if the field that is chosen contains duplicate values (i.e., location is used, for a company which only has one location), then each duplicate value will be overwritten by the previous. Therefore, it is advisable to only sort by fields that are guaranteed to be unique.

CLI Examples:

```
salt myminion bamboohr.list_employees order_by=id
salt myminion bamboohr.list_employees order_by=displayName
salt myminion bamboohr.list_employees order_by=workEmail
```

```
salt.modules.bamboohr.list_meta_fields()
```

Show all meta data fields for this company.

CLI Example:

```
salt myminion bamboohr.list_meta_fields
```

```
salt.modules.bamboohr.list_users(order_by='id')
```

Show all users for this company.

CLI Example:

```
salt myminion bamboohr.list_users
```

By default, the return data will be keyed by ID. However, it can be ordered by any other field. Keep in mind that if the field that is chosen contains duplicate values (i.e., location is used, for a company which only has one location), then each duplicate value will be overwritten by the previous. Therefore, it is advisable to only sort by fields that are guaranteed to be unique.

CLI Examples:

```
salt myminion bamboohr.list_users order_by=id
salt myminion bamboohr.list_users order_by=email
```

```
salt.modules.bamboohr.show_employee(emp_id, fields=None)
```

Show all employees for this company.

CLI Example:
By default, the fields normally returned from bamboohr.list_employees are returned. These fields are:

- canUploadPhoto
- department
- displayName
- firstName
- id
- jobTitle
- lastName
- location
- mobilePhone
- nickname
- photoUploaded
- photoUrl
- workEmail
- workPhone
- workPhoneExtension

If needed, a different set of fields may be specified, separated by commas:

CLI Example:

```
salt myminion bamboohr.show_employee 1138 displayName,dateOfBirth
```

A list of available fields can be found at http://www.bamboohr.com/api/documentation/employees.php

salt.modules.bamboohr.update_employee(emp_id, key=None, value=None, items=None)

Update one or more items for this employee. Specifying an empty value will clear it for that employee.

CLI Examples:

```
salt myminion bamboohr.update_employee 1138 nickname Curly
salt myminion bamboohr.update_employee 1138 nickname ''
salt myminion bamboohr.update_employee 1138 items='{"nickname": "Curly"}'
salt myminion bamboohr.update_employee 1138 items='{"nickname": ""}'
```

32.17.12 salt.modules.beacons

Module for managing the Salt beacons on a minion

New in version 2015.8.0.

salt.modules.beacons.add(name, beacon_data, **kwargs)

Add a beacon on the minion

Parameters

- **name** -- Name of the beacon to configure
- **beacon_data** -- Dictionary or list containing configuration for beacon.

Returns  Boolean and status message on success or failure of add.
CLI Example:

```bash
salt '*' beacons.add ps "{'salt-master': 'stopped', 'apache2': 'stopped'}"
```

**salt.modules.beacons.delete**(*name, **kwargs*)
Delete a beacon item

**Parameters**

- **name** -- Name of the beacon to delete

**Returns**

Boolean and status message on success or failure of delete.

CLI Example:

```bash
salt '*' beacons.delete ps
salt '*' beacons.delete load
```

**salt.modules.beacons.disable(**kwargs)**
Disable all beaconsd jobs on the minion

**Returns**

Boolean and status message on success or failure of disable.

CLI Example:

```bash
salt '*' beacons.disable
```

**salt.modules.beacons.disable_beacon**(*name, **kwargs*)
Disable beacon on the minion

**Name**

Name of the beacon to disable.

**Returns**

Boolean and status message on success or failure of disable.

CLI Example:

```bash
salt '*' beacons.disable_beacon ps
```

**salt.modules.beacons.enable(**kwargs)**
Enable all beacons on the minion

**Returns**

Boolean and status message on success or failure of enable.

CLI Example:

```bash
salt '*' beacons.enable
```

**salt.modules.beacons.enable_beacon**(*name, **kwargs*)
Enable beacon on the minion

**Name**

Name of the beacon to enable.

**Returns**

Boolean and status message on success or failure of enable.

CLI Example:

```bash
salt '*' beacons.enable_beacon ps
```

**salt.modules.beacons.list**(return_yaml=True)
List the beacons currently configured on the minion

**Parameters**

- **return_yaml** -- Whether to return YAML formatted output, default True

**Returns**

List of currently configured Beacons.
32.17.13 salt.modules.bigip

An execution module which can manipulate an f5 bigip via iControl REST

    maturity  develop
    platform  f5_bigip_11.6

Salt modules.bigip.add_pool_member(hostname, username, password, name, member)
A function to connect to a bigip device and add a new member to an existing pool.

    hostname   The host/address of the bigip device
    username   The iControl REST username
    password   The iControl REST password
    name       The name of the pool to modify
    member     The name of the member to add i.e. 10.1.1.2:80

CLI Example:

    salt '*' bigip.add_pool_members bigip admin admin my-pool 10.2.2.1:80

Salt modules.bigip.commit_transaction(hostname, username, password, label)
A function to connect to a bigip device and commit an existing transaction.

    hostname   The host/address of the bigip device
    username   The iControl REST username
    password   The iControl REST password
    label      the label of this transaction stored within the grain: bigip_f5_trans:<label>
CLI Example:

```
salt '*' bigip.commit_transaction bigip admin admin my_transaction
```

```
salt.modules.bigip.create_monitor(hostname, username, password, monitor_type, name, **kwargs)
```

A function to connect to a bigip device and create a monitor.

- **hostname** The host/address of the bigip device
- **username** The iControl REST username
- **password** The iControl REST password
- **monitor_type** The type of monitor to create
- **name** The name of the monitor to create
- **kwargs** Consult F5 BIGIP user guide for specific options for each monitor type. Typically, tmsh arg names are used.

CLI Example:

```
salt '*' bigip.create_monitor bigip admin admin http my-http-monitor timeout=10 interval=5
```

```
salt.modules.bigip.create_node(hostname, username, password, name, address, trans_label=None)
```

A function to connect to a bigip device and create a node.

- **hostname** The host/address of the bigip device
- **username** The iControl REST username
- **password** The iControl REST password
- **name** The name of the node
- **address** The address of the node
- **trans_label** The label of the transaction stored within the grain: bigip_f5_trans:<label>

CLI Example:

```
salt '*' bigip.create_node bigip admin admin 10.1.1.2
```

```
salt.modules.bigip.create_pool(hostname, username, password, name, members=None, allow_nat=None, allow_snat=None, description=None, gatewayfailsafe_device=None, ignore_persisted_weight=None, ip_tos_to_client=None, ip_tos_to_server=None, link_qos_to_client=None, link_qos_to_server=None, load_balancing_mode=None, min_active_members=None, min_up_members=None, min_up_members_action=None, min_up_members_checking=None, monitor=None, profiles=None, queue_depth_limit=None, queue_on_connection_limit=None, queue_time_limit=None, reselect_tries=None, servicedown_action=None, slow_ramp_time=None)
```

A function to connect to a bigip device and create a pool.

- **hostname** The host/address of the bigip device
- **username** The iControl REST username
- **password** The iControl REST password
name The name of the pool to create.

members List of comma delimited pool members to add to the pool. i.e. 10.1.1.1:80,10.1.1.2:80,10.1.1.3:80

allow_nat [yes | no]

allow_snat [yes | no]

description [string]

gateway_failsafe_device [string]

ignore_persisted_weight [enabled | disabled]

ip_tos_to_client [pass-through | [integer]]

ip_tos_to_server [pass-through | [integer]]

link_qos_to_client [pass-through | [integer]]

link_qos_to_server [pass-through | [integer]]

load_balancing_mode [dynamic-ratio-member | dynamic-ratio-node | fastest-app-response | fastest-node | least-connections-members | least-connections-node | least-sessions | observed-member | observed-node | predictive-member | predictive-node | ratio-least-connections-member | ratio-least-connections-node | ratio-member | ratio-node | ratio-session | round-robin | weighted-least-connections-member | weighted-least-connections-node]

min_active_members [integer]

min_up_members [integer]

min_up_members_action [failover | reboot | restart-all]

min_up_members_checking [enabled | disabled]

monitor [name]

profiles [none | profile_name]

queue_depth_limit [integer]

queue_on_connection_limit [enabled | disabled]

queue_time_limit [integer]

reselect_tries [integer]

service_down_action [drop | none | reselect | reset]

slow_ramp_time [integer]

CLI Example:

```
salt '*' bigip.create_pool bigip admin admin my-pool 10.1.1.1:80,10.1.1.2:80,10.1.1.3:80
```

salt.modules.bigip.create_profile( hostname, username, password, profile_type, name, **kwargs)

A function to connect to a bigip device and create a profile.

hostname The host/address of the bigip device

username The iControl REST username

password The iControl REST password

profile_type The type of profile to create
name  The name of the profile to create

kwargs  [ arg=val ] ... [arg=key1:val1,key2:val2] ...

Consult F5 BIGIP user guide for specific options for each monitor type. Typically, tmsh arg names are used.

Creating Complex Args  Profiles can get pretty complicated in terms of the amount of possible config options. Use the following shorthand to create complex arguments such as lists, dictionaries, and lists of dictionaries. An option is also provided to pass raw json as well.

lists 
\[i,i,i\]: param='item1,item2,item3'

Dictionary 
\[k:v,k:v,k,v\]: param='key-1:val-1,key-2:val2,key-3:va-3'

List of Dictionaries 
\[k:v,k:v|k:v,k:v|k:v,k:v\]: param='key-1:val-1,key-2:val-2|key-1:val-1,key-2:val-2|key-1:val-1,key-2:val-2'

JSON: \'j{ ... }j\': cert-key-chain='j{ "default": { "cert": "default.crt","chain": "default.crt","key": "default.key" } }j'

Escaping Delimiters: Use \, or \: or \| to escape characters which shouldn't be treated as delimiters i.e. ciphers='DEFAULT:\!SSLv3'

CLI Examples:

```bash
salt '*' bigip.create_profile bigip admin admin http my-http-profile defaultsFrom=/Common/http
salt '*' bigip.create_profile bigip admin admin http my-http-profile defaultsFrom=/Common/http \n   enforcement=maxHeaderCount:3200,maxRequests:10
```

salt.modules.bigip.create_virtual

\(hostname, \) username, password, name, destination, pool=None, address_status=None, auto_lasthop=None, bwc_policy=None, cmp_enabled=None, connection_limit=None, dhcp_relay=None, description=None, fallback_persistence=None, flow_eviction_policy=None, gtm_score=None, ip_forward=None, ip_protocol=None, internal=None, twelve_forward=None, last_hop_pool=None, mask=None, mirror=None, nat64=None, persist=None, profiles=None, policies=None, rate_class=None, rate_limit=None, rate_limit_mode=None, rate_limit_dst=None, rate_limit_src=None, rules=None, related_rules=None, reject=None, source=None, source_address_translation=None, source_port=None, state=None, traffic_classes=None, translate_address=None, translate_port=None, vlans=None)

A function to connect to a bigip device and create a virtual server.

hostname  The host/address of the bigip device

username  The iControl REST username

password  The iControl REST password

name  The name of the virtual to create

destination  [ [virtual_address_name:port] | [ipv4-port] | [ipv6.port] ]

pool  [ [pool_name] | none]

address_status  [yes | no]

auto_lasthop  [default | enabled | disabled ]

bwc_policy [none | string]
cmp_enabled [yes | no]
dhcp_relay [yes | no]
connection_limit [integer]
description [string]
state [disabled | enabled]
fallback_persistence [none | [profile name] ]
flow_eviction_policy [none | [eviction policy name] ]
gtm_score [integer]

ip_forward [yes | no]
ip_protocol [any | protocol]
internal [yes | no]
twelve_forward (12-forward) [yes | no]
last_hop-pool [ [pool_name] | none]
mask { [ipv4] | [ipv6] }
mirror { [disabled | enabled | none] }
nat64 [enabled | disabled]
persist [none | profile1,profile2,profile3 ... ]
profiles [none | default | profile1,profile2,profile3 ... ]
policies [none | default | policy1,policy2,policy3 ... ]
rate_class [name]

rate_limit [integer]

rate_limit_mode [destination | object | object-destination | object-source | object-source-destination | source | source-destination]
rate_limit_dst [integer]
rate_limit_src [integer]
rules [none | [rule_one,rule_two ... ] ]
related_rules [none | [rule_one,rule_two ... ] ]

reject [yes | no]
source { [ipv4[/prefixlen]] | [ipv6[/prefixlen]] }
source_address_translation [none | snat:pool_name | lsn | automap ]
source_port [change | preserve | preserve-strict]
state [enabled | disabled]

traffic_classes [none | default | class_one,class_two ... ]
translate_address [enabled | disabled]
translate_port [enabled | disabled]
vlans  [none | default | [enabled|disabled]:vlan1,vlan2,vlan3 ... ]

CLI Examples:

```bash
salt '*' bigip.create_virtual bigip admin admin my-virtual-3 26.2.2.5:80 \
pool=my-http-pool http profiles=http,tcp
salt '*' bigip.create_virtual bigip admin admin my-virtual-3 43.2.2.5:80 \
pool=test-http-pool http profiles=http,websecurity persist=cookie,hash \n  policies=asm_auto_l7_policy__http-virtual \n  rules=_sys_APM_ExchangeSupport_helper,_sys_https_redirect \n  related_rules=_sys_APM_activesync,_sys_APM_ExchangeSupport_helper \n  source_address_translation=snat:my-snats-pool \n  translate_address=enabled translate_port=enabled \n  traffic_classes=my-class,other-class \
  vlans=enabled:external,internal
```

```python
salt.modules.bigip.delete_monitor( hostname, username, password, monitor_type, name )
A function to connect to a bigip device and delete an existing monitor.

hostname  The host/address of the bigip device
username  The iControl REST username
password  The iControl REST password
monitor_type  The type of monitor to delete
name  The name of the monitor to delete

CLI Example:

```bash
salt '*' bigip.delete_monitor bigip admin admin http my-http-monitor
```

```python
salt.modules.bigip.delete_node( hostname, username, password, name, trans_label=None )
A function to connect to a bigip device and delete a specific node.

hostname  The host/address of the bigip device
username  The iControl REST username
password  The iControl REST password
name  The name of the node which will be deleted.

trans_label  The label of the transaction stored within the grain: bigip_f5_trans:<label>

CLI Example:

```bash
salt '*' bigip.delete_node bigip admin admin my-node
```

```python
salt.modules.bigip.delete_pool( hostname, username, password, name )
A function to connect to a bigip device and delete a specific pool.

hostname  The host/address of the bigip device
username  The iControl REST username
password  The iControl REST password
name  The name of the pool which will be deleted

CLI Example:

```bash
```
salt.modules.bigip.delete_pool_member(hostname, username, password, name, member)

A function to connect to a bigip device and delete a specific pool.

hostname  The host/address of the bigip device
username  The iControl REST username
password  The iControl REST password
name      The name of the pool to modify
member    The name of the pool member to delete

CLI Example:
salt '*' bigip.delete_node bigip admin admin my-pool 10.2.2.2:80

salt.modules.bigip.delete_profile(hostname, username, password, profile_type, name)

A function to connect to a bigip device and delete an existing profile.

hostname  The host/address of the bigip device
username  The iControl REST username
password  The iControl REST password
profile_type  The type of profile to delete
name      The name of the profile to delete

CLI Example:
salt '*' bigip.delete_profile bigip admin admin http my-http-profile

salt.modules.bigip.delete_transaction(hostname, username, password, label)

A function to connect to a bigip device and delete an existing transaction.

hostname  The host/address of the bigip device
username  The iControl REST username
password  The iControl REST password
label    The label of this transaction stored within the grain: bigip_f5_trans:<label>

CLI Example:
salt '*' bigip.delete_transaction bigip admin admin my_transaction

salt.modules.bigip.delete_virtual(hostname, username, password, name)

A function to connect to a bigip device and delete a specific virtual.

hostname  The host/address of the bigip device
username  The iControl REST username
password  The iControl REST password
name      The name of the virtual to delete

CLI Example:
salt 'bigip.delete_virtual bigip admin admin my-virtual

```
salt.modules.bigip.list_monitor(hostname, username, password, monitor_type, name=None)
A function to connect to a bigip device and list an existing monitor. If no name is provided then all monitors
of the specified type will be listed.
hostname  The host/address of the bigip device
username  The iControl REST username
password  The iControl REST password
monitor_type  The type of monitor(s) to list
name  The name of the monitor to list
CLI Example:
```
salt 'bigip.list_monitor bigip admin admin http my-http-monitor

```
salt.modules.bigip.list_node(hostname, username, password, name=None, trans_label=None)
A function to connect to a bigip device and list all nodes or a specific node.
hostname  The host/address of the bigip device
username  The iControl REST username
password  The iControl REST password
name  The name of the node to list. If no name is specified then all nodes will be listed.
trans_label  The label of the transaction stored within the grain: bigip_f5_trans:<label>
CLI Example:
```
salt 'bigip.list_node bigip admin admin my-node

```
salt.modules.bigip.list_pool(hostname, username, password, name=None)
A function to connect to a bigip device and list all pools or a specific pool.
hostname  The host/address of the bigip device
username  The iControl REST username
password  The iControl REST password
name  The name of the pool to list. If no name is specified then all pools will be listed.
CLI Example:
```
salt 'bigip.list_pool bigip admin admin my-pool

```
salt.modules.bigip.list_profile(hostname, username, password, profile_type, name=None)
A function to connect to a bigip device and list an existing profile. If no name is provided then all profiles of
the specified type will be listed.
hostname  The host/address of the bigip device
username  The iControl REST username
password  The iControl REST password
profile_type  The type of profile(s) to list
name  The name of the profile to list

32.17. Full list of builtin execution modules 751
CLI Example:

```bash
salt '*' bigip.list_profile bigip admin admin http my-http-profile
```

**salt.modules.bigip.list_transaction** *(hostname, username, password, label)*

A function to connect to a bigip device and list an existing transaction.

- **hostname** The host/address of the bigip device
- **username** The iControl REST username
- **password** The iControl REST password
- **label** The label of this transaction stored within the grain: `bigip_f5_trans:<label>`

CLI Example:

```bash
salt '*' bigip.list_transaction bigip admin admin my_transaction
```

**salt.modules.bigip.list_virtual** *(hostname, username, password, name=None)*

A function to connect to a bigip device and list all virtuals or a specific virtual.

- **hostname** The host/address of the bigip device
- **username** The iControl REST username
- **password** The iControl REST password
- **name** The name of the virtual to list. If no name is specified than all virtuals will be listed.

CLI Example:

```bash
salt '*' bigip.list_virtual bigip admin admin my-virtual
```

**salt.modules.bigip.modify_monitor** *(hostname, username, password, monitor_type, name, **kwargs)*

A function to connect to a bigip device and modify an existing monitor.

- **hostname** The host/address of the bigip device
- **username** The iControl REST username
- **password** The iControl REST password
- **monitor_type** The type of monitor to modify
- **name** The name of the monitor to modify
- **kwargs** Consult F5 BIGIP user guide for specific options for each monitor type. Typically, tmsh arg names are used.

CLI Example:

```bash
salt '*' bigip.modify_monitor bigip admin admin http my-http-monitor timeout=16
interval=6
```

**salt.modules.bigip.modify_node** *(hostname, username, password, name, connection_limit=None, description=None, dynamic_ratio=None, logging=None, monitor=None, rate_limit=None, ratio=None, session=None, state=None, trans_label=None)*

A function to connect to a bigip device and modify an existing node.

- **hostname** The host/address of the bigip device
- **username** The iControl REST username
password  The iControl REST password
name  The name of the node to modify
connection_limit [integer]
description [string]
dynamic_ratio [integer]
logging [enabled | disabled]
monitor [(name) | none | default]
ratio [integer]
session [user-enabled | user-disabled]
state [user-down | user-up]
trans_label  The label of the transaction stored within the grain: bigip_f5_trans:<label>

CLI Example:
salt '*' bigip.modify_node bigip admin admin 10.1.1.2 ratio=2 logging=enabled

salt.modules.bigip.modify_pool(hostname, username, password, name, allow_nat=None, allow_snat=None, description=None, gateway_failsafe_device=None, ignore_persisted_weight=None, ip_tos_to_client=None, ip_tos_to_server=None, link_qos_to_client=None, link_qos_to_server=None, load_balancing_mode=None, min_active_members=None, min_up_members=None, min_up_members_action=None, min_up_members_checking=None, monitor=None, profiles=None, queue_depth_limit=None, queue_on_connection_limit=None, queue_time_limit=None, reselect_tries=None, service_down_action=None, slow_ramp_time=None)

A function to connect to a bigip device and modify an existing pool.

hostname  The host/address of the bigip device
username  The iControl REST username
password  The iControl REST password
name  The name of the pool to modify.
allow_nat [yes | no]
allow_snat [yes | no]
description [string]
gateway_failsafe_device [string]
ignore_persisted_weight [yes | no]
ip_tos_to_client [pass-through | [integer]]
ip_tos_to_server [pass-through | [integer]]
link_qos_to_client [pass-through | [integer]]
link_qos_to_server [pass-through | [integer]]
load_balancing_mode [dynamic-ratio-member | dynamic-ratio-node | fastest-app-response | fastest-node | least-connections-members | least-connections-node | least-sessions | observed-member | observed-node | predictive-member | predictive-node | ratio-least-connections-member | ratio-least-connections-node | ratio-member | ratio-node | ratio-session | round-robin | weighted-least-connections-member | weighted-least-connections-node]

min_active_members [integer]
min_up_members [integer]
min_up_members_action [failover | reboot | restart-all]
min_up_members_checking [enabled | disabled]
monitor [name]
profiles [none | profile_name]
queue_on_connection_limit [enabled | disabled]
queue_depth_limit [integer]
queue_time_limit [integer]
reselect_tries [integer]
service_down_action [drop | none | reselect | reset]
slow_ramp_time [integer]

CLI Example:
salt '*' bigip.modify_pool bigip admin admin my-pool 10.1.1.80,10.1.1.2:80,10.1.1.3:80 min_active_members=1

salt.modules.bigip.modify_pool_member(hostname, username, password, name, member,
connection_limit=None, description=None,
dynamic_ratio=None, inherit_profile=None, logging=None, monitor=None, priority_group=None,
profiles=None, rate_limit=None, ratio=None, session=None, state=None)

A function to connect to a bigip device and modify an existing member of a pool.

hostname The host/address of the bigip device
username The iControl REST username
password The iControl REST password
name The name of the pool to modify
member The name of the member to modify i.e. 10.1.1.2:80
connection_limit [integer]
description [string]
dynamic_ratio [integer]
inherit_profile [enabled | disabled]
logging [enabled | disabled]
monitor [name]
priority_group [integer]
Salt Documentation, Release 2015.8.12

proﬁles [none | proﬁle_name]
rate_limit [integer]
ratio [integer]
session [user-enabled | user-disabled]
state [ user-up | user-down ]
CLI Example:
salt '*' bigip.modify_pool_member bigip admin admin my-pool 10.2.2.1:80 state=use,→down session=user-disabled

salt.modules.bigip.modify_profile(hostname, username,
**kwargs)
A function to connect to a bigip device and create a proﬁle.

password,

proﬁle_type,

name,

A function to connect to a bigip device and create a proﬁle.
hostname e host/address of the bigip device
username e iControl REST username
password e iControl REST password
proﬁle_type e type of proﬁle to create
name e name of the proﬁle to create
kwargs [ arg=val ] ... [arg=key1:val1,key2:val2] ...
Consult F5 BIGIP user guide for speciﬁc options for each monitor type. Typically, tmsh arg names are
used.
Creating Complex Args
Proﬁles can get prey complicated in terms of the amount of possible conﬁg options. Use the
following shorthand to create complex arguments such as lists, dictionaries, and lists of dictionaries.
An option is also provided to pass raw json as well.
lists [i,i,i]: param='item1,item2,item3'
Dictionary [k:v,k:v,k,v]: param='key-1:val-1,key-2:val2,key-3:va-3'
List of Dictionaries [k:v,k:v|k:v,k:v|k:v,k:v]: param='key-1:val-1,key2:val-2|key-1:val-1,key-2:val-2|key-1:val-1,key-2:val-2'
JSON: 'j{ ... }j': cert-key-chain='j{ "default":
{ "cert":
"default.crt","chain": "default.crt","key": "default.key" } }j'
Escaping Delimiters: Use \, or \: or \| to escape characters which shouldn't be treated as delimiters i.e. ciphers='DEFAULT\:!SSLv3'
CLI Examples:
salt '*' bigip.modify_profile bigip admin admin http my-http-profile defaultsFrom=
,→'/Common/http'
salt '*' bigip.modify_profile bigip admin admin http my-http-profile defaultsFrom=
,→'/Common/http' \
enforcement=maxHeaderCount:3200,maxRequests:10
salt '*' bigip.modify_profile bigip admin admin client-ssl my-client-ssl-1
,→retainCertificate=false \

32.17. Full list of builtin execution modules

755


salt.modules.bigip.modify_virtual(hostname, username, password, name, destination=None, pool=None, address_status=None, auto_lasthop=None, bwc_policy=None, cmp_enabled=None, connection_limit=None, dhcp_relay=None, description=None, fallback_persistence=None, flow_eviction_policy=None, gtm_score=None, ip_forward=None, ip_protocol=None, internal=None, twelve_forward=None, last_hop_pool=None, mask=None, mirror=None, nat64=None, persist=None, profiles=None, policies=None, rate_class=None, rate_limit=None, rate_limit_mode=None, rate_limit_dst=None, source=None, source_address_translation=None, source_port=None, state=None, traffic_classes=None, translate_address=None, translate_port=None, vlans=None)

A function to connect to a bigip device and modify an existing virtual server.

hostname  The host/address of the bigip device
username  The iControl REST username
password  The iControl REST password
name  The name of the virtual to modify
destination  [ [virtual_address_name:port] | [ipv4:port] | [ipv6:port] ]
pool  [ [pool_name] | none ]
address_status  [yes | no]
auto_lasthop  [default | enabled | disabled ]
bwc_policy  [none] | string]
cmp_enabled  [yes | no]
dhcp_relay  [yes | no]
connection_limit  [integer]
description  [string]
state  [disabled | enabled]
fallback_persistence  [none | [profile name] ]
flow_eviction_policy  [none | [eviction policy name] ]
gtm_score  [integer]
ip_forward  [yes | no]
ip_protocol  [any | protocol]
internal  [yes | no]
twelve_forward  (12-forward) [yes | no]
last_hop_pool  [ [pool_name] | none ]
mask  { [ipv4] | [ipv6] }
**mirror** { [disabled | enabled | none] }

**nat64** [enabled | disabled]

**persist** [none | profile1,profile2,profile3 ... ]

**profiles** [none | default | profile1,profile2,profile3 ... ]

**policies** [none | default | policy1,policy2,policy3 ... ]

**rate_class** [name]

**rate_limit** [integer]

**rate_limitr_mode** [destination | object | object-destination | object-source | object-source-destination | source | source-destination]

**rate_limit_dst** [integer]

**rate_limit_src** [integer]

**rules** [none | [rule_one,rule_two ... ] ]

**related_rules** [none | [rule_one,rule_two ... ] ]

**reject** [yes | no]

**source** { [ipv4[/prefixlen]] | [ipv6[/prefixlen]] }

**source_address_translation** [none | snat:pool_name | lsn | automap ]

**source_port** [change | preserve | preserve-strict]

**state** [enabled | disable]

**traffic_classes** [none | default | class_one,class_two ... ]

**translate_address** [enabled | disabled]

**translate_port** [enabled | disabled]

**vlans** [none | default | [enabled|disabled]:vlan1,vlan2,vlan3 ... ]

**CLI Example:**

```bash
salt '*' bigip.modifyVirtual bigip admin admin my-virtual source_address_translation=none

salt '*' bigip.modifyVirtual bigip admin admin my-virtual rules=my-rule,my-other-rule
```

**salt.modules.bigip.replace_pool_members** *(hostname, username, password, name, members)*

A function to connect to a bigip device and replace members of an existing pool with new members.

**hostname** The host/address of the bigip device

**username** The iControl REST username

**password** The iControl REST password

**name** The name of the pool to modify

**members** List of comma delimited pool members to replace existing members with. i.e. 10.1.1.1:80,10.1.1.2:80,10.1.1.3:80

**CLI Example:**

```bash
salt '*' bigip.replace_pool_members bigip admin admin my-pool 10.2.2.1:80,10.2.2.2:80,10.2.2.3:80
```
salt.modules.bigip.start_transaction(hostname, username, password, label)
A function to connect to a bigip device and start a new transaction.

hostname The host/address of the bigip device
username The iControl REST username
password The iControl REST password
label The name / alias for this transaction. The actual transaction id will be stored within a grain called bigip_f5_trans:<label>

CLI Example:
```
salt '*' bigip.start_transaction bigip admin admin my_transaction
```

32.17.14 salt.modules.blockdev

Module for managing block devices

New in version 2014.7.0.

salt.modules.blockdev.dump(device, args=None)
Return all contents of dumpe2fs for a specified device

args a list containing only the desired arguments to return

CLI Example:
```
salt '*' blockdev.dump /dev/sdX1
```

salt.modules.blockdev.format(device, fs_type='ext4', inode_size=None, lazy_itable_init=None)
Format a filesystem onto a block device

New in version 2015.8.2.

device The block device in which to create the new filesystem
fs_type The type of filesystem to create
inode_size Size of the inodes

This option is only enabled for ext and xfs filesystems

lazy_itable_init If enabled and the uninit_bg feature is enabled, the inode table will not be fully initialized by mke2fs. This speeds up filesystem initialization noticeably, but it requires the kernel to finish initializing the filesystem in the background when the filesystem is first mounted. If the option value is omitted, it defaults to 1 to enable lazy inode table zeroing.

This option is only enabled for ext filesystems

CLI Example:
```
salt '*' blockdev.format /dev/sdX1
```

salt.modules.blockdev.fstype(device)
Return the filesystem name of a block device

New in version 2015.8.2.

device The name of the block device

CLI Example:
salt '' blockdev.fstype /dev/sdX1

```bash
salt '*' blockdev.fstype /dev/sdX1
```

**salt.modules.blockdev.resize2fs**(*device*)
Resizes the filesystem.

CLI Example: .. code-block:: bash

```bash
salt '*' blockdev.resize2fs /dev/sdX1
```

**salt.modules.blockdev.tune**(*device, **kwargs*)
Set attributes for the specified device

CLI Example:

```bash
salt '*' blockdev.tune /dev/sdX1 read-ahead=1024 read-write=True
```

Valid options are: read-ahead, filesystem-read-ahead, read-only, read-write.

See the blockdev(8) manpage for a more complete description of these options.

**salt.modules.blockdev.wipe**(*device*)
Remove the filesystem information

CLI Example:

```bash
salt '*' blockdev.wipe /dev/sdX1
```

### 32.17.15 salt.modules.bluez

Support for Bluetooth (using BlueZ in Linux).

The following packages are required packages for this module:

```bash
bluez >= 5.7 bluez-libs >= 5.7 bluez-utils >= 5.7 pybluez >= 0.18
```

**salt.modules.bluez.address()**
Get the many addresses of the Bluetooth adapter

CLI Example:

```bash
salt '*' bluetooth.address
```

**salt.modules.bluez.block**(*bdaddr*)
Block a specific bluetooth device by BD Address

CLI Example:

```bash
```

**salt.modules.bluez.discoverable**(*dev*)
Enable this bluetooth device to be discoverable.

CLI Example:

```bash
salt '*' bluetooth.discoverable hci0
```

**salt.modules.bluez.noscan**(*dev*)
Turn off scanning modes on this device.

CLI Example:
salt '*' bluetooth.noscan hci0

```python
def pair(address, key):
    # Pair the bluetooth adapter with a device
    pass
```

CLI Example:

```
salt '*' bluetooth.pair DE:AD:BE:EF:CA:FE 1234
```

Where DE:AD:BE:EF:CA:FE is the address of the device to pair with, and 1234 is the passphrase.

TODO: This function is currently broken, as the bluez-simple-agent program no longer ships with BlueZ >= 5.0. It needs to be refactored.

```python
def power(dev, mode):
    # Power a bluetooth device on or off
    pass
```

CLI Examples:

```
salt '*' bluetooth.power hci0 on
salt '*' bluetooth.power hci0 off
```

```python
def scan():
    # Scan for bluetooth devices in the area
    pass
```

CLI Example:

```
salt '*' bluetooth.scan
```

```python
def start():
    # Start the bluetooth service.
    pass
```

CLI Example:

```
salt '*' bluetooth.start
```

```python
def stop():
    # Stop the bluetooth service.
    pass
```

CLI Example:

```
salt '*' bluetooth.stop
```

```python
def unblock(bdaddr):
    # Unblock a specific bluetooth device by BD Address
    pass
```

CLI Example:

```
```

```python
def unpair(address):
    # Unpair the bluetooth adapter from a device
    pass
```

CLI Example:

```
salt '*' bluez.unpair DE:AD:BE:EF:CA:FE
```

Where DE:AD:BE:EF:CA:FE is the address of the device to unpair.

TODO: This function is currently broken, as the bluez-simple-agent program no longer ships with BlueZ >= 5.0. It needs to be refactored.
salt.modules.bluez.version()
    Return Bluez version from bluetoothd -v

    CLI Example:

    >>> salt '!' bluetoothd.version

32.17.16 salt.modules.boto_asg

Connection module for Amazon Autoscale Groups

New in version 2014.7.0.

configuration This module accepts explicit autoscale credentials but can also utilize IAM roles assigned to the instance trough Instance Profiles. Dynamic credentials are then automatically obtained from AWS API and no further configuration is necessary. More Information available at:

If IAM roles are not used you need to specify them either in a pillar or in the minion's config file:

    asg.keyid: GKTADJGHEIQSXMKKRBJ08H
    asg.key: askdjghsdfjkgWupUjasdflkdfklgjsdfjajkghs

A region may also be specified in the configuration:

    asg.region: us-east-1

If a region is not specified, the default is us-east-1.

It's also possible to specify key, keyid and region via a profile, either as a passed in dict, or as a string to pull from pillars or minion config:

    myprofile:
        keyid: GKTADJGHEIQSXMKKRBJ08H
        key: askdjghsdfjkgWupUjasdflkdfklgjsdfjajkghs
        region: us-east-1

depends boto

salt.modules.boto_asg.create(name, launch_config_name, availability_zones, min_size, max_size, desired_capacity=None, load_balancers=None, default_cooldown=None, health_check_type=None, health_check_period=None, placement_group=None, vpc_zone_identifier=None, tags=None, termination_policies=None, suspended_processes=None, scaling_policies=None, region=None, notification_arn=None, notification_types=None, key=None, keyid=None, profile=None)

Create an autoscale group.

CLI example:

    >>> salt myminion boto_asg.create myasg mylc ["us-east-1a", "us-east-1e"] 1 10 load_balancers=['"myelb", "myelb2"] tags='["key": "Name", value="myasg", "propagate_at_launch": True]'}

32.17. Full list of builtin execution modules
salt.modules.boto_asg.create_launch_configuration(
    name, image_id, key_name=None, 
    security_groups=None, user_data=None, 
    instance_type='m1.small', 
    kernel_id=None, ramdisk_id=None, 
    block_device_mappings=None, instance_monitoring=False, 
    spot_price=None, instance_profile_name=None, 
    ebs_optimized=False, associate_public_ip_address=None, 
    volume_type=None, delete_on_termination=True, 
    iops=None, 
    use_block_device_types=False, region=None, key=None, 
    keyid=None, profile=None)

Create a launch configuration.
CLI example:

```
salt myminion boto_asg.create_launch_configuration mylc image_id=ami-0b9c9f62 key_name='mykey' security_groups='["mygroup"]' instance_type='c3.2xlarge'
```

salt.modules.boto_asg.delete(name, force=False, region=None, key=None, keyid=None, profile=None)

Delete an autoscale group.
CLI example:

```
salt myminion boto_asg.delete myasg region=us-east-1
```

salt.modules.boto_asg.delete_launch_configuration(name, region=None, key=None, keyid=None, profile=None)

Delete a launch configuration.
CLI example:

```
salt myminion boto_asg.delete_launch_configuration mylc
```

salt.modules.boto_asg.exists(name, region=None, key=None, keyid=None, profile=None)

Check to see if an autoscale group exists.
CLI example:

```
salt myminion boto_asg.exists myasg region=us-east-1
```

salt.modules.boto_asg.get_cloud_init_mime(cloud_init)

Get a mime multipart encoded string from a cloud-init dict. Currently supports scripts and cloud-config.
CLI Example:

```
salt myminion boto.get_cloud_init_mime <cloud init>
```

salt.modules.boto_asg.get_config(name, region=None, key=None, keyid=None, profile=None)

Get the configuration for an autoscale group.
CLI example:
salt.myminion.boto_asg.get_config(name='myasg', region='us-east-1')

salt.modules.boto_asg.get_instances(name='myasg', lifecycle_state='InService', health_status='Healthy', attribute='private_ip_address', region=None, key=None, keyid=None, profile=None)

return attribute of all instances in the named autoscale group.

CLI example:
salt-call boto_asg.get_instances my_autoscale_group_name

salt.modules.boto_asg.get_scaling_policy_arn(as_group=None, scaling_policy_name=None, region=None, key=None, keyid=None, profile=None)

Return the arn for a scaling policy in a specific autoscale group or None if not found. Mainly used as a helper method for boto_cloudwatch_alarm, for linking alarms to scaling policies.

CLI Example:
salt '*' boto_asg.get_scaling_policy_arn mygroup mypolicy

salt.modules.boto_asg.launch_configuration_exists(name=None, region=None, key=None, keyid=None, profile=None)

Check for a launch configuration's existence.

CLI example:
salt myminion boto_asg.launch_configuration_exists mylc

salt.modules.boto_asg.update(name='myasg', launch_config_name='mylc', availability_zones=['us-east-1a', 'us-east-1e'], min_size=1, max_size=10, desired_capacity=1, load_balancers=['myelb', 'myelb2'], default_cooldown=0, health_check_type=None, health_check_period=1, placement_group=None, vpc_zone_identifier=None, tags=[{'key': 'Name', 'value': 'myasg', 'propagate_at_launch': True}], suspended_processes=None, scaling_policies=None, notification_arn=None, notification_types=None, region=None, key=None, keyid=None, profile=None)

Update an autoscale group.

CLI example:
salt myminion boto_asg.update myasg mylc ['us-east-1a', 'us-east-1e'] 1 10 load_balancers=['myelb', 'myelb2'] tags=[{'key': 'Name', 'value': 'myasg', 'propagate_at_launch': True}]

32.17.17 salt.modules.boto_cfn

Connection module for Amazon Cloud Formation

New in version 2015.5.0.

configuration This module accepts explicit AWS credentials but can also utilize IAM roles assigned to the instance through Instance Profiles. Dynamic credentials are then automatically obtained from AWS API and no further configuration is necessary. More information available at:

32.17. Full list of builtin execution modules
If IAM roles are not used you need to specify them either in a pillar or in the minion's config file:

```yaml
[cfn]
keyid: GKTADJGHEIQSXMKKRBJ08H
key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
```

A region may also be specified in the configuration:

```yaml
[cfn]
region: us-east-1
```

depends boto

salt.modules.boto_cfn.create(name, template_body=None, template_url=None, parameters=None, notification_arns=None, disable_rollback=None, timeout_in_minutes=None, capabilities=None, tags=None, on_failure=None, stack_policy_body=None, stack_policy_url=None, region=None, key=None, keyid=None, profile=None)

Create a CFN stack.

CLI example to create a stack:

```bash
salt myminion boto_cfn.create mystack template_url='https://s3.amazonaws.com/bucket/template.cft' region=us-east-1
```

salt.modules.boto_cfn.delete(name, region=None, key=None, keyid=None, profile=None)

Delete a CFN stack.

CLI example to delete a stack:

```bash
salt myminion boto_cfn.delete mystack region=us-east-1
```

salt.modules.boto_cfn.describe(name, region=None, key=None, keyid=None, profile=None)

Describe a stack.

New in version 2015.8.0.

CLI example:

```bash
salt myminion boto_cfn.describe mystack region=us-east-1
```

salt.modules.boto_cfn.exists(name, region=None, key=None, keyid=None, profile=None)

Check to see if a stack exists.

CLI example:

```bash
salt myminion boto_cfn.exists mystack region=us-east-1
```

salt.modules.boto_cfn.get_template(name, region=None, key=None, keyid=None, profile=None)

Check to see if attributes are set on a CFN stack.

CLI example:

```bash
salt myminion boto_cfn.get_template mystack
```
**salt.modules.boto_cfn.update_stack**

```python
name, template_body=None, template_url=None,
parameters=None, notification_arns=None, disable_rollback=False, timeout_in_minutes=None, capabilities=None, tags=None, use_previous_template=None,
stack_policy_during_update_body=None,
stack_policy_during_update_url=None,
stack_policy_body=None, stack_policy_url=None, region=None, key=None, keyid=None, profile=None)
```

Update a CFN stack.
New in version 2015.8.0.

CLI example to update a stack:

```bash
salt myminion boto_cfn.update_stack mystack template_url='https://s3.amazonaws.com/bucket/template.cft' region=us-east-1
```

**salt.modules.boto_cfn.validate_template**

```python
(template_body=None, template_url=None, region=None, key=None, keyid=None, profile=None)
```

Validate cloudformation template
New in version 2015.8.0.

CLI example:

```bash
salt myminion boto_cfn.validate_template mystack-template
```

### 32.17.18 salt.modules.boto_cloudwatch

Connection module for Amazon CloudWatch
New in version 2014.7.0.

**configuration**

This module accepts explicit credentials but can also utilize IAM roles assigned to the instance through Instance Profiles. Dynamic credentials are then automatically obtained from AWS API and no further configuration is necessary. More Information available at:

```bash
```

If IAM roles are not used you need to specify them either in a pillar or in the minion's config file:

```bash
cloudwatch.keyid: GKTADJGHEIQSXMKKRBJ08H
cloudwatch.key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
```

A region may also be specified in the configuration:

```bash
cloudwatch.region: us-east-1
```

If a region is not specified, the default is us-east-1.

It's also possible to specify key, keyid and region via a profile, either as a passed in dict, or as a string to pull from pillars or minion config:

```bash
myprofile:
  keyid: GKTADJGHEIQSXMKKRBJ08H
  key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
  region: us-east-1
```
depends boto

salt.modules.boto_cloudwatch.convert_to_arn(arns, region=None, key=None, keyid=None, profile=None)

Convert a list of strings into actual arns. Converts convenience names such as `scaling_policy:...`

CLI Example:

```
salt '*' convert_to_arn 'scaling_policy:'
```

salt.modules.boto_cloudwatch.create_or_update_alarm(connection=None, name=None, metric=None, namespace=None, statistic=None, comparison=None, threshold=None, period=None, evaluation_periods=None, unit=None, description=' ', dimensions=None, alarm_actions=None, insufficient_data_actions=None, ok_actions=None, region=None, key=None, keyid=None, profile=None)

Create or update a cloudwatch alarm.

**Params are the same as:** http://boto.readthedocs.org/en/latest/ref/cloudwatch.html#boto.ec2.cloudwatch.alarm.MetricAlarm.

Dimensions must be a dict. If the value of Dimensions is a string, it will be json decoded to produce a dict. alarm_actions, insufficient_data_actions, and ok_actions must be lists of string. If the passed-in value is a string, it will be split on ";" to produce a list. The strings themselves for alarm_actions, insufficient_data_actions, and ok_actions must be Amazon resource names (ARNs); however, this method also supports an arn lookup notation, as follows:

```
arn:aws:.... ARN as per http://docs.aws.amazon.com/general/latest/gr/aws-arns-and-namespaces.html scaling_policy:<as_name>:<scaling_policy_name> The named autoscale group scaling policy, for the named group (e.g. scaling_policy:my-asg:ScaleDown)
```

This is convenient for setting up autoscaling as follows. First specify a boto_asg.present state for an ASG with scaling_policies, and then set up boto_cloudwatch_alarm.present states which have alarm_actions that reference the scaling_policy.

CLI example:

```
salt myminion boto_cloudwatch.create_alarm name=myalarm ... region=us-east-1
```

salt.modules.boto_cloudwatch.delete_alarm(name, region=None, key=None, keyid=None, profile=None)

Delete a cloudwatch alarm

CLI example to delete a queue:

```
salt myminion boto_cloudwatch.delete_alarm myalarm region=us-east-1
```

salt.modules.boto_cloudwatch.get_alarm(name, region=None, key=None, keyid=None, profile=None)

Get alarm details. Also can be used to check to see if an alarm exists.

CLI example:

```
salt myminion boto_cloudwatch.get_alarm myalarm region=us-east-1
```
salt.modules.boto_cloudwatch.get_all_alarms(region=None, prefix=None, key=None, keyid=None, profile=None)

Get all alarm details. Produces results that can be used to create an sls file.

If prefix parameter is given, alarm names in the output will be prepended with the prefix; alarms that have the prefix will be skipped. This can be used to convert existing alarms to be managed by salt, as follows:

1. Make a ``backup`` of all existing alarms

   $ 
   salt-call boto_cloudwatch.get_all_alarms --out=txt | sed `s/local: //`` > legacy_alarms.sls 

2. Get all alarms with new prefixed names

   $ 
   salt-call boto_cloudwatch.get_all_alarms `prefix="**MANAGED BY SALT**"` --out=txt | sed `s/local: //`` > managed_alarms.sls 

3. Insert the managed alarms into cloudwatch

   $ salt-call state.template managed_alarms.sls 

4. Manually verify that the new alarms look right

5. Delete the original alarms

   $ sed s/present/absent/ legacy_alarms.sls > remove_legacy_alarms.sls $ salt-call state.template remove_legacy_alarms.sls 

6. Get all alarms again, verify no changes

   $ salt-call boto_cloudwatch.get_all_alarms --out=txt | sed `s/local: //`` > final_alarms.sls $ diff final_alarms.sls managed_alarms.sls 

CLI example:

```
salt myminion boto_cloudwatch.get_all_alarms region=us-east-1 --out=txt
```

### 32.17.19 salt.modules.boto_dynamodb

Connection module for Amazon DynamoDB

New in version 2015.5.0.

**configuration** This module accepts explicit DynamoDB credentials but can also utilize IAM roles assigned to the instance through Instance Profiles. Dynamic credentials are then automatically obtained from AWS API and no further configuration is necessary. More information available at:

If IAM roles are not used you need to specify them either in a pillar or in the minion's config file:

```
keyid: GKTADJGHEIQSXMKKRBJ08H 
key: askdjghsdfkjgkHwUpUjasdfklgjsdfjajkghs
```

A region may also be specified in the configuration:

```
region: us-east-1
```

If a region is not specified, the default is us-east-1.

It's also possible to specify key, keyid and region via a profile, either as a passed in dict, or as a string to pull from pillars or minion config:

```
.. code-block:: yaml

    myprofile: keyid: GKTADJGHEIQXSXMKKRBJ08H key: askdjghsdfkjgkHwUpUjasdfklgjsdfjajkghs region: us-east-1
```

**depends** boto

### 32.17. Full list of builtin execution modules
salt.modules.boto_dynamodb.create_table(table_name, region=None, key=None, keyid=None, profile=None, read_capacity_units=None, write_capacity_units=None, hash_key=None, hash_key_data_type=None, range_key=None, range_key_data_type=None, local_indexes=None, global_indexes=None)

Creates a DynamoDB table.

CLI Example:

```
salt myminion boto_dynamodb.create_table table_name /region=us-east-1 /hash_key=id /hash_key_data_type=N /range_key=created_at /range_key_data_type=N /read_capacity_units=1 /write_capacity_units=1
```

salt.modules.boto_dynamodb.delete(table_name, region=None, key=None, keyid=None, profile=None)

Delete a DynamoDB table.

CLI Example:

```
salt myminion boto_dynamodb.delete table_name region=us-east-1
```

salt.modules.boto_dynamodb.exists(table_name, region=None, key=None, keyid=None, profile=None)

Check to see if a table exists.

CLI Example:

```
salt myminion boto_dynamodb.exists table_name region=us-east-1
```

### 32.17.20 salt.modules.boto_ec2

Connection module for Amazon EC2

New in version 2015.8.0.

**configuration** This module accepts explicit EC2 credentials but can also utilize IAM roles assigned to the instance through Instance Profiles. Dynamic credentials are then automatically obtained from AWS API and no further configuration is necessary. More Information available at:

```
```

If IAM roles are not used you need to specify them either in a pillar or in the minion's config file:

```
ec2.keyid: GKTADJGHEIQSXMKKRBJ08H
ec2.key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
```

A region may also be specified in the configuration:

```
e2.region: us-east-1
```
If a region is not specified, the default is us-east-1.

It's also possible to specify key, keyid, and region via a profile, either as a passed in dict, or as a string to pull from pillars or minion config:

```yaml
myprofile:
  keyid: GKTADJGHEIQSXMKKRBJ08H
  key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
  region: us-east-1
```

**depends** boto

**salt.modules.boto_ec2.create_key(key_name, save_path, region=None, key=None, keyid=None, profile=None)**

Creates a key and saves it to a given path. Returns the private key.

CLI Example:

```bash
salt myminion boto_ec2.create mykey /root/
```

**salt.modules.boto_ec2.delete_key(key_name, region=None, key=None, keyid=None, profile=None)**

Deletes a key. Always returns True

CLI Example:

```bash
salt myminion boto_ec2.delete_key mykey
```

**salt.modules.boto_ec2.exists(instance_id=None, name=None, tags=None, region=None, key=None, keyid=None, profile=None)**

Given a instance id, check to see if the given instance id exists.

Returns True if the given an instance with the given id, name, or tags exists; otherwise, False is returned.

CLI Example:

```bash
salt myminion boto_ec2.exists myinstance
```

**salt.modules.boto_ec2.find_instances(instance_id=None, name=None, tags=None, region=None, key=None, keyid=None, profile=None, return_objs=False)**

Given instance properties, find and return matching instance ids

CLI Examples:

```bash
salt myminion boto_ec2.find_instances # Lists all instances
salt myminion boto_ec2.find_instances name=myinstance
salt myminion boto_ec2.find_instances tags=\"{"mytag": \"value\"}\"'
```

**salt.modules.boto_ec2.get_attribute(attribute, instance_name=None, instance_id=None, region=None, key=None, keyid=None, profile=None)**

Get an EC2 instance attribute.

CLI Example:

```bash
salt myminion boto_ec2.get_attribute sourceDestCheck instance_name=my_instance
```

Available attributes:

- instanceType
• kernel
• ramdisk
• userData
• disableApiTermination
• instanceInitiatedShutdownBehavior
• rootDeviceName
• blockDeviceMapping
• productCodes
• sourceDestCheck
• groupSet
• ebsOptimized
• sriovNetSupport

salt.modules.boto_ec2.get_id(name=None, tags=None, region=None, key=None, keyid=None, profile=None)

Given instance properties, return the instance id if it exist.

CLI Example:

```
salt myminion boto_ec2.get_id myinstance
```

salt.modules.boto_ec2.get_key(key_name, region=None, key=None, keyid=None, profile=None)

Check to see if a key exists. Returns fingerprint and name if it does and False if it doesn't

CLI Example:

```
salt myminion boto_ec2.get_key mykey
```

salt.modules.boto_ec2.get_keys(keynames=None, filters=None, region=None, key=None, keyid=None, profile=None)

Gets all keys or filters them by name and returns a list. keynames (list):: A list of the names of keypairs to retrieve. If not provided, all key pairs will be returned. filters (dict) :: Optional filters that can be used to limit the results returned. Filters are provided in the form of a dictionary consisting of filter names as the key and filter values as the value. The set of allowable filter names/values is dependent on the request being performed. Check the EC2 API guide for details.

CLI Example:

```
salt myminion boto_ec2.get_keys
```

salt.modules.boto_ec2.get_zones(region=None, key=None, keyid=None, profile=None)

Get a list of AZs for the configured region.

CLI Example:

```
salt myminion boto_ec2.get_zones
```

salt.modules.boto_ec2.import_key(key_name, public_key_material, region=None, key=None, keyid=None, profile=None)

Imports the public key from an RSA key pair that you created with a third-party tool. Supported formats: - OpenSSH public key format (e.g., the format in ~/.ssh/authorized_keys) - Base64 encoded DER format - SSH public key file format as specified in RFC4716 - DSA keys are not supported. Make sure your key generator is set up to create RSA keys. Supported lengths: 1024, 2048, and 4096.
CLI Example:

```bash
salt myminion botoEc2.import mykey publicKey
```

```python
salt.modules.boto_ec2.run(
    image_id, name=None, tags=None, instance_type='m1.small',
    key_name=None, security_groups=None, user_data=None, placement=None, region=None, key=None, keyid=None, profile=None)
```

Create and start an EC2 instance.
Returns True if the instance was created; otherwise False.

CLI Example:

```bash
salt myminion botoEc2.run ami-b80c2b87 name=myinstance
```

```python
salt.modules.boto_ec2.set_attribute(
    attribute, attribute_value, instance_name=None, instance_id=None, region=None, key=None, keyid=None, profile=None)
```

Set an EC2 instance attribute. Returns whether the operation succeeded or not.

CLI Example:

```bash
salt myminion botoEc2.set_attribute sourceDestCheck False instance_name=my_instance
```

Available attributes:

- instanceType
- kernel
- ramdisk
- userData
- disableApiTermination
- instanceInitiatedShutdownBehavior
- rootDeviceName
- blockDeviceMapping
- productCodes
- sourceDestCheck
- groupSet
- ebsOptimized
- sriovNetSupport

```python
salt.modules.boto_ec2.terminate(
    instance_id=None, name=None, region=None, key=None, keyid=None, profile=None)
```

Terminate the instance described by instance_id or name.

CLI Example:

```bash
salt myminion botoEc2.terminate name=myinstance
salt myminion botoEc2.terminate instance_id=i-a46b9f
```
32.17.21 salt.modules.boto_elasticache

Connection module for Amazon Elasticache

New in version 2014.7.0.

configuration This module accepts explicit elasticache credentials but can also utilize IAM roles assigned to the instance trough Instance Profiles. Dynamic credentials are then automatically obtained from AWS API and no further configuration is necessary. More Information available at:

If IAM roles are not used you need to specify them either in a pillar or in the minion's config file:

```
elasticache.keyid: GKTADJGHEIQSXMKKRBJ08H
elasticache.key: askdjghsdfjkgWupUjasdfklgjsdfjajkghs
```

A region may also be specified in the configuration:

```
elasticache.region: us-east-1
```

If a region is not specified, the default is us-east-1.

It's also possible to specify key, keyid and region via a profile, either as a passed in dict, or as a string to pull from pillars or minion config:

```
myprofile:
    keyid: GKTADJGHEIQSXMKKRBJ08H
    key: askdjghsdfjkgWupUjasdfklgjsdfjajkghs
    region: us-east-1
```

depends boto

salt.modules.boto_elasticache.authorize_cache_security_group_ingress(name, ec2_security_group_name, ec2_security_group_owner_id, region=None, key=None, keyid=None, profile=None)

Authorize network ingress from an ec2 security group to a cache security group.

CLI example:

```
salt myminion boto_elasticache.authorize_cache_security_group_ingress
    --myelasticachesg myec2sg 879879
```
salt.modules.boto_elasticache.create(name, num_cache_nodes=None, engine=None, cache_node_type=None, replication_group_id=None, engine_version=None, cache_parameter_group_name=None, cache_subnet_group_name=None, cache_security_group_names=None, security_group_ids=None, preferred_availability_zone=None, preferred_maintenance_window=None, port=None, notification_topic_arn=None, auto_minor_version_upgrade=None, wait=None, region=None, key=None, keyid=None, profile=None)

Create a cache cluster.

CLI example:

```shell
salt myminion boto_elasticache.create myelasticache 1 redis cache.t1.micro
  cache_security_group_names='["myelasticachesg"]'
```

salt.modules.boto_elasticache.create_cache_security_group(name, description, region=None, key=None, keyid=None, profile=None)

Create a cache security group.

CLI example:

```shell
salt myminion boto_elasticache.create_cache_security_group myelasticachesg
  'My Cache Security Group'
```

salt.modules.boto_elasticache.create_replication_group(name, primary_cluster_id, replication_group_description, wait=None, region=None, key=None, keyid=None, profile=None)

Create replication group.

CLI example:

```shell
salt myminion boto_elasticache.create_replication_group myelasticache
  myprimarycluster description
```

salt.modules.boto_elasticache.create_subnet_group(name, description, subnet_ids, tags=None, region=None, key=None, keyid=None, profile=None)

Create an ElastiCache subnet group

CLI example to create an ElastiCache subnet group:

```shell
salt myminion boto_elasticache.create_subnet_group my-subnet-group
  "group description" '[subnet-12345678, subnet-87654321]' region=us-east-1
```

salt.modules.boto_elasticache.delete(name, wait=False, region=None, key=None, keyid=None, profile=None)

Delete a cache cluster.

CLI example:
Salt Documentation, Release 2015.8.12

```
salt myminion boto_elasticache.delete myelasticache
```

```
salt.modules.boto_elasticache.delete_cache_security_group(name, region=None, key=None, keyid=None, profile=None)

Delete a cache security group.

CLI example:
```
salt myminion boto_elasticache.delete_cache_security_group myelasticachesg 'My Cache Security Group'
```

```
salt.modules.boto_elasticache.delete_subnet_group(name, region=None, key=None, keyid=None, profile=None)

Delete an ElastiCache subnet group.

CLI example:
```
salt myminion boto_elasticache.delete_subnet_group my-subnet-group --region=us-east-1
```

```
salt.modules.boto_elasticache.describe_replication_group(name, region=None, key=None, keyid=None, profile=None, parameter=None)

Get replication group information.

CLI example:
```
salt myminion boto_elasticache.describe_replication_group mygroup
```

```
salt.modules.boto_elasticache.exists(name, region=None, key=None, keyid=None, profile=None)

Check to see if a cache cluster exists.

CLI example:
```
salt myminion boto_elasticache.exists myelasticache
```

```
salt.modules.boto_elasticache.get_cache_subnet_group(name, region=None, key=None, keyid=None, profile=None)

Get information about a cache subnet group.

CLI example:
```
salt myminion boto_elasticache.get_cache_subnet_group mycache_subnet_group
```

```
salt.modules.boto_elasticache.get_config(name, region=None, key=None, keyid=None, profile=None)

Get the configuration for a cache cluster.

CLI example:
```
salt myminion boto_elasticache.get_config myelasticache
```

```
salt.modules.boto_elasticache.get_group_host(name, region=None, key=None, keyid=None, profile=None)

Get hostname from replication cache group.

CLI example:
```
salt myminion boto_elasticache.get_group_host myelasticachegroup

```
salt.modules.boto_elasticache.get_node_host(name, region=None, key=None, keyid=None, profile=None)
```

Get hostname from cache node

CLI example:
```
salt myminion boto_elasticache.get_node_host myelasticache
```

salt.modules.boto_elasticache.group_exists(name, region=None, key=None, keyid=None, profile=None)

Check to see if a replication group exists.

CLI example:
```
salt myminion boto_elasticache.group_exists myelasticache
```

salt.modules.boto_elasticache.revoke_cache_security_group_ingress(name, ec2_security_group_name, ec2_security_group_owner_id, region=None, key=None, keyid=None, profile=None)

Revoke network ingress from an ec2 security group to a cache security group.

CLI example:
```
salt myminion boto_elasticache.revoke_cache_security_group_ingress myelasticachesg myec2sg 879879
```

salt.modules.boto_elasticache.subnet_group_exists(name, tags=None, region=None, key=None, keyid=None, profile=None)

Check to see if an ElastiCache subnet group exists.

CLI example:
```
salt myminion boto_elasticache.subnet_group_exists my-param-group
```

32.17.22 salt.modules.boto_elb

Connection module for Amazon ELB

New in version 2014.7.0.

configuration This module accepts explicit elb credentials but can also utilize IAM roles assigned to the instance through Instance Profiles. Dynamic credentials are then automatically obtained from AWS API and no further configuration is necessary. More Information available at:

```
```
If IAM roles are not used you need to specify them either in a pillar or in the minion's config file:

```
elb.keyid: GKTADJGHEIQSXMKKRBJ08H
elb.key: askdjghsdfjkghWupUjasdflkdsfjksdfjghs
```

A region may also be specified in the configuration:

```
elb.region: us-east-1
```

If a region is not specified, the default is us-east-1.

It's also possible to specify key, keyid and region via a profile, either as a passed in dict, or as a string to pull from pillars or minion config:

```
myprofile:
    keyid: GKTADJGHEIQSXMKKRBJ08H
    key: askdjghsdfjkghWupUjasdflkdsfjksdfjghs
    region: us-east-1
```

depends boto >= 2.33.0

salt.modules.boto_elb.apply_security_groups(name, security_groups, region=None, key=None, keyid=None, profile=None)

Apply security groups to ELB.

CLI example:

```
salt myminion boto_elb.apply_security_groups myelb ['"mysecgroup1"']
```

salt.modules.boto_elb.attach_subnets(name, subnets, region=None, key=None, keyid=None, profile=None)

Attach ELB to subnets.

CLI example:

```
salt myminion boto_elb.attach_subnets myelb ['"mysubnet"']
```

salt.modules.boto_elb.create(name, availability_zones, listeners=None, subnets=None, security_groups=None, scheme='internet-facing', region=None, key=None, keyid=None, profile=None)

Create an ELB

CLI example to create an ELB:

```
salt myminion boto_elb.create myelb ['"us-east-1a", "us-east-1e"]' listeners='[[443, 80, "HTTPS", "HTTP", "arn:aws:iam::1111111111:server-certificate/mycert"]]' region='us-east-1'
```

salt.modules.boto_elb.create_listeners(name, listeners=None, region=None, key=None, keyid=None, profile=None)

Create listeners on an ELB.

CLI example:

```
salt myminion boto_elb.create_listeners myelb listeners="["HTTPS", "HTTP", 443, 80, "arn:aws:iam::1111111111:server-certificate/mycert"]"
```

salt.modules.boto_elb.delete(name, region=None, key=None, keyid=None, profile=None)

Delete an ELB.

CLI example to delete an ELB:
salt myminion boto_elb.delete myelb region=us-east-1

salt.modules.boto_elb.delete_listeners(name, ports, region=None, key=None, keyid=None, profile=None)
Delete listeners on an ELB.
CLI example:
salt myminion boto_elb.delete_listeners myelb '80,443'

salt.modules.boto_elb.deregister_instances(name, instances, region=None, key=None, keyid=None, profile=None)
Deregister instances with an ELB. Instances is either a string instance id or a list of string instance id's.
Returns:
• True: instance(s) deregistered successfully
• False: instance(s) failed to be deregistered
• None: instance(s) not valid or not registered, no action taken
CLI example:
salt myminion boto_elb.deregister_instances myelb instance_id
salt myminion boto_elb.deregister_instances myelb "[instance_id, instance_id]"

salt.modules.boto_elb.detach_subnets(name, subnets, region=None, key=None, keyid=None, profile=None)
Detach ELB from subnets.
CLI example:
salt myminion boto_elb.detach_subnets myelb '"mysubnet"'

salt.modules.boto_elb.disable_availability_zones(name, availability_zones, region=None, key=None, keyid=None, profile=None)
Disable availability zones for ELB.
CLI example:
salt myminion boto_elb.disable_availability_zones myelb '"us-east-1a"'

salt.modules.boto_elb.enable_availability_zones(name, availability_zones, region=None, key=None, keyid=None, profile=None)
Enable availability zones for ELB.
CLI example:
salt myminion boto_elb.enable_availability_zones myelb '"us-east-1a"'

salt.modules.boto_elb.exists(name, region=None, key=None, keyid=None, profile=None)
Check to see if an ELB exists.
CLI example:
salt myminion boto_elb.exists myelb region=us-east-1
salt.modules.boto_elb.get_attributes(name, region=None, key=None, keyid=None, profile=None)

Check to see if attributes are set on an ELB.

CLI example:
```
salt myminion boto_elb.get_attributes myelb
```

salt.modules.boto_elb.get_elb_config(name, region=None, key=None, keyid=None, profile=None)

Get an ELB configuration.

CLI example:
```
salt myminion boto_elb.exists myelb region=us-east-1
```

salt.modules.boto_elb.get_health_check(name, region=None, key=None, keyid=None, profile=None)

Get the health check configured for this ELB.

CLI example:
```
salt myminion boto_elb.get_health_check myelb
```

salt.modules.boto_elb.get_instance_health(name, region=None, key=None, keyid=None, profile=None, instances=None)

Get a list of instances and their health state

CLI example:
```
salt myminion boto_elb.get_instance_health myelb
salt myminion boto_elb.get_instance_health myelb region=us-east-1 instances="[instance_id,instance_id]"
```

salt.modules.boto_elb.register_instances(name, instances, region=None, key=None, keyid=None, profile=None)

Register instances with an ELB. Instances is either a string instance id or a list of string instance id's.

Returns:
- True: instance(s) registered successfully
- False: instance(s) failed to be registered

CLI example:
```
salt myminion boto_elb.register_instances myelb instance_id
salt myminion boto_elb.register_instances myelb "[instance_id,instance_id]"
```

salt.modules.boto_elb.set_attributes(name, attributes, region=None, key=None, keyid=None, profile=None)

Set attributes on an ELB.

**name (string)** Name of the ELB instance to set attributes for

**attributes** A dict of attributes to set.

Valid attributes are:

- access_log (dict)
  - enabled (bool) Enable storage of access logs.
s3_bucket_name (string)  The name of the S3 bucket to place logs.

s3_bucket_prefix (string)  Prefix for the log file name.

emit_interval (int)  Interval for storing logs in S3 in minutes. Valid values are 5 and 60.

cross_zone_load_balancing (dict)

enabled (bool)  Enable cross-zone load balancing.

timeout (int)  Maximum allowed time in seconds for sending existing connections to an instance that is deregistering or unhealthy. Default is 300.

CLI example to set attributes on an ELB:

```python
salt myminion boto_elb.set_attributes myelb '{"access_log": {"enabled": "true", "s3_bucket_name": "mybucket", "s3_bucket_prefix": "mylogs/", "emit_interval": "5"}, region=us-east-1}
```

salt.modules.boto_elb.set_health_check(name, health_check, region=None, key=None, keyid=None, profile=None)

Set attributes on an ELB.

CLI example to set attributes on an ELB:

```python
salt myminion boto_elb.set_health_check myelb '{"target": "HTTP:80/"}'
```

32.17.23 salt.modules.boto_iam

Connection module for Amazon IAM

New in version 2014.7.0.

configuration  This module accepts explicit iam credentials but can also utilize IAM roles assigned to the instance trough Instance Profiles. Dynamic credentials are then automatically obtained from AWS API and no further configuration is necessary. More Information available at:

```
```

If IAM roles are not used you need to specify them either in a pillar or in the minion's config file:

```
iam.keyid: GKTADJGHEIQSXMKKRBJ08H
iam.key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
iam.region: us-east-1
```

It's also possible to specify key, keyid and region via a profile, either as a passed in dict, or as a string to pull from pillars or minion config:

```
myprofile:
  keyid: GKTADJGHEIQSXMKKRBJ08H
  key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
  region: us-east-1
```

depends  boto
salt.modules.boto_iam.add_user_to_group

    
    Add user to group.
    
    ```
    salt myminion boto_iam.add_user_to_group myuser mygroup
    ```

salt.modules.boto_iam.associate_profile_to_role

    
    Associate an instance profile with an IAM role.
    
    ```
    salt myminion boto_iam.associate_profile_to_role myirole myiprofile
    ```

salt.modules.boto_iam.build_policy

    
    Build a default assume role policy.
    
    ```
    salt myminion boto_iam.build_policy
    ```

salt.modules.boto_iam.create_access_key

    
    Create access key id for a user.
    
    ```
    salt myminion boto_iam.create_access_key myuser
    ```

salt.modules.boto_iam.create_group

    
    Create a group.
    
    ```
    salt myminion boto_iam.create_group group
    ```

salt.modules.boto_iam.create_instance_profile

    
    Create an instance profile.
    
    ```
    salt myminion boto_iam.create_instance_profile myiprofile
    ```

salt.modules.boto_iam.create_login_profile

    
    Creates a login profile for the specified user, give the user the ability to access AWS services and the AWS Management Console.
    
    ```
    salt myminion boto_iam.create_login_profile
    ```
salt myminion boto_iam.create_login_profile user_name password

salt.modules.boto_iam.create_role(name, policy_document=None, path=None, region=None, key=None, keyid=None, profile=None)
Create an instance role.
CLI Example:
salt myminion boto_iam.create_role myrole

salt.modules.boto_iam.create_role_policy(role_name, policy_name, policy, region=None, key=None, keyid=None, profile=None)
Create or modify a role policy.
CLI Example:
salt myminion boto_iam.create_role_policy myirole mypolicy

salt.modules.boto_iam.create_user(user_name, path=None, region=None, key=None, keyid=None, profile=None)
Create a user.
New in version 2015.8.0.
CLI Example:
salt myminion boto_iam.create_user myuser

salt.modules.boto_iam.delete_access_key(access_key_id, user_name=None, region=None, key=None, keyid=None, profile=None)
Delete access key id from a user.
New in version 2015.8.0.
CLI Example:
salt myminion boto_iam.delete_access_key myuser

salt.modules.boto_iam.delete_group_policy(group_name, policy_name, region=None, key=None, keyid=None, profile=None)
Delete a group policy.
CLI Example:

```bash
salt myminion boto_iam.delete_group_policy mygroup mypolicy
```

salt.modules.boto_iam.delete_instance_profile(name, region=None, key=None, keyid=None, profile=None)
Delete an instance profile.
CLI Example:
salt myminion boto_iam.delete_instance_profile myiprofile
salt.modules.boto_iam.delete_role(name, region=None, key=None, keyid=None, profile=None)
Delete an IAM role.
CLI Example:
salt myminion boto_iam.delete_role myirole

salt.modules.boto_iam.delete_role_policy(role_name, policy_name, region=None, key=None,
keyid=None, profile=None)
Delete a role policy.
CLI Example:
salt myminion boto_iam.delete_role_policy myirole mypolicy

salt.modules.boto_iam.delete_server_cert(cert_name, region=None, key=None, keyid=None,
profile=None)
Deletes a certificate from Amazon.
New in version 2015.8.0.
CLI Example:
salt myminion boto_iam.delete_server_cert mycert_name

salt.modules.boto_iam.delete_user(user_name, region=None, key=None, keyid=None, profile=None)
Delete a user.
New in version 2015.8.0.
CLI Example:
salt myminion boto_iam.delete_user myuser

salt.modules.boto_iam.delete_user_policy(user_name, policy_name, region=None, key=None,
keyid=None, profile=None)
Delete a user policy.
CLI Example:
salt myminion boto_iam.delete_user_policy myuser mypolicy

salt.modules.boto_iam.describe_role(name, region=None, key=None, keyid=None, profile=None)
Get information for a role.
CLI Example:
salt myminion boto_iam.describe_role myirole

salt.modules.boto_iam.disassociate_profile_from_role(profile_name, role_name, region=None,
key=None, keyid=None, profile=None)
Disassociate an instance profile from an IAM role.
CLI Example:
salt myminion boto_iam.disassociate_profile_from_role myirole myiprofile
salt.modules.boto_iam.get_account_id(region=None, key=None, keyid=None, profile=None)
Get the AWS account id associated with the used credentials.

CLI Example:
```python
salt myminion boto_iam.get_account_id
```

salt.modules.boto_iam.get_account_policy(region=None, key=None, keyid=None, profile=None)
Get account policy for the AWS account.
New in version 2015.8.0.

CLI Example:
```python
salt myminion boto_iam.get_account_policy
```

salt.modules.boto_iam.get_all_access_keys(user_name, marker=None, max_items=None, region=None, key=None, keyid=None, profile=None)
Get all access keys from a user.
New in version 2015.8.0.

CLI Example:
```python
salt myminion boto_iam.get_all_access_keys myuser
```

salt.modules.boto_iam.get_all_group_policies(group_name, region=None, key=None, keyid=None, profile=None)
Get a list of policy names from a group.

CLI Example:
```python
salt myminion boto_iam.get_all_group_policies mygroup
```

salt.modules.boto_iam.get_all_user_policies(user_name, marker=None, max_items=None, region=None, key=None, keyid=None, profile=None)
Get all user policies.
New in version 2015.8.0.

CLI Example:
```python
salt myminion boto_iam.get_group mygroup
```

salt.modules.boto_iam.get_group(group_name, marker=None, max_items=None, region=None, key=None, keyid=None, profile=None)
Get group information.
New in version 2015.8.0.

CLI Example:
```python
salt myminion boto_iam.get_group mygroup
```

salt.modules.boto_iam.get_group_policy(group_name, policy_name, region=None, key=None, keyid=None, profile=None)
Retrieves the specified policy document for the specified group.
New in version 2015.8.0.
CLI Example:

```
salt myminion boto_iam.get_group_policy mygroup policyman
```

```
salt.modules.boto_iam.get_role_policy(role_name, policy_name, region=None, key=None, keyid=None, profile=None)
```

Get a role policy.

CLI Example:

```
salt myminion boto_iam.get_role_policy myirole mypolicy
```

```
salt.modules.boto_iam.get_server_certificate(cert_name, region=None, key=None, keyid=None, profile=None)
```

Returns certificate information from Amazon

New in version 2015.8.0.

CLI Example:

```
salt myminion boto_iam.get_server_certificate mycert_name
```

```
salt.modules.boto_iam.get_user(user_name=None, region=None, key=None, keyid=None, profile=None)
```

Get user information.

New in version 2015.8.0.

CLI Example:

```
salt myminion boto_iam.get_user myuser
```

```
salt.modules.boto_iam.get_user_policy(user_name, policy_name, region=None, key=None, keyid=None, profile=None)
```

Retrieves the specified policy document for the specified user.

New in version 2015.8.0.

CLI Example:

```
salt myminion boto_iam.get_user_policy myuser mypolicyname
```

```
salt.modules.boto_iam.instance_profile_exists(name, region=None, key=None, keyid=None, profile=None)
```

Check to see if an instance profile exists.

CLI Example:

```
salt myminion boto_iam.instance_profile_exists myiprofile
```

```
salt.modules.boto_iam.list_role_policies(role_name, region=None, key=None, keyid=None, profile=None)
```

Get a list of policy names from a role.

CLI Example:

```
salt myminion boto_iam.list_role_policies myirole
```

```
salt.modules.boto_iam.profile_associated(role_name, profile_name, region, key, keyid, profile)
```

Check to see if an instance profile is associated with an IAM role.
Salt Documentation, Release 2015.8.12

CLI Example:
```
salt myminion boto_iam.profile_associated myrole myiprofile
```

```
salt.modules.boto_iam.put_group_policy(group_name, policy_name, policy_json, region=None, key=None, keyid=None, profile=None)
```

Adds or updates the specified policy document for the specified group.
New in version 2015.8.0.

CLI Example:
```
salt myminion boto_iam.put_group_policy mygroup policymame policyrules
```

```
salt.modules.boto_iam.put_user_policy(user_name, policy_name, policy_json, region=None, key=None, keyid=None, profile=None)
```

Adds or updates the specified policy document for the specified user.
New in version 2015.8.0.

CLI Example:
```
salt myminion boto_iam.put_user_policy myuser policymame policyrules
```

```
salt.modules.boto_iam.remove_user_from_group(group_name, user_name, region=None, key=None, keyid=None, profile=None)
```

Remove user from group.
New in version 2015.8.0.

CLI Example:
```
salt myminion boto_iam.remove_user_from_group mygroup myuser
```

```
salt.modules.boto_iam.role_exists(name, region=None, key=None, keyid=None, profile=None)
```

Check to see if an IAM role exists.

CLI Example:
```
salt myminion boto_iam.role_exists myirole
```

```
salt.modules.boto_iam.update_account_password_policy(allow_users_to_change_password=None, hard_expiry=None, max_password_age=None, minimum_password_length=None, password_reuse_prevention=None, require_lowercase_characters=None, require_numbers=None, require_symbols=None, require_uppercase_characters=None, region=None, key=None, keyid=None, profile=None)
```

Update the password policy for the AWS account.
New in version 2015.8.0.

CLI Example:
salt myminion boto_iam.update_account_password_policy True

salt.modules.boto_iam.update_assume_role_policy(role_name, policy_document, region=None, key=None, keyid=None, profile=None)

Update an assume role policy for a role.
New in version 2015.8.0.
CLI Example:
salt myminion boto_iam.update_assume_role_policy myrole '{"Statement":"..."}"

salt.modules.boto_iam.upload_server_cert(cert_name, cert_body, private_key, cert_chain=None, path=None, region=None, key=None, keyid=None, profile=None)

Upload a certificate to Amazon.
New in version 2015.8.0.
CLI Example:
salt myminion boto_iam.upload_server_cert mycert_name crt priv_key

Parameters

- **cert_name** -- The name for the server certificate. Do not include the path in this value.
- **cert_body** -- The contents of the public key certificate in PEM-encoded format.
- **private_key** -- The contents of the private key in PEM-encoded format.
- **cert_chain** -- The contents of the certificate chain. This is typically a concatenation of the PEM-encoded public key certificates of the chain.
- **path** -- The path for the server certificate.
- **region** -- The name of the region to connect to.
- **key** -- The key to be used in order to connect
- **keyid** -- The keyid to be used in order to connect
- **profile** -- The profile that contains a dict of region, key, keyid

Returns True / False

salt.modules.boto_iam.user_exists_in_group(user_name, group_name, region=None, key=None, keyid=None, profile=None)

Check if user exists in group.
New in version 2015.8.0.
CLI Example:
salt myminion boto_iam.user_exists_in_group myuser mygroup

32.17.24 salt.modules.boto_kms

Connection module for Amazon KMS
New in version 2015.8.0.

**configuration** This module accepts explicit kms credentials but can also utilize IAM roles assigned to the instance through Instance Profiles. Dynamic credentials are then automatically obtained from AWS API and no further configuration is necessary. More Information available at:

```
```

If IAM roles are not used you need to specify them either in a pillar or in the minion's config file:

```
kms.keyid: GKTADJGHEIQSXMKKRBJ08H
kms.key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
```

A region may also be specified in the configuration:

```
kms.region: us-east-1
```

If a region is not specified, the default is us-east-1.

It's also possible to specify key, keyid and region via a profile, either as a passed in dict, or as a string to pull from pillars or minion config:

```
myprofile:
  keyid: GKTADJGHEIQSXMKKRBJ08H
  key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
  region: us-east-1
```

**depends** boto

```
salt.modules.boto_kms.create_alias(alias_name, target_key_id, region=None, key=None, keyid=None, profile=None)
```

Create a display name for a key.

CLI example:

```
salt myminion boto_kms.create_alias 'alias/mykey' key_id
```

```
salt.modules.boto_kms.create_grant(key_id, grantee_principal, retiring_principal=None, operations=None, constraints=None, grant_tokens=None, region=None, key=None, keyid=None, profile=None)
```

Adds a grant to a key to specify who can access the key and under what conditions.

CLI example:

```
salt myminion boto_kms.create_grant 'alias/mykey' 'arn:aws:iam::111111111111:role/myrole' operations='["Encrypt","Decrypt"]'
```

```
salt.modules.boto_kms.create_key(policy=None, description=None, key_usage=None, region=None, key=None, keyid=None, profile=None)
```

Creates a master key.

CLI example:

```
salt myminion boto_kms.create_key '{"Statement":...}!' "My master key"
```

```
salt.modules.boto_kms.decrypt(ciphertext_blob, encryption_context=None, grant_tokens=None, region=None, key=None, keyid=None, profile=None)
```

Decrypt ciphertext.

CLI example:
salt myminion boto_kms.decrypt encrypted_ciphertext

salt.modules.boto_kms.describe_key(key_id, region=None, key=None, keyid=None, profile=None)
Get detailed information about a key.
CLI example:
salt myminion boto_kms.describe_key 'alias/mykey'

salt.modules.boto_kms.disable_key(key_id, region=None, key=None, keyid=None, profile=None)
Mark key as disabled.
CLI example:
salt myminion boto_kms.disable_key 'alias/mykey'

salt.modules.boto_kms.disable_key_rotation(key_id, region=None, key=None, keyid=None, profile=None)
Disable key rotation for specified key.
CLI example:
salt myminion boto_kms.disable_key_rotation 'alias/mykey'

salt.modules.boto_kms.enable_key(key_id, region=None, key=None, keyid=None, profile=None)
Mark key as enabled.
CLI example:
salt myminion boto_kms.enable_key 'alias/mykey'

salt.modules.boto_kms.enable_key_rotation(key_id, region=None, key=None, keyid=None, profile=None)
Disable key rotation for specified key.
CLI example:
salt myminion boto_kms.enable_key_rotation 'alias/mykey'

salt.modules.boto_kms.encrypt(key_id, plaintext, encryption_context=None, grant_tokens=None, region=None, key=None, keyid=None, profile=None)
Encrypt plaintext into cipher text using specified key.
CLI example:
salt myminion boto_kms.encrypt 'alias/mykey' 'myplaindata' '{"aws:username": "myuser"}'

salt.modules.boto_kms.generate_data_key(key_id, encryption_context=None, number_of_bytes=None, key_spec=None, grant_tokens=None, region=None, key=None, keyid=None, profile=None)
Generate a secure data key.
CLI example:
salt myminion boto_kms.generate_data_key 'alias/mykey' number_of_bytes=1024 key_spec=AES_128
salt.modules.boto_kms.generate_data_key_without_plaintext(key_id, encryption_context=None, number_of_bytes=None, key_spec=None, grant_tokens=None, region=None, key=None, keyid=None, profile=None)

Generate a secure data key without a plaintext copy of the key.

CLI example:

```
salt myminion boto_kms.generate_data_key_without_plaintext 'alias/mykey' number_of_bytes=1024 key_spec=AES_128
```

salt.modules.boto_kms.generate_random(number_of_bytes=None, region=None, key=None, keyid=None, profile=None)

Generate a random string.

CLI example:

```
salt myminion boto_kms.generate_random number_of_bytes=1024
```

salt.modules.boto_kms.get_key_policy(key_id, policy_name, region=None, key=None, keyid=None, profile=None)

Get the policy for the specified key.

CLI example:

```
salt myminion boto_kms.get_key_policy 'alias/mykey' mypolicy
```

salt.modules.boto_kms.get_key_rotation_status(key_id, region=None, key=None, keyid=None, profile=None)

Get status of whether or not key rotation is enabled for a key.

CLI example:

```
salt myminion boto_kms.get_key_rotation_status 'alias/mykey'
```

salt.modules.boto_kms.key_exists(key_id, region=None, key=None, keyid=None, profile=None)

Check for the existence of a key.

CLI example:

```
salt myminion boto_kms.key_exists 'alias/mykey'
```

salt.modules.boto_kms.list_grants(key_id, limit=None, marker=None, region=None, key=None, keyid=None, profile=None)

List grants for the specified key.

CLI example:

```
salt myminion boto_kms.list_grants 'alias/mykey'
```

salt.modules.boto_kms.list_key_policies(key_id, limit=None, marker=None, region=None, key=None, keyid=None, profile=None)

List key_policies for the specified key.

CLI example:
salt myminion boto_kms.list_key_policies 'alias/mykey'

```
salt.modules.boto_kms.put_key_policy(key_id, policy_name, policy, region=None, key=None, keyid=None, profile=None)
```

Attach a key policy to the specified key.

CLI example:
```
salt myminion boto_kms.put_key_policy 'alias/mykey' default '{"Statement":...}"
```

salt.modules.boto_kms.re_encrypt(ciphertext_blob, destination_key_id, source_encryption_context=None, destination_encryption_context=None, grant_tokens=None, region=None, key=None, keyid=None, profile=None)

Reencrypt encrypted data with a new master key.

CLI example:
```
salt myminion boto_kms.re_encrypt 'encrypted_data' 'alias/mynewkey' default '{"Statement":...}"
```

salt.modules.boto_kms.revoke_grant(key_id, grant_id, region=None, key=None, keyid=None, profile=None)

Revoke a grant from a key.

CLI example:
```
salt myminion boto_kms.revoke_grant 'alias/mykey' 8u89hf-j09j...
```

salt.modules.boto_kms.update_key_description(key_id, description, region=None, key=None, keyid=None, profile=None)

Update a key's description.

CLI example:
```
salt myminion boto_kms.update_key_description 'alias/mykey' 'My key'
```

32.17.25 salt.modules.boto_rds

Connection module for Amazon RDS

New in version 2015.8.0.

configuration This module accepts explicit rds credentials but can also utilize IAM roles assigned to the instance through Instance Profiles. Dynamic credentials are then automatically obtained from AWS API and no further configuration is necessary. More Information available at:

```
```

If IAM roles are not used you need to specify them either in a pillar or in the minion's config file:

```
[rds]
keyid: GKTADJGHEIQSXMKKRBJ08H
key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
```

A region may also be specified in the configuration:
If a region is not specified, the default is us-east-1.

It's also possible to specify key, keyid and region via a profile, either as a passed in dict, or as a string to pull from pillars or minion config:

```
myprofile:
  keyid: GKTADJGHEIQSXMKKRBJ08H
  key: askdjghsdfjkgWupUjasdflkdfklgjsdfjakghs
  region: us-east-1
```

```
depends boto

salt.modules.boto_rds.create(name, allocated_storage, db_instance_class, engine, master_username, master_user_password, db_name=None, db_security_groups=None, vpc_security_group_ids=None, availability_zone=None, db_subnet_group_name=None, preferred_maintenance_window=None, db_parameter_group_name=None, backup_retention_period=None, preferred_backup_window=None, port=None, multi_az=None, engine_version=None, auto_minor_version_upgrade=None, license_model=None, iops=None, option_group_name=None, character_set_name=None, publicly_accessible=None, wait_status=None, tags=None, region=None, key=None, keyid=None, profile=None)
```

Create an RDS

CLI example to create an RDS:

```
salt myminion boto_rds.create myrds 10 db.t2.micro MySQL sqlusr sqlpassw
```

```
salt.modules.boto_rds.create_option_group(name, engine_name, major_engine_version, option_group_description, tags=None, region=None, key=None, keyid=None, profile=None)
```

Create an RDS option group

CLI example to create an RDS option group:

```
salt myminion boto_rds.create_option_group my-opt-group mysql 5.6
  "group description"
```

```
salt.modules.boto_rds.create_parameter_group(name, db_parameter_group_family, description, tags=None, region=None, key=None, keyid=None, profile=None)
```

Create an RDS parameter group

CLI example to create an RDS parameter group:

```
salt myminion boto_rds.create_parameter_group my-param-group mysql5.6
  "group description"
```

```
salt.modules.boto_rds.create_read_replica(name, source_name, db_instance_class=None, availability_zone=None, port=None, auto_minor_version_upgrade=None, iops=None, option_group_name=None, publicly_accessible=None, tags=None, region=None, key=None, keyid=None, profile=None)
```

32.17. Full list of builtin execution modules
Create an RDS read replica

CLI example to create an RDS read replica:

```
salt myminion boto_rds.create_read_replica replicaname source_name
```

salt.modules.boto_rds.create_subnet_group

Create an RDS subnet group

CLI example to create an RDS subnet group:

```
salt myminion boto_rds.create_subnet_group my-subnet-group
    description "groupA"
    region=us-east-1

[subnet-12345678, subnet-87654321]
```

salt.modules.boto_rds.delete

Delete an RDS instance.

CLI example:

```
salt myminion boto_rds.delete myrds skip_final_snapshot=True
    region=us-east-1
```

salt.modules.boto_rds.delete_option_group

Delete an RDS option group.

CLI example:

```
salt myminion boto_rds.delete_option_group my-opt-group
    region=us-east-1
```

salt.modules.boto_rds.delete_parameter_group

Delete an RDS parameter group.

CLI example:

```
salt myminion boto_rds.delete_parameter_group my-param-group
    region=us-east-1
```

salt.modules.boto_rds.delete_subnet_group

Delete an RDS subnet group.

CLI example:

```
salt myminion boto_rds.delete_subnet_group my-subnet-group
    region=us-east-1
```

salt.modules.boto_rds.describe

Return RDS instance details.

CLI example:
```
salt myminion boto_rds.describe myrds
```

```python
salt.modules.boto_rds.exists(name, tags=None, region=None, key=None, keyid=None, profile=None)
```
Check to see if an RDS exists.
CLI example:
```
salt myminion boto_rds.exists myrds region=us-east-1
```

```python
salt.modules.boto_rds.get_endpoint(name, tags=None, region=None, key=None, keyid=None, profile=None)
```
Return the endpoint of an RDS instance.
CLI example:
```
salt myminion boto_rds.get_endpoint myrds
```

```python
salt.modules.boto_rds.option_group_exists(name, tags=None, region=None, key=None, keyid=None, profile=None)
```
Check to see if an RDS option group exists.
CLI example:
```
salt myminion boto_rds.option_group_exists myoptiongr region=us-east-1
```

```python
salt.modules.boto_rds.parameter_group_exists(name, tags=None, region=None, key=None, keyid=None, profile=None)
```
Check to see if an RDS parameter group exists.
CLI example:
```
salt myminion boto_rds.parameter_group_exists myparamgroup region=us-east-1
```

```python
salt.modules.boto_rds.subnet_group_exists(name, tags=None, region=None, key=None, keyid=None, profile=None)
```
Check to see if an RDS subnet group exists.
CLI example:
```
salt myminion boto_rds.subnet_group_exists my-param-group region=us-east-1
```

```python
salt.modules.boto_rds.update_parameter_group(name, parameters, apply_method='pending-reboot', tags=None, region=None, key=None, keyid=None, profile=None)
```
Update an RDS parameter group.
CLI example:
```
salt myminion boto_rds.update_parameter_group my-param-group region=us-east-1 parameters='{"back_log":1, "binlog_cache_size":4096}"
```

### 32.17.26 salt.modules.boto_route53

Connection module for Amazon Route53

### 32.17. Full list of builtin execution modules

793
New in version 2014.7.0.

**configuration** This module accepts explicit route53 credentials but can also utilize IAM roles assigned to the instance through Instance Profiles. Dynamic credentials are then automatically obtained from AWS API and no further configuration is necessary. More Information available at:

```
http://docs.aws.amazon.com/AWSEC2/latest/UserGuide/iam-roles-for-amazon-
ec2.html
```

If IAM roles are not used you need to specify them either in a pillar or in the minion's config file:

```
route53.keyid: GKTADJGHEIQSXMKKRBJ08H
route53.key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
```

A region may also be specified in the configuration:

```
route53.region: us-east-1
```

If a region is not specified, the default is 'universal', which is what the boto_route53 library expects, rather than None.

It's also possible to specify key, keyid and region via a profile, either as a passed in dict, or as a string to pull from pillars or minion config:

```
myprofile:
    keyid: GKTADJGHEIQSXMKKRBJ08H
    key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
    region: us-east-1
```

**depends** boto

salt.modules.boto_route53.add_record(name, value, zone, record_type, identifier=None, ttl=None, region=None, key=None, keyid=None, profile=None, wait_for_sync=True, split_dns=False, private_zone=False)

Add a record to a zone.

CLI example:

```
salt myminion boto_route53.add_record test.example.org 1.1.1.1 example.org A
```

salt.modules.boto_route53.create_zone(zone, private=False, vpc_id=None, vpc_region=None, region=None, key=None, keyid=None, profile=None)

Create a Route53 hosted zone.

New in version 2015.8.0.

**zone** DNZ zone to create

**private** True/False if the zone will be a private zone

**vpc_id** VPC ID to associate the zone to (required if private is True)

**vpc_region** VPC Region (required if private is True)

**region** region endpoint to connect to

**key** AWS key

**keyid** AWS keyid

**profile** AWS pillar profile
CLI Example:

```
salt myminion boto_route53.create_zone example.org
```

salt.modules.boto_route53.delete_record(name, zone, record_type, identifier=None, all_records=False, region=None, key=None, keyid=None, profile=None, wait_for_sync=True, split_dns=False, private_zone=False)

Modify a record in a zone.

CLI example:

```
salt myminion boto_route53.delete_record test.example.org example.org A
```

salt.modules.boto_route53.delete_zone(zone, region=None, key=None, keyid=None, profile=None)

Delete a Route53 hosted zone.

New in version 2015.8.0.

CLI Example:

```
salt myminion boto_route53.delete_zone example.org
```

salt.modules.boto_route53.get_record(name, zone, record_type, fetch_all=False, region=None, key=None, keyid=None, profile=None, split_dns=False, private_zone=False)

Get a record from a zone.

CLI example:

```
salt myminion boto_route53.get_record test.example.org example.org A
```

salt.modules.boto_route53.update_record(name, value, zone, record_type, identifier=None, ttl=None, region=None, key=None, keyid=None, profile=None, wait_for_sync=True, split_dns=False, private_zone=False)

Modify a record in a zone.

CLI example:

```
salt myminion boto_route53.modify_record test.example.org 1.1.1.1 example.org A
```

salt.modules.boto_route53.zone_exists(zone, region=None, key=None, keyid=None, profile=None)

Check for the existence of a Route53 hosted zone.

New in version 2015.8.0.

CLI Example:

```
salt myminion boto_route53.zone_exists example.org
```

### 32.17.27 salt.modules.boto_secgroup

Connection module for Amazon Security Groups

New in version 2014.7.0.
**configuration**  This module accepts explicit EC2 credentials but can also utilize IAM roles assigned to the instance through Instance Profiles. Dynamic credentials are then automatically obtained from AWS API and no further configuration is necessary. More Information available at:

```plaintext
```

If IAM roles are not used you need to specify them either in a pillar or in the minion's config file:

```plaintext
secgroup.keyid: GKTADJGHEIQSXMKKRBJ08H
secgroup.key: askdjghsdfjklgWupUjasdflkdfklgjsdfjajkghs
```

A region may also be specified in the configuration:

```plaintext
secgroup.region: us-east-1
```

If a region is not specified, the default is us-east-1.

It's also possible to specify key, keyid and region via a profile, either as a passed in dict, or as a string to pull from pillars or minion config:

```plaintext
myprofile:
  keyid: GKTADJGHEIQSXMKKRBJ08H
  key: askdjghsdfjklgWupUjasdflkdfklgjsdfjajkghs
  region: us-east-1
```

**depends**  boto

```plaintext
salt.modules.boto_secgroup.authorize(name=None, source_group_name=None, source_group_owner_id=None, ip_protocol=None, from_port=None, to_port=None, cidr_ip=None, group_id=None, source_group_group_id=None, region=None, key=None, keyid=None, profile=None, vpc_id=None, vpc_name=None, egress=False)
```

Add a new rule to an existing security group.

CLI example:

```plaintext
salt myminion boto_secgroup.authorize mysecgroup ip_protocol=tcp from_port=80 to_port=80 cidr_ip=['[10.0.0.0/8', '192.168.0.0/24']
```

```plaintext
salt.modules.boto_secgroup.convert_to_group_ids(groups, vpc_id, vpc_name=None, region=None, key=None, keyid=None, profile=None)
```

Given a list of security groups and a vpc_id, convert_to_group_ids will convert all list items in the given list to security group ids.

CLI example:

```plaintext
salt myminion boto_secgroup.convert_to_group_ids mysecgroup vpc=89yhh7h
```

```plaintext
salt.modules.boto_secgroup.create(name, description, vpc_id=None, vpc_name=None, region=None, key=None, keyid=None, profile=None)
```

Create a security group.

CLI example:

```plaintext
salt myminion boto_secgroup.create mysecgroup 'My Security Group'
```
salt.modules.boto_secgroup.delete(name=None, group_id=None, region=None, key=None, keyid=None, profile=None, vpc_id=None, vpc_name=None)

Delete a security group.

CLI example:
```bash
salt myminion boto_secgroup.delete mysecgroup
```

salt.modules.boto_secgroup.exists(name=None, region=None, key=None, keyid=None, profile=None, vpc_id=None, vpc_name=None, group_id=None)

Check to see if a security group exists.

CLI example:
```bash
salt myminion boto_secgroup.exists mysecgroup
```

salt.modules.boto_secgroup.get_config(name=None, group_id=None, region=None, key=None, keyid=None, profile=None, vpc_id=None, vpc_name=None)

Get the configuration for a security group.

CLI example:
```bash
salt myminion boto_secgroup.get_config mysecgroup
```

salt.modules.boto_secgroup.get_group_id(name, vpc_id=None, vpc_name=None, region=None, key=None, keyid=None, profile=None)

Get a Group ID given a Group Name or Group Name and VPC ID

CLI example:
```bash
salt myminion boto_secgroup.get_group_id mysecgroup
```

salt.modules.boto_secgroup.revoke(name=None, source_group_name=None, source_group_owner_id=None, ip_protocol=None, from_port=None, to_port=None, cidr_ip=None, group_id=None, source_group_group_id=None, region=None, key=None, keyid=None, profile=None, vpc_id=None, vpc_name=None, egress=False)

Remove a rule from an existing security group.

CLI example:
```bash
salt myminion boto_secgroup.revoke mysecgroup ip_protocol=tcp from_port=80 to_port=80 cidr_ip='10.0.0.0/8'
```

### 32.17.28 salt.modules.boto_sns

Connection module for Amazon SNS

**configuration**  This module accepts explicit sns credentials but can also utilize IAM roles assigned to the instance through Instance Profiles. Dynamic credentials are then automatically obtained from AWS API and no further configuration is necessary. More Information available at:

```
```

If IAM roles are not used you need to specify them either in a pillar or in the minion's config file:
sns.keyid: GKTADJGHEIQXSXMRRBPKPJ8H
sns.key: askdjghsdfjkgWupUjasflkdfklgjsdfjajkghs

A region may also be specified in the configuration:
sns.region: us-east-1

If a region is not specified, the default is us-east-1.

It’s also possible to specify key, keyid and region via a profile, either as a passed in dict, or as a string to pull from pillars or minion config:

```yaml
myprofile:
  keyid: GKTADJGHEIQXSXMRRBPKPJ8H
  key: askdjghsdfjkgWupUjasflkdfklgjsdfjajkghs
  region: us-east-1
```

depends boto

salt.modules.boto_sns.create(name, region=None, key=None, keyid=None, profile=None)
Create a SNS topic.

CLI example to create a topic:

```
salt myminion boto_sns.create mytopic region=us-east-1
```

salt.modules.boto_sns.delete(name, region=None, key=None, keyid=None, profile=None)
Delete a SNS topic.

CLI example to delete a topic:

```
salt myminion boto_sns.delete mytopic region=us-east-1
```

salt.modules.boto_sns.exists(name, region=None, key=None, keyid=None, profile=None)
Check to see if an SNS topic exists.

CLI example:

```
salt myminion boto_sns.exists mytopic region=us-east-1
```

salt.modules.boto_sns.get_all_subscriptions_by_topic(name, region=None, key=None, keyid=None, profile=None)
Get list of all subscriptions to a specific topic.

CLI example to delete a topic:

```
salt myminion boto_sns.get_all_subscriptions_by_topic mytopic region=us-east-1
```

salt.modules.boto_sns.get_all_topics(region=None, key=None, keyid=None, profile=None)
Returns a list of all topics.

CLI example:

```
salt myminion boto_sns.get_all_topics
```

salt.modules.boto_sns.get_arn(name, region=None, key=None, keyid=None, profile=None)
Returns the full ARN for a given topic name.

CLI example:
32.17.29 salt.modules.boto_sqs

Connection module for Amazon SQS

New in version 2014.7.0.

**configuration** This module accepts explicit sqs credentials but can also utilize IAM roles assigned to the instance through Instance Profiles. Dynamic credentials are then automatically obtained from AWS API and no further configuration is necessary. More Information available at:

If IAM roles are not used you need to specify them either in a pillar or in the minion's config file:

```yaml
sqs.keyid: GKTADJGHEIQSXMKKRBJ08H
sqs.key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
```

A region may also be specified in the configuration:

```yaml
sqs.region: us-east-1
```

If a region is not specified, the default is us-east-1.

It's also possible to specify key, keyid and region via a profile, either as a passed in dict, or as a string to pull from pillars or minion config:

```yaml
myprofile:
  keyid: GKTADJGHEIQSXMKKRBJ08H
  key: askdjghsdfjkghWupUjasdflkdfklgjsdfjajkghs
  region: us-east-1
```

**depends** boto

salt.modules.boto_sqs.create(name, region=None, key=None, keyid=None, profile=None)

Create an SQS queue.

CLI example to create a queue:

```bash
salt myminion boto_sqs.create myqueue region=us-east-1
```

salt.modules.boto_sqs.delete(name, region=None, key=None, keyid=None, profile=None)

Delete an SQS queue.

CLI example to delete a queue:
salt myminion boto_sqs.delete myqueue region=us-east-1

salt.modules.boto_sqs.exists(name, region=None, key=None, keyid=None, profile=None)
Check to see if a queue exists.
CLI example:
salt myminion boto_sqs.exists myqueue region=us-east-1

salt.modules.boto_sqs.get_attributes(name, region=None, key=None, keyid=None, profile=None)
Check to see if attributes are set on an SQS queue.
CLI example:
salt myminion boto_sqs.get_attributes myqueue

salt.modules.boto_sqs.set_attributes(name, attributes, region=None, key=None, keyid=None, profile=None)
Set attributes on an SQS queue.
CLI example to set attributes on a queue:
salt myminion boto_sqs.set_attributes myqueue '{ReceiveMessageWaitTimeSeconds: 20}' region=us-east-1

32.17.30  salt.modules.boto_vpc

Connection module for Amazon VPC
New in version 2014.7.0.

configuration This module accepts explicit VPC credentials but can also utilize IAM roles assigned to
the instance trough Instance Profiles. Dynamic credentials are then automatically obtained from
AWS API and no further configuration is necessary. More Information available at:
http://docs.aws.amazon.com/AWSEC2/latest/UserGuide/iam-roles-for-amazon-
ec2.html

If IAM roles are not used you need to specify them either in a pillar or in the minion's config file:

vpc.keyid: GKTADJGHEIQSXMKKRBJ08H
vpc.key: askdjghsdfjkgHwupUjasdflkdklgjdsdfjajkgkhs

A region may also be specified in the configuration:

vpc.region: us-east-1

If a region is not specified, the default is us-east-1.
It's also possible to specify key, keyid and region via a profile, either as a passed in dict, or as a
string to pull from pillars or minion config:

myprofile:
  keyid: GKTADJGHEIQSXMKKRBJ08H
  key: askdjghsdfjkgHwupUjasdflkdklgjdsdfjajkgkhs
  region: us-east-1
Changed in version 2015.8.0: All methods now return a dictionary. Create and delete methods return:

```python
created: true
```

or

```python
created: false
error:
  message: error message
```

Request methods (e.g., `describe_vpc`) return:

```python
vpcs:
  - {...}
  - {...}
```

or

```python
error:
  message: error message
```

depends boto

```python
salt.modules.boto_vpc.associate_dhcp_options_to_vpc(dhcp_options_id, vpc_id=None, vpc_name=None, region=None, key=None, keyid=None, profile=None)
```

Given valid DHCP options id and a valid VPC id, associate the DHCP options record with the VPC.

Returns True if the DHCP options record were associated and returns False if the DHCP options record was not associated.

CLI Example:

```bash
salt myminion boto_vpc.associate_dhcp_options_to_vpc 'dhcp-a0bl34pp' 'vpc-6b1fe402'
```

```python
salt.modules.boto_vpc.associate_network_acl_to_subnet(network_acl_id=None, subnet_id=None, network_acl_name=None, subnet_name=None, region=None, key=None, keyid=None, profile=None)
```

Given a network acl and subnet ids or names, associate a network acl to a subnet.

CLI Example:

```bash
salt myminion boto_vpc.associate_network_acl_to_subnet
  network_acl_id='acl-5fb85d36' subnet_id='subnet-6a1fe403'
```

```bash
salt myminion boto_vpc.associate_network_acl_to_subnet
  network_acl_id='myacl' subnet_id='mysubnet'
```
salt.modules.boto_vpc.associate_new_dhcp_options_to_vpc(vpc_id, domain_name=None, domain_name_servers=None, ntp_servers=None, netbios_name_servers=None, netbios_node_type=None, region=None, key=None, keyid=None, profile=None)

.. deprecated:: Boron  This function has been deprecated in favor of boto_vpc.create_dhcp_options, which now takes vpc_id or vpc_name as kwargs.

This function will be removed in the Salt Boron release.

Given valid DHCP options and a valid VPC id, create and associate the DHCP options record with the VPC.

CLI Example:

```
salt myminion boto_vpc.associate_new_dhcp_options_to_vpc 'vpc-6b1fe402' domain_\n  -name='example.com' domain_name_servers='[1.2.3.4]' ntp_servers='[5.6.7.8]'  \n  netbios_name_servers='[10.0.0.1]' netbios_node_type=1
```

salt.modules.boto_vpc.associate_new_network_acl_to_subnet(vpc_id, subnet_id, network_acl_name=None, tags=None, region=None, key=None, keyid=None, profile=None)

.. deprecated:: Boron  This function has been deprecated in favor of boto_vpc.create_network_acl, which now takes subnet_id or subnet_name as kwargs.

This function will be removed in the Salt Boron release.

Given a vpc ID and a subnet ID, associates a new network act to a subnet.

Returns a dictionary containing the network acl id and the new association id if successful. If unsuccessful, returns False.

CLI Example:

```
salt myminion boto_vpc.associate_new_network_acl_to_subnet 'vpc-6b1fe402' 'subnet-\n  --6a1fe403'
```

salt.modules.boto_vpc.associate_route_table(route_table_id=None, subnet_id=None, route_table_name=None, subnet_name=None, region=None, key=None, keyid=None, profile=None)

Given a route table and subnet name or id, associates the route table with the subnet.

CLI Example:

```
salt myminion boto_vpc.associate_route_table 'rtb-1f382e7d' 'subnet-6a1fe403'
```

salt.modules.boto_vpc.associate_route_table route_table_name='myrtb' \  subnet_name='mysubnet'

salt.modules.boto_vpc.create(cidr_block, instance_tenancy=None, vpc_name=None, enable_dns_support=None, enable_dns_hostnames=None, tags=None, region=None, key=None, keyid=None, profile=None)

Given a valid CIDR block, create a VPC.
An optional instance_tenancy argument can be provided. If provided, the valid values are `default` or `dedicated`.

An optional vpc_name argument can be provided.

Returns [created: true] if the VPC was created and returns [created: False] if the VPC was not created.

CLI Example:

```
salt myminion boto_vpc.create '10.0.0.0/24'
```

salt.modules.boto_vpc.create_customer_gateway(vpn_connection_type, ip_address, bgp_asn, customer_gateway_name=None, tags=None, region=None, key=None, keyid=None, profile=None)

Given a valid VPN connection type, a static IP address and a customer gateway’s Border Gateway Protocol (BGP) Autonomous System Number, create a customer gateway.

Returns the customer gateway id if the customer gateway was created and returns False if the customer gateway was not created.

CLI Example:

```
salt myminion boto_vpc.create_customer_gateway 'ipsec.1', '12.1.2.3', 65534
```

salt.modules.boto_vpc.create_dhcp_options(domain_name=None, domain_name_servers=None, ntp_servers=None, netbios_name_servers=None, netbios_node_type=None, dhcp_options_name=None, tags=None, vpc_id=None, vpc_name=None, region=None, key=None, keyid=None, profile=None)

Given valid DHCP options, create a DHCP options record, optionally associating it with an existing VPC.

Returns True if the DHCP options record was created and returns False if the DHCP options record was not deleted.

Changed in version 2015.8.0: Added vpc_name and vpc_id arguments

CLI Example:

```
salt myminion boto_vpc.create_dhcp_options domain_name='example.com' \
   domain_name_servers='[1.2.3.4] ntp_servers='[5.6.7.8]' \
   netbios_name_servers='[10.0.0.1]' netbios_node_type=1 \
   vpc_name='myvpc'
```

salt.modules.boto_vpc.create_internet_gateway(internet_gateway_name=None, vpc_id=None, vpc_name=None, tags=None, region=None, key=None, keyid=None, profile=None)

Create an Internet Gateway, optionally attaching it to an existing VPC.

Returns the internet gateway id if the internet gateway was created and returns False if the internet gateways was not created.

New in version 2015.8.0.

CLI Example:

```
salt myminion boto_vpc.create_internet_gateway \
   internet_gateway_name=myigw vpc_name=myvpc
```
salt.modules.boto_vpc.create_network_acl(vpc_id=None, vpc_name=None, network_acl_name=None, subnet_id=None, subnet_name=None, tags=None, region=None, key=None, keyid=None, profile=None)

Given a vpc_id, creates a network acl.
Returns the network acl id if successful, otherwise returns False.
Changed in version 2015.8.0: Added vpc_name, subnet_id, and subnet_name arguments
CLI Example:
salt myminion boto_vpc.create_network_acl 'vpc-6b1fe402'

salt.modules.boto_vpc.create_network_acl_entry(network_acl_id=None, rule_number=None, protocol=None, rule_action=None, cidr_block=None, egress=None, network_acl_name=None, icmp_code=None, icmp_type=None, port_range_from=None, port_range_to=None, region=None, key=None, keyid=None, profile=None)

Creates a network acl entry.
CLI Example:
salt myminion boto_vpc.create_network_acl_entry 'acl-5fb85d36' '32767' 'all' 'deny' '0.0.0.0/0' egress=true

salt.modules.boto_vpc.create_route(route_table_id=None, destination_cidr_block=None, route_table_name=None, gateway_id=None, internet_gateway_name=None, instance_id=None, interface_id=None, region=None, key=None, keyid=None, profile=None)

Creates a route.
CLI Example:
salt myminion boto_vpc.create_route 'rtb-1f382e7d' '10.0.0.0/16' gateway_id='vgw-a1b2c3'

salt.modules.boto_vpc.create_route_table(vpc_id=None, vpc_name=None, route_table_name=None, tags=None, region=None, key=None, keyid=None, profile=None)

Creates a route table.
Changed in version 2015.8.0: Added vpc_name argument
CLI Examples:
salt myminion boto_vpc.create_route_table vpc_id='vpc-6b1fe402' route_table_name='myroutetable'
salt myminion boto_vpc.create_route_table vpc_name='myvpc' route_table_name='myroutetable'

salt.modules.boto_vpc.create_subnet(vpc_id=None, cidr_block=None, vpc_name=None, availability_zone=None, subnet_name=None, tags=None, region=None, key=None, keyid=None, profile=None)

Given a valid VPC ID or Name and a CIDR block, create a subnet for the VPC.
An optional availability zone argument can be provided.

Returns True if the VPC subnet was created and returns False if the VPC subnet was not created.

Changed in version 2015.8.0: Added vpc_name argument

CLI Examples:

```python
salt myminion boto_vpc.create_subnet vpc_id='vpc-6b1fe402' \  subnet_name='mysubnet' cidr_block='10.0.0.0/25'
salt myminion boto_vpc.create_subnet vpc_name='myvpc' \  subnet_name='mysubnet', cidr_block='10.0.0.0/25'
```

salt.modules.boto_vpc.customer_gateway_exists(customer_gateway_id=None, customer_gateway_name=None, region=None, key=None, keyid=None, profile=None)

Given a customer gateway ID, check if the customer gateway ID exists.

Returns True if the customer gateway ID exists; Returns False otherwise.

CLI Example:

```python
salt myminion boto_vpc.customer_gateway_exists cgw-b6a247df
salt myminion boto_vpc.customer_gateway_exists customer_gatway_name=mycgw
```

salt.modules.boto_vpc.delete(vpc_id=None, name=None, vpc_name=None, tags=None, region=None, key=None, keyid=None, profile=None)

Given a VPC ID or VPC name, delete the VPC.

Returns {deleted: true} if the VPC was deleted and returns {deleted: false} if the VPC was not deleted.

CLI Example:

```python
salt myminion boto_vpc.delete vpc_id='vpc-6b1fe402'
salt myminion boto_vpc.delete name='myvpc'
```

salt.modules.boto_vpc.delete_customer_gateway(customer_gateway_id=None, customer_gateway_name=None, region=None, key=None, keyid=None, profile=None)

Given a customer gateway ID or name, delete the customer gateway.

Returns True if the customer gateway was deleted and returns False if the customer gateway was not deleted.

Changed in version 2015.8.0: Added customer_gateway_name argument

CLI Example:

```python
salt myminion boto_vpc.delete_customer_gateway 'cgw-b6a247df'
```

salt.modules.boto_vpc.delete_dhcp_options(dhcp_options_id=None, dhcp_options_name=None, region=None, key=None, keyid=None, profile=None)

Delete dhcp options by id or name.

New in version 2015.8.0.

CLI Example:

```python
salt myminion boto_vpc.delete_dhcp_options 'dopt-b6a247df'
```
salt.modules.boto_vpc.delete_internet_gateway(internet_gateway_id=None, internet_gateway_name=None, detach=False, region=None, key=None, keyid=None, profile=None)

Delete an internet gateway (by name or id).

Returns True if the internet gateway was deleted and otherwise False.

New in version 2015.8.0.

CLI Examples:

```
salt myminion boto_vpc.delete_internet_gateway internet_gateway_id=igw-1a2b3c
salt myminion boto_vpc.delete_internet_gateway internet_gateway_name=myigw
```

salt.modules.boto_vpc.delete_network_acl(network_acl_id=None, network_acl_name=None, disassociate=False, region=None, key=None, keyid=None, profile=None)

Delete a network acl based on the network_acl_id or network_acl_name provided.

CLI Examples:

```
salt myminion boto_vpc.delete_network_acl network_acl_id='acl-5fb85d36' disassociate=false
salt myminion boto_vpc.delete_network_acl network_acl_name='myacl' disassociate=true
```

salt.modules.boto_vpc.delete_network_acl_entry(network_acl_id=None, rule_number=None, egress=None, network_acl_name=None, region=None, key=None, keyid=None, profile=None)

Deletes a network acl entry.

CLI Example:

```
salt myminion boto_vpc.delete_network_acl_entry 'acl-5fb85d36' '32767'
```

salt.modules.boto_vpc.delete_route(route_table_id=None, destination_cidr_block=None, route_table_name=None, region=None, key=None, keyid=None, profile=None)

Deletes a route.

CLI Example:

```
salt myminion boto_vpc.delete_route 'rtb-1f382e7d' '10.0.0.0/16'
```

salt.modules.boto_vpc.delete_route_table(route_table_id=None, route_table_name=None, region=None, key=None, keyid=None, profile=None)

Deletes a route table.

CLI Examples:

```
salt myminion boto_vpc.delete_route_table route_table_id='rtb-1f382e7d'
salt myminion boto_vpc.delete_route_table route_table_name='myroutetable'
```

salt.modules.boto_vpc.delete_subnet(subnet_id=None, subnet_name=None, region=None, key=None, keyid=None, profile=None)

Given a subnet ID or name, delete the subnet.
Returns True if the subnet was deleted and returns False if the subnet was not deleted.

Changed in version 2015.8.0: Added subnet_name argument

CLI Example:

```bash
salt myminion boto_vpc.delete_subnet 'subnet-6a1fe403'
```

salt.modules.boto_vpc.describe(vpc_id=None, vpc_name=None, region=None, key=None, keyid=None, profile=None)

Given a VPC ID describe its properties.

Returns a dictionary of interesting properties.

Changed in version 2015.8.0: Added vpc_name argument

CLI Example:

```bash
salt myminion boto_vpc.describe vpc_id=vpc-123456
salt myminion boto_vpc.describe vpc_name=myvpc
```

salt.modules.boto_vpc.describe_route_table(route_table_id=None, route_table_name=None, tags=None, region=None, key=None, keyid=None, profile=None)

Given route table properties, return route table details if matching table(s) exist.

New in version 2015.8.0.

CLI Example:

```bash
salt myminion boto_vpc.describe_route_table route_table_id='rtb-1f382e7d'
```

salt.modules.boto_vpc.describe_subnet(subnet_id=None, subnet_name=None, region=None, key=None, keyid=None, profile=None)

Given a subnet id or name, describe its properties.

Returns a dictionary of interesting properties.

New in version 2015.8.0.

CLI Examples:

```bash
salt myminion boto_vpc.describe_subnet subnet_id=subnet-123456
salt myminion boto_vpc.describe_subnet subnet_name=mysubnet
```

salt.modules.boto_vpc.describe_subnets(subnet_ids=None, subnet_names=None, vpc_id=None, cidr=None, region=None, key=None, keyid=None, profile=None)

Given a VPC ID or subnet CIDR, returns a list of associated subnets and their details. Return all subnets if VPC ID or CIDR are not provided. If a subnet id or CIDR is provided, only its associated subnet details will be returned.

New in version 2015.8.0.

CLI Examples:

```bash
salt myminion boto_vpc.describe_subnets

salt myminion boto_vpc.describe_subnets subnet_ids=['subnet-ba1987ab', 'subnet-ba1987cd']
```
salt myminion boto_vpc.describe_subnets vpc_id=vpc-123456

salt myminion boto_vpc.describe_subnets cidr=10.0.0.0/21

salt.modules.boto_vpc.describe_vpcs(vpc_id=None, name=None, cidr=None, tags=None, region=None, key=None, keyid=None, profile=None)

Describe all VPCs, matching the filter criteria if provided.
Returns a a list of dictionaries with interesting properties.
New in version 2015.8.0.
CLI Example:
salt myminion boto_vpc.describe_vpcs

salt.modules.boto_vpc.dhcp_options_exists(dhcp_options_id=None, name=None, dhcp_options_name=None, tags=None, region=None, key=None, keyid=None, profile=None)

Check if a dhcp option exists.
Returns True if the dhcp option exists; Returns False otherwise.
CLI Example:
salt myminion boto_vpc.dhcp_options_exists dhcp_options_id='dhcp-a0bl34pp'

salt.modules.boto_vpc.disassociate_network_acl(subnet_id=None, vpc_id=None, subnet_name=None, vpc_name=None, region=None, key=None, keyid=None, profile=None)

Given a subnet ID, disassociates a network acl.
CLI Example:
salt myminion boto_vpc.disassociate_network_acl 'subnet-6a1fe403'

salt.modules.boto_vpc.disassociate_route_table(association_id, region=None, key=None, keyid=None, profile=None)

Dissociates a route table.

association_id  The Route Table Association ID to disassociate
CLI Example:
salt myminion boto_vpc.disassociate_route_table 'rtbassoc-d8ccddba'

salt.modules.boto_vpc.exists(vpc_id=None, name=None, cidr=None, tags=None, region=None, key=None, keyid=None, profile=None)

Given a VPC ID, check to see if the given VPC ID exists.
Returns True if the given VPC ID exists and returns False if the given VPC ID does not exist.
CLI Example:
salt myminion boto_vpc.exists myvpc

salt.modules.boto_vpc.get_id(name=None, cidr=None, tags=None, region=None, key=None, keyid=None, profile=None)

Given VPC properties, return the VPC id if a match is found.
CLI Example:

```bash
salt myminion boto_vpc.get_id myvpc
```

`salt.modules.boto_vpc.get_resource_id(resource, name=None, resource_id=None, region=None, key=None, keyid=None, profile=None)`

Get an AWS id for a VPC resource by type and name.

New in version 2015.8.0.

CLI Example:

```bash
salt myminion boto_vpc.get_resource_id internet_gateway myigw
```

`salt.modules.boto_vpc.get_subnet_association(subnets, region=None, key=None, keyid=None, profile=None)`

Given a subnet (aka: a vpc zone identifier) or list of subnets, returns vpc association.

Returns a VPC ID if the given subnets are associated with the same VPC ID. Returns False on an error or if the given subnets are associated with different VPC IDs.

CLI Examples:

```bash
salt myminion boto_vpc.get_subnet_association subnet-61b47516
salt myminion boto_vpc.get_subnet_association ['subnet-61b47516', 'subnet-2cb9785b']
```

`salt.modules.boto_vpc.network_acl_exists(network_acl_id=None, name=None, network_acl_name=None, tags=None, region=None, key=None, keyid=None, profile=None)`

Checks if a network acl exists.

Returns True if the network acl exists or returns False if it doesn't exist.

CLI Example:

```bash
salt myminion boto_vpc.network_acl_exists network_acl_id='acl-5fb85d36'
```

`salt.modules.boto_vpc.replace_network_acl_entry(network_acl_id=None, rule_number=None, protocol=None, rule_action=None, cidr_block=None, egress=None, network_acl_name=None, icmp_code=None, icmp_type=None, port_range_from=None, port_range_to=None, region=None, key=None, keyid=None, profile=None)`

Replaces a network acl entry.

CLI Example:

```bash
salt myminion boto_vpc.replace_network_acl_entry 'acl-5fb85d36' '32767' 'all' 'deny' '0.0.0.0/0' egress=true
```

`salt.modules.boto_vpc.replace_route(route_table_id=None, destination_cidr_block=None, route_table_name=None, gateway_id=None, instance_id=None, interface_id=None, region=None, key=None, keyid=None, profile=None)`

Replaces a route.
**salt.modules.boto_vpc.replace_route_table_association**

```
salt myminion boto_vpc.replace_route_table_association 'rtbassoc-d8ccddba' 'rtb-1f382e7d'
```

Replaces a route table association.

---

**salt.modules.boto_vpc.resource_exists**

```
salt myminion boto_vpc.resource_exists internet_gateway myigw
```

Given a resource type and name, return {exists: true} if it exists, {exists: false} if it does not exist, or {error: {message: error text}} on error.

New in version 2015.8.0.

---

**salt.modules.boto_vpc.route_exists**

```
salt myminion boto_vpc.route_exists destination_cidr_block='10.0.0.0/20' gateway_id='local' route_table_name='test'
```

Checks if a route exists.

New in version 2015.8.0.

---

**salt.modules.boto_vpc.route_table_exists**

```
salt myminion boto_vpc.route_table_exists route_table_id='rtb-1f382e7d'
```

Checks if a route table exists.

---

**salt.modules.boto_vpc.subnet_exists**

```
salt myminion boto_vpc.subnet_exists subnet_id='subnet-6a1fe403'
```

Check if a subnet exists.

Returns True if the subnet exists, otherwise returns False.

Changed in version 2015.8.0: Added subnet_name argument Deprecated name argument

---

```
salt myminion boto_vpc.replace_route 'rtb-1f382e7d' '10.0.0.0/16' gateway_id='vgw-alb2c3'
```
32.17.31 salt.modules.bower

Manage and query Bower packages

This module manages the installed packages using Bower. Note that npm, git and bower must be installed for this module to be available.

salt.modules.bower.install(pkg, dir, pkgs=None, runas=None, env=None)

Install a Bower package.

If no package is specified, the dependencies (from bower.json) of the package in the given directory will be installed.

pkg  A package name in any format accepted by Bower, including a version identifier

dir  The target directory in which to install the package

pkgs  A list of package names in the same format as the pkg parameter

runas  The user to run Bower with

env  Environment variables to set when invoking Bower. Uses the same env format as the cmd.run execution function.

CLI Example:

```
salt '*' bower.install underscore /path/to/project
salt '*' bower.install jquery#2.0 /path/to/project
```

salt.modules.bower.list(dir, runas=None, env=None)

List installed Bower packages.

dir  The directory whose packages will be listed

runas  The user to run Bower with

env  Environment variables to set when invoking Bower. Uses the same env format as the cmd.run execution function.

CLI Example:

```
salt '*' bower.list /path/to/project
```

salt.modules.bower.uninstall(pkg, dir, runas=None, env=None)

Uninstall a Bower package.

pkg  A package name in any format accepted by Bower

dir  The target directory from which to uninstall the package

runas  The user to run Bower with

env  Environment variables to set when invoking Bower. Uses the same env format as the cmd.run execution function.

CLI Example:

```
salt '*' bower.uninstall underscore /path/to/project
```
32.17.32 salt.modules.brew

Homebrew for Mac OS X

Important: If you feel that Salt should be using this module to manage packages on a minion, and it is using a different module (or gives an error similar to 'pkg.install' is not available), see here.

salt.modules.brew.install(name=None, pkgs=None, taps=None, options=None, **kwargs)

Install the passed package(s) with brew install

name The name of the formula to be installed. Note that this parameter is ignored if `"pkgs" is passed.

CLI Example:
	salt '*' pkg.install <package name>

taps Unofficial GitHub repos to use when updating and installing formulas.

CLI Example:
	salt '*' pkg.install <package name> tap='<tap>'
	salt '*' pkg.install zlib taps='homebrew/dupes'
	salt '*' pkg.install php54 taps='["josegonzalez/php", "homebrew/dupes"]'

options Options to pass to brew. Only applies to initial install. Due to how brew works, modifying chosen options requires a full uninstall followed by a fresh install. Note that if `"pkgs" is used, all options will be passed to all packages. Unrecognized options for a package will be silently ignored by brew.

CLI Example:
	salt '*' pkg.install <package name> tap='<tap>'
	salt '*' pkg.install php54 taps='["josegonzalez/php", "homebrew/dupes"]'

Multiple Package Installation Options:

pkgs A list of formulas to install. Must be passed as a python list.

CLI Example:
	salt '*' pkg.install pkgs=["foo","bar"]

Returns a dict containing the new package names and versions:

{'<package>': {'old': '<old-version>',
             'new': '<new-version>'}}

CLI Example:
	salt '*' pkg.install package package package'

salt.modules.brew.latest_version('names', **kwargs)

Return the latest version of the named package available for upgrade or installation

Note that this currently not fully implemented but needs to return something to avoid a traceback when calling pkg.latest.

CLI Example:
salt '*' pkg.latest_version <package name>
salt '*' pkg.latest_version <package1> <package2> <package3>

salt.modules.brew.list_pkgs(versions_as_list=False, **kwargs)
List the packages currently installed in a dict:

```
{'<package_name>': '<version>'}
```

CLI Example:
salt '*' pkg.list_pkgs

salt.modules.brew.list_upgrades(refresh=True, **kwargs)
Check whether or not an upgrade is available for all packages

CLI Example:
salt '*' pkg.list_upgrades

salt.modules.brew.refresh_db()
Update the homebrew package repository.

CLI Example:
salt '*' pkg.refresh_db

salt.modules.brew.remove(name=None, pkgs=None, **kwargs)
Removes packages with brew uninstall.

name The name of the package to be deleted.

Multiple Package Options:

pkgs A list of packages to delete. Must be passed as a python list. The name parameter will be ignored if this option is passed.

New in version 0.16.0.

Returns a dict containing the changes.

CLI Example:

```
salt '*' pkg.remove <package name>
salt '*' pkg.remove <package1>,<package2>,<package3>
salt '*' pkg.remove pkgs=['foo', 'bar']
```

salt.modules.brew.upgrade(refresh=True)
Upgrade outdated, unpinned brews.

refresh Fetch the newest version of Homebrew and all formulae from GitHub before installing.

Return a dict containing the new package names and versions:

```
{'<package>': {'old': '<old-version>',
               'new': '<new-version>'}}
```

CLI Example:
salt '*' pkg.upgrade
salt.modules.brew.update_available(pkg)
    Check whether or not an upgrade is available for a given package
    CLI Example:
    
    salt '*' pkg.upgrade_available <package name>

salt.modules.brew.version(*names, **kwargs)
    Returns a string representing the package version or an empty string if not installed. If more than one package
    name is specified, a dict of name/version pairs is returned.
    CLI Example:
    
    salt '*' pkg.version <package name>
    salt '*' pkg.version <package1> <package2> <package3>

32.17.33 salt.modules.bridge

Module for gathering and managing bridging information

salt.modules.bridge.add(br=None)
    Creates a bridge
    CLI Example:
    
    salt '*' bridge.add br0

salt.modules.bridge.addif(br=None, iface=None)
    Adds an interface to a bridge
    CLI Example:
    
    salt '*' bridge.addif br0 eth0

salt.modules.bridge.delete(br=None)
    Deletes a bridge
    CLI Example:
    
    salt '*' bridge.delete br0

salt.modules.bridge.delif(br=None, iface=None)
    Removes an interface from a bridge
    CLI Example:
    
    salt '*' bridge.delif br0 eth0

salt.modules.bridge.find_interfaces(*args)
    Returns the bridge to which the interfaces are bond to
    CLI Example:
    
    salt '*' bridge.find_interfaces eth0 [eth1...]

salt.modules.bridge.interfaces(br=None)
    Returns interfaces attached to a bridge
    CLI Example:
salt ' '*' bridge.interfaces br0

salt.modules.bridge.list()
Returns the machine's bridges list

CLI Example:
salt ' '*' bridge.list

salt.modules.bridge.show(br=None)
Returns bridges interfaces along with enslaved physical interfaces. If no interface is given, all bridges are
shown, else only the specified bridge values are returned.

CLI Example:
salt ' '*' bridge.show
salt ' '*' bridge.show br0

salt.modules.bridge.stp(br=None, state='disable', iface=None)
Sets Spanning Tree Protocol state for a bridge

CLI Example:
salt ' '*' bridge.stp br0 enable
salt ' '*' bridge.stp br0 disable

For BSD-like operating systems, it is required to add the interface on which to enable the STP.

CLI Example:
salt ' '*' bridge.stp bridge0 enable fxp0
salt ' '*' bridge.stp bridge0 disable fxp0

32.17.34 salt.modules.bsd_shadow

Manage the password database on BSD systems

**Important:** If you feel that Salt should be using this module to manage passwords on a minion, and it is using a
different module (or gives an error similar to `shadow.info` is not available), see [here](#).

salt.modules.bsd_shadow.default_hash()
Returns the default hash used for unset passwords

CLI Example:
salt ' '*' shadow.default_hash

salt.modules.bsd_shadow.del_password(name)
New in version 2015.8.2.
Delete the password from name user

CLI Example:
salt ' '*' shadow.del_password username

32.17. Full list of builtin execution modules
salt.modules.bsd_shadow.info(name)
   Return information for the specified user
   CLI Example:
   ```
   salt '*' shadow.info someuser
   ```

salt.modules.bsd_shadow.set_change(name, change)
   Sets the time at which the password expires (in seconds since the EPOCH). See man usermod on NetBSD and
   OpenBSD or man pw on FreeBSD. "0" means the password never expires.
   CLI Example:
   ```
   salt '*' shadow.set_change username 1419980400
   ```

salt.modules.bsd_shadow.set_expire(name, expire)
   Sets the time at which the account expires (in seconds since the EPOCH). See man usermod on NetBSD and
   OpenBSD or man pw on FreeBSD. "0" means the account never expires.
   CLI Example:
   ```
   salt '*' shadow.set_expire username 1419980400
   ```

salt.modules.bsd_shadow.set_password(name, password)
   Set the password for a named user. The password must be a properly defined hash. The password hash can be
   generated with this command:
   ```
   python -c "import crypt; print crypt.crypt('password',ciphersalt)"
   ```
   NOTE: When constructing the ciphersalt string, you must escape any dollar signs, to avoid them being
   interpolated by the shell.
   'password' is, of course, the password for which you want to generate a hash.
   ciphersalt is a combination of a cipher identifier, an optional number of rounds, and the cryptographic
   salt. The arrangement and format of these fields depends on the cipher and which flavor of BSD you are using.
   For more information on this, see the manpage for crypt(3). On NetBSD, additional information is available
   in passwd.conf(5).
   It is important to make sure that a supported cipher is used.
   CLI Example:
   ```
   salt '*' shadow.set_password someuser '$1$UYCIxa628.9qXjpQCjM4a..'`
   ```

32.17.35 salt.modules.btrfs

Module for managing BTRFS file systems.
salt.modules.btrfs.add(mountpoint, *devices, **kwargs)
   Add a devices to a BTRFS filesystem.
   General options:
   - **nodiscard**: Do not perform whole device TRIM
   - **force**: Force overwrite existing filesystem on the disk
   CLI Example:
salt '⋆' btrfs.add /mountpoint /dev/sda1 /dev/sda2

`salt.modules.btrfs.convert(device, permanent=False, keeplf=False)`  
Convert ext2/3/4 to BTRFS. Device should be mounted.

Filesystem can be converted temporarily so the further processing and rollback is possible, or permanently, where previous extended filesystem image gets deleted. Please note, permanent conversion takes a while as BTRFS filesystem needs to be properly rebalanced afterwards.

General options:

- **permanent**: Specify if the migration should be permanent (false by default)
- **keeplf**: Keep *lost+found* of the partition (removed by default, but still in the image, if not permanent migration)

CLI Example:

```
salt '⋆' btrfs.convert /dev/sda1
salt '⋆' btrfs.convert /dev/sda1 permanent=True
```

salt '⋆' btrfs.defragment(path)

Defragment mounted BTRFS filesystem. In order to defragment a filesystem, device should be properly mounted and writable.

If passed a device name, then defragmented whole filesystem, mounted on in. If passed a mount point of the filesystem, then only this mount point is defragmented.

CLI Example:

```
salt '⋆' btrfs.defragment /dev/sda1
salt '⋆' btrfs.defragment /path/on/filesystem
```

salt '⋆' btrfs.delete(mountpoint, *devices, **kwargs)

Remove devices from a BTRFS filesystem.

CLI Example:

```
salt '⋆' btrfs.delete /mountpoint /dev/sda1 /dev/sda2
```

salt '⋆' btrfs.devices()

Get known BTRFS formatted devices on the system.

CLI Example:

```
salt '⋆' btrfs.devices
```

salt '⋆' btrfs.features()

List currently available BTRFS features.

CLI Example:

```
salt '⋆' btrfs.mkfs_features
```

salt '⋆' btrfs.info(device)

Get BTRFS filesystem information.

CLI Example:

```
salt '⋆' btrfs.info /dev/sda1
```
salt.modules.btrfs.mkfs(*devices, **kwargs)
Create a file system on the specified device. By default wipes out with force.

General options:

- allocsize: Specify the BTRFS offset from the start of the device.
- bytecount: Specify the size of the resultant filesystem.
- nodesize: Node size.
- leafsize: Specify the node size, the tree block size in which btrfs stores data.
- noforce: Prevent force overwrite when an existing filesystem is detected on the device.
- sectorsize: Specify the sectorsize, the minimum data block allocation unit.
- nodiscard: Do not perform whole device TRIM operation by default.
- uuid: Pass UUID or pass True to generate one.

Options:

- dto: (raid0|raid1|raid5|raid6|raid10|single|dup) Specify how the data must be spanned across the devices specified.
- mto: (raid0|raid1|raid5|raid6|raid10|single|dup) Specify how metadata must be spanned across the devices specified.

- features (call salt <host> btrfs.features for full list of available features)

See the mkfs.btrfs(8) manpage for a more complete description of corresponding options description.

CLI Example:

```
salt '*' btrfs.mkfs /dev/sda1
salt '*' btrfs.mkfs /dev/sda1 noforce=True
```

salt.modules.btrfs.properties(obj, type=None, set=None)
List properties for given btrfs object. The object can be path of BTRFS device, mount point, or any directories/files inside the BTRFS filesystem.

General options:

- type: Possible types are s[ubvol], f[ilesystem], i[node] and d[evice].
- force: Force overwrite existing filesystem on the disk
- set: <key=value,key1=value1…> Options for a filesystem properties.

CLI Example:

```
salt '*' btrfs.properties /mountpoint
salt '*' btrfs.properties /dev/sda1 type=subvol set='ro=false,label="My Storage"'
```

salt.modules.btrfs.resize(mountpoint, size)
Resize filesystem.

General options:

- mountpoint: Specify the BTRFS mountpoint to resize.
- size: ([+/-]<newsize>[kMgGtPbE]|max) Specify the new size of the target.

CLI Example:
salt '*' btrfs.resize /mountpoint size=+1g
salt '*' btrfs.resize /dev/sda1 size=max

salt.modules.btrfs.usage(path)
Show in which disk the chunks are allocated.

CLI Example:
salt '*' btrfs.usage /your/mountpoint

salt.modules.btrfs.version()
Return BTRFS version.

CLI Example:
salt '*' btrfs.version

32.17.36 salt.modules.cabal

Manage and query Cabal packages

New in version 2015.8.0.

salt.modules.cabal.install(pkg=None, pkgs=None, user=None, install_global=False, env=None)
Install a cabal package.

pkg  A package name in format accepted by cabal-install. See: https://wiki.haskell.org/Cabal-Install
pkgs A list of packages names in same format as pkg
user The user to run cabal install with
install_global Install package globally instead of locally
env Environment variables to set when invoking cabal. Uses the same env format as the cmd.run execution function

CLI Example:
salt '*' cabal.install shellcheck
salt '*' cabal.install shellcheck=0.3.5

salt.modules.cabal.list(pkg=None, user=None, installed=False, env=None)
List packages matching a search string.

pkg  Search string for matching package names
user The user to run cabal list with
installed If True, only return installed packages.
env Environment variables to set when invoking cabal. Uses the same env format as the cmd.run execution function

CLI example:
salt '*' cabal.list
salt '*' cabal.list ShellCheck
salt.modules.cabal.uninstall(pkg, user=None, env=None)
   Uninstall a cabal package.
   pkg  The package to uninstall
   user  The user to run ghc-pkg unregister with
   env  Environment variables to set when invoking cabal. Uses the same env format as the cmd.run execution function

salt.modules.cabal.update(user=None, env=None)
   Updates list of known packages.

32.17.37 salt.modules.cassandra
   Cassandra NoSQL Database Module
   depends
      • pycassa Cassandra Python adapter
   configuration  The location of the `nodetool' command, host, and thrift port needs to be specified via pillar:

   ```
   cassandra.nodetool: /usr/local/bin/nodetool
cassandra.host: localhost
cassandra.thrift_port: 9160
   ```

salt.modules.cassandra.column_families(keyspace=None)
   Return existing column families for all keyspaces or just the provided one.
   CLI Example:
   ```
   salt '*' cassandra.column_families
   salt '*' cassandra.column_families <keyspace>
   ```

salt.modules.cassandra.column_family_definition(keyspace, column_family)
   Return a dictionary of column family definitions for the given keyspace/column_family
   CLI Example:
   ```
   salt '*' cassandra.column_family_definition <keyspace> <column_family>
   ```

salt.modules.cassandra.compactionstats()
   Return compactionstats info
   CLI Example:
   ```
   salt '*' cassandra.compactionstats
   ```

salt.modules.cassandra.info()
   Return cassandra node info
   CLI Example:
   ```
   salt '*' cassandra.info
   ```

salt.modules.cassandra.keysspaces()
   Return existing keyspaces
   CLI Example:
Salt Documentation, Release 2015.8.12

```
salt '*' cassandra.keyspaces

salt.modules.cassandra.netstats()
Return netstats info
CLI Example:
salt '*' cassandra.netstats

salt.modules.cassandra.ring()
Return cassandra ring info
CLI Example:
salt '*' cassandra.ring

salt.modules.cassandra.tpstats()
Return tpstats info
CLI Example:
salt '*' cassandra.tpstats

salt.modules.cassandra.version()
Return the cassandra version
CLI Example:
salt '*' cassandra.version
```

32.17.38  **salt.modules.cassandra_cql**

Cassandra Database Module

New in version 2015.5.0.

**depends** DataStax Python Driver for Apache Cassandra [https://github.com/datastax/python-driver](https://github.com/datastax/python-driver)

**pip**
install cassandra-driver

**referenced by** Salt's cassandra_cql returner

**configuration** The Cassandra cluster members and connection port can either be specified in the master or minion config, the minion's pillar or be passed to the module.

Example configuration in the config for a single node:

```
cassandra:
    cluster: 192.168.50.10
    port: 9000
```

Example configuration in the config for a cluster:

```
cassandra:
    cluster:
        - 192.168.50.10
        - 192.168.50.11
        - 192.168.50.12
    port: 9000
    username: cas_admin
```
salt.modules.cassandra_cql.cql_query(query, contact_points=None, port=None, cql_user=None, cql_pass=None)

Run a query on a Cassandra cluster and return a dictionary.

Parameters

- **query** *(str)* -- The query to execute.
- **contact_points** *(str | list[str]*) -- The Cassandra cluster addresses, can either be a string or a list of IPs.
- **cql_user** *(str)* -- The Cassandra user if authentication is turned on.
- **cql_pass** *(str)* -- The Cassandra user password if authentication is turned on.
- **port** *(int)* -- The Cassandra cluster port, defaults to None.
- **params** *(str)* -- The parameters for the query, optional.

Returns A dictionary from the return values of the query

Return type *list[dict]*

salt.modules.cassandra_cql.create_keyspace(keyspace, replication_strategy='SimpleStrategy', replication_factor=1, replication_datacenters=None, contact_points=None, port=None, cql_user=None, cql_pass=None)

Create a new keyspace in Cassandra.

Parameters

- **keyspace** *(str)* -- The keyspace name
- **replication_strategy** *(str)* -- either SimpleStrategy or NetworkTopologyStrategy
- **replication_factor** *(int)* -- number of replicas of data on multiple nodes. not used if using NetworkTopologyStrategy
- **replication_datacenters** *(str | dict[str, int])* -- string or dict of data-center names to replication factors, required if using NetworkTopologyStrategy (will be a dict if coming from state file).
- **contact_points** *(str | list[str]*) -- The Cassandra cluster addresses, can either be a string or a list of IPs.
- **cql_user** *(str)* -- The Cassandra user if authentication is turned on.
- **cql_pass** *(str)* -- The Cassandra user password if authentication is turned on.
- **port** *(int)* -- The Cassandra cluster port, defaults to None.

Returns The info for the keyspace or False if it does not exist.

Return type *dict*
salt.modules.cassandra_cql.create_user(username, password, superuser=False, contact_points=None, port=None, cql_user=None, cql_pass=None)

Create a new cassandra user with credentials and superuser status.

Parameters

- **username** *(str)* -- The name of the new user.
- **password** *(str)* -- The password of the new user.
- **superuser** *(bool)* -- Is the new user going to be a superuser? default: False
- **contact_points** *(str | list[str])* -- The Cassandra cluster addresses, can either be a string or a list of IPs.
- **cql_user** *(str)* -- The Cassandra user if authentication is turned on.
- **cql_pass** *(str)* -- The Cassandra user password if authentication is turned on.
- **port** *(int)* -- The Cassandra cluster port, defaults to None.

Returns

Return type

dict

```python
salt 'minion1' cassandra_cql.create_user username=joe password=secret
salt 'minion1' cassandra_cql.create_user username=joe password=secret
  superuser=True
salt 'minion1' cassandra_cql.create_user username=joe password=secret
  superuser=True contact_points=minion1
```

salt.modules.cassandra_cql.drop_keyspace(keyspace, contact_points=None, port=None, cql_user=None, cql_pass=None)

Drop a keyspace if it exists in a Cassandra cluster.

Parameters

- **keyspace** *(str)* -- The keyspace to drop.
- **contact_points** *(str | list[str])* -- The Cassandra cluster addresses, can either be a string or a list of IPs.
- **cql_user** *(str)* -- The Cassandra user if authentication is turned on.
- **cql_pass** *(str)* -- The Cassandra user password if authentication is turned on.
- **port** *(int)* -- The Cassandra cluster port, defaults to None.

Returns

The info for the keyspace or False if it does not exist.

Return type

dict

CLI Example:

```python
salt 'minion1' cassandra_cql.drop_keyspace keyspace=test
salt 'minion1' cassandra_cql.drop_keyspace keyspace=test contact_points=minion1
```
salt.modules.cassandra_cql.grant_permission(username, resource=None, resource_type='keyspace', permission=None, contact_points=None, port=None, cql_user=None, cql_pass=None)

Grant permissions to a user.

Parameters

- **username (str)** -- The name of the user to grant permissions to.
- **resource (str)** -- The resource (keyspace or table), if None, permissions for all resources are granted.
- **resource_type (str)** -- The resource_type (keyspace or table), defaults to `keyspace`.
- **permission (str)** -- A permission name (e.g. select), if None, all permissions are granted.
- **contact_points (str | list[str])** -- The Cassandra cluster addresses, can either be a string or a list of IPs.
- **cql_user (str)** -- The Cassandra user if authentication is turned on.
- **cql_pass (str)** -- The Cassandra user password if authentication is turned on.
- **port (int)** -- The Cassandra cluster port, defaults to None.

Returns

Return type

```python
salt 'minion1' cassandra_cql.grant_permission
salt 'minion1' cassandra_cql.grant_permission username=joe resource=test_keyspace permission=select
salt 'minion1' cassandra_cql.grant_permission username=joe resource=test_table resource_type=table permission=select contact_points=minion1
```

salt.modules.cassandra_cql.info(contact_points=None, port=None, cql_user=None, cql_pass=None)

Show the Cassandra information for this cluster.

Parameters

- **contact_points (str | list[str])** -- The Cassandra cluster addresses, can either be a string or a list of IPs.
- **cql_user (str)** -- The Cassandra user if authentication is turned on.
- **cql_pass (str)** -- The Cassandra user password if authentication is turned on.
- **port (int)** -- The Cassandra cluster port, defaults to None.

Returns

The information for this Cassandra cluster.

Return type

```
salt 'minion1' cassandra_cql.info
salt 'minion1' cassandra_cql.info contact_points=minion1
```
salt.modules.cassandra_cql.keyspace_exists(keyspace, contact_points=None, port=None, cql_user=None, cql_pass=None)

Check if a keyspace exists in a Cassandra cluster.

:param keyspace The keyspace name to check for. :type keyspace: str :param contact_points: The Cassandra cluster addresses, can either be a string or a list of IPs. :type contact_points: str | list[str] :param cql_user: The Cassandra user if authentication is turned on. :type cql_user: str :param cql_pass: The Cassandra user password if authentication is turned on. :type cql_pass: str :param port: The Cassandra cluster port, defaults to None. :type port: int :return: The info for the keyspace or False if it does not exist. :rtype: dict

CLI Example:

```bash
salt 'minion1' cassandra_cql.keyspace_exists keyspace=system
salt 'minion1' cassandra_cql.list_keyspaces keyspace=system contact_points=minion1
```

salt.modules.cassandra_cql.list_column_families(keyspace=None, contact_points=None, port=None, cql_user=None, cql_pass=None)

List column families in a Cassandra cluster for all keyspaces or just the provided one.

Parameters

- **keyspace** *(str)* -- The keyspace to provide the column families for, optional.
- **contact_points** *(str | list[str])* -- The Cassandra cluster addresses, can either be a string or a list of IPs.
- **cql_user** *(str)* -- The Cassandra user if authentication is turned on.
- **cql_pass** *(str)* -- The Cassandra user password if authentication is turned on.
- **port** *(int)* -- The Cassandra cluster port, defaults to None.

Returns The column families in this Cassandra cluster.

Return type list[dict]

CLI Example:

```bash
salt 'minion1' cassandra_cql.list_column_families
salt 'minion1' cassandra_cql.list_column_families contact_points=minion1
salt 'minion1' cassandra_cql.list_column_families keyspace=system
```

salt.modules.cassandra_cql.list_keyspaces(contact_points=None, port=None, cql_user=None, cql_pass=None)

List keyspaces in a Cassandra cluster.

Parameters

- **contact_points** *(str | list[str])* -- The Cassandra cluster addresses, can either be a string or a list of IPs.
- **cql_user** *(str)* -- The Cassandra user if authentication is turned on.
- **cql_pass** *(str)* -- The Cassandra user password if authentication is turned on.
- **port** *(int)* -- The Cassandra cluster port, defaults to None.

Returns The keyspaces in this Cassandra cluster.

Return type list[dict]
CLI Example:

```
salt 'minion1' cassandra_cql.list_keyspaces
salt 'minion1' cassandra_cql.list_keyspaces contact_points=minion1 port=9000
```

```
salt.modules.cassandra_cql.list_permissions(username=None, resource=None, resource_type='keyspace', permission=None, contact_points=None, port=None, cql_user=None, cql_pass=None)
```

List permissions.

**Parameters**

- `username (str)` -- The name of the user to list permissions for.
- `resource (str)` -- The resource (keyspace or table), if None, permissions for all resources are listed.
- `resource_type (str)` -- The resource_type (keyspace or table), defaults to `keyspace`.
- `permission (str)` -- A permission name (e.g. select), if None, all permissions are listed.
- `contact_points (str | list[str])` -- The Cassandra cluster addresses, can either be a string or a list of IPs.
- `cql_user (str)` -- The Cassandra user if authentication is turned on.
- `cql_pass (str)` -- The Cassandra user password if authentication is turned on.
- `port (int)` -- The Cassandra cluster port, defaults to None.

**Returns** Dictionary of permissions.

**Return type** dict

```
salt 'minion1' cassandra_cql.list_permissions
salt 'minion1' cassandra_cql.list_permissions username=joe resource=test_keyspace permission=select
salt 'minion1' cassandra_cql.list_permissions username=joe resource=test_table resource_type=table permission=select contact_points=minion1
```

```
salt.modules.cassandra_cql.list_users(contact_points=None, port=None, cql_user=None, cql_pass=None)
```

List existing users in this Cassandra cluster.

**Parameters**

- `contact_points (str | list[str])` -- The Cassandra cluster addresses, can either be a string or a list of IPs.
- `port (int)` -- The Cassandra cluster port, defaults to None.
- `cql_user (str)` -- The Cassandra user if authentication is turned on.
- `cql_pass (str)` -- The Cassandra user password if authentication is turned on.

**Returns** The list of existing users.

**Return type** dict
```
salt 'minion1' cassandra_cql.list_users
salt 'minion1' cassandra_cql.list_users contact_points=minion1
```

```
salt.modules.cassandra_cql.version(contact_points=None, port=None, cql_user=None, cql_pass=None)
```

Show the Cassandra version.

**Parameters**

- `contact_points` *(str | list[str])* -- The Cassandra cluster addresses, can either be a string or a list of IPs.
- `cql_user` *(str)*  -- The Cassandra user if authentication is turned on.
- `cql_pass` *(str)*  -- The Cassandra user password if authentication is turned on.
- `port` *(int)*  -- The Cassandra cluster port, defaults to None.

**Returns**  The version for this Cassandra cluster.

**Return type**  *str*

**CLI Example:**

```
salt 'minion1' cassandra_cql.version
salt 'minion1' cassandra_cql.version contact_points=minion1
```

32.17.39  **salt.modules.chassis**

Glue execution module to link to the *fx2 proxymodule*.

**Depends:**  *iDRAC Remote execution module (salt.modules.dracr)*

For documentation on commands that you can direct to a Dell chassis via proxy, look in the documentation for *salt.modules.dracr*.

This execution module calls through to a function in the *fx2 proxy module* called *chconfig*. That function looks up the function passed in the *cmd* parameter in *salt.modules.dracr* and calls it.

New in version 2015.8.2.

```
salt.modules.chassis.chassis_credentials()
salt.modules.chassis.cmd(cmd, *args, **kwargs)
```

32.17.40  **salt.modules.chef**

Execute chef in server or solo mode

```
salt.modules.chef.client(whyrun=False, localmode=False, logfile=None, **kwargs)
```

Execute a chef client run and return a dict with the stderr, stdout, return code, and pid.

**CLI Example:**

```
salt '*' chef.client server=https://localhost
```

*server*  The chef server URL
client_key  Set the client key file location

config  The configuration file to use

config-file-jail  Directory under which config files are allowed to be loaded (no client.rb or knife.rb outside this path will be loaded).

environment  Set the Chef Environment on the node

group  Group to set privilege to

json-attributes  Load attributes from a JSON file or URL

log_level  Set the log level (debug, info, warn, error, fatal)

logfile  Set the log file location

node-name  The node name for this client

override-runlist  Replace current run list with specified items for a single run

pid  Set the PID file location, defaults to /tmp/chef-client.pid

run-lock-timeout  Set maximum duration to wait for another client run to finish, default is indefinitely.

runlist  Permanently replace current run list with specified items

user  User to set privilege to

validation_key  Set the validation key file location, used for registering new clients

whyrun  Enable whyrun mode when set to True

salt.modules.chef.solo(whyrun=False, logfile=None, **kwargs)
Execute a chef solo run and return a dict with the stderr, stdout, return code, and pid.

CLI Example:

```
salt '*' chef.solo override-runlist=test
```

config  The configuration file to use

environment  Set the Chef Environment on the node

group  Group to set privilege to

json-attributes  Load attributes from a JSON file or URL

log_level  Set the log level (debug, info, warn, error, fatal)

logfile  Set the log file location

node-name  The node name for this client

override-runlist  Replace current run list with specified items for a single run

recipe-url  Pull down a remote gzipped tarball of recipes and untar it to the cookbook cache

run-lock-timeout  Set maximum duration to wait for another client run to finish, default is indefinitely.

user  User to set privilege to

whyrun  Enable whyrun mode when set to True
32.17.41 `salt.modules.chocolatey`

A dead simple module wrapping calls to the Chocolatey package manager (http://chocolatey.org)

New in version 2014.1.0.

```
salt.modules.chocolatey.bootstrap(force=False)
```

Download and install the latest version of the Chocolatey package manager via the official bootstrap.

Chocolatey requires Windows PowerShell and the .NET v4.0 runtime. Depending on the host's version of Windows, chocolatey.bootstrap will attempt to ensure these prerequisites are met by downloading and executing the appropriate installers from Microsoft.

Note that if PowerShell is installed, you may have to restart the host machine for Chocolatey to work.

- **force** Run the bootstrap process even if Chocolatey is found in the path.

CLI Example:

```
salt '*' chocolatey.bootstrap
salt '*' chocolatey.bootstrap force=True
```

```
salt.modules.chocolatey.chocolatey_version()
```

New in version 2014.7.0.

Returns the version of Chocolatey installed on the minion.

CLI Example:

```
salt '*' chocolatey.chocolatey_version
```

```
salt.modules.chocolatey.install(name, version=None, source=None, force=False, install_args=None, override_args=False, force_x86=False)
```

Instructs Chocolatey to install a package.

- **name** The name of the package to be installed. Only accepts a single argument.
- **version** Install a specific version of the package. Defaults to latest version.
- **source** Chocolatey repository (directory, share or remote URL feed) the package comes from. Defaults to the official Chocolatey feed.
- **force** Reinstall the current version of an existing package.
- **install_args** A list of install arguments you want to pass to the installation process i.e product key or feature list
- **override_args** Set to true if you want to override the original install arguments (for the native installer) in the package and use your own. When this is set to False install_args will be appended to the end of the default arguments
- **force_x86** Force x86 (32bit) installation on 64 bit systems. Defaults to false.

CLI Example:

```
salt '*' chocolatey.install <package name>
salt '*' chocolatey.install <package name> version=<package version>
salt '*' chocolatey.install <package name> install_args=<args> override_args=True
```

```
salt.modules.chocolatey.install_cygwin(name, install_args=None, override_args=False)
```

Instructs Chocolatey to install a package via Cygwin.
name The name of the package to be installed. Only accepts a single argument.

install_args A list of install arguments you want to pass to the installation process i.e product key or feature list

override_args

Set to true if you want to override the original install arguments (for the native installer) in the package and use your own. When this is set to False install_args will be appended to the end of the default arguments

CLI Example:

```
salt '*' chocolatey.install_cygwin <package name>
salt '*' chocolatey.install_cygwin <package name> install_args=<args> override_args=True
```

salt.modules.chocolatey.install_gem(name, version=None, install_args=None, override_args=False)

Instructs Chocolatey to install a package via Ruby's Gems.

name The name of the package to be installed. Only accepts a single argument.

version Install a specific version of the package. Defaults to latest version available.

install_args A list of install arguments you want to pass to the installation process i.e product key or feature list

override_args

Set to true if you want to override the original install arguments (for the native installer) in the package and use your own. When this is set to False install_args will be appended to the end of the default arguments

CLI Example:

```
salt '*' chocolatey.install_gem <package name>
salt '*' chocolatey.install_gem <package name> version=<package version>
salt '*' chocolatey.install_gem <package name> install_args=<args> override_args=True
```

salt.modules.chocolatey.install_missing(name, version=None, source=None)

Instructs Chocolatey to install a package if it doesn't already exist.

Changed in version 2014.7.0: If the minion has Chocolatey >= 0.9.8.24 installed, this function calls chocolatey.install instead, as installmissing is deprecated as of that version and will be removed in Chocolatey 1.0.

name The name of the package to be installed. Only accepts a single argument.

version Install a specific version of the package. Defaults to latest version available.

source Chocolatey repository (directory, share or remote URL feed) the package comes from. Defaults to the official Chocolatey feed.

CLI Example:

```
salt '*' chocolatey.install_missing <package name>
salt '*' chocolatey.install_missing <package name> version=<package version>
```

salt.modules.chocolatey.install_python(name, version=None, install_args=None, override_args=False)

Instructs Chocolatey to install a package via Python's easy_install.
name  The name of the package to be installed. Only accepts a single argument.

version  Install a specific version of the package. Defaults to latest version available.

install_args  A list of install arguments you want to pass to the installation process i.e product key or feature list

override_args

Set to true if you want to override the original install arguments (for the native installer) in the package and use your own. When this is set to False install_args will be appended to the end of the default arguments

CLI Example:

```bash
salt '*' chocolatey.install_python <package name>
salt '*' chocolatey.install_python <package name> version=<package version>
salt '*' chocolatey.install_python <package name> install_args=<args> override_args=True
```

salt.modules.chocolatey.install_webpi(name, install_args=None, override_args=False)
Instructs Chocolatey to install a package via the Microsoft Web PI service.

name  The name of the package to be installed. Only accepts a single argument.

install_args  A list of install arguments you want to pass to the installation process i.e product key or feature list

override_args

Set to true if you want to override the original install arguments (for the native installer) in the package and use your own. When this is set to False install_args will be appended to the end of the default arguments

CLI Example:

```bash
salt '*' chocolatey.install_webpi <package name>
salt '*' chocolatey.install_webpi <package name> install_args=<args> override_args=True
```

salt.modules.chocolatey.install_windowsfeatures(name)
Instructs Chocolatey to install a Windows Feature via the Deployment Image Servicing and Management tool.

name  The name of the feature to be installed. Only accepts a single argument.

CLI Example:

```bash
salt '*' chocolatey.install_windowsfeatures <package name>
```

salt.modules.chocolatey.list(narrow=None, all_versions=False, pre_versions=False, source=None, local_only=False)
Instructs Chocolatey to pull a vague package list from the repository.

narrow  Term used to narrow down results. Searches against name/description/tag.

all_versions  Display all available package versions in results. Defaults to False.

pre_versions  Display pre-release packages in results. Defaults to False.

source  Chocolatey repository (directory, share or remote URL feed) the package comes from. Defaults to the official Chocolatey feed.

local_only  Display packages only installed locally
CLI Example:

```bash
salt '*' chocolatey.list <narrow>
salt '*' chocolatey.list <narrow> all_versions=True
```

`salt.modules.chocolatey.list_webpi()`
Instructs Chocolatey to pull a full package list from the Microsoft Web PI repository.

CLI Example:

```bash
salt '*' chocolatey.list_webpi
```

`salt.modules.chocolatey.list_windowsfeatures()`
Instructs Chocolatey to pull a full package list from the Windows Features list, via the Deployment Image Servicing and Management tool.

CLI Example:

```bash
salt '*' chocolatey.list_windowsfeatures
```

`salt.modules.chocolatey.uninstall(name=None, version=None, uninstall_args=None, override_args=False)`
Instructs Chocolatey to uninstall a package.

- **name** The name of the package to be uninstalled. Only accepts a single argument.
- **version** Uninstalls a specific version of the package. Defaults to latest version installed.
- **uninstall_args** A list of uninstall arguments you want to pass to the uninstallation process i.e product key or feature list
- **override_args**

  Set to true if you want to override the original uninstall arguments (for the native uninstaller) in the package and use your own. When this is set to False uninstall_args will be appended to the end of the default arguments

CLI Example:

```bash
salt '*' chocolatey.uninstall <package name>
salt '*' chocolatey.uninstall <package name> version=<package version>
salt '*' chocolatey.uninstall <package name> version=<package version> uninstall_args=<args> override_args=True
```

`salt.modules.chocolatey.update(name=None, source=None, pre_versions=False)`
Instructs Chocolatey to update packages on the system.

- **name** The name of the package to update, or ``all`` to update everything installed on the system.
- **source** Chocolatey repository (directory, share or remote URL feed) the package comes from. Defaults to the official Chocolatey feed.
- **pre_versions** Include pre-release packages in comparison. Defaults to False.

CLI Example:

```bash
salt '*' chocolatey.update all
salt '*' chocolatey.update <package name> pre_versions=True
```

`salt.modules.chocolatey.version(name=None, check_remote=False, source=None, pre_versions=False)`
Instructs Chocolatey to check an installed package version, and optionally compare it to one available from a remote feed.
name  The name of the package to check.

check_remote  Get the version number of the latest package from the remote feed. Defaults to False.

source  Chocolatey repository (directory, share or remote URL feed) the package comes from. Defaults to the official Chocolatey feed.

pre_versions  Include pre-release packages in comparison. Defaults to False.

CLI Example:

```bash
salt "*" chocolatey.version <package name>
salt "*" chocolatey.version <package name> check_remote=True
```

32.17.42  salt.modules.cloud

Salt-specific interface for calling Salt Cloud directly

**salt.modules.cloud.action** *(fun=\None, cloudmap=\None, names=\None, provider=\None, instance=\None, **kwargs)*

Execute a single action on the given provider/instance

CLI Example:

```bash
salt '*' cloud.action start instance=myinstance
salt '*' cloud.action stop instance=myinstance
salt '*' cloud.action show_image provider=my-ec2-config image=ami-1624987f
```

**salt.modules.cloud.create** *(provider, names, **kwargs)*

Create an instance using Salt Cloud

CLI Example:

```bash
salt minionname cloud.create my-ec2-config myinstance image=ami-1624987f size='t1.micro' ssh_username=ec2-user securitygroup=default delvol_on_destroy=True
```

**salt.modules.cloud.destroy** *(names)*

Destroy the named VM(s)

CLI Example:

```bash
salt '*' cloud.destroy myinstance
```

**salt.modules.cloud.full_query** *(query_type='list_nodes_full')*

List all available cloud provider data

CLI Example:

```bash
salt '*' cloud.full_query
```

**salt.modules.cloud.get_instance** *(name, provider=\None)*

Return details on an instance.

Similar to the cloud action show_instance but returns only the instance details.

CLI Example:

```bash
salt '*' cloud.get_instance myinstance
```

SLS Example:
salt.modules.cloud.get_instance

Return true if the instance is found on a provider

CLI Example:
salt '*' cloud.get_instance myinstance

salt.modules.cloud.has_instance(name, provider=None)

List cloud provider images for the given providers

CLI Example:
salt '*' cloud.get_instance myinstance

salt.modules.cloud.list_images(provider='all')

List cloud provider images for the given providers

CLI Example:
salt '*' cloud.list_images my-gce-config

salt.modules.cloud.list_locations(provider='all')

List cloud provider locations for the given providers

CLI Example:
salt '*' cloud.list_locations my-gce-config

salt.modules.cloud.list_sizes(provider='all')

List cloud provider sizes for the given providers

CLI Example:
salt '*' cloud.list_sizes my-gce-config

salt.modules.cloud.network_create(provider, names, **kwargs)

Create private network

CLI Example:
salt minionname cloud.network_create my-nova names=['salt'] cidr='192.168.100.0/24'

salt.modules.cloud.network_list(provider)

List private networks

CLI Example:
salt minionname cloud.network_list my-nova

salt.modules.cloud.profile(profile, names, vm_overrides=None, **kwargs)

Spin up an instance using Salt Cloud

CLI Example:
salt '*' cloud.profile my-gce-config myinstance

salt.modules.cloud.query(query_type='list_nodes')

List cloud provider data for all providers

CLI Examples:
salt '*' cloud.query
salt '*' cloud.query list_nodes_full
salt '*' cloud.query list_nodes_select
salt.modules.cloud.select_query(query_type='list_nodes_select')
    List selected nodes
    CLI Example:
    salt '*' cloud.select_query

salt.modules.cloud.virtual_interface_create(provider, names, **kwargs)
    Attach private interfaces to a server
    CLI Example:
    salt minionname cloud.virtual_interface_create my-nova names=['salt-master'] net_
       --name='salt'

salt.modules.cloud.virtual_interface_list(provider, names, **kwargs)
    List virtual interfaces on a server
    CLI Example:
    salt minionname cloud.virtual_interface_list my-nova names=['salt-master']

salt.modules.cloud.volume_attach(provider, names, **kwargs)
    Attach volume to a server
    CLI Example:
    salt minionname cloud.volume_attach my-nova myblock server_name=myserver device='/
       --dev/xvdf'

salt.modules.cloud.volume_create(provider, names, **kwargs)
    Create volume
    CLI Example:
    salt minionname cloud.volume_create my-nova myblock size=100 voltype=SSD

salt.modules.cloud.volume_delete(provider, names, **kwargs)
    Delete volume
    CLI Example:
    salt minionname cloud.volume_delete my-nova myblock

salt.modules.cloud.volume_detach(provider, names, **kwargs)
    Detach volume from a server
    CLI Example:
    salt minionname cloud.volume_detach my-nova myblock server_name=myserver

salt.modules.cloud.volume_list(provider)
    List block storage volumes
    CLI Example:
    salt minionname cloud.volume_list my-nova
32.17.43  \texttt{salt.modules.cmdmod}

A module for shelling out.

Keep in mind that this module is insecure, in that it can give whomever has access to the master root execution access to all salt minions.

\texttt{salt.modules.cmdmod.exec_code}(\texttt{lang}, \texttt{code}, \texttt{cwd=None})

Pass in two strings, the first naming the executable language, aka - python2, python3, ruby, perl, lua, etc. the second string containing the code you wish to execute. The stdout will be returned.

CLI Example:

\begin{verbatim}
salt '*' cmd.exec_code ruby 'puts "cheese"'
\end{verbatim}

\texttt{salt.modules.cmdmod.exec_code_all}(\texttt{lang}, \texttt{code}, \texttt{cwd=None})

Pass in two strings, the first naming the executable language, aka - python2, python3, ruby, perl, lua, etc. the second string containing the code you wish to execute. All cmd artifacts (stdout, stderr, retcode, pid) will be returned.

CLI Example:

\begin{verbatim}
salt '*' cmd.exec_code_all ruby 'puts "cheese"'
\end{verbatim}

\texttt{salt.modules.cmdmod.has_exec}(\texttt{cmd})

Returns true if the executable is available on the minion, false otherwise

CLI Example:

\begin{verbatim}
salt '*' cmd.has_exec cat
\end{verbatim}

\texttt{salt.modules.cmdmod.retcode}(\texttt{cmd}, \texttt{cwd=None}, \texttt{stdin=None}, \texttt{runas=None}, \texttt{shell='\texttt{/bin/sh}'}; \texttt{python_shell=None}, \texttt{env=None}, \texttt{clean_env=False}, \texttt{template=None}, \texttt{umask=None}, \texttt{output_loglevel='debug'}, \texttt{log_callback=None}, \texttt{timeout=None}, \texttt{reset_system_locale=True}, \texttt{ignore_retcode=False}, \texttt{saltenv='base'}, \texttt{use_vt=False}, **\texttt{kwargs})

Execute a shell command and return the command’s return code.

\texttt{cmd}: The command to run. ex: `ls -lart /home'

\texttt{cwd} The current working directory to execute the command in, defaults to /root

\texttt{stdin} A string of standard input can be specified for the command to be run using the stdin parameter. This can be useful in cases where sensitive information must be read from standard input.:  

\texttt{runas} User to run script as.

\texttt{shell} Shell to execute under. Defaults to the system default shell.

\texttt{python_shell} If False, let python handle the positional arguments. Set to True to use shell features, such as pipes or redirection

\texttt{env}

A list of environment variables to be set prior to execution. Example:

\begin{verbatim}
salt://scripts/foo.sh: 
  cmd.script:
  - env:
    - BATCH: 'yes'
\end{verbatim}
Warning: The above illustrates a common PyYAML pitfall, that yes, no, on, off, true, and false are all loaded as boolean True and False values, and must be enclosed in quotes to be used as strings. More info on this (and other) PyYAML idiosyncrasies can be found here.

Variables as values are not evaluated. So $PATH in the following example is a literal `$PATH':

```
salt://scripts/bar.sh:
  cmd.script:
    - env: "PATH=/some/path:$PATH"
```

One can still use the existing $PATH by using a bit of Jinja:

```
{% set current_path = salt['environ.get']('PATH', '/bin:/usr/bin') %}
mycommand:
  cmd.run:
    - name: ls -l /
    - env:
      - PATH: {{ [current_path, '/my/special/bin']|join(':') }}
```

**clean_env**: Attempt to clean out all other shell environment variables and set only those provided in the `env` argument to this function.

**template** If this setting is applied then the named templating engine will be used to render the downloaded file. Currently jinja, mako, and weppy are supported.

**rstrip** Strip all whitespace off the end of output before it is returned.

**umask** The umask (in octal) to use when running the command.

**output_loglevel** Control the loglevel at which the output from the command is logged. Note that the command being run will still be logged (loglevel: DEBUG) regardless, unless quiet is used for this value.

**timeout** A timeout in seconds for the executed process to return.

**use_vt** Use VT utils (saltstack) to stream the command output more interactively to the console and the logs. This is experimental.

Note that env represents the environment variables for the command, and should be formatted as a dict, or a YAML string which resolves to a dict.

**Return type** int

**Return type** None

**Returns** Return Code as an int or None if there was an exception.

CLI Example:

```
salt '*' cmd.retcode "file /bin/bash"
```

The template arg can be set to `jinja` or another supported template engine to render the command arguments before execution. For example:

```
salt '*' cmd.retcode template=jinja "file {{grains.pythonpath[0]}}/python"
```

A string of standard input can be specified for the command to be run using the stdin parameter. This can be useful in cases where sensitive information must be read from standard input.

32.17. Full list of builtin execution modules
Execute the passed command and return the output as a string

Note that `env` represents the environment variables for the command, and should be formatted as a dict, or a YAML string which resolves to a dict.

- **cmd**: The command to run. Ex: `ls -lart /home`
- **cwd**: The current working directory to execute the command in, defaults to `/root`
- **stdin**: A string of standard input can be specified for the command to be run using the `stdin` parameter. This can be useful in cases where sensitive information must be read from standard input.
- **runas**: User to run script as.
- **shell**: Shell to execute under. Defaults to the system default shell.
- **python_shell**: If False, let python handle the positional arguments. Set to True to use shell features, such as pipes or redirection
- **env**: A list of environment variables to be set prior to execution. Example:

  ```yaml
  salt://scripts/foo.sh:
  cmd.script:
    - env:
  - BATCH: 'yes'
  ```

**Warning**: The above illustrates a common PyYAML pitfall, that `yes`, `no`, `on`, `off`, `true`, and `false` are all loaded as boolean `True` and `False` values, and must be enclosed in quotes to be used as strings. More info on this (and other) PyYAML idiosyncrasies can be found here.

Variables as values are not evaluated. So `PATH` in the following example is a literal `'$PATH'`:

  ```yaml
  salt://scripts/bar.sh:
  cmd.script:
  - env: "PATH=/some/path:$PATH"
  ```

One can still use the existing `PATH` by using a bit of Jinja:

```python
{% set current_path = salt['environ.get']('PATH', '/bin:/usr/bin') %}
mycommand:
  cmd.run:
    - name: ls -l /
    - env:
      - PATH: {{ [current_path, '/my/special/bin']|join(':') }}
```

- **clean_env**: Attempt to clean out all other shell environment variables and set only those provided in the `env` argument to this function.
**template** If this setting is applied then the named templating engine will be used to render the downloaded file. Currently jinja, mako, and wempy are supported.

**rstrip** Strip all whitespace off the end of output before it is returned.

**umask** The umask (in octal) to use when running the command.

**output_loglevel** Control the loglevel at which the output from the command is logged. Note that the command being run will still be logged (loglevel: DEBUG) regardless, unless **quiet** is used for this value.

**timeout** A timeout in seconds for the executed process to return.

**use_vt** Use VT utils (saltstack) to stream the command output more interactively to the console and the logs. This is experimental.

---

**Warning:** This function does not process commands through a shell unless the python_shell flag is set to True. This means that any shell-specific functionality such as `echo` or the use of pipes, redirection or `&&`, should either be migrated to cmd.shell or have the python_shell=True flag set here.

The use of python_shell=True means that the shell will accept _any_ input including potentially malicious commands such as `'good_command;rm -rf /'`. Be absolutely certain that you have sanitized your input prior to using python_shell=True

---

CLI Example:

```
salt '*' cmd.run "ls -l | awk '/foo/{print \$2}'"
```

The template arg can be set to `jinja` or another supported template engine to render the command arguments before execution. For example:

```
salt '*' cmd.run template=jinja "ls -l /tmp/{{grains.id}} | awk '/foo/{print \$2}'"
```

Specify an alternate shell with the shell parameter:

```
salt '*' cmd.run "Get-ChildItem C:\" shell='powershell'
```

A string of standard input can be specified for the command to be run using the **stdin** parameter. This can be useful in cases where sensitive information must be read from standard input:

```
salt '*' cmd.run "grep f" stdin='one\ntwo\nthree\nfour\nfive\n'
```

If an equal sign (=) appears in an argument to a Salt command it is interpreted as a keyword argument in the format **key=value**. That processing can be bypassed in order to pass an equal sign through to the remote shell command by manually specifying the kwarg:

```
salt '*' cmd.run cmd='sed -e s/=/:/g'
```

**salt.modules.cmdmod.run_all**

```
salt.modules.cmdmod.run_all(cmd, cwd=None, stdin=None, runas=None, shell='/bin/sh', python_shell=None, env=None, clean_env=False, template=None, rstrip=True, umask=None, output_loglevel='debug', log_callback=None, timeout=None, reset_system_locale=True, ignore_retcode=False, saltenv='base', use_vt=False, redirect_stderr=False, **kwargs)
```

Execute the passed command and return a dict of return data

**cmd** The command to run. ex: `'ls -lart /home'`

**cwd** The current working directory to execute the command in, defaults to `/root`
stdin  A string of standard input can be specified for the command to be run using the stdin parameter. This can be useful in cases where sensitive information must be read from standard input.

runas  User to run script as.

shell  Shell to execute under. Defaults to the system default shell.

python_shell  If False, let python handle the positional arguments. Set to True to use shell features, such as pipes or redirection.

ev  A list of environment variables to be set prior to execution. Example:

```
salt://scripts/foo.sh:
  cmd.script:
    - env:
      - BATCH: 'yes'
```

**Warning:** The above illustrates a common PyYAML pitfall, that yes, no, on, off, true, and false are all loaded as boolean True and False values, and must be enclosed in quotes to be used as strings. More info on this (and other) PyYAML idiosyncrasies can be found [here](#).

Variables as values are not evaluated. So $PATH in the following example is a literal `$PATH`:

```
salt://scripts/bar.sh:
  cmd.script:
    - env: "PATH=/some/path:$PATH"
```

One can still use the existing $PATH by using a bit of Jinja:

```
{% set current_path = salt['environ.get']('PATH', '/bin:/usr/bin') %}
mycommand:
  cmd.run:
    - name: ls -l /
    - env:
      - PATH: {{ [current_path, '/my/special/bin']|join(':') }}
```

clean_env  Attempt to clean out all other shell environment variables and set only those provided in the `env` argument to this function.

template  If this setting is applied then the named templating engine will be used to render the downloaded file. Currently jinja, mako, and wempy are supported

rstrip  Strip all whitespace off the end of output before it is returned.

umask  The umask (in octal) to use when running the command.

output_loglevel  Control the loglevel at which the output from the command is logged. Note that the command being run will still be logged (loglevel: DEBUG) regardless, unless quiet is used for this value.

timeout  A timeout in seconds for the executed process to return.

use_vt  Use VT utils (saltstack) to stream the command output more interactively to the console and the logs. This is experimental.

Note that env represents the environment variables for the command, and should be formatted as a dict, or a YAML string which resolves to a dict.
**redirect_stderr** [False] If set to `True`, then stderr will be redirected to stdout. This is helpful for cases where obtaining both the retcode and output is desired, but it is not desired to have the output separated into both stdout and stderr.

New in version 2015.8.2.

CLI Example:

```bash
salt '*' cmd.run_all "ls -l | awk '/foo/{print \$2}'"
```

The template arg can be set to `jinja` or another supported template engine to render the command arguments before execution. For example:

```bash
salt '*' cmd.run_all template=jinja "ls -l /tmp/{{grains.id}} | awk '/foo/{print \$2}"
```

A string of standard input can be specified for the command to be run using the `stdin` parameter. This can be useful in cases where sensitive information must be read from standard input:

```bash
salt '*' cmd.run_all "grep f" stdin='one
two
three
four
five'
```

salt.modules.cmdmod.run_chroot(root, cmd, cwd=None, stdin=None, runas=None, shell='/bin/sh', python_shell=True, env=None, clean_env=False, template=None, rstrip=True, umask=None, output_loglevel='quiet', log_callback=None, quiet=False, timeout=None, reset_system_locale=True, ignore_retcode=False, saltenv='base', use_vt=False, **kwargs)

New in version 2014.7.0.

This function runs `cmd.run_all` wrapped within a chroot, with dev and proc mounted in the chroot

**root**: Path to the root of the jail to use.

**cmd**: The command to run. ex: `ls -lart /home`

**cwd** The current working directory to execute the command in, defaults to /root

**stdin** A string of standard input can be specified for the command to be run using the `stdin` parameter. This can be useful in cases where sensitive information must be read from standard input.

**runas** User to run script as.

**shell** Shell to execute under. Defaults to the system default shell.

**python_shell** If False, let python handle the positional arguments. Set to True to use shell features, such as pipes or redirection

**env** A list of environment variables to be set prior to execution. Example:

```python
salt://scripts/foo.sh:
  cmd.script:
    - env:
    - BATCH: 'yes'
```

**Warning**: The above illustrates a common PyYAML pitfall, that yes, no, on, off, true, and false are all loaded as boolean True and False values, and must be enclosed in quotes to be used as strings. More info on this (and other) PyYAML idiosyncrasies can be found [here](#).
Variables as values are not evaluated. So $PATH in the following example is a literal `$PATH':

```
salt://scripts/bar.sh:
cmd.script:
  - env: "PATH=/some/path:$PATH"
```

One can still use the existing $PATH by using a bit of Jinja:

```
{% set current_path = salt['environ.get']('PATH', '/bin:/usr/bin') %}
mycommand:
  cmd.run:
    - name: ls -l /
    - env:
      - PATH: {{ [current_path, '/my/special/bin']|join(':') }}
```

clean_env: Attempt to clean out all other shell environment variables and set only those provided in the `env' argument to this function.

template If this setting is applied then the named templating engine will be used to render the downloaded file. Currently jinja, mako, and wempy are supported

rstrip Strip all whitespace off the end of output before it is returned.

umask The umask (in octal) to use when running the command.

output_loglevel Control the loglevel at which the output from the command is logged. Note that the command being run will still be logged (loglevel: DEBUG) regardless, unless quiet is used for this value.

timeout A timeout in seconds for the executed process to return.

use_vt Use VT utils (saltstack) to stream the command output more interactively to the console and the logs. This is experimental.

CLI Example:

```
salt '*' cmd.run_chroot /var/lib/lxc/container_name/rootfs 'sh /tmp/bootstrap.sh'
```

salt.modules.cmdmod.run_stderr(cmd, cwd=None, stdin=None, runas=None, shell='/bin/sh',
  python_shell=None, env=None, clean_env=False, template=None, rstrip=True, umask=None, output_loglevel='debug',
  log_callback=None, timeout=None, reset_system_locale=True,
  ignore_retcode=False, saltenv='base', use_vt=False, **kwargs)

Execute a command and only return the standard error

cmd: The command to run. ex: `ls -lart /home'

cwd The current working directory to execute the command in, defaults to /root

stdin A string of standard input can be specified for the command to be run using the stdin parameter. This can be useful in cases where sensitive information must be read from standard input:

runas User to run script as.

shell Shell to execute under. Defaults to the system default shell.

python_shell If False, let python handle the positional arguments. Set to True to use shell features, such as pipes or redirection

env A list of environment variables to be set prior to execution. Example:
Warning: The above illustrates a common PyYAML pitfall, that yes, no, on, off, true, and false are all loaded as boolean True and False values, and must be enclosed in quotes to be used as strings. More info on this (and other) PyYAML idiosyncrasies can be found [here](#).

Variables as values are not evaluated. So $PATH in the following example is a literal `$PATH':

```yaml
salt://scripts/bar.sh:
  cmd.script:
    - env:
      - "PATH=/some/path:$PATH"
```

One can still use the existing $PATH by using a bit of Jinja:

```python
{% set current_path = salt['environ.get']('PATH', '/bin:/usr/bin') %}
mycommand:
  cmd.run:
    - name: ls -l /
    - env:
      - PATH: {{ [current_path, '/my/special/bin']|join(':') }}
```

**clean_env:** Attempt to clean out all other shell environment variables and set only those provided in the `env` argument to this function.

**template** If this setting is applied then the named templating engine will be used to render the downloaded file. Currently jinja, mako, and wempy are supported

**rstrip** Strip all whitespace off the end of output before it is returned.

**umask** The umask (in octal) to use when running the command.

**output_loglevel** Control the loglevel at which the output from the command is logged. Note that the command being run will still be logged (loglevel: DEBUG) regardless, unless quiet is used for this value.

**timeout** A timeout in seconds for the executed process to return.

**use_vt** Use VT utils (saltstack) to stream the command output more interactively to the console and the logs. This is experimental.

Note that env represents the environment variables for the command, and should be formatted as a dict, or a YAML string which resolves to a dict.

**CLI Example:**

```bash
salt '*' cmd.run_stderr "ls -l | awk '/foo/{print \$2}''
```

The template arg can be set to `jinja' or another supported template engine to render the command arguments before execution. For example:

```bash
salt '*' cmd.run_stderr template=jinja "ls -l /tmp/{{grains.id}} | awk '/foo/ \$2''
```
A string of standard input can be specified for the command to be run using the `stdin` parameter. This can be useful in cases where sensitive information must be read from standard input:

```
salt 'x' cmd.run_stderr "grep f" stdin='one\ntwo\nthree\nfour\nfive\n'
```

```
salt.modules.cmdmod.run_stdout(cmd, cwd=None, stdin=None, runas=None, shell='/bin/sh', python_shell=None, env=None, clean_env=False, template=None,.rstrip=True, umask=None, output_loglevel='debug', log_callback=None, timeout=None, reset_system_locale=True, ignore_retcode=False, saltenv='base', use_vt=False, **kwargs)
```

Execute a command, and only return the standard out

**cmd**  The command to run. ex: `ls -lart /home`

**cwd** The current working directory to execute the command in, defaults to /root

**stdin** A string of standard input can be specified for the command to be run using the `stdin` parameter. This can be useful in cases where sensitive information must be read from standard input:

**runas** User to run script as.

**shell** Shell to execute under. Defaults to the system default shell.

**python_shell** If False, let python handle the positional arguments. Set to True to use shell features, such as pipes or redirection

**env**

A list of environment variables to be set prior to execution. Example:

```
salt://scripts/foo.sh:
cmd.script:
- env:
  - BATCH: 'yes'
```

**Warning:** The above illustrates a common PyYAML pitfall, that `yes`, `no`, `on`, `off`, `true`, and `false` are all loaded as boolean `True` and `False` values, and must be enclosed in quotes to be used as strings. More info on this (and other) PyYAML idiosyncrasies can be found [here](#).

Variables as values are not evaluated. So $PATH in the following example is a literal `$PATH`:

```
salt://scripts/bar.sh:
cmd.script:
- env: "PATH=/some/path:$PATH"
```

One can still use the existing $PATH by using a bit of Jinja:

```
{% set current_path = salt['environ.get']('PATH', '/bin:/usr/bin') %}

mycommand:
  cmd.run:
  - name: ls -l /
  - env:
    - PATH: {{ [current_path, '/my/special/bin']|join(':') }}
```

**clean_env**: Attempt to clean out all other shell environment variables and set only those provided in the `env` argument to this function.
**template** If this setting is applied then the named templating engine will be used to render the downloaded file. Currently jinja, mako, and wempy are supported.

**rstrip** Strip all whitespace off the end of output before it is returned.

**umask** The umask (in octal) to use when running the command.

**output_loglevel** Control the loglevel at which the output from the command is logged. Note that the command being run will still be logged (loglevel: DEBUG) regardless, unless `quiet` is used for this value.

**timeout** A timeout in seconds for the executed process to return.

**use_vt** Use VT utils (saltstack) to stream the command output more interactively to the console and the logs. This is experimental.

Note that `env` represents the environment variables for the command, and should be formatted as a dict, or a YAML string which resolves to a dict.

CLI Example:

```
salt '*' cmd.run_stdout "ls -l | awk '/foo/{print \$2}''
```

The template arg can be set to `jinja` or another supported template engine to render the command arguments before execution. For example:

```
salt '*' cmd.run_stdout template=jinja "ls -l /tmp/{{grains.id}} | awk '/foo/\n\n{print \$2}''
```

A string of standard input can be specified for the command to be run using the `stdin` parameter. This can be useful in cases where sensitive information must be read from standard input:

```
salt '*' cmd.run_stdout "grep f stdin='one	
two
three
four
five\n'"
```

### salt.modules.cmdmod.script

```
salt.modules.cmdmod.script(source, args=None, cwd=None, stdin=None, runas=None, shell='/bin/sh';
  python_shell=None, env=None, template=None, umask=None, output_loglevel='debug';
  log_callback=None, quiet=False, timeout=None,
  reset_system_locale=True, __env__=None, saltenv='base'; use_vt=False,
  **kwargs)
```

Download a script from a remote location and execute the script locally. The script can be located on the salt master file server or on an HTTP/FTP server.

The script will be executed directly, so it can be written in any available programming language.

**source** The location of the script to download. If the file is located on the master in the directory named spam, and is called eggs, the source string is `salt://spam/eggs`

**args** String of command line args to pass to the script. Only used if no args are specified as part of the `name` argument. To pass a string containing spaces in YAML, you will need to doubly-quote it: `''arg1 'arg two' arg3''`

**cwd** The current working directory to execute the command in, defaults to `/root`

**stdin** A string of standard input can be specified for the command to be run using the `stdin` parameter. This can be useful in cases where sensitive information must be read from standard input.:  

**runas** User to run script as.

**shell** Shell to execute under. Defaults to the system default shell.

**python_shell** If False, let python handle the positional arguments. Set to True to use shell features, such as pipes or redirection

**env** A list of environment variables to be set prior to execution. Example:
Warning: The above illustrates a common PyYAML pitfall, that yes, no, on, off, true, and false are all loaded as boolean True and False values, and must be enclosed in quotes to be used as strings. More info on this (and other) PyYAML idiosyncrasies can be found here.

Variables as values are not evaluated. So $PATH in the following example is a literal `$PATH`:

```bash
salt://scripts/bar.sh:
cmd.script:
  - env: "PATH=/some/path:$PATH"
```

One can still use the existing $PATH by using a bit of Jinja:

```bash
{% set current_path = salt['environ.get']('PATH', '/bin:/usr/bin') %}
mycommand:
cmd.run:
  - name: ls -l /
  - env:
    - PATH: {{ [current_path, '/my/special/bin']|join(':') }}
```

template If this setting is applied then the named templating engine will be used to render the downloaded file. Currently jinja, mako, and wempy are supported

umask The umask (in octal) to use when running the command.

output_loglevel Control the loglevel at which the output from the command is logged. Note that the command being run will still be logged (loglevel: DEBUG) regardless, unless quiet is used for this value.

quiet The command will be executed quietly, meaning no log entries of the actual command or its return data. This is deprecated as of the 2014.1.0 release, and is being replaced with output_loglevel: quiet.

timeout If the command has not terminated after timeout seconds, send the subprocess sigterm, and if sigterm is ignored, follow up with sigkill

use_vt Use VT utils (saltstack) to stream the command output more interactively to the console and the logs. This is experimental.

CLI Example:

```
salt '*' cmd.script salt://scripts/runme.sh
salt '*' cmd.script salt://scripts/runme.sh 'arg1 arg2 "arg 3"'
salt '*' cmd.script salt://scripts/windows_task.ps1 args=' -Input c:\tmp\infile.\txt' shell='powershell'

salt '*' cmd.script salt://scripts/runme.sh stdin='one
two
three
four
five
'
```

salt.modules.cmdmod.script_retcode(source, args=None, cwd=None, stdin=None, runas=None, shell='bin/sh', python_shell=None, env=None, template='jinja', umask=None, timeout=None, reset_system_locale=True, __env__=None, saltenv='base', output_loglevel='debug', log_callback=None, use_vt=False, **kwargs)
Download a script from a remote location and execute the script locally. The script can be located on the salt master file server or on an HTTP/FTP server.

The script will be executed directly, so it can be written in any available programming language.

The script can also be formatted as a template, the default is jinja.

Only evaluate the script return code and do not block for terminal output

**source**  The location of the script to download. If the file is located on the master in the directory named spam, and is called eggs, the source string is salt://spam/eggs

**args**  String of command line args to pass to the script. Only used if no args are specified as part of the `name` argument. To pass a string containing spaces in YAML, you will need to doubly-quote it: 
```
arg1 `arg two` arg3
```

**cwd**  The current working directory to execute the command in, defaults to /root

**stdin**  A string of standard input can be specified for the command to be run using the `stdin` parameter. This can be useful in cases where sensitive information must be read from standard input:

**runas**  User to run script as.

**shell**  Shell to execute under. Defaults to the system default shell.

**python_shell**  If False, let python handle the positional arguments. Set to True to use shell features, such as pipes or redirection

**env**  A list of environment variables to be set prior to execution. Example:

```yaml
salt://scripts/foo.sh:
  cmd.script:
    - env:
      - BATCH: 'yes'
```

**Warning:**  The above illustrates a common PyYAML pitfall, that `yes`, `no`, `on`, `off`, `true`, and `false` are all loaded as boolean `True` and `False` values, and must be enclosed in quotes to be used as strings. More info on this (and other) PyYAML idiosyncrasies can be found [here](#).

Variables as values are not evaluated. So `$PATH` in the following example is a literal `''PATH'`:

```yaml
salt://scripts/bar.sh:
  cmd.script:
    - env: "PATH=/some/path:$PATH"
```

One can still use the existing $PATH by using a bit of Jinja:

```yaml
{% set current_path = salt['environ.get']('PATH', '/bin:/usr/bin') %}

mycommand:
  cmd.run:
    - name: ls -l /
    - env:
      - PATH: {{ [current_path, '/my/special/bin']|join(':') }}
```

**template**  If this setting is applied then the named templating engine will be used to render the downloaded file. Currently jinja, mako, and wempy are supported

**umask**  The umask (in octal) to use when running the command.
**output_loglevel**  Control the loglevel at which the output from the command is logged. Note that the command being run will still be logged (loglevel: DEBUG) regardless, unless **quiet** is used for this value.

**quiet** The command will be executed quietly, meaning no log entries of the actual command or its return data.

This is deprecated as of the 2014.1.0 release, and is being replaced with **output_loglevel**: quiet.

**timeout**  If the command has not terminated after timeout seconds, send the subprocess sigterm, and if sigterm is ignored, follow up with sigkill.

**use_vt**  Use VT utils (saltstack) to stream the command output more interactively to the console and the logs.

This is experimental.

CLI Example:

```bash
salt '*' cmd.script_retcode salt://scripts/runme.sh
salt '*' cmd.script_retcode salt://scripts/runme.sh 'arg1 arg2 "arg 3"
salt '*' cmd.script_retcode salt://scripts/windows_task.ps1 args=' -$Input c:
  \tmp\infile.txt' shell='powershell'
```

A string of standard input can be specified for the command to be run using the **stdin** parameter. This can be useful in cases where sensitive information must be read from standard input:

```bash
salt '*' cmd.script_retcode salt://scripts/runme.sh stdin=
  'one\ntwo\nthree\nfour\nfive\n'
```

salt.modules.cmdmod.shell(cmd, cwd=None, stdin=None, runas=None, shell='/bin/sh', env=None, clean_env=False, template=None, rstrip=True, umask=None, output_loglevel='debug', log_callback=None, quiet=False, timeout=None, reset_system_locale=True, ignore_retcode=False, saltenv='base', use_vt=False, **kwargs)

Execute the passed command and return the output as a string.

New in version 2015.5.0.

**cmd**  The command to run. ex: `ls -lart /home`

**cwd**  The current working directory to execute the command in, defaults to /root

**stdin**  A string of standard input can be specified for the command to be run using the **stdin** parameter. This can be useful in cases where sensitive information must be read from standard input:

**runas**  User to run script as.

**shell**  Shell to execute under. Defaults to the system default shell.

**env**  A list of environment variables to be set prior to execution. Example:

```bash
salt://scripts/foo.sh:
  cmd.script:
    - env:
      - BATCH: 'yes'
```

**Warning:** The above illustrates a common PyYAML pitfall, that yes, no, on, off, true, and false are all loaded as boolean True and False values, and must be enclosed in quotes to be used as strings. More info on this (and other) PyYAML idiosyncrasies can be found [here](#).

Variables as values are not evaluated. So $PATH in the following example is a literal `$PATH`:
salt://scripts/bar.sh:
  cmd.script:
    - env: "PATH=/some/path:$PATH"

One can still use the existing $PATH by using a bit of Jinja:

```yaml
{% set current_path = salt['environ.get']('PATH', '/bin:/usr/bin') %}
mycommand:
  cmd.run:
    - name: ls -l /
    - env:
      - PATH: {{ [current_path, '/my/special/bin']|join(':') }}
```

clean_env: Attempt to clean out all other shell environment variables and set only those provided in the `env` argument to this function.

template If this setting is applied then the named templating engine will be used to render the downloaded file. Currently jinja, mako, and wempy are supported

rstrip Strip all whitespace off the end of output before it is returned.

umask The umask (in octal) to use when running the command.

output_loglevel Control the loglevel at which the output from the command is logged. Note that the command being run will still be logged (loglevel: DEBUG) regardless, unless quiet is used for this value.

timeout A timeout in seconds for the executed process to return.

use_vt Use VT utils (saltstack) to stream the command output more interactively to the console and the logs. This is experimental.

**Warning:** This passes the cmd argument directly to the shell without any further processing! Be absolutely sure that you have properly sanitized the command passed to this function and do not use untrusted inputs.

Note that env represents the environment variables for the command, and should be formatted as a dict, or a YAML string which resolves to a dict.

CLI Example:

```bash
salt '*' cmd.shell "ls -l | awk '/foo/{print \$2}"
```

The template arg can be set to `jinja` or another supported template engine to render the command arguments before execution. For example:

```bash
salt '*' cmd.shell template=jinja "ls -l /tmp/{{grains.id}} | awk '/foo/{print \$2}"
```

Specify an alternate shell with the shell parameter:

```bash
salt '*' cmd.shell "Get-ChildItem C:\" shell='powershell'
```

A string of standard input can be specified for the command to be run using the stdin parameter. This can be useful in cases where sensitive information must be read from standard input:

```bash
salt '*' cmd.shell "grep f" stdin='one\ntwo\nthree\nfour\nfive\n'
```
If an equal sign (=) appears in an argument to a Salt command it is interpreted as a keyword argument in the format key=val. That processing can be bypassed in order to pass an equal sign through to the remote shell command by manually specifying the kwarg:

```
salt '*' cmd.shell cmd='sed -e s/=/:/g'
```

**salt.modules.cmdmod.shells()**

Lists the valid shells on this system via the /etc/shells file

New in version 2015.5.0.

CLI Example:

```
salt '*' cmd.shells
```

**salt.modules.cmdmod/tty(device, echo=None)**

Echo a string to a specific tty

CLI Example:

```
salt '*' cmd.tty tty0 'This is a test'
salt '*' cmd.tty pts3 'This is a test'
```

**salt.modules.cmdmod.which(cmd)**

Returns the path of an executable available on the minion, None otherwise

CLI Example:

```
salt '*' cmd.which cat
```

**salt.modules.cmdmod.which_bin(cmds)**

Returns the first command found in a list of commands

CLI Example:

```
salt '*' cmd.which_bin '[pip2, pip, pip-python]'
```

### 32.17.44 salt.modules.composer

Use composer to install PHP dependencies for a directory

**salt.modules.composer.did_composer_install(dir)**

Test to see if the vendor directory exists in this directory

- dir Directory location of the composer.json file

CLI Example:

```
salt '*' composer.did_composer_install /var/www/application
```

**salt.modules.composer.install(dir, composer=None, php=None, runas=None, prefer_source=None, prefer_dist=None, no_scripts=None, no_plugins=None, optimize=None, no_dev=None, quiet=False, composer_home='/root')**

Install composer dependencies for a directory.

If composer has not been installed globally making it available in the system PATH & making it executable, the composer and php parameters will need to be set to the location of the executables.

- dir Directory location of the composer.json file.
**composer** Location of the composer.phar file. If not set composer will just execute `"composer"` as if it is installed globally. (i.e. /path/to/composer.phar)

**php** Location of the php executable to use with composer. (i.e. /usr/bin/php)

**runas** Which system user to run composer as.

**prefer_source** --prefer-source option of composer.

**prefer_dist** --prefer-dist option of composer.

**no_scripts** --no-scripts option of composer.

**no_plugins** --no-plugins option of composer.

**optimize** --optimize-autoloader option of composer. Recommended for production.

**no_dev** --no-dev option for composer. Recommended for production.

**quiet** --quiet option for composer. Whether or not to return output from composer.

**composer_home** $COMPOSER_HOME environment variable

**CLI Example:**

```bash
salt '*' composer.install /var/www/application
salt '*' composer.install /var/www/application no_dev=True optimize=True
```

**salt.modules.composer.selfupdate**

```py
composer=none, php=none, runas=none, quiet=False, composer_home='/root')
```

Update composer itself.

If composer has not been installed globally making it available in the system PATH & making it executable, the composer and php parameters will need to be set to the location of the executables.

**composer** Location of the composer.phar file. If not set composer will just execute `"composer"` as if it is installed globally. (i.e. /path/to/composer.phar)

**php** Location of the php executable to use with composer. (i.e. /usr/bin/php)

**runas** Which system user to run composer as.

**quiet** --quiet option for composer. Whether or not to return output from composer.

**composer_home** $COMPOSER_HOME environment variable

**CLI Example:**

```bash
salt '*' composer.selfupdate
```

**salt.modules.composer.update**

```py
(dir, composer=none, php=none, runas=none, prefer_source=none, prefer_dist=none, no_scripts=none, no_plugins=none, optimize=none, no_dev=none, quiet=False, composer_home='/root')
```

Update composer dependencies for a directory.

If composer install has not yet been run, this runs composer install instead.

If composer has not been installed globally making it available in the system PATH & making it executable, the composer and php parameters will need to be set to the location of the executables.

**dir** Directory location of the composer.json file.

**composer** Location of the composer.phar file. If not set composer will just execute `"composer"` as if it is installed globally. (i.e. /path/to/composer.phar)
**php** Location of the php executable to use with composer. (i.e. /usr/bin/php)

**runas** Which system user to run composer as.

**prefer_source** --prefer-source option of composer.

**prefer_dist** --prefer-dist option of composer.

**no_scripts** --no-scripts option of composer.

**no_plugins** --no-plugins option of composer.

**optimize** --optimize-autoloader option of composer. Recommended for production.

**no_dev** --no-dev option for composer. Recommended for production.

**quiet** --quiet option for composer. Whether or not to return output from composer.

**composer_home** $COMPOSER_HOME environment variable

CLI Example:

```
salt '*' composer.update /var/www/application

salt '*' composer.update /var/www/application no_dev=True optimize=True
```

### 32.17.45 salt.modules.config

Return config information

**salt.modules.config.backup_mode** *(backup=’‘)*

Return the backup mode

CLI Example:

```
salt '*' config.backup_mode
```

**salt.modules.config.dot_vals** *(value)*

Pass in a configuration value that should be preceded by the module name and a dot, this will return a list of all read key/value pairs

CLI Example:

```
salt '*' config.dot_vals host
```

**salt.modules.config.gather_bootstrap_script** *(bootstrap=’None’)*

Download the salt-bootstrap script, and return its location

**bootstrap** URL of alternate bootstrap script

CLI Example:

```
salt '*' config.gather_bootstrap_script
```

**salt.modules.config.get** *(key, default=’’, delimiter=’‘, merge=’None’)*

Attempt to retrieve the named value from the minion config file, pillar, grains or the master config. If the named value is not available, return the value specified by **default**. If not specified, the default is an empty string.

Values can also be retrieved from nested dictionaries. Assume the below data structure:
To retrieve the value associated with the `apache` key, in the sub-dictionary corresponding to the `pkg` key, the following command can be used:

```
salt myminion config.get pkg:apache
```

The `:` (colon) is used to represent a nested dictionary level.

Changed in version 2015.5.0: The `delimiter` argument was added, to allow delimiters other than `:` to be used.

This function traverses these data stores in this order, returning the first match found:

- Minion configuration
- Minion's grains
- Minion's pillar data
- Master configuration (requires `pillar_opts` to be set to `True` in Minion config file in order to work)

This means that if there is a value that is going to be the same for the majority of minions, it can be configured in the Master config file, and then overridden using the grains, pillar, or Minion config file.

Adding config options to the Master or Minion configuration file is easy:

```yaml
my-config-option: value
cafe-menu:
  - egg and bacon
  - egg sausage and bacon
  - egg and spam
  - egg bacon and spam
  - egg bacon sausage and spam
  - spam bacon sausage and spam
  - spam egg spam spam bacon and spam
  - spam sausage spam spam bacon spam tomato and spam
```

**Note:** Minion configuration options built into Salt (like those defined here) will always be defined in the Minion configuration and thus cannot be overridden by grains or pillar data. However, additional (user-defined) configuration options (as in the above example) will not be in the Minion configuration by default and thus can be overridden using grains/pillar data by leaving the option out of the minion config file.

**Arguments**

- `delimiter` New in version 2015.5.0.
  
  Override the delimiter used to separate nested levels of a data structure.

- `merge` New in version 2015.5.0.
  
  If passed, this parameter will change the behavior of the function so that, instead of traversing each data store above in order and returning the first match, the data stores are first merged together and then searched. The pillar data is merged into the master config data, then the grains are merged, followed by the Minion config data. The resulting data structure is then searched for a match. This allows for configurations to be more flexible.

**Note:** The merging described above does not mean that grain data will end up in the Minion's pillar data, or pillar data will end up in the master config data, etc. The data is just combined for the purposes...
of searching an amalgam of the different data stores.

The supported merge strategies are as follows:

- **recurse** - If a key exists in both dictionaries, and the new value is not a dictionary, it is replaced. Otherwise, the sub-dictionaries are merged together into a single dictionary, recursively on down, following the same criteria. For example:

  ```python
  >>> dict1 = {'foo': {'bar': 1, 'qux': True},
             'hosts': ['a', 'b', 'c'],
             'only_x': None}
  >>> dict2 = {'foo': {'baz': 2, 'qux': False},
             'hosts': ['d', 'e', 'f'],
             'only_y': None}
  >>> merged = {'foo': {'bar': 1, 'baz': 2, 'qux': False},
              'hosts': ['d', 'e', 'f'],
              'only_dict1': None,
              'only_dict2': None}
  ```

- **overwrite** - If a key exists in the top level of both dictionaries, the new value completely overwrites the old. For example:

  ```python
  >>> dict1 = {'foo': {'bar': 1, 'qux': True},
             'hosts': ['a', 'b', 'c'],
             'only_x': None}
  >>> dict2 = {'foo': {'baz': 2, 'qux': False},
             'hosts': ['d', 'e', 'f'],
             'only_y': None}
  >>> merged = {'foo': {'baz': 2, 'qux': False},
              'hosts': ['d', 'e', 'f'],
              'only_dict1': None,
              'only_dict2': None}
  ```

CLI Example:

```
salt '*' config.get pkg:apache
salt '*' config.get lxc.container_profile:centos merge=recurse
```

salt.modules.config.manage_mode(mode)

Return a mode value, normalized to a string

CLI Example:

```
salt '*' config.manage_mode
```

salt.modules.config.merge(value, default='\', omit_opts=False, omit_master=False, omit_pillar=False)

Retrieves an option based on key, merging all matches.

Same as option() except that it merges all matches, rather than taking the first match.

CLI Example:

```
salt '*' config.merge schedule
```
salt.modules.config.option(value, default='\'', omit_opts=False, omit_master=False, omit_pillar=False)

Pass in a generic option and receive the value that will be assigned

CLI Example:

```bash
salt '*' config.option redis.host
```

salt.modules.config.valid_fileproto(uri)

Returns a boolean value based on whether or not the URI passed has a valid remote file protocol designation

CLI Example:

```bash
salt '*' config.valid_fileproto salt://path/to/file
```

32.17.46 salt.modules.consul

Interact with Consul

https://www.consul.io

salt.modules.consul.acl_clone(consul_url=None, **kwargs)

Information about an ACL token.

Parameters

- **consul_url** -- The Consul server URL.
- **id** -- Unique identifier for the ACL to update.

Returns 

Boolean, message of success or failure, and new ID of cloned ACL.

CLI Example:

```bash
salt '*' consul.acl_info id='c1c4d223-91cb-3d1f-1ee8-f2af9e7b6716'
```

salt.modules.consul.acl_create(consul_url=None, **kwargs)

Create a new ACL token.

Parameters

- **consul_url** -- The Consul server URL.
- **name** -- Meaningful indicator of the ACL's purpose.
- **type** -- Type is either client or management. A management token is comparable to a root user and has the ability to perform any action including creating, modifying, and deleting ACLs.
- **rules** -- The Consul server URL.

Returns 

Boolean & message of success or failure.

CLI Example:

```bash
salt '*' consul.acl_create
```

salt.modules.consul.acl_delete(consul_url=None, **kwargs)

Delete an ACL token.

Parameters

- **consul_url** -- The Consul server URL.
Salt modules

- **id** -- Unique identifier for the ACL to update.

**Returns** Boolean & message of success or failure.

CLI Example:

```python
salt '...' consul.acl_delete id='c1c4d223-91cb-3d1f-1ee8-f2af9e7b6716'
```

**salt.modules.consul.acl_info** *(consul_url=None, **kwargs)*

Information about an ACL token.

- **Parameters**
  - **consul_url** -- The Consul server URL.
  - **id** -- Unique identifier for the ACL to update.

- **Returns** Information about the ACL requested.

CLI Example:

```python
salt '...' consul.acl_info id='c1c4d223-91cb-3d1f-1ee8-f2af9e7b6716'
```

**salt.modules.consul.acl_list** *(consul_url=None, **kwargs)*

List the ACL tokens.

- **Parameters**
  - **consul_url** -- The Consul server URL.

- **Returns** List of ACLs

CLI Example:

```python
salt '...' consul.acl_list
```

**salt.modules.consul.acl_update** *(consul_url=None, **kwargs)*

Update an ACL token.

- **Parameters**
  - **consul_url** -- The Consul server URL.
  - **name** -- Meaningful indicator of the ACL’s purpose.
  - **id** -- Unique identifier for the ACL to update.
  - **type** -- Type is either client or management. A management token is comparable to a root user and has the ability to perform any action including creating, modifying, and deleting ACLs.
  - **rules** -- The Consul server URL.

- **Returns** Boolean & message of success or failure.

CLI Example:

```python
salt '...' consul.acl_update
```

**salt.modules.consul.agent_check_deregister** *(consul_url=None, checkid=None)*

The agent will take care of deregistering the check from the Catalog.

- **Parameters**
  - **consul_url** -- The Consul server URL.
  - **checkid** -- The ID of the check to deregister from Consul.
**Returns** Boolean and message indicating success or failure.

CLI Example:

```
salt '*' consul.agent_check_deregister checkid='Memory Utilization'
```

salt.modules.consul.agent_check_fail(*args, **kwargs)

This endpoint is used with a check that is of the TTL type. When this is called, the status of the check is set to critical and the TTL clock is reset.

**Parameters**

- `consul_url` -- The Consul server URL.
- `checkid` -- The ID of the check to deregister from Consul.
- `note` -- A human-readable message with the status of the check.

**Returns** Boolean and message indicating success or failure.

CLI Example:

```
salt '*' consul.agent_check_fail checkid='redis_check1' note='Forcing check into critical state.'
```

salt.modules.consul.agent_check_pass(*args, **kwargs)

This endpoint is used with a check that is of the TTL type. When this is called, the status of the check is set to passing and the TTL clock is reset.

**Parameters**

- `consul_url` -- The Consul server URL.
- `checkid` -- The ID of the check to mark as passing.
- `note` -- A human-readable message with the status of the check.

**Returns** Boolean and message indicating success or failure.

CLI Example:

```
salt '*' consul.agent_check_pass checkid='redis_check1' note='Forcing check into passing state.'
```

salt.modules.consul.agent_check_register(*args, **kwargs)

The register endpoint is used to add a new check to the local agent.

**Parameters**

- `consul_url` -- The Consul server URL.
- `name` -- The description of what the check is for.
- `id` -- The unique name to use for the check, if not provided `name` is used.
- `notes` -- Human readable description of the check.
- `script` -- If script is provided, the check type is a script, and Consul will evaluate that script based on the interval parameter.
- `http` -- Check will perform an HTTP GET request against the value of HTTP (expected to be a URL) based on the interval parameter.
- `ttl` -- If a TTL type is used, then the TTL update endpoint must be used periodically to update the state of the check.
• interval -- Interval at which the check should run.

Returns Boolean and message indicating success or failure.

CLI Example:
```
salt '*' consul.agent_check_register name='Memory Utilization' script='/usr/local/bin/check_mem.py' interval='15s'
```

salt.modules.consul.agent_check_warn(consul_url=None, checkid=None, **kwargs)
This endpoint is used with a check that is of the TTL type. When this is called, the status of the check is set to warning and the TTL clock is reset.

Parameters
• consul_url -- The Consul server URL.
• checkid -- The ID of the check to deregister from Consul.
• note -- A human-readable message with the status of the check.

Returns Boolean and message indicating success or failure.

CLI Example:
```
salt '*' consul.agent_check_warn checkid='redis_check1' note='Forcing check into warning state.'
```

salt.modules.consul.agent_checks(consul_url=None)
Returns the checks the local agent is managing

Parameters consul_url -- The Consul server URL.

Returns Returns the checks the local agent is managing

CLI Example:
```
salt '*' consul.agent_checks
```

salt.modules.consul.agent_join(consul_url=None, address=None, **kwargs)
Triggers the local agent to join a node

Parameters
• consul_url -- The Consul server URL.
• address -- The address for the agent to connect to.
• wan -- Causes the agent to attempt to join using the WAN pool.

Returns Boolean and message indicating success or failure.

CLI Example:
```
salt '*' consul.agent_join address='192.168.1.1'
```

salt.modules.consul.agent_leave(consul_url=None, node=None)
Used to instruct the agent to force a node into the left state.

Parameters
• consul_url -- The Consul server URL.
• node -- The node the agent will force into left state

Returns Boolean and message indicating success or failure.
CLI Example:
```
salt '*' consul.agent_leave node='web1.example.com'
```

salt.modules.consul.agent_maintenance(consul_url=None, **kwargs)
Manages node maintenance mode

Parameters
- **consul_url** -- The Consul server URL.
- **enable** -- The enable flag is required. Acceptable values are either true (to enter maintenance mode) or false (to resume normal operation).
- **reason** -- If provided, its value should be a text string explaining the reason for placing the node into maintenance mode.

Returns Boolean and message indicating success or failure.

CLI Example:
```
salt '*' consul.agent_maintenance enable='False' reason='Upgrade in progress'
```

salt.modules.consul.agent_members(consul_url=None, **kwargs)
Returns the members as seen by the local serf agent

Parameters
- **consul_url** -- The Consul server URL.

Returns Returns the members as seen by the local serf agent

CLI Example:
```
salt '*' consul.agent_members
```

salt.modules.consul.agent_self(consul_url=None)
Returns the local node configuration

Parameters
- **consul_url** -- The Consul server URL.

Returns Returns the local node configuration

CLI Example:
```
salt '*' consul.agent_self
```

salt.modules.consul.agent_service_deregister(consul_url=None, serviceid=None)
Used to remove a service.

Parameters
- **consul_url** -- The Consul server URL.
- **serviceid** -- A serviceid describing the service.

Returns Boolean and message indicating success or failure.

CLI Example:
```
salt '*' consul.agent_service_deregister serviceid='redis'
```

salt.modules.consul.agent_service_maintenance(consul_url=None, serviceid=None, **kwargs)
Used to place a service into maintenance mode.
Parameters

- **consul_url** -- The Consul server URL.
- **serviceid** -- A name of the service.
- **enable** -- Whether the service should be enabled or disabled.
- **reason** -- A human readable message of why the service was enabled or disabled.

Returns Boolean and message indicating success or failure.

CLI Example:

```bash
salt '*' consul.agent_service_deregister serviceid='redis'
    enable='True' reason='Down for upgrade'
```

salt.modules.consul.agent_service_register(consul_url=None, **kwargs)
The used to add a new service, with an optional health check, to the local agent.

Parameters

- **consul_url** -- The Consul server URL.
- **name** -- A name describing the service.
- **address** -- The address used by the service, defaults to the address of the agent.
- **port** -- The port used by the service.
- **id** -- Unique ID to identify the service, if not provided the value of the name parameter is used.
- **tags** -- Identifying tags for service, string or list.
- **script** -- If script is provided, the check type is a script, and Consul will evaluate that script based on the interval parameter.
- **http** -- Check will perform an HTTP GET request against the value of HTTP (expected to be a URL) based on the interval parameter.
- **check_ttl** -- If a TTL type is used, then the TTL update endpoint must be used periodically to update the state of the check.
- **check_interval** -- Interval at which the check should run.

Returns Boolean and message indicating success or failure.

CLI Example:

```bash
salt '*' consul.agent_service_register name='redis'
    tags='["master", "v1"]' address='127.0.0.1' port='8080'
    check_script="/usr/local/bin/check_redis.py" interval='10s'
```

salt.modules.consul.agent_services(consul_url=None)

Returns the services the local agent is managing

Parameters **consul_url** -- The Consul server URL.

Returns Returns the services the local agent is managing

CLI Example:

```bash
salt '*' consul.agent_services
```
salt.modules.consul.catalog_datacenters(consul_url=None)
Return list of available datacenters from catalog.

Parameters
 consul_url -- The Consul server URL.

Returns The list of available datacenters.

CLI Example:
salt '*' consul.catalog_datacenters

salt.modules.consul.catalog_deregister(consul_url=None, **kwargs)
Deregisters a node, service, or check

Parameters
  • consul_url -- The Consul server URL.
  • node -- The node to deregister.
  • datacenter -- By default, the datacenter of the agent is queried; however, the dc can be
    provided using the `dc` parameter.
  • checkid -- The ID of the health check to deregister.
  • serviceid -- The ID of the service to deregister.

Returns Boolean & message of success or failure.

CLI Example:
salt '*' consul.catalog_register node='node1' serviceid='redis_server1' checkid='redis_check1'

salt.modules.consul.catalog_node(consul_url=None, node=None, **kwargs)
Information about the registered node.

Parameters
  • consul_url -- The Consul server URL.
  • node -- The node to request information about.
  • dc -- By default, the datacenter of the agent is queried; however, the dc can be
    provided using the `dc` parameter.

Returns Information about the requested node.

CLI Example:
salt '*' consul.catalog_service service='redis'

salt.modules.consul.catalog_nodes(consul_url=None, **kwargs)
Return list of available nodes from catalog.

Parameters
  • consul_url -- The Consul server URL.
  • dc -- By default, the datacenter of the agent is queried; however, the dc can be provided
    using the `dc` parameter.

Returns The list of available nodes.

CLI Example:
```
salt '...' consul.catalog_nodes
```

```python
catalog_register(consul_url=None, **kwargs)
```
Registers a new node, service, or check

**Parameters**

- `consul_url` -- The Consul server URL.
- `dc` -- By default, the datacenter of the agent is queried; however, the dc can be provided using the `dc` parameter.
- `node` -- The node to register.
- `address` -- The address of the node.
- `service` -- The service that will be registered.
- `service_address` -- The address that the service listens on.
- `service_port` -- The port for the service.
- `service_id` -- A unique identifier for the service, if this is not provided, a `name` will be used.
- `service_tags` -- Any tags associated with the service.
- `check` -- The name of the health check to register.
- `check_status` -- The initial status of the check, must be one of unknown, passing, warning, or critical.
- `check_service` -- The service that the check is performed against.
- `check_id` -- Unique identifier for the service.
- `check_notes` -- An opaque field that is meant to hold human-readable text.

**Returns**

Boolean & message of success or failure.

CLI Example:
```
salt '...' consul.catalog_register node='node1' address='192.168.1.1' service='redis' service_address='127.0.0.1' service_port='8080' service_id='redis_server1'
```

```
catalog_service(consul_url=None, service=None, **kwargs)
```
Information about the registered service.

**Parameters**

- `consul_url` -- The Consul server URL.
- `dc` -- By default, the datacenter of the agent is queried; however, the dc can be provided using the `dc` parameter.
- `tag` -- Filter returned services with tag parameter.

**Returns**

Information about the requested service.

CLI Example:
```
salt '...' consul.catalog_service service='redis'
```

```
catalog_services(consul_url=None, **kwargs)
```
Return list of available services rom catalog.
Parameters

• **consul_url** -- The Consul server URL.

• **dc** -- By default, the datacenter of the agent is queried; however, the dc can be provided using the `"dc"` parameter.

Returns The list of available services.

CLI Example:

```
salt '*' consul.catalog_services
```

salt.modules.consul.delete(*consul_url=None, key=None, **kwargs*)
Delete values from Consul

Parameters

• **consul_url** -- The Consul server URL.

• **key** -- The key to use as the starting point for the list.

• **recurse** -- Delete values recursively beginning at the value of key.

• **cas** -- This flag is used to turn the DELETE into a Check-And-Set operation.

Returns Boolean & message of success or failure.

CLI Example:

```
salt '*' consul.delete key='web'
salt '*' consul.delete key='web' recurse='True'
```

salt.modules.consul.event_fire(*consul_url=None, name=None, **kwargs*)
List the ACL tokens.

Parameters

• **consul_url** -- The Consul server URL.

• **name** -- The name of the event to fire.

• **dc** -- By default, the datacenter of the agent is queried; however, the dc can be provided using the `"dc"` parameter.

• **node** -- Filter by node name.

• **service** -- Filter by service name.

• **tag** -- Filter by tag name.

Returns List of ACLs

CLI Example:

```
salt '*' consul.event_fire name='deploy'
```

salt.modules.consul.event_list(*consul_url=None, **kwargs*)
List the recent events.

Parameters

• **consul_url** -- The Consul server URL.

• **name** -- The name of the event to fire.
Returns  List of ACLs

CLI Example:

```bash
salt '*' consul.event_list
```

```python
salt.modules.consul.get(consul_url=None, key=None, recurse=False, decode=False, raw=False)
```

Get key from Consul

Parameters

- **consul_url** -- The Consul server URL.
- **key** -- The key to use as the starting point for the list.
- **recurse** -- Return values recursively beginning at the value of key.
- **decode** -- By default values are stored as Base64 encoded values, decode will return the whole key with the value decoded.
- **raw** -- Simply return the decoded value of the key.

Returns  The keys in Consul.

CLI Example:

```bash
salt '*' consul.get key='web/key1'
salt '*' consul.list key='web' recurse='True
salt '*' consul.list key='web' recurse='True' decode='True'
```

By default values stored in Consul are base64 encoded, passing the decode option will show them as the decoded values.

```bash
salt '*' consul.list key='web' recurse='True' decode='True' raw='True'
```

By default Consult will return other information about the key, the raw option will return only the raw value.

```python
salt.modules.consul.health_checks(consul_url=None, service=None, **kwargs)
```

Health information about the registered service.

Parameters

- **consul_url** -- The Consul server URL.
- **service** -- The service to request health information about.
- **dc** -- By default, the datacenter of the agent is queried; however, the dc can be provided using the "dc" parameter.

Returns  Health information about the requested node.

CLI Example:

```bash
salt '*' consul.health_checks service='redis1'
```

```python
salt.modules.consul.health_node(consul_url=None, node=None, **kwargs)
```

Health information about the registered node.

Parameters

- **consul_url** -- The Consul server URL.
- **node** -- The node to request health information about.
• **dc** -- By default, the datacenter of the agent is queried; however, the dc can be provided using the "dc" parameter.

**Returns** Health information about the requested node.

CLI Example:

```bash
salt '*' consul.health_node node='node1'
```

`salt.modules.consul.health_service` (*consul_url=None, service=None, **kwargs*)

Health information about the registered service.

**Parameters**

- **consul_url** -- The Consul server URL.
- **service** -- The service to request health information about.
- **dc** -- By default, the datacenter of the agent is queried; however, the dc can be provided using the "dc" parameter.
- **tag** -- Filter returned services with tag parameter.
- **passing** -- Filter results to only nodes with all checks in the passing state.

**Returns** Health information about the requested node.

CLI Example:

```bash
salt '*' consul.health_service service='redis1'
salt '*' consul.health_service service='redis1' passing='True'
```

`salt.modules.consul.health_state` (*consul_url=None, state=None, **kwargs*)

Returns the checks in the state provided on the path.

**Parameters**

- **consul_url** -- The Consul server URL.
- **state** -- The state to show checks for. The supported states are any, unknown, passing, warning, or critical. The any state is a wildcard that can be used to return all checks.
- **dc** -- By default, the datacenter of the agent is queried; however, the dc can be provided using the "dc" parameter.

**Returns** The checks in the provided state.

CLI Example:

```bash
salt '*' consul.health_state state='redis1'
salt '*' consul.health_state service='redis1' passing='True'
```

`salt.modules.consul.list` (*consul_url=None, key=None, **kwargs*)

List keys in Consul

**Parameters**

- **consul_url** -- The Consul server URL.
- **key** -- The key to use as the starting point for the list.

**Returns** The list of keys.
CLI Example:

```bash
salt '*' consul.list
salt '*' consul.list key='web'
```

salt.modules.consul.put

Put values into Consul.

Parameters

- **consul_url** -- The Consul server URL.
- **key** -- The key to use as the starting point for the list.
- **value** -- The value to set the key to.
- **flags** -- This can be used to specify an unsigned value between 0 and 2^64-1. Clients can choose to use this however makes sense for their application.
- **cas** -- This flag is used to turn the PUT into a Check-And-Set operation.
- **acquire** -- This flag is used to turn the PUT into a lock acquisition operation.
- **release** -- This flag is used to turn the PUT into a lock release operation.

Returns

Boolean & message of success or failure.

CLI Example:

```bash
salt '*' consul.put key='web/key1' value='Hello there'
salt '*' consul.put key='web/key1' value='Hello there'
  acquire='d5d371f4-c380-5280-12fd-8810be175592'
salt '*' consul.put key='web/key1' value='Hello there'
  release='d5d371f4-c380-5280-12fd-8810be175592'
```

salt.modules.consul.session_create

Used to create a session.

Parameters

- **consul_url** -- The Consul server URL.
- **lockdelay** -- Duration string using a ``s`` suffix for seconds. The default is 15s.
- **node** -- Must refer to a node that is already registered, if specified. By default, the agent's own node name is used.
- **name** -- A human-readable name for the session
- **checks** -- A list of associated health checks. It is highly recommended that, if you override this list, you include the default ``serfHealth``.
- **behavior** -- Can be set to either release or delete. This controls the behavior when a session is invalidated. By default, this is release, causing any locks that are held to be released. Changing this to delete causes any locks that are held to be deleted. delete is useful for creating ephemeral key/value entries.
- **ttl** -- Session is invalidated if it is not renewed before the TTL expires

Returns

Boolean and message indicating success or failure.

CLI Example:
```
salt '*' consul.session_create node='node1' name='my-session'
    behavior='delete' ttl='3600s'
```

```python
salt.modules.consul.session_destroy(consul_url=None, session=None, **kwargs)
```
Destroy session

**Parameters**

- **consul_url** -- The Consul server URL.
- **session** -- The ID of the session to destroy.
- **dc** -- By default, the datacenter of the agent is queried; however, the dc can be provided using the ``dc`` parameter.

**Returns**  
Boolean & message of success or failure.

**CLI Example:**

```
salt '*' consul.session_destroy session='c1c4d223-91cb-3d1f-1ee8-f2af9e7b6716'
```

```python
salt.modules.consul.session_info(consul_url=None, session=None, **kwargs)
```
Information about a session

**Parameters**

- **consul_url** -- The Consul server URL.
- **session** -- The ID of the session to return information about.
- **dc** -- By default, the datacenter of the agent is queried; however, the dc can be provided using the ``dc`` parameter.

**Returns**  
Boolean & message of success or failure.

**CLI Example:**

```
salt '*' consul.session_info session='c1c4d223-91cb-3d1f-1ee8-f2af9e7b6716'
```

```python
salt.modules.consul.session_list(consul_url=None, return_list=False, **kwargs)
```
Used to list sessions.

**Parameters**

- **consul_url** -- The Consul server URL.
- **dc** -- By default, the datacenter of the agent is queried; however, the dc can be provided using the ``dc`` parameter.
- **return_list** -- By default, all information about the sessions is returned, using the return_list parameter will return a list of session IDs.

**Returns**  
A list of all available sessions.

**CLI Example:**

```
salt '*' consul.session_list
```

```python
salt.modules.consul.status_leader(consul_url=None)
```
Returns the current Raft leader

**Parameters**

- **consul_url** -- The Consul server URL.

**Returns**  
The address of the Raft leader.
Salt Documentation, Release 2015.8.12

CLI Example:

```bash
salt '*' consul.status_leader
```

```bash
salt.modules.consul.status_peers(consul_url)
```

Returns the current Raft peer set

**Parameters**

- `consul_url` -- The Consul server URL.

**Returns**

Retrieves the Raft peers for the datacenter in which the agent is running.

CLI Example:

```bash
salt '*' consul.status_peers
```

32.17.47 salt.modules.container_resource

Common resources for LXC and systemd-nspawn containers

New in version 2015.8.0.

These functions are not designed to be called directly, but instead from the `lxc`, `nspawn`, and `docker_ng` execution modules. They provide for common logic to be re-used for common actions.

```bash
salt.modules.container_resource.cache_file(source)
```

Wrapper for `cp.cache_file` which raises an error if the file was unable to be cached.

CLI Example:

```bash
salt myminion container_resource.cache_file salt://foo/bar/baz.txt
```

```bash
salt.modules.container_resource.copy_to(\*args, **kwargs)
```

Common logic for copying files to containers

- `path` path to the container parent (for LXC only) default: `/var/lib/lxc` (system default)

CLI Example:

```bash
salt myminion container_resource.copy_to mycontainer /local/file/path /container/ \nfile/path container_type=docker exec_driver=nsenter
```

```bash
salt.modules.container_resource.run(\*args, **kwargs)
```

Common logic for running shell commands in containers

- `path` path to the container parent (for LXC only) default: `/var/lib/lxc` (system default)

CLI Example:

```bash
salt myminion container_resource.run mycontainer 'ps aux' container_type=docker \nexec_driver=nsenter output=stdout
```

32.17.48 salt.modules.cp

Minion side functions for `salt-cp`

```bash
salt.modules.cp.cache_dir(path, saltenv='base', include_empty=False, include_pat=None, exclude_pat=None, env=None)
```

Download and cache everything under a directory from the master
**include_pat** [None] Glob or regex to narrow down the files cached from the given path. If matching with a regex, the regex must be prefixed with E@, otherwise the expression will be interpreted as a glob. New in version 2014.7.0.

**exclude_pat** [None] Glob or regex to exclude certain files from being cached from the given path. If matching with a regex, the regex must be prefixed with E@, otherwise the expression will be interpreted as a glob.

**Note:** If used with **include_pat**, files matching this pattern will be excluded from the subset of files defined by **include_pat**. New in version 2014.7.0.

**CLI Examples:**

```
salt '*' cp.cache_dir salt://path/to/dir
salt '*' cp.cache_dir salt://path/to/dir include_pat='E@*.py$'
```

**salt.modules.cp.cache_file**(path, saltenv='base', env=None)

Used to cache a single file on the salt-minion Returns the location of the new cached file on the minion

**CLI Example:**

```
salt '*' cp.cache_file salt://path/to/file
```

There are two ways of defining the fileserver environment (a.k.a. saltenv) from which to cache the file. One is to use the saltenv parameter, and the other is to use a querystring syntax in the salt:// URL. The below two examples are equivalent:

```
salt '*' cp.cache_file salt://foo/bar.conf saltenv=config
salt '*' cp.cache_file salt://foo/bar.conf?saltenv=config
```

**Note:** It may be necessary to quote the URL when using the querystring method, depending on the shell being used to run the command.

**salt.modules.cp.cache_files**(paths, saltenv='base', env=None)

Used to gather many files from the master, the gathered files will be saved in the minion cachedir reflective to the paths retrieved from the master.

**CLI Example:**

```
salt '*' cp.cache_files salt://path/to/file1,salt://path/to/file1
```

There are two ways of defining the fileserver environment (a.k.a. saltenv) from which to cache the files. One is to use the saltenv parameter, and the other is to use a querystring syntax in the salt:// URL. The below two examples are equivalent:

```
salt '*' cp.cache_files salt://foo/bar.conf,salt://foo/baz.conf saltenv=config
salt '*' cp.cache_files salt://foo/bar.conf?saltenv=config,salt://foo/baz.conf?saltenv=config
```

The querystring method is less useful when all files are being cached from the same environment, but is a good way of caching files from multiple different environments in the same command. For example, the below command will cache the first file from the config1 environment, and the second one from the config2 environment.
salt '*' cp.cache_files salt://foo/bar.conf?saltenv=config1,salt://foo/bar.conf?saltenv=config2

Note: It may be necessary to quote the URL when using the querystring method, depending on the shell being used to run the command.

salt.modules.cp.cache_local_file(path)
Cache a local file on the minion in the localfiles cache

CLI Example:

```
salt '*' cp.cache_local_file /etc/hosts
```

salt.modules.cp.cache_master(saltenv='base', env=None)
Retrieve all of the files on the master and cache them locally

CLI Example:

```
salt '*' cp.cache_master
```

get_dir supports the same template and gzip arguments as get_file.

salt.modules.cp.get_dir(path, dest, saltenv='base', template=None, gzip=None, env=None, **kwargs)
Used to recursively copy a directory from the salt master

CLI Example:

```
salt '*' cp.get_dir salt://path/to/dir/ /minion/dest
```

get_dir supports the same template and gzip arguments as get_file.

salt.modules.cp.get_file(path, dest, saltenv='base', makedirs=False, template=None, gzip=None, env=None, **kwargs)
Used to get a single file from the salt master

CLI Example:

```
salt '*' cp.get_file salt://path/to/file /minion/dest
```

Template rendering can be enabled on both the source and destination file names like so:

```
salt '*' cp.get_file "salt://{{grains.os}}/vimrc" /etc/vimrc template=jinja
```

This example would instruct all Salt minions to download the vimrc from a directory with the same name as their os grain and copy it to /etc/vimrc

For larger files, the cp.get_file module also supports gzip compression. Because gzip is CPU-intensive, this should only be used in scenarios where the compression ratio is very high (e.g. pretty-printed JSON or YAML files).

Use the gzip named argument to enable it. Valid values are 1..9, where 1 is the lightest compression and 9 the heaviest. 1 uses the least CPU on the master (and minion), 9 uses the most.

There are two ways of defining the fileserver environment (a.k.a. saltenv) from which to retrieve the file. One is to use the saltenv parameter, and the other is to use a querystring syntax in the salt:// URL. The below two examples are equivalent:

```
salt '*' cp.get_file salt://foo/bar.conf /etc/foo/bar.conf saltenv=config
salt '*' cp.get_file salt://foo/bar.conf?saltenv=config /etc/foo/bar.conf
```
Note: It may be necessary to quote the URL when using the querystring method, depending on the shell being used to run the command.

salt.modules.cp.get_file_str(path, saltenv='base', env=None)

Return the contents of a file from a URL.

Returns False if Salt was unable to cache a file from a URL.

CLI Example:

```
salt '*' cp.get_file_str salt://my/file
```

salt.modules.cp.get_template(path, dest, template='jinja', saltenv='base', env=None, makedirs=False, **kwargs)

Render a file as a template before setting it down. Warning, order is not the same as in fileclient.cp for non breaking old API.

CLI Example:

```
salt '*' cp.get_template salt://path/to/template /minion/dest
```

salt.modules.cp.get_url(path, dest='`', saltenv='base', env=None)

Used to get a single file from a URL.

- **path** A URL to download a file from. Supported URL schemes are: salt://, http://, https://, ftp://, s3://, swift:// and file:// (local filesystem). If no scheme was specified, this is equivalent of using file://. If a file:// URL is given, the function just returns absolute path to that file on a local filesystem. The function returns False if Salt was unable to fetch a file from a salt:// URL.

- **dest** The default behaviour is to write the fetched file to the given destination path. If this parameter is omitted or set as empty string (''), the function places the remote file on the local filesystem inside the Minion cache directory and returns the path to that file.

Note: To simply return the file contents instead, set destination to None. This works with salt://, http://, https:// and file:// URLs. The files fetched by http:// and https:// will not be cached.

- **saltenv** [base] Salt fileserver environment from which to retrieve the file. Ignored if path is not a salt:// URL.

CLI Example:

```
salt '*' cp.get_url salt://my/file /tmp/this_file_is_mine
salt '*' cp.get_url http://www.slashdot.org /tmp/index.html
```

salt.modules.cp.hash_file(path, saltenv='base', env=None)

Return the hash of a file, to get the hash of a file on the salt master file server prepend the path with salt://<file on server> otherwise, prepend the file with / for a local file.

CLI Example:

```
salt '*' cp.hash_file salt://path/to/file
```

salt.modules.cp.is_cached(path, saltenv='base', env=None)

Return a boolean if the given path on the master has been cached on the minion

CLI Example:
salt 'salt://path/to/file' cp.is_cached

salt.modules.cp.list_master(saltenv='base', prefix='.', env=None)
List all of the files stored on the master

CLI Example:
salt '*' cp.list_master

salt.modules.cp.list_master_dirs(saltenv='base', prefix='.', env=None)
List all of the directories stored on the master

CLI Example:
salt '*' cp.list_master_dirs

salt.modules.cp.list_master_symlinks(saltenv='base', prefix='.', env=None)
List all of the symlinks stored on the master

CLI Example:
salt '*' cp.list_master_symlinks

salt.modules.cp.list_minion(saltenv='base', env=None)
List all of the files cached on the minion

CLI Example:
salt '*' cp.list_minion

salt.modules.cp.list_states(saltenv='base', env=None)
List all of the available state modules in an environment

CLI Example:
salt '*' cp.list_states

salt.modules.cp.push(path, keep_symlinks=False, upload_path=None)
Push a file from the minion up to the master, the file will be saved to the salt master in the master's minion files cachedir (defaults to /var/cache/salt/master/minions/minion-id/files)

Since this feature allows a minion to push a file up to the master server it is disabled by default for security purposes. To enable, set file_recv to True in the master configuration file, and restart the master.

keep_symlinks Keep the path value without resolving its canonical form
upload_path Provide a different path inside the master's minion files cachedir

CLI Example:
salt '*' cp.push /etc/fstab
salt '*' cp.push /etc/system-release keep_symlinks=True
salt '*' cp.push /etc/fstab upload_path='/new/path/fstab'

salt.modules.cp.push_dir(path, glob=None, upload_path=None)
Push a directory from the minion up to the master, the files will be saved to the salt master in the master's minion files cachedir (defaults to /var/cache/salt/master/minions/minion-id/files). It also has a glob for matching specific files using globbing.

New in version 2014.7.0.
Since this feature allows a minion to push files up to the master server it is disabled by default for security purposes. To enable, set file_recv to True in the master configuration file, and restart the master.

**upload_path**  Provide a different path and directory name inside the master's minion files cachedir

CLI Example:

```bash
salt '*' cp.push /usr/lib/mysql
salt '*' cp.push /usr/lib/mysql upload_path="/newmysql/path"
salt '*' cp.push_dir /etc/modprobe.d/ glob="*.conf"
```

salt.modules.cp.recv(files, dest)
Used with salt-cp, pass the files dict, and the destination.
This function receives small fast copy files from the master via salt-cp. It does not work via the CLI.

### 32.17.49 salt.modules.cpan

Manage Perl modules using CPAN

New in version 2015.5.0.

salt.modules.cpan.install(module)
Install a Perl module from CPAN

CLI Example:

```bash
salt '*' cpan.install Template::Alloy
```

salt.modules.cpan.list()
List installed Perl modules, and the version installed

CLI Example:

```bash
salt '*' cpan.list
```

salt.modules.cpan.remove(module, details=False)
Attempt to remove a Perl module that was installed from CPAN. Because the cpan command doesn’t actually support `''uninstall``-like functionality, this function will attempt to do what it can, with what it has from CPAN.

Until this function is declared stable, USE AT YOUR OWN RISK!

CLI Example:

```bash
salt '*' cpan.remove Old::Package
```

salt.modules.cpan.show(module)
Show information about a specific Perl module

CLI Example:

```bash
salt '*' cpan.show Template::Alloy
```

salt.modules.cpan.show_config()
Return a dict of CPAN configuration values

CLI Example:
32.17.50  salt.modules.cron

Work with cron

Note: Salt does not escape cron metacharacters automatically. You should backslash-escape percent characters and any other metacharacters that might be interpreted incorrectly by the shell.

salt.modules.cron.list_tab(user)
  Return the contents of the specified user's crontab
  CLI Example:
  ```
salt '*' cron.list_tab root
  ```

salt.modules.cron.ls(user)
  This function is an alias of list_tab.
  Return the contents of the specified user's crontab
  CLI Example:
  ```
salt '*' cron.list_tab root
  ```

salt.modules.cron.raw_cron(user)
  Return the contents of the user's crontab
  CLI Example:
  ```
salt '*' cron.raw_cron root
  ```

salt.modules.cron.rm(user, cmd, minute=None, hour=None, daymonth=None, month=None, dayweek=None, identifier=None)
  This function is an alias of rm_job.
  Remove a cron job for a specified user. If any of the day/time params are specified, the job will only be removed if the specified params match.
  CLI Example:
  ```
salt '*' cron.rm_job root /usr/local/weekly
salt '*' cron.rm_job root /usr/bin/foo dayweek=1
  ```

salt.modules.cron.rm_env(user, name)
  Remove cron environment variable for a specified user.
  CLI Example:
  ```
salt '*' cron.rm_env root MAILTO
  ```

salt.modules.cron.rm_job(user, cmd, minute=None, hour=None, daymonth=None, month=None, dayweek=None, identifier=None)
  Remove a cron job for a specified user. If any of the day/time params are specified, the job will only be removed if the specified params match.
  CLI Example:
salt '*/' cron.rm_job root /usr/local/weekly
salt '*/' cron.rm_job root /usr/bin/foo dayweek=1

salt.modules.cron.rm_special(user, special, cmd)
    Remove a special cron job for a specified user.
    CLI Example:
    salt '*' cron.rm_job root @hourly /usr/bin/foo

salt.modules.cron.set_env(user, name, value=None)
    Set up an environment variable in the crontab.
    CLI Example:
    salt '*' cron.set_env root MAILTO user@example.com

salt.modules.cron.set_job(user, minute, hour, daymonth, month, dayweek, cmd, comment=None, identifier=None)
    Sets a cron job up for a specified user.
    CLI Example:
    salt '*' cron.set_job root '*' '*' '*' '*' '*' 1 /usr/local/weekly

salt.modules.cron.set_special(user, special, cmd)
    Set up a special command in the crontab.
    CLI Example:
    salt '*' cron.set_special root @hourly 'echo foobar'

salt.modules.cron.write_cron_file(user, path)
    Writes the contents of a file to a user's crontab
    CLI Example:
    salt '*' cron.write_cron_file root /tmp/new_cron
    Changed in version 2015.8.9.
    Note: Solaris and AIX require that path is readable by user

salt.modules.cron.write_cron_file_verbose(user, path)
    Writes the contents of a file to a user's crontab and return error message on error
    CLI Example:
    salt '*' cron.write_cron_file_verbose root /tmp/new_cron
    Changed in version 2015.8.9.
    Note: Solaris and AIX require that path is readable by user
32.17.51 salt.modules.cyg

Manage cygwin packages.

Module file to accompany the cyg state.

salt.modules.cyg.check_valid_package(package, cyg_arch='x86_64', mirrors=None)
Check if the package is valid on the given mirrors.

salt.modules.cyg.install(packages=None, cyg_arch='x86_64', mirrors=None)
Install one or several packages.

packages [None] The packages to install

 cyg_arch [x86_64] Specify the architecture to install the package under Current options are x86 and x86_64

CLI Example:

```
salt '*' cyg.install dos2unix
salt '*' cyg.install dos2unix mirrors=[{'http://mirror': 'http://url/to/public/key}]
```

salt.modules.cyg.list(package='`, cyg_arch='x86_64')
List locally installed packages.

 package [] package name to check. else all

 cyg_arch: Cygwin architecture to use Options are x86 and x86_64

CLI Example:

```
salt '*' cyg.list
```

salt.modules.cyg.uninstall(packages, cyg_arch='x86_64', mirrors=None)
Uninstall one or several packages.

packages The packages to uninstall.

 cyg_arch [x86_64] Specify the architecture to remove the package from Current options are x86 and x86_64

CLI Example:

```
salt '*' cyg.uninstall dos2unix
salt '*' cyg.uninstall dos2unix mirrors=[{'http://mirror': 'http://url/to/public/key}]
```

salt.modules.cyg.update(cyg_arch='x86_64', mirrors=None)
Update all packages.

 cyg_arch [x86_64] Specify the cygwin architecture update Current options are x86 and x86_64

CLI Example:

```
salt '*' cyg.update
salt '*' cyg.update dos2unix mirrors=[{'http://mirror': 'http://url/to/public/key}]
```

32.17.52 salt.modules.daemontools

daemontools service module. This module will create daemontools type service watcher.
This module is compatible with the *service* states, so it can be used to maintain services using the *provider* argument:

```python
myservice:
  service.running:
    - provider: daemontools
```

**salt.modules.daemontools.available** *(name)*

Returns True if the specified service is available, otherwise returns False.

CLI Example:

```bash
salt '*' daemontools.available foo
```

**salt.modules.daemontools.disabled** *(name)*

Return True if the named service is enabled, false otherwise

New in version 2015.5.6.

CLI Example:

```bash
salt '*' daemontools.disabled <service name>
```

**salt.modules.daemontools.enabled** *(name, **kwargs)*

Return True if the named service is enabled, false otherwise A service is considered enabled if in your service directory: - an executable ./run file exist - a file named ``down`` does not exist

New in version 2015.5.7.

**name**  Service name

CLI Example:

```bash
salt '*' daemontools.enabled <service name>
```

**salt.modules.daemontools.full_restart** *(name)*

Calls daemontools.restart() function

CLI Example:

```bash
salt '*' daemontools.full_restart <service name>
```

**salt.modules.daemontools.get_all**

Return a list of all available services

CLI Example:

```bash
salt '*' daemontools.get_all
```

**salt.modules.daemontools.missing** *(name)*

The inverse of daemontools.available. Returns True if the specified service is not available, otherwise returns False.

CLI Example:

```bash
salt '*' daemontools.missing foo
```

**salt.modules.daemontools.reload** *(name)*

Wrapper for term()

CLI Example:
salt.modules.daemontools.reload(name)

Restart service via daemontools. This will stop/start service

CLI Example:

```
salt '*' daemontools.reload <service name>
```

salt.modules.daemontools.restart(name)

Starts service via daemontools

CLI Example:

```
salt '*' daemontools.restart <service name>
```

salt.modules.daemontools.start(name)

Starts service via daemontools

CLI Example:

```
salt '*' daemontools.start <service name>
```

salt.modules.daemontools.status(name, sig=None)

Return the status for a service via daemontools, return pid if running

CLI Example:

```
salt '*' daemontools.status <service name>
```

salt.modules.daemontools.stop(name)

Stops service via daemontools

CLI Example:

```
salt '*' daemontools.stop <service name>
```

salt.modules.daemontools.term(name)

Send a TERM to service via daemontools

CLI Example:

```
salt '*' daemontools.term <service name>
```

32.17.53 salt.modules.darwin_pkgutil

Installer support for OS X.

Installer is the native .pkg/.mpkg package manager for OS X.

salt.modules.darwin_pkgutil.install(source, package_id=None)

Install a .pkg from an URI or an absolute path.

CLI Example:

```
salt '*' darwin_pkgutil.install source=/vagrant/build_essentials.pkg package_id=com.apple.pkg.gcc4.2Leo
```

salt.modules.darwin_pkgutil.is_installed(package_id)

Returns whether a given package id is installed.

CLI Example:

```
salt '*' darwin_pkgutil.is_installed com.apple.pkg.gcc4.2Leo
```
salt.modules.darwin_pkgutil.list()
List the installed packages.

CLI Example:
salt '*' darwin_pkgutil.list

32.17.54 salt.modules.darwin_sysctl
Module for viewing and modifying sysctl parameters

salt.modules.darwin_sysctl.assign(name, value)
Assign a single sysctl parameter for this minion

- **name** The name of the sysctl value to edit.
- **value** The sysctl value to apply.

CLI Example:
salt '*' sysctl.assign net.inet.icmp.icmplim 50

salt.modules.darwin_sysctl.get(name)
Return a single sysctl parameter for this minion

- **name** The name of the sysctl value to display.

CLI Example:
salt '*' sysctl.get hw.physmem

salt.modules.darwin_sysctl.persist(name, value, config='/etc/sysctl.conf', apply_change=False)
Assign and persist a simple sysctl parameter for this minion

- **name** The name of the sysctl value to edit.
- **value** The sysctl value to apply.
- **config** The location of the sysctl configuration file.
- **apply_change** Default is False; Default behavior only creates or edits the sysctl.conf file. If apply is set to True, the changes are applied to the system.

CLI Example:
salt '*' sysctl.persist net.inet.icmp.icmplim 50
salt '*' sysctl.persist coretemp_load NO config=/etc/sysctl.conf

salt.modules.darwin_sysctl.show(config_file=False)
Return a list of sysctl parameters for this minion

CLI Example:
salt '*' sysctl.show

32.17.55 salt.modules.data
Manage a local persistent data structure that can hold any arbitrary data specific to the minion
salt.modules.data.cas(key, value, old_value)
  Check and set a value in the minion datastore
  CLI Example:
  
salt '*' data.cas <key> <value> <old_value>

salt.modules.data.clear()
  Clear out all of the data in the minion datastore, this function is destructive!
  CLI Example:
  
salt '*' data.clear

salt.modules.data.dump(new_data)
  Replace the entire datastore with a passed data structure
  CLI Example:
  
salt '*' data.dump '{'eggs': 'spam'}'

salt.modules.data.get(key, default=None)
  Get a (list of) value(s) from the minion datastore
  New in version 2015.8.0.
  CLI Example:
  
salt '*' data.get <key(s)>

salt.modules.data.getval(key)
  Get a value from the minion datastore
  Deprecated since version Boron: Use get instead
  CLI Example:
  
salt '*' data.getval <key>

salt.modules.data.getvals(*keylist)
  Get values from the minion datastore
  Deprecated since version Boron: Use get instead
  CLI Example:
  
salt '*' data.getvals <key> [<key> ...]

salt.modules.data.has_key(key)
  Check if key is in the minion datastore
  New in version 2015.8.0.
  CLI Example:
  
salt '*' data.has_key <mykey>

salt.modules.data.items()
  Get items from the minion datastore
  New in version 2015.8.0.
CLI Example:

```
salt '*' data.items
```

`salt.modules.data.keys()`  
Get all keys from the minion datastore  
New in version 2015.8.0.  
CLI Example:

```
salt '*' data.keys
```

`salt.modules.data.load()`  
Return all of the data in the minion datastore  
CLI Example:

```
salt '*' data.load
```

`salt.modules.data.pop(key, default=None)`  
Pop (return & delete) a value from the minion datastore  
New in version 2015.5.2.  
CLI Example:

```
salt '*' data.pop <key> "there was no val"
```

`salt.modules.data.update(key, value)`  
Update a key with a value in the minion datastore  
CLI Example:

```
salt '*' data.update <key> <value>
```

`salt.modules.data.values()`  
Get values from the minion datastore  
New in version 2015.8.0.  
CLI Example:

```
salt '*' data.values
```

### 32.17.56 `salt.modules.ddns`

Support for RFC 2136 dynamic DNS updates.

**depends**

- dnspython Python module

**configuration** If you want to use TSIG authentication for the server, there are a couple of optional configuration parameters made available to support this (the keyname is only needed if the keyring contains more than one key):

```
keyring: keyring file (default=None)  
keyname: key name in file (default=None)
```
The keyring file needs to be in json format and the key name needs to end with an extra period in the file, similar to this:

```json
{"keyname.: ":keycontent"}
```

salt.modules.ddns.add_host(zone, name, ttl, ip, nameserver='127.0.0.1', replace=True, **kwargs)
Add, replace, or update the A and PTR (reverse) records for a host.

CLI Example:
```
salt ns1 ddns.add_host example.com host1 60 10.1.1.1
```

salt.modules.ddns.delete(zone, name, rdtype=None, data=None, nameserver='127.0.0.1', **kwargs)
Delete a DNS record.

CLI Example:
```
salt ns1 ddns.delete example.com host1 A
```

salt.modules.ddns.delete_host(zone, name, nameserver='127.0.0.1', **kwargs)
Delete the forward and reverse records for a host.

Returns true if any records are deleted.

CLI Example:
```
salt ns1 ddns.delete_host example.com host1
```

salt.modules.ddns.update(zone, name, ttl, rdtype, data, nameserver='127.0.0.1', replace=False, **kwargs)
Add, replace, or update a DNS record. nameserver must be an IP address and the minion running this module must have update privileges on that server. If replace is true, first deletes all records for this name and type.

CLI Example:
```
salt ns1 ddns.update example.com host1 60 A 10.0.0.1
```

32.17.57 salt.modules.deb_apache

Support for Apache

Please note: The functions in here are Debian-specific. Placing them in this separate file will allow them to load only on Debian-based systems, while still loading under the apache namespace.

salt.modules.deb_apache.a2dismod(mod)
Runs a2dismod for the given mod.

This will only be functional on Debian-based operating systems (Ubuntu, Mint, etc).

CLI Examples:
```
salt '*' apache.a2dismod vhost_alias
```

salt.modules.deb_apache.a2dissite(site)
Runs a2dissite for the given site.

This will only be functional on Debian-based operating systems (Ubuntu, Mint, etc).

CLI Examples:
**salt.modules.deb_apache.a2enmod** *(mod)*

Runs `a2enmod` for the given mod.

This will only be functional on Debian-based operating systems (Ubuntu, Mint, etc).

CLI Examples:

```bash
salt '*' apache.a2enmod vhost_alias
```

**salt.modules.deb_apache.a2ensite** *(site)*

Runs `a2ensite` for the given site.

This will only be functional on Debian-based operating systems (Ubuntu, Mint, etc).

CLI Examples:

```bash
salt '*' apache.a2ensite example.com
```

**salt.modules.deb_apache.check_mod_enabled** *(mod)*

Checks to see if the specific mod symlink is in `/etc/apache2/mods-enabled`.

This will only be functional on Debian-based operating systems (Ubuntu, Mint, etc).

CLI Examples:

```bash
salt '*' apache.check_mod_enabled status.conf
salt '*' apache.check_mod_enabled status.load
```

**salt.modules.deb_apache.check_site_enabled** *(site)*

Checks to see if the specific Site symlink is in `/etc/apache2/sites-enabled`.

This will only be functional on Debian-based operating systems (Ubuntu, Mint, etc).

CLI Examples:

```bash
salt '*' apache.check_site_enabled example.com
```

### 32.17.58 **salt.modules.deb_postgres**

Module to provide Postgres compatibility to salt for debian family specific tools.

**salt.modules.deb_postgres.cluster_create** *(version, name='main', port=None, locale=None, encoding=None, datadir=None)*

Adds a cluster to the Postgres server.

CLI Example:

```bash
salt '*' postgres.cluster_create '9.3'
salt '*' postgres.cluster_create '9.3' 'main'
salt '*' postgres.cluster_create '9.3' locale='fr_FR'
```

**salt.modules.deb_postgres.cluster_exists** *(version, name='main')*

Checks if a given version and name of a cluster exists.

CLI Example:
salt '('* postgres.cluster_exists '9.3'
salt '('* postgres.cluster_exists '9.3' 'main'
salt.modules.deb_postgres.cluster_list( verbose=False)
    Return a list of cluster of Postgres server (tuples of version and name).
    CLI Example:
salt '*' postgres.cluster_list
salt '*' postgres.cluster_list verbose=True

salt.modules.deb_postgres.cluster_remove(version, name='main', stop=False)
    Remove a cluster on a Postgres server. By default it doesn't try to stop the cluster.
    CLI Example:
salt '*' postgres.cluster_remove '9.3'
salt '*' postgres.cluster_remove '9.3' 'main'
salt '*' postgres.cluster_remove '9.3' 'main' stop=True

32.17.59 salt.modules.debbuild

Debian Package builder system

New in version 2015.8.0.

This system allows for all of the components to build debs safely in chrooted environments. This also provides a function to generate debian repositories

This module implments the pkgbuild interface

salt.modules.debbuild.build(runas, tgt, dest_dir, spec, sources, deps, env, template, saltenv='base',
                          log_dir='/var/log/salt/pkgbuild')
    Given the package destination directory, the tarball containing debian files (e.g. control) and package sources, use pbuilder to safely build the platform package
    CLI Example:
    This example command should build the libnacl package for Debian using pbuilder and place it in /var/www/html/ on the minion

salt.modules.debbuild.make_repo(repodir, keyid=None, env=None)
    Given the repodir, create a Debian repository out of the dsc therein
    CLI Example:
salt '*' pkgbuild.make_repo /var/www/html/

salt.modules.debbuild.make_src_pkg(dest_dir, spec, sources, env=None, template=None,
                                   saltenv='base')
    Create a platform specific source package from the given platform spec/control file and sources
CLI Example:

Debian

```
```

This example command should build the libnacl SOURCE package and place it in /var/www/html/ on the minion.

32.17.60 salt.modules.debconfmod

Support for Debconf

salt.modules.debconfmod.get_selections(fetchempty=True)

Answers to debconf questions for all packages in the following format:

```
{ 'package': [[ 'question', 'type', 'value'], ...] }
```

CLI Example:

```
salt '*' debconf.get_selections
```

salt.modules.debconfmod.set(package, question, type, value, *extra)

Set answers to debconf questions for a package.

CLI Example:

```
salt '*' debconf.set <package> <question> <type> <value> [<value> ...]
```

salt.modules.debconfmod.set_file(path, saltenv='base', **kwargs)

Set answers to debconf questions from a file.

CLI Example:

```
salt '*' debconf.set_file salt://path/to/pkg.selections
```

salt.modules.debconfmod.set_template(path, template, context, defaults, saltenv='base', **kwargs)

Set answers to debconf questions from a template.

- **path**: location of the file containing the package selections
- **template**: template format
- **context**: variables to add to the template environment
- **default**: default values for the template environment

CLI Example:

```
salt '*' debconf.set_template salt://path/to/pkg.selections.jinja jinja None None
```

salt.modules.debconfmod.show(name)

Answers to debconf questions for a package in the following format:

```
[[ 'question', 'type', 'value'], ...]
```

If debconf doesn't know about a package, we return None.

CLI Example:
32.17.61 salt.modules.debian_ip

The networking module for Debian based distros

References:

salt.modules.debian_ip.apply_network_settings(**settings)**
Apply global network configuration.

CLI Example:
```
salt '*' ip.apply_network_settings
```

salt.modules.debian_ip.build_bond(iface, **settings)**
Create a bond script in /etc/modprobe.d with the passed settings and load the bonding kernel module.

CLI Example:
```
salt '*' ip.build_bond bond0 mode=balance-alb
```

salt.modules.debian_ip.build_interface(iface, iface_type, enabled, **settings)**
Build an interface script for a network interface.

CLI Example:
```
salt '*' ip.build_interface eth0 eth <settings>
```

salt.modules.debian_ip.build_network_settings(**settings)**
Build the global network script.

CLI Example:
```
salt '*' ip.build_network_settings <settings>
```

salt.modules.debian_ip.build_routes(iface, **settings)**
Add route scripts for a network interface using up commands.

CLI Example:
```
salt '*' ip.build_routes eth0 <settings>
```

salt.modules.debian_ip.down(iface, iface_type)
Shutdown a network interface

CLI Example:
```
salt '*' ip.down eth0 eth
```

salt.modules.debian_ip.get_bond(iface)
Return the content of a bond script

CLI Example:
```
salt '*' ip.get_bond bond0
```
salt.modules.debian_ip.get_interface(iface)
Return the contents of an interface script

CLI Example:
salt '*' ip.get_interface eth0

salt.modules.debian_ip.get_network_settings()
Return the contents of the global network script.

CLI Example:
salt '*' ip.get_network_settings

salt.modules.debian_ip.get_routes(iface)
Return the routes for the interface

CLI Example:
salt '*' ip.get_routes eth0

salt.modules.debian_ip.up(iface, iface_type)
Start up a network interface

CLI Example:
salt '*' ip.up eth0 eth

32.17.62 salt.modules.debian_service
Service support for Debian systems (uses update-rc.d and /sbin/service)

Important: If you feel that Salt should be using this module to manage services on a minion, and it is using a different module (or gives an error similar to `service.start' is not available), see here.

salt.modules.debian_service.available(name)
Returns True if the specified service is available, otherwise returns False.

CLI Example:
salt '*' service.available sshd

salt.modules.debian_service.disable(name, **kwargs)
Disable the named service to start at boot

CLI Example:
salt '*' service.disable <service name>

salt.modules.debian_service.disabled(name)
Return True if the named service is enabled, false otherwise

CLI Example:
salt '*' service.disabled <service name>
salt.modules.debian_service.enable(name, **kwargs)
   Enable the named service to start at boot
   CLI Example:
   ```
salt '*' service.enable <service name>
   ```

salt.modules.debian_service.enabled(name, **kwargs)
   Return True if the named service is enabled, false otherwise
   CLI Example:
   ```
salt '*' service.enabled <service name>
   ```

salt.modules.debian_service.force_reload(name)
   Force-reload the named service
   CLI Example:
   ```
salt '*' service.force_reload <service name>
   ```

salt.modules.debian_service.get_all()
   Return all available boot services
   CLI Example:
   ```
salt '*' service.get_all
   ```

salt.modules.debian_service.get_disabled()
   Return a set of services that are installed but disabled
   CLI Example:
   ```
salt '*' service.get_disabled
   ```

salt.modules.debian_service.get_enabled()
   Return a list of service that are enabled on boot
   CLI Example:
   ```
salt '*' service.get_enabled
   ```

salt.modules.debian_service.missing(name)
   The inverse of service.available. Returns True if the specified service is not available, otherwise returns False.
   CLI Example:
   ```
salt '*' service.missing sshd
   ```

salt.modules.debian_service.reload(name)
   Reload the named service
   CLI Example:
   ```
salt '*' service.reload <service name>
   ```

salt.modules.debian_service.restart(name)
   Restart the named service
   CLI Example:
salt ']' service.restart <service name>

salt.modules.debian_service.start(name)
Start the specified service
CLI Example:
salt '*' service.start <service name>

salt.modules.debian_service.status(name, sig=None)
Return the status for a service, pass a signature to use to find the service via ps
CLI Example:
salt '*' service.status <service name>

salt.modules.debian_service.stop(name)
Stop the specified service
CLI Example:
salt '*' service.stop <service name>

32.17.63 salt.modules.defaults

salt.modules.defaults.get(key, default='``
defaults.get is used much like pillar.get except that it will read a default value for a pillar from defaults.json or defaults.yaml files that are stored in the root of a salt formula.
CLI Example:
salt '*' defaults.get core:users:root

The defaults is computed from pillar key. The first entry is considered as the formula namespace.
For example, querying core:users:root will try to load salt://core/defaults.yaml and salt://core/defaults.json.

32.17.64 salt.modules.devmap

Device-Mapper module

salt.modules.devmap.multipath_flush(device)
Device-Mapper Multipath flush
CLI Example:
salt '*' devmap.multipath_flush mpath1

salt.modules.devmap.multipath_list()
Device-Mapper Multipath list
CLI Example:
salt '*' devmap.multipath_list
32.17.65  salt.modules.dig

Compendium of generic DNS utilities. The `dig' command line tool must be installed in order to use this module.

salt.modules.dig.A(host, nameserver=None)
Return the A record for host.
Always returns a list.
CLI Example:
```
salt ns1 dig.A www.google.com
```

salt.modules.dig.AAAA(host, nameserver=None)
Return the AAAA record for host.
Always returns a list.
CLI Example:
```
salt ns1 dig.AAAA www.google.com
```

salt.modules.dig.MX(domain, resolve=False, nameserver=None)
Return a list of lists for the MX of domain.
If the resolve argument is True, resolve IPs for the servers.
It's limited to one IP, because although in practice it's very rarely a round robin, it is an acceptable configuration and pulling just one IP lets the data be similar to the non-resolved version. If you think an MX has multiple IPs, don't use the resolver here, resolve them in a separate step.
CLI Example:
```
salt ns1 dig.MX google.com
```

salt.modules.dig.NS(domain, resolve=True, nameserver=None)
Return a list of IPs of the nameservers for domain
If resolve is False, don't resolve names.
CLI Example:
```
salt ns1 dig.NS google.com
```

salt.modules.dig.SPF(domain, record='SPF', nameserver=None)
Return the allowed IPv4 ranges in the SPF record for domain.
If record is SPF and the SPF record is empty, the TXT record will be searched automatically. If you know the domain uses TXT and not SPF, specifying that will save a lookup.
CLI Example:
```
salt ns1 dig.SPF google.com
```

salt.modules.dig.TXT(host, nameserver=None)
Return the TXT record for host.
Always returns a list.
CLI Example:
salt modules.dig.check_ip(addr)
    Check if address is a valid IP. returns True if valid, otherwise False.
    CLI Example:
    
    salt ns1 dig.check_ip 127.0.0.1

32.17.66 salt.modules.disk

Module for gathering disk information

salt.modules.disk.blkid(device=None)
    Return block device attributes: UUID, LABEL, etc. This function only works on systems where blkid is available.
    CLI Example:
    
    salt '*' disk.blkid
    salt '*' disk.blkid /dev/sda

salt.modules.disk.inodeusage(args=None)
    Return inode usage information for volumes mounted on this minion
    CLI Example:

    salt '*' disk.inodeusage

salt.modules.disk.percent(args=None)
    Return partition information for volumes mounted on this minion
    CLI Example:

    salt '*' disk.percent /var

salt.modules.disk.usage(args=None)
    Return usage information for volumes mounted on this minion
    CLI Example:

    salt '*' disk.usage

32.17.67 salt.modules.djangomod

Manage Django sites

salt.modules.djangomod.collectstatic(settings_module, bin_env=None, no_post_process=False, ignore=None, dry_run=False, clear=False, link=False, no_default_ignore=False, pythonpath=None, env=None)

    Collect static files from each of your applications into a single location that can easily be served in production.
    CLI Example:

    salt '*' django.collectstatic <settings_module>
salt.modules.djangomod.command(settings_module, command, bin_env=None, pythonpath=None, env=None, *args, **kwargs)

Run arbitrary django management command

CLI Example:
```
salt '*' django.command <settings_module> <command>
```

salt.modules.djangomod.createsuperuser(settings_module, username, email, bin_env=None, database=None, pythonpath=None, env=None)

Create a super user for the database. This function defaults to use the --noinput flag which prevents the creation of a password for the superuser.

CLI Example:
```
salt '*' django.createsuperuser <settings_module> user user@example.com
```

salt.modules.djangomod.loaddata(settings_module, fixtures, bin_env=None, database=None, pythonpath=None, env=None)

Load fixture data

Fixtures: comma separated list of fixtures to load

CLI Example:
```
salt '*' django.loaddata <settings_module> <comma delimited list of fixtures>
```

salt.modules.djangomod.syncdb(settings_module, bin_env=None, migrate=False, database=None, pythonpath=None, env=None, noinput=True)

Run syncdb

Execute the Django-Admin syncdb command, if South is available on the minion the migrate option can be passed as True calling the migrations to run after the syncdb completes

CLI Example:
```
salt '*' django.syncdb <settings_module>
```

32.17.68 salt.modules.dnsmasq

Module for managing dnsmasq

salt.modules.dnsmasq.fullversion()

Shows installed version of dnsmasq and compile options.

CLI Example:
```
salt '*' dnsmasq.version
```

salt.modules.dnsmasq.get_config(config_file='/etc/dnsmasq.conf')

Dumps all options from the config file.

config_file The location of the config file from which to obtain contents. Defaults to /etc/dnsmasq.conf.

CLI Examples:
```
salt '*' dnsmasq.get_config
salt '*' dnsmasq.get_config config_file=/etc/dnsmasq.conf
```
salt.modules.dnsmasq.set_config(config_file='/etc/dnsmasq.conf', follow=True, **kwargs)
Sets a value or a set of values in the specified file. By default, if conf-dir is configured in this file, salt will attempt to set the option in any file inside the conf-dir where it has already been enabled. If it does not find it inside any files, it will append it to the main config file. Setting follow to False will turn off this behavior.

If a config option currently appears multiple times (such as dhcp-host, which is specified at least once per host), the new option will be added to the end of the main config file (and not to any includes). If you need an option added to a specific include file, specify it as the config_file.

Parameters

- **config_file** (string) -- config file where settings should be updated / added.
- **follow** (bool) -- attempt to set the config option inside any file within the conf-dir where it has already been enabled.
- **kwargs** -- key value pairs that contain the configuration settings that you want set.

CLI Examples:

```shell
salt '*' dnsmasq.set_config domain=mydomain.com
salt '*' dnsmasq.set_config follow=False domain=mydomain.com
salt '*' dnsmasq.set_config config_file=/etc/dnsmasq.conf domain=mydomain.com
```

salt.modules.dnsmasq.version()
Shows installed version of dnsmasq.

CLI Example:

```shell
salt '*' dnsmasq.version
```

32.17.69 salt.modules.dnsutil

Compendium of generic DNS utilities

salt.modules.dnsutil.A(host, nameserver=None)
Return the A record(s) for host.
Always returns a list.

CLI Example:

```shell
salt ns1 dnsutil.A www.google.com
```

salt.modules.dnsutil.AAAA(host, nameserver=None)
Return the AAAA record(s) for host.
Always returns a list.
New in version 2014.7.5.

CLI Example:

```shell
salt ns1 dnsutil.AAAA www.google.com
```

salt.modules.dnsutil.MX(domain, resolve=False, nameserver=None)
Return a list of lists for the MX of domain.
If the 'resolve' argument is True, resolve IPs for the servers.
It's limited to one IP, because although in practice it's very rarely a round robin, it is an acceptable configuration and pulling just one IP lets the data be similar to the non-resolved version. If you think an MX has multiple IPs, don't use the resolver here, resolve them in a separate step.

CLI Example:
```
salt ns1 dig.MX google.com
```

```
salt.modules.dnsutil.NS(domain, resolve=True, nameserver=None)
```
Return a list of IPs of the nameservers for `domain`

If `resolve` is False, don't resolve names.

CLI Example:
```
salt ns1 dig.NS google.com
```

```
salt.modules.dnsutil.SPF(domain, record='SPF', nameserver=None)
```
Return the allowed IPv4 ranges in the SPF record for `domain`.

If record is SPF and the SPF record is empty, the TXT record will be searched automatically. If you know the domain uses TXT and not SPF, specifying that will save a lookup.

CLI Example:
```
salt ns1 dig.SPF google.com
```

```
salt.modules.dnsutil.check_ip(ip_addr)
```
Check that string `ip_addr` is a valid IP

CLI Example:
```
salt ns1 dig.check_ip 127.0.0.1
```

```
salt.modules.dnsutil.hosts_append(hostsfile='/etc/hosts', ip_addr=None, entries=None)
```
Append a single line to the `/etc/hosts` file.

CLI Example:
```
salt '*'' dnsutil.hosts_append /etc/hosts 127.0.0.1 ad1.yuk.co,ad2.yuk.co
```

```
salt.modules.dnsutil.hosts_remove(hostsfile='/etc/hosts', entries=None)
```
Remove a host from the `/etc/hosts` file. If doing so will leave a line containing only an IP address, then the line will be deleted. This function will leave comments and blank lines intact.

CLI Examples:
```
salt '*'' dnsutil.hosts_remove /etc/hosts ad1.yuk.co
salt '*'' dnsutil.hosts_remove /etc/hosts ad2.yuk.co,ad1.yuk.co
```

```
salt.modules.dnsutil.parse_hosts(hostsfile='/etc/hosts', hosts=None)
```
Parse `/etc/hosts` file.

CLI Example:
```
salt '*'' dnsutil.parse_hosts
```

```
salt.modules.dnsutil.parse_zone(zonefile=None, zone=None)
```
Parses a zone file. Can be passed raw zone data on the API level.

CLI Example:
salt ns1 dnsutil.parse_zone /var/lib/named/example.com.zone

salt.modules.dnsutil.serial(zone='`, update=False)
Return, store and update a dns serial for your zone files.

zone: a keyword for a specific zone
update: store an updated version of the serial in a grain

If update is False, the function will retrieve an existing serial or return the current date if no serial is stored. Nothing will be stored.

If update is True, the function will set the serial to the current date if none exist or if the existing serial is for a previous date. If a serial for greater than the current date is already stored, the function will increment it.

This module stores the serial in a grain, you can explicitly set the stored value as a grain named dnsserial_<zone_name>.

CLI Example:
	salt ns1 dnsutil.serial example.com

32.17.70 salt.modules.dockerio

Management of Docker Containers

New in version 2014.1.0.

Deprecated since version 2015.8.0: Future feature development will be done only in dockerng. See the documentation for this module for information on the deprecation path.

Note: The DockerIO integration is still in beta; the API is subject to change

General Notes

As we use states, we don't want to be continuously popping dockers, so we will map each container id (or image) with a grain whenever it is relevant.

As a corollary, we will resolve a container id either directly by the id or try to find a container id matching something stocked in grain.

Installation Prerequisites

- You will need the docker-py python package in your python installation path that is running salt. Its version should support Docker Remote API v1.12.

Currently, docker-py 0.6.0 is known to support Docker Remote API v1.12

```
pip install docker-py==0.6.0
```
Prerequisite Pillar Configuration for Authentication

- To push or pull you will need to be authenticated as the docker-py bindings require it
- For this to happen, you will need to configure a mapping in the pillar representing your per URL authentication bits:

```python
docker-registries:
    registry_url:
        email: foo@foo.com
        password: s3cr3t
        username: foo
```

- You need at least an entry to the default docker index:

```python
docker-registries:
    https://index.docker.io/v1/:
        email: foo@foo.com
        password: s3cr3t
        username: foo
```

- You can define multiple registry blocks for them to be aggregated. The only thing to keep in mind is that their ID must finish with `-docker-registries`:

```python
ac-docker-registries:
    https://index.bar.io/v1/:
        email: foo@foo.com
        password: s3cr3t
        username: foo

ab-docker-registries:
    https://index.foo.io/v1/:
        email: foo@foo.com
        password: s3cr3t
        username: foo
```

This could be also written as:

```python
docker-registries:
    https://index.bar.io/v1/:
        email: foo@foo.com
        password: s3cr3t
        username: foo

    https://index.foo.io/v1/:
        email: foo@foo.com
        password: s3cr3t
        username: foo
```

Methods

- Registry Dialog
  - login
  - push
  - pull
• Docker Management
  - version
  - info

• Image Management
  - search
  - inspect_image
  - get_images
  - remove_image
  - import_image
  - build
  - tag
  - save
  - load

• Container Management
  - start
  - stop
  - restart
  - kill
  - wait
  - get_containers
  - inspect_container
  - remove_container
  - is_running
  - top
  - port
  - logs
  - diff
  - commit
  - create_container
  - export
  - get_container_root

Runtime Execution within a specific, already existing/running container

Idea is to use lxc-attach to execute inside the container context. We do not want to use docker run but want to execute something inside a running container.

These are the available methods:
- retcode
- run
- run_all
- run_stderr
- run_stdout
- script
- script_retcode

```python
salt.modules.dockerio.build(path=None, tag=None, quiet=False, fileobj=None, nocache=False, rm=True, timeout=None)
```

Build a docker image from a dockerfile or an URL

- path: url/branch/docker_dir or path on the filesystem to the dockerfile
- tag: tag of the image
- quiet: quiet mode, Default is False
- nocache: do not use docker image cache, Default is False
- rm: remove intermediate commits, Default is True
- timeout: timeout value before aborting (in seconds)

CLI Example:

```bash
salt '*' docker.build vieux/apache
salt '*' docker.build github.com/creack/docker-firefox
```

```python
salt.modules.dockerio.commit(container, repository=None, tag=None, message=None, author=None, conf=None)
```

Commit a container (promotes it to an image)

- container: container id
- repository: repository/image to commit to
- tag: tag of the image (Optional)
- message: commit message (Optional)
- author: author name (Optional)
- conf: conf (Optional)

CLI Example:

```bash
salt '*' docker.commit <container id>
```

```python
salt.modules.dockerio.create_container(image, command=None, hostname=None, user=None, detach=True, stdin_open=False, tty=False, mem_limit=None, ports=None, environment=None, dns=None, volumes=None, volumes_from=None, name=None, cpu_shares=None, cpuset=None, binds=None)
```

Create a new container

- image: image to create the container from
- command: command to execute while starting
hostname  hostname of the container
user  user to run docker as
detach  daemon mode, Default is True
environment  environment variable mapping ( {'foo': 'BAR'} )
ports  port redirections ( {'222': {}} )
volumes  list of volume mappings in either local volume, bound volume, or read-only bound volume form:

```python
([['/var/lib/mysql/', '/usr/local/etc/ssl:/etc/ssl', '/etc/passwd:/etc/passwd:rw']])
```
binds  complete dictionary of bound volume mappings:

```python
{
    '/usr/local/etc/ssl/certs/internal.crt': {
        'bind': '/etc/ssl/certs/com.example.internal.crt',
        'ro': True
    },
    '/var/lib/mysql': {
        'bind': '/var/lib/mysql/',
        'ro': False
    }
}
```

This dictionary is suitable for feeding directly into the Docker API, and all keys are required. (see http://docker-py.readthedocs.org/en/latest/volumes/)
tty  attach ttys, Default is False
stdin_open  let stdin open, Default is False
name  name given to container
cpu_shares  CPU shares (relative weight)
cpuset  CPUs in which to allow execution ('0-3' or '0,1')

CLI Example:

```shell
salt '*' docker.create_container o/ubuntu volumes="["/s","/m:/f"]"
```
salt.modules.dockerio.diff(container)
Get container diffs

cpu_shares  CPU shares (relative weight)
cpuset  CPUs in which to allow execution ('0-3' or '0,1')

CLI Example:

```shell
salt '*' docker.diff <container id>
```
salt.modules.dockerio.exists(container)
Check if a given container exists

cpu_shares  CPU shares (relative weight)
cpuset  CPUs in which to allow execution ('0-3' or '0,1')

CLI Example:

```shell
salt '*' docker.exists <container id>
```
salt.modules.dockerio.export(container, path)
   Export a container to a file
   container  container id
   path  path to which file is to be exported
   CLI Example:
   
   salt '*' docker.export <container id>

salt.modules.dockerio.get_container_root(container)
   Get the container rootfs path
   container  container id or grain
   CLI Example:
   
   salt '*' docker.get_container_root <container id>

salt.modules.dockerio.get_containers(all=True, trunc=False, since=None, before=None, limit=-1, host=False, inspect=False)
   Get a list of mappings representing all containers
   all  return all containers, Default is True
   trunc  set it to True to have the short ID, Default is False
   host  include the Docker host's ipv4 and ipv6 address in return, Default is False
   inspect  Get more granular information about each container by running a docker inspect
   CLI Example:
   
   salt '*' docker.get_containers
   salt '*' docker.get_containers host=True
   salt '*' docker.get_containers host=True inspect=True

salt.modules.dockerio.get_images(name=None, quiet=False, all=True)
   List docker images
   name  repository name
   quiet  only show image id, Default is False
   all  show all images, Default is True
   CLI Example:
   
   salt '*' docker.get_images <name> [quiet=True|False] [all=True|False]

salt.modules.dockerio.import_image(src, repo, tag=None)
   Import content from a local tarball or a URL to a docker image
   src  content to import (URL or absolute path to a tarball)
   repo  repository to import to
   tag  set tag of the image (Optional)
   CLI Example:
   
   salt '*' docker.import_image <src> <repo> [tag]
salt.modules.dockerio.info()
Get the version information about docker. This is similar to docker info command

CLI Example:
```
salt '*' docker.info
```

salt.modules.dockerio.inspect_container(container)
Get container information. This is similar to docker inspect command but only for containers

container container id

CLI Example:
```
salt '*' docker.inspect_container <container id>
```

salt.modules.dockerio.inspect_image(image)
Inspect the status of an image and return relative data. This is similar to docker inspect command but only for images.

image name of the image

CLI Example:
```
salt '*' docker.inspect_image <image>
```

salt.modules.dockerio.is_running(container)
Check if the specified container is running

container container id

Returns True if container is running otherwise returns False

CLI Example:
```
salt '*' docker.is_running <container id>
```

salt.modules.dockerio.kill(container, signal=None)
Kill a running container

container container id

signal signal to send

New in version 2015.8.0.

CLI Example:
```
salt '*' docker.kill <container id>
```

salt.modules.dockerio.load(imagepath)
Load the specified file at imagepath into docker that was generated from a docker save command e.g. docker load < imagepath

imagepath imagepath to docker tar file

CLI Example:
```
salt '*' docker.load /path/to/image
```

salt.modules.dockerio.login(url=None, username=None, password=None, email=None)
Wrapper to the docker.py login method (does not do much yet)
url  registry url to authenticate to
username  username to authenticate
password  password to authenticate
eMail  email to authenticate

CLI Example:
```
salt '*' docker.login <url> <username> <password> <email>
```

salt.modules.docker.io.logs(container)
Return logs for a specified container

container  container id

CLI Example:
```
salt '*' docker.logs <container id>
```

salt.modules.docker.io.port(container, private_port)
Private port mapping allocation information. This method is broken on docker-py side. Just use the result of inspect to mangle port allocation

container  container id
private_port  private port on the container to query for

CLI Example:
```
salt '*' docker.port <container id> <private port>
```

salt.modules.docker.io.pull(repo, tag=None, insecure_registry=False)
Pulls an image from any registry. See documentation at top of this page to configure authenticated access

repo  name of repository
tag  specific tag to pull (Optional)
insecure_registry  set as True to use insecure (non HTTPS) registry. Default is False (only available if using docker-py >= 0.5.0)

CLI Example:
```
salt '*' docker.pull <repository> [tag]
```

salt.modules.docker.io.push(repo, tag=None, quiet=False, insecure_registry=False)
Pushes an image to any registry. See documentation at top of this page to configure authenticated access

repo  name of repository
tag  specific tag to push (Optional)
quiet  set as True to quiet output, Default is False
insecure_registry  set as True to use insecure (non HTTPS) registry. Default is False (only available if using docker-py >= 0.5.0)

CLI Example:
```
salt '*' docker.push <repository> [tag] [quiet=True|False]
```
The Salt modules for Docker provide various functions to manage containers and images. Here are some key functions explained:

**salt.modules.dockerio.remove_container(container, force=False, v=False)**
Remove a container from a docker installation.
- **container**: Container id
- **force**: remove a running container, Default is False
- **v**: remove the volumes associated to the container, Default is False

CLI Example:
```
salt '*' docker.remove_container <container id> [force=True|False] [v=True|False]
```

**salt.modules.dockerio.remove_image(image)**
Remove an image from a system.
- **image**: Name of image

CLI Example:
```
salt '*' docker.remove_image <image>
```

**salt.modules.dockerio.restart(container, timeout=10)**
Restart a running container.
- **container**: Container id
- **timeout**: Timeout for container to exit gracefully before killing it, Default is 10 seconds

CLI Example:
```
salt '*' docker.restart <container id> [timeout=20]
```

**salt.modules.dockerio.retcode(container, cmd)**
Wrapper for cmdmod.retcode inside a container context.
- **container**: Container id (or grain)
- **cmd**: Command to execute

**Note:** The return is True or False depending on the commands success.

**Warning:** Be advised that this function allows for raw shell access to the named container! If allowing users to execute this directly it may allow more rights than intended!

CLI Example:
```
salt '*' docker.retcode <container id> 'ls -l /etc'
```

**salt.modules.dockerio.run(container, cmd)**
Wrapper for cmdmod.run inside a container context.
- **container**: Container id (or grain)
- **cmd**: Command to execute
Note: The return is a bit different as we use the docker struct. Output of the command is in `out` and result is always True.

Warning: Be advised that this function allows for raw shell access to the named container! If allowing users to execute this directly it may allow more rights than intended!

CLI Example:
```
salt '*' docker.run <container id> 'ls -l /etc'
```

salt.modules.dockerio.run_all(container, cmd)
Wrapper for cmdmod.run_all inside a container context

container container id (or grain)
cmd command to execute

Note: The return is a bit different as we use the docker struct. Output of the command is in `out` and result is False if command failed to execute.

Warning: Be advised that this function allows for raw shell access to the named container! If allowing users to execute this directly it may allow more rights than intended!

CLI Example:
```
salt '*' docker.run_all <container id> 'ls -l /etc'
```

salt.modules.dockerio.run_stderr(container, cmd)
Wrapper for cmdmod.run_stderr inside a container context

container container id (or grain)
cmd command to execute

Note: The return is a bit different as we use the docker struct. Output of the command is in `out` and result is always True.

Warning: Be advised that this function allows for raw shell access to the named container! If allowing users to execute this directly it may allow more rights than intended!

CLI Example:
```
salt '*' docker.run_stderr <container id> 'ls -l /etc'
```

salt.modules.dockerio.run_stdout(container, cmd)
Wrapper for cmdmod.run_stdout inside a container context

container container id (or grain)
cmd command to execute
**cmd** command to execute

---

**Note:** The return is a bit different as we use the docker struct. Output of the command is in `out` and result is always `True`.

---

**Warning:** Be advised that this function allows for raw shell access to the named container! If allowing users to execute this directly it may allow more rights than intended!

CLI Example:

```bash
salt '*' docker.run_stdout <container id> 'ls -l /etc'
```

salt.modules.dockerio.save\(image, filename\)

New in version 2015.5.0.

Save the specified image to filename from docker e.g. `docker save image > filename`

- **image** name of image
- **filename** The filename of the saved docker image

CLI Example:

```bash
salt '*' docker.save arch_image /path/to/save/image
```

salt.modules.dockerio.script\(container, source, args=None, cwd=None, stdin=None, runas=None, shell='/bin/sh', env=None, template='jinja', umask=None, timeout=None, reset_system_locale=True, no_clean=False, saltenv='base'\)

Wrapper for `cmdmod.script` inside a container context

- **container** container id (or grain)
- **additional parameters** See `cmd.script`

---

**Warning:** Be advised that this function allows for raw shell access to the named container! If allowing users to execute this directly it may allow more rights than intended!

Download a script from a remote location and execute the script in the container. The script can be located on the salt master file server or on an HTTP/FTP server.

The script will be executed directly, so it can be written in any available programming language.

The script can also be formatted as a template, the default is Jinja. Arguments for the script can be specified as well.

CLI Example:

```bash
salt '*' docker.script <container id> salt://docker_script.py
salt '*' docker.script <container id> salt://scripts/runme.sh 'arg1 arg2 "arg 3"'
salt '*' docker.script <container id> salt://scripts/windows_task.ps1 args='-
   Input c:\tmp\infile.txt' shell='powershell'
```

A string of standard input can be specified for the command to be run using the stdin parameter. This can be useful in cases where sensitive information must be read from standard input.
CLI Example:

```bash
salt '*' docker.script <container id> salt://scripts/runme.sh stdin=
    one
two
three
four
five
```

salt.modules.dockerio.script_retcode(container, source, cwd=None, stdin=None, runas=None, shell='/bin/sh', env=None, template='jinja', umask=None, timeout=None, reset_system_locale=True, no_clean=False, saltenv='base')

Wrapper for cmdmod.script_retcode inside a container context

container  container id (or grain)
additional parameters  See cmd.script_retcode

**Warning:** Be advised that this function allows for raw shell access to the named container! If allowing users to execute this directly it may allow more rights than intended!

CLI Example:

```bash
salt '*' docker.script_retcode <container id> salt://docker_script.py
```

salt.modules.dockerio.search(term)
Search for an image on the registry

  term  search keyword

CLI Example:

```
salt '*' docker.search <term>
```

salt.modules.dockerio.start(container, binds=None, port_bindings=None, lxc_conf=None, publish_all_ports=None, links=None, privileged=False, dns=None, volumes_from=None, network_mode=None, restart_policy=None, cap_add=None, cap_drop=None)

Start the specified container

container  container id

CLI Example:

```
salt '*' docker.start <container id>
```

salt.modules.dockerio.stop(container, timeout=10)
Stop a running container

container  container id

timeout  timeout for container to exit gracefully before killing it, Default is 10 seconds

CLI Example:

```
salt '*' docker.stop <container id> [timeout=20]
```

salt.modules.dockerio.tag(image, repository, tag=None, force=False)
Tag an image into a repository

image  name of image

repository  name of repository
tag  tag to apply (Optional)
force  force apply tag, Default is False

CLI Example:

```
salt '*' docker.tag <image> <repository> [tag] [force=True|False]
```

salt.modules.dockerio.top(container)
Run the docker top command on a specific container

```
salt '*' docker.top <container id>
```

salt.modules.dockerio.version()
Get docker version

```
salt '*' docker.version
```

salt.modules.dockerio.wait(container)
Wait for a container to exit gracefully

```
salt '*' docker.wait <container id>
```

### 32.17.71 salt.modules.dockerng

Management of Docker Containers

New in version 2015.8.0.

**Why Make a Second Docker Execution Module?**

We have received a lot of feedback on our Docker support. In the process of implementing recommended improvements, it became obvious that major changes needed to be made to the functions and return data. In the end, a complete rewrite was done.

The changes being too significant, it was decided that making a separate execution module and state module (called dockerng) would be the best option. This will give users a couple release cycles to modify their scripts, SLS files, etc. to use the new functionality, rather than forcing users to change everything immediately.

In the Nitrogen release of Salt (due in 2017), this execution module will take the place of the default Docker execution module, and backwards-compatible naming will be maintained for a couple releases after that to allow users time to replace references to dockerng with docker.

**Installation Prerequisites**

This execution module requires at least version 1.4.0 of both docker-py and Docker. docker-py can easily be installed using `pip install`: 
Authentication

To push or pull images, credentials must be configured. Because a password must be used, it is recommended to place this configuration in Pillar data. The configuration schema is as follows:

```yaml
docker-registries:
  <registry_url>:
    email: <email_address>
    password: <password>
    username: <username>
```

For example:

```yaml
docker-registries:
  https://index.docker.io/v1/:
    email: foo@foo.com
    password: s3cr3t
    username: foo
```

Multiple registries can be configured. This can be done in one of two ways. The first way is to configure each registry under the `docker-registries` pillar key.

```yaml
docker-registries:
  https://index.docker.io/v1/:
    email: foo@foo.com
    password: s3cr3t
    username: foo
  https://index.bar.io/v1/:
    email: foo@foo.com
    password: s3cr3t
    username: foo
```

The second way is to use separate pillar variables ending in `-docker-registries`:

```yaml
foo-docker-registries:
  https://index.foo.io/v1/:
    email: foo@foo.com
    password: s3cr3t
    username: foo

bar-docker-registries:
  https://index.bar.io/v1/:
    email: foo@foo.com
    password: s3cr3t
    username: foo
```

Both methods can be combined; any registry configured under `docker-registries` or `*-docker-registries` will be detected.

Configuration Options

The following configuration options can be set to fine-tune how Salt uses Docker:
• **docker.url**: URL to the docker service (default: local socket).

• **docker.version**: API version to use

• **docker.exec_driver**: Execution driver to use, one of nsenter, lxc-attach, or docker-exec. See the Executing Commands Within a Running Container section for more details on how this config parameter is used.

These configuration options are retrieved using `config.get` (click the link for further information).

**Functions**

• **Information Gathering**
  - `dockerng.depends`
  - `dockerng.diff`
  - `dockerng.exists`
  - `dockerng.history`
  - `dockerng.images`
  - `dockerng.info`
  - `dockerng.inspect`
  - `dockerng.inspect_container`
  - `dockerng.inspect_image`
  - `dockerng.list_containers`
  - `dockerng.list_tags`
  - `dockerng.logs`
  - `dockerng.pid`
  - `dockerng.port`
  - `dockerng ps`
  - `dockerng.state`
  - `dockerng.search`
  - `dockerng.top`
  - `dockerng.version`

• **Container Management**
  - `dockerng.create`
  - `dockerng.copy_from`
  - `dockerng.copy_to`
  - `dockerng.export`
  - `dockerng.rm`

• **Management of Container State**
  - `dockerng.kill`
  - `dockerng.pause`
Executing Commands Within a Running Container

Multiple methods exist for executing commands within Docker containers:

- **lxc-attach**: Default for older versions of docker
- **nsenter**: Enters container namespace to run command
- **docker-exec**: Native support for executing commands in Docker containers (added in Docker 1.3)

Adding a configuration option (see `config.get`) called `docker.exec_driver` will tell Salt which execution driver to use:

```python
docker.exec_driver: docker-exec
```

If this configuration option is not found, Salt will use the appropriate interface (either `nsenter` or `lxc-attach`) based on the Execution Driver value returned from `docker info`. `docker-exec` will not be used by default, as it is presently (as of version 1.6.2) only able to execute commands as the effective user of the container. Thus, if a USER directive was used to run as a non-privileged user, `docker-exec` would be unable to perform the action as root. Salt
can still use `docker-exec` as an execution driver, but must be explicitly configured (as in the example above) to do so at this time.

If possible, try to manually specify the execution driver, as it will save Salt a little work.

This execution module provides functions that shadow those from the `cmd` module. They are as follows:

- `dockerng.retcode`
- `dockerng.run`
- `dockerng.run_all`
- `dockerng.run_stderr`
- `dockerng.run_stdout`
- `dockerng.script`
- `dockerng.script_retcode`

**Detailed Function Documentation**

`salt.modules.dockerng.build(path=None, image=None, cache=True, rm=True, api_response=False, fileobj=None)`

Builds a docker image from a Dockerfile or a URL

- `path` Path to directory on the Minion containing a Dockerfile
- `image` Image to be built, in `repo:tag` notation. If just the repository name is passed, a tag name of `latest` will be assumed. If building from a URL, this parameter can be omitted.
- `cache` [True] Set to `False` to force the build process not to use the Docker image cache, and pull all required intermediate image layers
- `rm` [True] Remove intermediate containers created during build
- `api_response` [False] If `True`: an `API_Response` key will be present in the return data, containing the raw output from the Docker API.
- `fileobj` Allows for a file-like object containing the contents of the Dockerfile to be passed in place of a `file` argument. This argument should not be used from the CLI, only from other Salt code.

**RETURN DATA**

A dictionary containing one or more of the following keys:

- `Id` - ID of the newly-built image
- `Time_Elapsed` - Time in seconds taken to perform the build
- `Intermediate Containers` - IDs of containers created during the course of the build process
  (Only present if `rm=False`)
- `Images` - A dictionary containing one or more of the following keys:
  - `Already_Pulled` - Layers that that were already present on the Minion
  - `Pulled` - Layers that that were pulled
  (Only present if the image specified by the `image` argument was not present on the Minion, or if `cache=False`)

32.17. Full list of builtin execution modules 911
• **Status** - A string containing a summary of the pull action (usually a message saying that an image was
downloaded, or that it was up to date).

(Only present if the image specified by the `image` argument was not present on the Minion, or if
`cache=False`)

CLI Example:

```
salt myminion dockerng.build /path/to/docker/build/dir image=myimage:dev
salt myminion dockerng.build https://github.com/myuser/myrepo.git image=myimage:latest
```

**salt.modules.dockerng.commit**(name, image, message=None, author=None)
Commits a container, thereby promoting it to an image. Equivalent to running the `docker commit` Docker
CLI command.

*name*  Container name or ID to commit

*image*  Image to be committed, in `repo:tag` notation. If just the repository name is passed, a tag name of
`latest` will be assumed.

*message*  Commit message (Optional)

*author*  Author name (Optional)

**RETURN DATA**
A dictionary containing the following keys:

• **Id** - ID of the newly-created image

• **Image** - Name of the newly-created image

• **Time_Elapsed** - Time in seconds taken to perform the commit

CLI Example:

```
salt myminion dockerng.commit mycontainer myuser/myimage
salt myminion dockerng.commit mycontainer myuser/myimage:mytag
```

**salt.modules.dockerng.connect_container_to_network**(container, network_id)
Connect container to network.

*container*  Container name or ID

*network_id*  ID of network

CLI Example:

```
salt myminion dockerng.connect_container_to_network web-1 e1f9d2454d872b68dd9e8744c6e7a4c66b86f10abaccd21e14f7f014f729b2bc
```

**salt.modules.dockerng.copy_from**(name, *args, **kwargs)
Copy a file from inside a container to the Minion

*name*  Container name

*source*  Path of the file on the container's filesystem

*dest*  Destination on the Minion. Must be an absolute path. If the destination is a directory, the file will be
copied into that directory.

*overwrite*  [False] Unless this option is set to `True`, then if a file exists at the location specified by the `dest`
argument, an error will be raised.
makedirs  [False] Create the parent directory on the container if it does not already exist.

RETURN DATA
A boolean (True if successful, otherwise False)

CLI Example:
```
salt myminion dockerng.copy_from mycontainer /var/log/nginx/access.log /home/myuser
```

salt.modules.dockerng.copy_to(name, *args, **kwargs)
Copy a file from the host into a container

name  Container name

source  File to be copied to the container. Can be a local path on the Minion or a remote file from the Salt
files.

dest  Destination on the container. Must be an absolute path. If the destination is a directory, the file will be
copied into that directory.

exec_driver  [None] If not passed, the execution driver will be detected as described above.

overwrite  [False] Unless this option is set to True, then if a file exists at the location specified by the dest
argument, an error will be raised.

makedirs  [False] Create the parent directory on the container if it does not already exist.

RETURN DATA
A boolean (True if successful, otherwise False)

CLI Example:
```
salt myminion dockerng.copy_to mycontainer /tmp/foo /root/foo
```

salt.modules.dockerng.create(*args, **kwargs)
Create a new container

name  Name for the new container. If not provided, Docker will randomly generate one for you.

image  Image from which to create the container

command or cmd  Command to run in the container

Example: command=bash or cmd=bash

Changed in version 2015.8.1: cmd is now also accepted

hostname  Hostname of the container. If not provided, and if a name has been provided, the hostname will
default to the name that was passed.

Example: hostname=web1

Warning: If the container is started with network_mode=host, the hostname will be overridden
by the hostname of the Minion.

domainname  Domain name of the container

Example: domainname=domain.tld
interactive [False] Leave stdin open
  Example: interactive=True

tty [False] Attach TTYs
  Example: tty=True

detach [True] If True, run command in the background (daemon mode)
  Example: detach=False

user User under which to run docker
  Example: user=foo

memory [0] Memory limit. Can be specified in bytes or using single-letter units (i.e. 512M, 2G, etc.). A value of 0 (the default) means no memory limit.
  Example: memory=512M, memory=1073741824

memory_swap [-1] Total memory limit (memory plus swap). Set to -1 to disable swap. A value of 0 means no swap limit.
  Example: memory_swap=1G, memory_swap=2147483648

mac_address MAC address to use for the container. If not specified, a random MAC address will be used.
  Example: mac_address=01:23:45:67:89:0a

network_disabled [False] If True, networking will be disabled within the container
  Example: network_disabled=True

working_dir Working directory inside the container
  Example: working_dir=/var/log/nginx

entrypoint Entrypoint for the container. Either a string (e.g. "mycmd --arg1 --arg2") or a Python list (e.g. "['mycmd','--arg1','--arg2']")
  Example: entrypoint="cat access.log"

environment Either a dictionary of environment variable names and their values, or a Python list of strings in the format VARNAME=value.
  Example: "{'VAR1': 'value','VAR2': 'value'}, ['VAR1=value','VAR2=value']"

ports A list of ports to expose on the container. Can be passed as comma-separated list or a Python list. If the protocol is omitted, the port will be assumed to be a TCP port.
  Example: 1111,2222/udp, "[1111/tcp,2222/udp]"

volumes [None] List of directories to expose as volumes. Can be passed as a comma-separated list or a Python list.
  Example: volumes=/mnt/vol1,/mnt/vol2, volumes=[/mnt/vol1,/mnt/vol2]

cpu_shares CPU shares (relative weight)
  Example: cpu_shares=0.5, cpu_shares=1

cpuset CPUs on which which to allow execution, specified as a string containing a range (e.g. 0-3) or a comma-separated list of CPUs (e.g. 0,1).
  Example: cpuset="0-3", cpuset="0,1"
client_timeout  Timeout in seconds for the Docker client. This is not a timeout for this function, but for receiving a response from the API.

Note: This is only used if Salt needs to pull the requested image.

labels  Add Metadata to the container. Can be a list of strings/dictionaries or a dictionary of strings (keys and values).

Example: labels=LABEL1,LABEL2, labels="{'LABEL1': 'value1','LABEL2': 'value2'}"

validate_ip_addrs  [True] For parameters which accept IP addresses as input, IP address validation will be performed. To disable, set this to False.

binds  Files/directories to bind mount. Each bind mount should be passed in the format <host_path>:<container_path>:<read_only>, where <read_only> is one of rw (for read-write access) or ro (for read-only access). Optionally, the read-only information can be left off the end and the bind mount will be assumed to be read-write. Examples 2 and 3 below are equivalent.

Example 1: binds=/srv/www:/var/www:ro
Example 2: binds=/srv/www:/var/www:rw
Example 3: binds=/srv/www:/var/www

port_bindings  Bind exposed ports which were exposed using the ports argument to `dockerng.create`. These should be passed in the same way as the `--publish` argument to the `docker run` CLI command:

- ip:hostPort:containerPort - Bind a specific IP and port on the host to a specific port within the container.
- ip::containerPort - Bind a specific IP and an ephemeral port to a specific port within the container.
- hostPort:containerPort - Bind a specific port on all of the host's interfaces to a specific port within the container.
- containerPort - Bind an ephemeral port on all of the host's interfaces to a specific port within the container.

Multiple bindings can be separated by commas, or passed as a Python list. The below two examples are equivalent:

Example 1: port_bindings="5000:5000,2123:2123/udp,8080"
Example 2: port_bindings="['5000:5000','2123:2123/udp','8080']"

Note: When configuring bindings for UDP ports, the protocol must be passed in the containerPort value, as seen in the examples above.

lxc_conf  Additional LXC configuration parameters to set before starting the container.

Example: lxc_conf="{lxc.utsname: docker}"

Note: These LXC configuration parameters will only have the desired effect if the container is using the LXC execution driver, which has not been the default for some time.
publish_all_ports  [False] Allocates a random host port for each port exposed using the ports argument to dockerng.create.

Example: publish_all_ports=True

links Link this container to another. Links should be specified in the format <container_name_or_id>:<link_alias>. Multiple links can be passed, either as a comma-separated list or a Python list.

Example 1: links=mycontainer:myalias,links=web1:link1,web2:link2
Example 2: links="["mycontainer:myalias"],["web1:link1","web2:link2"]"

dns List of DNS nameservers. Can be passed as a comma-separated list or a Python list.

Example: dns=8.8.8.8,8.8.4.4 or dns=\"[8.8.8.8,8.8.4.4]\"\n
Note: To skip IP address validation, use validate_ip_addrs=False

dns_search List of DNS search domains. Can be passed as a comma-separated list or a Python list.

Example: dns_search=foo1.domain.tld,foo2.domain.tld or
dns_search=\"[foo1.domain.tld,foo2.domain.tld]\"\n
volumes_from Container names or IDs from which the container will get volumes. Can be passed as a comma-separated list or a Python list.

Example: volumes_from=foo,volumes_from=foo,bar,volumes_from=\"[foo,bar]\"\n
network_mode  [bridge] One of the following:

- bridge - Creates a new network stack for the container on the docker bridge
- null - No networking (equivalent of the Docker CLI argument --net=none)
- container:<name_or_id> - Reuses another container's network stack
- host - Use the host's network stack inside the container

Warning: Using host mode gives the container full access to the host's system's services (such as D-bus), and is therefore considered insecure.

Example: network_mode=null,network_mode=container:web1

restart_policy Set a restart policy for the container. Must be passed as a string in the format policy[:retry_count] where policy is one of always or on-failure, and retry_count is an optional limit to the number of retries. The retry count is ignored when using the always restart policy.

Example 1: restart_policy=on-failure:5
Example 2: restart_policy=always

cap_add List of capabilities to add within the container. Can be passed as a comma-separated list or a Python list. Requires Docker 1.2.0 or newer.

Example: cap_add=SYS_ADMIN,MKNOD, cap_add=\"[SYS_ADMIN,MKNOD]\"\n
cap_drop List of capabilities to drop within the container. Can be passed as a comma-separated string or a Python list. Requires Docker 1.2.0 or newer.

Example: cap_drop=SYS_ADMIN,MKNOD, cap_drop=\"[SYS_ADMIN,MKNOD]\"
**extra_hosts** Additional hosts to add to the container's /etc/hosts file. Can be passed as a comma-separated list or a Python list. Requires Docker 1.3.0 or newer.

Example: `extra_hosts=web1:10.9.8.7,web2:10.9.8.8`

*Note:* To skip IP address validation, use `validate_ip_addrs=False`

**pid_mode** Set to `host` to use the host container's PID namespace within the container. Requires Docker 1.5.0 or newer.

Example: `pid_mode=host`

**RETURN DATA**

A dictionary containing the following keys:

- **Id** - ID of the newly-created container
- **Name** - Name of the newly-created container

**CLI Example:**

```
# Create a data-only container
salt myminion dockerng.create myuser/mycontainer volumes="/mnt/vol1,/mnt/vol2"

# Create a CentOS 7 container that will stay running once started
salt myminion dockerng.create centos:7 name=mycent7 interactive=True tty=True --command=bash
```

**salt.modules.dockerng.create_network**(name, driver=None)

Create a new network

- **network_id** - ID of network
- **driver** - Driver of the network

**CLI Example:**

```
salt myminion dockerng.create_network web_network driver=bridge
```

**salt.modules.dockerng.create_volume**(name, driver=None, driver_opts=None)

Create a new volume

New in version 2015.8.4.

- **name** - name of volume
- **driver** - Driver of the volume
- **driver_opts** - Options for the driver volume

**CLI Example:**

```
salt myminion dockerng.create_volume my_volume driver=local
```

**salt.modules.dockerng.dangling**(prune=False, force=False)

Return top-level images (those on which no other images depend) which do not have a tag assigned to them. These include:

- Images which were once tagged but were later untagged, such as those which were superseded by committing a new copy of an existing tagged image.
- Images which were loaded using `docker.load` (or the `docker load` Docker CLI command), but not tagged.
prune [False] Remove these images
force [False] If True, and if prune=True, then forcibly remove these images.

RETURN DATA
If prune=False, the return data will be a list of dangling image IDs.
If prune=True, the return data will be a dictionary with each key being the ID of the dangling image, and
the following information for each image:

- Comment - Any error encountered when trying to prune a dangling image
  (Only present if prune failed)
- Removed - A boolean (True if prune was successful, False if not)

CLI Example:
salt myminion dockerng.dangling
salt myminion dockerng.dangling prune=True

salt.modules.dockerng.depends(name)
Returns the containers and images, if any, which depend on the given image

name Name or ID of image

RETURN DATA
A dictionary containing the following keys:

- Containers - A list of containers which depend on the specified image
- Images - A list of IDs of images which depend on the specified image

CLI Example:
salt myminion dockerng.depends myimage
salt myminion dockerng.depends 0123456789ab

salt.modules.dockerng.diff(name, *args, **kwargs)
Get information on changes made to container's filesystem since it was created. Equivalent to running the
docker diff Docker CLI command.

name Container name or ID

RETURN DATA
A dictionary containing any of the following keys:

- Added - A list of paths that were added.
- Changed - A list of paths that were changed.
- Deleted - A list of paths that were deleted.

These keys will only be present if there were changes, so if the container has no differences the return dict will
be empty.

CLI Example:
salt myminion dockerng.diff mycontainer

salt.modules.dockerng.disconnect_container_from_network(container, network_id)
Disconnect container from network.
container  Container name or ID
network_id  ID of network

CLI Example:

```
salt myminion dockerng.disconnect_container_from_network web-1 1f9d2454d0872b68dd9e8744c6e7a4c66b86ef10abaccc21e14f7f014f729b2bc
```

salt.modules.dockerng.exists(name)
Check if a given container exists
name  Container name or ID

RETURN DATA
A boolean (True if the container exists, otherwise False)

CLI Example:

```
salt myminion dockerng.exists mycontainer
```

salt.modules.dockerng.export(name, *args, **kwargs)
Exports a container to a tar archive. It can also optionally compress that tar archive, and push it up to the Master.
name  Container name or ID
path  Absolute path on the Minion where the container will be exported
overwrite  [False] Unless this option is set to True, then if a file exists at the location specified by the path argument, an error will be raised.
makedirs  [False] If True, then if the parent directory of the file specified by the path argument does not exist, Salt will attempt to create it.
compression  [None] Can be set to any of the following:
  - gzip or gz for gzip compression
  - bzip2 or bz2 for bzip2 compression
  - xz or lzma for XZ compression (requires xz-utils, as well as the lzma module from Python 3.3, available in Python 2 and Python 3.0-3.2 as backports.lzma)

This parameter can be omitted and Salt will attempt to determine the compression type by examining the filename passed in the path parameter.
push  [False] If True, the container will be pushed to the master using cp.push.

---

Note: This requires file_recv to be set to True on the Master.

RETURN DATA
A dictionary will containing the following keys:

- Path - Path of the file that was exported
- Push - Reports whether or not the file was successfully pushed to the Master
  (Only present if push=True)
- Size - Size of the file, in bytes
- Size_Human - Size of the file, in human-readable units

32.17. Full list of builtin execution modules 919
**Time_Elapsed** - Time in seconds taken to perform the export

CLI Examples:

```bash
salt myminion dockerng.export mycontainer /tmp/mycontainer.tar
salt myminion dockerng.export mycontainer /tmp/mycontainer.tar.xz push=True
```

```python
salt.modules.dockerng.history(name, quiet=False)
```

Return the history for an image. Equivalent to running the docker history Docker CLI command.

- **name** Container name or ID
- **quiet** [False] If True, the return data will simply be a list of the commands run to build the container.

```bash
$ salt myminion dockerng.history nginx:latest quiet=True
```

**RETURN DATA**

If quiet=False, the return value will be a list of dictionaries containing information about each step taken to build the image. The keys in each step include the following:

- **Command** - The command executed in this build step
- **Id** - Layer ID
- **Size** - Cumulative image size, in bytes
- **Size_Human** - Cumulative image size, in human-readable units
- **Tags** - Tag(s) assigned to this layer
- **Time_Created_Epoch** - Time this build step was completed (Epoch time)
- **Time_Created_Local** - Time this build step was completed (Minion's local timezone)

CLI Example:

```bash
salt myminion dockerng.exists mycontainer
```

```python
salt.modules.dockerng.images(verbos=False, **kwargs)
```

Returns information about the Docker images on the Minion. Equivalent to running the docker images Docker CLI command.

- **all** [False] If True, untagged images will also be returned
verbose [False] If True, a docker inspect will be run on each image returned.

RETURN DATA
A dictionary with each key being an image ID, and each value some general info about that image (time created, size, tags associated with the image, etc.)

CLI Example:

```bash
salt myminion dockerng.images
salt myminion dockerng.images all=True
```

salt.modules.dockerng.import(source, image, api_response=False)
Imports content from a local tarball or a URL as a new docker image

source Content to import (URL or absolute path to a tarball). URL can be a file on the Salt fileserver (i.e. salt://path/to/rootfs/tarball.tar.xz. To import a file from a saltenv other than base (e.g. dev), pass it at the end of the URL (ex. salt://path/to/rootfs/tarball.tar.xz?saltenv=dev).

image Image to be created by the import, in repo:tag notation. If just the repository name is passed, a tag name of latest will be assumed.

api_response [False] If True an api_response key will be present in the return data, containing the raw output from the Docker API.

RETURN DATA
A dictionary containing the following keys:

- **Id** - ID of the newly-created image
- **Image** - Name of the newly-created image
- **Time_Elapsed** - Time in seconds taken to perform the commit

CLI Example:

```bash
salt myminion dockerng.import /tmp/cent7-minimal.tar.xz myuser/centos
salt myminion dockerng.import /tmp/cent7-minimal.tar.xz myuser/centos:7
salt myminion dockerng.import salt://dockerimages/cent7-minimal.tar.xz myuser/
  centos:7
```

salt.modules.dockerng.info(*args, **kwargs)
Returns a dictionary of system-wide information. Equivalent to running the docker info Docker CLI command.

CLI Example:

```bash
salt myminion dockerng.info
```

salt.modules.dockerng.inspect(name)
This is a generic container/image inspecton function. It will first attempt to get container information for the passed name/ID using docker.inspect_container, and then will try to get image information for the passed name/ID using docker.inspect_image. If it is already known that the name/ID is an image, it is slightly more efficient to use docker.inspect_image.

name Container/image name or ID

RETURN DATA
A dictionary of container/image information

CLI Example:
salt.modules.dockerng.inspect_container(name, *args, **kwargs)

Retrieves container information. Equivalent to running the docker inspect Docker CLI command, but will only look for container information.

name Container name or ID

RETURN DATA
A dictionary of container information

CLI Example:

salt myminion dockerng.inspect_container mycontainer
salt myminion dockerng.inspect_container 0123456789ab

salt.modules.dockerng.inspect_image(name)

Retrieves image information. Equivalent to running the docker inspect Docker CLI command, but will only look for image information.

Note: To inspect an image, it must have been pulled from a registry or built locally. Images on a Docker registry which have not been pulled cannot be inspected.

name Image name or ID

RETURN DATA
A dictionary of image information

CLI Examples:

salt myminion dockerng.inspect_image busybox
salt myminion dockerng.inspect_image centos:6
salt myminion dockerng.inspect_image 0123456789ab

salt.modules.dockerng.inspect_network(network_id)

Inspect Network

network_id ID of network

CLI Example:

salt myminion dockerng.inspect_network@
--1f9d2454d0872b68dd9e8744c6e7a4c66b86f10abaccc21e14f7f014f729b2bc

salt.modules.dockerng.inspect_volume(name)

Inspect Volume

New in version 2015.8.4.

name Name of volume

CLI Example:

salt myminion dockerng.inspect_volume my_volume
salt.modules.dockerng.kill(*args, **kwargs)
Kill all processes in a running container instead of performing a graceful shutdown

name Container name or ID

RETURN DATA
A dictionary will be returned, containing the following keys:
- status - A dictionary showing the prior state of the container as well as the new state
- result - A boolean noting whether or not the action was successful
- comment - Only present if the container cannot be killed

CLI Example:
salt myminion dockerng.kill mycontainer

salt.modules.dockerng.layers(name)
Returns a list of the IDs of layers belonging to the specified image, with the top-most layer (the one corresponding to the passed name) appearing last.

name Image name or ID

CLI Example:
salt myminion dockerng.layers centos:7

salt.modules.dockerng.list_containers(**kwargs)
Returns a list of containers by name. This is different from dockerng.ps in that dockerng.ps returns its results organized by container ID.

all [False] If True, stopped containers will be included in return data

CLI Example:
salt myminion dockerng.inspect_image <image>

salt.modules.dockerng.list_tags()
Returns a list of tagged images

CLI Example:
salt myminion dockerng.list_tags

salt.modules.dockerng.load(path, image=None)
Load a tar archive that was created using dockerng.save (or via the Docker CLI using docker save).

path Path to docker tar archive. Path can be a file on the Minion, or the URL of a file on the Salt fileserver (i.e. salt://path/to/docker/saved/image.tar). To load a file from a saltenv other than base (e.g. dev), pass it at the end of the URL (ex. salt://path/to/rootfs.tarball.tar.xz?saltenv=dev).

image [None] If specified, the topmost layer of the newly-loaded image will be tagged with the specified repo and tag using dockerng.tag. The image name should be specified in repo:tag notation. If just the repository name is passed, a tag name of latest will be assumed.

RETURN DATA
A dictionary will be returned, containing the following keys:
- Path - Path of the file that was saved
• **Layers** - A list containing the IDs of the layers which were loaded. Any layers in the file that was loaded, which were already present on the Minion, will not be included.

• **Image** - Name of tag applied to topmost layer

  *(Only present if tag was specified and tagging was successful)*

• **Time_Elapsed** - Time in seconds taken to load the file

• **Warning** - Message describing any problems encountered in an attempt to tag the topmost layer

  *(Only present if tag was specified and tagging failed)*

CLI Example:

```bash
salt myminion dockerng.load /path/to/image.tar
salt myminion dockerng.load salt://path/to/docker/saved/image.tar image=myuser/
```

salt.modules.dockerng.logs(name)

Returns the logs for the container. Equivalent to running the `docker logs` Docker CLI command.

```bash
name Container name or ID
```

CLI Example:

```bash
salt myminion dockerng.logs mycontainer
```

salt.modules.dockerng.networks(names=None, ids=None)

List existing networks

```bash
names Filter by name
ids Filter by id
```

CLI Example:

```bash
salt myminion dockerng.networks names=["["network-web"]"]
salt myminion dockerng.networks ids=[
  "1f9d2454d0872b68d9e8744c6e7a4c66b86f10abaccc21e14f7f014f729b2bc"]
```

salt.modules.dockerng.pause(*args, **kwargs)

Pauses a container

```bash
name Container name or ID
```

RETURN DATA

A dictionary will be returned, containing the following keys:

• **status** - A dictionary showing the prior state of the container as well as the new state

• **result** - A boolean noting whether or not the action was successful

• **comment** - Only present if the container cannot be paused

CLI Example:

```bash
salt myminion dockerng.pause mycontainer
```

salt.modules.dockerng.pid(name, *args, **kwargs)

Returns the PID of a container

```bash
name Container name or ID
```
CLI Example:

```bash
salt myminion dockerng.pid mycontainer
salt myminion dockerng.pid 0123456789ab
```

```python
salt.modules.dockerng.port(name, *args, **kwargs)
```

Returns port mapping information for a given container. Equivalent to running the `docker port` Docker CLI command.

- **name** Container name or ID
- **private_port** [None] If specified, get information for that specific port. Can be specified either as a port number (i.e. `5000`), or as a port number plus the protocol (i.e. `5000/udp`).

If this argument is omitted, all port mappings will be returned.

**RETURN DATA**

A dictionary of port mappings, with the keys being the port and the values being the mapping(s) for that port.

CLI Examples:

```bash
salt myminion dockerng.port mycontainer
salt myminion dockerng.port mycontainer 5000
salt myminion dockerng.port mycontainer 5000/udp
```

```python
salt.modules.dockerng.ps(filters=None, **kwargs)
```

Returns information about the Docker containers on the Minion. Equivalent to running the `docker ps` Docker CLI command.

- **all** [False] If True, stopped containers will also be returned
- **host** [False] If True, local host’s network topology will be included
- **verbose** [False] If True, a `docker inspect` will be run on each container returned.

- **filters**: None A dictionary of filters to be processed on the container list. Available filters:
  - **exited (int)**: Only containers with specified exit code
  - **status (str)**: One of restarting, running, paused, exited
  - **label (str)**: format either ``key`` or ``key=value``

**RETURN DATA**

A dictionary with each key being an container ID, and each value some general info about that container (time created, name, command, etc.)

CLI Example:

```bash
salt myminion dockerng.ps
salt myminion dockerng.ps all=True
salt myminion dockerng.ps filters="{'label': 'role=web'}"
```

```python
salt.modules.dockerng.pull(image, insecure_registry=False, api_response=False, client_timeout=60)
```

Pulls an image from a Docker registry. See the documentation at the top of this page to configure authenticated access.

- **image** Image to be pulled, in `repo:tag` notation. If just the repository name is passed, a tag name of `latest` will be assumed.
- **insecure_registry** [False] If True, the Docker client will permit the use of insecure (non-HTTPS) registries.
api_response: [False] If True, an API_Response key will be present in the return data, containing the raw output from the Docker API.

Note: This may result in a lot of additional return data, especially for larger images.

client_timeout: Timeout in seconds for the Docker client. This is not a timeout for this function, but for receiving a response from the API.

RETURN DATA
A dictionary will be returned, containing the following keys:

- **Layers** - A dictionary containing one or more of the following keys:
  - *Already_Pulled* - Layers that were already present on the Minion
  - *Pulled* - Layers that were pulled

- **Status** - A string containing a summary of the pull action (usually a message saying that an image was downloaded, or that it was up to date)

- **Time_Elapsed** - Time in seconds taken to perform the pull

CLI Example:
```
salt myminion dockerng.pull centos
salt myminion dockerng.pull centos:6
```

salt.modules.dockerng.push(image, insecure_registry=False, api_response=False, client_timeout=60)

Changed in version 2015.8.4: The Id and Image keys are no longer present in the return data. This is due to changes in the Docker Remote API.

Pushes an image to a Docker registry. See the documentation at top of this page to configure authenticated access.

image: Image to be pushed, in repo:tag notation.

Changed in version 2015.8.4: If just the repository name is passed, then all tagged images for the specified repo will be pushed. In prior releases, a tag of latest was assumed if the tag was omitted.

insecure_registry: [False] If True, the Docker client will permit the use of insecure (non-HTTPS) registries.

api_response: [False] If True, an API_Response key will be present in the return data, containing the raw output from the Docker API.

client_timeout: Timeout in seconds for the Docker client. This is not a timeout for this function, but for receiving a response from the API.

RETURN DATA
A dictionary will be returned, containing the following keys:

- **Layers** - A dictionary containing one or more of the following keys:
  - *Already_Pushed* - Layers that were already present on the Minion
  - *Pulled* - Layers that were pulled

- **Time_Elapsed** - Time in seconds taken to perform the push

CLI Example:
```
salt myminion dockerng.push myuser/mycontainer
salt myminion dockerng.push myuser/mycontainer:mytag
```
salt.modules.dockerng.remove_network(network_id)
    Remove a network
    network_id  ID of network
    CLI Example:
    
    salt myminion dockerng.remove_network
    
    1f9d2454d0872b68dd9e8744c6e7a4c66b86f10abaccc21e14f7f014f729b2bc

salt.modules.dockerng.remove_volume(name)
    Remove a volume
    New in version 2015.8.4.
    name  Name of volume
    CLI Example:
    
    salt myminion dockerng.remove_volume my_volume

salt.modules.dockerng.restart(name, *args, **kwargs)
    Restarts a container
    name  Container name or ID
    timeout  [10] Timeout in seconds after which the container will be killed (if it has not yet gracefully shut down)

RETURN DATA
    A dictionary will be returned, containing the following keys:
    • status - A dictionary showing the prior state of the container as well as the new state
    • result - A boolean noting whether or not the action was successful
    • restarted - If restart was successful, this key will be present and will be set to True.
    CLI Examples:
    
    salt myminion dockerng.restart mycontainer
    salt myminion dockerng.restart mycontainer timeout=20

salt.modules.dockerng.retcode(name, cmd, exec_driver=None, stdin=None, python_shell=True,
    output_loglevel='debug', use_vt=False, ignore_retcode=False,
    keep_env=None)
    Run cmd.retcode within a container
    name  Container name or ID in which to run the command
    cmd  Command to run
    exec_driver  [None] If not passed, the execution driver will be detected as described above.
    stdin  [None] Standard input to be used for the command
    output_loglevel  [debug] Level at which to log the output from the command. Set to quiet to suppress logging.
    use_vt  [False] Use SaltStack's utils.vt to stream output to console.
    keep_env  [None] If not passed, only a sane default PATH environment variable will be set. If True, all environment variables from the container's host will be kept. Otherwise, a comma-separated list (or Python list) of environment variable names can be passed, and those environment variables will be kept.
Salt Documentation, Release 2015.8.12

CLI Example:

```bash
salt myminion dockerng.retcode mycontainer 'ls -l /etc'
```

salt.modules.dockerng.run(*args, **kwargs)
Removes a container

- **name**: Container name or ID
- **force**: [False] If True, the container will be killed first before removal, as the Docker API will not permit a running container to be removed. This option is set to False by default to prevent accidental removal of a running container.
- **volumes**: [False] Also remove volumes associated with container

RETURN DATA
A list of the IDs of containers which were removed

CLI Example:

```bash
salt myminion dockerng.rm mycontainer
salt myminion dockerng.rm mycontainer force=True
```

salt.modules.dockerng.rmi(*names, **kwargs)
Removes an image

- **name**: Name (in repo:tag notation) or ID of image.
- **force**: [False] If True, the image will be removed even if the Minion has containers created from that image
- **prune**: [True] If True, untagged parent image layers will be removed as well, set this to False to keep them.

RETURN DATA
A dictionary will be returned, containing the following two keys:

- **Layers** - A list of the IDs of image layers that were removed
- **Tags** - A list of the tags that were removed
- **Errors** - A list of any errors that were encountered

CLI Examples:

```bash
salt myminion dockerng.rmi busybox
salt myminion dockerng.rmi busybox force=True
salt myminion dockerng.rmi foo bar baz
```

salt.modules.dockerng.run(name, cmd, exec_driver=None, stdin=None, python_shell=True, output_loglevel='debug', use_vt=False, ignore_retcode=False, keep_env=None)
Run cmd.run within a container

- **name**: Container name or ID in which to run the command
- **cmd**: Command to run
- **exec_driver**: [None] If not passed, the execution driver will be detected as described above.
- **stdin**: [None] Standard input to be used for the command
- **output_loglevel**: [debug] Level at which to log the output from the command. Set to quiet to suppress logging.
- **use_vt**: [False] Use SaltStack's utils.vt to stream output to console.
`keep_env` [None] If not passed, only a sane default PATH environment variable will be set. If True, all environment variables from the container's host will be kept. Otherwise, a comma-separated list (or Python list) of environment variable names can be passed, and those environment variables will be kept.

CLI Example:
```
salt myminion dockerng.run mycontainer 'ls -l /etc'
```

salt.modules.dockerng.run_all(name, cmd, exec_driver=None, stdin=None, python_shell=True, output_loglevel='debug', use_vt=False, ignore_retcode=False, keep_env=None)

Run `cmd.run_all` within a container

Note: While the command is run within the container, it is initiated from the host. Therefore, the PID in the return dict is from the host, not from the container.

name Container name or ID in which to run the command

`cmd` Command to run

exec_driver [None] If not passed, the execution driver will be detected as described *above.*

stdin [None] Standard input to be used for the command

output_loglevel [debug] Level at which to log the output from the command. Set to `quiet` to suppress logging.

use_vt [False] Use SaltStack's `utils.vt` to stream output to console.

`keep_env` [None] If not passed, only a sane default PATH environment variable will be set. If True, all environment variables from the container's host will be kept. Otherwise, a comma-separated list (or Python list) of environment variable names can be passed, and those environment variables will be kept.

CLI Example:
```
salt myminion dockerng.run_all mycontainer 'ls -l /etc'
```

salt.modules.dockerng.run_stderr(name, cmd, exec_driver=None, stdin=None, python_shell=True, output_loglevel='debug', use_vt=False, ignore_retcode=False, keep_env=None)

Run `cmd.run_stderr` within a container

name Container name or ID in which to run the command

`cmd` Command to run

exec_driver [None] If not passed, the execution driver will be detected as described *above.*

stdin [None] Standard input to be used for the command

output_loglevel [debug] Level at which to log the output from the command. Set to `quiet` to suppress logging.

use_vt [False] Use SaltStack's `utils.vt` to stream output to console.

`keep_env` [None] If not passed, only a sane default PATH environment variable will be set. If True, all environment variables from the container's host will be kept. Otherwise, a comma-separated list (or Python list) of environment variable names can be passed, and those environment variables will be kept.

CLI Example:
salt myminion dockerng.run_stderr mycontainer 'ls -l /etc'

```python
salt.modules.dockerng.run_stdout(name, cmd, exec_driver=None, stdin=None, python_shell=True, output_loglevel='debug', use_vt=False, ignore_retcode=False, keep_env=None)
```

Run `cmd.run_stdout` within a container

- **name**: Container name or ID in which to run the command
- **cmd**: Command to run
- **exec_driver**: [None] If not passed, the execution driver will be detected as described above.
- **stdin**: [None] Standard input to be used for the command
- **output_loglevel**: [debug] Level at which to log the output from the command. Set to quiet to suppress logging.
- **use_vt**: [False] Use SaltStack's utils.vt to stream output to console.
- **keep_env**: [None] If not passed, only a sane default PATH environment variable will be set. If True, all environment variables from the container's host will be kept. Otherwise, a comma-separated list (or Python list) of environment variable names can be passed, and those environment variables will be kept.

CLI Example:

```
salt myminion dockerng.run_stdout mycontainer 'ls -l /etc'
```

```python
salt.modules.dockerng.save(name, path, overwrite=False, makedirs=False, compression=None, **kwargs)
```

Saves an image and to a file on the minion. Equivalent to running the docker `save` Docker CLI command, but unlike `docker save` this will also work on named images instead of just images IDs.

- **name**: Name or ID of image. Specify a specific tag by using the `repo:tag` notation.
- **path**: Absolute path on the Minion where the image will be exported
- **overwrite**: [False] Unless this option is set to True, then if the destination file exists an error will be raised.
- **makedirs**: [False] If True, then if the parent directory of the file specified by the path argument does not exist, Salt will attempt to create it.
- **compression**: [None] Can be set to any of the following:
  - gzip or gz for gzip compression
  - bzip2 or bz2 for bzip2 compression
  - xz or lzma for XZ compression (requires `xz-utils`, as well as the `lzma` module from Python 3.3, available in Python 2 and Python 3.0-3.2 as `backports.lzma`)

This parameter can be omitted and Salt will attempt to determine the compression type by examining the filename passed in the `path` parameter.

**Note**: Since the Docker API does not support `docker save`, compression will be a bit slower with this function than with `docker.export` since the image(s) will first be saved and then the compression done afterwards.

- **push**: [False] If True, the container will be pushed to the master using `cp.push`.

930 Chapter 32. Reference
Note: This requires `file_recv` to be set to `True` on the Master.

RETURN DATA
A dictionary will be returned, containing the following keys:

- **Path** - Path of the file that was saved
- **Push** - Reports whether or not the file was successfully pushed to the Master
  
  *(Only present if push=True)*
- **Size** - Size of the file, in bytes
- **Size_Human** - Size of the file, in human-readable units
- **Time_Elapsed** - Time in seconds taken to perform the save

CLI Examples:

```bash
salt myminion dockerng.save centos:7 /tmp/cent7.tar
salt myminion dockerng.save 0123456789ab cdef01234567 /tmp/saved.tar
```

```python
salt.modules.dockerng.script(name, source, saltenv='base', args=None, template=None, exec_driver=None, stdin=None, python_shell=True, output_loglevel='debug', ignore_retcode=False, use_vt=False, keep_env=None)
```

Run `cmd.script` within a container

Note: While the command is run within the container, it is initiated from the host. Therefore, the PID in the return dict is from the host, not from the container.

**name**  Container name or ID

**source**  Path to the script. Can be a local path on the Minion or a remote file from the Salt fileserver.

**args**  A string containing additional command-line options to pass to the script.

**template**  [None] Templating engine to use on the script before running.

**exec_driver**  [None] If not passed, the execution driver will be detected as described above.

**stdin**  [None] Standard input to be used for the script

**output_loglevel**  [debug] Level at which to log the output from the script. Set to `quiet` to suppress logging.

**use_vt**  [False] Use SaltStack's utils.vt to stream output to console.

**keep_env**  [None] If not passed, only a sane default PATH environment variable will be set. If `True`, all environment variables from the container's host will be kept. Otherwise, a comma-separated list (or Python list) of environment variable names can be passed, and those environment variables will be kept.

CLI Example:

```bash
salt myminion dockerng.script mycontainer salt://docker_script.py
salt myminion dockerng.script mycontainer salt://scripts/runme.sh 'arg1 arg2 "arg\n3\n"'
salt myminion dockerng.script mycontainer salt://scripts/runme.sh stdin=\n'one\ntwo\nthree\nfour\nfive\n' output_loglevel=quiet
```
salt.modules.dockerng.script_retcode(name, source, saltenv='base', args=None, template=None, exec_driver=None, stdin=None, python_shell=True, output_loglevel='debug', ignore_retcode=False, use_vt=False, keep_env=None)

Run `cmd.script_retcode` within a container

name Container name or ID

source Path to the script. Can be a local path on the Minion or a remote file from the Salt fileserver.

args A string containing additional command-line options to pass to the script.

template [None] Templating engine to use on the script before running.

exec_driver [None] If not passed, the execution driver will be detected as described above.

stdin [None] Standard input to be used for the script

output_loglevel [debug] Level at which to log the output from the script. Set to quiet to suppress logging.

use_vt [False] Use SaltStack's utils.vt to stream output to console.

keep_env [None] If not passed, only a sane default PATH environment variable will be set. If True, all environment variables from the container's host will be kept. Otherwise, a comma-separated list (or Python list) of environment variable names can be passed, and those environment variables will be kept.

CLI Example:

```shell
salt myminion dockerng.script_retcode mycontainer salt://docker_script.py
salt myminion dockerng.script_retcode mycontainer salt://scripts/runme.sh 'arg1\n  arg2 "arg 3"

salt myminion dockerng.script_retcode mycontainer salt://scripts/runme.sh stdin=\n  'one\ntwo\nthree\nfour\nfive\n' output_loglevel=quiet
```

salt.modules.dockerng.search(name, official=False, trusted=False)

Searches the registry for an image

name Search keyword

official [False] Limit results to official builds

trusted [False] Limit results to trusted builds

RETURN DATA

A dictionary with each key being the name of an image, and the following information for each image:

- Description - Image description
- Official - A boolean (True if an official build, False if not)
- Stars - Number of stars the image has on the registry
- Trusted - A boolean (True if a trusted build, False if not)

CLI Example:

```shell
salt myminion dockerng.search centos
salt myminion dockerng.search centos official=True
```

salt.modules.dockerng.signal(*args, **kwargs)

Send a signal to a container. Signals can be either strings or numbers, and are defined in the Standard Signals section of the signal(7) manpage. Run man 7 signal on a Linux host to browse this manpage.

name Container name or ID
**signal** Signal to send to container

**RETURN DATA**
If the signal was successfully sent, `True` will be returned. Otherwise, an error will be raised.

CLI Example:
```
salt myminion dockerng.signal mycontainer SIGHUP
```

```
salt.modules.dockerng.start(*args, **kwargs)
Start a container

**name** Container name or ID

**RETURN DATA**
A dictionary will be returned, containing the following keys:

- **status** - A dictionary showing the prior state of the container as well as the new state
- **result** - A boolean noting whether or not the action was successful
- **comment** - Only present if the container cannot be started

CLI Example:
```
salt myminion dockerng.start mycontainer
```

```
salt.modules.dockerng.state(name, *args, **kwargs)
Returns the state of the container

**name** Container name or ID

**RETURN DATA**
A string representing the current state of the container (either `running`, `paused`, or `stopped`)

CLI Example:
```
salt myminion dockerng.state mycontainer
```

```
salt.modules.dockerng.stop(*args, **kwargs)
Stops a running container

**name** Container name or ID

**unpause** [False] If `True` and the container is paused, it will be unpaused before attempting to stop the container.

**timeout** [10] Timeout in seconds after which the container will be killed (if it has not yet gracefully shut down)

**RETURN DATA**
A dictionary will be returned, containing the following keys:

- **status** - A dictionary showing the prior state of the container as well as the new state
- **result** - A boolean noting whether or not the action was successful
- **comment** - Only present if the container can not be stopped

CLI Examples:
salt.myminion.dockerng.stop mycontainer
salt.myminion.dockerng.stop mycontainer unpause=True
salt.myminion.dockerng.stop mycontainer timeout=20

salt.modules.dockerng.tag(name, image, force=False)
Tag an image into a repository and return True. If the tag was unsuccessful, an error will be raised.

name  ID of image
image  Tag to apply to the image, in repo:tag notation. If just the repository name is passed, a tag name of latest will be assumed.
force  [False] Force apply tag

CLI Example:
salt.myminion.dockerng.tag 0123456789ab myrepo/mycontainer
salt.myminion.dockerng.tag 0123456789ab myrepo/mycontainer:mytag

salt.modules.dockerng.top(name, *args, **kwargs)
Runs the docker top command on a specific container

name  Container name or ID

CLI Example:

RETURN DATA
A list of dictionaries containing information about each process

salt.myminion.dockerng.top mycontainer
salt.myminion.dockerng.top 0123456789ab

salt.modules.dockerng.unpause(*args, **kwargs)
Unpauses a container

name  Container name or ID

RETURN DATA
A dictionary will be returned, containing the following keys:

•status  - A dictionary showing the prior state of the container as well as the new state
•result  - A boolean noting whether or not the action was successful
•comment  - Only present if the container can not be unpaused

CLI Example:
salt.myminion.dockerng.pause mycontainer

salt.modules.dockerng.version()
Returns a dictionary of Docker version information. Equivalent to running the docker version Docker CLI command.

CLI Example:
salt.myminion.dockerng.version

salt.modules.dockerng.volumes(filters=None)
List existing volumes

New in version 2015.8.4.
filters
There is one available filter: dangling=true

CLI Example:

```
salt myminion dockerng.volumes filters="{'dangling': True}"```

salt.modules.dockerng.wait(name, ignore_already_stopped=False, fail_on_exit_status=False)
Wait for the container to exit gracefully, and return its exit code

Note: This function will block until the container is stopped.

name Container name or ID
ignore_already_stopped Boolean flag that prevent execution to fail, if a container is already stopped.
fail_on_exit_status Boolean flag to report execution as failure if exit_status is different than 0.

RETURN DATA
A dictionary will be returned, containing the following keys:

- **status** - A dictionary showing the prior state of the container as well as the new state
- **result** - A boolean noting whether or not the action was successful
- **exit_status** - Exit status for the container
- **comment** - Only present if the container is already stopped

CLI Example:

```
salt myminion dockerng.wait mycontainer```

32.17.72 salt.modules.dpkg

Support for DEB packages

salt.modules.dpkg.bin_pkg_info(path, saltenv='base')
New in version 2015.8.0.

Parses RPM metadata and returns a dictionary of information about the package (name, version, etc.).

path Path to the file. Can either be an absolute path to a file on the minion, or a salt fileserver URL (e.g. salt://path/to/file.rpm). If a salt fileserver URL is passed, the file will be cached to the minion so that it can be examined.

saltenv [base] Salt fileserver environment from which to retrieve the package. Ignored if path is a local file path on the minion.

CLI Example:

```
salt '*' lowpkg.bin_pkg_info /root/foo-1.2.3-1ubuntu1_all.deb
salt '*' lowpkg.bin_pkg_info salt://foo-1.2.3-1ubuntu1_all.deb```

salt.modules.dpkg.file_dict(*packages)
List the files that belong to a package, grouped by package. Not specifying any packages will return a list of _every_ file on the system's package database (not generally recommended).

CLI Examples:
salt.modules.dpkg.file_list(*packages*)

List the files that belong to a package. Not specifying any packages will return a list of _every_ file on the system's package database (not generally recommended).

CLI Examples:

```
salt '*' lowpkg.file_list httpd
salt '*' lowpkg.file_list httpd postfix
salt '*' lowpkg.file_list
```

salt.modules.dpkg.info(*packages*)

Returns a detailed summary of package information for provided package names. If no packages are specified, all packages will be returned.

packages The names of the packages for which to return information.

CLI example:

```
salt '*' lowpkg.info
salt '*' lowpkg.info apache2 bash
```

salt.modules.dpkg.list_pkgs(*packages*)

List the packages currently installed in a dict:

```
{'<package_name>': '<version>'}
```

External dependencies:

Virtual package resolution requires aptitude. Because this function uses dpkg, virtual packages will be reported as not installed.

CLI Example:

```
salt '*' lowpkg.list_pkgs
salt '*' lowpkg.list_pkgs httpd
```

salt.modules.dpkg.unpurge(*packages*)

Change package selection for each package specified to `install`

CLI Example:

```
salt '*' lowpkg.unpurge curl
```

32.17.73 salt.modules.drac

Manage Dell DRAC

salt.modules.drac.change_password(username, password, uid=None)

   Change users password

   CLI Example:
salt dell drac.change_password [USERNAME] [PASSWORD] [UID - optional]
salt dell drac.change_password diana secret

salt.modules.drac.create_user(username, password, permissions, users=None)
Create user accounts

CLI Example:
salt dell drac.create_user [USERNAME] [PASSWORD] [PRIVELEGES]
salt dell drac.create_user diana secret login,test_alerts,clear_logs

DRAC Privileges
- login: Login to iDRAC
- drac: Configure iDRAC
- user_management: Configure Users
- clear_logs: Clear Logs
- server_control_commands: Execute Server Control Commands
- console_redirection: Access Console Redirection
- virtual_media: Access Virtual Media
- test_alerts: Test Alerts
- debug_commands: Execute Debug Commands

salt.modules.drac.delete_user(username, uid=None)
Delete a user

CLI Example:
salt dell drac.delete_user [USERNAME] [UID - optional]
salt dell drac.delete_user diana 4

salt.modules.drac.email_alerts(action)
Enable/Disable email alerts

CLI Example:
salt dell drac.email_alerts True
salt dell drac.email_alerts False

salt.modules.drac.list_users()
List all DRAC users

CLI Example:
salt dell drac.list_users

salt.modules.drac.nameservers("ns")
Configure the nameservers on the DRAC

CLI Example:
salt dell drac.nameservers [NAMESERVERS]
salt dell drac.nameservers ns1.example.com ns2.example.com
salt.modules.drac.\texttt{network\_info}()  
Return Network Configuration  

CLI Example:  

```
salt dell drac.network_info
```

salt.modules.drac.\texttt{server\_hardreset}()  
Performs a reset (reboot) operation on the managed server.  

CLI Example:  

```
salt dell drac.server_hardreset
```

salt.modules.drac.\texttt{server\_poweroff}()  
Powers down the managed server.  

CLI Example:  

```
salt dell drac.server_poweroff
```

salt.modules.drac.\texttt{server\_poweron}()  
Powers up the managed server.  

CLI Example:  

```
salt dell drac.server_poweron
```

salt.modules.drac.\texttt{server\_pxe}()  
Configure server to PXE perform a one off PXE boot  

CLI Example:  

```
salt dell drac.server_pxe
```

salt.modules.drac.\texttt{server\_reboot}()  
Issues a power-cycle operation on the managed server. This action is similar to pressing the power button on the system's front panel to power down and then power up the system.  

CLI Example:  

```
salt dell drac.server_reboot
```

salt.modules.drac.\texttt{set\_network}(ip, netmask, gateway)  
Configure Network  

CLI Example:  

```
salt dell drac.set_network [DRAC IP] [NETMASK] [GATEWAY]  
salt dell drac.set_network 192.168.0.2 255.255.255.0 192.168.0.1
```

salt.modules.drac.\texttt{set\_permissions}(username, permissions, uid=None)  
Configure users permissions  

CLI Example:  

```
salt dell drac.set_permissions [USERNAME] [PRIVELEGES] [USER INDEX - optional]  
salt dell drac.set_permissions diana login,test_alerts,clear_logs 4
```

**DRAC Privileges**
- login: Login to iDRAC
- drac: Configure iDRAC
- user_management: Configure Users
- clear_logs: Clear Logs
- server_control_commands: Execute Server Control Commands
- console_redirection: Access Console Redirection
- virtual_media: Access Virtual Media
- test_alerts: Test Alerts
- debug_commands: Execute Debug Commands

**salt.modules.drac.set_snmp**(community)
Configure SNMP community string

CLI Example:
```
salt dell drac.set_snmp [COMMUNITY]
salt dell drac.set_snmp public
```

**salt.modules.drac.syslog**(server, enable=True)
Configure syslog remote logging, by default syslog will automatically be enabled if a server is specified. However, if you want to disable syslog you will need to specify a server followed by False

CLI Example:
```
salt dell drac.syslog [SYSLOG IP] [ENABLE/DISABLE]
salt dell drac.syslog 0.0.0.0 False
```

**salt.modules.drac.system_info()**
Return System information

CLI Example:
```
salt dell drac.system_info
```

### 32.17.74 salt.modules.dracr

Manage Dell DRAC.

New in version 2015.8.2.

**salt.modules.dracr.bare_rac_cmd**(cmd, host=None, admin_username=None, admin_password=None)

**salt.modules.dracr.change_password**(username, password, uid=None, host=None, admin_username=None, admin_password=None, module=None)

Change user's password

CLI Example:
```
salt dell dracr.change_password [USERNAME] [PASSWORD] uid=[OPTIONAL]
  host=<remote DRAC> admin_username=<DRAC user>
  admin_password=<DRAC PW>
salt dell dracr.change_password diana secret
```
Note that if only a username is specified then this module will look up details for all 16 possible DRAC users. This is time consuming, but might be necessary if one is not sure which user slot contains the one you want. Many late-model Dell chassis have 'root' as UID 1, so if you can depend on that then setting the password is much quicker. Raises an error if the supplied password is greater than 20 chars.

```python
salt.modules.dracr.create_user(username, password, permissions, users=None, host=None, admin_username=None, admin_password=None)
```

Create user accounts

CLI Example:

```bash
salt dell dracr.create_user [USERNAME] [PASSWORD] [PRIVELEGES]
salt dell dracr.create_user diana secret login,test_alerts,clear_logs
```

**DRAC Privileges**

- login: Login to iDRAC
- drac: Configure iDRAC
- user_management: Configure Users
- clear_logs: Clear Logs
- server_control_commands: Execute Server Control Commands
- console_redirection: Access Console Redirection
- virtual_media: Access Virtual Media
- test_alerts: Test Alerts
- debug_commands: Execute Debug Commands

```python
salt.modules.dracr.delete_user(username, uid=None, host=None, admin_username=None, admin_password=None)
```

Delete a user

CLI Example:

```bash
salt dell dracr.delete_user [USERNAME] [UID - optional]
salt dell dracr.delete_user diana 4
```

```python
salt.modules.dracr.deploy_password(username, password, host=None, admin_username=None, admin_password=None, module=None)
```

Change the QuickDeploy password, used for switches as well

CLI Example:

```bash
salt dell dracr.deploy_password [USERNAME] [PASSWORD] [PRIVELEGES]
    host=<remote DRAC> admin_username=<DRAC user> admin_password=<DRAC PW>
salt dell dracr.change_password diana secret
```

Note that if only a username is specified then this module will look up details for all 16 possible DRAC users. This is time consuming, but might be necessary if one is not sure which user slot contains the one you want. Many late-model Dell chassis have 'root' as UID 1, so if you can depend on that then setting the password is much quicker.
CLI Example:

```bash
salt dell dracr.deploy_snmp SNMP_STRING
    host=<remote DRAC or CMC> admin_username=<DRAC user>
    admin_password=<DRAC PW>
salt dell dracr.deploy_password diana secret
```

```
salt.modules.dracr.email_alerts(action, host=None, admin_username=None, admin_password=None)
Enable/Disable email alerts
```

CLI Example:

```bash
salt dell dracr.email_alerts True
salt dell dracr.email_alerts False
```

```
salt.modules.dracr.get_chassis_datacenter(host=None, admin_username=None, admin_password=None)
Get the datacenter of the chassis.
```

host The chassis host.

admin_username The username used to access the chassis.

admin_password The password used to access the chassis.

CLI Example:

```bash
salt '*' dracr.set_chassis_location host=111.222.333.444
    admin_username=root admin_password=secret
```

```
salt.modules.dracr.get_chassis_location(host=None, admin_username=None, admin_password=None)
Get the location of the chassis.
```

host The chassis host.

admin_username The username used to access the chassis.

admin_password The password used to access the chassis.

CLI Example:

```bash
salt '*' dracr.set_chassis_location host=111.222.333.444
    admin_username=root admin_password=secret
```

```
salt.modules.dracr.get_chassis_name(host=None, admin_username=None, admin_password=None)
Get the name of a chassis.
```

host The chassis host.

admin_username The username used to access the chassis.

admin_password The password used to access the chassis.

CLI Example:

```bash
salt '*' dracr.get_chassis_name host=111.222.333.444
    admin_username=root admin_password=secret
```

```
salt.modules.dracr.get_dns_dracname(host=None, admin_username=None, admin_password=None)
```

32.17. Full list of builtin execution modules 941
salt.modules.dracr.get_general(cnf_sec, cnf_var, host=None, admin_username=None, admin_password=None)
salt.modules.dracr.get_slotname(slot, host=None, admin_username=None, admin_password=None)

Get the name of a slot number in the chassis.

slot  The number of the slot for which to obtain the name.

host  The chassis host.

admin_username  The username used to access the chassis.

admin_password  The password used to access the chassis.

CLI Example:
```
salt-call --local dracr.get_slotname 0 host=111.222.333.444
   admin_username=root admin_password=secret
```
	salt.modules.dracr.idrac_general(blade_name, command, idrac_password=None, host=None, admin_username=None, admin_password=None)

Run a generic racadm command against a particular blade in a chassis. Blades are usually named things like `server-1', `server-2', etc. If the iDRAC has a different password than the CMC, then you can pass it with the idrac_password kwarg.

Parameters

- **blade_name** -- Name of the blade to run the command on
- **command** -- Command like to pass to racadm
- **idrac_password** -- Password for the iDRAC if different from the CMC
- **host** -- Chassis hostname
- **admin_username** -- CMC username
- **admin_password** -- CMC password

Returns  stdout if the retcode is 0, otherwise a standard cmd.run_all dictionary

CLI Example:
```
salt fx2 chassis.cmd idrac_general server-1 'get BIOS.SysProfileSettings'
```
	salt.modules.dracr.inventory(host=None, admin_username=None, admin_password=None)
	salt.modules.dracr.list_slotnames(host=None, admin_username=None, admin_password=None)

List the names of all slots in the chassis.

host  The chassis host.

admin_username  The username used to access the chassis.

admin_password  The password used to access the chassis.

CLI Example:
```
salt-call --local dracr.list_slotnames host=111.222.333.444
   admin_username=root admin_password=secret
```
	salt.modules.dracr.list_users(host=None, admin_username=None, admin_password=None, module=None)

List all DRAC users

942  Chapter 32. Reference
CLI Example:
salt dell dracr.list_users

```
salt.modules.dracr.nameservers(ns, host=None, admin_username=None, admin_password=None, module=None)
```
Configure the nameservers on the DRAC

CLI Example:
```
salt dell dracr.nameservers [NAMESERVERS]
salt dell dracr.nameservers ns1.example.com ns2.example.com
    admin_username=root admin_password=calvin module=server-1
    host=192.168.1.1
```

```
salt.modules.dracr.network_info(host=None, admin_username=None, admin_password=None, module=None)
```
Return Network Configuration

CLI Example:
salt dell dracr.network_info

```
salt.modules.dracr.server_hardreset(host=None, admin_username=None, admin_password=None, module=None)
```
Performs a reset (reboot) operation on the managed server.

- **host**: The chassis host.
- **admin_username**: The username used to access the chassis.
- **admin_password**: The password used to access the chassis.
- **module**: The element to hard reset on the chassis such as a blade. If not provided, the chassis will be reset.

CLI Example:
```
salt dell dracr.server_hardreset
salt dell dracr.server_hardreset module=server-1
```

```
salt.modules.dracr.server_power(status, host=None, admin_username=None, admin_password=None, module=None)
```
status One of `powerup', `powerdown', `powercycle', `hardreset', `graceshutdown'

- **host**: The chassis host.
- **admin_username**: The username used to access the chassis.
- **admin_password**: The password used to access the chassis.
- **module**: The element to reboot on the chassis such as a blade. If not provided, the chassis will be rebooted.

CLI Example:
```
salt dell dracr.server_reboot
salt dell dracr.server_reboot module=server-1
```

```
salt.modules.dracr.server_poweroff(host=None, admin_username=None, admin_password=None, module=None)
```
Power off the managed server.

- **host**: The chassis host.
admin_username  The username used to access the chassis.
admin_password  The password used to access the chassis.
module  The element to power off on the chassis such as a blade. If not provided, the chassis will be powered off.

CLI Example:

```
salt dell dracr.server_poweroff
salt dell dracr.server_poweroff module=server-1
```

class=server_poweron

Powers up the managed server.

host  The chassis host.
admin_username  The username used to access the chassis.
admin_password  The password used to access the chassis.
module  The element to power on located on the chassis such as a blade. If not provided, the chassis will be powered on.

CLI Example:

```
salt dell dracr.server_poweron
salt dell dracr.server_poweron module=server-1
```

class=server_powerstatus

return the power status for the passed module

CLI Example:

```
salt dell dracr.server_powerstatus
```

class=server_pxe

Configure server to PXE perform a one off PXE boot

CLI Example:

```
salt dell dracr.server_pxe
```

class=server_reboot

Issues a power-cycle operation on the managed server. This action is similar to pressing the power button on the system’s front panel to power down and then power up the system.

host  The chassis host.
admin_username  The username used to access the chassis.
admin_password  The password used to access the chassis.
module  The element to reboot on the chassis such as a blade. If not provided, the chassis will be rebooted.

CLI Example:

```
salt dell dracr.server_reboot
salt dell dracr.server_reboot module=server-1
```
salt.modules.dracr.set_chassis_datacenter(location, host=None, admin_username=None, admin_password=None)

Set the location of the chassis.

location The name of the datacenter to be set on the chassis.
host The chassis host.
admin_username The username used to access the chassis.
admin_password The password used to access the chassis.

CLI Example:

```
salt '*' dracr.set_chassis_datacenter datacenter-name host=111.222.333.444 admin_username=root admin_password=secret
```

salt.modules.dracr.set_chassis_location(location, host=None, admin_username=None, admin_password=None)

Set the location of the chassis.

location The name of the location to be set on the chassis.
host The chassis host.
admin_username The username used to access the chassis.
admin_password The password used to access the chassis.

CLI Example:

```
salt '*' dracr.set_chassis_location location-name host=111.222.333.444 admin_username=root admin_password=secret
```

salt.modules.dracr.set_chassis_name(name, host=None, admin_username=None, admin_password=None)

Set the name of the chassis.

name The name to be set on the chassis.
host The chassis host.
admin_username The username used to access the chassis.
admin_password The password used to access the chassis.

CLI Example:

```
salt '*' dracr.set_chassis_name my-chassis host=111.222.333.444 admin_username=root admin_password=secret
```

salt.modules.dracr.set_dns_dracname(name, host=None, admin_username=None, admin_password=None)

salt.modules.dracr.set_general(cfg_sec, cfg_var, val, host=None, admin_username=None, admin_password=None)

salt.modules.dracr.set_network(ip, netmask, gateway, host=None, admin_username=None, admin_password=None)

Configure Network on the CMC or individual iDRAC. Use set_niccfg for blade and switch addresses.

CLI Example:
salt dell dracr.set_network [DRAC IP] [NETMASK] [GATEWAY]
salt dell dracr.set_network 192.168.0.2 255.255.255.0 192.168.0.1
   admin_username=root admin_password=calvin host=192.168.1.1

salt.modules.dracr.set_niccfg(ip=None, netmask=None, gateway=None, dhcp=False, host=None, admin_username=None, admin_password=None, module=None)
salt.modules.dracr.set_nicvlan(vlan=None, host=None, admin_username=None, admin_password=None, module=None)
salt.modules.dracr.set_permissions(username, permissions, uid=None, host=None, admin_username=None, admin_password=None)

Configure users permissions

CLI Example:
salt dell dracr.set_permissions [USERNAME] [PRIVELEGES]
   [USER INDEX - optional]
salt dell dracr.set_permissions diana login,test_alerts,clear_logs 4

**DRAC Privileges**

- **login**: Login to iDRAC
- **drac**: Configure iDRAC
- **user_management**: Configure Users
- **clear_logs**: Clear Logs
- **server_control_commands**: Execute Server Control Commands
- **console_redirection**: Access Console Redirection
- **virtual_media**: Access Virtual Media
- **test_alerts**: Test Alerts
- **debug_commands**: Execute Debug Commands

salt.modules.dracr.set_slotname(slot, name, host=None, admin_username=None, admin_password=None)

Set the name of a slot in a chassis.

- **slot**: The slot number to change.
- **name**: The name to set. Can only be 15 characters long.
- **host**: The chassis host.
- **admin_username**: The username used to access the chassis.
- **admin_password**: The password used to access the chassis.

CLI Example:
salt '*' dracr.set_slotname 2 my-slotname host=111.222.333.444
   admin_username=root admin_password=secret

salt.modules.dracr.set_snmp(community, host=None, admin_username=None, admin_password=None)

Configure CMC or individual iDRAC SNMP community string. Use `deploy_snmp` for configuring chassis switch SNMP.
CLI Example:

```
salt dell dracr.set_snmp [COMMUNITY]
salt dell dracr.set_snmp public
```

```
salt.modules.dracr.syslog(server, enable=True, host=None, admin_username=None, admin_password=None, module=None)
```

Configure syslog remote logging, by default syslog will automatically be enabled if a server is specified. However, if you want to disable syslog you will need to specify a server followed by False

CLI Example:

```
salt dell dracr.syslog [SYSLOG IP] [ENABLE/DISABLE]
salt dell dracr.syslog 0.0.0.0 False
```

```
salt.modules.dracr.system_info(host=None, admin_username=None, admin_password=None, module=None)
```

Return System information

CLI Example:

```
salt dell dracr.system_info
```

```
salt.modules.dracr.update_firmware(filename, host=None, admin_username=None, admin_password=None, module=None)
```

Updates firmware using local firmware file

This executes the following command on your FX2 (using username and password stored in the pillar data)

```
racadm update -f firmware.exe -u user –p pass
```

```
salt.modules.dracr.update_firmware_nfs_or_cifs(filename, share, host=None, admin_username=None, admin_password=None)
```

Executes the following for CIFS (using username and password stored in the pillar data)

```
racadm update -f <updatefile> -u user –p pass -l //IP-Address/share
```

Or for NFS (using username and password stored in the pillar data)

```
racadm update -f <updatefile> -u user –p pass -l IP-address:/share
```

Salt command for CIFS:

```
salt dell dracr.update_firmware_nfs_or_cifs firmware.exe //IP-Address/!
```

Salt command for NFS:

```
salt dell dracr.update_firmware_nfs_or_cifs firmware.exe IP-address:/share
```

32.17.75 salt.modules.drbd

DRBD administration module
salt.modules.drbd.overview()
    Show status of the DRBD devices
    CLI Example:
    ```
    salt '*' drbd.overview
    ```

32.17.76 salt.modules.ebuild

Support for Portage

Important: If you feel that Salt should be using this module to manage packages on a minion, and it is using a
different module (or gives an error similar to `pkg.install' is not available), see here.

optdepends
    • portage Python adapter

For now all package names MUST include the package category, i.e. 'vim' will not work, 'app-editors/vim'
will.

salt.modules.ebuild.check_db(*names, **kwargs)
    New in version 0.17.0.
    Returns a dict containing the following information for each specified package:
    1. A key `found`, which will be a boolean value denoting if a match was found in the package database.
    2. If `found` is False, then a second key called `suggestions` will be present, which will contain a list
       of possible matches. This list will be empty if the package name was specified in category/pkgname
       format, since the suggestions are only intended to disambiguate ambiguous package names (ones sub-
       mitted without a category).

    CLI Examples:
    ```
    salt '*' pkg.check_db <package1> <package2> <package3>
    ```

salt.modules.ebuild.check_extra_requirements(pkgname, pkgver)
    Check if the installed package already has the given requirements.
    CLI Example:
    ```
    salt '*' pkg.check_extra_requirements 'sys-devel/gcc' '^>4.1.2:4.1::
        ~gentoo[nls,fortran]'
    ```

salt.modules.ebuild.depclean(name=None, slot=None, fromrepo=None, pkgs=None)
    Portage has a function to remove unused dependencies. If a package is provided, it will only removed the
    package if no other package depends on it.
    name  The name of the package to be cleaned.
    slot  Restrict the remove to a specific slot. Ignored if name is None.
    fromrepo  Restrict the remove to a specific slot. Ignored if name is None.
    pkgs  Clean multiple packages. slot and fromrepo arguments are ignored if this argument is present. Must
          be passed as a python list.
Return a list containing the removed packages:

CLI Example:

```
salt '* pkg.depclean <package name>
```

salt.modules.ebuild.ex_mod_init(low)

If the config option `ebuild.enforce_nice_config` is set to True, this module will enforce a nice tree structure for /etc/portage/package.* configuration files.

New in version 0.17.0: Initial automatic enforcement added when pkg is used on a Gentoo system.

Changed in version 2014.1.0-Hydrogen: Configure option added to make this behaviour optional, defaulting to off.

See also:

- `ebuild.ex_mod_init` is called automatically when a state invokes a pkg state on a Gentoo system.
- `salt.states.pkg.mod_init()`
- `salt.modules.portage_config.enforce_nice_config()`

CLI Example:

```
salt '* pkg.ex_mod_init
```

salt.modules.ebuild.install(name=None, refresh=False, pkgs=None, sources=None, version=None, slot=None, fromrepo=None, binhost=None, **kwargs)

Changed in version 2015.8.12,2016.3.3,Carbon: On minions running systemd>=205, `systemd-run(1)` is now used to isolate commands which modify installed packages from the `salt-minion` daemon's control group. This is done to keep systemd from killing any emerge commands spawned by Salt when the `salt-minion` service is restarted. (see `KillMode` in the `systemd.kill(5)` manpage for more information). If desired, usage of `systemd-run(1)` can be suppressed by setting a `config option` called `systemd.scope`, with a value of `False` (no quotes).

Install the passed package(s), add `refresh=True` to sync the portage tree before package is installed.

- **name** The name of the package to be installed. Note that this parameter is ignored if either ``pkgs`` or ``sources`` is passed. Additionally, please note that this option can only be used to emerge a package from the portage tree. To install a tbz2 package manually, use the ``sources`` option described below.

CLI Example:

```
salt '* pkg.install <package name>
```

- **refresh** Whether or not to sync the portage tree before installing.
- **version** Install a specific version of the package, e.g. 1.0.9-r1. Ignored if ``pkgs`` or ``sources`` is passed.
- **slot** Similar to version, but specifies a valid slot to be installed. It will install the latest available version in the specified slot. Ignored if ``pkgs`` or ``sources`` or ``version`` is passed.

CLI Example:

```
salt '*' pkg.install sys-devel/gcc slot='4.4'
```

- **fromrepo** Similar to slot, but specifies the repository from the package will be installed. It will install the latest available version in the specified repository. Ignored if ``pkgs`` or ``sources`` or ``version`` is passed.

CLI Example:
uses  Similar to slot, but specifies a list of use flag. Ignored if ``pkgs'' or ``sources'' or ``version'' is passed.

CLI Example:

```
salt '*' pkg.install sys-devel/gcc uses=['"nptl","-nossp"]'
```

Multiple Package Installation Options:

**pkgs**  A list of packages to install from the portage tree. Must be passed as a python list.

CLI Example:

```
salt '*' pkg.install pkgs=['"foo","bar","~category/package:slot::repository[use]"
```

**sources**  A list of tbz2 packages to install. Must be passed as a list of dicts, with the keys being package names, and the values being the source URI or local path to the package.

CLI Example:

```
salt '*' pkg.install sources='[{"foo": "salt://foo.tbz2"},{"bar": "salt://bar.tbz2"}]'
```

**binhost**  has two options try and force. try - tells emerge to try and install the package from a configured binhost. force - forces emerge to install the package from a binhost otherwise it fails out.

Returns a dict containing the new package names and versions:

```
{
'<package>': {
'old': '<old-version>',
'new': '<new-version>'
}
```

salt.modules.ebuild.latest_version(names, **kwargs)

Return the latest version of the named package available for upgrade or installation. If more than one package name is specified, a dict of name/version pairs is returned.

CLI Example:

```
salt '*' pkg.latest_version <package name>
```

salt.modules.ebuild.list_pkgs(versions_as_list=False, **kwargs)

List the packages currently installed in a dict:

```
{
'<package_name>': '<version>'
```

CLI Example:

```
salt '*' pkg.list_pkgs
```

salt.modules.ebuild.list_upgrades(refresh=True, backtrack=3, **kwargs)

List all available package upgrades.

**refresh**  Whether or not to sync the portage tree before checking for upgrades.

**backtrack**  Specifies an integer number of times to backtrack if dependency calculation fails due to a conflict or an unsatisfied dependency (default: '3').

CLI Example:
salt '*' pkg.list_upgrades

salt.modules.ebuild.porttree_matches(name)
Returns a list containing the matches for a given package name from the portage tree. Note that the specific version of the package will not be provided for packages that have several versions in the portage tree, but rather the name of the package (i.e. `dev-python/paramiko`).

salt.modules.ebuild.purge(name=None, slot=None, fromrepo=None, pkgs=None, **kwargs)
Changed in version 2015.8.12, 2016.3.3, Carbon: On minions running systemd>=205, systemd-run(1) is now used to isolate commands which modify installed packages from the salt-minion daemon's control group. This is done to keep systemd from killing any emerge commands spawned by Salt when the salt-minion service is restarted. (see KillMode in the systemd.kill(5) manpage for more information). If desired, usage of systemd-run(1) can be suppressed by setting a config option called systemd.scope, with a value of False (no quotes).

Portage does not have a purge, this function calls remove followed by depclean to emulate a purge process

name The name of the package to be deleted.
slot Restrict the remove to a specific slot. Ignored if name is None.
fromrepo Restrict the remove to a specific slot. Ignored if name is None.

Multiple Package Options:

pkgs Uninstall multiple packages. slot and fromrepo arguments are ignored if this argument is present. Must be passed as a python list.

New in version 0.16.0.

Returns a dict containing the changes.

CLI Example:

```
salt '*' pkg.purge <package name>
salt '*' pkg.purge <package name> slot=4.4
salt '*' pkg.purge <package1>, <package2>, <package3>
salt '*' pkg.purge pkgs=
```

salt.modules.ebuild.refresh_db() Updates the portage tree (emerge --sync). Uses eix-sync if available.

CLI Example:

```
salt '*' pkg.refresh_db
```

salt.modules.ebuild.remove(name=None, slot=None, fromrepo=None, pkgs=None, **kwargs)
Changed in version 2015.8.12, 2016.3.3, Carbon: On minions running systemd>=205, systemd-run(1) is now used to isolate commands which modify installed packages from the salt-minion daemon's control group. This is done to keep systemd from killing any emerge commands spawned by Salt when the salt-minion service is restarted. (see KillMode in the systemd.kill(5) manpage for more information). If desired, usage of systemd-run(1) can be suppressed by setting a config option called systemd.scope, with a value of False (no quotes).

Remove packages via emerge --unmerge.

name The name of the package to be deleted.
slot Restrict the remove to a specific slot. Ignored if name is None.
fromrepo Restrict the remove to a specific slot. Ignored if name is None.
Multiple Package Options:

- **pkgs** Uninstall multiple packages. `slot` and `fromrepo` arguments are ignored if this argument is present. Must be passed as a python list.

New in version 0.16.0.

Returns a dict containing the changes.

CLI Example:

```bash
salt '*' pkg.remove <package name>
salt '*' pkg.remove <package name> slot=4.4 fromrepo=gentoo
salt '*' pkg.remove <package1>,<package2>,<package3>
salt '*' pkg.remove pkgs='["foo", "bar"]'
```

**salt.modules.ebuild.update** (*pkg, slot=None, fromrepo=None, refresh=False, binhost=None*)

Changed in version 2015.8.12, 2016.3.3, Carbon: On minions running systemd>=205, `systemd-run(1)` is now used to isolate commands which modify installed packages from the salt-minion daemon's control group. This is done to keep systemd from killing any emerge commands spawned by Salt when the salt-minion service is restarted. (see `KillMode` in the `systemd.kill(5)` manpage for more information). If desired, usage of `systemd-run(1)` can be suppressed by setting a config option called `systemd.scope`, with a value of `False` (no quotes).

Updates the passed package (`emerge --update package`) that has been provided.

- **slot** Restrict the update to a particular slot. It will update to the latest version within the slot.

- **fromrepo** Restrict the update to a particular repository. It will update to the latest version within the repository.

- **binhost** has two options try and force. try - tells emerge to try and install the package from a configured binhost. force - forces emerge to install the package from a binhost otherwise it fails out.

Return a dict containing the new package names and versions:

```python
{'<package>': {'old': '<old-version>',
              'new': '<new-version>'}}
```

CLI Example:

```bash
salt '*' pkg.update <package name>
```

**salt.modules.ebuild.upgrade** (*refresh=True, binhost=None, backtrack=3*)

Changed in version 2015.8.12, 2016.3.3, Carbon: On minions running systemd>=205, `systemd-run(1)` is now used to isolate commands which modify installed packages from the salt-minion daemon's control group. This is done to keep systemd from killing any emerge commands spawned by Salt when the salt-minion service is restarted. (see `KillMode` in the `systemd.kill(5)` manpage for more information). If desired, usage of `systemd-run(1)` can be suppressed by setting a config option called `systemd.scope`, with a value of `False` (no quotes).

Run a full system upgrade (`emerge -uDN @world`) that has been provided.

- **binhost** has two options try and force. try - tells emerge to try and install the package from a configured binhost. force - forces emerge to install the package from a binhost otherwise it fails out.

- **backtrack** Specifies an integer number of times to backtrack if dependency calculation fails due to a conflict or an unsatisfied dependency (default: 3).

Return a dict containing the new package names and versions:

```python
{'<package>': {'old': '<old-version>',
              'new': '<new-version>'}}
```
{'<package>': {'old': '<old-version>',
              'new': '<new-version>'}}

CLI Example:
salt '*' pkg.upgrade

salt.modules.ebuild.upgrade_available(name)
Check whether or not an upgrade is available for a given package

CLI Example:
salt '*' pkg.upgrade_available <package name>

salt.modules.ebuild.version(*names, **kwargs)
Returns a string representing the package version or an empty string if not installed. If more than one package name is specified, a dict of name/version pairs is returned.

CLI Example:
salt '*' pkg.version <package name>
salt '*' pkg.version <package1> <package2> <package3> ...

salt.modules.ebuild.version_clean(version)
Clean the version string removing extra data.

CLI Example:
salt '*' pkg.version_clean <version_string>

salt.modules.ebuild.version_cmp(pkg1, pkg2, **kwargs)
Do a cmp-style comparison on two packages. Return -1 if pkg1 < pkg2, 0 if pkg1 == pkg2, and 1 if pkg1 > pkg2. Return None if there was a problem making the comparison.

CLI Example:
salt '*' pkg.version_cmp '0.2.4-0' '0.2.4.1-0'

32.17.77 salt.modules.eix

Support for Eix

salt.modules.eix.sync()
Sync portage/overlay trees and update the eix database

CLI Example:
salt '*' eix.sync

salt.modules.eix.update()
Update the eix database

CLI Example:
salt '*' eix.update

32.17. Full list of builtin execution modules
32.17.78 salt.modules.elasticsearch

Elasticsearch - A distributed RESTful search and analytics server

Module to provide Elasticsearch compatibility to Salt (compatible with Elasticsearch version 1.5.2+)

New in version 2015.8.0.

depends elasticsearch-py

configuration This module accepts connection configuration details either as parameters or as configuration settings in /etc/salt/minion on the relevant minions:

```
elasticsearch:
  host: '10.10.10.100:9200'
elasticsearch:
  hosts:
  - '10.10.10.100:9200'
  - '10.10.10.101:9200'
  - '10.10.10.102:9200'
elasticsearch:
  hosts:
  - '10.10.10.100:9200'
  number_of_shards: 1
  number_of_replicas: 0
  functions_blacklist:
  - 'saltutil.find_job'
  - 'pillar.items'
  - 'grains.items'
```

This data can also be passed into pillar. Options passed into opts will overwrite options passed into pillar.

salt.modules.elasticsearch.alias_create(indices, alias, hosts=None, body=None, profile=None)

Create an alias for a specific index/indices

CLI example:
```
salt myminion elasticsearch.alias_create testindex_v1 testindex
```

salt.modules.elasticsearch.alias_delete(indices, aliases, hosts=None, body=None, profile=None)

Delete an alias of an index

CLI example:
```
salt myminion elasticsearch.alias_delete testindex_v1 testindex
```

salt.modules.elasticsearch.alias_exists(aliases, indices=None, hosts=None, profile=None)

Return a boolean indicating whether given alias exists

CLI example:
```
salt myminion elasticsearch.alias_exists testindex
```

salt.modules.elasticsearch.alias_get(indices=None, aliases=None, hosts=None, profile=None)

Check for the existence of an alias and if it exists, return it
CLI example:
```
salt myminion elasticsearch.alias_get testindex
```

```
salt.modules.elasticsearch.document_create(index, doc_type, body=None, id=None, hosts=None, profile=None)
```
Create a document in a specified index

CLI example:
```
salt myminion elasticsearch.document_create testindex doctype1 '{}'
```

```
salt.modules.elasticsearch.document_delete(index, doc_type, id, hosts=None, profile=None)
```
Delete a document from an index

CLI example:
```
salt myminion elasticsearch.document_delete testindex doctype1 AUx-384m0Bug_8U80wQZ
```

```
salt.modules.elasticsearch.document_exists(index, id, doc_type='_all', hosts=None, profile=None)
```
Return a boolean indicating whether given document exists

CLI example:
```
salt myminion elasticsearch.document_exists testindex AUx-384m0Bug_8U80wQZ
```

```
salt.modules.elasticsearch.document_get(index, id, doc_type='_all', hosts=None, profile=None)
```
Check for the existence of a document and if it exists, return it

CLI example:
```
salt myminion elasticsearch.document_get testindex AUx-384m0Bug_8U80wQZ
```

```
salt.modules.elasticsearch.index_create(index, body=None, hosts=None, profile=None)
```
Create an index

CLI example:
```
salt myminion elasticsearch.index_create testindex
```

```
salt.modules.elasticsearch.index_delete(index, hosts=None, profile=None)
```
Delete an index

CLI example:
```
salt myminion elasticsearch.index_delete testindex
```

```
salt.modules.elasticsearch.index_exists(index, hosts=None, profile=None)
```
Return a boolean indicating whether given index exists

CLI example:
```
salt myminion elasticsearch.index_exists testindex
```

```
salt.modules.elasticsearch.index_get(index, hosts=None, profile=None)
```
Check for the existence of an index and if it exists, return it

CLI example:
salt myminion elasticsearch.index_get testindex

salt.modules.elasticsearch.index_template_create(name, body, hosts=None, profile=None)

Create an index template

CLI example:

```
salt myminion elasticsearch.index_template_create testindex_templ '{ "template": "logstash-*", "order": 1, "settings": { "number_of_shards": 1 } }'
```

salt.modules.elasticsearch.index_template_delete(name, hosts=None, profile=None)

Delete an index template (type) along with its data

CLI example:

```
salt myminion elasticsearch.index_template_delete testindex_templ user
```

salt.modules.elasticsearch.index_template_exists(name, hosts=None, profile=None)

Return a boolean indicating whether given index template exists

CLI example:

```
salt myminion elasticsearch.index_template_exists testindex_templ
```

salt.modules.elasticsearch.index_template_get(name, hosts=None, profile=None)

Retrieve template definition of index or index/type

CLI example:

```
salt myminion elasticsearch.index_template_get testindex_templ user
```

salt.modules.elasticsearch.mapping_create(index, doc_type, body, hosts=None, profile=None)

Create a mapping in a given index

CLI example:

```
salt myminion elasticsearch.mapping_create testindex user '{ "user": { "properties": { "message": { "type": "string", "store": true } } } }'
```

salt.modules.elasticsearch.mapping_delete(index, doc_type, hosts=None, profile=None)

Delete a mapping (type) along with its data

CLI example:

```
salt myminion elasticsearch.mapping_delete testindex user
```

salt.modules.elasticsearch.mapping_get(index, doc_type, hosts=None, profile=None)

Retrieve mapping definition of index or index/type

CLI example:

```
salt myminion elasticsearch.mapping_get testindex user
```

32.17.79 salt.modules.environ

Support for getting and setting the environment variables of the current salt process.
salt.modules.environ.get(key, default='')
Get a single salt process environment variable.

key  String used as the key for environment lookup.

default  If the key is not found in the environment, return this value. Default: ''

CLI Example:
```
salt '*' environ.get foo
salt '*' environ.get baz default=False
```

salt.modules.environ.has_value(key, value=None)
Determine whether the key exists in the current salt process environment dictionary. Optionally compare the
current value of the environment against the supplied value string.

key  Must be a string. Used as key for environment lookup.

value:  Optional. If key exists in the environment, compare the current value with this value. Return True if
they are equal.

CLI Example:
```
salt '*' environ.has_value foo
```

salt.modules.environ.item(keys, default='')
Get one or more salt process environment variables. Returns a dict.

keys  Either a string or a list of strings that will be used as the keys for environment lookup.

default  If the key is not found in the environment, return this value. Default: ''

CLI Example:
```
salt '*' environ.item foo
salt '*' environ.item ['foo', 'baz'] default=None
```

salt.modules.environ.items()
Return a dict of the entire environment set for the salt process

CLI Example:
```
salt '*' environ.items
```

salt.modules.environ.setenv(environ, false_unsets=False, clear_all=False, update_minion=False)
Set multiple salt process environment variables from a dict. Returns a dict.

environ  Must be a dict. The top-level keys of the dict are the names of the environment variables to set. Each
key's value must be a string or False. Refer to the 'false_unsets' parameter for behavior when a value set
to False.

false_unsets  If a key's value is False and false_unsets is True, then the key will be removed from the salt
processes environment dict entirely. If a key's value is False and false_unsets is not True, then the key's
value will be set to an empty string. Default: False

clear_all  USE WITH CAUTION! This option can unset environment variables needed for salt to function
properly. If clear_all is True, then any environment variables not defined in the environ dict will be
deleted. Default: False

update_minion  If True, apply these environ changes to the main salt-minion process. If False, the environ
changes will only affect the current salt subprocess. Default: False
CLI Example:

```
salt '*' environ.setenv '{"foo": "bar", "baz": "quux"}"
salt '*' environ.setenv '{"a": "b", "c": False}' false_unsets=True
```

salt.modules.environ.setval(key, val, false_unsets=False)
Set a single salt process environment variable. Returns True on success.

**key** The environment key to set. Must be a string.

**val** The value to set. Must be a string or False. Refer to the `false_unsets` parameter for behavior when set to False.

**false_unsets** If val is False and false_unsets is True, then the key will be removed from the salt processes environment dict entirely. If val is False and false_unsets is not True, then the key's value will be set to an empty string. Default: False.

CLI Example:

```
salt '*' environ.setval foo bar
salt '*' environ.setval baz val=False false_unsets=True
```

### 32.17.80 salt.modules.eselect

Support for eselect, Gentoo's configuration and management tool.

salt.modules.eselect.exec_action(module, action, module_parameter=None, action_parameter=None, state_only=False)
Execute an arbitrary action on a module.

**module** name of the module to be executed

**action** name of the module's action to be run

**module_parameter** additional params passed to the defined module

**action_parameter** additional params passed to the defined action

**state_only** don't return any output but only the success/failure of the operation

CLI Example (updating the php implementation used for apache2):

```
salt '*' eselect.exec_action php update action_parameter='apache2'
```

salt.modules.eselect.get_current_target(module, module_parameter=None, action_parameter=None)
Get the currently selected target for the given module.

**module** name of the module to be queried for its current target

**module_parameter** additional params passed to the defined module

**action_parameter** additional params passed to the `show` action

CLI Example (current target of system-wide java-vm):

```
salt '*' eselect.get_current_target java-vm action_parameter='system'
```

CLI Example (current target of kernel symlink):

```
salt '*' eselect.get_current_target kernel
```
salt.modules.eeselect.get_modules()  
List available eselect modules.

CLI Example:
```
salt '*' eselect.get_modules
```

salt.modules.eeselect.get_target_list(module)  
List available targets for the given module.

module name of the module to be queried for its targets

CLI Example:
```
salt '*' eselect.get_target_list kernel
```

salt.modules.eeselect.set_target(module, target, module_parameter=None, action_parameter=None)  
Set the target for the given module. Target can be specified by index or name.

module name of the module for which a target should be set

target name of the target to be set for this module

module_parameter additional params passed to the defined module

action_parameter additional params passed to the defined action

CLI Example (setting target of system-wide java-vm):
```
salt '*' eselect.set_target java-vm icedtea-bin-7 action_parameter='system'
```

CLI Example (setting target of kernel symlink):
```
salt '*' eselect.set_target kernel linux-3.17.5-gentoo
```

32.17.81 salt.modules.esxi
Glues the VMware vSphere Execution Module to the VMware ESXi Proxy Minions to the esxi proxymodule.

New in version 2015.8.4.

Depends: vSphere Remote Execution Module (salt.modules.vsphere)

For documentation on commands that you can direct to an ESXi host via proxy, look in the documentation for salt.modules.vsphere.

This execution module calls through to a function in the ESXi proxy module called ch_config, which looks up the function passed in the command parameter in salt.modules.vsphere and calls it.

To execute commands with an ESXi Proxy Minion using the vSphere Execution Module, use the esxi.cmd <vsphere-function-name> syntax. Both args and kwargs needed for various vsphere execution module functions must be passed through in a kwarg- type manor.

```
salt 'esxi-proxy' esxi.cmd system_info
salt 'esxi-proxy' esxi.cmd get_service_policy service_name='ssh'
```

salt.modules.esxi.cmd(command, *args, **kwargs)
32.17.82  salt.modules.etcd_mod

Execution module to work with etcd

depends

- python-etcd

Configuration

To work with an etcd server you must configure an etcd profile. The etcd config can be set in either the Salt Minion configuration file or in pillar:

```
my_etd_config:
  etcd.host: 127.0.0.1
  etcd.port: 4001
```

It is technically possible to configure etcd without using a profile, but this is not considered to be a best practice, especially when multiple etcd servers or clusters are available.

```
etcd.host: 127.0.0.1
etcd.port: 4001
```

Note: The etcd configuration can also be set in the Salt Master config file, but in order to use any etcd configurations defined in the Salt Master config, the `pillar_opts` must be set to `True`.

Be aware that setting `pillar_opts` to `True` has security implications as this makes all master configuration settings available in all minion's pillars.

`salt.modules.etcd_mod.get(key, recurse=False, profile=None)`

New in version 2014.7.0.

Get a value from etcd, by direct path

CLI Examples:

```
salt myminion etcd.get /path/to/key
salt myminion etcd.get /path/to/key profile=my_etcd_config
salt myminion etcd.get /path/to/key recurse=True profile=my_etcd_config
```

`salt.modules.etcd_mod.ls(path='/', profile=None)`

New in version 2014.7.0.

Return all keys and dirs inside a specific path

CLI Example:

```
salt myminion etcd.ls /path/to/dir/
salt myminion etcd.ls /path/to/dir/ profile=my_etcd_config
```

`salt.modules.etcd_mod.rm(key, recurse=False, profile=None)`

New in version 2014.7.0.

Delete a key from etcd

CLI Example:
salt myminion etcd.rm /path/to/key
salt myminion etcd.rm /path/to/key profile=my_etcd_config
salt myminion etcd.rm /path/to/dir recurse=True profile=my_etcd_config

salt.modules.etcd_mod.set(key, value, profile=None)
New in version 2014.7.0.
Set a value in etcd, by direct path
CLI Example:
salt myminion etcd.set /path/to/key value
salt myminion etcd.set /path/to/key value profile=my_etcd_config

salt.modules.etcd_mod.tree(path=’/’, profile=None)
New in version 2014.7.0.
Recurse through etcd and return all values
CLI Example:
salt myminion etcd.tree
salt myminion etcd.tree profile=my_etcd_config
salt myminion etcd.tree /path/to/keys profile=my_etcd_config

32.17.83 salt.modules.event

Use the Salt Event System to fire events from the master to the minion and vice-versa.
salt.modules.event.fire(data, tag)
Fire an event on the local minion event bus. Data must be formed as a dict.
CLI Example:
salt '*' event.fire '{"data": "my event data"}' 'tag'

salt.modules.event.fire_master(data, tag, preload=None)
Fire an event off up to the master server
CLI Example:
salt '*' event.fire_master '{"data": "my event data"}' 'tag'

salt.modules.event.send(tag, data=None, preload=None, with_env=False, with_grains=False, with_pillar=False, **kwargs)
Send an event to the Salt Master
New in version 2014.7.0.
Parameters

- **tag** -- A tag to give the event. Use slashes to create a namespace for related events. E.g., myco/build/buildserver1/start, myco/build/buildserver1/success, myco/build/buildserver1/failure.
- **data** -- A dictionary of data to send in the event. This is free-form. Send any data points that are needed for whoever is consuming the event. Arguments on the CLI are interpreted as YAML so complex data structures are possible.
• **with_env** (Specify `True` to include all environment variables, or specify a list of strings of variable names to include.) -- Include environment variables from the current shell environment in the event data as `environ`. This is a short-hand for working with systems that seed the environment with relevant data such as Jenkins.

• **with_grains** (Specify `True` to include all grains, or specify a list of strings of grain names to include.) -- Include grains from the current minion in the event data as `grains`.

• **with_pillar** (Specify `True` to include all Pillar values, or specify a list of strings of Pillar keys to include. It is a best-practice to only specify a relevant subset of Pillar data.) -- Include Pillar values from the current minion in the event data as `pillar`. Remember Pillar data is often sensitive data so be careful. This is useful for passing ephemeral Pillar values through an event. Such as passing the `pillar={}` kwarg in `state.sls` from the Master, through an event on the Minion, then back to the Master.

• **kwargs** -- Any additional keyword arguments passed to this function will be interpreted as key-value pairs and included in the event data. This provides a convenient alternative to YAML for simple values.

CLI Example:

```
salt-call event.send myco/mytag foo=Foo bar=Bar
salt-call event.send 'myco/mytag' '{foo: Foo, bar: Bar}'
```

A convenient way to allow Jenkins to execute `salt-call` is via sudo. The following rule in sudoers will allow the jenkins user to run only the following command.

```
jenkins ALL=(ALL) NOPASSWD:SETENV: /usr/bin/salt-call event.send*
```

Call Jenkins via sudo (preserve the environment):

```
sudo -E salt-call event.send myco/jenkins/build/success with_env=[BUILD_ID, BUILD_←URL, GIT_BRANCH, GIT_COMMIT]
```

### 32.17.84 salt.modules.extfs

Module for managing ext2/3/4 file systems

**salt.modules.extfs.attributes**(device, args=None)

Return attributes from dumpe2fs for a specified device

CLI Example:

```
salt '*' extfs.attributes /dev/sda1
```

**salt.modules.extfs.blocks**(device, args=None)

Return block and inode info from dumpe2fs for a specified device

CLI Example:

```
salt '*' extfs.blocks /dev/sda1
```

**salt.modules.extfs.dump**(device, args=None)

Return all contents of dumpe2fs for a specified device

CLI Example:
**salt.modules.extfs.mkfs***(device, fs_type, **kwargs)**

Create a file system on the specified device

CLI Example:

```
salt '*' extfs.mkfs /dev/sda1 fs_type=ext4 opts='acl,noexec'
```

Valid options are:

- **block_size**: 1024, 2048 or 4096
- **check**: check for bad blocks
- **direct**: use direct IO
- **ext_opts**: extended file system options (comma-separated)
- **fragment_size**: size of fragments
- **force**: setting force to True will cause mke2fs to specify the -F option twice (it is already set once); this is truly dangerous
- **blocks_per_group**: number of blocks in a block group
- **number_of_groups**: ext4 option for a virtual block group
- **bytes_per_inode**: set the bytes/inode ratio
- **inode_size**: size of the inode
- **journal**: set to True to create a journal (default on ext3/4)
- **journal_opts**: options for the fs journal (comma separated)
- **blocks_file**: read bad blocks from file
- **label**: label to apply to the file system
- **reserved**: percentage of blocks reserved for super-user
- **last_dir**: last mounted directory
- **test**: set to True to not actually create the file system (mke2fs -n)
- **number_of_inodes**: override default number of inodes
- **creator_os**: override `"creator operating system"` field
- **opts**: mount options (comma separated)
- **revision**: set the filesystem revision (default 1)
- **super**: write superblock and group descriptors only
- **fs_type**: set the filesystem type (REQUIRED)
- **usage_type**: how the filesystem is going to be used
- **uuid**: set the UUID for the file system

See the `mke2fs(8)` manpage for a more complete description of these options.

**salt.modules.extfs.tune**(device, **kwargs)**

Set attributes for the specified device (using tune2fs)

CLI Example:
Valid options are:

- **max**: max mount count
- **count**: mount count
- **error**: error behavior
- **extended_opts**: extended options (comma separated)
- **force**: force, even if there are errors (set to True)
- **group**: group name or gid that can use the reserved blocks
- **interval**: interval between checks
- **journal**: set to True to create a journal (default on ext3/4)
- **journal_opts**: options for the fs journal (comma separated)
- **label**: label to apply to the file system
- **reserved**: percentage of blocks reserved for super-user
- **last_dir**: last mounted directory
- **opts**: mount options (comma separated)
- **feature**: set or clear a feature (comma separated)
- **mmp_check**: mmp check interval
- **reserved**: reserved blocks count
- **quota_opts**: quota options (comma separated)
- **time**: time last checked
- **user**: user or uid who can use the reserved blocks
- **uuid**: set the UUID for the file system

See the **mke2fs**(8) manpage for a more complete description of these options.

### 32.17.85 salt.modules.file

Manage information about regular files, directories, and special files on the minion, set/read user, group, mode, and data

**salt.modules.file.access**(path, mode)

New in version 2014.1.0.

Test whether the Salt process has the specified access to the file. One of the following modes must be specified:

CLI Example:

```
salt '*' file.access /path/to/file f
salt '*' file.access /path/to/file x
```

**salt.modules.file.append**(path, *args, **kwargs)

New in version 0.9.5.

Append text to the end of a file
path  path to file
*args strings to append to file

CLI Example:

```bash
salt '*' file.append /etc/motd "With all thine offerings thou shalt offer salt."
"Salt is what makes things taste bad when it isn't in them."
```

Attention

If you need to pass a string to append and that string contains an equal sign, you must include the argument name, args. For example:

```bash
salt '*' file.append /etc/motd args='cheese=spam'
salt '*' file.append /etc/motd args="['cheese=spam','spam=cheese']"
```

salt.modules.file.apply_template_on_contents(contents, template, context, defaults, saltenv)

Return the contents after applying the templating engine

contents template string

template template format

context Overrides default context variables passed to the template.

defaults Default context passed to the template.

CLI Example:

```bash
salt '*' file.apply_template_on_contents
    contents='This is a {{ template }} string.'
    template=jinja
    "context={}" "defaults={'template': 'cool'}"
    saltenv=base
```

salt.modules.file.basename(path)

Returns the final component of a pathname

New in version 2015.5.0.

This can be useful at the CLI but is frequently useful when scripting.

```python
{% set filename = salt['file.basename'](source_file) %}
```

CLI Example:

```bash
salt '*' file.basename 'test/test.config'
```

salt.modules.file.blockreplace(path, marker_start='#-- start managed zone --', marker_end='#-- end managed zone --', content='', append_if_not_found=False, prepend_if_not_found=False, backup='.bak', dry_run=False, show_changes=True)

New in version 2014.1.0.

Replace content of a text block in a file, delimited by line markers
A block of content delimited by comments can help you manage several lines entries without worrying about old entries removal.

**Note:** This function will store two copies of the file in-memory (the original version and the edited version) in order to detect changes and only edit the targeted file if necessary.

- **path**  
  Filesistem path to the file to be edited

- **marker_start**  
  The line content identifying a line as the start of the content block. Note that the whole line containing this marker will be considered, so whitespace or extra content before or after the marker is included in final output

- **marker_end**  
  The line content identifying a line as the end of the content block. Note that the whole line containing this marker will be considered, so whitespace or extra content before or after the marker is included in final output

- **content**  
  The content to be used between the two lines identified by marker_start and marker_stop.

- **append_if_not_found**  
  [False] If markers are not found and set to True then, the markers and content will be appended to the file.

- **prepend_if_not_found**  
  [False] If markers are not found and set to True then, the markers and content will be prepended to the file.

- **backup**  
  The file extension to use for a backup of the file if any edit is made. Set to False to skip making a backup.

- **dry_run**  
  Don’t make any edits to the file.

- **show_changes**  
  Output a unified diff of the old file and the new file. If False, return a boolean if any changes were made.

**CLI Example:**

```
salt '*' file.blockreplace /etc/hosts '
#-- start managed zone foobar : DO NOT\ 
   EDIT --'
#-- end managed zone foobar --'
10.0.1.1 foo.foobar
10.0.1.2 bar.foobar'
True
```

**salt.modules.file.check_file_meta** *(name, sfn, source, source_sum, user, group, mode, saltenv, contents=None)*

Check for the changes in the file metadata.

**CLI Example:**

```
salt '*' file.check_file_meta /etc/httpd/conf.d/httpd.conf salt://httpd.conf '{hash_type: 'md5', 'hsum': <md5sum>}' root, root, '755' base
```

**Note:** Supported hash types include sha512, sha384, sha256, sha224, sha1, and md5.

- **name**  
  Path to file destination

- **sfn**  
  Template-processed source file contents

- **source**  
  URL to file source

- **source_sum**  
  File checksum information as a dictionary
salt.modules.file.check_hash(path, file_hash)

Check if a file matches the given hash string

Returns true if the hash matched, otherwise false. Raises ValueError if the hash was not formatted correctly.

path  A file path
hash  A string in the form <hash_type>:<hash_value>. For example: md5:e138491e9d5b97023cea823fe17bac22

CLI Example:
salt '*' file.check_hash /etc/fstab md5:<md5sum>

salt.modules.file.check_managed(name, source, source_hash, user, group, mode, template, context, defaults, saltenv, contents=None, **kwargs)

Check to see what changes need to be made for a file

CLI Example:
salt '*' file.check_managed /etc/httpd/conf.d/httpd.conf salt://http/httpd.conf
  ..
  -->{hash_type: 'md5', 'hsum': <md5sum>}' root, root, '755' jinja True NoneNone base

salt.modules.file.check_managed_changes(name, source, source_hash, user, group, mode, template, context, defaults, saltenv, contents=None, **kwargs)

Return a dictionary of what changes need to be made for a file

CLI Example:
salt '*' file.check_managed_changes /etc/httpd/conf.d/httpd.conf salt://http/
  -->httpd.conf '{hash_type: 'md5', 'hsum': <md5sum>}' root, root, '755' jinja True
  -->None None base

salt.modules.file.check_perms(name, ret, user, group, mode, follow_symlinks=False)

Check the permissions on files and chown if needed

CLI Example:
salt '*' file.check_perms /etc/sudoers '{}' root root 400

Changed in version 2014.1.3: follow_symlinks option added

salt.modules.file.chgrp(path, group)

Change the group of a file

path  path to the file or directory

group  group owner
CLI Example:

```
salt '*' file.chgrp /etc/passwd root
```

`salt.modules.file.chown(path, user, group)`  
Chown a file, pass the file the desired user and group  

- **path** path to the file or directory  
- **user** user owner  
- **group** group owner  

CLI Example:

```
salt '*' file.chown /etc/passwd root root
```

`salt.modules.file.comment(path, regex, char='#', backup='.bak')`  
Deprecated since version 0.17.0: Use `replace()` instead.  
Comment out specified lines in a file  

- **path** The full path to the file to be edited  
- **regex** A regular expression used to find the lines that are to be commented; this pattern will be wrapped in parenthesis and will move any preceding/trailing ^ or $ characters outside the parenthesis (e.g., the pattern ^foo$ will be rewritten as ^(foo)$)  
- **char** [#{]} The character to be inserted at the beginning of a line in order to comment it out  
- **backup** [.bak] The file will be backed up before edit with this file extension  

**Warning:** This backup will be overwritten each time `sed / comment / uncomment` is called. Meaning the backup will only be useful after the first invocation.

CLI Example:

```
salt '*' file.comment /etc/modules pcspk
```

`salt.modules.file.comment_line(path, regex, char='#', cmnt=True, backup='.bak')`  
Comment or Uncomment a line in a text file.  

**Parameters**

- **path** -- string The full path to the text file.  
- **regex** -- string A regex expression that begins with ^ that will find the line you wish to comment. Can be as simple as \^color =  
- **char** -- string The character used to comment a line in the type of file you're referencing. Default is #  
- **cmnt** -- boolean True to comment the line. False to uncomment the line. Default is True.  
- **backup** -- string The file extension to give the backup file. Default is .bak  

**Returns** boolean Returns True if successful, False if not  

CLI Example:

The following example will comment out the pcspk line in the /etc/modules file using the default # character and create a backup file named modules.bak
The following example will uncomment the log_level setting in minion config file if it is set to either warning, info, or debug using the # character and create a backup file named minion.bk.

```
salt '*' file.comment_line '/etc/modules' '^pcspkr'
```

```
salt '*' file.comment_line 'C:\salt\conf\minion' '^log_level: (warning|info|debug) _' '#' False '.bk'
```

**salt.modules.file.contains** *(path, text)*

Deprecation notice: Since version 0.17.0, use **search()** instead.

Return True if the file at path contains text

```
salt '*' file.contains /etc/crontab 'mymaintenance.sh'
```

**salt.modules.file.contains_glob** *(path, glob_expr)*

Deprecation notice: Since version 0.17.0, use **search()** instead.

Return True if the given glob matches a string in the named file

```
salt '*' file.contains_glob /etc/foobar '*cheese*' 
```

**salt.modules.file.contains_regex** *(path, regex, lchar='`)*

Deprecation notice: Since version 0.17.0, use **search()** instead.

Return True if the given regular expression matches on any line in the text of a given file.

If the lchar argument (leading char) is specified, it will strip lchar from the left side of each line before trying to match

```
salt '*' file.contains_regex /etc/crontab
```

**salt.modules.file.contains_regex_multiline** *(path, regex)*

Deprecation notice: Since version 0.17.0, use **search()** instead.

Return True if the given regular expression matches anything in the text of a given file.

Traverses multiple lines at a time, via the salt BufferedReader (reads in chunks)

```
salt '*' file.contains_regex_multiline /etc/crontab '^maint' 
```

**salt.modules.file.copy** *(src, dst, recurse=False, remove_existing=False)*

Copy a file or directory from source to dst

In order to copy a directory, the recurse flag is required, and will by default overwrite files in the destination with the same path, and retain all other existing files. (similar to cp -r on unix)

remove_existing will remove all files in the target directory, and then copy files from the source.
Note: The copy function accepts paths that are local to the Salt minion. This function does not support `salt://`, `http://`, or the other additional file paths that are supported by `states.file.managed` and `states.file.recurse`.

CLI Example:

```bash
salt '*' file.copy /path/to/src /path/to/dst
salt '*' file.copy /path/to/src_dir /path/to/dst_dir recurse=True
salt '*' file.copy /path/to/src_dir /path/to/dst_dir recurse=True remove_=True
```

```
salt.modules.file.delete_backup(path, backup_id)
New in version 0.17.0.
Delete a previous version of a file that was backed up using Salt's file state backup system.
path The path on the minion to check for backups
backup_id The numeric id for the backup you wish to delete, as found using `file.list_backups`
```

CLI Example:

```bash
salt '*' file.restore_backup /foo/bar/baz.txt 0
```

```
salt.modules.file.directory_exists(path)
Tests to see if path is a valid directory. Returns True/False.
```

CLI Example:

```bash
salt '*' file.directory_exists /etc
```

```
salt.modules.file.dirname(path)
Returns the directory component of a pathname
New in version 2015.5.0.
This can be useful at the CLI but is frequently useful when scripting.
```

```bash
{% from salt['file.dirname'](tpldir) + '/vars.jinja' import parent_vars %}
```

CLI Example:

```bash
salt '*' file.dirname 'test/path/filename.config'
```

```
salt.modules.file.diskusage(path)
Recursively calculate disk usage of path and return it in bytes
```

CLI Example:

```bash
salt '*' file.diskusage /path/to/check
```

```
salt.modules.file.extract_hash(hash_fn, hash_type='sha256', file_name=')
This routine is called from the file.managed state to pull a hash from a remote file. Regular expressions are used line by line on the source_hash file, to find a potential candidate of the indicated hash type. This avoids many problems of arbitrary file lay out rules. It specifically permits pulling hash codes from debian *.dsc files.
```

For example:
**CLI Example:**
```
salt '*' file.extract_hash /etc/foo sha512 /path/to/hash/file
```

**salt.modules.file**. **file_exists**(path)
Tests to see if path is a valid file. Returns True/False.

**CLI Example:**
```
salt '*' file.file_exists /etc/passwd
```

**salt.modules.file**. **find**(path, *args,**kwargs**)
Approximate the Unix find(1) command and return a list of paths that meet the specified criteria.

The options include match criteria:

- name = path-glob  # case sensitive
- iname = path-glob  # case insensitive
- regex = path-regex  # case sensitive
- iregex = path-regex  # case insensitive
- type = file-types  # match any listed type
- user = users  # match any listed user
- group = groups  # match any listed group
- size = [+-]number[size-unit]  # default unit = byte
- mtime = interval  # modified since date
- grep = regex  # search file contents

and/or actions:

- delete [= file-types]  # default type = 'f'
- exec = command [arg ...]  # where {} is replaced by pathname
- print [= print-opts]

and/or depth criteria:

- maxdepth = maximum depth to transverse in path
- mindepth = minimum depth to transverse before checking files or directories

The default action is print=path

**path-glob:**

- * = match zero or more chars
- ? = match any char
- [abc] = match a, b, or c
- [!abc] or [^abc] = match anything except a, b, and c
- [x-y] = match chars x through y
- [!x-y] or [^x-y] = match anything except chars x through y
- {a,b,c} = match a or b or c
path-regex: a Python Regex (regular expression) pattern to match pathnames

file-types: a string of one or more of the following:

<table>
<thead>
<tr>
<th>A</th>
<th>B</th>
<th>C</th>
<th>D</th>
<th>P</th>
<th>F</th>
<th>L</th>
<th>S</th>
</tr>
</thead>
<tbody>
<tr>
<td>a: all file types</td>
<td>b: block device</td>
<td>c: character device</td>
<td>d: directory</td>
<td>p: FIFO (named pipe)</td>
<td>f: plain file</td>
<td>l: symlink</td>
<td>s: socket</td>
</tr>
</tbody>
</table>

users: a space and/or comma separated list of user names and/or uids

groups: a space and/or comma separated list of group names and/or gids

size-unit:

<table>
<thead>
<tr>
<th>B</th>
<th>K</th>
<th>M</th>
<th>G</th>
<th>T</th>
</tr>
</thead>
<tbody>
<tr>
<td>b: bytes</td>
<td>k: kilobytes</td>
<td>m: megabytes</td>
<td>g: gigabytes</td>
<td>t: terabytes</td>
</tr>
</tbody>
</table>

interval:

\[[<\text{num}>w] [<\text{num}>d] [<\text{num}>h] [<\text{num}>m] [<\text{num}>s]\]

where:

<table>
<thead>
<tr>
<th>W</th>
<th>D</th>
<th>H</th>
<th>M</th>
<th>S</th>
</tr>
</thead>
<tbody>
<tr>
<td>w: week</td>
<td>d: day</td>
<td>h: hour</td>
<td>m: minute</td>
<td>s: second</td>
</tr>
</tbody>
</table>

print-opts: a comma and/or space separated list of one or more of the following:

<table>
<thead>
<tr>
<th>G</th>
<th>M</th>
<th>N</th>
<th>P</th>
<th>S</th>
<th>U</th>
</tr>
</thead>
<tbody>
<tr>
<td>group: group name</td>
<td>md5: MD5 digest of file contents</td>
<td>name: file basename</td>
<td>path: file absolute path</td>
<td>size: file size in bytes</td>
<td>type: file type</td>
</tr>
</tbody>
</table>

CLI Examples:

```
salt '*' file.find / type=f name=\*.bak size=+10m
salt '*' file.find /var mtime=+30d size=+10m print=path,size,mtime
salt '*' file.find /var/log name=\*.\[[0-9]\] mtime=+30d size=+10m delete
```

```
salt.modules.file.get_devmm(name)
```

Get major/minor info from a device

CLI Example:
salt '*/' file.get_devmm /dev/chr

salt.modules.file.get_diff(minionfile, masterfile, env=None, saltenv='base')
Return unified diff of file compared to file on master

CLI Example:
salt '*/' file.get_diff /home/fred/.vimrc salt://users/fred/.vimrc

salt.modules.file.get_gid(path, follow_symlinks=True)
Return the id of the group that owns a given file

path file or directory of which to get the gid
follow_symlinks indicated if symlinks should be followed

CLI Example:
salt '*/' file.get_gid /etc/passwd

Changed in version 0.16.4: follow_symlinks option added

salt.modules.file.get_group(path, follow_symlinks=True)
Return the group that owns a given file

path file or directory of which to get the group
follow_symlinks indicated if symlinks should be followed

CLI Example:
salt '*/' file.get_group /etc/passwd

Changed in version 0.16.4: follow_symlinks option added

salt.modules.file.get_hash(path, form='sha256', chunk_size=65536)
Get the hash sum of a file

This is better than get_sum for the following reasons:
- It does not read the entire file into memory.
- It does not return a string on error. The returned value of get_sum cannot really be trusted since it is vulnerable to collisions: get_sum(...,'xyz') == 'Hash xyz not supported'

path path to the file or directory
form desired sum format
chunk_size amount to sum at once

CLI Example:
salt '*/' file.get_hash /etc/shadow

salt.modules.file.get_managed(name, template, source, source_hash, user, group, mode, saltenv, context, defaults, **kwargs)
Return the managed file data for file.managed

name location where the file lives on the server
template template format
source managed source file
source_hash hash of the source file
user user owner
group group owner
mode file mode
context variables to add to the environment
default default values of for context_dict

CLI Example:

```
salt '*' file.get_managed /etc/httpd/conf.d/httpd.conf jinja salt://http/httpd.conf
   {hash_type: 'md5', 'hsum': '<md5sum>'} root root '755' base None None
```

**salt.modules.file.get_mode(path, follow_symlinks=True)**
Return the mode of a file

path file or directory of which to get the mode
follow_symlinks indicated if symlinks should be followed

CLI Example:

```
salt '*' file.get_mode /etc/passwd
```

*Changed in version 2014.1.0: follow_symlinks option added*

**salt.modules.file.get_selinux_context(path)**
Get an SELinux context from a given path

CLI Example:

```
salt '*' file.get_selinux_context /etc/hosts
```

**salt.modules.file.get_sum(path, form='sha256')**
Return the checksum for the given file. The following checksum algorithms are supported:

- md5
- sha1
- sha224
- sha256 (default)
- sha384
- sha512

path path to the file or directory
form desired sum format

CLI Example:

```
salt '*' file.get_sum /etc/passwd sha512
```

**salt.modules.file.get_uid(path, follow_symlinks=True)**
Return the id of the user that owns a given file
**path**  file or directory of which to get the uid

**follow_symlinks**  indicated if symlinks should be followed

 CLI Example:

```
salt '*' file.get_uid /etc/passwd
```

Changed in version 0.16.4: follow_symlinks option added

**salt.modules.file.get_user(path, follow_symlinks=True)**

Return the user that owns a given file

**path**  file or directory of which to get the user

**follow_symlinks**  indicated if symlinks should be followed

 CLI Example:

```
salt '*' file.get_user /etc/passwd
```

Changed in version 0.16.4: follow_symlinks option added

**salt.modules.file.gid_to_group(gid)**

Convert the group id to the group name on this system

**gid**  gid to convert to a group name

 CLI Example:

```
salt '*' file.gid_to_group 0
```

**salt.modules.file.grep(path, pattern, *args)**

Grep for a string in the specified file

**Note:** This function’s return value is slated for refinement in future versions of Salt

 **path**  A file path

 **pattern**  A string. For example: test a[0-5]

 **args**  grep options. For example: " -v" " -i -B2"

 CLI Example:

```
salt '*' file.grep /etc/passwd nobody
salt '*' file.grep /etc/sysconfig/network-scripts/ifcfg-eth0 ipaddr " -i"
salt '*' file.grep /etc/sysconfig/network-scripts/ifcfg-eth0 ipaddr " -i -B2"
salt '*' file.grep "/etc/sysconfig/network-scripts/*" ipaddr " -i -l"
```

**salt.modules.file.group_to_gid(group)**

Convert the group to the gid on this system

 **group**  group to convert to its gid

 CLI Example:

```
salt '*' file.group_to_gid root
```
salt.modules.file.is_blkdev(name)
Check if a file exists and is a block device.

CLI Example:
```
salt '*' file.is_blkdev /dev/blk
```

salt.modules.file.is_chrdev(name)
Check if a file exists and is a character device.

CLI Example:
```
salt '*' file.is_chrdev /dev/chr
```

salt.modules.file.is_fifo(name)
Check if a file exists and is a FIFO.

CLI Example:
```
salt '*' file.is_fifo /dev/fifo
```

salt.modules.file.is_link(path)
Check if the path is a symbolic link

CLI Example:
```
salt '*' file.is_link /path/to/link
```

salt.modules.file.join(*args)
Return a normalized file system path for the underlying OS

New in version 2014.7.0.

This can be useful at the CLI but is frequently useful when scripting combining path variables:
```
{% set www_root = '/var' %}
{% set app_dir = 'myapp' %}

myapp_config:
  file:
    - managed
    - name: {{ salt['file.join'](www_root, app_dir, 'config.yaml') }}
```

CLI Example:
```
salt '*' file.join '/' 'usr' 'local' 'bin'
```

salt.modules.file.lchown(path, user, group)
Chown a file, pass the file the desired user and group without following symlinks.

path path to the file or directory
user user owner

group group owner

CLI Example:
```
salt '*' file.chown /etc/passwd root root
```
**salt.modules.file.line**(*path*, *content*, *match=None*, *mode=None*, *location=None*, *before=None*, *after=None*, *show_changes=True*, *backup=False*, *quiet=False*, *indent=True*)

New in version 2015.8.0.

Edit a line in the configuration file.

**Parameters**

- **path** -- Filesystem path to the file to be edited.
- **content** -- Content of the line.
- **match** -- Match the target line for an action by a fragment of a string or regular expression.
- **mode** --
  - **Ensure** If line does not exist, it will be added.
  - **Replace** If line already exist, it will be replaced.
  - **Delete** Delete the line, once found.
  - **Insert** Insert a line.
- **location** --
  - **start** Place the content at the beginning of the file.
  - **end** Place the content at the end of the file.
- **before** -- Regular expression or an exact case-sensitive fragment of the string.
- **after** -- Regular expression or an exact case-sensitive fragment of the string.
- **show_changes** -- Output a unified diff of the old file and the new file. If False return a boolean if any changes were made. Default is True

**Note:** Using this option will store two copies of the file in-memory (the original version and the edited version) in order to generate the diff.

- **backup** -- Create a backup of the original file with the extension: `"Year-Month-Day-Hour-Minutes-Seconds"`.
- **quiet** -- Do not raise any exceptions. E.g. ignore the fact that the file that is tried to be edited does not exist and nothing really happened.
- **indent** -- Keep indentation with the previous line.

If an equal sign (=) appears in an argument to a Salt command, it is interpreted as a keyword argument in the format of **key=val**. That processing can be bypassed in order to pass an equal sign through to the remote shell command by manually specifying the kwarg:

```bash
salt '*' file.line /path/to/file content="CREATEMAIL_SPOOL=no" match="CREATE_MAIL_\_SPOOL=yes" mode="replace"
```

**CLI Examples:**

```bash
salt '*' file.line /etc/nsswitch.conf "networks: files dns", after="hosts:. "
```

**salt.modules.file.link**(*src*, *path*)

New in version 2014.1.0.

Create a hard link to a file
CLI Example:
```bash
salt '*' file.link /path/to/file /path/to/link
```

**salt.modules.file.list_backups** (*path*, *limit=None*)

New in version 0.17.0.
Lists the previous versions of a file backed up using Salt's `file state backup` system.

- **path**: The path on the minion to check for backups
- **limit**: Limit the number of results to the most recent N backups

CLI Example:
```bash
salt '*' file.list_backups /foo/bar/baz.txt
```

**salt.modules.file.list_backups_dir** (*path*, *limit=None*)

Lists the previous versions of a directory backed up using Salt's `file state backup` system.

- **path**: The directory on the minion to check for backups
- **limit**: Limit the number of results to the most recent N backups

CLI Example:
```bash
salt '*' file.list_backups_dir /foo/bar/baz/
```

**salt.modules.file.lstat** (*path*)

New in version 2014.1.0.
Returns the lstat attributes for the given file or dir. Does not support symbolic links.

CLI Example:
```bash
salt '*' file.lstat /path/to/file
```

**salt.modules.file.makedirs** (*path*, *user=None*, *group=None*, *mode=None*)

Ensure that the directory containing this path is available.

**Note:** The path must end with a trailing slash otherwise the directory/directories will be created up to the parent directory. For example if path is `/opt/code`, then it would be treated as `/opt/` but if the path ends with a trailing slash like `/opt/code/`, then it would be treated as `/opt/code/`.

CLI Example:
```bash
salt '*' file.makedirs /opt/code/
```

**salt.modules.file.makedirs_perms** (*name*, *user=None*, *group=None*, *mode=`0755`*)

Taken and modified from os.makedirs to set user, group and mode for each directory created.

CLI Example:
```bash
salt '*' file.makedirs_perms /opt/code
```

**salt.modules.file.manage_file** (*name*, *sfn*, *ret*, *source*, *source_sum*, *user*, *group*, *mode*, *saltenv*, *backup*, *makedirs=False*, *template=None*, *show_diff=True*, *contents=None*, *dir_mode=None*, *followSymlinks=True*)

Checks the destination against what was retrieved with `get_managed` and makes the appropriate modifications (if necessary).
name  location to place the file
sfn  location of cached file on the minion

This is the path to the file stored on the minion. This file is placed on the minion using cp.cache_file. If the hash sum of that file matches the source_sum, we do not transfer the file to the minion again.

This file is then grabbed and if it has template set, it renders the file to be placed into the correct place on the system using salt.files.utils.copyfile()
ret  The initial state return data structure. Pass in None to use the default structure.
source  file reference on the master
source_hash  sum hash for source
user  user owner
group  group owner
backup  backup_mode
makedirs  make directories if they do not exist
template  format of templating
show_diff  Include diff in state return
contents:  contents to be placed in the file
dir_mode  mode for directories created with makedirs

CLI Example:

    salt '*' file.manage_file /etc/httpd/conf.d/httpd.conf '{hash_type: 'md5', 'hsum': <md5sum>}' root root '755' base ''

Changed in version 2014.7.0: follow_symlinks option added

salt.modules.file.mkdir(dir_path, user=None, group=None, mode=None)

Ensure that a directory is available.

CLI Example:

    salt '*' file.mkdir /opt/jetty/context

salt.modules.file.mknod(name, ntype, major=0, minor=0, user=None, group=None, mode='0600')

New in version 0.17.0.

Create a block device, character device, or fifo pipe. Identical to the gnu mknod.

CLI Examples:

    salt '*' file.mknod /dev/chr c 180 31
    salt '*' file.mknod /dev/blk b 8 999
    salt '*' file.mknod /dev/fifo p

salt.modules.file.mknod_blkdev(name, major, minor, user=None, group=None, mode='0660')

New in version 0.17.0.

Create a block device.

CLI Example:

    salt '*' file.mknod_blkdev /dev/blk 8 999
salt.modules.file.mknod_chrdev(name, major, minor, user=None, group=None, mode='0660')
New in version 0.17.0.
Create a character device.
CLI Example:
```
salt '*' file.mknod_chrdev /dev/chr 180 31
```

salt.modules.file.mknod_fifo(name, user=None, group=None, mode='0660')
New in version 0.17.0.
Create a FIFO pipe.
CLI Example:
```
salt '*' file.mknod_fifo /dev/fifo
```

salt.modules.file.move(src, dst)
Move a file or directory
CLI Example:
```
salt '*' file.move /path/to/src /path/to/dst
```

salt.modules.file.normpath(path)
Returns Normalize path, eliminating double slashes, etc.
New in version 2015.5.0.
This can be useful at the CLI but is frequently useful when scripting.
```
{% from salt['file.normpath'](tpldir + '/../vars.jinja') import parent_vars %}
```
CLI Example:
```
salt '*' file.normpath 'a/b/c/..
```

salt.modules.file.open_files(by_pid=False)
Return a list of all physical open files on the system.
CLI Examples:
```
salt '*' file.open_files
salt '*' file.open_files by_pid=True
```

salt.modules.file.pardir()
Return the relative parent directory path symbol for underlying OS
New in version 2014.7.0.
This can be useful when constructing Salt Formulas.
```
{% set pardir = salt['file.pardir']() %}
{% set final_path = salt['file.join']('subdir', pardir, 'confdir') %}
```
CLI Example:
```
salt '*' file.pardir
```
salt.modules.file.patch(originalfile, patchfile, options='`, dry_run=False)

New in version 0.10.4.

Apply a patch to a file
Equivalent to:

```
patch <options> <originalfile> <patchfile>
```

originalfile  The full path to the file or directory to be patched
patchfile  A patch file to apply to originalfile
options  Options to pass to patch.

CLI Example:

```
salt '*' file.patch /opt/file.txt /tmp/file.txt.patch
```

salt.modules.file.path_exists_glob(path)
Tests to see if path after expansion is a valid path (file or directory). Expansion allows usage of `*` and character ranges `[]`. Tilde expansion is not supported. Returns True/False.

New in version Hellium.

CLI Example:

```
salt '*' file.path_exists_glob /etc/pam*/pass*
```

salt.modules.file.prepend(path, *args, **kwargs)

New in version 2014.7.0.

Prepend text to the beginning of a file

path  path to file
*args  strings to prepend to the file

CLI Example:

```
salt '*' file.prepend /etc/motd \
    "With all thine offerings thou shalt offer salt." \
    "Salt is what makes things taste bad when it isn't in them."
```

Attention

If you need to pass a string to append and that string contains an equal sign, you must include the argument name, args. For example:

```
salt '*' file.prepend /etc/motd args='cheese=spam'
salt '*' file.prepend /etc/motd args="['cheese=spam','spam=cheese']"
```

salt.modules.file.psed(path, before, after, limit='`, backup='.bak', flags='gMS', escape_all=False, multi=False)

Deprecated since version 0.17.0: Use replace() instead.

Make a simple edit to a file (pure Python version)
Equivalent to:

```
```

32.17. Full list of builtin execution modules
```
sed <backup> <options> "/<limit>/ s/<before>/<after>/<flags> <file>"
```

**path**  The full path to the file to be edited

*before*  A pattern to find in order to replace with *after*

*after*  Text that will replace *before*

*limit*  ['']  An initial pattern to search for before searching for *before*

*backup*  [.bak]  The file will be backed up before edit with this file extension; WARNING: each time `sed/comment/uncomment` is called will overwrite this backup

*flags*  [gMS]

Flags to modify the search. Valid values are:

- **g**: Replace all occurrences of the pattern, not just the first.
- **I**: Ignore case.
- **L**: Make `\w, \W, \b, \B, \s` and `\S` dependent on the locale.
- **M**: Treat multiple lines as a single line.
- **S**: Make `.` match all characters, including newlines.
- **U**: Make `\w, \W, \b, \B, \d, \D, \s` and `\S` dependent on Unicode.
- **X**: Verbose (whitespace is ignored).

*multi*: **False**  If True, treat the entire file as a single line

Forward slashes and single quotes will be escaped automatically in the *before* and *after* patterns.

CLI Example:

```
salt '*' file.sed /etc/httpd/httpd.conf 'LogLevel warn' 'LogLevel info'
```

**salt.modules.file.readdir(path)**

New in version 2014.1.0.

Return a list containing the contents of a directory

CLI Example:

```
salt '*' file.readdir /path/to/dir/
```

**salt.modules.file.readlink(path, canonicalize=False)**

New in version 2014.1.0.

Return the path that a symlink points to If canonicalize is set to True, then it return the final target

CLI Example:

```
salt '*' file.readlink /path/to/link
```

**salt.modules.file.remove(path)**

Remove the named file. If a directory is supplied, it will be recursively deleted.

CLI Example:

```
salt '*' file.remove /tmp/foo
```
salt.modules.file.rename(src, dst)

Rename a file or directory

CLI Example:
```
salt '*' file.rename /path/to/src /path/to/dst
```

salt.modules.file.replace(path, pattern, repl, count=0, flags=8, bufsize=1, append_if_not_found=False, prepend_if_not_found=False, not_found_content=None, backup='.bak', dry_run=False, search_only=False, show_changes=True, ignore_if_missing=False, preserve_inode=True)

New in version 0.17.0.

Replace occurrences of a pattern in a file. If show_changes is True, then a diff of what changed will be returned, otherwise a True will be returned when changes are made, and False when no changes are made.

This is a pure Python implementation that wraps Python's sub().

path Filesystem path to the file to be edited

pattern A regular expression, to be matched using Python's search().

repl The replacement text

count [0] Maximum number of pattern occurrences to be replaced. If count is a positive integer n, only n occurrences will be replaced, otherwise all occurrences will be replaced.

flags (list or int) A list of flags defined in the re module documentation. Each list item should be a string that will correlate to the human-friendly flag name. E.g., ['IGNORECASE', 'MULTILINE']. Optionally, flags may be an int, with a value corresponding to the XOR (|) of all the desired flags. Defaults to 8 (which supports `MULTILINE`).

bufsize (int or str) How much of the file to buffer into memory at once. The default value 1 processes one line at a time. The special value file may be specified which will read the entire file into memory before processing.

append_if_not_found [False] New in version 2014.7.0.

If set to True, and pattern is not found, then the content will be appended to the file.

prepend_if_not_found [False] New in version 2014.7.0.

If set to True and pattern is not found, then the content will be prepended to the file.

not_found_content New in version 2014.7.0.

Content to use for append/prepend if not found. If None (default), uses repl. Useful when repl uses references to group in pattern.

backup [.bak] The file extension to use for a backup of the file before editing. Set to False to skip making a backup.

dry_run [False] If set to True, no changes will be made to the file, the function will just return the changes that would have been made (or a True/False value if show_changes is set to False).

search_only [False] If set to true, this no changes will be performed on the file, and this function will simply return True if the pattern was matched, and False if not.

show_changes [True] If True, return a diff of changes made. Otherwise, return True if changes were made, and False if not.
Note: Using this option will store two copies of the file in memory (the original version and the edited version) in order to generate the diff. This may not normally be a concern, but could impact performance if used with large files.

ignore_if_missing [False] New in version 2015.8.0.

If set to True, this function will simply return False if the file doesn’t exist. Otherwise, an error will be thrown.

Preserve the inode of the file, so that any hard links continue to share the inode with the original filename. This works by copying the file, reading from the copy, and writing to the file at the original inode. If False, the file will be moved rather than copied, and a new file will be written to a new inode, but using the original filename. Hard links will then share an inode with the backup, instead (if using backup to create a backup copy).

If an equal sign (=) appears in an argument to a Salt command it is interpreted as a keyword argument in the format key=val. That processing can be bypassed in order to pass an equal sign through to the remote shell command by manually specifying the kwarg:

```
salt '*' file.replace /path/to/file pattern='=' repl='';'
salt '*' file.replace /path/to/file pattern="bind-address\s*=" repl='bind-address: '
```

CLI Examples:

```
salt '*' file.replace /etc/httpd/httpd.conf pattern='LogLevel warn' repl="\'LogLevel info'"
salt '*' file.replace /some/file pattern='before' repl='after' flags='[MULTILINE,\n\nIGNORECASE]'"'
```

salt.modules.file.restore_backup(path, backup_id)

New in version 0.17.0.

Restore a previous version of a file that was backed up using Salt’s file state backup system.

**path** The path on the minion to check for backups

**backup_id** The numeric id for the backup you wish to restore, as found using file.list_backups

CLI Example:

```
salt '*' file.restore_backup /foo/bar/baz.txt 0
```

salt.modules.file.restorecon(path, recursive=False)

Reset the SELinux context on a given path

CLI Example:

```
salt '*' file.restorecon /home/user/.ssh/authorized_keys
```

salt.modules.file.rmdir(path)

New in version 2014.1.0.

Remove the specified directory. Fails if a directory is not empty.

CLI Example:
salt 'salt' salt.rmdir /tmp/foo/

salt.modules.file.search(path, pattern, flags=8, bufsize=1, ignore_if_missing=False, multiline=False)

New in version 0.17.0.
Search for occurrences of a pattern in a file
Except for multiline, params are identical to replace().

multiline If true, inserts `MULTILINE' into flags and sets bufsize to `file'.
New in version 2015.8.0.

CLI Example:
salt 'salt' salt.search /etc/crontab 'mymaintenance.sh'

salt.modules.file.sed(path, before, after, limit='', backup='.bak', options='r -e', flags='g', escape_all=False, negate_match=False)

Deprecated since version 0.17.0: Use replace() instead.
Make a simple edit to a file
Equivalent to:

```
sed <backup> <options> "/<limit>/ s/<before>/<after>/<flags> <file>"
```

path  The full path to the file to be edited
before  A pattern to find in order to replace with after
after  Text that will replace before
limit [''] An initial pattern to search for before searching for before
backup [.bak] The file will be backed up before edit with this file extension; WARNING: each time sed/comment/uncomment is called will overwrite this backup
options [-r -e] Options to pass to sed
flags [g] Flags to modify the sed search; e.g., i for case-insensitive pattern matching
negate_match [False] Negate the search command (!)

New in version 0.17.0.
Forward slashes and single quotes will be escaped automatically in the before and after patterns.

CLI Example:
salt 'salt' salt.sed /etc/httpd/httpd.conf 'LogLevel warn' 'LogLevel info'

salt.modules.file.sed_contains(path, text, limit='', flags='g')

Deprecated since version 0.17.0: Use search() instead.
Return True if the file at path contains text. Utilizes sed to perform the search (line-wise search).
Note: the p flag will be added to any flags you pass in.

CLI Example:
salt 'salt' salt.contains /etc/crontab 'mymaintenance.sh'
salt.modules.file.**seek_read**(path, size, offset)

New in version 2014.1.0.

Seek to a position on a file and read it

- **path** path to file
- **seek** amount to read at once
- **offset** offset to start into the file

CLI Example:

```bash
salt '*' file.seek_read /path/to/file 4096 0
```

salt.modules.file.**seek_write**(path, data, offset)

New in version 2014.1.0.

Seek to a position on a file and write to it

- **path** path to file
- **data** data to write to file
- **offset** position in file to start writing

CLI Example:

```bash
salt '*' file.seek_write /path/to/file 'some data' 4096
```

salt.modules.file.**set_mode**(path, mode)

Set the mode of a file

- **path** file or directory of which to set the mode
- **mode** mode to set the path to

CLI Example:

```bash
salt '*' file.set_mode /etc/passwd 0644
```

salt.modules.file.**set_selinux_context**(path, user=None, role=None, type=None, range=None)

Set a specific SELinux label on a given path

CLI Example:

```bash
salt '*' file.set_selinux_context path <role> <type> <range>
```

salt.modules.file.**source_list**(source, source_hash, saltenv)

Check the source list and return the source to use

CLI Example:

```bash
salt '*' file.source_list salt://http/httpd.conf '{hash_type: 'md5', 'hsum': ←<md5sum>}' base
```

salt.modules.file.**stats**(path, hash_type=None, follow_symlinks=True)

Return a dict containing the stats for a given file

CLI Example:

```bash
salt '*' file.stats /etc/passwd
```
salt.modules.file.statvfs(path)
   New in version 2014.1.0.
   Perform a statvfs call against the filesystem that the file resides on
   CLI Example:
   ```
   salt '* file.statvfs /path/to/file
   ```

salt.modules.file.symlink(src, path)
   Create a symbolic link (symlink, soft link) to a file
   CLI Example:
   ```
   salt '* file.symlink /path/to/file /path/to/link
   ```

salt.modules.file.touch(name, atime=None, mtime=None)
   New in version 0.9.5.
   Just like the touch command, create a file if it doesn't exist or simply update the atime and mtime if it already does.
   atime: Access time in Unix epoch time
   mtime: Last modification in Unix epoch time
   CLI Example:
   ```
   salt '* file.touch /var/log/emptyfile
   ```

salt.modules.file.truncate(path, length)
   New in version 2014.1.0.
   Seek to a position on a file and delete everything after that point
   path path to file
   length offset into file to truncate
   CLI Example:
   ```
   salt '* file.truncate /path/to/file 512
   ```

salt.modules.file.uid_to_user(uid)
   Convert a uid to a user name
   uid uid to convert to a username
   CLI Example:
   ```
   salt '* file.uid_to_user 0
   ```

salt.modules.file.uncomment(path, regex='\#', char='#', backup='.bak')
   Deprecated since version 0.17.0: Use replace() instead.
   Uncomment specified commented lines in a file
   path The full path to the file to be edited
   regex A regular expression used to find the lines that are to be uncommented. This regex should not include the comment character. A leading ^ character will be stripped for convenience (for easily switching between comment() and uncomment()).
   char [\#] The character to remove in order to uncomment a line
backup [.bak] The file will be backed up before edit with this file extension; WARNING: each time sed/comment/uncomment is called will overwrite this backup

CLI Example:
```
salt '*' file.uncomment /etc/hosts.deny 'ALL: PARANOID'
```

**salt.modules.file.user_to_uid**(user)

Convert user name to a uid

user user name to convert to its uid

CLI Example:
```
salt '*' file.user_to_uid root
```

**salt.modules.file.write**(path, *args, **kwargs)

Write text to a file, overwriting any existing contents.

path path to file

*args strings to write to the file

CLI Example:
```
salt '*' file.write /etc/motd "With all thine offerings thou shalt offer salt."
```

Attention

If you need to pass a string to append and that string contains an equal sign, you must include the argument name, args. For example:

```
salt '*' file.write /etc/motd args='cheese=spam'
salt '*' file.write /etc/motd args="['cheese=spam','spam=cheese']"
```

32.17.86 salt.modules.firewalld

Support for firewalld.

New in version 2015.2.0.

**salt.modules.firewalld.add_masquerade**(zone)

Enable masquerade on a zone.

New in version 2015.8.0.

CLI Example:
```
salt '*' firewalld.add_masquerade
```

**salt.modules.firewalld.add_port**(zone, port, permanent=True)

Allow specific ports in a zone.

New in version 2015.8.0.
CLI Example:

```bash
salt '*' firewalld.add_port internal 443/tcp
```

```
salt.modules.firewalld.add_port_fwd(zone, src, dest, proto='tcp', dstaddr='')
```

Add port forwarding.

New in version 2015.8.0.

CLI Example:

```bash
salt '*' firewalld.add_port_fwd public 80 443 tcp
```

```
salt.modules.firewalld.add_service(name, zone=None, permanent=True)
```

Add a service for zone. If zone is omitted, default zone will be used.

CLI Example:

```bash
salt '*' firewalld.add_service ssh
```

To assign a service to a specific zone:

```bash
salt '*' firewalld.add_service ssh my_zone
```

```
salt.modules.firewalld.allow_icmp(zone, icmp)
```

Allow a specific ICMP type on a zone

New in version 2015.8.0.

CLI Example:

```bash
salt '*' firewalld.allow_icmp zone echo-reply
```

```
salt.modules.firewalld.block_icmp(zone, icmp)
```

Block a specific ICMP type on a zone

New in version 2015.8.0.

CLI Example:

```bash
salt '*' firewalld.block_icmp zone echo-reply
```

```
salt.modules.firewalld.default_zone()
```

Print default zone for connections and interfaces

CLI Example:

```bash
salt '*' firewalld.default_zone
```

```
salt.modules.firewalld.delete_service(name, restart=True)
```

Delete an existing service

CLI Example:

```bash
salt '*' firewalld.delete_service my_service
```

By default firewalld will be reloaded. However, to avoid reloading you need to specify the restart as False

```bash
salt '*' firewalld.delete_service my_service False
```
salt.modules.firewalld.delete_zone(zone, restart=True)
Delete an existing zone

CLI Example:
salt '*' firewalld.delete_zone my_zone

By default firewalld will be reloaded. However, to avoid reloading you need to specify the restart as False

salt '*' firewalld.delete_zone my_zone False

salt.modules.firewalld.get_icmp_types()
Print predefined icmptypes

CLI Example:
salt '*' firewalld.get_icmp_types

salt.modules.firewalld.get_masquerade(zone)
Show if masquerading is enabled on a zone

CLI Example:
salt '*' firewalld.get_masquerade zone

salt.modules.firewalld.get_services()
Print predefined services

CLI Example:
salt '*' firewalld.get_services

salt.modules.firewalld.get_zones()
Print predefined zones

CLI Example:
salt '*' firewalld.get_zones

salt.modules.firewalld.list_all(zone=None)
List everything added for or enabled in a zone

CLI Example:
salt '*' firewalld.list_all

List a specific zone

salt '*' firewalld.list_all my_zone

salt.modules.firewalld.list_icmp_block(zone)
List ICMP blocks on a zone

New in version 2015.8.0.

CLI Example:
salt '*' firewalld.list_icmp_block zone
salt.modules.firewalld.list_port_fwd(zone)
List port forwarding
New in version 2015.8.0.
CLI Example:
```
salt '*' firewalld.list_port_fwd public
```

salt.modules.firewalld.list_ports(zone)
List all ports in a zone.
New in version 2015.8.0.
CLI Example:
```
salt '*' firewalld.list_ports
```

salt.modules.firewalld.list_services(zone=None)
List services added for zone as a space separated list. If zone is omitted, default zone will be used.
CLI Example:
```
salt '*' firewalld.list_services
```

List a specific zone
```
salt '*' firewalld.list_services my_zone
```

salt.modules.firewalld.list_zones()
List everything added for or enabled in all zones
CLI Example:
```
salt '*' firewalld.list_zones
```

salt.modules.firewalld.new_service(name, restart=True)
Add a new service
CLI Example:
```
salt '*' firewalld.new_service my_service
```
By default firewalld will be reloaded. However, to avoid reloading you need to specify the restart as False
```
salt '*' firewalld.new_service my_service False
```

salt.modules.firewalld.new_zone(zone, restart=True)
Add a new zone
CLI Example:
```
salt '*' firewalld.new_zone my_zone
```
By default firewalld will be reloaded. However, to avoid reloading you need to specify the restart as False
```
salt '*' firewalld.new_zone my_zone False
```

salt.modules.firewalld.remove_masquerade(zone)
Remove masquerade on a zone.
New in version 2015.8.0.

CLI Example:

```bash
salt '*' firewalld.remove_masquerade
```

```
salt.modules.firewalld.remove_port(zone, port, permanent=True)
```

Remove a specific port from a zone.

New in version 2015.8.0.

CLI Example:

```bash
salt '*' firewalld.remove_port internal 443/tcp
```

```
salt.modules.firewalld.remove_port_fwd(zone, src, dest, proto='tcp')
```

Remove Port Forwarding.

New in version 2015.8.0.

CLI Example:

```bash
salt '*' firewalld.remove_port_fwd public 80 443 tcp
```

```
salt.modules.firewalld.remove_service(name, zone=None, permanent=True)
```

Remove a service from zone. This option can be specified multiple times. If zone is omitted, default zone will be used.

CLI Example:

```bash
salt '*' firewalld.remove_service ssh
```

To remove a service from a specific zone

```bash
salt '*' firewalld.remove_service ssh dmz
```

```
salt.modules.firewalld.set_default_zone(zone)
```

Set default zone

CLI Example:

```bash
salt '*' firewalld.set_default_zone damian
```

```
salt.modules.firewalld.version()
```

Return version from firewall-cmd

CLI Example:

```bash
salt '*' firewalld.version
```

### 32.17.87 salt.modules.freebsd_sysctl

Module for viewing and modifying sysctl parameters

```
salt.modules.freebsd_sysctl.assign(name, value)
```

Assign a single sysctl parameter for this minion

CLI Example:
```
salt '*' sysctl.assign net.inet.icmp.icmplim 50
```

**salt.modules.freebsd_sysctl.get(name)**

Return a single sysctl parameter for this minion

CLI Example:

```
salt '*' sysctl.get hw.physmem
```

**salt.modules.freebsd_sysctl.persist(name, value, config='/etc/sysctl.conf')**

Assign and persist a simple sysctl parameter for this minion

CLI Example:

```
salt '*' sysctl.persist net.inet.icmp.icmplim 50
salt '*' sysctl.persist coretemp_load NO config=/boot/loader.conf
```

**salt.modules.freebsd_sysctl.show(config_file=False)**

Return a list of sysctl parameters for this minion

CLI Example:

```
salt '*' sysctl.show
```

### 32.17.88 salt.modules.freebsdjail

The jail module for FreeBSD

**salt.modules.freebsdjail.fstab(jail)**

Display contents of a fstab(5) file defined in specified jail's configuration. If no file is defined, return False.

CLI Example:

```
salt '*' jail.fstab <jail name>
```

**salt.modules.freebsdjail.get_enabled()**

Return which jails are set to be run

CLI Example:

```
salt '*' jail.get_enabled
```

**salt.modules.freebsdjail.is_enabled()**

See if jail service is actually enabled on boot

CLI Example:

```
salt '*' jail.is_enabled <jail name>
```

**salt.modules.freebsdjail.restart(jail='')**

Restart the specified jail or all, if none specified

CLI Example:

```
salt '*' jail.restart [<jail name>]
```

**salt.modules.freebsdjail.show_config(jail)**

Display specified jail's configuration
**salt.modules.freebsdjail**

**start(jail='')**
Start the specified jail or all, if none specified

CLI Example:
```
salt '*' jail.start [<jail name>]
```

**status(jail)**
See if specified jail is currently running

CLI Example:
```
salt '*' jail.status <jail name>
```

**stop(jail='')**
Stop the specified jail or all, if none specified

CLI Example:
```
salt '*' jail.stop [<jail name>]
```

**sysctl()**
Dump all jail related kernel states (sysctl)

CLI Example:
```
salt '*' jail.sysctl
```

**salt.modules.freebsdkmod**

Module to manage FreeBSD kernel modules

**available()**
Return a list of all available kernel modules

CLI Example:
```
salt '*' kmod.available
```

**check_available(mod)**
Check to see if the specified kernel module is available

CLI Example:
```
salt '*' kmod.check_available vmm
```

**is_loaded(mod)**
Check to see if the specified kernel module is loaded

CLI Example:
```
salt '*' kmod.is_loaded vmm
```

**load(mod, persist=False)**
Load the specified kernel module
mod  Name of the module to add

persist  Write the module to sysrc kld_modules to make it load on system reboot

CLI Example:

```
salt '*' kmod.load bhyve
```

```python
salt.modules.freebsdkmod.lsmod()
```
Return a dict containing information about currently loaded modules

CLI Example:

```
salt '*' kmod.lsmod
```

```python
salt.modules.freebsdkmod.mod_list(only_persist=False)
```
Return a list of the loaded module names

CLI Example:

```
salt '*' kmod.mod_list
```

```python
salt.modules.freebsdkmod.remove(mod, persist=False)
```
Remove the specified kernel module

CLI Example:

```
salt '*' kmod.remove vmm
```

### 32.17.90 salt.modules.freebsdpkg

Remote package support using pkg_add(1)

**Important:** If you feel that Salt should be using this module to manage packages on a minion, and it is using a different module (or gives an error similar to `pkg.install' is not available), see [here](#).

**Warning:** This module has been completely rewritten. Up to and including version 0.17.0, it supported pkg_add(1), but checked for the existence of a pkgng local database and, if found, would provide some of pkgng's functionality. The rewrite of this module has removed all pkgng support, and moved it to the pkgng execution module. For versions <= 0.17.0, the documentation here should not be considered accurate. If your Minion is running one of these versions, then the documentation for this module can be viewed using the `sys.doc` function:

```
salt bsdminion sys.doc pkg
```

This module acts as the default package provider for FreeBSD 9 and older. If you need to use pkgng on a FreeBSD 9 system, you will need to override the pkg provider by setting the `providers` parameter in your Minion config file, in order to use pkgng.

```
providers:
  pkg: pkgng
```

More information on pkgng support can be found in the documentation for the pkgng module.

### 32.17. Full list of builtin execution modules
This module will respect the PACKAGEROOT and PACKAGESITE environment variables, if set, but these values can also be overridden in several ways:

1. **Salt configuration parameters.** The configuration parameters freebsdpkg.PACKAGEROOT and freebsdpkg.PACKAGESITE are recognized. These config parameters are looked up using `config.get` and can thus be specified in the Master config file, Grains, Pillar, or in the Minion config file. Example:

   ```
   ```

2. **CLI arguments.** Both the packageroot (used interchangeably with fromrepo for API compatibility) and packagesite CLI arguments are recognized, and override their config counterparts from section 1 above.

   ```
   salt -G 'os:FreeBSD' pkg.install zsh fromrepo=ftp://ftp2.freebsd.org/
   salt -G 'os:FreeBSD' pkg.install zsh packageroot=ftp://ftp2.freebsd.org/
   salt -G 'os:FreeBSD' pkg.install zsh packagesite=ftp://ftp2.freebsd.org/pub/
   FreeBSD/ports/ia64/packages-9-stable/Latest/
   ```

   .. note::
   These arguments can also be passed through in states:
   ```yaml
   .. code-block:: yaml
   zsh:
     pkg.installed:
   ```

**salt.modules.freebsdpkg.file_dict(*packages)**

List the files that belong to a package, grouped by package. Not specifying any packages will return a list of _every_ file on the system's package database (not generally recommended).

**CLI Examples:**

```
salt '*' pkg.file_list httpd
salt '*' pkg.file_list httpd postfix
salt '*' pkg.file_list
```

**salt.modules.freebsdpkg.file_list(*packages)**

List the files that belong to a package. Not specifying any packages will return a list of _every_ file on the system's package database (not generally recommended).

**CLI Examples:**

```
salt '*' pkg.file_list httpd
salt '*' pkg.file_list httpd postfix
salt '*' pkg.file_list
```

**salt.modules.freebsdpkg.install(name=None, refresh=False, fromrepo=None, pkgs=None, sources=None, **kwargs)**

Install package(s) using `pkg_add(1)`

- **name** The name of the package to be installed.
- **refresh** Whether or not to refresh the package database before installing.
- **fromrepo** or **packageroot** Specify a package repository from which to install. Overrides the system default, as well as the PACKAGEROOT environment variable.
packagesite Specify the exact directory from which to install the remote package. Overrides the PACKAGE-SITE environment variable, if present.

Multiple Package Installation Options:

**pkgs** A list of packages to install from a software repository. Must be passed as a python list.

CLI Example:
```
salt '*' pkg.install pkgs='["foo", "bar"]'
```

**sources** A list of packages to install. Must be passed as a list of dicts, with the keys being package names, and the values being the source URI or local path to the package.

CLI Example:
```
salt '*' pkg.install sources='["foo": "salt://foo.deb"], ["bar": "salt://bar.deb"]'
```

Return a dict containing the new package names and versions:

```
{'<package>': {'old': '<old-version>', 'new': '<new-version>'}}
```

CLI Example:
```
salt '*' pkg.install <package name>
```

```
salt.modules.freebsdpgk.latest_version('names', **kwargs)
pkg_add(1) is not capable of querying for remote packages, so this function will always return results as if there is no package available for install or upgrade.
```

CLI Example:
```
salt '*' pkg.latest_version <package name>
salt '*' pkg.latest_version <package1> <package2> <package3> ...
```

```
salt.modules.freebsdpgk.list_pkgs(versions_as_list=False, with_origin=False, **kwargs)
List the packages currently installed as a dict:
```
```
[{'<package_name>': '<version>'}
```

with_origin [False] Return a nested dictionary containing both the origin name and version for each installed package.

New in version 2014.1.0.

CLI Example:
```
salt '*' pkg.list_pkgs
```

```
salt.modules.freebsdpgk.refresh_db()
pkg_add(1) does not use a local database of available packages, so this function simply returns True. it exists merely for API compatibility.
```

CLI Example:
```
salt '*' pkg.refresh_db
```
salt.modules.freebsdpkg.remove(name=None, pkgs=None, **kwargs)

Remove packages using pkg_delete(1)

**name**  The name of the package to be deleted.

**pkgs**  A list of packages to delete. Must be passed as a python list. The **name** parameter will be ignored if this option is passed.

New in version 0.16.0.

Returns a dict containing the changes.

**CLI Example:**

```
salt '*' pkg.remove <package name>
salt '*' pkg.remove <package1>,<package2>,<package3>
salt '*' pkg.remove pkgs='["foo", "bar"]'
```

salt.modules.freebsdpkg.upgrade()

Upgrades are not supported with pkg_add(1). This function is included for API compatibility only and always returns an empty dict.

**CLI Example:**

```
salt '*' pkg.upgrade
```

salt.modules.freebsdpkg.version(*names, **kwargs)

Returns a string representing the package version or an empty string if not installed. If more than one package name is specified, a dict of name/version pairs is returned.

**with_origin** [False] Return a nested dictionary containing both the origin name and version for each specified package.

New in version 2014.1.0.

**CLI Example:**

```
salt '*' pkg.version <package name>
salt '*' pkg.version <package1> <package2> <package3> ...
```

32.17.91 salt.modules.freebsdports

Install software from the FreeBSD ports(7) system

New in version 2014.1.0.

This module allows you to install ports using BATCH=yes to bypass configuration prompts. It is recommended to use the ports state to install ports, but it it also possible to use this module exclusively from the command line.

```
salt minion-id ports.config security/nmap IPV6=off
salt minion-id ports.install security/nmap
```

salt.modules.freebsdports.config(name, reset=False, **kwargs)

Modify configuration options for a given port. Multiple options can be specified. To see the available options for a port, use ports.showconfig.

**name**  The port name, in category/name format
reset [False] If True, runs a make rmconfig for the port, clearing its configuration before setting the desired options

CLI Examples:

```bash
salt '*' ports.config security/nmap IPV6=off
```

`salt.modules.freebsdports.deinstall(name)`  
De-install a port.

CLI Example:

```bash
salt '*' ports.deinstall security/nmap
```

`salt.modules.freebsdports.install(name, clean=True)`  
Install a port from the ports tree. Installs using BATCH=yes for non-interactive building. To set config options for a given port, use `ports.config`.

clean [True] If True, cleans after installation. Equivalent to running make install clean BATCH=yes.

Note: It may be helpful to run this function using the -t option to set a higher timeout, since compiling a port may cause the Salt command to exceed the default timeout.

CLI Example:

```bash
salt -t 1200 '*' ports.install security/nmap
```

`salt.modules.freebsdports.list_all()`  
Lists all ports available.

CLI Example:

```bash
salt '*' ports.list_all
```

**Warning:** Takes a while to run, and returns a LOT of output

`salt.modules.freebsdports.rmconfig(name)`  
Clear the cached options for the specified port; run a make rmconfig

name The name of the port to clear

CLI Example:

```bash
salt '*' ports.rmconfig security/nmap
```

`salt.modules.freebsdports.search(name)`  
Search for matches in the ports tree. Globs are supported, and the category is optional

CLI Examples:

```bash
salt '*' ports.search 'security/*'
salt '*' ports.search 'security/n*'  
salt '*' ports.search nmap
```
Warning: Takes a while to run

```python
salt.modules.freebsdports.showconfig(name, default=False, dict_return=False)
```
Show the configuration options for a given port.

**default** [False] Show the default options for a port (not necessarily the same as the current configuration)

**dict_return** [False] Instead of returning the output of `make showconfig`, return the data in a dictionary

**CLI Example:**
```
salt '*' ports.showconfig security/nmap
salt '*' ports.showconfig security/nmap default=True
```

```python
salt.modules.freebsdports.update(extract=False)
```
Update the ports tree

**extract** [False] If True, runs a `portsnap extract` after fetching, should be used for first-time installation of the ports tree.

**CLI Example:**
```
salt '*' ports.update
```

## 32.17.92 salt.modules.freebsdservice

The service module for FreeBSD

**Important:** If you feel that Salt should be using this module to manage services on a minion, and it is using a different module (or gives an error similar to `service.start' is not available), see here.

```python
salt.modules.freebsdservice.available(name)
```
Check that the given service is available.

**CLI Example:**
```
salt '*' service.available sshd
```

```python
salt.modules.freebsdservice.disable(name, **kwargs)
```
Disable the named service to start at boot

**Arguments the same as for enable()**

**CLI Example:**
```
salt '*' service.disable <service name>
```

```python
salt.modules.freebsdservice.disabled(name)
```
Return True if the named service is enabled, false otherwise

**CLI Example:**
```
salt '*' service.disabled <service name>
```

```python
salt.modules.freebsdservice.enable(name, **kwargs)
```
Enable the named service to start at boot
**name** service name

**config** [/etc/rc.conf] Config file for managing service. If config value is empty string, then /etc/rc.conf.d/<service> used. See man rc.conf(5) for details.

Also service.config variable can be used to change default.

CLI Example:

```
salt '*' service.enable <service name>
```

salt.modules.freebsdservice.enabled(name, \*

Return True if the named service is enabled, false otherwise

**name** Service name

CLI Example:

```
salt '*' service.enabled <service name>
```

salt.modules.freebsdservice.get_all()

Return a list of all available services

CLI Example:

```
salt '*' service.get_all
```

salt.modules.freebsdservice.get_disabled()

Return what services are available but not enabled to start at boot

CLI Example:

```
salt '*' service.get_disabled
```

salt.modules.freebsdservice.get_enabled()

Return what services are set to run on boot

CLI Example:

```
salt '*' service.get_enabled
```

salt.modules.freebsdservice.missing(name)

The inverse of service.available. Returns True if the specified service is not available, otherwise returns False.

CLI Example:

```
salt '*' service.missing sshd
```

salt.modules.freebsdservice.reload(name)

Restart the named service

CLI Example:

```
salt '*' service.reload <service name>
```

salt.modules.freebsdservice.restart(name)

Restart the named service

CLI Example:
```python
salt '*' service.restart <service name>
```

```python
salt.modules.freebsdservice.start(name)
Start the specified service

CLI Example:
```
salt '*' service.start <service name>
```

```python
salt.modules.freebsdservice.status(name, sig=None)
Return the status for a service (True or False).

name Name of service

CLI Example:
```
salt '*' service.status <service name>
```

```python
salt.modules.freebsdservice.stop(name)
Stop the specified service

CLI Example:
```
salt '*' service.stop <service name>
```

### 32.17.93 salt.modules.gem

Manage ruby gems.

```python
salt.modules.gem.install(gems, ruby=None, gem_bin=None, runas=None, version=None, rdoc=False, ri=False, pre_releases=False, proxy=None)
```

Installs one or several gems.

**Parameters**

- **gems** -- string The gems to install
- **gem_bin** -- string : None Full path to gem binary to use.
- **ruby** -- string : None If RVM or rbenv are installed, the ruby version and gemset to use. Ignored if gem_bin is specified.
- **runas** -- string : None The user to run gem as.
- **version** -- string : None Specify the version to install for the gem. Doesn't play nice with multiple gems at once
- **rdoc** -- boolean : False Generate RDoc documentation for the gem(s).
- **ri** -- boolean : False Generate RI documentation for the gem(s).
- **pre_releases** -- boolean : False Include pre-releases in the available versions
- **proxy** -- string : None Use the specified HTTP proxy server for all outgoing traffic. Format: http://hostname[:port]

CLI Example:
```
salt '*' gem.install vagrant
```
```
salt '*' gem.install redphone gem_bin=/opt/sensu/embedded/bin/gem
```
salt.modules.gem.list(prefix='*', ruby=None, runas=None, gem_bin=None)
List locally installed gems.

Parameters

- **prefix** -- string : Only list gems when the name matches this prefix.
- **gem_bin** -- string : None Full path to gem binary to use.
- **ruby** -- string : None If RVM or rbenv are installed, the ruby version and gemset to use. Ignored if gem_bin is specified.
- **runas** -- string : None The user to run gem as.

CLI Example:
```
salt '*' gem.list
```

salt.modules.gem.list_upgrades(ruby=None, runas=None, gem_bin=None)
New in version 2015.8.0.
Check if an upgrade is available for installed gems

gem_bin [None] Full path to gem binary to use.
ruby [None] If RVM or rbenv are installed, the ruby version and gemset to use. Ignored if gem_bin is specified.
runas [None] The user to run gem as.

CLI Example:
```
salt '*' gem.list_upgrades
```

salt.modules.gem.sources_add(source_uri, ruby=None, runas=None, gem_bin=None)
Add a gem source.

Parameters

- **source_uri** -- string The source URI to add.
- **gem_bin** -- string : None Full path to gem binary to use.
- **ruby** -- string : None If RVM or rbenv are installed, the ruby version and gemset to use. Ignored if gem_bin is specified.
- **runas** -- string : None The user to run gem as.

CLI Example:
```
salt '*' gem.sources_add http://rubygems.org/
```

salt.modules.gem.sources_list(ruby=None, runas=None, gem_bin=None)
List the configured gem sources.

Parameters

- **gem_bin** -- string : None Full path to gem binary to use.
- **ruby** -- string : None If RVM or rbenv are installed, the ruby version and gemset to use. Ignored if gem_bin is specified.
- **runas** -- string : None The user to run gem as.

CLI Example:
salt '*' gem.sources_list

salt.modules.gem.sources_remove(source_uri, ruby=None, runas=None, gem_bin=None)
Remove a gem source.

Parameters

• source_uri -- string The source URI to remove.
• gem_bin -- string : None Full path to gem binary to use.
• ruby -- string : None If RVM or rbenv are installed, the ruby version and gemset to use. Ignored if gem_bin is specified.
• runas -- string : None The user to run gem as.

CLI Example:
salt '*' gem.sources_remove http://rubygems.org/

salt.modules.gem.uninstall(gems, ruby=None, runas=None, gem_bin=None)
Uninstall one or several gems.

Parameters

• gems -- string The gems to uninstall.
• gem_bin -- string : None Full path to gem binary to use.
• ruby -- string : None If RVM or rbenv are installed, the ruby version and gemset to use. Ignored if gem_bin is specified.
• runas -- string : None The user to run gem as.

CLI Example:
salt '*' gem.uninstall vagrant

salt.modules.gem.update(gems, ruby=None, runas=None, gem_bin=None)
Update one or several gems.

Parameters

• gems -- string The gems to update.
• gem_bin -- string : None Full path to gem binary to use.
• ruby -- string : None If RVM or rbenv are installed, the ruby version and gemset to use. Ignored if gem_bin is specified.
• runas -- string : None The user to run gem as.

CLI Example:
salt '*' gem.update vagrant

salt.modules.gem.update_system(version='', ruby=None, runas=None, gem_bin=None)
Update rubygems.

Parameters

• version -- string : (newest) The version of rubygems to install.
• gem_bin -- string : None Full path to gem binary to use.
• **ruby** -- string : None If RVM or rbenv are installed, the ruby version and gemset to use.
  Ignored if **gem_bin** is specified.
• **runas** -- string : None The user to run gem as.

CLI Example:
```
salt '*' gem.update_system
```

### 32.17.94 salt.modules.genesis

Module for managing container and VM images

New in version 2014.7.0.

`salt.modules.genesis.avail_platforms()`

Return which platforms are available

CLI Example:
```
salt myminion genesis.avail_platforms
```

`salt.modules.genesis.bootstrap(platform, root, img_format='dir', fs_format='ext2', arch=None, flavor=None, repo_url=None, static_qemu=None)`

Create an image for a specific platform.

Please note that this function MUST be run as root, as images that are created make files belonging to root.

**platform** Which platform to use to create the image. Currently supported platforms are rpm, deb and pacman.

**root** Local path to create the root of the image filesystem.

**img_format** Which format to create the image in. By default, just copies files into a directory on the local filesystem (`dir`). Future support will exist for `sparse`.

**fs_format** When using a non-`dir` **img_format**, which filesystem to format the image to. By default, `ext2`.

**arch** Architecture to install packages for, if supported by the underlying bootstrap tool. Currently only used for deb.

**flavor** Which flavor of operating system to install. This correlates to a specific directory on the distribution repositories. For instance, `wheezy` on Debian.

**repo_url** Mainly important for Debian-based repos. Base URL for the mirror to install from. (e.x.: `http://ftp.debian.org/debian/`)

**static_qemu** Local path to the static qemu binary required for this arch. (e.x.: `/usr/bin/qemu-amd64-static`)

**pkg_conf** The location of the conf files to copy into the image, to point the installer to the right repos and configuration.

CLI Examples:
```
salt myminion genesis.bootstrap pacman /root/arch
salt myminion genesis.bootstrap rpm /root/redhat
salt myminion genesis.bootstrap deb /root/wheezy arch=amd64
  --flavor=wheezy static_qemu=/usr/bin/qemu-x86_64-static
```

`salt.modules.genesis.pack(name, root, path=None, pack_format='tar', compress='bzip2')`

Pack up a directory structure, into a specific format

CLI Examples:
salt.modules.genesis.unpack(name, dest=None, path=None, pack_format='tar', compress='bz2')

Unpack an image into a directory structure

CLI Example:

```
salt myminion genesis.unpack centos /root/centos
```

### 32.17.95 salt.modules.gentoo_service

Top level package command wrapper, used to translate the os detected by grains to the correct service manager

**Important:** If you feel that Salt should be using this module to manage services on a minion, and it is using a different module (or gives an error similar to `service.start` is not available), see here.

salt.modules.gentoo_service.available(name)

Returns True if the specified service is available, otherwise returns False.

CLI Example:

```
salt '*' service.available sshd
```

salt.modules.gentoo_service.disable(name, **kwargs)

Disable the named service to start at boot

CLI Example:

```
salt '*' service.disable <service name>
```

salt.modules.gentoo_service.disabled(name)

Return True if the named service is enabled, false otherwise

CLI Example:

```
salt '*' service.disabled <service name>
```

salt.modules.gentoo_service.enable(name, **kwargs)

Enable the named service to start at boot

CLI Example:

```
salt '*' service.enable <service name>
```

salt.modules.gentoo_service.enabled(name, **kwargs)

Return True if the named service is enabled, false otherwise

CLI Example:

```
salt '*' service.enabled <service name>
```

salt.modules.gentoo_service.get_all()

Return all available boot services

CLI Example:
salt 'salt '*' service.get_all

salt.modules.gentoo_service.get_disabled()
    Return a set of services that are installed but disabled
    CLI Example:
        salt 'salt '*' service.get_disabled

salt.modules.gentoo_service.get_enabled()
    Return a list of service that are enabled on boot
    CLI Example:
        salt 'salt '*' service.get_enabled

salt.modules.gentoo_service.missing(name)
    The inverse of service.available. Returns True if the specified service is not available, otherwise returns False.
    CLI Example:
        salt 'salt '*' service.missing sshd

salt.modules.gentoo_service.restart(name)
    Restart the named service
    CLI Example:
        salt 'salt '*' service.restart <service name>

salt.modules.gentoo_service.start(name)
    Start the specified service
    CLI Example:
        salt 'salt '*' service.start <service name>

salt.modules.gentoo_service.status(name, sig=None)
    Return the status for a service, returns the PID or an empty string if the service is running or not, pass a signature to use to find the service via ps
    CLI Example:
        salt 'salt '*' service.status <service name> [service signature]

salt.modules.gentoo_service.stop(name)
    Stop the specified service
    CLI Example:
        salt 'salt '*' service.stop <service name>

32.17.96 salt.modules.gentoolkitmod

Support for Gentoolkit
salt.modules.gentoolkitmod.eclean_dist

```python
(destructive=False, package_names=False,
 size_limit=0, time_limit=0, fetch_restricted=False,
 exclude_file='/etc/eclean/distfiles.exclude')
```

Clean obsolete portage sources

**destructive**  Only keep minimum for reinstallation

**package_names**  Protect all versions of installed packages. Only meaningful if used with destructive=True

**size_limit <size>**  Don't delete distfiles bigger than <size>.  <size> is a size specification: ``10M'' is ``ten megabytes'', ``200K'' is ``two hundreds kilobytes'', etc. Units are: G, M, K and B.

**time_limit <time>**  Don't delete distfiles files modified since <time> <time> is an amount of time: ``1y'' is ``one year'', ``2w'' is ``two weeks'', etc. Units are: y (years), m (months), w (weeks), d (days) and h (hours).

**fetch_restricted**  Protect fetch-restricted files. Only meaningful if used with destructive=True

**exclude_file**  Path to exclusion file. Default is /etc/eclean/distfiles.exclude  This is the same default eclean-dist uses. Use None if this file exists and you want to ignore.

Returns a dict containing the cleaned, saved, and deprecated dists:

```
{'cleaned': {'dist file': <size>},
 'deprecated': {'package': {'dist file': }},
 'saved': {'package': {'dist file': }},
 'total_cleaned': <size>}
```

CLI Example:

```
salt '*' gentoolkit.eclean_dist destructive=True
```

salt.modules.gentoolkitmod.eclean_pkg

```python
(destructive=False, package_names=False, time_limit=0,
 exclude_file='/etc/eclean/packages.exclude')
```

Clean obsolete binary packages

**destructive**  Only keep minimum for reinstallation

**package_names**  Protect all versions of installed packages. Only meaningful if used with destructive=True

**time_limit <time>**  Don't delete distfiles files modified since <time> <time> is an amount of time: ``1y'' is ``one year'', ``2w'' is ``two weeks'', etc. Units are: y (years), m (months), w (weeks), d (days) and h (hours).

**exclude_file**  Path to exclusion file. Default is /etc/eclean/packages.exclude  This is the same default eclean-pkg uses. Use None if this file exists and you want to ignore.

Returns a dict containing the cleaned binary packages:

```
{'cleaned': {'dist file': <size>},
 'total_cleaned': <size>}
```

CLI Example:

```
salt '*' gentoolkit.eclean_pkg destructive=True
```

class glsa_check_list

List the status of Gentoo Linux Security Advisories

**glsa_list**  can contain an arbitrary number of GLSA ids, filenames containing GLSAs or the special identifiers 'all' and 'affected'
Returns a dict containing glsa ids with a description, status, and CVEs:

```
{<glsa_id>: {'description': <glsa_description>,
             'status': <glsa status>,
             'CVEs': [<list of CVEs>])}
```

CLI Example:

```
salt '*' gentoolkit.glsa_check_list 'affected'
```

```
salt.modules.gentoolkitmod.revdep_rebuild(lib=None)
```

Fix up broken reverse dependencies

`lib` Search for reverse dependencies for a particular library rather than every library on the system. It can be a full path to a library or basic regular expression.

CLI Example:

```
salt '*' gentoolkit.revdep_rebuild
```

## 32.17.97 salt.modules.git

Support for the Git SCM

```
salt.modules.git.add(cwd, filename, opts='--dry-run', user=None, ignore_retcode=False)
```

Changed in version 2015.8.0: The `--verbose` command line argument is now implied

Interface to `git-add(1)`

`cwd` The path to the git checkout

`filename` The location of the file/directory to add, relative to `cwd`

`opts` Any additional options to add to the command line, in a single string

**Note:** On the Salt CLI, if the `opts` are preceded with a dash, it is necessary to precede them with `opts=` (as in the CLI examples below) to avoid causing errors with Salt’s own argument parsing.

`user` User under which to run the git command. By default, the command is run by the user under which the minion is running.

`ignore_retcode` [False] If True, do not log an error to the minion log if the git command returns a nonzero exit status.

New in version 2015.8.0.

CLI Examples:

```
salt myminion git.add /path/to/repo foo/bar.py
salt myminion git.add /path/to/repo foo/bar.py opts='--dry-run'
```

```
salt.modules.git.archive(cwd, output, rev='HEAD', fmt=None, prefix=None, user=None, ignore_retcode=False, **kwargs)
```

Changed in version 2015.8.0: Returns True if successful, raises an error if not.

Interface to `git-archive(1)`, exports a tarball/zip file of the repository
cwd  The path to be archived

Note: git archive permits a partial archive to be created. Thus, this path does not need to be the
root of the git repository. Only the files within the directory specified by cwd (and its subdirectories)
will be in the resulting archive. For example, if there is a git checkout at /tmp/foo, then passing
/tmp/foo/bar as the cwd will result in just the files underneath /tmp/foo/bar to be exported as
an archive.

output  The path of the archive to be created

overwrite  [False] Unless set to True, Salt will over overwrite an existing archive at the path specified by the
output argument.

New in version 2015.8.0.

rev  [HEAD] The revision from which to create the archive

format  Manually specify the file format of the resulting archive. This argument can be omitted, and git
archive will attempt to guess the archive type (and compression) from the filename. zip, tar,
tar.gz, and tgz are extensions that are recognized automatically, and git can be configured to support
other archive types with the addition of git configuration keys.

See the git-archive(1) manpage explanation of the --format argument (as well as the CONFIGURA-
TION section of the manpage) for further information.

New in version 2015.8.0.

fmt  Replaced by format in version 2015.8.0

Deprecated since version 2015.8.0.

prefix  Prepend \<prefix\> to every filename in the archive. If unspecified, the name of the directory at the
top level of the repository will be used as the prefix (e.g. if cwd is set to /foo/bar/baz, the prefix
will be baz, and the resulting archive will contain a top-level directory by that name).

Note: The default behavior if the --prefix option for git archive is not specified is to not prepend
a prefix, so Salt’s behavior differs slightly from git archive in this respect. Use prefix=' ' to create
an archive with no prefix.

Changed in version 2015.8.0: The behavior of this argument has been changed slightly. As of this version,
it is necessary to include the trailing slash when specifying a prefix, if the prefix is intended to create a
top-level directory.

user  User under which to run the git command. By default, the command is run by the user under which the
minion is running.

ignore_retcode  [False] If True, do not log an error to the minion log if the git command returns a nonzero
exit status.

New in version 2015.8.0.

CLI Example:

```
salt myminion git.archive /path/to/repo /path/to/archive.tar
```

salt.modules.git.branch(cwd, name=None, opts=' ', user=None, ignore_retcode=False)

Interface to git-branch(1)

cwd  The path to the git checkout
**name**  Name of the branch on which to operate. If not specified, the current branch will be assumed.

**opts**  Any additional options to add to the command line, in a single string

---

**Note:** To create a branch based on something other than HEAD, pass the name of the revision as **opts**. If the revision is in the format `remote/rename/branch`, then this will also set the remote tracking branch.

Additionally, on the Salt CLI, if the opts are preceded with a dash, it is necessary to precede them with **opts=** (as in the CLI examples below) to avoid causing errors with Salt's own argument parsing.

---

**user**  User under which to run the git command. By default, the command is run by the user under which the minion is running.

**ignore_retcode**  [False] If **True**, do not log an error to the minion log if the git command returns a nonzero exit status.

New in version 2015.8.0.

CLI Examples:

```
# Set remote tracking branch
salt myminion git.branch /path/to/repo mybranch opts='--set-upstream-to origin/mybranch'
# Create new branch
salt myminion git.branch /path/to/repo mybranch upstream/somebranch
# Delete branch
salt myminion git.branch /path/to/repo mybranch opts='--d'
# Rename branch (2015.8.0 and later)
salt myminion git.branch /path/to/repo newbranch opts='--m oldbranch'
```

---

**salt.modules.git.checkout**  
(cwd, rev=None, force=False, opts='', user=None, ignore_retcode=False)

Interface to `git-checkout(1)`

**cwd**  The path to the git checkout

**opts**  Any additional options to add to the command line, in a single string

---

**Note:** On the Salt CLI, if the opts are preceded with a dash, it is necessary to precede them with **opts=** (as in the CLI examples below) to avoid causing errors with Salt's own argument parsing.

---

**rev**  The remote branch or revision to checkout.

Changed in version 2015.8.0: Optional when using `-b` or `-B` in **opts**.

**force**  [False] Force a checkout even if there might be overwritten changes

**user**  User under which to run the git command. By default, the command is run by the user under which the minion is running.

**ignore_retcode**  [False] If **True**, do not log an error to the minion log if the git command returns a nonzero exit status.

New in version 2015.8.0.

CLI Examples:

```
# Checking out local local revisions
salt myminion git.checkout /path/to/repo somebranch user=jeff
salt myminion git.checkout /path/to/repo opts='testbranch -- conf/file1 file2'
salt myminion git.checkout /path/to/repo rev=origin/mybranch opts='--track'
```
## Checking out remote revision into new branch

```bash
salt myminion git.checkout /path/to/repo upstream/master opts='--b newbranch'
```

## Checking out current revision into new branch (2015.8.0 and later)

```bash
salt myminion git.checkout /path/to/repo opts='--b newbranch'
```

### salt.modules.git.clone(cwd, url=None, name=None, opts='-', user=None, identity=None, https_user=None, https_pass=None, ignore_retcode=False, repository=None)

Interface to `git-clone(1)`

- **cwd** Location of git clone
  
  Changed in version 2015.8.0: If `name` is passed, then the clone will be made within this directory.

- **url** The URL of the repository to be cloned
  
  Changed in version 2015.8.0: Argument renamed from `repository` to `url`

- **name** Optional alternate name for the top-level directory to be created by the clone
  
  New in version 2015.8.0.

- **opts** Any additional options to add to the command line, in a single string

- **user** User under which to run the git command. By default, the command is run by the user under which the minion is running.
  
  Run git as a user other than what the minion runs as

- **identity** Path to a private key to use for ssh URLs
  
  **Warning:** Unless Salt is invoked from the minion using `salt-call`, the key(s) must be passphrase-less. For greater security with passphraseless private keys, see the `sshd(8)` manpage for information on securing the keypair from the remote side in the `authorized_keys` file.

  Changed in version 2015.8.7: Salt will no longer attempt to use passphrase-protected keys unless invoked from the minion using `salt-call`, to prevent blocking waiting for user input.

- **https_user** Set HTTP Basic Auth username. Only accepted for HTTPS URLs.
  
  New in version 2015.5.0.

- **https_pass** Set HTTP Basic Auth password. Only accepted for HTTPS URLs.
  
  New in version 2015.5.0.

- **ignore_retcode** `[False]` If `True`, do not log an error to the minion log if the git command returns a nonzero exit status.
  
  New in version 2015.8.0.

### CLI Example:

```bash
salt myminion git.clone /path/to/repo_parent_dir git://github.com/saltstack/salt.
```

### salt.modules.git.commit(cwd, message, opts='-', user=None, filename=None, ignore_retcode=False)

Interface to `git-commit(1)`

- **cwd** The path to the git checkout

- **message** Commit message
opts  Any additional options to add to the command line, in a single string

Note: On the Salt CLI, if the opts are preceded with a dash, it is necessary to precede them with opts=
(as in the CLI examples below) to avoid causing errors with Salt's own argument parsing.
The -m option should not be passed here, as the commit message will be defined by the message argument.

user  User under which to run the git command. By default, the command is run by the user under which the
minion is running.

filename  The location of the file/directory to commit, relative to cwd. This argument is optional, and can be
used to commit a file without first staging it.

Note: This argument only works on files which are already tracked by the git repository.

New in version 2015.8.0.

ignore_retcode  [False] If True, do not log an error to the minion log if the git command returns a nonzero
exit status.

New in version 2015.8.0.

CLI Examples:

```bash
salt myminion git.commit /path/to/repo 'The commit message'
salt myminion git.commit /path/to/repo 'The commit message' filename=foo/bar.py
```

salt.modules.git.config_get(key, cwd=None, user=None, ignore_retcode=False, **kwargs)
Get the value of a key in the git configuration file

key  The name of the configuration key to get

Changed in version 2015.8.0: Argument renamed from setting_name to key

cwd  The path to the git checkout

Changed in version 2015.8.0: Now optional if global is set to True

global  [False] If True, query the global git configuration. Otherwise, only the local git configuration will be
queried.

New in version 2015.8.0.

all  [False] If True, return a list of all values set for key. If the key does not exist, None will be returned.

New in version 2015.8.0.

user  User under which to run the git command. By default, the command is run by the user under which the
minion is running.

ignore_retcode  [False] If True, do not log an error to the minion log if the git command returns a nonzero
exit status.

New in version 2015.8.0.

CLI Examples:

```bash
salt myminion git.config_get user.name cwd=/path/to/repo
salt myminion git.config_get user.email global=True
salt myminion git.config_get core.gitproxy cwd=/path/to/repo all=True
```
salt.modules.git.config_get_regexp(key, value_regex=None, cwd=None, user=None, ignore_retcode=False, **kwargs)

New in version 2015.8.0.

Get the value of a key or keys in the git configuration file using regexes for more flexible matching. The return data is a dictionary mapping keys to lists of values matching the value_regex. If no values match, an empty dictionary will be returned.

- **key**: Regex on which key names will be matched
- **value_regex**: If specified, return all values matching this regex. The return data will be a dictionary mapping keys to lists of values matching the regex.

**Important**: Only values matching the value_regex will be part of the return data. So, if key matches a multivar, then it is possible that not all of the values will be returned. To get all values set for a multivar, simply omit the value_regex argument.

- **cwd**: The path to the git checkout. Must be an absolute path, or the word global to indicate that a global key should be set.
- **global**: [False] If True, query the global git configuration. Otherwise, only the local git configuration will be queried.
- **user**: User under which to run the git command. By default, the command is run by the user under which the minion is running.
- **ignore_retcode**: [False] If True, do not log an error to the minion log if the git command returns a nonzero exit status.

CLI Examples:

```
# Matches any values for key 'foo.bar'
salt myminion git.config_get_regexp /path/to/repo foo.bar
# Matches any value starting with 'baz' set for key 'foo.bar'
salt myminion git.config_get_regexp /path/to/repo foo.bar 'baz.*'
# Matches any key starting with 'user.'
salt myminion git.config_get_regexp '^user\.' global=True
```

salt.modules.git.config_set(key, value=None, multivar=None, cwd=None, user=None, ignore_retcode=False, **kwargs)

Changed in version 2015.8.0: Return the value(s) of the key being set

Set a key in the git configuration file

- **key**: The name of the configuration key to set
- **value**: The value to set for the specified key. Incompatible with the multivar argument.
- **add**: [False] Add a value to a key, creating/updating a multivar
- **multivar**: Set a multivar all at once. Values can be comma-separated or passed as a Python list. Incompatible with the value argument.

Changed in version 2014.7.0: Made cwd argument optional if is_global=True

Chapter 32. Reference
New in version 2015.8.0.

**user** User under which to run the git command. By default, the command is run by the user under which the minion is running.

**ignore_retcode** [False] If True, do not log an error to the minion log if the git command returns a nonzero exit status.

New in version 2015.8.0.

**global** [False] If True, set a global variable

**is_global** [False] If True, set a global variable

Depreciated since version 2015.8.0: Use `global` instead

CLI Example:

```
salt myminion git.config_set user.email me@example.com
cwd=/path/to/repo
salt myminion git.config_set user.email foo@bar.com global=True
```

salt.modules.git.config_unset(**key, value_regex=None, cwd=None, user=None, ignore_retcode=False, **kwargs)**

New in version 2015.8.0.

Unset a key in the git configuration file

**cwd** The path to the git checkout. Must be an absolute path, or the word `global` to indicate that a global key should be unset.

**key** The name of the configuration key to unset

**value_regex** Regular expression that matches exactly one key, used to delete a single value from a multivar. Ignored if `all` is set to `True`.

**all** [False] If True unset all values for a multivar. If False, and `key` is a multivar, an error will be raised.

**global** [False] If True, unset set a global variable. Otherwise, a local variable will be unset.

**user** User under which to run the git command. By default, the command is run by the user under which the minion is running.

**ignore_retcode** [False] If True, do not log an error to the minion log if the git command returns a nonzero exit status.

CLI Example:

```
salt myminion git.config_unset /path/to/repo foo.bar
salt myminion git.config_unset /path/to/repo foo.bar all=True
```

salt.modules.git.current_branch(**cwd, user=None, ignore_retcode=False)**

Returns the current branch name of a local checkout. If HEAD is detached, return the SHA1 of the revision which is currently checked out.

**cwd** The path to the git checkout

**user** User under which to run the git command. By default, the command is run by the user under which the minion is running.

**ignore_retcode** [False] If True, do not log an error to the minion log if the git command returns a nonzero exit status.

New in version 2015.8.0.

CLI Example:
salt myminion git.current_branch /path/to/repo

salt.modules.git.describe(cwd, rev='HEAD', user=None, ignore_retcode=False)
Returns the git-describe(1) string (or the SHA1 hash if there are no tags) for the given revision.

cwd  The path to the git checkout
rev   [HEAD] The revision to describe
user  User under which to run the git command. By default, the command is run by the user under which the
       minion is running.
ignore_retcode  [False] If True, do not log an error to the minion log if the git command returns a nonzero
                  exit status.

       New in version 2015.8.0.

CLI Examples:
salt myminion git.describe /path/to/repo
salt myminion git.describe /path/to/repo develop

salt.modules.git.diff(cwd, item1=None, item2=None, opts='', user=None, no_index=False, cached=False, paths=None)

Interface to git-diff(1)

cwd  The path to the git checkout
item1 and item2  Revision(s) to pass to the git diff command. One or both of these arguments may be
                  ignored if some of the options below are set to True. When cached is False, and no revisions are
                  passed to this function, then the current working tree will be compared against the index (i.e. unstaged
                  changes). When two revisions are passed, they will be compared to each other.

opts  Any additional options to add to the command line, in a single string

       Note: On the Salt CLI, if the opts are preceded with a dash, it is necessary to precede them with opts=
       (as in the CLI examples below) to avoid causing errors with Salt's own argument parsing.

user  User under which to run the git command. By default, the command is run by the user under which the
       minion is running.

no_index  [False] When it is necessary to diff two files in the same repo against each other, and not diff two
          different revisions, set this option to True. If this is left False in these instances, then a normal git
          diff will be performed against the index (i.e. unstaged changes), and files in the paths option will be
          used to narrow down the diff output.

       Note: Requires Git 1.5.1 or newer. Additionally, when set to True, item1 and item2 will be ignored.

cached  [False] If True, compare staged changes to item1 (if specified), otherwise compare them to the most
         recent commit.

       Note: item2 is ignored if this option is is set to True.
**paths**  File paths to pass to the `git diff` command. Can be passed as a comma-separated list or a Python list.

**CLI Example:**

```sh
# Perform diff against the index (staging area for next commit)
salt myminion git.diff /path/to/repo

# Compare staged changes to the most recent commit
salt myminion git.diff /path/to/repo cached=True

# Compare staged changes to a specific revision
salt myminion git.diff /path/to/repo mybranch cached=True

# Perform diff against the most recent commit (includes staged changes)
salt myminion git.diff /path/to/repo HEAD

# Diff two commits
salt myminion git.diff /path/to/repo abcdef1 aabbccd

# Diff two commits, only showing differences in the specified paths
salt myminion git.diff /path/to/repo abcdef1 aabbccd paths=path/to/file1,path/to/file2

# Diff two files with one being outside the working tree
salt myminion git.diff /path/to/repo no_index=True paths=path/to/file1,/absolute/!path/to/file2
```

**salt.modules.git.fetch**(cwd, remote=None, force=False, refspecs=None, opts='', user=None, identity=None, ignore_retcode=False)

Changed in version 2015.8.2: Return data is now a dictionary containing information on branches and tags that were added/updated

Interface to `git-fetch(1)`

**cwd**  The path to the git checkout

**remote**  Optional remote name to fetch. If not passed, then `git` will use its default behavior (as detailed in `git-fetch(1)`).

New in version 2015.8.0.

**force**  Force the fetch even when it is not a fast-forward.

New in version 2015.8.0.

**refspecs**  Override the refspec(s) configured for the remote with this argument. Multiple refspecs can be passed, comma-separated.

New in version 2015.8.0.

**opts**  Any additional options to add to the command line, in a single string

**Note:**  On the Salt CLI, if the `opts` are preceded with a dash, it is necessary to precede them with `opts=` (as in the CLI examples below) to avoid causing errors with Salt's own argument parsing.

**user**  User under which to run the git command. By default, the command is run by the user under which the minion is running.

**identity**  Path to a private key to use for ssh URLs

**Warning:**  Unless Salt is invoked from the minion using `salt-call`, the key(s) must be passphrase-less. For greater security with passphraseless private keys, see the `sshd(8)` manpage for information on securing the keypair from the remote side in the `authorized_keys` file.
Changed in version 2015.8.7: Salt will no longer attempt to use passphrase-protected keys unless invoked from the minion using `salt-call`, to prevent blocking waiting for user input.

**ignore_retcode**  [False] If `True`, do not log an error to the minion log if the git command returns a nonzero exit status.

New in version 2015.8.0.

CLI Example:

```bash
salt myminion git.fetch /path/to/repo upstream
salt myminion git.fetch /path/to/repo identity=/root/.ssh/id_rsa
```

### `salt.modules.git.init` 
(cwd, bare=False, template=None, separate_git_dir=None, shared=None, opts='', user=None, ignore_retcode=False)

- **Interface to `git-init(1)`**
- **cwd** The path to the directory to be initialized
- **bare**  [False] If `True`, init a bare repository

New in version 2015.8.0.

- **template** Set this argument to specify an alternate template directory

New in version 2015.8.0.

- **separate_git_dir** Set this argument to specify an alternate $GIT_DIR

New in version 2015.8.0.

- **shared** Set sharing permissions on git repo. See `git-init(1)` for more details.

New in version 2015.8.0.

- **opts** Any additional options to add to the command line, in a single string

**Note:** On the Salt CLI, if the opts are preceded with a dash, it is necessary to precede them with opts= (as in the CLI examples below) to avoid causing errors with Salt’s own argument parsing.

- **user** User under which to run the git command. By default, the command is run by the user under which the minion is running.

- **ignore_retcode**  [False] If `True`, do not log an error to the minion log if the git command returns a nonzero exit status.

New in version 2015.8.0.

CLI Examples:

```bash
salt myminion git.init /path/to/repo
# Init a bare repo (before 2015.8.0)
salt myminion git.init /path/to/bare/repo.git opts='--bare'
# Init a bare repo (2015.8.0 and later)
salt myminion git.init /path/to/bare/repo.git bare=True
```

### `salt.modules.git.is_worktree` (cwd, user=None)

New in version 2015.8.0.

This function will attempt to determine if `cwd` is part of a worktree by checking its `.git` to see if it is a file containing a reference to another gitdir.

- **cwd** path to the worktree to be removed
user  User under which to run the git command. By default, the command is run by the user under which the minion is running.

CLI Example:

```
salt myminion git.is_worktree /path/to/repo
```

`salt.modules.git.list_branches`(cwd, remote=False, user=None, ignore_retcode=False)
New in version 2015.8.0.

Return a list of branches

- **cwd**  The path to the git checkout
- **remote**  [False] If True, list remote branches. Otherwise, local branches will be listed.

Warning:  This option will only return remote branches of which the local checkout is aware, use `git.fetch` to update remotes.

user  User under which to run the git command. By default, the command is run by the user under which the minion is running.

ignore_retcode  [False] If True, do not log an error to the minion log if the git command returns a nonzero exit status.

New in version 2015.8.0.

CLI Examples:

```
salt myminion git.list_branches /path/to/repo
salt myminion git.list_branches /path/to/repo remote=True
```

`salt.modules.git.list_tags`(cwd, user=None, ignore_retcode=False)
New in version 2015.8.0.

Return a list of tags

- **cwd**  The path to the git checkout
- **user**  User under which to run the git command. By default, the command is run by the user under which the minion is running.
- **ignore_retcode**  [False] If True, do not log an error to the minion log if the git command returns a nonzero exit status.

New in version 2015.8.0.

CLI Examples:

```
salt myminion git.list_tags /path/to/repo
```

`salt.modules.git.list_worktrees`(cwd, stale=False, user=None, **kwargs)
New in version 2015.8.0.

Returns information on worktrees

Changed in version 2015.8.4: Version 2.7.0 added the list subcommand to `git-worktree(1)` which provides a lot of additional information. The return data has been changed to include this information, even for pre-2.7.0 versions of git. In addition, if a worktree has a detached head, then any tags which point to the worktree’s HEAD will be included in the return data.
Note: By default, only worktrees for which the worktree directory is still present are returned, but this can be changed using the all and stale arguments (described below).

cwd  The path to the git checkout
user  User under which to run the git command. By default, the command is run by the user under which the minion is running.
all  [False] If True, then return all worktrees tracked under $GIT_DIR/worktrees, including ones for which the gitdir is no longer present.
stale  [False] If True, return only worktrees whose gitdir is no longer present.

Note: Only one of all and stale can be set to True.

CLI Examples:

```
salt myminion git.list_worktrees /path/to/repo
salt myminion git.list_worktrees /path/to/repo all=True
salt myminion git.list_worktrees /path/to/repo stale=True
```

salt.modules.git.ls_remote(cwd=None, remote='origin', ref=None, opts='', user=None, identity=None, https_user=None, https_pass=None, ignore_retcode=False)

Interface to git-ls-remote(1). Returns the upstream hash for a remote reference.

cwd  The path to the git checkout. Optional (and ignored if present) when remote is set to a URL instead of a remote name.
remote  [origin] The name of the remote to query. Can be the name of a git remote (which exists in the git checkout defined by the cwd parameter), or the URL of a remote repository.

Changed in version 2015.8.0: Argument renamed from repository to remote
ref  The name of the ref to query. Optional, if not specified, all refs are returned. Can be a branch or tag name, or the full name of the reference (for example, to get the hash for a Github pull request number 1234, ref can be set to refs/pull/1234/head

Changed in version 2015.8.0: Argument renamed from branch to ref
Changed in version 2015.8.4: Defaults to returning all refs instead of master.
opts  Any additional options to add to the command line, in a single string

New in version 2015.8.0.
user  User under which to run the git command. By default, the command is run by the user under which the minion is running.
identity  Path to a private key to use for ssh URLs

Warning: Unless Salt is invoked from the minion using salt-call, the key(s) must be passphrase-less. For greater security with passphraseless private keys, see the sshd(8) manpage for information on securing the keypair from the remote side in the authorized_keys file.

Changed in version 2015.8.7: Salt will no longer attempt to use passphrase-protected keys unless invoked from the minion using salt-call, to prevent blocking waiting for user input.
https_user  Set HTTP Basic Auth username. Only accepted for HTTPS URLs.

    New in version 2015.5.0.

https_pass  Set HTTP Basic Auth password. Only accepted for HTTPS URLs.

    New in version 2015.5.0.

ignore_retcode  [False] If True, do not log an error to the minion log if the git command returns a nonzero exit status.

    New in version 2015.8.0.

CLI Example:

    salt myminion git.ls_remote /path/to/repo origin master
    salt myminion git.ls_remote remote=https://mydomain.tld/repo.git ref=mytag opts='--tags'

salt.modules.git.merge(cwd, rev=None, opts=' ', user=None, ignore_retcode=False, **kwargs)

    Interface to git-merge(1)

    cwd  The path to the git checkout

    rev  Revision to merge into the current branch. If not specified, the remote tracking branch will be merged.

    New in version 2015.8.0.

    branch  The remote branch or revision to merge into the current branch

    Revision to merge into the current branch

    Deprecated since version 2015.8.0: Use rev instead.

    opts  Any additional options to add to the command line, in a single string

    Note: On the Salt CLI, if the opts are preceded with a dash, it is necessary to precede them with opts= (as in the CLI examples below) to avoid causing errors with Salt's own argument parsing.

    user  User under which to run the git command. By default, the command is run by the user under which the minion is running.

    ignore_retcode  [False] If True, do not log an error to the minion log if the git command returns a nonzero exit status.

    New in version 2015.8.0.

CLI Example:

    # Fetch first...
    salt myminion git.fetch /path/to/repo
    # ... then merge the remote tracking branch
    salt myminion git.merge /path/to/repo
    # ... or merge another rev
    salt myminion git.merge /path/to/repo rev=upstream/foo

salt.modules.git.merge_base(cwd, refs=None, octopus=False, is_ancestor=False, independent=False, fork_point=None, opts=' ', user=None, ignore_retcode=False, **kwargs)

    New in version 2015.8.0.

    Interface to git-merge-base(1).

    cwd  The path to the git checkout
refs  Any refs/commits to check for a merge base. Can be passed as a comma-separated list or a Python list.

all  [False] Return a list of all matching merge bases. Not compatible with any of the below options except for octopus.

octopus  [False] If True, then this function will determine the best common ancestors of all specified commits, in preparation for an n-way merge. See here for a description of how these bases are determined.

Set all to True with this option to return all computed merge bases, otherwise only the ```best``` will be returned.

is_ancestor  [False] If True, then instead of returning the merge base, return a boolean telling whether or not the first commit is an ancestor of the second commit.

Note:  This option requires two commits to be passed.

Changed in version 2015.8.2: Works properly in git versions older than 1.8.0, where the ```--is-ancestor``` CLI option is not present.

independent  [False] If True, this function will return the IDs of the refs/commits passed which cannot be reached by another commit.

fork_point  If passed, then this function will return the commit where the commit diverged from the ref specified by fork_point. If no fork point is found, None is returned.

Note:  At most one commit is permitted to be passed if a fork_point is specified. If no commits are passed, then HEAD is assumed.

opts  Any additional options to add to the command line, in a single string

Note:  On the Salt CLI, if the opts are preceded with a dash, it is necessary to precede them with ```opts=``` (as in the CLI examples below) to avoid causing errors with Salt’s own argument parsing.

This option should not be necessary unless new CLI arguments are added to git-merge-base(1) and are not yet supported in Salt.

user  User under which to run the git command. By default, the command is run by the user under which the minion is running.

ignore_retcode  [False] if True, do not log an error to the minion log if the git command returns a nonzero exit status.

CLI Examples:

```
salt myminion git.merge_base /path/to/repo HEAD upstream/mybranch
salt myminion git.merge_base /path/to/repo 8f2e542,4ad8cab,cdc9886 octopus=True
salt myminion git.merge_base /path/to/repo refs=8f2e542,4ad8cab,cdc9886 independent=True
salt myminion git.merge_base /path/to/repo refs=8f2e542,4ad8cab is_ancestor=True
salt myminion git.merge_base /path/to/repo fork_point=upstream/master
salt myminion git.merge_base /path/to/repo refs=mybranch fork_point=upstream/master
```

salt.modules.git.merge_tree(cwd, ref1, ref2, base=None, user=None, ignore_retcode=False)

New in version 2015.8.0.
Interface to `git-merge-tree(1)`, shows the merge results and conflicts from a 3-way merge without touching the index.

**cwd** The path to the git checkout

**ref1** First ref/commit to compare

**ref2** Second ref/commit to compare

**base** The base tree to use for the 3-way-merge. If not provided, then `git.merge_base` will be invoked on `ref1` and `ref2` to determine the merge base to use.

**user** User under which to run the git command. By default, the command is run by the user under which the minion is running.

**ignore_retcode** [False] if True, do not log an error to the minion log if the git command returns a nonzero exit status.

CLI Examples:

```bash
salt myminion git.merge_tree /path/to/repo HEAD upstream/dev
salt myminion git.merge_tree /path/to/repo HEAD upstream/dev base=aaf3c3d
```

**salt.modules.git.pull(cwd, opts=' ', user=None, identity=None, ignore_retcode=False)**

Interface to `git-pull(1)`

**cwd** The path to the git checkout

**opts** Any additional options to add to the command line, in a single string

**user** User under which to run the git command. By default, the command is run by the user under which the minion is running.

**identity** Path to a private key to use for ssh URLs

---

**Warning**: Unless Salt is invoked from the minion using `salt-call`, the key(s) must be passphrase-less. For greater security with passphraseless private keys, see the `sshd(8)` manpage for information on securing the keypair from the remote side in the `authorized_keys` file.

---

Changed in version 2015.8.7: Salt will no longer attempt to use passphrase-protected keys unless invoked from the minion using `salt-call`, to prevent blocking waiting for user input.

**ignore_retcode** [False] if True, do not log an error to the minion log if the git command returns a nonzero exit status.

New in version 2015.8.0.

CLI Example:

```bash
salt myminion git.pull /path/to/repo opts='--rebase origin master'
```

**salt.modules.git.push(cwd, remote=None, ref=None, opts=' ', user=None, identity=None, ignore_retcode=False, **kwargs)**

Interface to `git-push(1)`

**cwd** The path to the git checkout
**remote**  Name of the remote to which the ref should be pushed
   
   New in version 2015.8.0.

**ref**  [master] Name of the ref to push

   **Note:** Being a refspec, this argument can include a colon to define local and remote ref names.

**branch**  Name of the ref to push

   Deprecated since version 2015.8.0: Use ref instead

**opts**  Any additional options to add to the command line, in a single string

   **Note:** On the Salt CLI, if the opts are preceded with a dash, it is necessary to precede them with opts= (as in the CLI examples below) to avoid causing errors with Salt’s own argument parsing.

**user**  User under which to run the git command. By default, the command is run by the user under which the minion is running.

**identity**  Path to a private key to use for ssh URLs

   **Warning:** Unless Salt is invoked from the minion using salt-call, the key(s) must be passphrase-less. For greater security with passphraseless private keys, see the sshd(8) manpage for information on securing the keypair from the remote side in the authorized_keys file.

   Changed in version 2015.8.7: Salt will no longer attempt to use passphrase-protected keys unless invoked from the minion using salt-call, to prevent blocking waiting for user input.

**ignore_retcode**  [False] If True, do not log an error to the minion log if the git command returns a nonzero exit status.

   New in version 2015.8.0.

**CLI Example:**

```bash
# Push master as origin/master
salt myminion git.push /path/to/repo origin master
# Push issue21 as upstream/develop
salt myminion git.push /path/to/repo upstream issue21:develop
# Delete remote branch 'upstream/temp'
salt myminion git.push /path/to/repo upstream :temp
```

salt.modules.git.rebase(cwd, rev='master', opts='-', user=None, ignore_retcode=False)

   Interface to git-rebase(1)

   **cwd**  The path to the git checkout

   **rev**  [master] The revision to rebase onto the current branch

   **opts**  Any additional options to add to the command line, in a single string

   **Note:** On the Salt CLI, if the opts are preceded with a dash, it is necessary to precede them with opts= (as in the CLI examples below) to avoid causing errors with Salt’s own argument parsing.
**user** User under which to run the git command. By default, the command is run by the user under which the minion is running.

**ignore_retcode** [False] If True, do not log an error to the minion log if the git command returns a nonzero exit status.

New in version 2015.8.0.

**CLI Example:**

```
salt myminion git.rebase /path/to/repo master
salt myminion git.rebase /path/to/repo 'origin master'
salt myminion git.rebase /path/to/repo origin/master opts='--onto newbranch'
```

salt.modules.git.remote_get(cwd, remote='origin', user=None, redact_auth=True, ignore_retcode=False)

Get the fetch and push URL for a specific remote

cwd  The path to the git checkout

**remote** [origin] Name of the remote to query

**user** User under which to run the git command. By default, the command is run by the user under which the minion is running.

**redact_auth** [True] Set to False to include the username/password if the remote uses HTTPS Basic Auth. Otherwise, this information will be redacted.

**Warning:** Setting this to False will not only reveal any HTTPS Basic Auth that is configured, but the return data will also be written to the job cache. When possible, it is recommended to use SSH for authentication.

New in version 2015.5.6.

**ignore_retcode** [False] If True, do not log an error to the minion log if the git command returns a nonzero exit status.

New in version 2015.8.0.

**CLI Examples:**

```
salt myminion git.remote_get /path/to/repo
salt myminion git.remote_get /path/to/repo upstream
```

salt.modules.git.remote_refs(url, heads=False, tags=False, user=None, identity=None, https_user=None, https_pass=None, ignore_retcode=False)

New in version 2015.8.0.

Return the remote refs for the specified URL

**url** URL of the remote repository

**heads** [False] Restrict output to heads. Can be combined with tags.

**tags** [False] Restrict output to tags. Can be combined with heads.

**user** User under which to run the git command. By default, the command is run by the user under which the minion is running.

**identity** Path to a private key to use for ssh URLs
Changed in version 2015.8.7: Salt will no longer attempt to use passphrase-protected keys unless invoked from the minion using `salt-call`, to prevent blocking waiting for user input.

**https_user**  Set HTTP Basic Auth username. Only accepted for HTTPS URLs.

**https_pass**  Set HTTP Basic Auth password. Only accepted for HTTPS URLs.

**ignore_retcode**  [False] If `True`, do not log an error to the minion log if the git command returns a nonzero exit status.

CLl Example:
```
salt myminion git.remote_refs https://github.com/saltstack/salt.git
```

```
salt.modules.git.remote_set(cwd, url, remote='origin', user=None, https_user=None, https_pass=None, push_url=None, push_https_user=None, push_https_pass=None, ignore_retcode=False)
```

- **cwd**  The path to the git checkout
- **url**  Remote URL to set
- **remote**  [origin] Name of the remote to set
- **push_url**  If unset, the push URL will be identical to the fetch URL.
  
  New in version 2015.8.0.
- **user**  User under which to run the git command. By default, the command is run by the user under which the minion is running.

**https_user**  Set HTTP Basic Auth username. Only accepted for HTTPS URLs.

  New in version 2015.5.0.

**https_pass**  Set HTTP Basic Auth password. Only accepted for HTTPS URLs.

  New in version 2015.5.0.

**push_https_user**  Set HTTP Basic Auth user for `push_url`. Ignored if `push_url` is unset. Only accepted for HTTPS URLs.

  New in version 2015.8.0.

**push_https_pass**  Set HTTP Basic Auth password for `push_url`. Ignored if `push_url` is unset. Only accepted for HTTPS URLs.

  New in version 2015.8.0.

**ignore_retcode**  [False] If `True`, do not log an error to the minion log if the git command returns a nonzero exit status.

  New in version 2015.8.0.

CLI Examples:
```
salt myminion git.remote_set /path/to/repo git@github.com:user/repo.git
```
```
salt myminion git.remote_set /path/to/repo git@github.com:user/repo.git
  --remote=upstream
```

```
salt myminion git.remote_set /path/to/repo https://github.com/user/repo.git
  --remote=upstream push_url=git@github.com:user/repo.git
```
**salt.modules.git.remotes** *(cwd, user=None, redact_auth=True, ignore_retcode=False)*

Get fetch and push URLs for each remote in a git checkout

- **cwd** The path to the git checkout
- **user** User under which to run the git command. By default, the command is run by the user under which the minion is running.
- **redact_auth** [True] Set to False to include the username/password for authenticated remotes in the return data. Otherwise, this information will be redacted.

**Warning:** Setting this to False will not only reveal any HTTPS Basic Auth that is configured, but the return data will also be written to the job cache. When possible, it is recommended to use SSH for authentication.

New in version 2015.5.6.

- **ignore_retcode** [False] If True, do not log an error to the minion log if the git command returns a nonzero exit status.

New in version 2015.8.0.

**CLI Example:**
```
salt myminion git.remotes /path/to/repo
```

**salt.modules.git.reset** *(cwd, opts='', user=None, ignore_retcode=False)*

Interface to *git-reset(1)*, returns the stdout from the git command

- **cwd** The path to the git checkout
- **opts** Any additional options to add to the command line, in a single string

**Note:** On the Salt CLI, if the opts are preceded with a dash, it is necessary to precede them with opts= (as in the CLI examples below) to avoid causing errors with Salt's own argument parsing.

- **user** User under which to run the git command. By default, the command is run by the user under which the minion is running.
- **ignore_retcode** [False] If True, do not log an error to the minion log if the git command returns a nonzero exit status.

New in version 2015.8.0.

**CLI Examples:**
```
# Soft reset to a specific commit ID
salt myminion git.reset /path/to/repo ac3ee5c
# Hard reset
salt myminion git.reset /path/to/repo opts='--hard origin/master'
```

**salt.modules.git.rev_parse** *(cwd, rev=None, opts='', user=None, ignore_retcode=False)*

New in version 2015.8.0.

- **cwd** The path to the git checkout

**Note:** On the Salt CLI, if the opts are preceded with a dash, it is necessary to precede them with opts= (as in the CLI examples below) to avoid causing errors with Salt's own argument parsing.
rev  Revision to parse. See the SPECIFYING REVISIONS section of the git-rev-parse(1) manpage for details on how to format this argument.

This argument is optional when using the options in the Options for Files section of the git-rev-parse(1) manpage.

opts  Any additional options to add to the command line, in a single string

user  User under which to run the git command. By default, the command is run by the user under which the minion is running.

ignore_retcode  [False] If True, do not log an error to the minion log if the git command returns a nonzero exit status.

CLI Examples:

```bash
# Get the full SHA1 for HEAD
salt myminion git.rev_parse /path/to/repo HEAD
# Get the short SHA1 for HEAD
salt myminion git.rev_parse /path/to/repo HEAD opts='--short'
# Get the develop branch's upstream tracking branch
salt myminion git.rev_parse /path/to/repo 'develop@{upstream}' opts='--abbrev-ref'
# Get the SHA1 for the commit corresponding to tag v1.2.3
salt myminion git.rev_parse /path/to/repo 'v1.2.3^commit'
# Find out whether or not the repo at /path/to/repo is a bare repository
salt myminion git.rev_parse /path/to/repo opts='--is-bare-repository'
```

salt.modules.git.revision(cwd, rev='HEAD', short=False, user=None, ignore_retcode=False)

Returns the SHA1 hash of a given identifier (hash, branch, tag, HEAD, etc.)

cwd  The path to the git checkout

rev  [HEAD] The revision

short  [False] If True, return an abbreviated SHA1 git hash

user  User under which to run the git command. By default, the command is run by the user under which the minion is running.

ignore_retcode  [False] If True, do not log an error to the minion log if the git command returns a nonzero exit status.

New in version 2015.8.0.

CLI Example:

```bash
salt myminion git.revision /path/to/repo mybranch
```

salt.modules.git.rm(cwd, filename, opts=' ', user=None, ignore_retcode=False)

Interface to git-rm(1)

cwd  The path to the git checkout

filename  The location of the file/directory to remove, relative to cwd

Note: To remove a directory, -r must be part of the opts parameter.

opts  Any additional options to add to the command line, in a single string
Note: On the Salt CLI, if the opts are preceded with a dash, it is necessary to precede them with `opts=` (as in the CLI examples below) to avoid causing errors with Salt’s own argument parsing.

**user**  User under which to run the git command. By default, the command is run by the user under which the minion is running.

**ignore_retcode**  [False] If True, do not log an error to the minion log if the git command returns a nonzero exit status.

New in version 2015.8.0.

CLI Examples:

```
salt myminion git.rm /path/to/repo foo/bar.py
salt myminion git.rm /path/to/repo foo/bar.py opts='--dry-run'
salt myminion git.rm /path/to/repo foo/baz opts=''-r"
```

**salt.modules.git.stash**  
`cwd, action='save', opts='', user=None, ignore_retcode=False`

Interface to `git-stash(1)`, returns the stdout from the git command

- **cwd** The path to the git checkout
- **opts** Any additional options to add to the command line, in a single string. Use this to complete the git stash command by adding the remaining arguments (i.e. 'save <stash comment>', 'apply stash@{2}', 'show', etc.). Omitting this argument will simply run `git stash`.
- **user**  User under which to run the git command. By default, the command is run by the user under which the minion is running.
- **ignore_retcode**  [False] If True, do not log an error to the minion log if the git command returns a nonzero exit status.

New in version 2015.8.0.

CLI Examples:

```
salt myminion git.stash /path/to/repo save opts='work in progress'
salt myminion git.stash /path/to/repo apply opts='stash@{1}'
salt myminion git.stash /path/to/repo drop opts='stash@{1}'
salt myminion git.stash /path/to/repo list
```

**salt.modules.git.status**  
`cwd, user=None, ignore_retcode=False`

Changed in version 2015.8.0: Return data has changed from a list of lists to a dictionary

Returns the changes to the repository

- **cwd** The path to the git checkout
- **user**  User under which to run the git command. By default, the command is run by the user under which the minion is running.
- **ignore_retcode**  [False] If True, do not log an error to the minion log if the git command returns a nonzero exit status.

New in version 2015.8.0.

CLI Example:

```
salt myminion git.status /path/to/repo
```
salt.modules.git.submodule(cwd, command, opts='', user=None, identity=None, ignore_retcode=False, **kwargs)

Changed in version 2015.8.0: Added the command argument to allow for operations other than update to be run on submodules, and deprecated the init argument. To do a submodule update with init=True moving forward, use command=update opts='--init'

Interface to git-submodule(1)

cwd The path to the submodule

command Submodule command to run, see git-submodule(1) <git submodule> for more information. Any additional arguments after the command (such as the URL when adding a submodule) must be passed in the opts parameter.

New in version 2015.8.0.

opts Any additional options to add to the command line, in a single string

Note: On the Salt CLI, if the opts are preceded with a dash, it is necessary to precede them with opts= (as in the CLI examples below) to avoid causing errors with Salt’s own argument parsing.

init [False] If True, ensures that new submodules are initialized

Deprecated since version 2015.8.0: Pass init as the command parameter, or include --init in the opts param with command set to update.

user User under which to run the git command. By default, the command is run by the user under which the minion is running.

identity Path to a private key to use for ssh URLs

Warning: Unless Salt is invoked from the minion using salt-call, the key(s) must be passphrase-less. For greater security with passphraseless private keys, see the sshd(8) manpage for information on securing the keypair from the remote side in the authorized_keys file.

Changed in version 2015.8.7: Salt will no longer attempt to use passphrase-protected keys unless invoked from the minion using salt-call, to prevent blocking waiting for user input.

ignore_retcode [False] If True, do not log an error to the minion log if the git command returns a nonzero exit status.

New in version 2015.8.0.

CLI Example:

```bash
# Update submodule and ensure it is initialized (before 2015.8.0)
salt myminion git.submodule /path/to/repo/sub/repo init=True

# Update submodule and ensure it is initialized (2015.8.0 and later)
salt myminion git.submodule /path/to/repo/sub/repo update opts='--init'

# Rebase submodule (2015.8.0 and later)
salt myminion git.submodule /path/to/repo/sub/repo update opts='--rebase'

# Add submodule (2015.8.0 and later)
salt myminion git.submodule /path/to/repo/sub/repo add opts='https://mydomain.tld/repo.git'
```
# Unregister submodule (2015.8.0 and later)
salt myminion git.submodule /path/to/repo/sub/repo deinit

salt.modules.git.symbolic_ref(cwd, ref, value=None, opts='`, user=None, ignore_retcode=False)

New in version 2015.8.0.

Interface to `git-symbolic-ref(1)`

- **cwd**  The path to the git checkout
- **ref**  Symbolic ref to read/modify
- **value**  If passed, then the symbolic ref will be set to this value and an empty string will be returned.
  
  If not passed, then the ref to which `ref` points will be returned, unless `--delete` is included in `opts` (in which case the symbolic ref will be deleted).
- **opts**  Any additional options to add to the command line, in a single string
- **user**  User under which to run the git command. By default, the command is run by the user under which the minion is running.
- **ignore_retcode**  [False] If True, do not log an error to the minion log if the git command returns a nonzero exit status.

New in version 2015.8.0.

CLI Examples:

```bash
# Get ref to which HEAD is pointing
salt myminion git.symbolic_ref /path/to/repo HEAD
```

```bash
# Set/overwrite symbolic ref 'FOO' to local branch 'foo'
salt myminion git.symbolic_ref /path/to/repo FOO refs/heads/foo
```

```bash
# Delete symbolic ref 'FOO'
salt myminion git.symbolic_ref /path/to/repo FOO opts='--delete'
```

salt.modules.git.version(versioninfo=False)

New in version 2015.8.0.

Returns the version of Git installed on the minion

- **versioninfo**  [False] If True, return the version in a versioninfo list (e.g. `[2,5,0]`)

CLI Example:

```bash
salt myminion git.version
```

salt.modules.git.worktree_add(cwd, worktree_path, ref=None, reset_branch=None, force=None, detach=False, opts='`, user=None, ignore_retcode=False, **kwargs)

New in version 2015.8.0.

Interface to `git-worktree(1)`, adds a worktree

- **cwd**  The path to the git checkout
- **worktree_path**  Path to the new worktree. Can be either absolute, or relative to `cwd`.
- **branch**  Name of new branch to create. If omitted, will be set to the basename of the `worktree_path`. For example, if the `worktree_path` is `/foo/bar/baz`, then `branch` will be `baz`.
- **ref**  Name of the ref on which to base the new worktree. If omitted, then HEAD is use, and a new branch will be created, named for the basename of the `worktree_path`. For example, if the `worktree_path` is `/foo/bar/baz` then a new branch `baz` will be created, and pointed at HEAD.
reset_branch  [False] If False, then `git-worktree(1)` will fail to create the worktree if the targeted branch already exists. Set this argument to `True` to reset the targeted branch to point at `ref`, and checkout the newly-reset branch into the new worktree.

force  [False] By default, `git-worktree(1)` will not permit the same branch to be checked out in more than one worktree. Set this argument to `True` to override this.

opts  Any additional options to add to the command line, in a single string

---

Note: On the Salt CLI, if the opts are preceded with a dash, it is necessary to precede them with `opts=` to avoid causing errors with Salt's own argument parsing.

All CLI options for adding worktrees as of Git 2.5.0 are already supported by this function as of Salt 2015.8.0, so using this argument is unnecessary unless new CLI arguments are added to `git-worktree(1)` and are not yet supported in Salt.

user  User under which to run the git command. By default, the command is run by the user under which the minion is running.

ignore_retcode  [False] If True, do not log an error to the minion log if the git command returns a nonzero exit status.

New in version 2015.8.0.

CLI Examples:

```
salt myminion git.worktree_add /path/to/repo/main ../hotfix ref=origin/master
salt myminion git.worktree_add /path/to/repo/main ../hotfix branch=hotfix21 --ref=v2.1.9.3
```

```
salt.modules.git.worktree_prune(cwd, dry_run=False, verbose=True, expire=None, opts='*', user=None, ignore_retcode=False)
```

New in version 2015.8.0.

Interface to `git-worktree(1)`, prunes stale worktree administrative data from the gitdir

cwd  The path to the main git checkout or a linked worktree

dry_run  [False] If True, then this function will report what would have been pruned, but no changes will be made.

verbose  [True] Report all changes made. Set to False to suppress this output.

expire  Only prune unused worktree data older than a specific period of time. The date format for this parameter is described in the documentation for the `gc.pruneWorktreesExpire` config param in the `git-config(1)` manpage.

opts  Any additional options to add to the command line, in a single string

---

Note: On the Salt CLI, if the opts are preceded with a dash, it is necessary to precede them with `opts=` to avoid causing errors with Salt's own argument parsing.

All CLI options for pruning worktrees as of Git 2.5.0 are already supported by this function as of Salt 2015.8.0, so using this argument is unnecessary unless new CLI arguments are added to `git-worktree(1)` and are not yet supported in Salt.

user  User under which to run the git command. By default, the command is run by the user under which the minion is running.
ignore_retcode  [False] If True, do not log an error to the minion log if the git command returns a nonzero exit status.

New in version 2015.8.0.

CLI Examples:

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>salt myminion git.worktree_prune</td>
<td>Path to the worktree to be removed</td>
</tr>
<tr>
<td>/path/to/repo dry_run=True</td>
<td>User under which to run the git command. By default, the command is run by the user under which the minion is running.</td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
</tbody>
</table>

salt.modules.git.worktree_rm(cwd, user=None)

New in version 2015.8.0.

Recursively removes the worktree located at cwd, returning True if successful. This function will attempt to determine if cwd is actually a worktree by invoking git.is_worktree. If the path does not correspond to a worktree, then an error will be raised and no action will be taken.

**Warning:** There is no undoing this action. Be VERY careful before running this function.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>cwd</td>
<td>Path to the worktree to be removed</td>
</tr>
<tr>
<td>user</td>
<td>User under which to run the git command. By default, the command is run by the user under which the minion is running.</td>
</tr>
</tbody>
</table>

CLI Examples:

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>salt myminion git.worktree_rm</td>
<td>Path to the worktree to be removed</td>
</tr>
<tr>
<td>/path/to/worktree</td>
<td>User under which to run the git command. By default, the command is run by the user under which the minion is running.</td>
</tr>
</tbody>
</table>

### 32.17.98 salt.modules.glance

Module for handling openstack glance calls.

**optdepends**

- glanceclient Python adapter

**configuration** This module is not usable until the following are specified either in a pillar or in the minion's config file:

```yaml
keystone.user: admin
keystone.password: verybadpass
keystone.tenant: admin
keystone.insecure: False  #(optional)
keystone.auth_url: 'http://127.0.0.1:5000/v2.0/
```

If configuration for multiple openstack accounts is required, they can be set up as different configuration profiles: For example:

```yaml
openstack1:
    keystone.user: admin
    keystone.password: verybadpass
    keystone.tenant: admin
    keystone.auth_url: 'http://127.0.0.1:5000/v2.0/

openstack2:
    keystone.user: admin
```

---

**32.17. Full list of builtin execution modules**

1033
With this configuration in place, any of the glance functions can make use of a configuration profile by declaring it explicitly. For example:

```bash
salt '*' glance.image_list profile=openstack1
```

**salt.modules.glance.image_create**(*name*, *location=None*, *profile=None*, *visibility=None*, *container_format='bare'*, *disk_format='raw'*, *protected=None*, *copy_from=None*, *is_public=None*)

Create an image (glance image-create)

**CLI Example, old format:**

```bash
salt '*' glance.image_create name=f16-jeos is_public=true \ 
disk_format=qcow2 container_format=ovf \ 
copy_from=http://berrange.fedorapeople.org/ \ 
images/2012-\ 
02-29/f16-x86_64-openstack-sda.qcow2
```

**CLI Example, new format resembling Glance API v2:**

```bash
salt '*' glance.image_create name=f16-jeos visibility=public \ 
disk_format=qcow2 container_format=ovf \ 
copy_from=http://berrange.fedorapeople.org/ \ 
images/2012-\ 
02-29/f16-x86_64-openstack-sda.qcow2
```

The parameter `visibility` defaults to `public` if neither `visibility` nor `is_public` is specified.

**salt.modules.glance.image_delete**(*id=None*, *name=None*, *profile=None*)

Delete an image (glance image-delete)

**CLI Examples:**

```bash
salt '*' glance.image_delete c2eb2eb0-53e1-4a80-b990-8ec887eae7df
salt '*' glance.image_delete id=c2eb2eb0-53e1-4a80-b990-8ec887eae7df
salt '*' glance.image_delete name=f16-jeos
```

**salt.modules.glance.image_list**(*id=None*, *profile=None*, *name=None*)

Return a list of available images (glance image-list)

**CLI Example:**

```bash
salt '*' glance.image_list
```

**salt.modules.glance.image_schema**(*profile=None*)

Returns names and descriptions of the schema `image`'s properties for this profile's instance of glance

**CLI Example:**

```bash
salt '*' glance.image_schema
```

**salt.modules.glance.image_show**(*id=None*, *name=None*, *profile=None*)

Return details about a specific image (glance image-show)

**CLI Example:**
**salt.modules.glance**

- **image_show**
  
  Display image details.

- **image_update**
  
  Update properties of given image. Known to work for:
  - `min_ram` (in MB)
  - `protected` (bool)
  - `visibility` ('public' or 'private')

  CLI Example:
  
  ```
salt '*' glance.image_update id=c2eb2eb0-53e1-4a80-b990-8ec887eae7df
salt '*' glance.image_update name=f16-jeos
  ```

- **schema_get**
  
  Known valid names of schemas are:
  - `image`
  - `images`
  - `member`
  - `members`

  CLI Example:
  
  ```
salt '*' glance.schema_get name=f16-jeos
  ```

**32.17.99 salt.modules.glusterfs**

Manage a glusterfs pool.

- **add_volume_bricks**
  
  Add brick(s) to an existing volume.

  ```
salt.modules.glusterfs.add_volume_bricks(name, bricks)
  ```

- **create**
  
  Create a glusterfs volume.

  ```
salt.modules.glusterfs.create(name, bricks, stripe=False, replica=False, device_vg=False, transport='tcp', start=False, force=False)
  ```

  - `name` Name of the gluster volume
  - `bricks` Bricks to create volume from, in `<peer>:<brick path>` format. For multiple bricks use list format: `['<peer1>:<brick1>', '<peer2>:<brick2>']`
  - `stripe` Stripe count, the number of bricks should be a multiple of the stripe count for a distributed striped volume
  - `replica` Replica count, the number of bricks should be a multiple of the replica count for a distributed replicated volume
  - `device_vg` If true, specifies volume should use block backend instead of regular posix backend. Block device backend volume does not support multiple bricks
  - `transport` Transport protocol to use, can be `tcp`, `rdma` or `tcp,rdma`
  - `start` Start the volume after creation
  - `force` Force volume creation, this works even if creating in root FS
CLI Example:

```
salt host1 glusterfs.create newvolume host1:/brick
salt gluster1 glusterfs.create vol2 ['"gluster1:/export/vol2/brick", 
                                 "gluster2:/export/vol2/brick"]
replica=2 start=True
```

```python
salt.modules.glusterfs.delete(target, stop=True)
```

Deletes a gluster volume

**target**  Volume to delete

**stop**  Stop volume before delete if it is started, True by default

```python
salt.modules.glusterfs.info(name)
```

New in version 2015.8.4.

Return the gluster volume info.

**name**  Volume name

**CLI Example:**

```
salt '*' glusterfs.info myvolume
```

```python
salt.modules.glusterfs.list_peers()
```

Return a list of gluster peers

**CLI Example:**

```
salt '*' glusterfs.list_peers
```

GLUSTER direct CLI example (to show what salt is sending to gluster):

```
$ gluster peer status
```

GLUSTER CLI 3.4.4 return example (so we know what we are parsing):

```
Number of Peers: 2

Hostname: ftp2 Port: 24007 Uuid: cbc256b-e66e-4ec7-a718-21082d396c24 State: Peer in Cluster (Connected)

Hostname: ftp3 Uuid: 5ea10457-6cb2-427b-a770-7897509625e9 State: Peer in Cluster (Connected)
```

```python
salt.modules.glusterfs.list_volumes()
```

List configured volumes

**CLI Example:**

```
salt '*' glusterfs.list_volumes
```

```python
salt.modules.glusterfs.peer(name)
```

Add another node into the peer list.

**name**  The remote host to probe.

**CLI Example:**

```
salt 'one.gluster.*' glusterfs.peer two
```

GLUSTER direct CLI example (to show what salt is sending to gluster):

```
$ gluster peer probe ftp2
```
GLUSTER CLI 3.4.4 return example (so we know what we are parsing): #if the `peer` is the local host:
  peer probe: success: on localhost not needed
# if the peer was just added: peer probe: success
# if the peer was already part of the cluster: peer probe: success: host ftp2 port 24007 already in peer list

```
salt.modules.glusterfs.start_volume(name, force=False)
Salt a gluster volume.

  name  Volume name
  force Force the volume start even if the volume is started .. versionadded:: 2015.8.4
```
CLI Example:
```
salt '*' glusterfs.start mycluster
```

```
salt.modules.glusterfs.status(name)
Check the status of a gluster volume.

  name  Volume name
```
CLI Example:
```
salt '*' glusterfs.status myvolume
```

```
salt.modules.glusterfs.stop_volume(name, force=False)
Stop a gluster volume.

  name  Volume name
  force Force stop the volume .. versionadded:: 2015.8.4
```
CLI Example:
```
salt '*' glusterfs.stop_volume mycluster
```

32.17.100 salt.modules.gnomedesktop

GNOME implementations

```
salt.modules.gnomedesktop.get(schema=None, key=None, user=None, **kwargs)
Get key in a particular GNOME schema
```
CLI Example:
```
salt '*' gnome.get user=<username> schema=org.gnome.desktop.screensaver key=idle-activation-enabled
```

```
salt.modules.gnomedesktop.getClockFormat(**kwargs)
Return the current clock format, either 12h or 24h format.
```
CLI Example:
```
salt '*' gnome.getClockFormat user=<username>
```

```
salt.modules.gnomedesktop.getClockShowDate(**kwargs)
Return the current setting, if the date is shown in the clock
```
CLI Example:
salt '***' gnome.getClockShowDate user=<username>

salt.modules.gnomedesktop.getIdleActivation(**kwargs)
Get whether the idle activation is enabled

CLI Example:

    salt '***' gnome.getIdleActivation user=<username>

salt.modules.gnomedesktop.getIdleDelay(**kwargs)
Return the current idle delay setting in seconds

CLI Example:

    salt '***' gnome.getIdleDelay user=<username>

salt.modules.gnomedesktop.ping(**kwargs)
A test to ensure the GNOME module is loaded

CLI Example:

    salt '***' gnome.ping user=<username>

salt.modules.gnomedesktop.setClockFormat(clockFormat, **kwargs)
Set the clock format, either 12h or 24h format.

CLI Example:

    salt '***' gnome.setClockFormat <12h|24h> user=<username>

salt.modules.gnomedesktop.setClockShowDate(kvalue, **kwargs)
Set whether the date is visible in the clock

CLI Example:

    salt '***' gnome.setClockShowDate <True|False> user=<username>

salt.modules.gnomedesktop.setIdleActivation(kvalue, **kwargs)
Set whether the idle activation is enabled

CLI Example:

    salt '***' gnome.setIdleActivation <True|False> user=<username>

salt.modules.gnomedesktop.setIdleDelay(delaySeconds, **kwargs)
Set the current idle delay setting in seconds

CLI Example:

    salt '***' gnome.setIdleDelay <seconds> user=<username>

salt.modules.gnomedesktop.set(schema=None, key=None, user=None, value=None, **kwargs)
Set key in a particular GNOME schema

CLI Example:

    salt '***' gnome.set user=<username> schema=org.gnome.desktop.screensaver key=idle-activation-enabled value=False
32.17.101 salt.modules.gpg

Manage a GPG keychains, add keys, create keys, retrieve keys from keyservers. Sign, encrypt and sign plus encrypt text and files.

New in version 2015.5.0.

Note: The python-gnupg library and gpg binary are required to be installed.

salt.modules.gpg.create_key(*args,**kwargs)
Create a key in the GPG keychain

Note: GPG key generation requires a lot of entropy and randomness. Difficult to do over a remote connection, consider having another process available which is generating randomness for the machine. Also especially difficult on virtual machines, consider the rng-tools package.

The create_key process takes awhile so increasing the timeout may be necessary, e.g. -t 15.

key_type  The type of the primary key to generate. It must be capable of signing. `RSA' or `DSA'.
key_length  The length of the primary key in bits.
name_real  The real name of the user identity which is represented by the key.
name_comment  A comment to attach to the user id.
name_email  An email address for the user.
subkey_type  The type of the secondary key to generate.
subkey_length  The length of the secondary key in bits.
expire_date  The expiration date for the primary and any secondary key. You can specify an ISO date, A number of days/weeks/months/years, an epoch value, or 0 for a non-expiring key.
use_passphrase  Whether to use a passphrase with the signing key. Passphrase is received from Pillar.
user  Which user's keychain to access, defaults to user Salt is running as. Passing the user as salt will set the GnuPG home directory to the /etc/salt/gpgkeys.

gnupghome  Specify the location where GPG keyring and related files are stored.

CLI Example:
salt -t 15 '*' gpg.create_key

salt.modules.gpg.decrypt(user=None, text=None, filename=None, output=None, use_passphrase=False, gnupghome=None, bare=False)
Decrypt a message or file

user  Which user's keychain to access, defaults to user Salt is running as. Passing the user as salt will set the GnuPG home directory to the /etc/salt/gpgkeys.

text  The encrypted text to decrypt.
filename  The encrypted filename to decrypt.
output  The filename where the decrypted data will be written, default is standard out.
use_passphrase  Whether to use a passphrase with the signing key. Passphrase is received from Pillar.
gnu\ngnome Specify the location where GPG keyring and related files are stored.

bare If True, return the (armored) decrypted block as a string without the standard comment/res dict.

CLI Example:

```
salt '*' gpg.decrypt filename='/path/to/important.file.gpg'
salt '*' gpg.decrypt filename='/path/to/important.file.gpg' use_pasphrase=True
```

gt\nmodule\nsgp.delete_key(keyid=None, fingerprint=None, delete_secret=False, user=None, gnupghome=None)

Get a key from the GPG keychain

keyid The keyid of the key to be deleted.

fingerprint The fingerprint of the key to be deleted.

delete_secret Whether to delete a corresponding secret key prior to deleting the public key. Secret keys must be deleted before deleting any corresponding public keys.

user Which user's keychain to access, defaults to user Salt is running as. Passing the user as salt will set the GnuPG home directory to the /etc/salt/gpgkeys.

gnupghome Specify the location where GPG keyring and related files are stored.

CLI Example:

```
salt '*' gpg.delete_key keyid=3FAD9F1E
salt '*' gpg.delete_key fingerprint=53C96788253E58416D20BCD352952C84C3252192
salt '*' gpg.delete_key keyid=3FAD9F1E user=username
salt '*' gpg.delete_key keyid=3FAD9F1E user=username delete_secret=True
```

gt\nmodule\nsgp.encrypt(user=None, recipients=None, text=None, filename=None, output=None, sign=None, use_passphrase=False, gnupghome=None, bare=False)

Encrypt a message or file

user Which user's keychain to access, defaults to user Salt is running as. Passing the user as salt will set the GnuPG home directory to the /etc/salt/gpgkeys.

recipients The fingerprints for those recipient whom the data is being encrypted for.

text The text to encrypt.

filename The filename to encrypt.

output The filename where the signed file will be written, default is standard out.

sign Whether to sign, in addition to encrypt, the data. True to use default key or fingerprint to specify a different key to sign with.

use_passphrase Whether to use a passphrase with the signing key. Passphrase is received from Pillar.

gnupghome Specify the location where GPG keyring and related files are stored.

bare If True, return the (armored) encrypted block as a string without the standard comment/res dict.

CLI Example:

```
salt '*' gpg.encrypt text='Hello there. How are you?'
salt '*' gpg.encrypt filename='/path/to/important.file'
```
salt.gpg.encrypt filename='/path/to/important.file' use_pasphrase=True

salt.modules.gpg.export_key(keyids=None, secret=False, user=None, gnupghome=None)
Export a key from the GPG keychain

keyids The key ID(s) of the key(s) to be exported. Can be specified as a comma separated string or a list. Anything which GnuPG itself accepts to identify a key - for example, the key ID or the fingerprint could be used.

secret Export the secret key identified by the keyids information passed.

user Which user's keychain to access, defaults to user Salt is running as. Passing the user as salt will set the GnuPG home directory to the /etc/salt/gpgkeys.

gnupghome Specify the location where GPG keyring and related files are stored.

CLI Example:
salt '*' gpg.export_key keyids=3FAD9F1E
salt '*' gpg.export_key keyids=3FAD9F1E secret=True
salt '*' gpg.export_key keyids=['3FAD9F1E','3FBD8F1E'] user=username

salt.modules.gpg.get_key(keyid=None, fingerprint=None, user=None, gnupghome=None)
Get a key from the GPG keychain

keyid The key ID (short or long) of the key to be retrieved.

fingerprint The fingerprint of the key to be retrieved.

user Which user's keychain to access, defaults to user Salt is running as. Passing the user as salt will set the GnuPG home directory to the /etc/salt/gpgkeys.

gnupghome Specify the location where GPG keyring and related files are stored.

CLI Example:
salt '*' gpg.get_key keyid=3FAD9F1E
salt '*' gpg.get_key fingerprint=53C96788253E58416D20BCD352952C84C3252192
salt '*' gpg.get_key keyid=3FAD9F1E user=username

salt.modules.gpg.get_secret_key(keyid=None, fingerprint=None, user=None, gnupghome=None)
Get a key from the GPG keychain

keyid The key ID (short or long) of the key to be retrieved.

fingerprint The fingerprint of the key to be retrieved.

user Which user's keychain to access, defaults to user Salt is running as. Passing the user as salt will set the GnuPG home directory to the /etc/salt/gpgkeys.

gnupghome Specify the location where GPG keyring and related files are stored.

CLI Example:
salt '*' gpg.get_secret_key keyid=3FAD9F1E
salt '*' gpg.get_secret_key fingerprint=53C96788253E58416D20BCD352952C84C3252192
salt 'salt' gpg.get_secret_key keyid=3FAD9F1E user=username

salt.modules.gpg.import_key(*args, **kwargs)
Import a key from text or file

    text  The text containing to import.
    filename The filename containing the key to import.
    user  Which user's keychain to access, defaults to user Salt is running as. Passing the user as salt will set the GnuPG home directory to the /etc/salt/gpgkeys.

    gnupghome Specify the location where GPG keyring and related files are stored.

CLI Example:
salt '*' gpg.import_key text='----BEGIN PGP PUBLIC KEY BLOCK----
...----END PGP PUBLIC KEY BLOCK-----'
salt '*' gpg.import_key filename='/path/to/public-key-file'

salt.modules.gpg.list_keys(user=None, gnupghome=None)
List keys in GPG keychain

    user  Which user's keychain to access, defaults to user Salt is running as. Passing the user as salt will set the GnuPG home directory to the /etc/salt/gpgkeys.

    gnupghome Specify the location where GPG keyring and related files are stored.

CLI Example:
salt '*' gpg.list_keys

salt.modules.gpg.list_secret_keys(user=None, gnupghome=None)
List secret keys in GPG keychain

    user  Which user's keychain to access, defaults to user Salt is running as. Passing the user as salt will set the GnuPG home directory to the /etc/salt/gpgkeys.

    gnupghome Specify the location where GPG keyring and related files are stored.

CLI Example:
salt '*' gpg.list_secret_keys

salt.modules.gpg.receive_keys(*args, **kwargs)
Receive key(s) from keyserver and add them to keychain

    keyserver Keyserver to use for searching for GPG keys, defaults to pgp.mit.edu
    keys  The keyID(s) to retrieve from the keyserver. Can be specified as a comma separated string or a list.
    user  Which user's keychain to access, defaults to user Salt is running as. Passing the user as salt will set the GnuPG home directory to the /etc/salt/gpgkeys.

    gnupghome Specify the location where GPG keyring and related files are stored.

CLI Example:
salt '*' gpg.receive_keys keys='3FAD9F1E'
salt '*' gpg.receive_keys keys="['3FAD9F1E','3FBD9F2E']"
salt.modules.gpg.receive_keys

```
salt '*' gpg.receive_keys keys=3FAD9F1E user=username
```

salt.modules.gpg.search_keys
text=Text to search the keyserver for, e.g. email address, keyID or fingerprint.
keyserver=Keyserver to use for searching for GPG keys, defaults to pgp.mit.edu.
user=Which user's keychain to access, defaults to user Salt is running as. Passing the user as salt will set the GnuPG home directory to the /etc/salt/gpgkeys.

CLI Example:
```
salt '*' gpg.search_keys user@example.com
salt '*' gpg.search_keys user@example.com keyserver=keyserver.ubuntu.com
salt '*' gpg.search_keys user@example.com keyserver=keyserver.ubuntu.com
--user=username
```

salt.modules.gpg.sign

```
salt '*' gpg.sign text='Hello there. How are you?'
salt '*' gpg.sign filename='/path/to/important.file'
salt '*' gpg.sign filename='/path/to/important.file' use_passphrase=True
```

salt.modules.gpg.trust_key

```
salt '*' gpg.trust_key keyid=None, fingerprint=None, trust_level=None, user=None
```

32.17. Full list of builtin execution modules
salt.modules.gpg.verify(text=None, user=None, filename=None, gnupghome=None)

Verify a message or file

text  The text to verify.

filename  The filename to verify.

user  Which user's keychain to access, defaults to user Salt is running as. Passing the user as salt will set the GnuPG home directory to the /etc/salt/gpgkeys.

gnupghome  Specify the location where GPG keyring and related files are stored.

CLI Example:

```
salt '*' gpg.verify text='Hello there. How are you?'
salt '*' gpg.verify filename='/path/to/important.file'
salt '*' gpg.verify filename='/path/to/important.file' use_passphrase=True
```

32.17.102  salt.modules.grains

Return/control aspects of the grains data

salt.modules.grains.append(key, val, convert=False, delimiter=':')

New in version 0.17.0.

Append a value to a list in the grains config file. If the grain doesn't exist, the grain key is added and the value is appended to the new grain as a list item.

key  The grain key to be appended to

val  The value to append to the grain key

convert  If convert is True, convert non-list contents into a list. If convert is False and the grain contains non-list contents, an error is given. Defaults to False.

delimiter  The key can be a nested dict key. Use this parameter to specify the delimiter you use, instead of the default :. You can now append values to a list in nested dictionary grains. If the list doesn't exist at this level, it will be created.

New in version 2014.7.6.

CLI Example:

```
salt '*' grains.append key val
```

salt.modules.grains.delval(key, destructive=False)

New in version 0.17.0.

Delete a grain from the grains config file

key  The grain key from which to delete the value.

destructive  Delete the key, too. Defaults to False.
CLI Example:
```
salt '*' grains.delval key
```

```python
salt.modules.grains.filter_by(lookup_dict, grain='os_family', merge=None, default='default', base=None)
```

New in version 0.17.0.

Look up the given grain in a given dictionary for the current OS and return the result

Although this may occasionally be useful at the CLI, the primary intent of this function is for use in Jinja to make short work of creating lookup tables for OS-specific data. For example:

```python
{% set apache = salt['grains.filter_by']({
    'Debian': {'pkg': 'apache2', 'srv': 'apache2'},
    'RedHat': {'pkg': 'httpd', 'srv': 'httpd'},
}, default='Debian') %}
myapache:
    pkg.installed:
        - name: {{ apache.pkg }}
    service.running:
        - name: {{ apache.srv }}
```

Values in the lookup table may be overridden by values in Pillar. An example Pillar to override values in the example above could be as follows:

```python
apache:
    lookup:
        pkg: apache_13
        srv: apache
```

The call to `filter_by()` would be modified as follows to reference those Pillar values:

```python
{% set apache = salt['grains.filter_by']({
    ...,
}, merge=salt['pillar.get']('apache:lookup')) %}
```

### Parameters

- **lookup_dict** -- A dictionary, keyed by a grain, containing a value or values relevant to systems matching that grain. For example, a key could be the grain for an OS and the value could the name of a package on that particular OS.

- **grain** -- The name of a grain to match with the current system’s grains. For example, the value of the “os_family” grain for the current system could be used to pull values from the `lookup_dict` dictionary.

- **merge** -- A dictionary to merge with the results of the grain selection from `lookup_dict`. This allows Pillar to override the values in the `lookup_dict`. This could be useful, for example, to override the values for non-standard package names such as when using a different Python version from the default Python version provided by the OS (e.g., `python26-mysql` instead of `python-mysql`).

- **default** -- default lookup_dict’s key used if the grain does not exists or if the grain value has no match on lookup_dict. If unspecified the value is “default”.

New in version 2014.1.0.
• **base** -- A lookup_dict key to use for a base dictionary. The grain-selected lookup_dict is merged over this and then finally the merge dictionary is merged. This allows common values for each case to be collected in the base and overridden by the grain selection dictionary and the merge dictionary. Default is unset.

New in version 2015.5.0.

CLI Example:

```bash
salt '*' grains.filter_by '{Debian: Debheads rule, RedHat: I love my hat}'
# this one will render {D: {E: I, G: H}, J: K}
# next one renders {A: {B: G}, D: J}
salt '*' grains.filter_by '{default: {A: {B: C}, D: E}, F: {A: {B: G}}, H: {D: I}}' 'xxx' '{D: J}' 'F' 'default'
# next same as above when default='H' instead of 'F' renders {A: {B: C}, D: J}
```

salt.modules.grains.get(key, default='', delimiter=':')

Attempt to retrieve the named value from grains, if the named value is not available return the passed default. The default return is an empty string.

The value can also represent a value in a nested dict using a "::" delimiter for the dict. This means that if a dict in grains looks like this:

```json
{ 'pkg': { 'apache': 'httpd' }}
```

To retrieve the value associated with the apache key in the pkg dict this key can be passed:

```bash
pkg:apache
```

**Parameters delimiter** -- Specify an alternate delimiter to use when traversing a nested dict

New in version 2014.7.0.

CLI Example:

```bash
salt '*' grains.get pkg:apache
```

salt.modules.grains.get_or_set_hash(name, length=8, chars='abcdefghijklmnopqrstuvwxyz0123456789!@#$%^&*(-_=+)')

Perform a one-time generation of a hash and write it to the local grains. If that grain has already been set return the value instead.

This is useful for generating passwords or keys that are specific to a single minion that don't need to be stored somewhere centrally.

State Example:

```yaml
some_mysql_user:
  mysql_user:
    - present
    - host: localhost
    - password: {{ salt['grains.get_or_set_hash']('mysql:some_mysql_user') }}
```

CLI Example:

```bash
salt '*' grains.get_or_set_hash 'django:SECRET_KEY' 50
```
Warning: This function could return strings which may contain characters which are reserved as directives by the YAML parser, such as strings beginning with %. To avoid issues when using the output of this function in an SLS file containing YAML+Jinja, surround the call with single quotes.

salt.modules.grains.has_value(key)
Determine whether a named value exists in the grains dictionary.
Given a grains dictionary that contains the following structure:

```
{'pkg': {'apache': 'httpd'}}
```
One would determine if the apache key in the pkg dict exists by:

```
pkg:apache
```

CLI Example:
```
salt '*' grains.has_value pkg:apache
```

salt.modules.grains.item(*args, **kwargs)
Return one or more grains

CLI Example:
```
salt '*' grains.item os
salt '*' grains.item os osrelease oscodename
```
Sanitized CLI Example:
```
salt '*' grains.item host sanitize=True
```

salt.modules.grains.items(sanitize=False)
Return all of the minion’s grains

CLI Example:
```
salt '*' grains.items
```
Sanitized CLI Example:
```
salt '*' grains.items sanitize=True
```

salt.modules.grains.ls()
Return a list of all available grains

CLI Example:
```
salt '*' grains.ls
```

salt.modules.grains.remove(key, val, delimiter=':')
New in version 0.17.0.
Remove a value from a list in the grains config file

- **key**: The grain key to remove.
- **val**: The value to remove.
**delimiter**  The key can be a nested dict key. Use this parameter to specify the delimiter you use, instead of the default :. You can now append values to a list in nested dictionary grains. If the list doesn’t exist at this level, it will be created.

New in version 2015.8.2.

CLI Example:

```
salt '*' grains.remove key val
```

**salt.modules.grains.set** *(key, val='`, force=False, destructive=False, delimiter=':')*  
Set a key to an arbitrary value. It is used like setval but works with nested keys.

This function is conservative. It will only overwrite an entry if its value and the given one are not a list or a dict. The force parameter is used to allow overwriting in all cases.

New in version 2015.8.0.

**Parameters**

- **force** -- Force writing over existing entry if given or existing values are list or dict. Defaults to False.
- **destructive** -- If an operation results in a key being removed, delete the key, too. Defaults to False.
- **delimiter** -- Specify an alternate delimiter to use when traversing a nested dict, the default being :

CLI Example:

```
salt '*' grains.set 'apps:myApp:port' 2209
salt '*' grains.set 'apps:myApp' '{port: 2209}'
```

**salt.modules.grains.setval** *(key, val, destructive=False)*  
Set a grains value in the grains config file

**key**  The grain key to be set.

**val**  The value to set the grain key to.

**destructive**  If an operation results in a key being removed, delete the key, too. Defaults to False.

CLI Example:

```
salt '*' grains.setval key val
salt '*' grains.setval key "{'sub-key': 'val', 'sub-key2': 'val2'}"
```

**salt.modules.grains.setvals** *(grains, destructive=False)*  
Set new grains values in the grains config file

**destructive**  If an operation results in a key being removed, delete the key, too. Defaults to False.

CLI Example:

```
salt '*' grains.setvals "{'key1': 'val1', 'key2': 'val2'}"
```

### 32.17.103  salt.modules.groupadd

Manage groups on Linux, OpenBSD and NetBSD
**Important:** If you feel that Salt should be using this module to manage groups on a minion, and it is using a different module (or gives an error similar to `group.info` is not available), see [here](#).

```python
salt.modules.groupadd.add(name, gid=None, system=False)
```

Add the specified group

CLI Example:

```bash
salt '*' group.add foo 3456
```

```python
salt.modules.groupadd.adduser(name, username)
```

Add a user in the group.

CLI Example:

```bash
salt '*' group.adduser foo bar
```

Verifies if a valid username `bar` as a member of an existing group `foo`, if not then adds it.

```python
salt.modules.groupadd.chgid(name, gid)
```

Change the gid for a named group

CLI Example:

```bash
salt '*' group.chgid foo 4376
```

```python
salt.modules.groupadd.delete(name)
```

Remove the named group

CLI Example:

```bash
salt '*' group.delete foo
```

```python
salt.modules.groupadd.deluser(name, username)
```

Remove a user from the group.

CLI Example:

```bash
salt '*' group.deluser foo bar
```

Removes a member user `bar` from a group `foo`. If group is not present then returns True.

```python
salt.modules.groupadd.getent(refresh=False)
```

Return info on all groups

CLI Example:

```bash
salt '*' group.getent
```

```python
salt.modules.groupadd.info(name)
```

Return information about a group

CLI Example:

```bash
salt '*' group.info foo
```

```python
salt.modules.groupadd.members(name, members_list)
```

Replaces members of the group with a provided list.

CLI Example:
salt `*` group.members foo `user1,user2,user3,...`

Replaces a membership list for a local group `foo`.

32.17.104 salt.modules.grub_legacy

Support for GRUB Legacy

salt.modules.grub_legacy.conf()
Parse GRUB conf file

CLI Example:

```
salt `*` grub.conf
```

salt.modules.grub_legacy.version()
Return server version from grub --version

CLI Example:

```
salt `*` grub.version
```

32.17.105 salt.modules.guestfs

Interact with virtual machine images via libguestfs

```
depends
  • libguestfs
```

salt.modules.guestfs.mount(location, access='rw')
Mount an image

CLI Example:

```
salt `*` guest.mount /srv/images/fedora.qcow
```

32.17.106 salt.modules.hadoop

Support for hadoop

```
maintainer  Yann Jouanin <yann.jouanin@intelunix.fr>
maturity  new
depends
platform linux
```

salt.modules.hadoop.dfs(command=None, *args)
Execute a command on DFS

CLI Example:

```
salt `*` hadoop.dfs ls /
```
salt.modules.hadoop.dfs_absent(path)
Check if a file or directory is absent on the distributed FS.

CLI Example:

```
salt '*'.hadoop.dfs_absent /some_random_file
```

Returns True if the file is absent

salt.modules.hadoop.dfs_present(path)
Check if a file or directory is present on the distributed FS.

CLI Example:

```
salt '*'.hadoop.dfs_present /some_random_file
```

Returns True if the file is present

salt.modules.hadoop.namenode_format(force=None)
Format a name node

```
salt '*'.hadoop.namenode_format force=True
```

salt.modules.hadoop.version()
Return version from hadoop version

CLI Example:

```
salt '*'.hadoop.version
```

32.17.107 salt.modules.haproxyconn

Support for haproxy

New in version 2014.7.0.

salt.modules.haproxyconn.disable_server(name, backend, socket='/var/run/haproxy.sock')
Disable server in haproxy.

name Server to disable
backend haproxy backend
socket haproxy stats socket

CLI Example:

```
salt '*' haproxy.disable_server db1.example.com mysql
```

salt.modules.haproxyconn.enable_server(name, backend, socket='/var/run/haproxy.sock')
Enable Server in haproxy

name Server to enable
backend haproxy backend
socket haproxy stats socket

CLI Example:

```
salt '*' haproxy.enable_server web1.example.com www
```
salt.modules.haproxyconns.get_weight(name, backend, socket='/var/run/haproxy.sock')
Get server weight
   name  Server name
   backend haproxy backend
   socket  haproxy stats socket
CLI Example:
salt '*' haproxy.get_weight web1.example.com www

salt.modules.haproxyconns.list_servers (backend, socket='/var/run/haproxy.sock', objectify=False)
List servers in haproxy backend.
   backend  haproxy backend
   socket  haproxy stats socket
CLI Example:
salt '*' haproxy.list_servers mysql

salt.modules.haproxyconns.set_weight(name, backend, weight=0, socket='/var/run/haproxy.sock')
Set server weight
   name  Server name
   backend haproxy backend
   weight  Server Weight
   socket  haproxy stats socket
CLI Example:
salt '*' haproxy.set_weight web1.example.com www 13

salt.modules.haproxyconns.show_backends (socket='/var/run/haproxy.sock')
Show HaProxy Backends
   socket  haproxy stats socket
CLI Example:
salt '*' haproxy.show_backends

salt.modules.haproxyconns.show_frontends (socket='/var/run/haproxy.sock')
Show HaProxy frontends
   socket  haproxy stats socket
CLI Example:
salt '*' haproxy.show_frontends

32.17.108  salt.modules.hashutil
A collection of hashing and encoding functions
Salt Documentation, Release 2015.8.12

salt.modules.hashutil.\texttt{\textbf{base64\_decodestring}}(\textit{instr})
Decode a base64-encoded string
New in version 2014.7.0.
CLI Example:
\begin{verbatim}
salt '*' hashutil.base64_decodestring 'Z2V0IHNhbHRlZA=='\n\end{verbatim}

salt.modules.hashutil.\texttt{\textbf{base64\_encodestring}}(\textit{instr})
Encode a string as base64
New in version 2014.7.0.
CLI Example:
\begin{verbatim}
salt '*' hashutil.base64_encodestring 'get salted'
\end{verbatim}

salt.modules.hashutil.\texttt{\textbf{hmac\_signature}}(\textit{string, shared\_secret, challenge\_hmac})
Verify a challenging hmac signature against a string / shared-secret
New in version 2014.7.0.
Returns a boolean if the verification succeeded or failed.
CLI Example:
\begin{verbatim}
salt '*' hashutil.hmac_signature 'get salted' 'shared secret'
```eBWf9bstXg+NiP5A0wp85HMvZiYMPzEM9W5YMm/AmQ='
\end{verbatim}

salt.modules.hashutil.\texttt{\textbf{md5\_digest}}(\textit{instr})
Generate an md5 hash of a given string
New in version 2014.7.0.
CLI Example:
\begin{verbatim}
salt '*' hashutil.md5_digest 'get salted'
\end{verbatim}

salt.modules.hashutil.\texttt{\textbf{sha256\_digest}}(\textit{instr})
Generate an sha256 hash of a given string
New in version 2014.7.0.
CLI Example:
\begin{verbatim}
salt '*' hashutil.sha256_digest 'get salted'
\end{verbatim}

salt.modules.hashutil.\texttt{\textbf{sha512\_digest}}(\textit{instr})
Generate an sha512 hash of a given string
New in version 2014.7.0.
CLI Example:
\begin{verbatim}
salt '*' hashutil.sha512_digest 'get salted'
\end{verbatim}

32.17.109  salt.modules.hg
Support for the Mercurial SCM
salt.modules.hg.archive(cwd, output, rev='tip', fmt=None, prefix=None, user=None)
    Export a tarball from the repository
   .cwd  The path to the Mercurial repository
    output  The path to the archive tarball
    rev: tip  The revision to create an archive from
    fmt: None  Format of the resulting archive. Mercurial supports: tar, tbz2, tgz, zip, uzip, and files formats.
    prefix [None]  Prepend <prefix>/ to every filename in the archive
    user [None]  Run hg as a user other than what the minion runs as
    If prefix is not specified it defaults to the basename of the repo directory.
    CLI Example:
    ```
    salt '*' hg.archive /path/to/repo output=/tmp/archive.tgz fmt=tgz
    ```

salt.modules.hg.clone(cwd, repository, opts=None, user=None, identity=None)
    Clone a new repository
    cwd  The path to the Mercurial repository
    repository  The hg URI of the repository
    opts [None]  Any additional options to add to the command line
    user [None]  Run hg as a user other than what the minion runs as
    identity [None]  Private SSH key on the minion server for authentication (ssh://)
    New in version 2015.5.0.
    CLI Example:
    ```
    salt '*' hg.clone /path/to/repo https://bitbucket.org/birkenfeld/sphinx
    ```

salt.modules.hg.describe(cwd, rev='tip', user=None)
    Mimic git describe and return an identifier for the given revision
    cwd  The path to the Mercurial repository
    rev: tip  The path to the archive tarball
    user [None]  Run hg as a user other than what the minion runs as
    CLI Example:
    ```
    salt '*' hg.describe /path/to/repo
    ```

salt.modules.hg.pull(cwd, opts=None, user=None, identity=None, repository=None)
    Perform a pull on the given repository
    cwd  The path to the Mercurial repository
    repository [None]  Perform pull from the repository different from .hg/hgrc:[paths]:default
    opts [None]  Any additional options to add to the command line
    user [None]  Run hg as a user other than what the minion runs as
    identity [None]  Private SSH key on the minion server for authentication (ssh://)
    New in version 2015.5.0.
salt.modules.hg.revision(cwd, rev='tip', short=False, user=None)

Returns the long hash of a given identifier (hash, branch, tag, HEAD, etc)

cwd  The path to the Mercurial repository
rev: tip  The revision
short: False  Return an abbreviated commit hash
user  [None] Run hg as a user other than what the minion runs as

CLI Example:

```
salt '*' hg.revision /path/to/repo mybranch
```

salt.modules.hg.update(cwd, rev, force=False, user=None)

Update to a given revision

cwd  The path to the Mercurial repository
rev  The revision to update to
force  [False] Force an update
user  [None] Run hg as a user other than what the minion runs as

CLI Example:

```
salt devserver1 hg.update /path/to/repo somebranch
```

32.17.110  salt.modules.hipchat

Module for sending messages to hipchat.

New in version 2015.5.0.

configuration  This module can be used by either passing an api key and version directly or by specifying both in a configuration profile in the salt master/minion config.

For example:

```
hipchat:
    api_key: peWcBiMOS9HrZG15peWcBiMOS9HrZG15
    api_version: v1
```

salt.modules.hipchat.find_room(name, api_key=None, api_version=None)

CLI Example:

```
salt '*' hipchat.find_room name="Development Room"
```

```
salt '*' hipchat.find_room name="Development Room" api_key=peWcBiMOS9HrZG15peWcBiMOS9HrZG15 api_version=v1
```
salt.modules.hipchat.find_user(name, api_key=None, api_version=None)
Find a user by name and return it. :param name: The user name. :param api_key: The HipChat admin api key. :param api_version: The HipChat api version, if not specified in the configuration. :return: The user object.

CLI Example:
```
salt '*' hipchat.find_user name="Thomas Hatch"
salt '*' hipchat.find_user name="Thomas Hatch" api_key=peWcBiMOS9HrZG15peWcBiMOS9HrZG15 api_version=v1
```

salt.modules.hipchat.list_rooms(api_key=None, api_version=None)
List all HipChat rooms.

Parameters
- **api_key** -- The HipChat admin api key.
- **api_version** -- The HipChat api version, if not specified in the configuration.

Returns The room list.

CLI Example:
```
salt '*' hipchat.list_rooms
salt '*' hipchat.list_rooms api_key=peWcBiMOS9HrZG15peWcBiMOS9HrZG15 api_version=v1
```

salt.modules.hipchat.list_users(api_key=None, api_version=None)

CLI Example:
```
salt '*' hipchat.list_users
salt '*' hipchat.list_users api_key=peWcBiMOS9HrZG15peWcBiMOS9HrZG15 api_version=v1
```

salt.modules.hipchat.send_message(room_id, message, from_name, api_key=None, api_version=None, color='yellow', notify=False)
Send a message to a HipChat room. :param room_id: The room id or room name, either will work. :param message: The message to send to the HipChat room. :param from_name: Specify who the message is from. :param api_key: The HipChat api key, if not specified in the configuration. :param api_version: The HipChat api version, if not specified in the configuration. :param color: The color for the message, default: yellow. :param notify: Whether to notify the room, default: False. :return: Boolean if message was sent successfully.

CLI Example:
```
salt '*' hipchat.send_message room_id="Development Room" message="Build is done" from_name="Build Server"
salt '*' hipchat.send_message room_id="Development Room" message="Build failed" from_name="Build Server" color="red" notify=True
```

32.17.111 salt.modules.hosts
Manage the information in the hosts file
salt.modules.hosts.add_host(ip, alias)
Add a host to an existing entry, if the entry is not in place then create it with the given host

CLI Example:
```
salt '*' hosts.add_host <ip> <alias>
```

salt.modules.hosts.get_alias(ip)
Return the list of aliases associated with an ip

CLI Example:
```
salt '*' hosts.get_alias <ip addr>
```

salt.modules.hosts.get_ip(host)
Return the ip associated with the named host

CLI Example:
```
salt '*' hosts.get_ip <hostname>
```

salt.modules.hosts.has_pair(ip, alias)
Return true if the alias is set

CLI Example:
```
salt '*' hosts.has_pair <ip> <alias>
```

salt.modules.hosts.list_hosts()
Return the hosts found in the hosts file in this format:
```
{
    '<ip addr>': ['alias1', 'alias2', ...]
}
```

CLI Example:
```
salt '*' hosts.list_hosts
```

salt.modules.hosts.rm_host(ip, alias)
Remove a host entry from the hosts file

CLI Example:
```
salt '*' hosts.rm_host <ip> <alias>
```

salt.modules.hosts.set_host(ip, alias)
Set the host entry in the hosts file for the given ip, this will overwrite any previous entry for the given ip

CLI Example:
```
salt '*' hosts.set_host <ip> <alias>
```

32.17.112 salt.modules.htpasswd

Support for htpasswd command. Requires the apache2-utils package for Debian-based distros.

New in version 2014.1.0.

The functions here will load inside the webutil module. This allows other functions that don't use htpasswd to use the webutil module name.
salt.modules.htpasswd.useradd(pwfile, user, password, opts=",", runas=None)
Add a user to htpasswd file using the htpasswd command. If the htpasswd file does not exist, it will be created.

pwfile  Path to htpasswd file
user  User name
password  User password
opts  Valid options that can be passed are:

- n  Don’t update file; display results on stdout.
- m  Force MD5 encryption of the password (default).
- d  Force CRYPT encryption of the password.
- p  Do not encrypt the password (plaintext).
- s  Force SHA encryption of the password.
runas  The system user to run htpasswd command with

CLI Examples:

```bash
salt '*' webutil.useradd /etc/httpd/htpasswd larry badpassword
salt '*' webutil.useradd /etc/httpd/htpasswd larry badpass opts=ns
```

salt.modules.htpasswd.useradd_all(pwfile, user, password, opts=",", runas=None)
Add a user to htpasswd file using the htpasswd command. If the htpasswd file does not exist, it will be created.

pwfile  Path to htpasswd file
user  User name
password  User password
opts  Valid options that can be passed are:

- n  Don’t update file; display results on stdout.
- m  Force MD5 encryption of the password (default).
- d  Force CRYPT encryption of the password.
- p  Do not encrypt the password (plaintext).
- s  Force SHA encryption of the password.
runas  The system user to run htpasswd command with

CLI Examples:

```bash
salt '*' webutil.useradd /etc/httpd/htpasswd larry badpassword
salt '*' webutil.useradd /etc/httpd/htpasswd larry badpass opts=ns
```

salt.modules.htpasswd.userdel(pwfile, user, runas=None)
Delete a user from the specified htpasswd file.

pwfile  Path to htpasswd file
user  User name
runas  The system user to run htpasswd command with

CLI Examples:
**32.17.113 salt.modules.http**

Module for making various web calls. Primarily designed for webhooks and the like, but also useful for basic http testing.

New in version 2015.5.0.

salt.modules.http.query(`url`, **`kwargs`)

Query a resource, and decode the return data

New in version 2015.5.0.

CLI Example:

```bash
salt '*' http.query http://somelink.com/
salt '*' http.query http://somelink.com/ method=POST params='key1=val1&key2=val2'
salt '*' http.query http://somelink.com/ method=POST data='<xml>
  <somecontent/></xml>'
```

salt.modules.http.update_ca_bundle(`target=None`, `source=None`, `merge_files=None`)

Update the local CA bundle file from a URL

New in version 2015.5.0.

CLI Example:

```bash
salt '*' http.update_ca_bundle
salt '*' http.update_ca_bundle target=/path/to/cacerts.pem
salt '*' http.update_ca_bundle source=https://example.com/cacerts.pem
```

If the `target` is not specified, it will be pulled from the `ca_cert` configuration variable available to the minion. If it cannot be found there, it will be placed at `<<FILE_ROOTS>>/cacerts.pem`.

If the `source` is not specified, it will be pulled from the `ca_cert_url` configuration variable available to the minion. If it cannot be found, it will be downloaded from the cURL website, using an http (not https) URL. USING THE DEFAULT URL SHOULD BE AVOIDED!

`merge_files` may also be specified, which includes a string or list of strings representing a file or files to be appended to the end of the CA bundle, once it is downloaded.

CLI Example:

```bash
salt '*' http.update_ca_bundle merge_files=/path/to/mycert.pem
```

**32.17.114 salt.modules.ifttt**

Support for IFTTT

New in version 2015.8.0.

Requires an `api_key` in `/etc/salt/minion`

salt.modules.ifttt.trigger_event(`event=None`, **`kwargs`)

Trigger a configured event in IFTTT.

**Parameters**

- **event** -- The name of the event to trigger.
Returns A dictionary with status, text, and error if result was failure.

32.17.115 salt.modules.ilo

Manage HP ILO

depends hponcfg (SmartStart Scripting Toolkit Linux Edition)

salt.modules.ilo.change_password(username, password)
Reset a users password

CLI Example:
```
salt '*' ilo.change_password damianMyerscough
```

salt.modules.ilo.change_username(old_username, new_username)
Change a username

CLI Example:
```
salt '*' ilo.change_username damian diana
```

salt.modules.ilo.configure_network(ip, netmask, gateway)
Configure Network Interface

CLI Example:
```
salt '*' ilo.configure_network [IP ADDRESS] [NETMASK] [GATEWAY]
```

salt.modules.ilo.configure_snmp(community, snmp_port=161, snmp_trapport=161)
Configure SNMP

CLI Example:
```
salt '*' ilo.configure_snmp [COMMUNITY STRING] [SNMP PORT] [SNMP TRAP PORT]
```

salt.modules.ilo.create_user(name, password, *privileges)
Create user

CLI Example:
```
salt '*' ilo.create_user damian secretagent VIRTUAL_MEDIA_PRIV
```

If no permissions are specify the user will only have a read-only account.

Supported privelges:

- ADMIN_PRIV Enables the user to administer user accounts.
- REMOTE_CONS_PRIV Enables the user to access the Remote Console functionality.
- RESET_SERVER_PRIV Enables the user to remotely manipulate the server power setting.
- VIRTUAL_MEDIA_PRIV Enables the user permission to access the virtual media functionality.
- CONFIG_ILO_PRIV Enables the user to configure iLO settings.

salt.modules.ilo.delete_ssh_key(username)
Delete a users SSH key from the ILO

CLI Example:
salt 'ADDR' ilo.delete_user_sshkey damian

salt.modules.ilo.delete_user(username)
Delete a user
    CLI Example:
    salt 'ADDR' ilo.delete_user damian

salt.modules.ilo.disable_dhcp()
Disable DHCP
    CLI Example:
    salt 'ADDR' ilo.disable_dhcp

salt.modules.ilo.disable_ssh()
Disable the SSH daemon
    CLI Example:
    salt 'ADDR' ilo.disable_ssh

salt.modules.ilo.enable_dhcp()
Enable DHCP
    CLI Example:
    salt 'ADDR' ilo.enable_dhcp

salt.modules.ilo.enable_ssh()
Enable the SSH daemon
    CLI Example:
    salt 'ADDR' ilo.enable_ssh

salt.modules.ilo.get_user(username)
Returns local user information, excluding the password
    CLI Example:
    salt 'ADDR' ilo.get_user damian

salt.modules.ilo.global_settings()
Show global settings
    CLI Example:
    salt 'ADDR' ilo.global_settings

salt.modules.ilo.list_users()
List all users
    CLI Example:
    salt 'ADDR' ilo.list_users
salt.modules.ilo.list_users_info()
List all users in detail

CLI Example:
```
salt '*' ilo.list_users_info
```

salt.modules.ilo.network()
Grab the current network settings

CLI Example:
```
salt '*' ilo.network
```

salt.modules.ilo.set_http_port(port=80)
Configure the port HTTP should listen on

CLI Example:
```
salt '*' ilo.set_http_port 8080
```

salt.modules.ilo.set_https_port(port=443)
Configure the port HTTPS should listen on

CLI Example:
```
salt '*' ilo.set_https_port 4334
```

salt.modules.ilo.set_ssh_key(public_key)
Configure SSH public keys for specific users

CLI Example:
```
salt '*' ilo.set_ssh_key "ssh-dss AAAAB3NzaC1kc3MAAACBA... damian"
```

The SSH public key needs to be DSA and the last argument in the key needs to be the username (case-sensitive) of the ILO username.

salt.modules.ilo.set_ssh_port(port=22)
Enable SSH on a user defined port

CLI Example:
```
salt '*' ilo.set_ssh_port 2222
```

32.17.116 salt.modules.img

Virtual machine image management tools

salt.modules.img.bootstrap(location, size, fmt)
HIGHLY EXPERIMENTAL Bootstrap a virtual machine image

location: The location to create the image
size: The size of the image to create in megabytes
fmt: The image format, raw or qcow2

CLI Example:
salt.modules.img.mount_image(location)
Mount the named image and return the mount point

CLI Example:
```
salt '*' img.mount_image /tmp/foo
```

salt.modules.img.umount_image(mnt)
Unmount an image mountpoint

CLI Example:
```
salt '*' img.umount_image /mnt/foo
```

32.17.117 salt.modules.incron

Work with incron

salt.modules.incron.list_tab(user)
Return the contents of the specified user's incrontab

CLI Example:
```
salt '*' incron.list_tab root
```

salt.modules.incron.ls(user)
This function is an alias of list_tab.

Return the contents of the specified user's incrontab

CLI Example:
```
salt '*' incron.list_tab root
```

salt.modules.incron.raw_incron(user)
Return the contents of the user's incrontab

CLI Example:
```
salt '*' incron.raw_incron root
```

salt.modules.incron.raw_system_incron()
Return the contents of the system wide incrontab

CLI Example:
```
salt '*' incron.raw_system_incron
```

salt.modules.incron.rm(user, path, mask, cmd)
This function is an alias of rm_job.

Remove a incron job for a specified user. If any of the day/time params are specified, the job will only be removed if the specified params match.

CLI Example:
salt.modules.incron.rm_job(\textit{user, path, mask, cmd})

Remove a incron job for a specified user. If any of the day/time params are specified, the job will only be removed if the specified params match.

CLI Example:

\begin{verbatim}
salt 'x' incron.rm_job root /path
\end{verbatim}

salt.modules.incron.set_job(\textit{user, path, mask, cmd})

Sets an incron job up for a specified user.

CLI Example:

\begin{verbatim}
salt 'x' incron.set_job root '/root' 'IN_MODIFY' 'echo "$$ $@ $# $$ % $&''
\end{verbatim}

salt.modules.incron.write_incron_file(\textit{user, path})

Writes the contents of a file to a user's incrontab

CLI Example:

\begin{verbatim}
salt 'x' incron.write_incron_file root /tmp/new_incron
\end{verbatim}

salt.modules.incron.write_incron_file_verbose(\textit{user, path})

Writes the contents of a file to a user's incrontab and return error message on error

CLI Example:

\begin{verbatim}
salt 'x' incron.write_incron_file_verbose root /tmp/new_incron
\end{verbatim}

32.17.118 salt.modules.influx

InfluxDB - A distributed time series database

Module to provide InfluxDB compatibility to Salt (compatible with InfluxDB version 0.5+)

New in version 2014.7.0.

depends

- influxdb Python module

configuration This module accepts connection configuration details either as parameters or as configuration settings in /etc/salt/minion on the relevant minions:

\begin{verbatim}
influxdb.host: 'localhost'
influxdb.port: 8086
influxdb.user: 'root'
influxdb.password: 'root'
\end{verbatim}

This data can also be passed into pillar. Options passed into opts will overwrite options passed into pillar.

salt.modules.influx.db_create(\textit{name, user=None, password=None, host=None, port=None})

Create a database

\begin{itemize}
  \item \textbf{name} Database name to create
  \item \textbf{user} The user to connect as
\end{itemize}
password  The password of the user
host    The host to connect to
port    The port to connect to

CLI Example:
```
salt '*' influxdb.db_create <name>
salt '*' influxdb.db_create <name> <user> <password> <host> <port>
```

salt.modules.influx.db_exists(name, user=None, password=None, host=None, port=None)
Checks if a database exists in InfluxDB

name  Database name to create
user   The user to connect as
password  The password of the user
host   The host to connect to
port   The port to connect to

CLI Example:
```
salt '*' influxdb.db_exists <name>
salt '*' influxdb.db_exists <name> <user> <password> <host> <port>
```

salt.modules.influx.db_list(user=None, password=None, host=None, port=None)
List all InfluxDB databases

user   The user to connect as
password  The password of the user
host   The host to connect to
port   The port to connect to

CLI Example:
```
salt '*' influxdb.db_list
salt '*' influxdb.db_list <user> <password> <host> <port>
```

salt.modules.influx.db_remove(name, user=None, password=None, host=None, port=None)
Remove a database

name  Database name to remove
user   The user to connect as
password  The password of the user
host   The host to connect to
port   The port to connect to

CLI Example:
```
salt '*' influxdb.db_remove <name>
salt '*' influxdb.db_remove <name> <user> <password> <host> <port>
```
salt.modules.influx.login_test(name, password, database=None, host=None, port=None)

Checks if a credential pair can log in at all.

If a database is specified: it will check for database user existence. If a database is not specified: it will check for cluster admin existence.

name  The user to connect as
password  The password of the user
database  The database to try to log in to
host  The host to connect to
port  The port to connect to

CLI Example:

```
salt '*' influxdb.login_test <name>
salt '*' influxdb.login_test <name> <database>
salt '*' influxdb.login_test <name> <database> <user> <password> <host> <port>
```

salt.modules.influx.query(database, query, time_precision='s', chunked=False, user=None, password=None, host=None, port=None)

Querying data

database  The database to query
query  Query to be executed
time_precision  Time precision to use (‘s’, ‘m’, or ‘u’)
chunked  Whether is chunked or not
user  The user to connect as
password  The password of the user
host  The host to connect to
port  The port to connect to

CLI Example:

```
salt '*' influxdb.query <database> <query>
salt '*' influxdb.query <database> <query> <time_precision> <chunked> <user> <password> <host> <port>
```

salt.modules.influx.retention_policy_add(database, name, duration, replication, default=False, user=None, password=None, host=None, port=None)

Add a retention policy.

database  The database to operate on.
name  Name of the policy to modify.
duration  How long InfluxDB keeps the data.
replication  How many copies of the data are stored in the cluster.
default  Whether this policy should be the default or not. Default is False.

CLI Example:
salt '*' influxdb.retention_policy_add metrics default 1d 1

salt.modules.influx.retention_policy_alter(database, name, duration, replication, default=False, user=None, password=None, host=None, port=None)

Modify an existing retention policy.

**database** The database to operate on.

**name** Name of the policy to modify.

**duration** How long InfluxDB keeps the data.

**replication** How many copies of the data are stored in the cluster.

**default** Whether this policy should be the default or not. Default is False.

**CLI Example:**
salt '*' influxdb.retention_policy_modify metrics default 1d 1

salt.modules.influx.retention_policy_exists(database, name, user=None, password=None, host=None, port=None)

Check if a retention policy exists.

**database** The database to operate on.

**name** Name of the policy to modify.

**CLI Example:**
salt '*' influxdb.retention_policy_exists metrics default

salt.modules.influx.retention_policy_get(database, name, user=None, password=None, host=None, port=None)

Get an existing retention policy.

**database** The database to operate on.

**name** Name of the policy to modify.

**CLI Example:**
salt '*' influxdb.retention_policy_get metrics default

salt.modules.influx.user_chpass(name, passwd, database=None, user=None, password=None, host=None, port=None)

Change password for a cluster admin or a database user.

If a database is specified: it will update database user password. If a database is not specified: it will update cluster admin password.

**name** User name for whom to change the password

**passwd** New password

**database** The database on which to operate

**user** The user to connect as

**password** The password of the user

**host** The host to connect to

**port** The port to connect to
CLI Example:

```
salt '*' influxdb.user_chpass <name> <passwd>
salt '*' influxdb.user_chpass <name> <passwd> <database>
salt '*' influxdb.user_chpass <name> <passwd> <database> <user> <password> <host> <port>
```

```
salt.modules.influx.user_create(name, passwd, database=None, user=None, password=None, host=None, port=None)
```

Create a cluster admin or a database user.

If a database is specified: it will create database user. If a database is not specified: it will create a cluster admin.

- **name**: User name for the new user to create
- **passwd**: Password for the new user to create
- **database**: The database to create the user in
- **user**: The user to connect as
- **password**: The password of the user
- **host**: The host to connect to
- **port**: The port to connect to

CLI Example:

```
salt '*' influxdb.user_create <name> <passwd>
salt '*' influxdb.user_create <name> <passwd> <database>
salt '*' influxdb.user_create <name> <passwd> <database> <user> <password> <host> <port>
```

```
salt.modules.influx.user_exists(name, database=None, user=None, password=None, host=None, port=None)
```

Checks if a cluster admin or database user exists.

If a database is specified: it will check for database user existence. If a database is not specified: it will check for cluster admin existence.

- **name**: User name
- **database**: The database to check for the user to exist
- **user**: The user to connect as
- **password**: The password of the user
- **host**: The host to connect to
- **port**: The port to connect to

CLI Example:

```
salt '*' influxdb.user_exists <name>
salt '*' influxdb.user_exists <name> <database>
salt '*' influxdb.user_exists <name> <database> <user> <password> <host> <port>
```

```
salt.modules.influx.user_list(database=None, user=None, password=None, host=None, port=None)
```

List cluster admins or database users.
If a database is specified: it will return database users list. If a database is not specified: it will return cluster admins list.

**database**  The database to list the users from

**user**  The user to connect as

**password**  The password of the user

**host**  The host to connect to

**port**  The port to connect to

CLI Example:
```
salt '*' influxdb.user_list
salt '*' influxdb.user_list <database>
salt '*' influxdb.user_list <database> <user> <password> <host> <port>
```

```
salt.modules.influx.user_remove(name, database=None, user=None, password=None, host=None, port=None)
```
Remove a cluster admin or a database user.

If a database is specified: it will remove the database user. If a database is not specified: it will remove the cluster admin.

**name**  User name to remove

**database**  The database to remove the user from

**user**  User name for the new user to delete

**user**  The user to connect as

**password**  The password of the user

**host**  The host to connect to

**port**  The port to connect to

CLI Example:
```
salt '*' influxdb.user_remove <name>
salt '*' influxdb.user_remove <name> <database>
salt '*' influxdb.user_remove <name> <database> <user> <password> <host> <port>
```

### 32.17.119  `salt.modules.ini_manage`

Edit ini files

**maintainer**  <akilesh1597@gmail.com>

**maturity**  new

**depends**  re

**platform**  all

Use section as DEFAULT IMPLICIT if your ini file does not have any section (for example /etc/sysctl.conf)

```
salt.modules.ini_manage.get_option(file_name, section, option)
```
Get value of a key from a section in an ini file. Returns None if no matching key was found.

API Example:
import salt
sc = salt.client.get_local_client()
sc.cmd('target', 'ini.get_option',
       [path_to_ini_file, section_name, option])

CLI Example:
salt '*' ini.get_option /path/to/ini section_name option_name

salt.modules.ini_manage.get_section(file_name, section)
Retrieve a section from an ini file. Returns the section as dictionary. If the section is not found, an empty
dictionary is returned.

API Example:

import salt
sc = salt.client.get_local_client()
sc.cmd('target', 'ini.get_section',
       [path_to_ini_file, section_name])

CLI Example:
salt '*' ini.get_section /path/to/ini section_name

salt.modules.ini_manage.remove_option(file_name, section, option)
Remove a key/value pair from a section in an ini file. Returns the value of the removed key, or None if nothing
was removed.

API Example:

import salt
sc = salt.client.get_local_client()
sc.cmd('target', 'ini.remove_option',
       [path_to_ini_file, section_name, option])

CLI Example:
salt '*' ini.remove_option /path/to/ini section_name option_name

salt.modules.ini_manage.remove_section(file_name, section)
Remove a section in an ini file. Returns the removed section as dictionary, or None if nothing was removed.

API Example:

import salt
sc = salt.client.get_local_client()
sc.cmd('target', 'ini.remove_section',
       [path_to_ini_file, section_name])

CLI Example:
salt '*' ini.remove_section /path/to/ini section_name

salt.modules.ini_manage.set_option(file_name, sections=None, summary=True)
Edit an ini file, replacing one or more sections. Returns a dictionary containing the changes made.

file_name path of ini_file
sections  [None] A dictionary representing the sections to be edited ini file
Set `summary=False` if return data need not have previous option value

API Example:

```python
import salt
sc = salt.client.get_local_client()
sc.cmd('target', 'ini.set_option',
       ['path_to_ini_file', '{"section_to_change": {"key": "value"}}'])
```

CLI Example:

```
salt '*' ini.set_option /path/to/ini '{section_foo: {key: value}}'
```

### 32.17.120 `salt.modules.inspectlib` package

**Submodules**

`salt.modules.inspectlib.collector` module

```python
class salt.modules.inspectlib.collector.Inspector(db_path=None, pid_file=None)
```

- `IGNORE_FS_TYPES` = `['autofs', 'cifs', 'nfs', 'nfs4']`
- `IGNORE_MOUNTS` = `['proc', 'sysfs', 'devtmpfs', 'tmpfs', 'fuse.gvfs-fuse-daemon']`
- `IGNORE_PATHS` = `['/tmp', '/var/tmp', '/lost+found', '/var/run', '/var/lib/rpm', '/.snapshots', '/zfs', '/etc/ssh', '/root', '/home'`
- `MODE` = `['configuration', 'payload', 'all']`
- `request_snapshot(mode, priority=19, **kwargs)`
  - Take a snapshot of the system.
- `snapshot(mode)`
  - Take a snapshot of the system.

`salt.modules.inspectlib.collector.is_alive(pidfile)`

- Check if PID is still alive.

`salt.modules.inspectlib.collector.main(dbfile, pidfile, mode)`

- Main analyzer routine.

**salt.modules.inspectlib.dbhandle** module

```python
class salt.modules.inspectlib.dbhandle.DBHandle(path)
class salt.modules.inspectlib.dbhandle.DBHandleBase(path)
```

- Handle for the volatile database, which serves the purpose of caching the inspected data. This database can be destroyed or corrupted, so it should be simply re-created from scratch.
- `close()`
  - Close the database connection.
- `flush(table)`
  - Flush the table.
- `open(new=False)`
  - Init the database, if required.

32.17. Full list of builtin execution modules
purge()
    Purge whole database.

salt.modules.inspectlib.exceptions module

exception salt.modules.inspectlib.exceptions.InspectorQueryException
    Exception that is only for the inspector query.

exception salt.modules.inspectlib.exceptions.InspectorSnapshotException
    Snapshot exception.

exception salt.modules.inspectlib.exceptions.SIException
    System information exception.

salt.modules.inspectlib.query module

class salt.modules.inspectlib.query.Query(scope)
    Query the system. This class is actually puts all Salt features together, so there would be no need to pick it from various places.

    SCOPES = ['changes', 'configuration', 'identity', 'system', 'software', 'services', 'payload', 'all']

class salt.modules.inspectlib.query.SysInfo(systype)
    System information.

Module contents

32.17.121 salt.modules.introspect

Functions to perform introspection on a minion, and return data in a format usable by Salt States

salt.modules.introspect.enabled_service_owners()
    Return which packages own each of the services that are currently enabled.

    CLI Example:
    salt myminion introspect.enabled_service_owners

salt.modules.introspect.running_service_owners(exclude=('/dev', '/home', '/media', '/proc', '/run', '/sys', '/tmp', '/var'))
    Determine which packages own the currently running services. By default, excludes files whose full path starts with /dev, /home, /media, /proc, /run, /sys, /tmp and /var. This can be overridden by passing in a new list to exclude.

    CLI Example:
    salt myminion introspect.running_service_owners

salt.modules.introspect.service_highstate(requires=True)
    Return running and enabled services in a highstate structure. By default also returns package dependencies for those services, which means that package definitions must be created outside this function. To drop the package dependencies, set requires to False.

    CLI Example:
    salt myminion introspect.service_highstate salt myminion introspect.service_highstate requires=False
32.17.122  salt.modules.ipmi

Support IPMI commands over LAN. This module does not talk to the local systems hardware through IPMI drivers. It uses a python module pyghmi.

**depends**  
Python module pyghmi. You can install pyghmi using pip:

```
pip install pyghmi
```

**configuration**  
The following configuration defaults can be define (pillar or config files):

```
{  
ipmi.config:  
    api_host: 127.0.0.1  
    api_user: admin  
    api_pass: apassword  
    api_port: 623  
    api_kg: None
}
```

Usage can override the config defaults:

```
salt-call ipmi.get_user api_host=myipmienabled.system api_user=admin api_pass=pass uid=1
```

**salt.modules.ipmi.create_user**(uid, name, password, channel=14, callback=False, link_auth=True, ipmi_msg=True, privilege_level='administrator', **kwargs)

create/ensure a user is created with provided settings.

Parameters

- **privilege_level** -- User Privilege Limit. (Determines the maximum privilege level that the user is allowed to switch to on the specified channel.) * callback * user * operator * administrator * proprietary * no_access

- **kwargs** --
  - api_host=127.0.0.1
  - api_user=admin
  - api_pass=example
  - api_port=623
  - api_kg=None

CLI Examples:

```
salt-call ipmi.create_user uid=2 name=steverweber api_host=172.168.0.7 api_pass=nevertell
```

**salt.modules.ipmi.fast_connect_test**(**kwargs)

Returns True if connection success. This uses an aggressive timeout value!

Parameters **kwargs** --

- api_host=127.0.0.1
- api_user=admin
- api_pass=example
- api_port=623
api_kg=None

CLI Examples:

```
salt-call ipmi.fast_connect_test api_host=172.168.0.9
```

```
salt.modules.ipmi.get_bootdev(**kwargs)
```

Get current boot device override information.

Provides the current requested boot device. Be aware that not all IPMI devices support this. Even in BMCs that claim to, occasionally the BIOS or UEFI fail to honor it. This is usually only applicable to the next reboot.

**Parameters**

- **kwarg**s
  - api_host=127.0.0.1
  - api_user=admin
  - api_pass=example
  - api_port=623
  - api_kg=None

CLI Example:

```
salt-call ipmi.get_bootdev api_host=127.0.0.1 api_user=admin api_pass=pass
```

```
salt.modules.ipmi.get_channel_access(channel=14, read_mode='non_volatile', **kwargs)
```

:para**m** kwarg**s**:api_host='127.0.0.1' api_user='admin' api_pass='example' api_port=623

**Parameters**

- **channel** -- number [1:7]
- **read_mode** --
  - non_volatile = get non-volatile Channel Access
  - volatile = get present volatile (active) setting of Channel Access
- **kwarg**s
  - api_host=127.0.0.1
  - api_user=admin
  - api_pass=example
  - api_port=623
  - api_kg=None

**return** A Python dict with the following keys/values:

```
{
    'alerting':
    'per_msg_auth':
    'user_level_auth':
    'access_mode':{
        'ONE OF':
        0: 'disabled',
        1: 'pre_boot',
        2: 'always',
        3: 'shared'
    }
}
```
privilege_level: { (ONE OF)
    1: 'callback',
    2: 'user',
    3: 'operator',
    4: 'administrator',
    5: 'proprietary',
}

CLI Examples:

```
salt-call ipmi.get_channel_access channel=1
```

salt.modules.ipmi.get_channel_info(channel=14, **kwargs)

Get channel info

Parameters

- **channel** -- number [1:7]
- **kwargs** --
  - api_host=127.0.0.1
  - api_user=admin
  - api_pass=example
  - api_port=623
  - api_kg=None

return channel session supports:

- no_session: channel is session-less
- single: channel is single-session
- multi: channel is multi-session
- auto: channel is session-based (channel could alternate between single- and multi-session operation, as can occur with a serial/modem channel that supports connection mode auto-detect)

CLI Examples:

```
salt-call ipmi.get_channel_info
```

salt.modules.ipmi.get_channel_max_user_count(channel=14, **kwargs)

Get max users in channel

Parameters

- **channel** -- number [1:7]
- **kwargs** --
  - api_host=127.0.0.1
  - api_user=admin
  - api_pass=example
  - api_port=623
- api_kg=None

Returns int -- often 16

CLI Examples:

```
salt-call ipmi.get_channel_max_user_count
```

`salt.modules.ipmi.get_health(**kwargs)`

Get Summarize health

This provides a summary of the health of the managed system. It additionally provides an iterable list of reasons for warning, critical, or failed assessments.

good health: {'badreadings': [], 'health': 0}

Parameters `kwargs` --

- api_host=127.0.0.1
- api_user=admin
- api_pass=example
- api_port=623
- api_kg=None

CLI Example:

```
salt-call ipmi.get_health api_host=127.0.0.1 api_user=admin api_pass=pass
```

`salt.modules.ipmi.get_power(**kwargs)`

Get current power state

The response, if successful, should contain `powerstate` key and either `on` or `off` to indicate current state.

Parameters `kwargs` --

- api_host=127.0.0.1
- api_user=admin
- api_pass=example
- api_port=623
- api_kg=None

CLI Example:

```
salt-call ipmi.get_power api_host=127.0.0.1 api_user=admin api_pass=pass
```

`salt.modules.ipmi.get_sensor_data(**kwargs)`

Get sensor readings

Iterates sensor reading objects

Parameters `kwargs` --

- api_host=127.0.0.1
- api_user=admin
- api_pass=example
- api_port=623
• api_kg=None

CLI Example:

```bash
salt-call ipmi.get_sensor_data api_host=127.0.0.1 api_user=admin api_pass=pass
```

```
salt.modules.ipmi.get_user(uid, channel=14, **kwargs)
Get user from uid and access on channel

Parameters
• uid -- user number [1:16]
• channel -- number [1:7]
• kwargs --
  - api_host=127.0.0.1
  - api_user=admin
  - api_pass=example
  - api_port=623
  - api_kg=None

return

name: (str)
uid: (int)
channel: (int)
access:
  - callback (bool)
  - link_auth (bool)
  - ipmi_msg (bool)
  - privilege_level: (str)[callback, user, operator, administrator, proprietary, no_access]
```

CLI Examples:

```bash
salt-call ipmi.get_user uid=2
```

```
salt.modules.ipmi.get_user_access(uid, channel=14, **kwargs)
Get user access

Parameters
• uid -- user number [1:16]
• channel -- number [1:7]
• kwargs --
  - api_host=127.0.0.1
  - api_user=admin
  - api_pass=example
  - api_port=623
  - api_kg=None

return
```
channel_info:
- max_user_count = maximum number of user IDs on this channel
- enabled_users = count of User ID slots presently in use
- users_with_fixed_names = count of user IDs with fixed names
access:
- callback
- link_auth
- ipmi_msg
- privilege_level: [reserved, callback, user, operator
  administrator, proprietary, no_access]

CLI Examples:
salt-call ipmi.get_user_access uid=2

salt.modules.ipmi.get_user_name(uid, return_none_on_error=True, **kwargs)
Get user name

Parameters
  • uid -- user number [1:16]
  • return_none_on_error -- return None on error
  • kwargs --
    - api_host=127.0.0.1
    - api_user=admin
    - api_pass=example
    - api_port=623
    - api_kg=None

CLI Examples:
salt-call ipmi.get_user_name uid=2

salt.modules.ipmi.get_users(channel=14, **kwargs)
get list of users and access information

Parameters
  • channel -- number [1:7]
  • kwargs --
    - api_host=127.0.0.1
    - api_user=admin
    - api_pass=example
    - api_port=623
    - api_kg=None

Returns
  • name: (str)
  • uid: (int)
  • channel: (int)
• access:
  – callback (bool)
  – link_auth (bool)
  – ipmi_msg (bool)
  – privilege_level: (str)[callback, user, operatorm administrator, proprietary, no_access]

CLI Examples:

```
salt-call ipmi.get_users api_host=172.168.0.7
```

```
salt.modules.ipmi.raw_command(netfn, command, bridge_request=None, data=(), retry=True, delay_xmit=None, **kwargs)
```

Send raw ipmi command

This allows arbitrary IPMI bytes to be issued. This is commonly used for certain vendor specific commands.

**Parameters**

- **netfn** -- Net function number
- **command** -- Command value
- **bridge_request** -- The target slave address and channel number for the bridge request.
- **data** -- Command data as a tuple or list
- **kwargs** --
  - api_host=127.0.0.1
  - api_user=admin
  - api_pass=example
  - api_port=623
  - api_kg=None

**Returns**

dict -- The response from IPMI device

CLI Examples:

```
salt-call ipmi.raw_command netfn=0x06 command=0x46 data=[0x02]
# this will return the name of the user with id 2 in bytes
```

```
salt.modules.ipmi.set_bootdev(bootdev='default', persist=False, uefiboott=False, **kwargs)
```

Set boot device to use on next reboot

**Parameters**

- **bootdev** --
  - network: Request network boot
  - hd: Boot from hard drive
  - safe: Boot from hard drive, requesting `safe mode`
  - optical: boot from CD/DVD/BD drive
  - setup: Boot into setup utility
  - default: remove any IPMI directed boot device request
• **persist** -- If true, ask that system firmware use this device beyond next boot. Be aware many systems do not honor this.

• **uefiboot** -- If true, request UEFI boot explicitly. Strictly speaking, the spec suggests that if not set, the system should BIOS boot and offers no "don't care" option. In practice, this flag not being set does not preclude UEFI boot on any system I've encountered.

• **kwargs** --
  – `api_host=127.0.0.1`
  – `api_user=admin`
  – `api_pass=example`
  – `api_port=623`
  – `api_kg=None`

**Returns** dict or True -- If callback is not provided, the response

CLI Examples:

```bash
salt-call ipmi.set_bootdev bootdev=network persist=True
```

salt.modules.ipmi.

```python
set_channel_access(channel=14, access_update_mode='non_volatile',
alerting=False, per_msg_auth=False,
user_level_auth=False, access_mode='always',
privilege_update_mode='non_volatile', privilege_level='administrator', **kwargs)
```

Set channel access

**Parameters**

• **channel** -- number [1:7]

• **access_update_mode** --
  – ‘`dont_change’ = don’t set or change Channel Access
  – ‘`non_volatile’ = set non-volatile Channel Access
  – ‘`volatile’ = set volatile (active) setting of Channel Access

• **alerting** -- PEF Alerting Enable/Disable
  – True = enable PEF Alerting
  – False = disable PEF Alerting on this channel (Alert Immediate command can still be used to generate alerts)

• **per_msg_auth** -- Per-message Authentication
  – True = enable
  – False = disable Per-message Authentication. [Authentication required to activate any session on this channel, but authentication not used on subsequent packets for the session.]

• **user_level_auth** -- User Level Authentication Enable/Disable.
  – True = enable User Level Authentication. All User Level commands are to be authenticated per the Authentication Type that was negotiated when the session was activated.
False = disable User Level Authentication. Allow User Level commands to be executed without being authenticated.

If the option to disable User Level Command authentication is accepted, the BMC will accept packets with Authentication Type set to None if they contain user level commands.

For outgoing packets, the BMC returns responses with the same Authentication Type that was used for the request.

- **access_mode** -- Access Mode for IPMI messaging
  (PEF Alerting is enabled/disabled separately from IPMI messaging)
  - disabled = disabled for IPMI messaging
  - pre_boot = pre-boot only channel only available when system is in a powered down state or in BIOS prior to start of boot.
  - always = channel always available regardless of system mode. BIOS typically dedicates the serial connection to the BMC.
  - shared = same as always available, but BIOS typically leaves the serial port available for software use.

- **privilege_update_mode** -- Channel Privilege Level Limit.
  This value sets the maximum privilege level that can be accepted on the specified channel.
  - dont_change = don’t set or change channel Privilege Level Limit
  - non_volatile = non-volatile Privilege Level Limit according
  - volatile = volatile setting of Privilege Level Limit

- **privilege_level** -- Channel Privilege Level Limit
  - reserved = unused
  - callback
  - user
  - operator
  - administrator
  - proprietary = used by OEM

- **kwargs** --
  - api_host=127.0.0.1
  - api_user=admin
  - api_pass=example
  - api_port=623
  - api_kg=None

CLI Examples:

```
salt-call ipmi.set_channel_access privilege_level='administrator'
```
**salt.modules.ipmi.set_identify**(on=True, duration=600, **kwargs)

Request identify light

Request the identify light to turn off, on for a duration, or on indefinitely. Other than error exceptions,

Parameters

- **on** -- Set to True to force on or False to force off
- **duration** -- Set if wanting to request turn on for a duration in seconds, None = indefinitely.
- **kwargs** --
  - api_host=127.0.0.1
  - api_user=admin
  - api_pass=example
  - api_port=623
  - api_kg=None

CLI Examples:

```bash
salt-call ipmi.set_identify
```

**salt.modules.ipmi.set_power**(state='power_on', wait=True, **kwargs)

Request power state change

Parameters

- **name** --
  - power_on -- system turn on
  - power_off -- system turn off (without waiting for OS)
  - shutdown -- request OS proper shutdown
  - reset -- reset (without waiting for OS)
  - boot -- If system is off, then `on', else `reset'
- **ensure** -- If (bool True), do not return until system actually completes requested state change for 300 seconds. If a non-zero (int), adjust the wait time to the requested number of seconds
- **kwargs** --
  - api_host=127.0.0.1
  - api_user=admin
  - api_pass=example
  - api_port=623
  - api_kg=None

Returns dict -- A dict describing the response retrieved

CLI Examples:

```bash
salt-call ipmi.set_power state=shutdown wait=True
```
salt.modules.ipmi.set_user_access(uid, channel=14, callback=True, link_auth=True, ipmi_msg=True, privilege_level='administrator', **kwargs)

Set user access

Parameters

- **uid** -- user number [1:16]
- **channel** -- number [1:7]
- **link_auth** -- User Link authentication enable/disable (used to enable whether this user's name and password information will be used for link authentication, e.g. PPP CHAP) for the given channel. Link authentication itself is a global setting for the channel and is enabled/disabled via the serial/modem configuration parameters.
- **ipmi_msg** -- User IPMI Messaging: (used to enable/disable whether this user's name and password information will be used for IPMI Messaging. In this case, 'IPMI Messaging' refers to the ability to execute generic IPMI commands that are not associated with a particular payload type. For example, if IPMI Messaging is disabled for a user, but that user is enabled for activating the SOL payload type, then IPMI commands associated with SOL and session management, such as Get SOL Configuration Parameters and Close Session are available, but generic IPMI commands such as Get SEL Time are unavailable.)
- **privilege_level** -- User Privilege Limit. (Determines the maximum privilege level that the user is allowed to switch to on the specified channel.)
  - callback
  - user
  - operator
  - administrator
  - proprietary
  - no_access
- **kwargs** --
  - api_host=127.0.0.1
  - api_user=admin
  - api_pass=example
  - api_port=623
  - api_kg=None

**Parm callback** User Restricted to Callback

- False = User Privilege Limit is determined by the User Privilege Limit parameter, below, for both callback and non-callback connections.
- True = User Privilege Limit is determined by the User Privilege Limit parameter for callback connections, but is restricted to Callback level for non-callback connections. Thus, a user can only initiate a Callback when they 'call in' to the BMC, but once the callback connection has been made, the user could potentially establish a session as an Operator.

CLI Examples:

```
salt-call ipmi.set_user_access uid=2 privilege_level='operator'
```
salt.modules.ipmi.set_user_name(uid, name, **kwargs)
Set user name

Parameters

- **uid** -- user number [1:16]
- **name** -- username (limit of 16 bytes)
- **kwargs** --
  - api_host=127.0.0.1
  - api_user=admin
  - api_pass=example
  - api_port=623
  - api_kg=None

CLI Examples:

```
salt-call ipmi.set_user_name uid=2 name='steverweber'
```

salt.modules.ipmi.set_user_password(uid, mode='set_password', password=None, **kwargs)
Set user password and (modes)

Parameters

- **uid** -- id number of user. see: get_names_uid()['name']
- **mode** --
  - disable = disable user connections
  - enable = enable user connections
  - set_password = set or ensure password
  - test_password = test password is correct
- **password** -- max 16 char string (optional when mode is [disable or enable])
- **kwargs** --
  - api_host=127.0.0.1
  - api_user=admin
  - api_pass=example
  - api_port=623
  - api_kg=None

Returns  True on success when mode = test_password, return False on bad password

CLI Example:

```
salt-call ipmi.set_user_password api_host=127.0.0.1 api_user=admin api_pass=pass
uid=1 password=newPass
```

salt.modules.ipmi.user_delete(uid, channel=14, **kwargs)
Delete user (helper)

Parameters
• **uid** -- user number [1:16]
• **channel** -- number [1:7]
• **kwargs** --
  - `api_host=127.0.0.1`
  - `api_user=admin`
  - `api_pass=example`
  - `api_port=623`
  - `api_kg=None`

CLI Examples:
```
salt-call ipmi.user_delete uid=2
```

### 32.17.123 salt.modules.ipset

Support for ipset

**salt.modules.ipset.add**(*set=None, entry=None, family='ipv4', **kwargs*)

Append an entry to the specified set.

CLI Example:
```
salt '*' ipset.add setname 192.168.1.26
```

**salt.modules.ipset.check**(*set=None, entry=None, family='ipv4')

Check that an entry exists in the specified set.

- **set** The ipset name
- **entry** An entry in the ipset. This parameter can be a single IP address, a range of IP addresses, or a subnet block. Example:
```
192.168.0.1
192.168.0.2-192.168.0.19
192.168.0.0/25
```
- **family** IP protocol version: ipv4 or ipv6

CLI Example:
```
salt '*' ipset.check setname '192.168.0.1 comment "Hello"'
```

**salt.modules.ipset.check_set**(*set=None, family='ipv4')

Check that given ipset set exists.

New in version 2014.7.0.

CLI Example:
```
salt '*' ipset.check_set setname
```
salt.modules.ipset.delete(set=None, entry=None, family='ipv4', **kwargs)
Delete an entry from the specified set.

CLI Example:

salt.modules.ipset.delete_set(set=None, family='ipv4')
New in version 2014.7.0.
Delete ipset set.

CLI Example:
salt '*' ipset.delete_set custom_set
IPv6:
salt '*' ipset.delete_set custom_set family=ipv6

salt.modules.ipset.flush(set=None, family='ipv4')
Flush entries in the specified set, Flush all sets if set is not specified.

CLI Example:
salt '*' ipset.flush
salt '*' ipset.flush set
IPv6:
salt '*' ipset.flush
salt '*' ipset.flush set

salt.modules.ipset.list_sets(family='ipv4')
New in version 2014.7.0.
List all ipset sets.

CLI Example:
salt '*' ipset.list_sets

salt.modules.ipset.new_set(set=None, set_type=None, family='ipv4', comment=False, **kwargs)
New in version 2014.7.0.
Create new custom set

CLI Example:
salt '*' ipset.new_set custom_set list:set
salt '*' ipset.new_set custom_set list:set comment=True
IPv6:
salt '*' ipset.new_set custom_set list:set family=ipv6

salt.modules.ipset.rename_set(set=None, new_set=None, family='ipv4')
New in version 2014.7.0.
Delete ipset set.

CLI Example:
salt '!' ipset.rename_set custom_set new_set=new_set_name

IPv6:
salt '!' ipset.rename_set custom_set new_set=new_set_name family=ipv6

salt.modules.ipset.rename_set custom_set new_set=new_set_name

salt.modules.ipset.rename_set custom_set new_set=new_set_name family=ipv6

salt.modules.ipset.rename_set custom_set new_set=new_set_name family=ipv6

salt.modules.ipset.test(set=None, entry=None, family='ipv4', **kwargs)
Test if an entry is in the specified set.

CLI Example:
salt '!' ipset.test setname 192.168.0.2
IPv6:
salt '!' ipset.test setname fd81:fc56:9ac7::/48

salt.modules.ipset.test(setname=192.168.0.2)
IPv6:
salt.modules.ipset.test(setname=fd81:fc56:9ac7::/48)

salt.modules.ipset.version()
Return version from ipset --version

CLI Example:
salt '!' ipset.version

32.17.124 salt.modules.iptables

Support for iptables

salt.modules.iptables.append(table='filter', chain=None, rule=None, family='ipv4')
Append a rule to the specified table/chain.

This function accepts a rule in a standard iptables command format, starting with the chain. Trying to force users to adapt to a new method of creating rules would be irritating at best, and we already have a parser that can handle it.

CLI Example:
salt '!' iptables.append filter INPUT
rule='-m state --state RELATED,ESTABLISHED -j ACCEPT'
IPv6:
salt '!' iptables.append filter INPUT
rule='-m state --state RELATED,ESTABLISHED -j ACCEPT' 
family=ipv6

salt.modules.iptables.append filter INPUT
    rule='-m state --state RELATED,ESTABLISHED -j ACCEPT'
IPv6:
salt '!' iptables.append filter INPUT
    rule='-m state --state RELATED,ESTABLISHED -j ACCEPT' 
    family=ipv6

salt.modules.iptables.build_rule(table='filter', chain=None, command=None, position='', full=None, family='ipv4', **kwargs)
Build a well-formatted iptables rule based on kwargs. A table and chain are not required, unless full is True.

If full is True, then table, chain and command are required. command may be specified as either a short option ('I') or a long option (--insert). This will return the iptables command, exactly as it would be used from the command line.

If a position is required (as with -I or -D), it may be specified as position. This will only be useful if full is True.

If connstate is passed in, it will automatically be changed to state.

To pass in jump options that doesn't take arguments, pass in an empty string.

CLI Examples:
salt 'iptables.build_rule match=state \  
    connstate=RELATED,ESTABLISHED jump=ACCEPT

salt 'iptables.build_rule filter INPUT command=I position=3 \  
    full=True match=state state=RELATED,ESTABLISHED jump=ACCEPT

salt 'iptables.build_rule filter INPUT command=A \  
    full=True match=state state=RELATED,ESTABLISHED \  
    source='127.0.0.1' jump=ACCEPT

.. Invert Rules

salt 'iptables.build_rule filter INPUT command=A \  
    full=True match=state state=RELATED,ESTABLISHED \  
    source='! 127.0.0.1' jump=ACCEPT

salt 'iptables.build_rule filter INPUT command=A \  
    full=True match=state state=RELATED,ESTABLISHED \  
    destination='not 127.0.0.1' jump=ACCEPT

IPv6:
salt 'iptables.build_rule match=state \  
    connstate=RELATED,ESTABLISHED jump=ACCEPT \  
    family=ipv6

salt 'iptables.build_rule filter INPUT command=I position=3 \  
    full=True match=state state=RELATED,ESTABLISHED jump=ACCEPT \  
    family=ipv6

salt.modules.iptables.check(table='filter', chain=None, rule=None, family='ipv4')

Check for the existence of a rule in the table and chain

This function accepts a rule in a standard iptables command format, starting with the chain. Trying to
force users to adapt to a new method of creating rules would be irritating at best, and we already have a
parser that can handle it.

CLI Example:

salt 'iptables.check filter INPUT \  
    rule='^-m state --state RELATED,ESTABLISHED -j ACCEPT'

IPv6:
salt 'iptables.check filter INPUT \  
    rule='^-m state --state RELATED,ESTABLISHED -j ACCEPT' \  
    family=ipv6

salt.modules.iptables.check_chain(table='filter', chain=None, family='ipv4')

New in version 2014.1.0.

Check for the existence of a chain in the table

CLI Example:

salt 'iptables.check_chain filter INPUT

IPv6:
salt 'iptables.check_chain filter INPUT family=ipv6

salt.modules.iptables.delete(table, chain=None, position=None, rule=None, family='ipv4')

Delete a rule from the specified table/chain, specifying either the rule in its entirety, or the rule's position
in the chain.

This function accepts a rule in a standard iptables command format, starting with the chain. Trying to force users to adapt to a new method of creating rules would be irritating at best, and we already have a parser that can handle it.

CLI Examples:

```bash
salt '*' iptables.delete filter INPUT position=3
salt '*' iptables.delete filter INPUT \
  rule='-m state --state RELATED,ESTABLISHED -j ACCEPT'

IPv6:
salt '*' iptables.delete filter INPUT position=3 family=ipv6
salt '*' iptables.delete filter INPUT \
  rule='-m state --state RELATED,ESTABLISHED -j ACCEPT' \
  family=ipv6
```

```bash
salt.modules.iptables.delete_chain(table='filter', chain=None, family='ipv4')
```

New in version 2014.1.0.

Delete custom chain to the specified table.

CLI Example:

```bash
salt '*' iptables.delete_chain filter CUSTOM_CHAIN
```

IPv6:

```bash
salt '*' iptables.delete_chain filter CUSTOM_CHAIN family=ipv6
```

```
salt.modules.iptables.flush(table='filter', chain='*', family='ipv4')
```

Flush the chain in the specified table, flush all chains in the specified table if not specified chain.

CLI Example:

```bash
salt '*' iptables.flush filter INPUT
```

IPv6:

```bash
salt '*' iptables.flush filter INPUT family=ipv6
```

```
salt.modules.iptables.get_policy(table='filter', chain=None, family='ipv4')
```

Return the current policy for the specified table/chain

CLI Example:

```bash
salt '*' iptables.get_policy filter INPUT
```

IPv6:

```bash
salt '*' iptables.get_policy filter INPUT family=ipv6
```

```
salt.modules.iptables.get_rules(family='ipv4')
```

Return a data structure of the current, in-memory rules

CLI Example:

```bash
salt '*' iptables.get_rules
```

IPv6:

```bash
salt '*' iptables.get_rules family=ipv6
```
salt.modules.iptables.get_saved_policy(table='filter', chain=None, conf_file=None, family='ipv4')

Return the current policy for the specified table/chain

CLI Examples:

```
salt '*' iptables.get_saved_policy filter INPUT
salt '*' iptables.get_saved_policy filter INPUT
    conf_file=/etc/iptables.saved
```

IPv6:
```
salt '*' iptables.get_saved_policy filter INPUT family=ipv6
salt '*' iptables.get_saved_policy filter INPUT
    conf_file=/etc/iptables.saved family=ipv6
```

salt.modules.iptables.get_saved_rules(conf_file=None, family='ipv4')

Return a data structure of the rules in the conf file

CLI Example:
```
salt '*' iptables.get_saved_rules
```

IPv6:
```
salt '*' iptables.get_saved_rules family=ipv6
```

salt.modules.iptables.insert(table='filter', chain=None, position=None, rule=None, family='ipv4')

Insert a rule into the specified table/chain, at the specified position.

This function accepts a rule in a standard iptables command format, starting with the chain. Trying to force users to adapt to a new method of creating rules would be irritating at best, and we already have a parser that can handle it.

If the position specified is a negative number, then the insert will be performed counting from the end of the list. For instance, a position of -1 will insert the rule as the second to last rule. To insert a rule in the last position, use the append function instead.

CLI Examples:
```
salt '*' iptables.insert filter INPUT position=3
    rule='^-m state --state RELATED,ESTABLISHED -j ACCEPT'
```

IPv6:
```
salt '*' iptables.insert filter INPUT position=3
    rule='^-m state --state RELATED,ESTABLISHED -j ACCEPT'
        family=ipv6
```

salt.modules.iptables.new_chain(table='filter', chain=None, family='ipv4')

New in version 2014.1.0.

Create new custom chain to the specified table.

CLI Example:
```
salt '*' iptables.new_chain filter CUSTOM_CHAIN
```

IPv6:
```
salt '*' iptables.new_chain filter CUSTOM_CHAIN family=ipv6
```

salt.modules.iptables.save(filename=None, family='ipv4')

Save the current in-memory rules to disk
Salt Documentation, Release 2015.8.12

CLI Example:

```bash
salt '*' iptables.save /etc/sysconfig/iptables
```

IPv6:
```bash
salt '*' iptables.save /etc/sysconfig/iptables family=ipv6
```

`salt.modules.iptables.set_policy(table='filter', chain=None, policy=None, family='ipv4')`
Set the current policy for the specified table/chain

CLI Example:

```bash
salt '*' iptables.set_policy filter INPUT ACCEPT
```

IPv6:
```bash
salt '*' iptables.set_policy filter INPUT ACCEPT family=ipv6
```

`salt.modules.iptables.version(family='ipv4')`
Return version from iptables --version

CLI Example:

```bash
salt '*' iptables.version
```

IPv6:
```bash
salt '*' iptables.version family=ipv6
```

32.17.125 salt.modules.jboss7

Module for managing JBoss AS 7 through the CLI interface.

New in version 2015.5.0.

In order to run each function, jboss_config dictionary with the following properties must be passed:

- cli_path: the path to jboss-cli script, for example: `/opt/jboss/jboss-7.0/bin/jboss-cli.sh`
- controller: the IP address and port of controller, for example: 10.11.12.13:9999
- cli_user: username to connect to jboss administration console if necessary
- cli_password: password to connect to jboss administration console if necessary

Example:

```python
jboss_config:
    cli_path: '/opt/jboss/jboss-7.0/bin/jboss-cli.sh'
    controller: 10.11.12.13:9999
    cli_user: 'jbossadm'
    cli_password: 'jbossadm'
```

`salt.modules.jboss7.create_datasource(jboss_config, name, datasource_properties)`
Create datasource in running jboss instance

jboss_config Configuration dictionary with properties specified above.

name Datasource name
datasource_properties A dictionary of datasource properties to be created:
- driver-name: mysql
- connection-url: `jdbc:mysql://localhost:3306/sampleDatabase`
- jndi-name: `java:jboss/datasources/sampleDS`
- user-name: sampleuser
- password: secret
- min-pool-size: 3
- use-java-context: True

CLI Example:

```python
salt '*' jboss7.create_datasource '{"cli_path": "integration.modules.sysmod.SysModuleTest.test_valid_docs", "controller": "10.11.12.13:9999", "cli_user": "jbossadm", "cli_password": "jbossadm"}', 'my_datasource' '{"driver-name": "mysql"},
"connection-url": "jdbc:mysql://localhost:3306/sampleDatabase", "jndi-name": "java:jboss/datasources/sampleDS", "user-name": "sampleuser", "password": "secret", "min-pool-size": 3, "use-java-context": True}'
```

salt.modules.jboss7.create_simple_binding(jboss_config, binding_name, value)

Create a simple jndi binding in the running jboss instance.

jboss_config  Configuration dictionary with properties specified above.

binding_name  Binding name to be created

value  Binding value

CLI Example:

```python
salt '*' jboss7.create_simple_binding '{"cli_path": "integration.modules.sysmod.SysModuleTest.test_valid_docs", "controller": "10.11.12.13:9999", "cli_user": "jbossadm", "cli_password": "jbossadm"}', my_binding_name my_binding_value
```

salt.modules.jboss7.deploy(jboss_config, source_file)

Deploy the application on the jboss instance from the local file system where minion is running.

jboss_config  Configuration dictionary with properties specified above.

source_file  Source file to deploy from

CLI Example:

```python
```

salt.modules.jboss7.list_deployments(jboss_config)

List all deployments on the jboss instance.

jboss_config  Configuration dictionary with properties specified above.

CLI Example:

```python
```
salt.modules.jboss7.read_datasource(jboss_config, name)
Read datasource properties in the running jboss instance.

jboss_config  Configuration dictionary with properties specified above.
name  Datasource name

CLI Example:

salt.modules.jboss7.read_simple_binding(jboss_config, binding_name)
Read jndi binding in the running jboss instance

jboss_config  Configuration dictionary with properties specified above.
binding_name  Binding name to be created

CLI Example:

salt '*' jboss7.read_simple_binding '{\"cli_path\": \"integration.modules.sysmod.SysModuleTest.test_valid_docs\", \"controller\": \"10.11.12.13:9999\", \"cli_user\": \"jbossadm\", \"cli_password\": \"jbossadm\"}'

my_binding_name

salt.modules.jboss7.reload(jboss_config)
Reload running jboss instance

jboss_config  Configuration dictionary with properties specified above.

CLI Example:

salt.modules.jboss7.remove_datasource(jboss_config, name)
Remove an existing datasource from the running jboss instance.

jboss_config  Configuration dictionary with properties specified above.
name  Datasource name

CLI Example:

salt '*' jboss7.remove_datasource '{"cli_path": "integration.modules.sysmod.SysModuleTest.test_valid_docs", "controller": "10.11.12.13:9999", "cli_user": "jbossadm", "cli_password": "jbossadm"}'

my_datasource_name

salt.modules.jboss7.status(jboss_config)
Get status of running jboss instance.

jboss_config  Configuration dictionary with properties specified above.

CLI Example:

salt.modules.jboss7.stop_server(jboss_config)
Stop running jboss instance

jboss_config  Configuration dictionary with properties specified above.

CLI Example:
```
```

salt.modules.jboss7.undeploy(jboss_config, deployment)
Undeploy the application from jboss instance

jboss_config  Configuration dictionary with properties specified above.

deployment  Deployment name to undeploy

CLI Example:
```
```

salt.modules.jboss7.update_datasource(jboss_config, name, new_properties)
Update an existing datasource in running jboss instance. If the property doesn't exist if will be created, if it does, it will be updated with the new value

jboss_config  Configuration dictionary with properties specified above.

name  Datasource name

new_properties  
A dictionary of datasource properties to be updated. For example:

- driver-name: mysql
- connection-url: 'jdbc:mysql://localhost:3306/sampleDatabase'
- jndi-name: `java:jboss/datasources/sampleDS'
- user-name: sampleuser
- password: secret
- min-pool-size: 3
- use-java-context: True

CLI Example:
```
```

salt.modules.jboss7.update_simple_binding(jboss_config, binding_name, value)
Update the simple jndi binding in the running jboss instance

jboss_config  Configuration dictionary with properties specified above.
binding_name  Binding name to be updated
value  New binding value

CLI Example:

```
salt '*' jboss7.update_simple_binding '{"cli_path": "integration.modules.sysmod.SysModuleTest.test_valid_docs", "controller": "10.11.12.13:9999", "cli_user": "jbossadm", "cli_password": "jbossadm"}' my_binding_name my_binding_value
```

### 32.17.126  salt.modules.jboss7_cli

Module for low-level interaction with JbossAS7 through CLI.

This module exposes two ways of interaction with the CLI, either through commands or operations.

---

**Note:** Following JBoss documentation (https://developer.jboss.org/wiki/CommandLineInterface): "Operations are considered a low level but comprehensive way to manage the AS controller, i.e. if it can't be done with operations it can't be done in any other way. Commands, on the other hand, are more user-friendly in syntax, although most of them still translate into operation requests and some of them even into a few composite operation requests, i.e. commands also simplify some management operations from the user's point of view."

---

The difference between calling a command or operation is in handling the result. Commands return a zero return code if operation is successful or return non-zero return code and print an error to standard output in plain text, in case of an error.

Operations return a json-like structure, that contain more information about the result. In case of a failure, they also return a specific return code. This module parses the output from the operations and returns it as a dictionary so that an execution of an operation can then be verified against specific errors.

**In order to run each function,** jboss_config dictionary with the following properties must be passed:

- **cli_path**: the path to jboss-cli script, for example: `/opt/jboss/jboss-7.0/bin/jboss-cli.sh`
- **controller**: the IP address and port of controller, for example: `10.11.12.13:9999`
- **cli_user**: username to connect to jboss administration console if necessary
- **cli_password**: password to connect to jboss administration console if necessary

Example:

```
jboss_config:
  cli_path: '/opt/jboss/jboss-7.0/bin/jboss-cli.sh'
  controller: 10.11.12.13:9999
  cli_user: 'jbossadm'
  cli_password: 'jbossadm'
```

`salt.modules.jboss7_cli.run_command(jboss_config, command, fail_on_error=True)`

Execute a command against jboss instance through the CLI interface.

- **jboss_config** Configuration dictionary with properties specified above.
- **command** Command to execute against jboss instance
- **fail_on_error** (default=True) Is true, raise CommandExecutionException exception if execution fails. If false, 'success' property of the returned dictionary is set to False

---

32.17.  Full list of builtin execution modules
salt.jboss7_cli.run_operation(jboss_config, operation, fail_on_error=True, retries=1)

Execute an operation against jboss instance through the CLI interface.

**jboss_config**  Configuration dictionary with properties specified above.

**operation**  An operation to execute against jboss instance

**fail_on_error** *(default=True)*  Is true, raise CommandExecutionException exception if execution fails. If false, 'success' property of the returned dictionary is set to False

**retries**  Number of retries in case of "JBAS012144: Could not connect to remote" error.

CLI Example:

```bash
salt '*' jboss7_cli.run_operation '{"cli_path": "integration.modules.sysmod.SysModuleTest.test_valid_docs", "controller": "10.11.12.13:9999", "cli_user": "jbossadm", "cli_password": "jbossadm"} my_operation
```

### 32.17.127 salt.modules.junos

Module for interfacing to Junos devices

ALPHA QUALITY code.

- `salt.modules.junos.call_rpc()`
- `salt.modules.junos.cli(command)`
- `salt.modules.junos.commit()`
- `salt.modules.junos.diff()`
- `salt.modules.junos.facts_refresh()`  
  Reload the facts dictionary from the device. Usually only needed if the device configuration is changed by some other actor.
- `salt.modules.junos.ping()`
- `salt.modules.junos.rollback()`
- `salt.modules.junos.set_hostname(hostname=None, commit_change=True)`

### 32.17.128 salt.modules.kerberos

Manage Kerberos KDC

**configuration**  In order to manage your KDC you will need to generate a keytab that can authenticate without requiring a password.

```bash
# ktadd -k /root/secure.keytab kadmin/admin kadmin/changepw
```

On the KDC minion you will need to add the following to the minion configuration file so Salt knows what keytab to use and what principal to authenticate as.

```bash
auth_keytab: /root/auth.keytab
auth_principal: kadmin/admin
```
salt.modules.kerberos.create_keytab(name, keytab, enctypes=None)
Create keytab
CLI Example:
```python
salt 'kdc.example.com' host/host1.example.com host1.example.com.keytab
```

salt.modules.kerberos.create_principal(name, enctypes=None)
Create Principal
CLI Example:
```python
salt 'kdc.example.com' kerberos.create_principal host/example.com
```

salt.modules.kerberos.delete_principal(name)
Delete Principal
CLI Example:
```python
salt 'kdc.example.com' kerberos.delete_principal host/example.com@EXAMPLE.COM
```

salt.modules.kerberos.get_policy(name)
Get policy details
CLI Example:
```python
salt 'kdc.example.com' kerberos.get_policy my_policy
```

salt.modules.kerberos.get_principal(name)
Get principal details
CLI Example:
```python
salt 'kdc.example.com' kerberos.get_principal root/admin
```

salt.modules.kerberos.get_privs()
Current privileges
CLI Example:
```python
salt 'kdc.example.com' kerberos.get_privs
```

salt.modules.kerberos.list_policies()
List policies
CLI Example:
```python
salt 'kdc.example.com' kerberos.list_policies
```

salt.modules.kerberos.list_principals()
Get all principals
CLI Example:
```python
salt 'kdc.example.com' kerberos.list_principals
```

32.17.129 salt.modules.key

Functions to view the minion's public key information

32.17. Full list of builtin execution modules
salt.modules.key.

- **finger()**
  Return the minion's public key fingerprint
  
  CLI Example:
  ```
  salt '*' key.finger
  ```

- **finger_master()**
  Return the fingerprint of the master's public key on the minion.
  
  CLI Example:
  ```
  salt '*' key.finger_master
  ```

32.17.130 salt.modules.keyboard

Module for managing keyboards on supported POSIX-like systems using systemd, or such as Redhat, Debian and Gentoo.

- **get_sys()**
  Get current system keyboard setting
  
  CLI Example:
  ```
  salt '*' keyboard.get_sys
  ```

- **get_x()**
  Get current X keyboard setting
  
  CLI Example:
  ```
  salt '*' keyboard.get_x
  ```

- **set_sys(layout)**
  Set current system keyboard setting
  
  CLI Example:
  ```
  salt '*' keyboard.set_sys dvorak
  ```

- **set_x(layout)**
  Set current X keyboard setting
  
  CLI Example:
  ```
  salt '*' keyboard.set_x dvorak
  ```

32.17.131 salt.modules.keystone

Module for handling openstack keystone calls.

- **optdepends**
  - keystoneclient Python adapter

- **configuration** This module is not usable until the following are specified either in a pillar or in the minion's config file:
keystone.user: admin
keystone.password: verybadpass
keystone.tenant: admin
keystone.tenant_id: f80919baedab48ec8931f200c65a50df
keystone.auth_url: 'http://127.0.0.1:5000/v2.0/

OR (for token based authentication)

keystone.token: 'ADMIN'
keystone.endpoint: 'http://127.0.0.1:35357/v2.0'

If configuration for multiple openstack accounts is required, they can be set up as different configuration profiles. For example:

openstack1:
  keystone.user: admin
  keystone.password: verybadpass
  keystone.tenant: admin
  keystone.tenant_id: f80919baedab48ec8931f200c65a50df
  keystone.auth_url: 'http://127.0.0.1:5000/v2.0/

openstack2:
  keystone.user: admin
  keystone.password: verybadpass
  keystone.tenant: admin
  keystone.tenant_id: f80919baedab48ec8931f200c65a50df
  keystone.auth_url: 'http://127.0.0.2:5000/v2.0/

With this configuration in place, any of the keystone functions can make use of a configuration profile by declaring it explicitly. For example:

```bash
salt '*' keystone.tenant_list profile=openstack1
```

salt.modules.keystone.auth(profile=None, **connection_args)
Set up keystone credentials. Only intended to be used within Keystone-enabled modules.

CLI Example:

```bash
salt '*' keystone.auth
```

salt.modules.keystone.ec2_credentials_create(user_id=None, name=None, tenant_id=None, tenant=None, profile=None, **connection_args)
Create EC2-compatible credentials for user per tenant

CLI Examples:

```bash
salt '*' keystone.ec2_credentials_create name=admin tenant=admin
salt '*' keystone.ec2_credentials_create user_id=c965f79c4f864eaaa9c3b41904e67082 tenant_id=722787eb540849158668370dc627ec5f
```

salt.modules.keystone.ec2_credentials_delete(user_id=None, name=None, access_key=None, profile=None, **connection_args)
Delete EC2-compatible credentials

CLI Examples:
salt.modules.keystone.ec2_credentials_delete 860f8c2c38ca4fab989f9bc56a061a64 access_
  --key=5f66d2f24f604b8bb9cd28886106f442
salt '!' key = 5f66d2f24f604b8bb9cd28886106f442
salt '!' key = 5f66d2f24f604b8bb9cd28886106f442

salt.modules.keystone.ec2_credentials_get(user_id=None, name=None, access=None, profile=None, **connection_args)

Return ec2_credentials for a user (keystone ec2-credentials-get)

CLI Examples:
salt '!' keystone.ec2_credentials_get c965f79c4f864eaaa9c3b41904e67082
  --access=722787eb54084915868370dc627ec5f
salt '!' keystone.ec2_credentials_get user_id=c965f79c4f864eaaa9c3b41904e67082
  --access=722787eb54084915868370dc627ec5f
salt '!' keystone.ec2_credentials_get name=nova
  --access=722787eb54084915868370dc627ec5f

salt.modules.keystone.ec2_credentials_list(user_id=None, name=None, profile=None, **connection_args)

Return a list of ec2_credentials for a specific user (keystone ec2-credentials-list)

CLI Examples:
salt '!' keystone.ec2_credentials_list 298ce377245c4ec9b70e1c639c89e654
salt '!' keystone.ec2_credentials_list user_id=298ce377245c4ec9b70e1c639c89e654
salt '!' keystone.ec2_credentials_list name=jack

salt.modules.keystone.endpoint_create(service, publicurl=None, internalurl=None, adminurl=None, region=None, profile=None, **connection_args)

Create an endpoint for an Openstack service

CLI Examples:
salt '!' keystone.endpoint_create nova 'http://public/url'
  'http://internal/url' 'http://adminurl/url' region

salt.modules.keystone.endpoint_delete(service, profile=None, **connection_args)

Delete endpoints of an Openstack service

CLI Examples:
salt '!' keystone.endpoint_delete nova

salt.modules.keystone.endpoint_get(service, profile=None, **connection_args)

Return a specific endpoint (keystone endpoint-get)

CLI Example:
salt '!' keystone.endpoint_get nova

salt.modules.keystone.endpoint_list(profile=None, **connection_args)

Return a list of available endpoints (keystone endpoints-list)

CLI Example:
salt '!' keystone.endpoint_list
salt.modules.keystone.role_create(name, profile=None, **connection_args)
Create a named role.

CLI Example:
salt '*' keystone.role_create admin

salt.modules.keystone.role_delete(role_id=None, name=None, profile=None, **connection_args)
Delete a role (keystone role-delete)

CLI Examples:
salt '*' keystone.role_delete c965f79c4f864eaa9c3b41904e67082
salt '*' keystone.role_delete role_id=c965f79c4f864eaa9c3b41904e67082
salt '*' keystone.role_delete name=admin

salt.modules.keystone.role_get(role_id=None, name=None, profile=None, **connection_args)
Return a specific roles (keystone role-get)

CLI Examples:
salt '*' keystone.role_get c965f79c4f864eaa9c3b41904e67082
salt '*' keystone.role_get role_id=c965f79c4f864eaa9c3b41904e67082
salt '*' keystone.role_get name=nova

salt.modules.keystone.role_list(profile=None, **connection_args)
Return a list of available roles (keystone role-list)

CLI Example:
salt '*' keystone.role_list

salt.modules.keystone.service_create(name, service_type, description=None, profile=None, **connection_args)
Add service to Keystone service catalog

CLI Examples:
salt '*' keystone.service_create nova compute 'OpenStack Compute Service'

salt.modules.keystone.service_delete(service_id=None, name=None, profile=None, **connection_args)
Delete a service from Keystone service catalog

CLI Examples:
salt '*' keystone.service_delete c965f79c4f864eaa9c3b41904e67082
salt '*' keystone.service_delete name=nova

salt.modules.keystone.service_get(service_id=None, name=None, profile=None, **connection_args)
Return a specific services (keystone service-get)

CLI Examples:
salt '*' keystone.service_get c965f79c4f864eaa9c3b41904e67082
salt '*' keystone.service_get service_id=c965f79c4f864eaa9c3b41904e67082
salt '*' keystone.service_get name=nova
salt.modules.keystone.service_list(profile=None, **connection_args)

Return a list of available services (keystone services-list)

CLI Example:
salt '*' keystone.service_list

salt.modules.keystone.tenant_create(name, description=None, enabled=True, profile=None, **connection_args)

Create a keystone tenant

CLI Examples:
salt '*' keystone.tenant_create nova description='nova tenant'
salt '*' keystone.tenant_create test enabled=False

salt.modules.keystone.tenant_delete(tenant_id=None, name=None, profile=None, **connection_args)

Delete a tenant (keystone tenant-delete)

CLI Examples:
salt '*' keystone.tenant_delete c965f79c4f864eaaa9c3b41904e67082
salt '*' keystone.tenant_delete tenant_id=c965f79c4f864eaaa9c3b41904e67082
salt '*' keystone.tenant_delete name=demo

salt.modules.keystone.tenant_get(tenant_id=None, name=None, profile=None, **connection_args)

Return a specific tenants (keystone tenant-get)

CLI Examples:
salt '*' keystone.tenant_get c965f79c4f864eaaa9c3b41904e67082
salt '*' keystone.tenant_get tenant_id=c965f79c4f864eaaa9c3b41904e67082
salt '*' keystone.tenant_get name=nova

salt.modules.keystone.tenant_list(profile=None, **connection_args)

Return a list of available tenants (keystone tenants-list)

CLI Example:
salt '*' keystone.tenant_list

salt.modules.keystone.tenant_update(tenant_id=None, name=None, description=None, enabled=None, profile=None, **connection_args)

Update a tenant's information (keystone tenant-update) The following fields may be updated: name, email, enabled. Can only update name if targeting by ID

CLI Examples:
salt '*' keystone.tenant_update name=admin enabled=True
salt '*' keystone.tenant_update c965f79c4f864eaaa9c3b41904e67082 name=admin
e-mail=admin@domain.com

salt.modules.keystone.token_get(profile=None, **connection_args)

Return the configured tokens (keystone token-get)

CLI Example:
salt 'salt' keystone.token_get c965f79c4f864eaaa9c3b41904e67082

salt.modules.keystone.user_create(name, password, email, tenant_id=None, enabled=True, profile=None, **connection_args)

Create a user (keystone user-create)

CLI Examples:
salt '*' keystone.user_create name=jack password=zero email=jack@halloween.town. org tenant_id=a28a7b5a999a455f84b1f5210264375e enabled=True

salt.modules.keystone.user_delete(user_id=None, name=None, profile=None, **connection_args)

Delete a user (keystone user-delete)

CLI Examples:
salt '*' keystone.user_delete c965f79c4f864eaaa9c3b41904e67082
salt '*' keystone.user_delete user_id=c965f79c4f864eaaa9c3b41904e67082
salt '*' keystone.user_delete name=nova

salt.modules.keystone.user_get(user_id=None, name=None, profile=None, **connection_args)

Return a specific users (keystone user-get)

CLI Examples:
salt '*' keystone.user_get c965f79c4f864eaaa9c3b41904e67082
salt '*' keystone.user_get user_id=c965f79c4f864eaaa9c3b41904e67082
salt '*' keystone.user_get name=nova

salt.modules.keystone.user_list(profile=None, **connection_args)

Return a list of available users (keystone user-list)

CLI Example:
salt '*' keystone.user_list

salt.modules.keystone.user_password_update(user_id=None, name=None, password=None, profile=None, **connection_args)

Update a user's password (keystone user-password-update)

CLI Examples:
salt '*' keystone.user_password_update c965f79c4f864eaaa9c3b41904e67082 password=12345
salt '*' keystone.user_password_update user_id=c965f79c4f864eaaa9c3b41904e67082 password=12345
salt '*' keystone.user_password_update name=nova password=12345

salt.modules.keystone.user_role_add(user_id=None, user=None, tenant_id=None, tenant=None, role_id=None, role=None, profile=None, **connection_args)

Add role for user in tenant (keystone user-role-add)

CLI Examples:
salt '*' keystone.user_role_add user_id=298ce377245c4ec9b70e1c639c89e654 tenant_id=716a092ece84e8eade4bbf9d16b3b role_id=ce377245c4ec9b70e1c639c89e6eade user=admin tenant=admin role=admin
salt.modules.keystone.user_role_list(user_id=None, tenant_id=None, user_name=None, tenant_name=None, profile=None, **connection_args)

Return a list of available user_roles (keystone user-roles-list)

CLI Examples:

```
salt '*' keystone.user_role_list user_id=298ce377245c4ec9b70e1c639c89e654
tenant_id=7167a092ece84bae8cead4bf9d15bb3b
salt '*' keystone.user_role_list user_id=admin tenant_name=admin
```

salt.modules.keystone.user_role_remove(user_id=None, user=None, tenant_id=None, tenant=None, role_id=None, role=None, profile=None, **connection_args)

Remove role for user in tenant (keystone user-role-remove)

CLI Examples:

```
salt '*' keystone.user_role_remove user_id=298ce377245c4ec9b70e1c639c89e654
tenant_id=7167a092ece84bae8cead4bf9d15bb3b role_id=ce377245c4ec9b70e1c639c89e8cead4
salt '*' keystone.user_role_remove user=admin tenant=admin role=admin
```

salt.modules.keystone.user_update(user_id=None, name=None, email=None, enabled=None, tenant=None, profile=None, **connection_args)

Update a user's information (keystone user-update) The following fields may be updated: name, email, enabled, tenant. Because the name is one of the fields, a valid user_id is required.

CLI Examples:

```
salt '*' keystone.user_update user_id=c965f79c4f864eaaa9c3b41904e67082 name=newname
salt '*' keystone.user_update user_id=c965f79c4f864eaaa9c3b41904e67082 name=newname
```

salt.modules.keystone.user_verify_password(user_id=None, name=None, password=None, profile=None, **connection_args)

Verify a user's password

CLI Examples:

```
salt '*' keystone.user_verify_password name=test password=foobar
salt '*' keystone.user_verify_password user_id=c965f79c4f864eaaa9c3b41904e67082 password=foobar
```

### 32.17.132 salt.modules.kmod

Module to manage Linux kernel modules

salt.modules.kmod.available()

Return a list of all available kernel modules

CLI Example:

```
salt '*' kmod.available
```

salt.modules.kmod.check_available(mod)

Check to see if the specified kernel module is available

CLI Example:
salt '*' kmod.check_available kvm

salt.modules.kmod.is_loaded(mod)
Check to see if the specified kernel module is loaded

CLI Example:
```
salt '*' kmod.is_loaded kvm
```

salt.modules.kmod.load(mod, persist=False)
Load the specified kernel module

mod Name of module to add
persist Write module to /etc/modules to make it load on system reboot

CLI Example:
```
salt '*' kmod.load kvm
```

salt.modules.kmod.lsmod()
Return a dict containing information about currently loaded modules

CLI Example:
```
salt '*' kmod.lsmod
```

salt.modules.kmod.mod_list(only_persist=False)
